Here the cadency begins at the words Aulus Cincius. If a sentence consists of three members, the inflection is best made at the end of the second member: for if it begins immediately after the speech of the voice shall be, and as it were might be considered as a period, and then be before the end of the sentence. Cicero begins his oration for Milo with a sentence of this form: "Although I fear, it may be a shame to be dissatisfied at the entrance of my discourse in defence of a most valiant man; and that it nowise becomes me, while Milo is more concerned for the safety of the state than for himself, not to show the same greatness of mind in his behalf: yet this new form of prosecution terrifies my eyes, which, whatever way they turn, want the ancient custom of the forum, and former manner of trials."

Here the cadency, beginning at the third member with the word yet, makes a proper division of the sentence, and easy for the speaker. But a period of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. Nor is it the same case here, as if; in a sentence of three members, the cadency be made at the second: for if it be made at the third, the time of raising the voice is before the end of the sentence, and may the space be allowed for its sinking. The following sentence of Cicero gives an instance of this, where he speaks to his son: "Although son Mark, having now been a hearer of Cratippus for a year, and this at Athens, you ought to abound in the precepts and doctrines of philosophy, by reason of the great character both of your instructor and the city; one of which can furnish you with knowledge, and the other with examples: yet, as I always to my advantage joined the Latin tongue with the Greek, and have done it not only in oratory, but likewise in philosophy; I think you ought to do the same, that you may be equally conversant in both languages." This turn in the period begins at the word yet; which standing near the middle, the voice is raised to that pitch in pronouncing the former part, as to admit of a gradual cadency, without being lost before the conclusion of the sentence. But where the sense does not suit with this division at the entrance upon the third member, it is best made at the fourth. Such is the following sentence of Cicero: "If I have any genius, which I am sensible is very small; or any readiness in speaking, wherein I do not deny but I have been much conversant; or any skill in oratory, from an acquaintance with the best arts, to which I confess I have been always inclined; no one has a better right to demand of me the fruit of all these things than this Aulus Cincius."

The cadency of this sentence does not begin till the words no one; yet it ends handsomely, and without disappointing the ear. Though indeed the three first members having each of them an inflection, check the elevation of the voice, and by that variety in the pronunciation add to the harmony of the sentence. An equality of the members should likewise be attended to in the composition of a period, the better to adjust their rise and cadency. And for this reason, in sentences of three members, where the cadency begins with the third; or in those of four members, where it begins at the fourth; it promotes the harmony to make the last member longest. This is properly the nature of rhetorical periods, which when rightly formed have both an equal beauty and dignity in their composition.

But as all discourse is made up of distinct sentences, and whenever we express our thoughts it is in some of the forms above mentioned; so the use of them is not promiscuous, but suited to answer different designs in speaking. And in this view they are considered and made use of by the orator, as will be shown hereafter.

§ 2. Of Order.

By order, rhetoricians mean the placing each word in a sentence in such a manner as will form and most contribute to the force, beauty, or evidence of the whole.

Order is of two kinds, natural and artificial. And each of these may be considered with respect to the parts either of simple or compound sentences.

As to simple sentences, we may call that order natural, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction. And it may properly enough admit of this name, as it is founded in the nature of a proposition, and the relation of the several words of it to each other. This is the order of the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon. And it is this: The name of Isocrates excited Aristotle to the profession of oratory. Here these words, the name of Isocrates, contain the subject of this sentence, with what relates to it; and all those which follow, excited Aristotle to the profession of oratory, make up the predicate and its dependents.
Eloquence. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty much to this method. It is one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subjects, whose properties they are: As when it is said, Evil communication corrupts good manners. And this we always do, except something follows which depends upon the adjective. So we say, He was a man eminent for his virtue; not an eminent man.

Artificial order, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, because the force of the sentence lies in the verb. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence one upon another, and place any of them first or last as they please. In short their order seems in a manner arbitrary, if he does not break in upon perspicuity, to which they usually attend. But most of these things are unsuitable to the genius of our language. One might say indeed, Convince him you cannot: instead of saying, You cannot convince him: Or, With my own eyes I saw it; for, I saw it with my own eyes. And again: in proportion to the increase of luxury the Roman state declined: for, The Roman state declined in proportion to the increase of luxury. But this inversion of words is proper in English composition only when it gives force to the expression; as in the higher style it often does. It serves to impress known truths upon the mind, but is unfit for communicating the first principles of knowledge.

As to compound sentences, that is, such as consist of two or more members, either simple or compounded; what relates to the words in each member separately is the same as in simple sentences. But with regard to the disposition of the several members, that may be called the natural order, which so places them as they mutually depend on each other. Thus the antecedent member naturally precedes the relative; as in this expression, Men are op. to forgive themselves what they blame in others. In hypothetical sentences the conditional member naturally stands first. Thus: If Socrates be a rational creature, he is a man. That member which expresses the effect of an action naturally comes last; as, Though you offer so good reasons, you will not prevail with him. The like may be said of time, with regard to things done in it; as, The Roman eloquence soon declined when Cicer was dead. And to name no more, the reason of a thing naturally follows that of which it is the reason; as thus: All the pleasures of life must be uncertain, since life itself is not secure.

When this order is inverted, it must be styled artificial. So to keep to the instances already given, the two members in the first sentence may be thus inverted: What they blame in others, men are apt to forgive themselves. In the second: This manner of life, Socrates is a man, if he be a rational creature. In the third: You will not prevail with him, though you offer so good reasons. And so on in the rest. As, When Cicer was dead, the Roman eloquence soon declined; and, Since life itself is not secure, all the pleasures of life must be uncertain. The variety of inversions in a sentence may generally be greater or less in proportion to the number of its members. In the following sentence of Cicero, the natural order seems to be this: If that greatness of mind be void of justice, which shows itself in dangers and labours, it is blameable. Which may be varied by changing the place of the first and third member, in the following manner: That greatness of mind is blameable which shows itself in dangers and labours, if it want justice. Or by altering the place of all the three members thus: That greatness of mind is blameable, if it be void of justice, which shows itself in dangers and labours, if it want justice. Or by altering the place of the first and second: That greatness of mind, which shows itself in dangers and labours, if it want justice, is blameable; where the relative and conditional members are both included in the antecedent member. The Latin tongue commonly admits of a much greater variety in the transposition of members, as well as in that of single words, than suits with our idiom. In the following sentence the natural order is much preferable, as it best suits with the proper elevation and cadency of the voice in its pronunciation: I am willing to remit all that is past, provided it may be done with safety. But should we invert the members, and say, Provided it may be done with safety, I am willing to remit all that is past; the harmony of the cadency would be lost. And if the latter member be included in the former, the alteration will still be worse; as, I am willing, provided it may be done with safety, to forgive all that is past. Here the inflection of the voice falls upon the same member as before, and destroys the beauty of the period by its elevation afterwards. Some sentences admit of no inversion of their members. Such are those whose members are connected by conjunctive or disjunctive particles. As, Virtue furnishes the mind with the truest pleasure in prosperity, and affords it the greatest comfort in adversity. And, A wise man is neither skated by prosperity, nor depressed by adversity. And the like may be said of those where the latter member begins with some illative or redditive particle. As in these instances: The chief thing to be regarded in life is virtue, for all other things are vain and uncertain. And, Though fortune is always inconstant, yet she has many vagaries. Neither of the members in any of these ways of expression, and...
O R A T O R Y.

Part III.

Elocution. and some others which might be named, can be included one in the other. In all the examples hitherto given, the sentences consist only of simple members; and indeed compound members are not so often inverted, nor included one in another, by reason of their length. However, we shall here produce one instance of each: 

Whoever considers the uncertainty of human affairs, and how frequently the greatest hopes are frustrated; he will see just reason to be always on his guard, and not place too much expedience on things so precarious. This sentence consists of two compound members, which here stand in their natural order, but may be thus inverted: He will see just reason to be always on his guard, and not place too much dependence on things so precarious; whoever considers the uncertainty of human affairs, and how often the greatest hopes are frustrated.

In the following sentence one compound member is included in another: Let us not conclude while dangers are at a distance, and do not immediately approach us, that we are secure; unless we use all necessary precaution to prevent them. Here the natural order would be: While dangers are at a distance, and do not immediately approach us; let us not conclude that we are secure, unless we use all necessary precaution to prevent them.

But there are some other considerations relating to order, which, being taken from the nature of things, equally suit all languages. So, in amplifying, there should be a constant gradation from a less to a greater; as when Cicero says, Ambition creates hatred, shyness, discords, seditions, and wars. On the contrary, in enumerating, we should descend from a greater to a less; as if, speaking of the ancient laws of Rome, one should say, They will die from youth to age, and from age to death, that they would not allow him to be taken, or even to be bound. In constituting any whole, we put the parts first; as, Invention, disposition, elocution, and pronunciation, make up the art of oratory. But in separating any whole, the parts follow: as, The art of oratory may be divided into these four parts; invention, disposition, elocution, and pronunciation. In every enumeration care must be taken not to mix the whole with the parts; but if it be mentioned at all, it must either be put first or last. So it would be wrong to say, He was a man of the greatest prudence, virtue, justice, and modesty: for the word virtue here contains in it the other three, and therefore should not be inserted among them. See Language, No. 17.

§ 3. Of Juncture and Number.

Quintilian, speaking of composition, represents a discourse as very happy in that respect, when the order, juncture, and number, are all just and proper. The first of these, which gives rules for the due placing of the words and members of a sentence, has been already explained. We now proceed to the other two, which relate to letters and syllables; the former treating of their connection, and the latter of their quantity.

1. As to juncture. A due attention is to be paid to the nature of the vowels, consonants, and syllables, in the connection of words, with regard to the sound.

As to the first, when a word ends with a vowel, and the next begins either with a different vowel, or the same repeated, it usually renders the pronunciation hollow and unpleasant. For, as Quintilian has justly ob-

served, "This makes a chasm in the sentence, and stops the course of it." For there must be some pause, in order to pronounce them both, or otherwise the sound of one will be lost. So, for instance, in pronouncing these words, the other day, unless you stop a little after the word the, the sound of e will not be heard; and if it is dropped, it will occasion a rougher sound, from the separation of th twice repeated so near together, as th'other day. Therefore to prevent both these inconveniences, we usually say, the other day. But the different consonants, which together with the vowels make up those syllables, often cause a considerable difference in the pronunciation, so as to render it more or less agreeable. As, if we say, he overtrod it, the words he overtread have not so harsh a sound as the other; though still they require some pause to keep them distinct. Besides, some vowels meet more amicably, and admit of a softer pronunciation than others. Those which have the weakest and smallest sound, follow best; because they occasion the least alteration of the organ in forming the two sounds. Such are e and i; and therefore, without any chasm in the sound, or hesitation of the voice, we say he is. But where the action of the organs is greater, and the sound stronger, the pronunciation is more difficult: as when we say, th'o' all. For here is a contrary motion of the lips, which are first put forward in sounding the o, and then drawn backward to pronounce the a; and therefore the sound is much softer to say, th'o' every, where their action is less. And the like ill effect commonly happens from the repetition of the same vowel: as if we say, go on, or, usually act thus. There is a considerable difference between these two expressions, in repeating the sound of the vowel, and where either of them is doubled in a single word. For then the same sound only is protracted by one continued motion of the organ; as in the words good, and deem. But here the sound is repeated again by a new action of the organ; which, if precipitated, obscures the sound of one of the vowels; and, if too much retarded, makes a chasm in the pronunciation; either of which is unpleasant to the ear.

But as the coalition of two vowels occasions an hollow and obscure sound, so the meeting of some consonants renders it very harsh and rough. Thus the words king Xerxes, and public good, when so placed have not only a roughness, but likewise a difficulty in their pronunciation, from the contrary action of the lips; which in the former are first drawn back and then forwards, but in the latter the contrary way; and in both of them with some considerable force. But this may very easily be avoided, by saying, with a little alteration in the words, Xerxes, the king, and the good of the public. So likewise the words ill company, have a hollow sound than bad company, for the same reason. To multiply instances of this kind seems unnecessary, which so frequently occur in all discourses.

The repetition of the same-syllable at the end and beginning of words, is the last thing to be considered. And a little observation will convince us, that where this happens, it generally renders the sound either confused or unpleasant. Cicero was often rallied on account of this verse:

O fortunatem natam me console Romam.

Every one will easily perceive a disagreeable sound in the:
ORATORY.

Part III.

For we are apt to confound accent with quantity, and pronounce those syllables longest on which we lay the accent, though in their nature they are not so. As in the word admirable, where none but the first syllable ad is pronounced long; though that is only rendered so by position, and the two following are so by nature.

And again, in the word measure, we sound the first a long for the same reason, and the second short; contrary to the nature of both these vowels. However, we shall offer a few things that may be of some use to modulate our periods and adjust their cadence.

A great number of monosyllables do not stand well together. For as there ought to be a greater distance in the pronunciation between one word and another, than between the syllables of the same word; such pauses, though short, yet, when too frequent, make the sound rough and uneven, and by that means spoil its harmony. And this may seem more necessary to be attended to, because the English language abounds so much with monosyllables. On the contrary, a continuation of many long words makes a sentence move too slow and heavily. And therefore such periods generally run best, which have a proper mixture of words of a different length. Besides, as every word has its accent, which with us stands for quantity, a number either of monosyllables, or long words, coming together, so far abates the harmony, as it lessens the variety.

Again, several words of the same ending do not stand well together, especially where the accent falls upon the same syllable in each of them. For this oversteeps too great a jingle by the similitude of sound; and is apt to displease, from an appearance of affectation. Of this kind is the following sentence: Nothing is more welcome, delightful, or wholesome, than rest to a wearied man.

In such expressions, therefore, if the order of the words cannot well be altered, some other word should be substituted in the room of one of them at least, to diversify the sound. So in the example here given, the sound might be varied by saying, Nothing is more welcome, plesant, or wholesome.

But to add no more, if a sentence end with a monosyllable, it is apt to hurt the cadency, and disappoint the ear: whereas words of a moderate length carry a greater force with them by the fulness of their sound, and afford the ear what it expected. And there is one sort of monosyllables more especially, which never stand well at the conclusion of a period, though we frequently find them there; and these are the signs of cases. Thus we say, Avarice is a crime, which wise men are too often guilty of. But the cadency would doubtless be more agreeable if it was altered thus: Avarice is a crime, of which wise men are too often guilty. Every one must perceive, when the accent falls upon the last syllable in the sentence, as it does if it end with if, the sound is not so pleasant as when it rests upon the preceding syllable in the word guilty. Nor are very long words well suited either to the beginning or conclusion of a period; for they retard the pronunciation at first, and fall too heavy at the end.

CHAP. III. Of Dignity.

DIGNITY consists in the right use of tropes and figures. It is not sufficient for an orator to express himself.
ORATORY.

Part III.

§ 1. Of Tropes.

A trope, which is a figure of words, has been usually defined to be the change of a word from its proper signification to some other with advantage, either as to beauty or strength. The words, with advantage, are added in the definition, because a trope ought not to be chosen, unless there is some good reason for using it rather than the proper word. But in what manner, or how far, it can be said of all tropes in general, that they change the proper signification of words, will best appear by considering the nature of each kind of them separately. Now in every trope a reference is had to two things, which occasions two ideas; one of the thing expressed, and another of that thing to which it has a respect, and is supplied by the mind. For all tropes are taken either from things internally related as the whole and a part; or externally, as cause and effect, subject and adjunct; or from some similitude that is found between them; or from a contrariety. The first of these is called synecdoche, the second metonomy, the third metaphor, and the last irony. We shall endeavour to illustrate this by examples. When we say, Hannibal beat the Romans; the meaning is, that Hannibal and his army did this. So that although in some sense a part may here be said to stand for the whole, which makes it a synecdoche; yet, strictly speaking, the word Hannibal does not alter its sense, but there is an elision in the expression, Hannibal being put for himself and his army. But if we say, Cicero should be read by all lovers of eloquence; here indeed the word Cicero appears to be changed from its proper sense, and to signify the books of Cicero; which is a metonomy, the author being put for his works; and therefore such expressions need not be deemed elliptical. Again, if any one, speaking of a subtle and crafty man, should say he is a fox; the meaning is, he is like a fox; which is a metaphor; where the word fox retains its proper sense, and denotes that animal, to which the man is compared on account of his craft. Lastly, If a person say to another, Well done; meaning that the thing was ill done, the word well keeps its own sense; but from the manner of its pronunciation, or some other circumstance attending the expression, it will be evident that the contrary is intended; which is called an irony. From these instances it may appear in what latitude we must understand the common definition of a trope, which makes it to consist in the change of a word from its proper sense into some other. But though in reality there are but four kinds of tropes, which are distinguished by so many different respects which things bear one to another; yet as these several respects are found in a variety of subjects, and attended with different circumstances, the names of them have from hence been greatly multiplied; which, however, may all be referred to some or other of those already mentioned, as will be shown when we come to treat of them in their order. And for distinction sake we shall call the former primary, and the latter secondary, tropes.

We now proceed to consider the reasons which have occasioned the introduction of tropes. And these, as Quintilian observes, are three; necessity, emphasis, and beauty.

1. Tropes were first introduced from necessity, deriv. Why introducing their origin unquestionably in a considerable degree from the barrenness of language, because no language which we know contains a sufficient number of proper words to express all the different conceptions of our minds: but the principal cause of their introduction seems to be that extensive influence which imagination possesses over every kind of speech. The mind considers the same thing various ways; views it in different lights; compares it with other things; and observes its several relations and affections; wherein they agree, and in what they differ. From all which reflections it is furnished with almost an infinite number of ideas; which cannot all of them be distinguished and expressed by proper words, since new cases occur daily. And were this possible, yet would it be impracticable, because the multitude of words must be so vasty great, that the memory could not retain them, nor be able to recall them as occasion required. Tropes have in a good measure redressed both these inconveniences; for by means of them the mind is not burdened with a numberless stock of different words, and yet nothing seems to want a name. Thus sometimes where a word is wanting to express any particular thing, it is clearly enough represented by the name of some other thing, by reason of the similitude between them. At other times, the cause is signified by the effect, the subject by the adjunct; or the contrary. And the whole is often understood by a part, or a part by the whole. And thus by the use of tropes the mind is helped to conceive of something not expressed, from that which is expressed. It is much the same case, as when we have occasion to speak of a person, whose name we are either unacquainted with, or have forgot; for by describing his person, mode, or some other circumstances relating to him, those we converse with as well understand whom we mean, as if we mentioned his name. So the shepherd in Virgil, whose...
ORATORY. Part III.

Elocution, when he could not think of the name of Archimedes, describes him by his works:

And what’s his name who form’d the sphere,
And show’d the seasons of the sliding year?

Besides, it sometimes happens in a discourse, that those things are necessary to be said, which, if expressed in their proper terms, would be offensive; but being clothed with metaphors, may be conveyed to the mind with decency. Thus then the imagination never contemplates any one idea single and alone, but always along with other ideas, which may be called its accessories, and which often operate more forcibly upon the mind than the principal idea itself does. In their nature they are often more agreeable, and frequently also more familiar, to our conceptions; or perhaps they remind us of a greater variety of important circumstances. Hence the name of the accessory is often preferred, as e.g. when we want to point out the time in which a state enjoyed its chief reputation, &c. the proper words might do, but the imagination suggests the flourishing period of a plant or tree; and we say “the Roman empire flourished most under Augustus:” Catiline, we say, was the head instead of the leader of his party, because the head is the principal part of the human figure.

2. A second reason above mentioned for the use of tropes was emphasis. Tropes do many times express things with greater force and evidence than can be done by proper words. We receive much the greater part of our knowledge by our senses. And similitudes taken from sensible things, as in metaphors, very much assist the mind in its reflections upon those things which do not come under the cognizance of the senses. For it is certain, that we are sooner or more strongly affected with sensible objects, than with things of which we can have no ideas but from the internal operations of our own minds. Nay, sometimes one bright and lively trope shall convey a fuller and more just idea of a thing than a large periphrasis. So when Virgil calls the Scipios two thunder-bolts of war, he gives a more lively image of the rapid force and speedy success of their arms, than could have been conveyed by a long description in plain words. And in many cases the tropical use of words is so emphatical, and suited to the idea we desire to excite, that in this respect it may be justly esteemed the most proper. So incensed with anger, inflamed with desire, fallen into an error, are all metaphorical expressions, used in a way of similitude; and yet perhaps no proper words can be made use of, which will convey a more lively image of the thing we design to represent by them.

But beauty and ornament, as was observed before, have been another cause of the use of tropes. Some subjects require a more florid and elegant dress than others. When we describe or explain, ornaments of speech and a gaiety of expression are requisite. And it is the business of an orator to entertain his hearers at the same time that he instructs them. Now Cicero, who was an admirable judge of the force and power of eloquence; has observed, that tropical expressions give the mind the greatest delight and entertainment. “I have often wondered (says he) why tropes should give greater pleasure than proper words. I imagine the reason must be, either that there is an appearance of wit in neglecting what is at hand, and making choice of something at a distance; or that the bearer is furnished with a different thought, without being led into a mistake, which affords a very agreeable pleasure; or that a whole similitude is conveyed to the mind by a single word; or that, particularly in the best and most lively metaphor, the image is presented to our sight, which is the quickest of our senses.” And therefore he supposes, that “as garments were first invented from necessity, to secure us from the injuries of the weather, but improved afterwards for ornament and distinction; so the poverty of language first introduced tropes, which were afterwards increased for delight.” Besides, a variety of expression is pleasing in a discourse. It is many times necessary that the same thing should be repeated; and if this be done in the same words, it will grow tiresome to the hearers, and sink their esteem of the speaker’s ability. Therefore, to prevent this, it is proper the expression should be varied, that although the sense be the same, it may give the mind a new pleasure by its different dress.

We come now, in the last place, to lay down some directions proper to be observed in the choice of tropes.

And first, as every trope gives us two ideas; one, of the word expressed; and another, which, by means of that, the mind connects with it; it is necessary, that the relation between these two appear very plain and evident. For an obscure trope is always faulty, unless where some particular reason makes it necessary. And therefore tropes ought not to be too far-fetched; lest that should render them dark. For which reason Cicero says, he should not choose to call any thing destructive to a person’s fortune, the Syrtis of his patrimony, but rather the rock of it; nor the Charybdis of his estate, but the gulf of it. For those who either did not know that the Syrtis were two quicksands upon the coast of Africa, or that Charybdis was a gulf in the strait of Sicily, both of them very destructive to mariners, would be at a loss to understand the meaning of the metaphor. Besides, metaphors taken from things we have seen, affect the mind more forcibly than those which are taken from such things as we have only heard of. Now there is scarcely any one who has not seen a rock or a gulf; but there are very few persons, comparatively, who have been either at Charybdis or the Syrtes. It is necessary therefore in a good trope, not only that there be a near affinity between the two ideas, but likewise that this affinity be very obvious and generally known, so that the word be no sooner pronounced but both images do immediately present themselves to the mind.

Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so as neither to heighten nor diminish the just idea of it. Indeed, sometimes when we speak of things indefinitely, we say too much, lest we should seem to say too little. And this manner of speaking is called an hyperbole; which is not uncommon in the sacred writings. So, for instance, Saul and Jonathan are said to be swifter than eagles, and stronger than lions. But even in this way of expression a proportion is to be observed. For some very considerable and unusual excess of the thing in its kind is at least designed by it; which, perhaps, cannot, or however is not necessary to be defined. And therefore Quintillian blames Cato for calling the top of a hill a wart; be-
ORATORY.

353

Art. I. PRIMARY TROPE.

I. Metaphor. A metaphor, as usually defined, is, a trope, which changes words from their proper significa
tion to another different from it, by reason of some simi
larity between them. But that a word, when used met
aphorically, does not alter its significance, but retains
its proper sense, was shown above. However, it may
not be amiss to explain this matter more fully, and set
it in a clearer light. Every metaphor, then, is nothing
else but a short similitude. Cicero calls it a similitude
reduced to a single word. And Quintilian to the same
purpose says, that "a metaphor is a short similitude,
and differs from it only in this, that the former is com-
pared to the thing we design to express, and the latter
is put for it. It is a similitude, when I say of a man,
he has acted like a lion; and a metaphor, when I say,
he is a lion." Thus far Quintilian. Now in every si-
mitude three things are requisite; two things that are
compared together, and a third in which the similitude
or likeness between them consists. And therefore,
to keep to this example, when Horace calls a Roman
soldier a lion, if the word lion did not retain its proper
sense, there could be no similitude; because there would
not be two things to be compared together with respect
to a third, which is necessary in every similitude, and
was designed by this expression. The sense of which is
plainly this: That as a lion seizes his prey with the
greatest fierceness, so a Roman soldier with like rage
and fury attacked his enemies. In the same manner,
when Cicero calls Piso the vulture of the province, his
meaning is, that he was like a vulture, or acted in such a
manner as a vulture acts, that is, appeared hostile to
the enemy. So that the real difference between a metaphor and a similitude con-
ists in this; that a metaphor has not those signs of com-
parison which are expressed in a similitude. But some
persons have run into mistakes in reasoning from tropes
of this kind. For they have so argued from metapho-
rical words, as if all the affections and properties of the
things expressed by them might be attributed to those
other things to which they are applied, and by that
means have strained the comparison (which has usually
but one particular view), in order to make it tally in
other respects, where there is not that similitude of
ideas. We will endeavour to make this evident by an-
other example from Cicero, where he calls Mark An-
tony the torch of the state. The similitude between An-
tony and a torch lay in this: That as a torch burns and
destroy everything within its reach, so Antony brought
devastation and ruin wherever he came. Now a torch
has not only a property to burn, but also to give light;
but the similitude would not hold in this respect, nor
was it as it was designed. For Cicero never calls a wicked
profligate man, as Antony was, the light of the state;
though he often gives that character to good and vir-

t

Vol. X V. Part I.
A second kind of metaphors lies between inanimate things, whether natural or artificial, which bear some similitude to each other. And this head is very extensive. Thus we say, floods of fire, and clouds of smoke, for large quantities. And so likewise, to inflame an account, that is, to heighten or increase it; with innumerable others of the like sort. In the two first of these instances, the terms proper to one element are applied to another; and as those elements of fire and water are opposite to each other, they show the extensiveness of this trope, that there are no things in nature so contrary, but may come within the limits of it, and be accommodated to each other in a way of similitude. In the last example, a natural action is applied to what is artificial.

A third sort of metaphors is, when inanimate things are applied to animals, on account of some like properties between them. Thus Homer calls Ajax, the bulwark of the Greeks, on account of his valour, which like a wall defended them from the Trojans. And nothing is more common with Cicero, than to brand ill men with the character of being the pest of the state, by reason of the mischief which they bring to the public. So likewise he calls Zeno the philosopher an acute man, for his great discernment and quick perception of things; fetching the allusion from metals when brought to an edge or a point. As, on the contrary, old Chremes in Terence calls himself a stone, for want of apprehension. And we say, a gay person, and a bright genius, by this kind of metaphor.

The fourth and last kind of metaphors is that by which the actions and other attributes of animals are accommodated to inanimate things. Thus Cicero, speaking of Clodius, says: "The very altars, when they saw that monster fall, seemed to move themselves and assert their right against him." Here the words save, move, and assert, are all metaphors taken from the properties of animals. And Virgil, when he would represent the impetuous force and rapidity of the river Araxes, says, it disdained a bridge. And it is a very usual epithet, which Homer gives to words, to call them singling, or winged, to intimate the swiftness of speech.

Lastly, as to the choice of metaphors, those are esteemed the finest and strongest, which give life and action to inanimate things. The reason of which is, because they do as it were invigorate all nature, introduce new forms of beings, and represent their images to the sight, which of all the senses is the quickest, most active, and yet most unwearyed. What can be more moving, or in stronger terms express the villany of Clodius, than when Cicero says, "The very altars of the gods seemed to exult at his death." And the same great orator particularly commends those metaphors, for their sprightliness and vivacity, which are taken from the sense of seeing; as when we say a bright thought, or a gay expression.

However, care must be taken not to venture upon too bold and daring metaphors. Poets indeed claim greater liberty in this respect, whose view is often to amuse, terrify, or delight, by heightening the just and natural images of things. But it is expected the orator should reason coolly, though strongly and forcibly; and not by theatrical representations so transport the mind, as to take it off from reflection, unless perhaps on some particular
ORATORY.

Elocution. — And yet, on the other hand, metaphors ought not to sink below the dignity of what they are designed to express; but the idea they convey should at least be equal to the proper word in the place of which they are substituted.

But there is a very great difference in the choice of metaphors, as they are designed either to praise or dispraise. One thing may be compared to another in a great variety of respects. And the same thing may be made to appear either noble or base, virtuous or vicious, by considering it in a different light. Such metaphors, therefore, as are chosen to commend, must be taken from great and laudable things; and on the contrary, those which are designed to discommend, from things vile and contemptible. Aristotle gives us a very pleasant example of this in the poet Simonides. A certain person, who had carried the prize at a race of mules, offered him a reward to write a poem in honour of that action. Simonides thought he did not bid high enough; and therefore put him off with saying, the subject was too mean to write in praise of mules, which were the offspring of asses. But upon his being offered a larger sum, he undertook the task; and, as Aristotle observes, when he has occasion to speak of the mules in that poem, he does not mention them by that name, but calls them the daughters of fleet and generous horses, though he might, with as much propriety have called them the daughters of dull asses. But it was the poet's business, in praising, to take the most advantageous part of the character. Where things are capable of such different turns, metaphorical expressions are generally most beautiful. And sometimes the same metaphor may be applied contrary ways, both in praise and dispraise, as it will suit different properties of the thing to which it refers. So a dove, in a metaphorical sense, may represent either innocence or fear; and an iron heart, may denote either courage or cruelty; as a head, strength or weakness of thought. And this ambiguity in the application of metaphorical words often affords occasion for jests and concise wit. We observed before, that Cicero never calls ill men lights of the state. But he once in this manner calls Sextius Clodius the light of the senate. For when his kinsman Publius Clodius had been killed by Milo, and his corpse was brought to Rome, Sextius raised the mob, and in a tumultuous manner carried it into the senate house, where they burnt it, and by that means set the building on fire: For which sedition Act, Cicero passes that joke upon him, under the metaphor of light, which elsewhere he always uses in a good sense.

But to proceed: All forced and harsh metaphors should be avoided; the one being less disagreeable to the mind than the other to the ear. Nor should they come too thick in a discourse. In a word, they ought not to be used, but either where a proper word is wanting, or they are more significant or beautiful than the proper word.

II. Metonymy. This, as defined by Quintilian, is, the putting one word for another. But Vossius describes it more fully, when he calls it, "A trope, which changes the name of things that are naturally united, but in such a manner as that the one is not of the essence of the other." That a metonymy is thus distinguished from the other tropes, has been sufficiently shown already in the two last chapters. When it is said, to put one word for another, or, to change the names of things, the meaning is, that the word so used changes its sense, and denotes something different from its proper signification. Thus, when Mars is put for war, and Ceres for corn, they lose their personal sense, and stand for the effects of which those deities were said to be the cause. So likewise, when Virgil says,

He drank the frothing bowl,

the word bowl must necessarily signify the liquor in the bowl. And when in another place, describing the temple of Juno at Carthage, in which the actions of the Trojan war were represented, and the images of the heroes, he makes Æneas, upon discovering that of Priam among the rest, cry out,

Lo here is Priam;

it is plain the word Priam there must stand not for his person, but his image or figure. And this property of changing the sense of the word appears peculiar to metonymy. In treating upon a metaphor, we observed the mistake of those who teach, that a word used metaphorically loses its proper signification; whereas it only changes its place, but not its sense; being applied to a thing to which it does naturally belong, by way of similitude. And as the not attending to this has made some persons into very great absurdities, in treating upon metaphorical expressions, and reasoning from them in the tropical sense; so the like has happened to others in some instances of a metonymy, where, by misapprehending their true nature, they have reasoned from them in the literal sense, as we shall show presently. A metonymy is not so extensive as a metaphor, nor altogether so necessary; because nothing is said by a metonymy, which cannot be expressed in proper words; whereas metaphors are often used for want of proper words to express some ideas. However, metonymies are very useful in language; for they enrich a discourse with an agreeable variety, and give both force and beauty to an expression. And what we observed with relation to a metaphor, is true also of this trope: that some metonymies, even in common discourse, are more frequently used than the proper words by which they are put. So, pale death, a blind way, and a happy state, are very common expressions with us. And it is more usual to say, This is such a person's hand, or I know his hand, than his writing, when we intend this latter sense of the word.

We now proceed to the division of metonymies; which are commonly distinguished into four kinds, from the different manner in which things are naturally, but externally, united to one another. Now things are thus united, or one thing depends upon another, either with respect to its production, or in the manner of its existence when produced. In the former way the effect depends upon its cause, and in the latter the adjunct upon its subjects. And hence arise four sorts of metonymies, which receive their names from the cause and effect, the subject and the adjunct.

It is called a metonymy of the cause, when the external cause is put for the effect. The external cause is twofold, the agent and end, which are usually called the efficient and final cause. Of the former kind are such metonymies, where the inventor or author is put for what was invented or effected by him. Thus, as
we said before, Ceres is sometimes put for corn, the use of which she was said first to have introduced; and Mars for war, over which he was thought to preside. And by this way of speaking, any artist or writer is put for his work. So Juvenal, blaming the luxury and profusion of the Romans, says, There are few tables without Mentor: that is, which were not made by him, or after his manner. And our Saviour says, in the parable of the rich man and Lazarus, They have Moses and the Prophets, meaning the books of Moses and the prophets. But under this sort of metonymy is included not only the agent, strictly so called, but also any means or instruments made use of in the doing of a thing, when put for the thing done. Thus, polite literature, is called humanity, because it cultivates and improves the human mind. And in that expression of Cicero, Words move nobody but him who understands the tongue; the word tongue, which is the instrument of speech, is put for speech or language. And in the like sense, arms are sometimes put for war, and the sword for slaughter. By the same kind of metonymy likewise any affection or quality is put for its effect. As when it is said, the end of government is to maintain justice; that is, such mutual offices among men as are the effects of justice. And so likewise in that of Cicero, It is the business of magistrates to check the levity of the multitude, by which he means tumults occasioned by their levity. Moreover, as human affections are attributed to the Deity in a metaphorical sense, so several parts of the human body are likewise ascribed to him by this kind of metonymy. Thus, his hand and his arm are used to express his power, as his ear and eye, his care and providence, these being the instruments of such effects in mankind. Metonymies of the final cause are those by which the end in doing a thing is put for the thing done. As when we say, The watch is set, meaning the watchmen, who are appointed for that purpose. And so likewise that expression, to make an example, as it signifies, to punish, in order to deter others from the like crimes by such an example. As also that of Virgil,

Phillis should garlands crop:

by which are meant flowers to make garlands.

The second kind of metonymy puts the effect for the efficient cause, whether the agent, or only the means and instrument. So Virgil calls the two Scipios the destruction of Libya, because they were the agents who effected it. And Horace compliments his patron Maecenas with the titles of being his guard and honour; that is, his guardian, and the author of his honour. But when Cicero tells the citizens of Rome, that the death of Clodius was their safety, he means the occasion only of their safety. And elsewhere he calls that a dark hope and blind expectation, the effect of which was dubious and uncertain to those who entertained it. And in like manner, the sons of the prophets, when they were eating the pottage which Elisha had ordered to be set before them, cried out, There is death in the pot; that is, some deadly thing, as is presently after explained. And thus sweat, which is the effect of labour, is sometimes put for labour. As in the threat denounced against Adam, In the sweat of thy face shalt thou eat bread, that is, by labour in cultivating the ground. And, in allusion to this way of speaking, Antony the orator tells Crassus, the improvement of the style by constant ex-
ercise, as he prescribed, was a thing of much sweat.

And virtue is said to be gained by sweat, that is, con-
tinued care and exercise in subduing the passions, and
bringing them to a proper regulation. But in these
two expressions there is likewise a metaphor, the effect
of bodily labour being applied to that of the mind.
In all these instances the effect is put for the efficient
cause.

The third kind of metonymy is, when the subject is
put for the adjunct. By subject here, in a large sense
of the word, may be understood that wherein some other
thing is contained, or about which it is conversant; as
likewise the possessor with respect to the thing he posses-
ses; and the thing signified, when put for the sign of it.
Now, by the first of these ways of speaking, the seat of
any faculty or affection is used for the faculty or affection
itself. So it is usual to say, a man of a clear head, when
we mean a clear mind or understanding; the seat of the
mind being supposed to be in the head. And a person
is said to have a warm heart, because the heart has been
thought the seat of the affections. In like manner, the
place where any actions are performed is put for the
actions done in it. As when Cicero says, 'Do not al-
ways think of the forum, the benches, the rostra, and
the senate,' meaning the discourses which were usually
made in those places. So likewise the country, or place
of residence, is put for the inhabitant, as in that passage
of Cicero: 'And to omit Greece, which always claim-
ed the pre-eminence for eloquence, and Athens, the in-
ventress of all sciences, where the art of speaking was
invented and perfected; in this city of ours, (meaning
Rome), no studies have prevailed more than that of elo-
quence:' where the words Greece and Athens stand to
denote the inhabitants of those places. And either may
also be referred those expressions in which the time is put
for the persons living in it; as the degeneracy of the
present age, the virtue of former times. In the second
way above mentioned, the object is used for the person
or thing employed about it: As when Cicero says,
'In time of battle the laws are silent; where by laws
he intends the judges, who pronounce sentence accord-
ing to law. By the third of these ways, in which the
possessor is put for the thing he possesses, we say, to de-

vour, destroy, or ruin a man, meaning not his person
but his estate. And mythologists explain the fable of Actaeon
by this trope, who is said to have been devoured by his
dogs; for by dogs they understand flatterers and parasi-
tes, who consumed his estate and brought him to beg-
gary. By the last way before recited, which puts the
thing signified for the sign, statues and pictures are
called by the names of the persons which they represent:
as in that jest of Cicero upon his brother Quintus, when,
as Macrobius, relates, 'being in the province which his
brother had governed, and seeing a large portrait of part
of his body, holding a shield, though Quintus was but
a little man, he said, My half brother is bigger than
my whole brother.' The Papish doctrine of transub-
stantiation is founded upon an abuse of this trope. For
when our Saviour, speaking of the bread and wine at
that time before him, says, 'This is my body, and this
is my blood,' his plain meaning is, they were the signs
of his body and blood, the thing signified being put for
the sign by this sort of metonymy. But the Papists take
the expression literally, which must doubtless be very
aburd:
Part III.

O R A T O R Y.

Elocution. absurd: since the words relate to the time then present, while Christ was yet living, and spoke them; when it was impossible for the bread and wine to be converted into his body and blood, it being evident to all who were present, that those elements, and his body, existed separately at the same time. But if the words are explained by this trope, the sense is plain and easy, and the way of speaking familiar to all writers. Whereas they who plead for the literal sense might with equal reason assert that those expressions above mentioned are to be taken literally, in which several parts of the human body, as the hand, the arm, the ear, and the eye, are ascribed to the Deity; or that, when our Saviour in a metaphorical sense calls himself a vine, and a door, these words were designed to be applied to him strictly and properly, and not by way of similitude only, as is the case in all metaphors.

The fourth kind of metonymy is that wherein the adjunct is put for the subject, which is done in the same variety of ways as the former. It is therefore a metonymy of the adjunct, when the thing contained is put for that which contains it. As when Virgil says, "They lie down upon purple:" that is, upon couches dyed with purple. And again, "They crown the wine:" meaning the bowl which contained the wine, it being the custom of the ancients to deck their bowls with garlands at their entertainments. By these tropes likewise virtues and vices are put for the persons in whom they are found. As in that beautiful passage of Cicero, where, comparing the profigate army of Catiline with the forces of the state, he says, "On this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that deceit; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion; in a word, equity, temperance, fortitude, prudence, and all virtues, engage with injustice, luxury, cowardice, rashness, and all vices." And to this trope those expressions are to be referred, in which any thing is put for the object about which it is conversant. As in that saying of the wise man, "Hope deferred makes the heart sick:" where hope is put for the thing hoped for. And thus Suetonius calls the emperor Titus the love and delight of mankind, whose mild and obliging temper rendered him the object of those agreeable affections to all persons under his government. A third use of this trope is putting a thing for the time in which it was done. Thus we say of a person, he has served so many campaigns, meaning so many summers, that being the usual time in which armies are drawn out into the field. Lastly, by this metonymy, the sign is put for the thing it signifies; as, the sceptre for the regal dignity, and the sword for the authority of the magistrate.

III. Synecdoche. This is a trope by which either the whole of a thing is put for a part of it, or a part of the whole, so that the two things, whose ideas are presented to the mind in this trope, are internally related to each other: by which, as has been shown already, it is distinguished from all the other tropes. In a synecdoche the word retains its proper sense, and the expression is elliptical, as will appear by the several species of it, wherein the ellipsis in most of the examples is very obvious, and may with no great difficulty be supplied. Now a thing may be considered as a whole in three different respects, which logicians call universal, essential, and integral whole. An universal whole is any genus with regard to its several species; as, an animal, with respect to mankind and brutis, or philosophy, with respect to the several arts and sciences comprised under it. An essential whole consists of matter and form; as, a man of body and soul. And an integral whole is any body or quantity, with respect to the several parts of which the matter of it is composed, and into which it may be divided; as, an human body with respect to its several members; or a year, as divisible into months, weeks, and days. And thus rhetoric is an integral whole in respect to the four parts that compose it; namely, invention, disposition, elocution, and pronunciation. So likewise any aggregate body, as a civil community, which is divisible into those who govern and are governed; or any army, consisting of the general and his soldiers. As a whole therefore, in each of these acceptations of the word, is frequently put for a part, and a part for the whole; hence arise six species or sorts of synecdoche.

The first of these puts the genus for the species.—Thus, virtue in general is sometimes used to denote some particular sort of virtue. As when Cicero mentions virtue as one of the four qualifications necessary in a general, he means greatness of mind. And so persons are often commended for instances of virtue shown in their conduct, which respect only some single virtue, as justice, temperance, or the like: And in this sense Cicero calls Claudius a deadly animal. So when our Saviour commisions his apostles to preach the gospel to every creature, the meaning is, every rational creature. And thus, likewise, to talk to a person sometimes denotes the same thing as to blame him, which is one way of talking.

The second kind of synecdoche puts the species for the genus. Thus bread denotes any kind of food; as when a person is said to get his bread by his labour. In the same way of speaking, money is put for any kind of wealth in general. And it is an usual expression to say, that wine destroys more than the sword; that is, than any hostile arms. And the legal form of banishment among the Romans was, to prohibit persons the use of fire and water; that is, the most common and ordinary necessities of life, in which all others were included.

The third species of this trope is, when the essential whole is put for one of its parts; that is, either for the matter or form. Thus, in the evangelist, Mary Magdalen says, They have taken away my Lord, and I know not where they have laid him, meaning his body. —So it is usual to say of a deceased person, He was buried at such a time. And in the inscriptions of sepulchral monuments we frequently meet with this expression, Here lies such a one; that is, his corpse. Nor are instances uncommon in which the whole being is put for the form. Thus when Cicero says, Those persons live, who have fled from the confinement of the body, as from a prison; by persons most necessarily be understood their souls, which are here distinguished from and set in opposition to their bodies. And so Virgil represents Æneas as meeting with Dido and some of his Trojan friends in the infernal regions; by which are meant their ghosts.

The fourth kind of synecdoche is, when either the matter or form is put for the whole being. Thus silver and
ORATORY.

Part III.

Election. and gold are used to signify money made of those metals; as when we say, I have so much silver, or so much gold. And the word soul, both in our own and other languages, is put for the whole person. So with us, a merry soul, and a dull soul; in Cicero, dear souls; and in Horace, candid souls, are all used in this tropical sense. But this way of speaking occurs nowhere more frequently than in the Sacred Writings. Thus, for instance, it is said, All the souls which came with Jacob into Egypt, meaning the persons. And again, The soul that smiteth it shall die; from which expression, and others of the like import, some persons, by not attending to the nature of the trope, have been erroneously led to infer that the soul is naturally mortal. But sometimes only part of the matter stands to express the whole essence or being. So we imitate the Latins in using the word caput or head to denote either a person or thing. For, as with them lepidum caput, so with us a witty head, signifies the same as a man of wit. And in the same sense, so many head of cattle means so many entire cattle.

By the fifth sort of synecdoche, the whole of any material thing or quantity, whether continued or discrete, is put for a part of it. So when Cicero says, A war is kindled through the whole world, in compliment to his country, he calls the Roman empire the world. And this expression is also used by historians. Thus Cornelius Nepos, speaking of the quarell between Mark Antony and Augustus, tells us, that each of them desired to be lord of the world. And in like manner St Luke says, There went out a decree from Caesar Augustus, that all the world should be taxed. So in St Paul's shipwreck, it is said, They ran the ship aground, that is, the head of her, for it is plain by what follows, that the stem was loose. And as to discrete quantity, our Saviour, using this trope, said he should be three days and three nights in the heart of the earth. Though he did not continue three whole days and nights in the grave, but only part of the first and third day, and the whole second day, with the two whole nights between the first and third day, according to our way of reckoning. For he was buried on Friday in the afternoon, and rested in the grave that night, with the following day, which was the Jewish Sabbath, and was risen on the morning of the next day. So that we must necessarily have recourse to this synecdoche which puts the whole for the part, to clear up that event.

By this kind of synecdoche also, the plural number is sometimes put for the singular. Thus St Matthew says, The thieves who were crucified with our Saviour reviled him: though it is plain from St Luke, that only one of them did so. It may also be referred to this trope, when a certain number is put for an uncertain one. So it is an usual way of expression to say, I have seen or done such a thing an hundred or a thousand times: when perhaps so many are not really intended, but only in general some considerable number.

The sixth and last kind of synecdoche puts a part of any material thing or quantity for the whole of it. So we say of a man, He sheltereth himself under such one's roof; that is, in his house. And of a fleet, that it consists of so many sail; meaning, so many ships. And by this trope, that is ascribed to a single person which was done by the assistance of others, and in conjunction with them: As when it is said, Hannibal killed forty thousand Romans at the battle of Cannae; For an army is an aggregative body, of which the general is the head, and consequently the chief part of it. And to this kind of synecdoche may also be referred such expressions in which the singular number is put for the plural: as if one should say, A man is liable to be misled by the influence of irregular passions; meaning all men, or mankind in general. Or when less than the real number is put for any round number: Thus some ancient writers, when they speak of the Grecian armada that came against Troy, call it a fleet of a thousand ships; though according to Homer's list, it contained 1180. And so likewise the Greek interpreters of the Old Testament are usually called the Seventy; whereas, in reality, they were seventy-two.

IV. Irony. This is a trope in which one contrary is signified by another: As if any one should say, Well done, when at the same time his design is to intimate that the thing was ill done. So, by this manner of expression, the speaker appears to mean something contrary to the sense of the word he makes use of. Not that the word is changed from its usual signification; but by the circumstances attending the expression, we perceive the contrary to what is spoken is intended. Quintilian observes, that an irony may be known one of these three ways: "By the manner of pronunciation, or from the nature of the person or the thing. For (as he adds) where any of these does not suit with the words, it is plain the speaker intends the contrary. The irony is very plain from the manner of pronunciation in that passage of Terence, where Simo speaking to his servant by way of reproof, says, "You have taken great care indeed." From the circumstances of the person, when Cicero, addressing to Catiline, says, "He went to your companion, that excellent man, Marcus Marcellus." When he calls him an excellent man, it is evident he means the contrary: because no good man would be a companion of Catiline. And when he begins his oration for Ligarius with saying, "Caesar, this is a new crime, and never heard of till now," the thing he is speaking of shows it to be an irony; for it was not new, as all who were present very well understood.

The subjects of irony are vices and follies of all kinds. And this way of exposing them is often more effectual than serious reasoning: For many persons, who, either from temper or want of reflection, cannot be moved by the force of an argument, are not proof against the poignantness of wit and raillery. And therefore we find the most grave and serious persons have not declined the use of this trope upon proper occasions. Socrates, whom the oracle pronounced the wisest man of his age, gave so much into it, that he got the name of sophron, that is, the droll. In the Sacred Writings we have a remarkable instance of it in the prophet Elijah, who challenged the prophets of Baal to prove the truth of their deity. For it is said expressly, "He mocked them, and said, Cry aloud, for he is a god; either he is talking, or he is pursuing, or he is on a journey, or peradventure he sleepeth, and must be awaked." And Solomon takes the like method to expose the follies of youth by this ironical apothecary, "Rejoice, O young man, in thy youth," with what
Part III.

ELECTION. What follows, which is all ironical. Nay, our Saviour himself thought fit thus to reprove the Jewish doctors, when he says, "Full well ye reject the commandment of God, that ye may keep your own tradition!" Where, by the words <span class="emphasis">
full well</span>, or as it is in the original, 

ωάκε, it is very evident that a severe reprimand was intended.

An irony is used on a variety of occasions, as we shall show from some instances in Cicero. Sometimes he applies it in a way of jest and banter: As when he says, "We have much reason to believe the modest man would not ask him for his debt, when he pursues his life." At other times by way of insult and derision: Thus when he would represent the forces of Catiline as mean and contemptible, "A terrible war, (says he), in which this band of rakes are to march under Catiline! Draw out all your garrisons against this formidable body." Again, at other times, to give the greater force to his argument, he would seem, as it were, by this trope to recall and correct what he had said before; as in his oration for Milo: "But it is foolish in us to compare Drusus, Africanus, Pompey, and ourselves with Clodius; all our calamities were tolerable, but no one can patiently bear the death of Clodius!"

Now the character of Clodius was so well known, that all who were present must be sensible he meant the contrary. And, to name more, an irony is never used to greater advantage, than when it is followed immediately by something very stinging. Thus, speaking of Piso, he says, "You have heard this philosopher: he denies that he was ever desirous of a triumph." And then addressing himself to him, he immediately adds, "O wretch! when you destroyed the senate, sold its authority, subjected your consulate to the tribune, overturned the state, betrayed my life and safety for the reward of a province; if you did not desire a triumph, what can you pretend you did not desire?" This must effectually confound the false gravity at that time assumed by Piso.

Art. II. SECONDARY TROPHES.

Secondary tropes are so called, because they are all of the same nature with the former, and may be referred to some or other of them, though they have received different names.

They are chiefly eight in number; Antonomasia, Communication, Litotes, Euphemism, Catachresis, Hyperbole, Metaphasis, and Allegory. The three first of these are simple tropes, and may all be referred to a Synechdoche. But the five last are of a mixed or complex nature, and not confined to any one of the primary tropes; as will appear in treating upon them in order.

I. A common or general word is sometimes used for the proper name of some particular thing or person which upon any account is eminent and remarkable. So we say, He is gone to the city, or he came from the city, that is, London. And by the Scriptures, we mean the Bible. So likewise, in speaking of persons, the orator is used for Cicero, the poet for Homer or Virgil, and the philosopher for Aristotle: and it is not unusual to say the apostle, when we mean St Paul. On the contrary, the proper names of things or persons are sometimes applied to any other of the same character. Thus we use the word gospel for any certain and undoubted truth. And Carthaginian faith proverbially stood for the greatest falsehood and deceit among the Romans. With the Greeks, Hercules signified a strong man, Nestor a wise man, and Iris a beggar; and the names of Samson, Solomon, and Job, now answer the like characters. Both these ways of expression are often very emphatical, and heighten the idea more than where things are expressed by their own name. To call a good orator Cicero, or an excellent poet a second Virgil, includes not only an encomium upon the arts themselves, but leads the mind to what is most perfect in them, and was peculiar to those persons. These forms of speech are called antonomasia, and come properly under a synecdoche; for in the former the whole is put for a part, and in the latter a part for the whole.

II. Nothing is more common with orators than a change of persons. Sometimes, to avoid envy, and prevent the imputation of pride, in assuming to themselves the praise of any laudable action, they ascribe it to their hearing, and do not say, we, but ye did so and so. At other times, when it is necessary to remind them of something which they have done amiss, or to caution them against some wrong step for the future; to prevent giving offence, they take it upon themselves, or at least join themselves with them, and do not say, you have done this, or do not you do this: but, we have done it, or let us not do it. And again, at other times, in compliment to their hearers, they join them as partners in the commendable actions or virtues of other persons; as when the whole body of the people is brought in to share the praise arising from the success of wise counsels or victorious arms. Such ways of speaking often occur both in Demosthenes and Cicero. They are called communication, and come properly under a synecdoche of the whole.

III. On the contrary, there is a mode of speech, Litotes, in which, by denying the contrary, more is intended where, by the words express. This way of speaking is called the way of understatement, and is often used for sake of modesty where a person is led to say anything which is not meant than to soften an expression which in direct terms might sound harsh or give offence. As if one should say, I do not commend you for that; meaning, I greatly disapprove, or blame you for it: where more being understood than the words expressly denote, it is properly a synecdoche of the part. Not that this manner of speaking is always to be so interpreted; but where it is not, there is no trope; which must be judged of by the circumstances of the discourse. But that it frequently is so used, might be easily shown from many instances; though it will be sufficient to mention two or three. Cicero speaking of Cotta, calls him no mean orator, whom he had just called a very great orator. And he says of Varro that he pursued his studies not without industry; and afterwards gives him the character of a man of the greatest application. Which passages, compared together, plainly show the import of those negative expressions. And a friend of Cicero, writing to him, begins his letter thus: "Although I am sensible the news I send you will not be very pleasant." This news was concerning the death of another friend of Cicero's; and there by the words not very pleasant, must, to be sure, be meant very unpleasant and melancholy; but he chose that expression in the beginning
beginning of his letter, as the softest and least shocking, the better to prepare him for the following account of what that news was. And in this way interpreters explain that passage in St Matthew: And thou Bethlehem in the land of Judah art not the least among the princes of Judah; where, by not the least, they understand the gr-uest, or very great, upon account of the honour it received by the birth of our Saviour, as the words immediately following plainly intimate.

IV. When any displeasing or contemptible thing is expressed by a more soft and acceptable word, it is called euphemism. And as the word made use of is either contrary to the proper word, or only different from it, it may be referred to different tropes. The Latins have a soft way of expressing their disregard to a person, by saying valut; which we have borrowed from them, and say, fare him well. When the contrary being intended to what is expressed, it comes properly under an irony. And as the word death carries in it an idea that is disagreeable to human nature, instead of saying a person is dead, we often say he is deceased, or departed; which we have also taken from the Latins, who use the words decessit and obit in the same sense. So that in both languages it comes under a synecdoche of the whole; to depart out of life being one sort of departure. But when the evangelist, speaking of Stephen, who was stoned to death, expresses it by saying, that he fell asleep; this is a beautiful metaphor, taken from the similitude between the death of a good man and sleep.

Catachresis signifies in general any harsh trope, though it is most commonly found in metaphors. It is principally used by poets, who make choice of it for novelty, or to enforce an expression, where the proper word does not seem strong enough. As when Milton, in describing the angel Raphael's descent from heaven, says, he

Sails between worlds and worlds;

where the novelty of the word enlivens the image more than if he had said flies. But it is sometimes found in the gravest authors, and even in the sacred writings. So we read of the blood of the grape. And Solomon says, the horse-leech hath two daughters. In all these instances the trope is a metaphor. But when St John says in the Revelations, I turned to see the voice that spake to me, it is here a metonymy of the adjunct; the word voice being put for the person who uttered it. In St Matthew we read of Simon the leper; not that he was then a leper, but had been so, and was cured; which is a synecdoche of the part. And when a criminal is said to have had his reward, that is, his punishment, it is an irony.

Hyperbole is the boldest of all tropes; for it exceeds the strict bounds of truth, and represents things either greater or less, better or worse, than they really are. But the representation is made in such a manner as not to impose on the hearers. For an hyperbole is not used to define or describe any thing accurately, but only to magnify or depress it in a considerable degree, when we either cannot or do not choose to represent it exactly. The excess in this trope is called auresis; as when we say of any thing that is very high, it reaches to the skies. The defect, or contrary extreme, is termed meiosis. So we say of a very lean person, he is nothing but skin and bones, or a mere skeleton. It is principally metaphorical, but sometimes taken from other tropes. When Saul and Jonathan are said to have been swifter than eagles, and stronger than lions, the expression is founded in similitude, and is therefore a metaphor. When, instead of saying Cato was a very virtuous man, the historian calls him the image of virtue; it is an hyperbolical metonymy of the adjunct for the subject. And when we read in the Mosaic history of cities fenced upon every side, there is a synecdoche. But if a man of weak sight be said to be eagle-eyed, it is an irony. Those hyperboles which are expressed comparatively, are commonly most emphatical, because they show a peculiarity in the excess. To say a thing is as light as a feather, carries the idea very far; but to say it is lighter, not only carries it still farther, but also heightens it, by leaving the mind at an uncertainty where to fix the limits.

Sometimes two or more tropes and those of Metalepsis, a different kind, are contained under one word; so where two or more tropes are met at once.

Seston and Marius proved very fatal to the Roman state. Julius Caesar was then a young man. But Sulla observing his aspiring genius, said of him, In one Caesar there are many Mariuses. Now in this expression there is a metalepsis. For the word Marius, by a synecdoche, or antonomasia, is put for any ambitious and turbulent person; and this again, by a metonymy of the cause, for the ill effects of such a temper to the public. So that Sulla's meaning, divested of these tropes, was, that Caesar would prove the most dangerous person to the Roman state that ever bred in it; which afterwards proved true in the event. So when Virgil, describing that part of the African coast where Aeneas arrived with his ships, says, A dark wood hung over it; the word dark, by a metonymy of the effect, is put for shady, and that again by the same trope for thick; his meaning is, a thick wood. But the words of Dido, in the same poet, contain a larger gradation, when she says,

Happy, oh truly happy, had I been,
If Trojan ships our coasts had never seen.

In which expression first by a metonymy of the adjunct, the ships are put for the Trojans in the ships; and these, by a synecdoche of the whole, for Æneas, who was one of them; and again his arriving on the coast, by a metonymy of the cause, for his seeing him; and lastly, her seeing him, by the same trope, for the passion she had for him. So that her meaning is, she had been happy, if she had never entertained a passion for Æneas. This trope is more frequently to be met with in poets than in orators, as they take greater liberty in using distant allusions than is suited to that perspicuity of expression which is required in oratory. But as Quintilian has well observed, all the intermediate links of the chain in this trope are of no further use than to lead the mind gradually from the first to the last, the better to perceive their connection. As in the example last mentioned, relating to Dido, if we drop all the intervening steps, and connect the words expressed with what is directly intended, they will be found to contain a very remote cause put for the effect, which comes un-
mixed allegories, that is, such wherein the proper name of the thing is expressed, which the whole similitude respects. Of this kind is that in the speech of King Philip of Macedon, given us by Justin, where he says, "I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunder-storm from the west, which will fill all places with a large shower of blood, wherever the tempest of victory shall carry it." The proper words war, blood, and victory, being joined to the tropes cloud, shower, and tempest, in this sentence, render the several parts of the similitude plain and evident. Quintilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one of the two things between which the comparison is made, are allegorically applied to the other: As when Cornelius Nepos says of Atticus, "If that pilot gain the greatest reputation who preserves his ship in a boisterous and rocky sea; ought not to be to be thought a man of singular prudence, who arrived in safety through so many and so great civil tempests? These are the allegories with which orators are chiefly concerned.

§ 2. Of Figures.

This term seems to have been borrowed from the The term stage, where the different habits and gestures of the figure actors, suitable to the several characters they sustained, were by the Greeks called acts, and by the Latins borrowed from the figure: And it is not unusual with us to say of a per-stage person, both with respect to his dress and action, that he makes a very bad, or a very graceful figure. And as language is the dress, as it were of our thoughts, in which they appear and are represented to others; so any particular manner of speaking, may, in a large sense of the word, be called its figure, in which latitude writers sometimes use it. But rhetoricians have restrained the sense of the word to such forms of speech as differ from the more common and ordinary ways of expression: as the theatrical habits of actors, and their deportment on the stage, are different from their usual garb and behaviour at other times. A figure therefore, in the sense it is used by rhetoricians, is a mode of speaking different from, and more beautiful and emphatical than, the ordinary and usual way of expressing the same sense; or, in other words, that language which is suggested either by the imagination or the passions. Now as the habits and gestures of our bodies are in a maner infinitely variable, so it is plain that the different forms of speech are almost innumerable. But every alteration from the common manner ought not to be esteemed a figure, nor deserves that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

The subject of figure seems to have been one of the last things which was brought into the place of oratory, in order to complete it. Aristotle, who treats so accurately upon other parts, says very little of this. But the Greek writers who came after him have abundantly supplied that deficiency. It is to them we owe the chief observations that have been made on this subject. They took notice of the several modes and turns of expression, observed their force and beauty, and gave them particular names by which they might be known and distinguished from each other.

Vol. XV. Part I.
thing again would many times be deemed a tautology by others.

And to this end the mind is

rulled, is not only allowable, but the repetition renders it more strong and affecting. So likewise to interrogate, exclaim, or admire, under the influence of a passion, impresses the hearers, and disposes them to attention; whereas at another time perhaps such ways of speaking would scarce be consistent with prudence.

There is a natural sympathy in men's minds, which disposes them to receive impressions from those with whom they converse. Thus one gay and pleasant companion gives a cheerfulness and vivacity to a whole company; whereas, on the contrary, one who is dull and phlegmatic damps the spirits of all about him, and affects them with the same gloomy temper.

Figures are peculiarly serviceable to an orator for answering these different intentions. And as he finds them in life, from thence he must copy them; as a painter does the features of the countenance, and the several parts of the body; figures being to the one what lines and colours are to the other. The design of Catiline to destroy the Roman state and burn the city, is a story well known. There was an army drawn together at a proper distance to favour the undertaking; and others were left in Rome, who had their parts assigned them for burning the city, and destroying those who should escape the flames. And, in a word, every thing was ready for putting in execution this horrid and barbarous scheme. So that nothing retarded it but the taking off Cicero, who was then consul, which was thought necessary to be done first. Cicero, upon information of the design against his life, finds means to prevent it, and the same day calls together the senate. And Catiline, who was a man of consummate boldness, had the confidence to appear in that assembly. Upon their meeting, Cicero opens to them the whole affair of the conspiracy, and the design against himself, in a most warm and pathetic harangue. In which he had two things in view; to raise the indignation of the senate against the conspirators, and particularly against Catiline; and, either by terrifying or exasperating him, to oblige him to leave the city. Now he does not begin his speech in his usual manner at other times, by addressing to his audience, bespeaking their favour and attention, or letting them gradually into the design of what he was about to say; but as Catiline was present, he immediately falls upon him with vehemence, in the following manner: "How far, Catiline, will you abuse our patience? How long will your fury insult us? What bounds will you set to your unbridled rage? Does neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you? Do not you perceive your designs are discovered, and that all who are present know of your conspiracy? Who of us, do you think, is ignorant of what you did the last night, and the night before, where you was, who was with you, and what you resolved on? O times, O manners! The senate knows this, the consul sees it; and yet this man lives! —lives? may, comes into the senate, joins in the public counsels, observes and marks out each of us for destruction?" And in the same impetuous strain he proceeds through.
Part III.

ORATORY.

Elocution. through his whole speech, interspersing a great variety of the like strong and moving figures. And the discourse had its desired effect: for when Catiline stood up afterwards to make his defence, the whole senate was so inflamed, and their resentments against him rose so high, from what Cicero had said, that they had not patience to hear him speak; upon which he left both them and the city. Had Cicero, instead of venting his just indignation against the author of so barbarous and inhuman a design, in the manner he did, by figures suited to strike the passions of his hearers; had he, instead of this, attempted to reason with him, and told the story in a cold and lifeless manner, he would have exposed himself to the contempt of Catiline; and by leaving the senate little or nothing moved at what he said, prevented perhaps their coming to those speedy and vigorous resolutions which were necessary at so critical a juncture. Let us suppose him to have expostulated with Catiline in much the same words as before, but thrown into a different form, and divorced of those pathetic figures. As thus: “Catiline, you have really abused our patience to a great degree. You have insulted us with your furious proceedings a long while. You seem to have fixed no bounds to your unbridled rage. Neither the night-guard of the palace, nor the city-watch, nor the people’s fear, nor the agreement among good men, nor the calling together of the senate in this fortified place, nor the counseleers and looks of this assembly, appear to move you in the least. I assure you we are all of us apprized of what you did the last night, and the night before, where you saw, and who were with you, and what resolutions you came to. These are sad times, the age is very degenerate; that the senate should know all this, the consul see it; and yet that this man should live, come into the senate, hear all our debates, and mark us out to destroy us.” You see the sense is entirely the same, and the words too in a great measure; so that there is little more than an alteration in the form of them. And yet who does not perceive how flat and languid such a way of talking must have appeared at that time? and how much it loses of that spirit and energy, which shows itself in Cicero’s manner of expression? Had he delivered himself thus, it might indeed have made the senate look upon Catiline as an abandoned wretch, lost to all virtue and goodness, and perhaps have moved some to pity him on that account; as we are easily induced to compassionate persons in such circumstances, especially when descended from noble and virtuous ancestors, which was his case. But sure it would have been ill suited to fire their minds with that generous regard for their country, and the necessary precautions for its security, which the circumstances of the state then required. Nor would Catiline have been at all deterred by it, but rather encouraged in the prosecution of his designs, from the little effect a speech so managed must probably have had upon the minds of the senators. But Cicero knew very well that the passions of mankind are the springs of action: that it is many times not sufficient for an orator to convince their minds, by setting the truth in a clear light; but he must also raise their hopes, alarm their fears, inflame their anger, or excite some other suitable passion, before they will be brought to act with that zeal and fervour which the case may require. And as he was admirably well skilled in this art of touching the passions, he seldom fails to fix upon the proper methods of doing it, and makes choice of such figures and modes of speaking as in the strongest manner represent the emotions of his own mind. For every passion is not to be expressed by the same figures, any more than it is drawn by the same lines, or painted with the same colours. When Dido finds that Aeneas is about to leave her, she uses all her arts to detain him. And as persons in great distress are seldom at a loss to express their condition in the most affecting way; she discovers her fear, anger, revenge, with the whole crowd of disorders which then possessed her mind, in a variety of moving figures, suited to raise the counter passions in his breast, as is finely represented by Virgil in that artful speech he has made for her, which we forbear to recite for no other reason but the length of it. But what particular figures are most accommodated to answer the several ends proposed by them, will best appear when we come to treat of them separately.

We shall therefore now proceed to lay down a few directions for the proper use of figures. And first they should always be accommodated to the sentiments, and rise in proportion to the images designed to be conveyed by them. So far as they are founded in reason, they are suited to impress the mind; but where the language outstrips the thought, though it may please the ear, and some weak persons may be carried away with a pomp of words, yet an intelligent hearer will soon see through the thin and airy dress. It is the sense which gives weight to the figure, as that by striking the imagination awakens the mind, and excites it to act in conformity to reason. Again, in the use of pathetic figures, it is generally better to be nervous than copious, that the images, by their closer union, may impress the mind with greater force and energy; though in such figures as are designed for ornament or illustration, a more diffusive way of painting is sometimes agreeable. But further, the too frequent use of figures ought to be avoided. For what was observed in relation to tropes, is also true with respect to these; that a great number of them is apt to darken and obscure the style. And besides, Cicero’s reflection in this case is very just, That “it is hard to say, what should be the reason, that those things, which most affect us with a sensible pleasure, and at first sight seemest move us, do likewise seemest cloy and satiate us.” But that it is so, we find by common experience. Lastly, figures should be so interwoven in a discourse, as not to render the style rough and uneven, sometimes high and at other times low; nor dry and jejune, nor pompous and florid. In a word, they should rather seem to arise from nature than art; to offer themselves, than to be the effect of study; and to appear not like patches upon a face, but the agreeable beauty of a sound and healthful complexion. But of this we shall have occasion to speak more at large hereafter, in treating upon the different kinds or characters of style.

As to the division of figures, which is what remains to be considered, they are usually divided into two sorts, figures of words, and figures of sentences. The difference between them consists in this; that in the former, if you alter the words, or sometimes only the situation of them, you destroy the figure; but in the latter the figure remains, whatever words are made use of,
Art. I. Verbal Figures.

These may be distinguished into three sorts, as they consist in a deficiency of words, a redundancy, or a repetition.

I. Of the first sort are ellipsis and asyndeton. Ellipsis, is when one or more words are wanting in a sentence to complete the construction, and fully express the sense. This figure is often used in proverbial speeches: as when we say, Many men, many minds; that is, have many minds; and, The more danger, the more honour; that is, gains more honour. But where more is intended by such expressions than mere brevity, and especially when they are the effect of some passion, the figure receives another name, and is called apoposis, which is placed among the figures of sentences, where we shall consider it.

Asyndeton, is when the particles that connect the members of a sentence one with another are left out, to represent either the celerity of an action, or the haste and eagerness of the speaker. Thus Caesar expresses his speedy conquest of Pharnaces: I came, I saw, I conquered. If he had inserted the copulative, and said, I came, and I saw, and I conquered, it would have retarded the expression, and not given so full and just an idea of the swiftness of the action. In the last article we took notice of the vehement and impetuous manner in which Cicero attacked Catiline in his first oration, where his design was to fire the minds of the senate against him, and oblige him to leave the city, both which points he gained by that speech. The next day, therefore, when Catiline was gone, he calls together the body of the citizens, and, makes a speech to them, which in a sort of raptur or transport of mind he thus begins, by acquainting them with the departure of Catiline, He is gone, departed, escaped, broke out; intimating at the same time both the excessive rage in which Catiline left Rome, and the great pleasure with which he was himself affected on that account. This concise way of speaking adds likewise a considerable emphasis to an expression, and by bringing the several parts of a thing nearer together affects the mind with a greater force. Thus Cicero sets Cato's character in a very strong and beautiful light by the use of this figure. "Nature itself (says he) has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtues."

II. The second sort of verbal figures is contrary to these, and consists in a redundancy or multiplicity of words; which are likewise two, pleonasmos and polycladoton.

When we use more words than are necessary to express a thing, it is called pleonasmos. This is done sometimes for greater emphasis, as when we say, Where in the world is he? At other times it is designed to ascertain the truth of what is said: So the servant in Terence, when the truth of what he had related was called in question, replies, It is certainly so; I saw it with these very eyes.

When the several parts of a sentence are united by proper particles, it is called polycladoton. This adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by retarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits with the gravity of his style. So he encourages the Athenians to prosecute the war against King Philip of Macedon, from this consideration, that now "they had ships and men, and money, and stores, and all other things which might contribute to the strength of the city, in greater number and plenty than in former times." Every article here has its weight, and carries in it a proper motive to animate them to the war. But if you remove the copulative, the sentence will lose much of its force.

III. The third kind of verbal figures consists in a repetition. And either the same word in sound or sense, is repeated; or one of a like sound, or signification, or both.

Of the former sort there are ten, called antanacasis, pleco, episeuxis, climax, anaphora, epiphrase, symppoe, epanalepsis, anadiplosis, and epanodos. The two first of these agree in sound, but differ in sense; the eight following agree in both.

When the same word in sound but not in sense is repeated, it is called antanacasis. This figure sometimes carries a poignancy in it; and when it appears natural and easy, discovers a ready turn of thought. As when a son, to clear himself of suspicion, assured his father he did not wait for his death; his father replied, But I desire you would wait for it. Here the word wait is taken in two different senses. It is likewise used on serious occasions, as in grave and moral percepts, which are apt to affect the mind with greater pleasure when delivered in an agreeable dress. As this: Care for those things in your youth, which in old age may free you from care: Where the word care in the former place signifies to provide, and in the latter anxiety of mind. And even our Saviour himself once uses this figure, when he says to one of his disciples,
Part III.

ORATORY.

who desired to be dismissed from attending him, that he might go and bury his father; Follow me, and let the dead bury their dead: Where dead in one place denotes a natural death, and in other a moral or spiritual death.

Sometimes the name of some person or thing is repeated again, to denote some particular character or property designed to be expressed by it; and then it is called place. Thus Cicero says, Young Catō wants experience, but yet he is Catō; meaning he had the steady temper of the family. And so in the proverbial expression, An ape is an ape, dress him ever so fine.

When a word is repeated again with vehemence in the same sense, it is called epiphraxis. This figure shows the earnestness of the speaker, and his great concern of mind about what he says; and therefore has a natural tendency to excite the attention of the audience. It is suited to express anger, surprise, sorrow, and several other passions. As when Cicero would express his indignation against Antony for having been the chief instrument in bringing on the civil war, he says to him: You, you, Antony pushed Caesar upon the civil war. And thus he tells Catiline in his first invective against him: You live; and live, not to lay aside, but to pursue, your wicked design. And when our Saviour would express his great concern and sorrow for the wickedness of the Jews, he does it in this pathetic manner: O Jerusalem, Jerusalem, who killed the prophets.

Climax is a beautiful kind of repetition, when the word, which ends the first member of a period, begins the second, and so through each member, till the whole is finished. There is a great deal of strength as well as beauty in this figure, where the several steps rise naturally, and are closely connected with each other. As in this example: There is no enjoyment of property without government, no government without a magistrate, no magistrate without obedience, and no obedience where every one acts as he pleases. But as Quintilian observes, this figure lies so open, that it is apt to look too much like art; for which reason he advises not to use it often. To prevent this, therefore, orators sometimes disguise it, by not repeating the same word which stood in the former member, but some other equivalent to it. As in the following instance of Cicero for Milo: "Nor did he commit himself only to the people, but also to the senate; nor to the senate only, but likewise to the public forces; nor to these only, but also to his power with whom the senate had entrusted the whole commonwealth.

When several sentences, or members of a sentence, begin with the same word, it is called anaphora. This is a lively and elegant figure, and serves very much to engage the attention. For by the frequent return of the same word the mind of the hearer is held in an agreeable suspense, till the whole is finished. "You do nothing (says Cicero to Catiline), you attempt nothing, you think nothing, but what I not only hear, but also see, and plainly perceive." It is frequently used by way of question; which renders it not only beautiful, but likewise strong and nervous. As at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the people's fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancestors have undergone the greatest labours?" Epitrophe is contrary to the former, and makes the repetition at the end of each member or sentence. As thus: "Since concord was lost; friendship was lost; fidelity was lost; liberty was lost; all was lost." And Cicero, in the charge which he brings against Mark Antony before the senate, makes use of this figure, when he says, "Do you lament the destruction of three Roman armies? the author of that destruction was Antony. Do you bewail the loss of most eminent citizens? They have been taken from you by Antony. Is the authority of this order weakened? It is weakened by Antony."

Symploce takes in both these last figures. As in that of Cicero: "You would pardon and acquit him, whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned." Here the several members both begin and end with the same word. We have a beautiful instance of it in St Paul, when he says, "Are they Hebrews? so am I. Are they Israelites? so am I. Are they the seed of Abraham? so am I."

When a sentence concludes with the word which it began, it is called epanalepsis. As in that expression of Plautus, "Virtue contains all things; he wants no good thing who has virtue." The figure is the same, but the principle not so honest, in the advice which we find given by the miser in Horace, when he says, "Get money, if you can, honestly; but however, get money." This figure adds a force to an expression, when the principal thing designed to be conveyed is thus repeated, by leaving it last upon the mind. And it heightens the beauty of it, when the sentence has an agreeable turn arising from two opposite parts. As in Cicero's compliment to Caesar: "We have seen your victory terminated by the war; your drawn sword in the city we have not seen." Hermogenes calls this a circle, because the sentence returns again to the same word, as that geometrical figure is formed by the orbicular motion of a line to the same point.

When the following sentence begins with the same word with which the former concluded, it is termed anadiplosis. As in the following instance: Let us think no price too great for truth; truth cannot be bought too dear. So in that passage of St John: His came to his own, and his own received him not. This figure generally suits best with grave and solemn discourse.

Epanodos is the inversion of a sentence, or repeating it backwards, so that it takes in the two last figures; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shows a readiness of thought. We have the following example of:
ORATORY.

Part III.

Election. If it is Minutius Felix, where he is exposing the folly of the Egyptian superstition. "Istis (says he), with Cynocephalus and her priests, laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother; in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous to lament what you worship, or to worship what you lament?" It serves likewise to illustrate and enforce the sense, by setting it in two opposite views. As in that expression of the prophet: "Woe unto them who call good evil, and evil good; who put darkness for light, and light for darkness!"

These figures which consist in a repetition of words of a like sound or signification, or both, are four; parenomasia, homoiopoton, synonymia, and derivatio; the two first of which respect words that are similar in sound only, the third in sense, and the last in both.

When two words very near in sound, but different in sense, respect each other in the same sentence, it is called parenomasia. As when we say, After a feast comes a fast; and, A friend in need is a friend indeed. We usually call it a pun, which new, and appropriately used, passes for wit, and serves to enliven conversation. Nor is it wholly to be excluded from grave and serious discourses; for a witty jest has many times had a better effect than a solid argument, and prevailed with those who could not be moved by close reasoning. And therefore Cicero and the best speakers have sometimes recourse to it upon weighty and solemn occasions, as will be shown hereafter in its proper place.

When the several parts of a sentence end with the same case, or tense of a like sound, this also is considered as a figure, and named homoiopoton. As thus: No marvel though wisdom complain that she is either sullenly despised, or carelessly neglected; either openly scorned, or secretly abhorred. This figure is esteemed most beautiful when the parts are all of the same length, or pretty near it; as it adds to the harmony of the period, and renders the cadency of the several members more musical from the just proportion between them. The Greek rhetoricians were much addicted to this figure, and Isocrates is particularly celebrated for it. But some of the best orators seem to have industriously avoided it, as carrying in it too much the appearance of art. And it is remarkable, that this figure appears nowhere so much in all the works of Demosthenes, as in an oration which he did not speak himself, but wrote for his friend Diodorus, a man of that taste, who was to pronounce it as his own.

The next figure above mentioned is synonymia. Now strictly speaking, synonymous words are those which have exactly the same sense. But there being few such, the use of the term is so far extended as to comprehend words of a near affinity in their signification, which in discourse are frequently put for one another. So, to desire, and intend, are sometimes used as equivalent terms; whereas to desire is no more than to wish for a thing, and to intend is to express that inclination in words. In like manner, esteem and honour are often taken for synonymous words, though they have not precisely the same sense, but one is the usual consequence of the other; for esteem is the good opinion we entertain of a person in our mind, and honour the outward expression of that esteem. When two or more such words come together, they constitute this figure. As when Cicero, speaking of Piso, says, "His whole countenance, which is the tacit language of the mind, has drawn men out into a stake, and deceived, cheated, imposed upon those who did not know him." This figure sometimes adds force to an expression, by enlivening the idea; and it often promotes the harmony and just cadency of a sentence, which otherwise would drop too soon, and disappoint the ear.

When such words as spring from the same root, as justice, just, injustice, unjust, and the like, come together in the same sentence, they make the figure called derivatio. Cicero, observing the vanity of the philosophers who affected praise at the same time that they declined it, used this figure, when he says of them, "The philosophers set their names to those very books which they write for the contempt of glory; and are desirous to be honoured and applauded, even for what they say in contempt of honour and applause." This figure receives an additional beauty when repeated, especially in two opposite members; as, He wished rather to die a present death, than to live a miserable life.

Art. II. FIGURES OF SENTENCES.

Of these, some are principally adapted for reasoning, and others to move the passions.

1. Those suited for proof, which are six: Prolepsis, or figures hypobole, anakoinosis, epitrope, parobole, and antistasis. of sentences; some Prolepsis or anticipation, is so called, when the orator first starts an objection, which he foresees may be raising and made either against his conduct or cause, and then answers its use is to forestall an adversary, and prevent moving the his exceptions, which cannot afterwards be introduced with so good a grace. Though it has likewise a farther advantage, as it serves to conciliate the audience, while the speaker appears desirous to represent matters fairly, and not to conceal any objection which may be made against him. The occasions of this figure are various; and the manner of introducing it very different. Sometimes the orator thinks it necessary to begin with it, in order to justify his conduct, and remove any exceptions which may be made against his design. Cicero, for several years together, after he first began to plead, had always been for the defendant in criminal cases. And therefore, when he was prevailed with to undertake the accusation of Verres, he begins his oration with this apology for himself: "If any one present should wonder, that when for several years past I have so conducted myself as to defend many and accuse none, I now on a sudden alter my custom, and undertake an accusation: when he shall have heard the occasion and reason of my design, he will both approve of it, and think no person so proper to manage this affair as myself." And then he proceeds to give an account of the reasons which moved him to engage in it. At other times the objection is admitted as an exception to what has been said, but not so as to affect it in general. Thus, when Cicero has represented the advantages of rhetoric and the polite arts, he starts this objection to what himself had said: "But some one will ask, whether those great men, the memory of whose glorious actions is delivered down to posterity, were acquainted with that sort of learning
Part III.

ORATORY.

To which he replies, "Indeed this can scarce be said of them all. However, the answer is easy. I have known several persons of excellent abilities, who, without learning, by the force of an extraordinary genius have been men of great virtue and solidity. Nay, I will add, that nature without learning, has oftener produced these qualifications, than learning without a genius. But yet it must still be owned, that where both these meet, they form something very excellent and singular." Again, at other times, the orator artfully represents the objection as something considerable and important, to give the greater weight to his answer when he has confuted it. Cicero, in his celebrated oration for the Manilian law, could not omit to take notice, that Lucullus had already gained several very considerable advantages over Mithridates. And therefore, having before described the war as very great and dangerous, apprehending these two accounts might appear somewhat inconsistent, and be liable to an objection, he puts it thus artfully himself: "But now, after what I have said of Lucullus, it may probably be asked, How then can the war be so great? be pleased to hear why!" And then he proceeds to show, from the power of King Mithridates at that time, his great abilities, long experience in military affairs, and fresh alliances, that the war was yet very great and dangerous. But sometimes, when the orator is sensible that what he has advanced lies open to an objection, he omits to make it in express terms; and yet proceeds to vindicate what he had said, as if it had been made. Thus, when Cicero had charged Verres with having plundered the inhabitants of Sicily of all their plate, jewels, and other valuable moveables, which he thought worth while to carry away, as the audience might imagine this to be scarcely credible, he takes it for granted they thought so, and therefore immediately adds, "As strange as this is, I affirm it positively, without any intention to aggravate the crime." And so he goes on to the proof of his assertion. But this figure is like-wise made use of to guard against some objection, which the speaker apprehends may be made against what he designs to say. And thus Cicero uses it in his oration for Sextius. "My province (says he), as I speak last, seems to call for affection to my friend, rather than his defence; complaint, rather than eloquence; expressions of grief, rather than art. And therefore, if I shall express myself with more warmth, or greater freedom, than those who have spoke before me, I hope you will grant me all that liberty of speech which you judge reasonable to be allowed to an affectionate sorrow and just resentment." This figure requires great prudence and discretion in the management of it. The speaker must consider well the temper, bias, and other circumstances of his hearers, in order to form a right judgment what parts of his discourse may be most liable to exception. For to object such things, which the hearers would never have thought of themselves, is to give himself a needless trouble; and to start such difficulties, which he cannot afterwards fairly remove, will expose both himself and his cause. But as nothing gives an audience greater pleasure and satisfaction, than to have their scruples fully answered as they rise in their thoughts; so, on the contrary, be a discourse otherwise ever so entertaining and agreeable, if there be any doubt left upon the minds of the hearers, it gives them a pain that continues with them till it be removed.

The figure hypobole or subjectio, is not much unlike the former; and is, when several things are mentioned that seem to make for the contrary side, and each of them refuted in order. It consists of three parts, when complete; a proposition, an enumeration of particulars with their answers, and a conclusion.—Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. "My departure (says he) is objected to me; which charge I cannot answer without commending myself. For what must I say? That I fled from a consciousness of guilt? But what is charged upon me as a crime, was so far from being a fault, that it is the most glorious action since the memory of man, (he means his punishing the associates of Catiline). That I feared being called to an account by the people? That was never talked of; and if it had been done, I should have come off with double honour. That I wanted the support of good and honest men? That is false. That I was afraid of death? That is a calumny. And I must therefore say, what I would not, unless compelled to it, that I withdrew to preserve the city." When the objections are put by way of question, as in the example here given, they add a briskness and poignancy to the figure. All the parts of it are not constantly expressed. For thus Cicero in his defence of Plancius introduces his adversary objecting, and himself answering, "The people judged ill, but they did judge; they should not have done it, but they had a power; I cannot submit to it, but many very great and wise men have."—Both the proposition and conclusion are here omitted.

The next figure in order is anacoinosis, or communication; by which the speaker deliberates either with the judges, the hearers, or the adversary himself. Thus Cicero addresses the judges in his accusation of Verres: "Now I desire your opinion what you think I ought to do. And I know your advice will be, though you do not declare it, what appears to me necessary to be done." In another place we find him reasoning in this manner with the adverse party: "What could you have done in such a case, and at such a time: when to have sat still, or withdrawn, would have been cowardice? When the wickedness and fury of Saturnius the tribune had called you into the capital; and the consul, to defend the safety and liberty of your country; whose authority, whose voice, which party would you have followed, and whose command would you have chosen to obey?" This figure carries in it an air of modesty and condescension, when the speaker seems unwilling to determine in his own cause, but refers it to the opinion of others. It likewise shows a persuasion of the equity of his cause, that he can leave it to their arbitration; and serves very much to conciliate their minds, while he joins them, as it were with himself, and makes them of his party. And when the appeal is made to the adverse party, it is of considerable advantage, either to extort a confession, or at least to silence him. And therefore the sacred writers sometimes very beautifully introduce God himself thus expostulating with makind; as the prophet

Malkobi,
ORATORY.

Another figure that comes under this head, is epistrope or concession; which grants one thing, to obtain another more advantageous. It is either real or feigned; and either whole of a thing, or in part only, is granted. We shall consider each of these separately, and illustrate them with proper examples. Nothing more confounds an adversary, than to grant him his whole argument; and at the same time either to show that it is nothing to the purpose, or to offer something else which may invalidate it. I alone, says the claimant by will against the heir at law, that no body was more nearly related to the deceased than you; that he was under some obligations to you; that you were in the army together; but what is all this to the will? And thus Cicero in his defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Caesar: "You have, Tubero, what an accuser would most desire, the accused person confessing the charge; but so as to affirm, that he was of the same party with you and your excellent father. Therefore own first that it was a crime in yourself, before you charge it as such upon Ligarius." Sometimes the orator gives up some particular point that would well admit of a dispute, to gain something more considerable, which he thinks cannot fairly be denied him. In the affair of Roscius, where the proof depended upon circumstances, Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father. And after he has shown there was no probable reason to be assigned for it, he adds, "Well, since you can offer no reason, although this might be sufficient for me, yet I will recede from my right; and upon the assurance I have of your innocence, I will grant you in this cause what I would not in another. I do not therefore insist upon your telling me why he killed his father, but ask how, he did it?" This appearance of candour and ingenuity, in such concessions removes the suspicion of art, and gives greater credit to what is denied. We have an example of a feigned or irontical concession in Cicero's defence of Flaccus; where, interceding for him on the account of his former good services in the time of Catiline's conspiracy, he says in a way of irony, If such things are to be overlooked, "let us appease the ghosts of Lentulus and Cathegus; let us recall those who are in exile; and let us be punished for our too great affection and love for our country." By this artful insinuation, the orator, after he has used all his arguments to persuade his hearers, does as it were set them at liberty, and leave them to their own election; it being the nature of man to adhere more steadfastly to what is not violently imposed, but referred to his own free and deliberative choice. And to these feigned concessions may be referred such reasons of, by which the orator both justifies a charge brought against him upon the supposition of its being true, and also proves that the charge itself is false. Thus Cicero, in his defence of Milo, represents the taking of Clodius, with which Milo was accused, as a glorious action; after he has shown that Milo's servants did it without the knowledge of their master.

Paradoxe or similitude, illustrates a thing by compa-
Part III.

ORATORY.

Elocution. always of advantage that the words and members of the sentence, expressing the contrasted objects, are similarly constructed, and made to correspond to each other. This leads us to remark the contrast more, by setting the things which we oppose more clearly over against each other: in the same manner as when we contrast a black and a white object, in order to perceive the full difference of their colour, we would choose to have both objects of the same bulk, and placed in the same light. Their resemblance to each other, in certain circumstances, makes their disagreement in others more palpable. At the same time I must observe, that the frequent use of antithesis, especially where the opposition in the words is nice and quaint, is apt to render the style disagreeable. A maxim, or moral saying, properly enough receives this form; both because it is supposed to be the fruit of meditation, and because it is designed to be engraved on the memory, which recalls it more easily by the help of such contrasted expressions. But where a string of such sentences succeed each other, where this becomes an author's favourite and prevailing manner of expressing himself, his style is faulty; and it is upon this account Seneca has been often and justly censured. Such a style appears too studied and laboured; it gives us the impression of an author attending more to his manner of saying things, than to the things themselves which he says. There is still another kind of antithesis, which consists in surprising us by the unexpected contrasts of things which it brings together; but it is such as is wholly beneath the dignity of an orator, or of grave compositions of any sort, and is fit only for pieces of professed wit and humour, calculated only to excite laughter or create ridicule.

II. Those suited to move the passions. Which are 13: namely, epanorthosis, paralepsis, parrrhesia, aporitithesis, exergasia, hypopyrosis, aporia, posiosis, erotesis, cephenesis, epiphrenoma, apophasis, and prosopopoeia.

Epanorthosis, or correction, is a figure, by which the speaker either recalls or amends what he had last said. It is used different ways. For sometimes one or more words are recalled by him, and others subjoined in their room; at other times, he avows to the public, what has said before is, for any reason, substituted as more suitable. This is a very extensive figure, and made use of in addressing different passions. We have an instance of it in Terence's Self-tormentor, where the old man, whose extraordinary concern for the absence of his son gave occasion to the name of the play, thus bewails his condition to his neighbour: 'I have an only son, Chremes. Atlas! Did I say that I have: I had indeed; but it is now uncertain whether I have or not.' Here, to aggravate his misfortune, he recalls a pleasing word, and substitutes another more affecting in its place. And Cicero, in his defence of Milo, speaking to the judges concerning Clodius, says, 'Are you only ignorant what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?' Again, in his defence of Plancius, he says, 'What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who when prince of the republic from a neighbouring war, and when consul from a civil one?' He is speaking there of Opimius. But in commending the moderation of Lucius Mummius, who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole expression, and by giving it a new turn, heightens the compliment he designed him: 'He chose rather (says he) to adorn Italy than his own house; though by adorning Italy his house seems to have received the greatest ornament.' And sometimes the correction is made by substituting something contrary to what has been said before; as in the following passage of Cicero: 'Cesar (meaning Augustus), though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged, and we dreaded his cruel and pernicious return from Brundusium, at a time when we neither asked, nor expected, nor desired it (because it was thought impossible), raised a very powerful army of invincible veterans; to effect which he threw away his whole estate: Though I have used an improper word; for he did not throw it away, but employed it for the safety of the government.' At other times, as has been said, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres, breaks out into this pathectic exclamation: O the element by which wondrous and singular patience, of the Roman people! He did not think the word elemecny strong enough, and therefore adds patience, as better answering his design. The sudden and unexpected turn of this figure gives a surprise to the mind, and by that means renders it the more pathetic.

Paralepsis, or omission, is another of these figures, when the speaker pretends to omit, or pass by, what at the same time he declares. It is used either in praise or dispraise. Thus Cicero, in his defence of Sextius, introduces his character in this manner, with a design to recommend him to the favour of the court: 'I might say many things of his liberality, kindness to his domestics, his command in the army, and moderation during his office in the province: but the honour of the state presents itself to my view; and calling me to it, advises me to omit these lesser matters.' But in his oration to the senate against Rullus the tribune, who had proposed a law to sell the public lands he has use of this figure to represent the pernicious effects of such a law, particularly with respect to the lands in Italy. 'I do not complain (says he) of the diminution of our revenues, and the woeful effects of this loss and damage. I omit what may give every one occasion for a very grievous and just complaint, that we could not preserve the principal estate of the public, the finest possession of the Roman people, the fund of our provisions, the granary of our wants, a revenue entrusted with the state; but that we must give up those lands to Rullus, which, after the power of Sylla, and the largesses of the Gracchi, are yet left us. I do not say, this is now the only revenue of the state, which continues when others cease, is an ornament in peace, fails us not in war, supports the army, and does not fear an enemy. I pass over all these things, and reserve them for my discourse to the people, and only speak at present of the danger of our peace and liberties.' His view here was to raise the indignation of the senate against Rullus, and excite them to oppose the law. There is a beautiful instance of this figure in St Paul's epistle to Philemon, where, after he has earnestly intreated him to receive again Onesimus his servant, who had run from him, and promised that if
Another of these pathetic figures is *Aparthidemus*, or *Elogeium*.

enumeration, when that, which might be expressed in general by a few words, is branched out into several particulars, to enlarge the idea, and render it the more affecting. Cicero, in pleading for the Manilian law, where his design is to conciliate the love and esteem of the people to Pompey, thus enlarges upon his character:

"Now, what language can equal the virtue of Cneius Pompey? What can be said either worthy of him, or new to you, or which every one has not heard? For those are not the only virtues of a general which are commonly thought so: labour in affairs, courage in dangers, industry in acting, despatch in performing, design in contriving; which are greater in him than in all other generals we have ever seen or heard of." And so likewise, when he endeavours to dispossess Pompey of the apprehension that Milo designed to assassinate him:

"If (says he) you fear Milo; if you imagine that either formerly, or at present, any ill design has been formed by him against your life; if the soldiers raised through Italy (as some of your officers give out), if these arms, if these cohorts in the Capitol, if the centurys, if the watch, if the generals which defend your person and house, are armed to prevent any attempt of Milo, appointed, prepared, and stationed on his account; he must be thought a person of great power, and incredible resolution, above the reach and capacity of a single man, that the most consummate general, and the whole republic, are in arms against him only. But who does not perceive, that all the disordered and sinking parts of the state are committed to you, to rectify and support them by these forces?" This might have been said in a few words, that such vast preparations could never be intended for so low a purpose. But the orator’s view was to expose that groundless report, and shame it out of countenance. And soon after he endeavours to raise compassion for Milo under those prejudices by the same figure: "See how various and changeable is the state of human life, how unsteady and volatile is fortune, what infidelity in friends, what disguises suited to the times, what flights, what fears, even of the nearest acquaintance, at the approach of dangers." Had no address to the passions been designed here, fewer of these reflections might have been sufficient. The use of this figure in amplification is very evident from the nature of it, which consists in unfolding of things, and by that means enlarging the conception of them.

*Exegesis*, or *exposition*, has an affinity with the former figure: but it differs from it in this, that it consists of several equivalent expressions or nearly such, in order to represent the same thing in a stronger manner; whereas the other enlarges the idea by an enumeration of different particulars. So that this figure has a near relation to *synonymia*, of which we have treated before under *Verbal Figures*. We have an instance of it in Cicero’s defence of Sextius, where he says, "Those who at any time have excited the populace to sedition, or blinded the minds of the ignorant by corruption, or traduced brave and excellent men, and such as deserved well of the public, have with us always been esteemed vain, bold, bad, and pernicious citizens. But those who repressed the attempts and endeavours of such, or by their authority, integrity, constancy, resolution, and prudence, withstood their insolence, have been always accounted men of solidity, the chief, the leaders, and supporters
Part III.  

Oratory.

Election, supporters of our dignity and government." Nothing more is intended by this passage, but to set the opposite characters of factious persons and true patriots in the strongest light, with a view to recommend the one, and create a just hatred and detestation of the other. So elsewhere he represents the justice of self-defence in no less different terms: "If reason (says he) prescribes this to the learned, and necessity to barbarians, custom to nations, and nature itself to brutes, always to ward off all manner of violence, by all possible ways; from their body, from their head, from their life; you cannot judge this to be a criminal and wicked action, without judging at the same time that all persons who fall among robbers and assassins must either perish by their weapons, or by your sentence."—He is addressing here to the judges in favour of Milo. The warmth and vehemence of the speaker often runs him into this figure, when he is affected with his subject, and thinks no words, no expressions, forcible enough to convey his sentiments; and therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage; as it warms the hearers, and impresses their minds, excites their passions, and helps them to see things in a stronger light.

Hypotyposis, or imagery, is a description of things painted in such strong and bright colours, as may help the imagination of the hearers to conceive of them rather as present to their view, than described in words. It is peculiarly suited for drawing characters; and often affords the finest ornaments in poetry and history, as well as oratory. Nor is it less moving, but suited to strike different passions, according to the nature of the subject, and artful management of the speaker. Cicero has thus drawn the picture of Catiline, consisting of an unaccountable mixture of contrary qualities. "He had (says he) the appearance of the greatest virtues: he made use of many instruments to carry on his designs, and pretended to be in the interest of the best men; he had a very engaging behaviour, and did not want industry and application; he gave into the greatest looseness, but was a good soldier. Nor do I believe there was ever the like monster in the world, made of such jarring and repugnant qualities and inclinations. Who at one time was more acceptable to the best men, and who more intimate with the worst? Who was once a better patriot, and who a greater enemy to this state? Who more devoted to pleasures, who more patient in labours? Who more rapacious, and yet more profuse? He suited himself to the humours of all he conversed with: was serious with the reserved, and pleasant with the jocose; grave with the aged, and facetious with the young; bold with the daring, and extravagant with the profligate. Such a character of a man, when accompanied with power and interest, must render him no less the object of fear than detestation, which was the design of Cicero in this description. And elsewhere, in order to prove with the same effect, he directs the expression of those conspirators with Catiline who were then in prison, he paints the most dismal scene of that horrid design in the strongest colours. "Methinks (says he) I see this city, the light of the world, and citadel of all nations, suddenly falling into one fire; I perceive heaps of miserable citizens buried in their ruined country; the countenance and fury of Cethegus raging in your slaughter, presents itself to my view." This figure is very serviceable to amplification, as we have formerly shewn in treating upon that subject. But no small judgment is required in the management of descriptions. Lesser circumstances should either be wholly omitted, or but slightly touched; and those which are more material drawn in their due proportion. Nature is as much the rule of the orator as of the painter, and what they both propose to imitate. And therefore, let a thought be ever so pleasing and beautiful in itself, it must not be introduced when foreign to the purpose, or out of its place, any more than a painter should attempt to alter nature when he proposes to copy it. This figure requires likewise a vigorous and lively genius. For the images in description can rise no higher than the conception of the speaker, since the idea must first be formed in his own mind before he can convey it to others; and agreeably to the clearness with which he conceives it himself, he will be able to express it in words.

Aporia, or doubt, expresses the debate of the mind with itself upon a pressing difficulty. A person in such a state is apt to hesitate, or start several things successively, without coming to any fixed resolution. The uneasiness arising from such a disorder of thought is naturally very moving. Of this kind is that of Cicero for Cincianus, when he says, "I know not which way to turn myself. Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked of in the court, mentioned in the senate? Can I remove an opinion so deep and long rooted in the minds of men? It is not in my power. You, judges, must support his innocence, and rescue him from this calumny." Orators sometimes choose to begin their discourse with this figure. A diffidence of mind at first is not unbecoming, but graceful. It carries in it an air of modesty; and tends very much to conciliate the affections of the hearers. Livy gives us a very elegant example of this in a speech of Scipio Africanus to his soldiers, when, calling them together after a sedition, he thus bespeaks them: "I never thought I should have been at a loss in what manner to address my army. Not that I have applied myself more to words than things; but because I have been accustomed to the genius of soldiers, having been trained up in the camp almost from my childhood. But I am in doubt what or how to speak to you, not knowing what name to give you. Shall I call you citizens, who have revolted from your country? Soldiers, who have disowned the authority of your general, and broke your military oath? Enemies? I perceive the mien, the aspect, and habit of citizens; but discern the actions, words, designs, and dispositions of enemies.

Sometimes a passion has that effect, not so much to render a person doubtful what to say, as to stop him in the midst of a sentence, and prevent his expressing the whole of what he designed; and then it is called Apostasia, or concealment. It denotes different passions: as anger, which, by reason of its heat and vehemence, causes persons to break off abruptly in their discourse. So the old man in Terence, when he was jealous that his servant obstructed his designs, uses this imperfect but threatening expression, Whom, if I find. And Neptune, when described by Virgil as very angry that the winds should presume to disturb the sea without his permission, after he has called them to him to know the reason of it, threatens them in this abrupt manner:
Whom I—but first I'll lay the storm."

But Cicero, in writing to Atticus, applies it to express grief, where he says, "I know nothing of Pompey, and believe he must be taken, if he is not got on shipboard. O incredible swiftness! But of our friend—Though I cannot accuse him without grief, for whom I am in so much concern and without. And in a letter to Cassius he uses it to express fear, when he says to him, "Brutus could scarce support himself at Mutina; if he is safe, we have carried the day. But if—heaven avert the omen! all must have recourse to you." His meaning is, "If Brutus should be defeated."

The next figure is *eretesis* or *interrogation*. But every interrogation or question is not figurative. When we inquire about a thing that is doubtful, in order to be informed, this is no figure, but the natural form of such expressions. As if I ask a person, *Where he is going?* or *what he is doing?* But then it becomes figurative when the same thing may be expressed in a direct manner; but the putting it by way of question gives it a much greater life and spirit. As when Cicero says, "Cicatline, how long will you abuse our patience? do not you perceive your designs are discovered?"

He might indeed have said, *You abuse our patience a long while. You must be sensible your designs are discovered. *But it is easy to perceive how much this latter way of expression falls short of the force and vehemence of the former. And so when Medea says, *I could save; and do you ask if I can destroy?* Had she said, *I could save, and I can destroy,* the sentence had been flat, and very unfit to express the rage and fury in which the poet there represents her. This figure is suited to express most passions and emotions of the mind, as anger, disdain, fear, desire, and others. It serves also to press and bear down an adversary. Cicero frequently makes use of it. As in his defence of Plancius: "I will make you this offer (says he), choose any tribe you please, and show, as you ought, by whom it was bribed; and if you cannot, as I believe you will not undertake it, I will prove how he gained it. Is this a fair contest? Will you engage on this foot? I cannot give you fairer play. Why do you dissemble? Why do you hesitate? I insist upon it, urge you to it, press it, require, and even demand it of you."

Such a way of pushing an antagonist shows the speaker has great confidence in his cause; otherwise he would never lay himself so open, if he was not assured no other party had nothing to reply. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression, provided it be neither too frequent, nor continued too long at once. And besides, the warmth and eager manner in which it is expressed, enlivens the hearers, and quickens their attention.

*Ephoponosis or exclamation,* is a vehement extension of the voice, occasioned by a commotion of mind, naturally venting itself by this figure, which is used by Cicero to express a variety of passions. It often denotes resentment or indignation. Thus, after his return from banishment, reflecting on those who had occasioned it, he breaks out into this moving exclamation: "O mournful day to the senate, and all good men, calamitous to the state, afflicting to me and my family, but glorious in the view of posterity!" His design was to excite an odium against the authors of his exile, when recalled in so honourable a manner. And again, in his defence of Cælius: "O the great force of truth: which easily supports itself against the wit, craft, subtility, and artful designs of men!" He had been just showing the absurdity of the charge against Cælius, and now endeavours to expose his accusers to the indignation of the court. At other times, it is used to express denunciation or contempt. As when it is used of Pompey's house, which was bought by Mark Antony, he says: "O consummate impudence! dare you go within that house! dare you enter that venerable threshold, and show your audacious countenance to the tutelar deities which reside there!" Nor is it less suited to indicate grief, as when he says of Milo: "O that happy country, which shall receive this man! ungrateful this, if it banish him! miserable if it lose him!" And sometimes it serves to express admiration: as when, in compliment to Cæsar, he says, "O admirable clemency! worthy of the greatest praise, the highest encomiums, and most lasting monuments!" It has its use also in ridicule and irony. As in his oration for Balbus, where he derides his accuser, by saying, "O excellent interpreter of the law! master of antiquity! corrector and aner of our constitution!" The sacred writers sometimes use it by way of intreaty or wish. As the royal psalmist: "O that I had the wings of a dove, that I might fly away, and be at rest!" And at other times in triumph and exultation, as in that of St. Paul: "O death, where is thy sting? O grave, where is thy victory?" It is frequently joined with the preceding figure *interrogation*; as appears in some of the instances here brought from Cicero. And it generally follows the representation of the thing which occasioned it. Though sometimes it is made use of to introduce it, and then it serves to prepare the mind by exciting its attention. Thus Cicero, in his defence of Cælius, to render the character of Clodia more odious, at whose instigation he was accused, insinuates that she had before poisoned her husband; and to heighten the barbarity of the fact, and make it appear the more shocking, he introduces the account of it with this moving exclamation: "O heavens, why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity!"

*Epiphonema, or exclamation,* has a great affinity with the former figure. And it is so called, when the speaker, at the conclusion of his argument, makes some lively and just remark upon what he has been saying, to give it the greater force, and render it the more affecting to his hearers. It is not so vehement and impetuous as exclamation, being usually expressive of the milder and more gentle passions. And the reflection ought not only to contain some plain and obvious truth, but likewise to arise naturally from the discourse which occasioned it, otherwise it loses its end. When Cicero has shown, that recourse is never to be had to force and violence, but in cases of the utmost necessity, he concludes with the following remark: "Thus to think, is prudence; to act, fortitude; both to think and act, perfect and consummate virtue." And elsewhere, after he has described a singular instance of cruelty and breach of friendship: "Hence (says he) we may learn, that no duties are so sacred and solemn which covetousness will not violate." This figure is frequently expressed in a way of admiration. As when Cicero has observed, that all men are desirous to live to an advanced age, but uneasy under it when
Part III.

ORATORY.

Elocution.

when attained, he makes this just reflection upon such a conduct: "So great is their inconstancy, folly, and perverseness!"

The next figure in order is apostrophe, or address, when the speaker breaks off from the series of his discourse, and addresses himself to some particular person present or absent, living or dead; or to inanimate nature, as endowed with sense and reason. By this means he has an opportunity of saying many things with greater freedom than perhaps would be consistent with decency if immediately directed to the persons themselves. He can admonish, chide, or censure, without giving offence. Nor is there any passion, but may be very advantageously expressed by this figure. When an orator has been speaking of any particular person, on a sudden to turn upon him, and apply the discourse to that person himself, is very moving; it is like attacking an adversary by surprise, when he is off his guard, and where he least expects it. Thus Cicero: "I desire, senators, to be merciful, but not to appear negligent in so great dangers of the state; though at present I cannot but condemn myself of remissness. There is a camp formed in Italy, at the entrance of Etruria, against the state; our enemies increase daily; but we see the commander of the camp, and general of the enemies, within our walls, in the very senate, contriving some intestine ruin to the state. If now, Catiline, I should order you to be seized and put to death, I have reason to fear, that all good men would rather think I had deferred it too long, than charge me with cruelty. But I am prevailed with for a certain reason not to do that yet, which ought to have been done long since." This sudden turn of the discourse to Catiline himself, and the address to him in that unexpected manner, must have touched him very sensibly. So, in his defence of Milo, expressing his concern if he should not succeed in it, he says: "And now I shall answer it to you, my brother Quintus, the partner of my misfortunes, who are now absent?" And elsewhere addressing to the soldiers of the Marian legion, who had been killed in an engagement with Mark Antony, he thus bespeaks them: "O happy death, which, due to nature, was paid to your country! I may esteem you truly born for your country, who likewise received your name from Mars; so that the same deity seems to have produced this city for the world, and you for this city." And in his oration for Balbus, he thus calls upon dumb nature to witness to Pompey's virtues: "I invoke you, mute regions; you, most distant countries; you seas, havens, islands, and shores. For what coast, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant? An appeal to heaven, or any part of inanimate nature, has something very sublime and solemn in it, which we often meet with in sacred writ. So the divine prophet: "Hear, O heavens! and give ear, O earth! for the Lord hath spoken. And in like manner, the prophet Jeremiah: "Be astonished, O ye heavens, at this." See APOTROPH.

Apostrophe, or the fiction of a person: by which either an absent person is introduced speaking; or one who is dead, as if he was alive and present; or speech is attributed to some inanimate being. There is no figure, perhaps, which serves more or better purposes to an orator than this. For by this means he is enabled to call in all nature to his assistance, and can assign to every thing such parts as he thinks convenient. There is scarce any thing fit to be said, but may be introduced this way. When he thinks his own character is not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence as coming from himself; he avoids this, by putting them into the mouth of some other person from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he sometimes chooses to secure himself from a suspicion of flattery, in carrying a compliment too high. We meet with several very beautiful instances of this figure in Cicero; but an example of each sort may here suffice, beginning with that of an absent person, from his defence of Milo, whom he thus introduces as speaking to the citizens of Rome: "Should he, holding the bloody sword, cry out, Attend, I pray, hearken, O citizens, I have killed Publius Clodius; by this sword, and by this right hand, I have kept off his rage from your necks, which no laws, no courts of judicature, could restrain; it is by my means, that justice, equity, laws, liberty, shame, and modesty, remain in the city. Is it to be feared how the city would bear this action? Is there any one now, who would not approve and commend it?" And in his oration for Balbus, he introduces Marius, who was then dead, to plead in his defence: Can Balbus (says he) be condemned, without condemning Marius for a like fact? Let him be present a little to your thoughts, since he cannot be so in person; that you may view him in your minds, though you cannot with your eyes. Let him tell you, he was not acquainted with leagues, void of examples, or ignorant of war." And again, in his first invective against Catiline, he presents his country to musing, contemplating with himself, and upbraiding him for suffering such a criminal as Catiline to live. "Should my country (says he), which is much dearer to me than my life, should all Italy, all the state, thus address me, Mark Tully what do you do? Do you suffer him, whom you have found to be an enemy, who you see is to be at the head of the war, whom you perceive your enemies wait for in their camp as their general, who has been the contriver of this wickedness, the chief of the conspiracy, the exciter of slaves and profligate citizens, to leave the city, which is rather to bring him in, than let him out? Will not you order him to be imprisoned, condemned, and executed? What prevents you? The custom of our ancestors. But private persons have often punished pernicious citizens in this state. The laws relating to the punishment of Roman citizens? But traitors never had the rights of citizens. Do you fear the censure of posterity? Truly you make a very handsome return to the people of Rome, who have set you from an obscure condition so early to the highest dignity; if you neglect their safety to avoid envy, or from the apprehension of any danger. And if you fear censure, which is most to be dreaded, that which may arise from justice and fortitude, or from cowardice and treachery? When Italy shall be wasted by a war, cities plundered, and houses burnt, do you think then to escape the severest censure?" In the management of this figure, care should be
be taken that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

In treating upon figures, we have hitherto considered them separately; but it may not be amiss to observe, that some expressions consist of a complication of them, and may come under the denomination of several figures, as well verbal as those of sentences, differently considered. Thus when Cicero says, "What, Tubero, did your drawn sword do in the Pharsalan battle? At whose side was its point directed? what was the intention of your arm?" As he speaks to Tubero, it is an apostrophe; as the expressions have much the same import, and are designed to heighten and aggravate the fact, it is *exagge-ration*; and as they are put by question, it is *interrogation*. So likewise, in his second Philippic, where he says, "What can I think? that I am condemned? I see nothing in my life, interest, actions, or abilities, as moderate as they are, which Antony can despise. Did he think he could easily lessen me in the senate? But they, who have commended many famous citizens for their good government of the state, never thanked any but me for preserving it. Would he contend with me for eloquence? This would be a favour indeed. For what could be a larger and more copious subject, than for me to speak for myself against Antony? His design was really this: thought he could not convince his associates, that he was truly an enemy to his country, unless he was so first to me." There are three figures in this passage; *doubt, interrogation*, and *subjection*. And again, when he introduces Sicily thus addressing Verres in a way of complaint: "What, Verres, have plundered and taken from me." Here is a *prose-popula*, joined with the verbal figure *anaphora*, as several members of the sentence begin with the same word. The like instances of complex figures frequently occur, and therefore we need not multiply examples of them here.

**PARTICULAR ELOCUTION,**

Or that part of Elocution which considers the several Properties and Ornaments of Language, as they are made use of to form different sorts of Style.

**CHAP. IV. Of Style, and its different Characters.**

The word *style* properly signifies the instrument which the ancients used in writing. For as they commonly wrote upon thine boards covered over with wax, and sometimes upon the barks of trees, they made use of a long instrument like a bodkin, pointed at one end, with which they cut their letters; and broad at the other, to erase any thing they chose to alter. And this the Latins called *stylus*. But though this be the first sense of the word, yet afterwards it came to denote the manner of expression. In which sense we likewise use it, by the same kind of trope that we call any one’s writing his *hand*. Style, then, in the common acceptation of the word at present, is the peculiar manner in which a man expresses his conceptions by means of language. It is a picture of the ideas which rise in his mind, and of the order in which they are there produced. As to *Election*, the reasons which occasion a variety of style, they are principally these.

Since both speech and writing are only sensible expressions of our thoughts, by which we communicate them to others; as all men think more or less differently, so consequently they in some measure differ in their style. No two persons who were to write upon one subject, would make use of all the same words. And were this possible, yet they would as certainly differ in their order and connection, as two painters, who used the same colours in painting the same picture, would necessarily vary their mixtures and disposition of them, in the several gradations of lights and shades. As every painter therefore has something peculiar in his manner, so has every writer in his style. It is from these internal characters, in a good measure, that critics undertake to discover the true authors of anonymous writings, and to show that others are spurious, and not the genuine productions of those whose names they bear; as they judge of the age of such writings from the words and manner of expression which have been in use at different times. And we may often observe in persons a fondness for some particular words or phrases, and a peculiarity in the turn or connection of their sentences, or in their transitions from one thing to another; by which their style may be known, even when they design to conceal it. For these things, through custom and habit, will sometimes drop from them, notwithstanding the greatest caution to prevent it.

There is likewise very often a considerable difference in the style of the same person, in several parts of his life. Young persons, whose invention is quick and lively, commonly run into a pompous and luxuriant style. Their fancy represents the images of things to their mind in a gay and sprightly manner, clothed with a variety of circumstances; and while they endeavour to set off each of these in the brightest and most glittering colours, this renders their style verbose and florid, but weakens the force and strength of it. And therefore, as their imagination gradually cools, and comes under the conduct of a more mature judgment, they find it proper to cut off many superfluities; so that by omitting unnecessary words and circumstances, and by a closer connection of things placed in a stronger light, if their style becomes less swelling and pompous, it is, however, more correct and nervous. But as old age sinks the powers of the mind, chills the imagination, and weakens the judgment; the style, too, in proportion usually grows dry and languid. Critics have observed something of this difference in the writings even of Cicero himself. To be master of a good style, therefore, it seems necessary that a person should be endowed with a vigorous mind and lively fancy, a strong memory, and a good judgment. It is by the imagination that the mind conceives the images of things. If the impressions of those images be clear and distinct, the style will be so too; since language is nothing but a copy of those images first conceived by the mind. But if the images be faint and imperfect, the style will accordingly be flat and languid. This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can describe them in a more strong and lively
Part III.

ORATORY.

Elocution. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disordered, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are workt or crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrasers to express them in their several connections and relations to each other. When the images of things offer themselves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and, therefore, without a large furniture of words and phrases, the style will necessarily become insipid and jejune, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination will furnish the mind with plenty of ideas, and a good memory will help to clothe them in proper language; but unless they be connected and united, they will be apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, faster than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinences, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly allusions of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of, which best suit the ideas they are designed to convey; rather than the most gay and pompous. All things are not said which offer themselves to the mind, and fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly touched, and others are more largely and fully, according to their different importance. And every thing is placed in that order, and clothed in such a dress, as may represent it to the greatest advantage. So that, in a word, the foundation of a good style is chiefly good sense. Where these qualities all meet in a considerable degree, such persons have the happiness to excel, either in speaking or writing. But this is not generally the case. Many persons of a vigorous and sprightly imagination, have but a weak judgement; and others much more judicious can think but slowly. And it is this, in a great measure, which makes the difference between speaking and writing well, as one or the other of these qualities is predominant. A person of a lively fancy, ready wit, and voluble tongue, will deliver himself off hand much better and more acceptably, than one who is capable, upon due premeditation, to discern farther into the subject, but cannot command his thoughts with the same ease and freedom. And this latter would have the same advantage of the other, were they both coolly to offer their sentiments in writing. Many things appear well in speaking, which will not bear a strict scrutiny. While the hearer's attention is obliged to keep pace with the speaker, he is not sure to observe every improvement of intelligence, but many slips easily escape him, which in reading are presently discovered. Hence it is often found, that discourses, which were thought very fine when heard, appear to have much less beauty, as well as strength, when they come to be read. And therefore it is not without reason, that Cicero recommends to all those who are candidates for eloquence, and desirous to become masters of a good style, to write much. This affords them an opportunity to digest their thoughts, weigh their words and expressions, and give every thing its proper force and evidence; as likewise, by reviewing a discourse when composed, to correct its errors, or supply its defects; till by practice they gain a readiness both to think justly, and to speak with propriety and eloquence. But it is time to proceed to some other causes of the diversity of style.

Different countries have not only a different language, but likewise a peculiarity of style suited to their temper and genius. The eastern nations had a lofty and majestic way of speaking. Their words are full and somberous, their expressions strong and forcible, and warmed with the most lively and moving figures. This is very evident from the Jewish writings in the Old Testament, in which we find a most agreeable mixture of simplicity and dignity. On the contrary, the style of the more northern languages generally partakes of the chillness of their climate. "There is (says Mr. Addison) a certain coldness and indifference in the phrases of our European languages, when they are compared with the oriental forms of speech. And it happens very luckily, that the Hebrew idioms run into the English tongue with a peculiar grace and beauty. Our language has received innumerable elegancies and improvements from that infusion of Hebraisms, which are derived to it out of the poetical passages in holy writ. They give a force and energy to our expressions, warm and animate our language, and convey our thoughts in more ardent and intense phrases than any that are to be met with in our own tongue. There is something so pathetic in this kind of diction, that it often sets the mind in a flame, and makes our hearts burn within us." Again, people of different nations vary in their customs and manners, which occasions a diversity in their style. This was very remarkable in the Attics, Asians, and Rhodians, and is often taken notice of by ancient writers. The Athenians, while they continued a free state, were an active, industrious, and frugal people: very polite indeed, and cultivated arts and sciences beyond any other nation; but as they had powerful enemies, and were exceedingly jealous of their liberties, this preserved them from wantonness and luxury. And their way of speaking was agreeable to their conduct; accurate and close, but very full and expressive.
ORATORY.

Elocution. The Asiatics, on the other hand, were more gay, and loose in their manners, devoted to luxury and pleasure; and accordingly they affected a florid and swelling style, filled with redundancies and superfluities of expression. Indeed some of the ancients have attributed this looseness of style to their way of pursuing eloquence at first. For as they were put upon it by conversing with the Greek colonists who settled among them, their manner, being imitating them, before they were masters of the language, they were often obliged to make use of circumlocutions, which afterwards became habitual, and very much weakened the force of their expressions, as it naturally would do. But one would think, if they were put to this necessity at first, when they found its ill effect, they might easily have amended it afterwards, as they grew better acquainted with the Greek language, had they been inclined so to do. The Rhodian style was a medium between the other two; not so concise and expressive as the Attic, nor yet so loose and redundant as the Asiatic. Quintilian says, it had a mixture of its author, and the humour of the people; and like plants set in a foreign soil, degenerated from the Attic purity, but not so wholly as to lose it. They first received it from Aeschines, who being worsted in his famous contest with Democthenes, retired thither, and taught rhetoric, which put them upon the study of eloquence.

The style of the same country likewise very much alters in different ages. Cicero tells us, that the first Latin historians aimed at nothing more than barely to make themselves intelligible, and that with so much brevity as they could. Those who succeeded them advanced a step farther; and gave somewhat a better turn and cadency to their sentences, though still without any dress or ornament. But afterwards, when the Greek language became fashionable at Rome, by copying after their writers, such as Herodotus, Thucydides, Xenophon, and others, they endeavoured to introduce all their beauties into their own tongue, which in Cicero's time was brought to its highest perfection. But it did not long continue in that state. A degeneracy of manners soon altered their taste, and corrupted their language, which Quintilian very much complains of in his time. The case was the same with respect to the Greek tongue; though that had the good fortune to continue its purity much longer than the Latin. Nor can any language be exempt from the common fate of all human productions; which have their beginning, perfection, and decay. Besides, there is a sort of fashion in language, as well as in other things; and the generality of people are always fond of running into the mode. Perhaps some one, or a few persons, fall into a manner, which happens to please. This gives them a reputation; and others immediately copy after them, till it generally prevail. Cicero tells us, that the most ancient Greek orators whose writings were extant in his time, such as Pericles, Alcibiades, and others, were subtle, acute, concise, and abounded in sense rather than words. But another set that followed them, of which were Critias, Theramenes, and Lysias, retained the good sense of the former, and at the same time took more care of their style; not leaving it so bare as the former had done, but furnishing it with a better dress. After these came Isocrates, who added all the flowers and beauties of eloquence. And as he had abundance of followers, they applied these ornaments and decorations according to their different genius: some for pomp and splendour; and others to invigorate their style, and give it the greater force and energy. And in this latter way Demosthenes principally excelled. Now as each of these manners had its peculiar beauties, and generally prevailed in different ages, Cicero thinks this could not have happened otherwise than from innate talent. And he attributes it to the same cause, that afterwards it sunk into a softer and smoother manner, not less exact and florid, but more cold and lifeless. If we take a view of our own tongue, Chaucer seems to have been the first who made any considerable attempts to cultivate it. And whoever looks into his writings will perceive the difference to be so great from what it is at present, that it scarce appears to be the same language. The gradual improvements it has since received, are very evident in the writers almost of every succeeding age since that time; and how much farther it may still be carried, time only can discover. See Language, passim: For the English language in particular, see N° 38; for the other European languages, as well as the Greek and Latin, see N° 27, &c.

Another cause of the variety of style arises from the different nature and properties of language. A difference in the letters, the make of the words, and the order of them, do all affect the style. So Quintilian observes, that the Latin tongue cannot equal the Greek in pronunciation, because it has no. The Latins want two of the softest Greek letters, s and ζ; and use others of a very hard sound, which the Greeks have not, as f and g. Again, many Latin words end in m; a letter of a broad and hollow sound, which never terminates any Greek word; but s does frequently, whose sound is much softer and sweeter. Besides, in the combination of syllables the letters b and d are often so situated, as to require too strong and unequal a force to be laid upon them, as in the words obversus and adjungo. Another advantage of the Greek tongue arises from the variety and different seat of the accents: for the Greeks often accent the last syllable, which both enlivens the pronunciation, and renders it more musical; whereas the Latins never do this. But the greatest advantage of the Greeks lies in their plenty and variety of words; for which reason they have less occasion for tropes or circumlocutions, which, when used from necessity, have generally less force, and weaken the style. But under these disadvantages, Quintilian seems to give his countrymen the best advice the case will admit of: That what they cannot do in words, they should make up in sense. If their expressions are not so soft and tender, they should exceed in strength; if they are less subtile, they should be more sublime; and if they have fewer proper words, they should excel in the beauty as well as number of their figures. If this account of Quintilian be just, that the Greek tongue does surpass the Latin in all these instances, it is certain that both of them have much greater advantages over some modern languages. The varying all their declinable words, both nouns and verbs, by terminations, and not by signs, contributes very much to the smoothness and harmony of their periods. Whereas in the modern languages, those small particles and pronouns which distinguish the cases of nouns and the tenses and persons of verbs, hinder the run of a period, and
Part III.

ORATORY.

Elocution and render the sound much more rough and uneven. Besides, the ancient languages seem to have a better and more equal mixture of vowels and consonants, which makes their pronunciation more easy and musical.

But the chief distinction of style arises from the different subjects or matter of discourse. The same way of speaking no more suits all subjects, than the same garment would all persons. A prince and a peasant ought not to have the same dress; and another different from both becomes those of a middle station in life. The style therefore should always be adapted to the nature of the subject, which rhetoricians have reduced to three ranks or degrees; the low or plain style, the middle or temperate, and the lofty or sublime: Which are likewise called characters, because they denote the quality of the subject upon which they treat. This division of style into three characters, was taken notice of very early by ancient writers. Some have observed it even in Homer, who seems to assign the sublime or magnificent to Ulysses, when he represents him as so copious and vehement an orator, that his words came from him like winter snow. On the contrary, he describes Menelaus as a polite speaker, but concise and moderate. And when he mentions Nestor, he represents his manner as between these two, not so high and lofty as the one, nor yet so low and depressed as the other; but smooth, even, and pleasant, or, as he expresses it, more sweet than honey. Quintilian observes, that although accuracy and politeness were general characters of the Attic writers; yet among their orators, Lycurgus excelled in the low and familiar way; Isocrates for his elegance, smoothness, and the fine turn of his periods; and Demosthenes for his flame and rapidity, by which he carried all before him. And Gellius tells us, that the like difference was found in the three philosophers who were sent from the Athenians to Rome (before the Romans had any relish for the polite arts) to solicit the remittance of a fine laid upon them for an injury done to a neighbouring state. Carneades, one of those ambassadors, was vehement and rapid in his harangues; Critolaus, neat and smooth; and Diogenes, modest and sober. The eloquence of these orators, and the agreeable variety of their different manner, so captivated the Roman youth, and inflamed them with a love of the Grecian arts, that old Cato, who did all he could to check it by hurrying away the ambassadors, could not prevent their vigorous pursuit of them, till the study became in a manner universal. And the old gentleman afterwards learned the Greek language himself, when it became more fashionable. Which a noble writer of ours represents as a punishment upon him for his former crime. It seldom happens that the same person excels in each of these characters. They seem to require a different genius, and most people are naturally led to one of them more than another; though all of them are requisite for an orator upon different occasions, as we shall show hereafter.

CHAP. V. Of the Low Style.

Thus we shall consider under two heads, thoughts and language; in each of which the several characters are distinguished from one another.

I. And with respect to the former, as the subjects proper for this style are either common things, or such

Vol. XV. Part I.

as should be treated in a plain and familiar way; so

plain thoughts are most suitable to it, and distinguish it

from the other characters.

Now, by plain thoughts, are meant such as are simple and obvious, and seem to rise naturally from the subject, when duly considered; so that any one, upon first hearing them, would be apt to imagine they must have occurred to himself. Not that this is really the case, but because the more natural a thing is, the more easy it seems to be; though in reality it is often otherwise; and the perfection of art lies in its nearest resemblance to nature. And therefore, in order to speak plainly and clearly upon any subject, it must first be duly considered, well understood, and thoroughly digested in the mind; which, though it require labour and study, yet the more a person is master of what he says, the less that labour will appear in his discourse. This natural plainness and simplicity, without any disguise or affectation, very much contributes to give credit to what is said. Nor is any thing more apt to impose on us, than the appearance of this, when artfully assumed. Cicero’s account of the fight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of this. "When Clodius knew (says he) that Milo was obliged to go to Lanuvium upon a solemn and necessary occasion, he immediately hastened from Rome, the day before, to assassinate him before Clodius’s own house, as appeared afterwards by the event. And this he did at a time, when his turbulent mob in the city wanted his assistance; whom he would not have left but for the advantage of that place and season to execute his wicked design. But the next day Milo was in the senate, where he continued till they broke up; then went home; changed his dress; staid there some time till his wife was ready; and afterwards set forward so late, that if Clodius had designed to return to Rome that day, he might have been here by that time. Clodius, prepared for his design, met him on horseback, having no chariot, no equipage, no Greek attendants as usual; and without his wife, which was scarcely ever known: whereas Milo was in a chariot with his wife, wrapped up in a cloak, and attended by a large retinue of maid servants, pages, and other persons unfit for an engagement. He met with Clodius before his house, about five o’clock in the evening; and was presently assaulted from a higher ground by many armed men, who killed the coachman. Upon which, Milo, throwing off his cloak, leaped out of the chariot, and bravely defended himself: and those who were with Clodius, having their swords drawn, some made up to the chariot to attack Milo; and others, who now thought he had been killed, began to fall upon his servants who were behind. And of these, such as had courage, and were faithful to their master, some were killed; and others when they saw the skirmish at the chariot, and could do their master no service (for they heard Clodius himself say that Milo was killed; and really thought it was so), did that, not by their master’s order, nor with his knowledge, nor when he was present, which every one would have his own servants to do in the like circumstances. I do not say this to fix any crime upon them, but only to relate what happened." His meaning is, they killed Clodius; which he avoids mentioning, to render what he says less offensive. Can any thing be told in a more plain and simple manner than this? Here is nothing said, but

†
what in itself seems highly probable, and what one would imagine the fact might easily suggest to any ordinary spectator. But in this, both the art and skill of it consist. For in the whole account, as, on the one hand, Milo is so described as to render it highly improbable he could have any design at that time against Clodius; so on the other, no one circumstance is omitted which might seem proper to persuade the hearers that Clodius was the aggressor in that engagement. And yet, if we may believe Aesopious, the quarrel was begun by some of Milo's retinue, and Clodius was afterwards killed by his express order. But as things are sometimes best illustrated by their opposites, we shall here produce a contrary instance of a very affected and unnatural way of relating a fact. Val. Maximus tells us of a learned man at Athens, who, by a blow which he received by a stone upon his head, entirely forgot all his learning, though he continued to remember everything else. And therefore, as he says, since this misfortune deprived him of the greatest enjoyment of his life, it had been happier for him never to have been learned, than afterwards to lose that pleasure. This is the plain sense of the story. But now let us hear him relate it, "A man (says he) of great learning at Athens, having received a blow upon his head by a stone, retained the memory of all other things very perfectly, and only forgot his learning, to which he had chiefly devoted himself. The direful and malignant wound invading his mind, and as it were designedly surveying the knowledge reposed there, cruelly seized on that part of it in particular from which he received the greatest pleasure, and buried the singular learning of the man with an invicious funeral. Who since he was not permitted to enjoy his studies, had better never have obtained access to them, than afterwards to have been deprived of the delight they afforded him." What an unnatural way is this of relating such an accident, to talk of a wound invading the mind, and surveying the knowledge reposed there, and cruelly seizing a particular part of it, and burying it with an invicious funeral? There is nothing in the story could lead him to this, but an over-fondness to refine upon it in a very affected manner. But there are two properties of plain thoughts, one of which ought constantly to attend them in common with all thoughts, and the other is often necessary to animate and enliven this character.

The former of these is justness and propriety, which is what reason dictates in all cases. What Cicero says of the death of Crassus the orator, seems very just, as well as natural. "It was (says he) an afflication to his friends, a loss to his country, and a concern to all good men; but such public calamities followed upon it, that heaven seemed rather to have favoured him with death, than to have deprived him of life." This thought seems very just, and agreeable to the sentiments of a good man, as Crassus was; to choose death rather than to outlive the happiness of his country, to which he himself had so much contributed. Quintilian has a reflection upon a like occasion, which is not so just and becoming. It is upon the death of his only son, a youth of very uncommon parts, as he represents him; and for whose use he had designed his Institutions of oratory: but he died before they were finished. The passage is this: "I have lost him of whom I had formed the greatest hopes, and in whom I had reposed the greatest comfort of my old age. What can I do now? or of what farther use can I think myself to be, thus disappointed by heaven? What good parent will pardon me, if I can any longer study, and not condemn such resolution, if, thus surviving all my family, I can make any other use of my voice, than to accuse the gods, and declare that providence does not govern the world?" Allowance may be made for the sallies of passion, even in wise men upon some shocking occasions; but when it proceeds to such a degree as to become impious, it is very indecent, as well as unjust. And all indecency is unnatural, as it is disagreeable to reason, which always directs to a decorum. That seems to be a very natural as well as just thought of Pliny the Younger, when he says, "The death of those persons always appears to me too hasty and unreasonable, who are preparing some lasting work. For persons wholly devoted to pleasures, live, as it were, from day to day, and daily finish the end for which they live; but those who have a view to posterity, and preserve their memory by their labours, always die untimely, because they leave something unfinished." We shall mention but one more instance; and that in a comparative view, to make it the more evident. The two sons of Junius Brutus, the first Roman consul, having been convicted of treason, in associating with Tarquin's party, were ordered, among others, to be put to death; and their father not only pronounced the sentence, but presided at the execution. This fact is mentioned by several of the Roman historians; and, as it carries in it not only the appearance of rigorous justice, but likewise of cruelty in Brutus, to have been present at the execution of his sons, they endeavour to vindicate him different ways. What Florus says seems rather an affectation of wit, than a just defence of the fact. He beheaded them (says he), that being a public parent, he might appear to have adopted the whole body of the people." Nor does Val. Maximus come up to the case, who says, "He put off the father to act the consul; and chose rather to lose the sons, than be wanting to public justice." This might be a reason for condemning them; and would have been equally true, had he not been present at their execution. But Livy, whose thoughts are generally very just and natural, assigns the best reason which perhaps can be given for his vindication, when he says, "Fortune made him the executioner of the sentence, who ought not to have been a spectator." By saying "fortune made him so, he represents it not as a matter of choice, like the other historians, but of necessity, from the nature of his office, which then obliged him to see the execution of that sentence he had himself before pronounced; as is the custom at present, in some popular governments.

The other property, which should often accompany plain and simple thoughts, is, that they be gay and sprightly. This, as has been said, is necessary to animate and enliven such discourses as require the low style. The fewer ornaments it admits of, the greater spirit and vivacity is requisite to prevent its being dry and jejune. A thought may be very brisk and lively, and at the same time appear very natural, as the effect of a ready and flowing wit. Such thoughts, attended with agreeable turns, are very suitable to this style; but care should be taken, lest, while fancy is too much indulged, the justness of them be overlooked. We shall give one instance, in which this seems to have been the case,
Part III.

O R A T O R Y.

Elocution. The case, from a celebrated English work, where the ingenious writer endeavours to show the disadvantages of persons not attending to their natural genius, but affecting to imitate others in those things for which they were not formed. "The great misfortune (says he) of this affectation is, that men not only lose a good quality, but also contract a bad one; they not only are unfit for what they are designed, but they assign themselves to what they are unfit for; and instead of making a very good figure one way, make a very ridiculous one another. Could the world be reformed to the obedience of that fancied dictate, *Follow nature*, which the oracle of Delphos pronounced to Cicero when he consulted what course of studies he should pursue, we should see almost every man as eminent in his proper sphere as Tully was in his. For my part, I could never consider this preposterous repugnancy to nature any otherwise, than not only as the greatest folly, but also one of the most heinous crimes; since it is a direct opposition to the disposition of providence, and (as Tully expresses it) like the sin of the giants, an actual rebellion against heaven." The advantages that arise from persons attending to their own genius, and pursuing its dictates, are here represented in a very lively and agreeable manner. But there is one thing asserted, which we fear will not hold; which is, that, *Could the world be reformed to that dictate, *Follow Nature*, we should see almost every man as eminent in his proper sphere as Tully was in his.* For though doubtless persons would generally succeed best if they kept to this rule; yet different degrees of ability are often found, where the bias and inclination is the same, and that accompanied with equal labour and diligence. *If this was not so, how happened it that no one came up to Tully in the art of oratory; especially in his own age, when there were the greatest opportunities for that study, and the highest encouragements were given to it, as it paved the way to riches, honours, and all the grand offices of the state?* It cannot well be questioned but that there were gentlemen, who had all the same advantages, accompanied with as strong a passion for this art, as Tully had, who yet fell much short of him in point of success. And experience shows, that the case has been the same in all other pursuits.

III. But it is time to proceed to the other head, the *language proper* for this style. And here it may be observed in general, that the dress ought to be agreeable to the thoughts, plain, simple, and unaffected.

But the first thing that comes under consideration is elegance, or a proper choice of words and expressions; which ought always to suit the ideas they are designed to convey. And therefore when an ancient writer, speaking of cruelty, calls it *nevus crudicitatis*, the blemish of cruelty; and another, applying the same word to ingratitude, says *nevus ingratiitudinis*, the blemish of ingratitude; that term does not sufficiently convey to us the odious nature of either of those vices, as indeed it was not their design it should. But otherwise, where the speaker has not some particular view in doing it, to sink too low is as much a fault as to rise too high. So to call ancient Rome the mistress of Italy, would as much lessen the just notion of the extent of her power, as the Roman writers aggravate it when they style her mistress of the world. But purity, both in the choice of words and expressions, is never more necessary than it is here. This may be called *neatness in language.* And to be plain and neat at the same time, is not only very consistent, but the former can no other way recommend itself, than as joined with the latter. Besides, the fewer advantages anything has to set it off, the more carefully they ought to be observed. Perspicuity is always to be regarded; and serves very much to keep up the attention, where other ornaments are wanting. Epithets should be sparingly used, since they enlarge the images of things, and contribute very much to heighten the style. Indeed they are sometimes necessary to set a thing in its just light; and then they should not be dropped. Thus, in speaking of Xerxes, it would be too low and flat to say, *He desceded with his army into Greece.* Here is no intimation given of their vast and unparalleled numbers, which ought to be done. Herodotus says, his whole army, of sea and land forces, amounted to 2,317,000 and upwards. Therefore, unless the number be mentioned, the least that can be said is, *that he desceded with a vast army.*

The next thing to be regarded is composition, which here does not require the greatest accuracy and exactness. A seeming negligence is sometimes a beauty in this style, as it appears more natural. Short sentences, or those of a moderate length, are likewise upon the whole best suited to this character. Long and accurate periods, finely wrought up with a gradual rise, harmonious numbers, a due proportion of the several parts, and a just cadency, are therefore improper, as they are plainly the effect of art. But yet some proportion should be observed in the members, that neither the ears be too much defrauded, nor the sense obscured. Of this kind is that expression of a Greek orator, blamed by Demetrius: *Ceres came readily to our assistance, but Aristotle not.* The latter member of this sentence is too short; and by dropping so suddenly, both disappoints the ears, and is somewhat obscure. It would have been plain and more agreeable thus, but *Aristides did not.* As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character. For one of its principal beauties is perspicuity. And a proper connection likewise of sentences, with a regular order in the dependence of things one upon another, very much contributes to this end. With regard to the collision of syllables in different words, for preventing either a hollowness or asperity of sound, greater liberty may be taken in this style than in the other characters. Here it may be allowed to say, *Virtue is amiable to all, though all do not pursue it.* But in a higher character, perhaps, in order to prevent the hollow sound of the words *though all,* a person would choose to vary the expression a little, and say, *though few pursue it.* So, *Xerxes’ expedition,* may be tolerable here; but in the florid style, *the expedition of Xerxes* would sound much better.

The last thing to be considered, with respect to the language is dignity, or the use of tropes and figures. And as to tropes, they ought to be used cautiously; unless such as are very common, and by time have either come into the place of proper words, or at least are equally plain and clear. So in the instance mentioned above, Diodorus Siculus, speaking of the forces of Xerxes, calls them an *innumerable company.* Where,
by a synecdoche, he has chosen to make use of an uncertain number for a certain, as less liable perhaps to exception. Other examples might be given if necessary.

And with regard to figures, as most of those which consist in words, and are therefore called verbal figures, serve chiefly to enliven an expression, and give an agreeable turn, they are often not improper for this character. Nor are figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles, as will be shown hereafter.

Upon the whole, therefore, pure nature, without any colouring, or appearance of art, is the distinguishing mark of the low style. The design of it is to make things plain and intelligible, and to set them in an easy light. And therefore the proper subjects of it are epistles, dialogues, philosophical dissertations, or any other discourses, that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasure, with its peculiar beauties that engage us. As we see persons of fashion and good breeding, though in the plainest habit, have yet something in their air and manner of behaviour that is very taking and amiable. Somewhat of the like nature attends this style. It has its difficulties, which are not so easily discerned but from experience. For it requires no small skill to treat a common subject in such a manner as to make it entertaining. The fewer ornaments it admits of, the greater art is necessary to attain this end. Loisly subjects often engage and captivate the mind by the sublimity of the ideas. And the florid style calls in all the assistance of language and eloquence. But the plain style is in a great measure stripped of those advantages; and has little more to recommend it, than its own native beauty and simplicity.

CHAPTER VI. OF THE MIDDLE STYLE.

This we shall treat in the same manner as we did the former, by considering first the matter, and then the language proper for it.

I. And as the subjects proper for this style are things of weight and importance, which require both a gravity and accuracy of expression; so fine thoughts are its distinguishing mark, as plain thoughts are of the low character, and lofty thoughts of the sublime. Now a fine thought may deserve that character from some or other of the following properties.

And the first property we shall mention is gravity and dignity. Thus Cicero in a speech to Cæsar, says, "It has been often told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you either lived, or was born for yourself only." Nothing could either be more fit and proper, than this was, when it was spoken; or at the same time a finer compliment upon Cæsar. For the civil war was now over, and the whole power of the Roman government in the hands of Cæsar; so that he might venture to say he had lived long enough for himself, there being no higher pitch of glory to which his ambition could aspire. But then there were many things in the state that wanted redressing, after those times of disorder and confusion, which he had not yet been able to effect, and of which Cicerón here takes an opportunity to remind him.

We shall produce another example from Curtius. Philotas, one of Alexander’s captains, having formed a conspiracy against him, was convicted of it, and put to death. Amintas, who was suspected of the same crime, by reason of his great intimacy with Philotas, when he comes to make his defence, among other things speaks thus: "I am so far from denying my intimacy with Philotas, that I own I courted his friendship. Do you wonder that we showed a regard to the son of Parmenie, whom you would have to be next to yourself, giving him the preference to all your other friends? You, Sir, if I may be allowed to speak the truth, have brought me into this danger. For to whom else is it owing, that those who endeavoured to please you, addressed themselves to Philotas? By his recommendation we have been raised to this share of your friendship. Such was his interest with you, that we courted his favour, and feared his displeasure. Did we not all in a manner engage ourselves by oath, to have the same friends, and the same enemies, which you had? Should we have refused to take this, which you, as it were, proposed to us? Therefore, if this be a crime, you have few innocent persons about you; nay, indeed none. For all desired to be the friends of Philotas; though all could not be so who desired it. Therefore, if you make no difference between his friends and accomplices, neither ought you to make any between those who desire to be his friends, and those who really were so." Could any thing be finer spoken, more proper, and becoming the character of a soldier, than this defence; especially to a prince of so great and generous a spirit as Alexander? There is something which appears like this in Tacitus with relation to the emperor Tiberius, but falls vastly short of it in the justness and dignity of the sentiment. Sejanus, his great favourite, and partner in his crimes, falling under his displeasure, was, like Philotas, put to death for a conspiracy. Now a Roman knight, who apprehended himself in danger on account of his friendship with Sejanus, thus apologizes for himself to the emperor, in the manner of Amintas. "It is not for us to examine the merit of a person whom you raise above others, nor your reasons for doing it. The gods have given you the sovereign power of all things, to us the glory of obeying. Let conspiracies formed against the state, or the life of the emperor, be punished; but as to friendships and private regards, the same reason that justifies you, Cesar, renders us innocent." The turn of the expressions is not much different from that in the case of Amintas; but the beauty of the thought is spoiled by the flattery of complimenting Tiberius upon an excess of power, which he employed to the destruction of many excellent men. There is not that impropriety in the defence of Amintas, which is equally brave and just.
good government, and in the esteem of his subjects, before he thought fit to accept of it. And Pliny, among other instances of the generosity of that prince, which he mentions in the same discourse, speaking of the liberty that he gave the Romans to purchase estates which had belonged to the emperors, and the peaceable possession they had of them, does it by a turn of thought no less beautiful than the former. "Such (says he) is the prince's bounty, such the security of the times, that he thinks us worthy to enjoy what has been possessed by emperors; and we are not afraid to be thought so." There is a sprightliness in this image, which gives it a beauty; as there is likewise in the following passage of the same discourse, where he says to Trajan, "Your life is displeasing to you, if it be not joined with the public safety; and you suffer us to wish you nothing but what is for the good of those who wish it." And of the same kind is that of Cicero to Caesar, when he says, "You, Caesar, are wont to forget nothing but injuries." It is a very handsome, as well as just reflection, made by Tacitus upon Galba's government, that "He seemed too great for a private man, while he was but a private man; and all would have thought him worthy of the empire, had he never been emperor." The beauty of a thought may give us delight, though the subject be sorrowful; and the images of things in themselves unpleasant may be so represented as to become agreeable. Sisigambis, the mother of Darius, after the death of her son, had been treated by Alexander with the greatest regard and tenderness, in whose power she then was. So soon as she heard therefore that he was dead, she grew weary of life, and could not bear to outlive him. Upon which Q. Curtius makes this fine reflection: "Though she had courage to survive Darius, yet she was ashamed to outlive Alexander." The next property of a fine thought, which we shall mention, is delicacy. As, in the objects of our senses, those things are said to be delicate which affect us gradually in a soft and agreeable manner; so a delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, disclose more than was at first perceived. Quintilian seems to refer to this, when he says: "Those things are grateful to the hearers, which, when they apprehend, they are delighted with their own sagacity; and themselves, as though they had not heard, but discovered them." Such thoughts are not unlike the sketches of some pictures, which let us into the design of the artist, and help us to discern more than the lines themselves express. Of this kind is that of Sallust: "In the greatest fortunes, there is the least liberty." This is not often so in fact, but ought to be; both to guard against an abuse of power, and to prevent the effects of a bad example to inferiors. Pliny, speaking of the emperor Trajan's entry into Rome, says, "Some declared, upon seeing you, they had lived long enough; others, that now they were more desirous to live." The compliment is fine either way, since both must esteem the sight of him the greatest happiness in life; and in that consistency lies the delicacy of the thought. It was a fine character given of Grotius, when very young, on the account of his surprising genius and uncommon proficiency in learning, that he was born a man: As if nature, at his coming into the world, had at once furnished him with those endowments which others gradually acquire by study and application.

The last property of a fine thought, which we shall take notice of, is novelty. Mankind is naturally pleased with new things; and when at the same time they are set in an agreeable light, this very much heightens the pleasure. Indeed there are few subjects, but what have been so often considered, that it is not to be expected they should afford many thoughts entirely new; but the same thought set in a different light, or applied to a different occasion, has in some degree a claim of novelty. And even where a thing hath been so well said already, that it cannot easily be mended, the revival of a fine thought often affords a pleasure and entertainment to the mind, though it can have no longer the claim of novelty. Cicero, in his treatise of an orator, among several other encomiums which he there gives to Crassus, says of him, "Crassus always excelled every person, but that day he excelled himself." He means as an orator. But elsewhere he applies the same thought to Caesar, upon another account; and with some addition to it. "You had (says he) before conquered all other conquerors by your equity and clemency, but to-day you have conquered yourself; you seem to have vanquished even victory herself, therefore you alone are truly invincible." This thought, with a little variation of the phrase, has since appeared in several later writers; and it is now grown common to say of a person, who excels in any way, upon his doing better than he did before, that he has outdone himself. The like has happened to another thought, which, with a little alteration, has been variously applied. It was said by Varro, That if the Muses were to talk Latin, they would talk like Plato. The younger Pliny, applying this compliment to a friend of his, says, "His letters are so finely written, that you would think the Muses themselves talked Latin." And Cicero tells us, It was said of Xenophon, that the Muses themselves seemed to speak Greek with his voice. And elsewhere, that Philosophers say, if Jupiter speaks Greek, he must speak like Plato. The thought is much the same in all these instances, and has been since revived by some modern writers.

II. We shall now consider the language proper for the Ionic and middle style. And in general it may be observed, that usage of as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind, and divert it from attending to the diction, so all the ornamentals of speech, and beauties of eloquence, have place here.

And first with regard to elegance, it is plain that a different choice of words makes a very great difference in the style, where the sense is the same. Sometimes one single word adds a grace and weight to an expression, which, if removed, the sense becomes flat and lifeless. Now such words as are most full and expressive suit best with his character. Epithets also, which are proper and well chosen, serve very much to beautify and enliven it, as they enlarge the ideas of things, and set them in a fuller light.

The most accurate composition, in all the parts of it, has place here. Periods, the most beautiful and harmonious, of a due length, and wrought up with the most exact order, just cadency, easy and smooth connect-
ORATORY.

Part III.

Elocution.

...tion of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this character.

But the principal distinction of style arises from tropes and figures. By these it is chiefly animated and raised to its different degrees or characters, as it receives a lesser or greater number of them; and those either more mild, or strong and powerful.

As to tropes, those which afford the most lively and pleasing ideas, especially metaphors, suit the middle character. It is a pretty remark, which has been made by some critics upon two verses of Virgil; one in his Eclogues, and the other in his Georgics. The former of these works is for the most part written in the low style, as the language of shepherds ought to be; but the latter in the middle style, suitable to the nature of the subject, and the persons for whom it was designed, the greatest men in Rome not thinking it below them to entertain themselves with rural affairs. Now in the Eclogue, as some copies read the verse, the shepherd, complaining of the barrenness of his land, says,

Infelix lolium et sterciles nascentur avenae.

In English thus:

Wild oats and darnel grow instead of corn.

But in the Georgic, where the same sense is intended, instead of the proper word nascentur, grow, the author substitutes a metaphor, dominantur, command, and says,

Infelix lolium et sterciles dominantur avenae.

That is in English;

Where corn is sown, darnel and oats command.

It was fit and natural for the shepherd to express his sense in the plainest terms; and it would have been wrong to represent him going so far out of his way, as to fetch a metaphor from government, in talking upon his own affairs. But in the Georgic, where the poet speaks in his own person, the metaphor is much more beautiful, and agreeable to the dignity of the work. This instance may show in some measure how the style is heightened by tropes, and the same thought may be accommodated to the several characters of style by the different manner of expression.

The like may also be said of figures either of words or sentences, in reference to this character; which admits of the finest descriptions, most lively images, and brightest figures, that serve either for delight, or to influence the passions without transport or cætaxis, which is the property of the sublime. This is indeed the proper seat of such embellishments, which support and make up a principal part of the middle or florid style. Having treated largely upon these in several preceding chapters, we shall here only briefly mention some of the most considerable.

Descriptions are not only a great ornament to a discourse, but represent things in a very lively and agreeable manner. In what a beautiful light has Cicero placed the polite arts and sciences, when, describing them from their effects, he thus represents to us the great advantages, as well as pleasure, which they afford to the mind? "Other studies neither suit with all times, nor all ages, nor all places; but these improve youth, delight old age, adorn prosperity, afford a refuge and so-lace in adversity; please at home, are no hinderance abroad; sleep, travel, and retire, with us." And they often affect us very powerfully, when they are addressed to the senses. Quintilian has painted the calamities of a city taken by storm in the brightest and strongest colours, which he represents by "Flames spreading themselves over the houses and temples, the cracking of falling buildings, and a confused noise from a variety of cries and shouts; some running they know not where, others in the last embraces of their friends; the shrieks of children, women, and old men unhappily reserved to such distress; the plundering of all places civil and sacred, the hurry and confusion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarrels among the conquerors where the plunder is largest." This seems to be a very natural, as well as moving, image of so dreadful a calamity.

Prosopopoeia is another very strong and beautiful figure, very proper for this character. Seneca has a fine instance of it in his "Consolationary Letter to Marcia," upon the death of her son. After many arguments he had made use of to alleviate her grief, he at last introduces her father, Cremutius Cordus, as thus addressing to her: "Imagine your father (says he) from the celestial regions, speaking to you in this manner: Daughter, why do you so long indulge your grief? why are you so ignorant, as to think it unhappy for your son, that, weary of life, he has withdrawn himself to his ancestors? Are you not sensible what disorders fortune occasions everywhere? and that she is kindest to those who have least concern with her? Need I mention to you princes who had been extremely happy, had a more timely death secured them from impending evil? or Roman generals, who wanted nothing to consummate their glory but that they lived too long? Why then is he bewailed longest in our family who died most happily! There is nothing, as you imagine, desirable among you, nothing great, nothing noble; but, on the contrary, all things are mean, full of trouble and anxiety, and partake very little of the light which we enjoy." This advice was very suitable for a philosopher; and he seems to have chosen this way of introducing it, to enforce the argument drawn from the happiness of good men in a future state, from the testimony of a person who was actually in the possession of it.

Similitudes and comparisons are another great ornament of this style, and oftentimes found here. Nothing can be finer than the comparison between those two great orators, Demosthenes and Cicero, made by Quintilian, when he says, "Demosthenes and Cicero differ in their elocution; one is more close, and the other more copious; the former concludes more, concisely, and the latter takes a larger compass, the one always with pungency, and the other generally with weight; one can have nothing taken from him, and the other nothing added to him; the latter has more of art, and the former more of nature. But this must be allowed to Demosthenes, that he made Cicero, in a great measure what he was. For as Tully even to himself confesses, that he was an imitation of the Greeks, he seems to me to have expressed the force of Demosthenes, the fluency of Plato, and the pleasantness of Isocrates." Similitudes, taken from natural things, serve very much to enliven the style,
Part III.

Elocution.

and give it a cheerfulness; which is a thing so common and well known, that we need not stay to give any instances of it.

Antithesis, or opposition both in the words and sense, has often the like beautiful effect. There is an agreeable contrast in that passage of Seneca: "Cesar does not allow himself many things, because he can do all things: his watching defends all others sleep, his labour their quiet, his industry their pleasure, his business their ease; since he has governed the world he has deprived himself of it." Had he said no more than only in general, that Cesar does not allow himself many things, because he can do all things, it might have passed for a fine thought; but, by adding so many particulars, all in the same form of expression, and beginning each member with the same word, he has both enlarged the idea, and beautified the antithesis, by a bright verbal figure.

These, and such like florid figures, are sometimes found in historians, but oftener in orators; and indeed this middle character, in the whole of it, is best accommodated to the subjects of history and oratory.

Chap. VII. Of the Sublime Style.

The noblest and the most difficult part of an orator's province is the sublime. Cicero requires in his perfect orator, whom he could not describe in words, but only conceive of in his mind. And indeed, the noblest genius and greatest art are both requisite to form this character. For where nature has been most liberal in furnishing the mind with lofty thoughts, bright images, and strong expressions; yet without the assistance of art there will sometimes be found a mixture of what is low, improper, or misplaced. And a great genius, like a too rich soil, must produce flowers and weeds promiscuously, without cultivation. But the justest propriety, joined with the greatest strength and highest elevation of thought, are required to complete the true sublime. Art, therefore, is necessary to regulate and perfect the taste of those who are desirous to excel in this character.

In explaining the nature and properties of this character, we shall, as in the two former, consider first the thoughts, and then the language, in each of which it is distinguished from them.

§ 1. Sublime, as it relates to Thoughts.

Lofty and grand sentiments are the basis and foundation of the true sublime. Longinus therefore advises those who aspire at this excellence, to accustom themselves to think upon the noblest subjects. A mind that always dwells upon low and common subjects can never raise itself sufficiently to represent things great and magnificent in their full extent and proper light. But he who inures himself to conceive the highest and most exacted ideas, and renders them familiar to his thoughts, will not often be at a loss how to express them; for when proper words are wanting, by metaphors and images taken from other things, he will be able to convey them in a just and adequate manner. What is more common than for two persons to conceive very differently of the same thing from the different manner of thinking to which they have been accustomed? After the great battle in Cilicia, between Alexander and Darius, in which the latter was routed, he sent ambassadors to Alexander with proposals of peace, offering him half his kingdom with his daughter in marriage. Parmenio, one of Alexander's chief captains, says to him upon this occasion, "For my part, was I Alexander, I would accept of these conditions." "And so would I (replies that aspiring monarch), was I Parmenio." The half of so vast a kingdom at present, and a right of succession to the whole by marriage, was the highest ambition to which the thoughts of Parmenio could rise. But Alexander had vastly higher views; he aimed at nothing less than universal monarchy; and therefore such a proposal seemed much beneath his regard. Noble and lofty thoughts are principally those which either relate to divine objects, or such things as amongst men are generally esteemed the greatest and most illustrious.

Of the former sort is that of Homer, when describing the goddess Discord, he says, that she

Walks on the ground, and hides her head in clouds.

This stretch of thought, says Longinus, as great as the distance between heaven and earth, does not more represent the stature of the goddess, than the measure of the poet's genius and capacity. But such images, however beautiful in poetry, are not so proper for an orator, whose business it is to make choice of those which are suited to the nature of things and the common reason of mankind. When Numa the second king of Rome was settled in his government, and at peace with his neighbours, in order to soften the fierce and martial temper of his subjects, who had been always accustomed to war during the reign of his predecessor Romulus, he endeavoured to impress their minds with an awe of the Deity; and for that end introduced a number of religious ceremonies, which he pretended to have received from the goddess Egeria. * * See Egeria. This must be esteemed an artful piece of policy at that time. But that sentiment is far more just and noble, with which Cicero endeavours to inspire the members of a community, in his treatise of Laws, when he says, that "Citizens ought first to be persuaded, that all things are under the rule and government of the gods; that every affair is directed by their wisdom and power; that the highest regard is due to them from men, since they observe every one's conduct, how he acts and behaves himself, and with what temper and devotion he worships them; and that they make a difference between the pious and impious." Persons under the influence of such a persuasion, could not fail of behaving well in society. And what he says to Caesar is no less in this style, when, interceding for Ligarius, he tells him, that "men in nothing approach nearer to deity, than in giving life to men." And Velleius Paterculus, speaking of Cato, gives him this sublime character, "That he was more like the gods than men; who never did a good thing, that he might seem to do it."

The other kind of lofty thoughts mentioned above, are those which relate to power, wisdom, courage, beneficence, and such other things as are of the highest esteem among mankind. Your fortune (says Tully to Caesar) has nothing greater than a power, nor your
O R A T O R Y.

Part III.

Election. nature than a will, to save many." He subjoins this compliment to what we have just cited from him; and applies that to Caesar, which was before only expressed in general, leaving him to draw the inference of his similitude to deity from the clemency of his nature. And elsewhere, as in a sort of transport for his success in defeating the conspiracy of Catiline, he thus be-speaks the Roman senate: "You have always decreed public thanks to others for their good government of the state, but to me alone for its preservation. Let that Scipio shine, by whose conduct and valour Hannibal was forced to leave Italy, and retire to Africa; let the other Scipio be greatly honoured, who destroy ed Carthage and Numantia, two cities the most dangerous to this empire; let Lucius Paulus be in high esteem, whose triumphal chariot was adorned with Perses, once a most powerful and noble prince; let Marius be in eternal honour, who twice delivered Italy from an invasion and the dread of servitude; let Pompey's name excel all these, whose actions and virtues are terminated by no other bounds but the course of the sun; yet among all their praises, there will still some place be left for my glory; unless indeed it be a greater thing to open for us new provinces to which we may resort, than to secure a place for our victorious generals to return in triumph." And Velleius Paterculus, as if he thought no encomium too high for this great orator, laments his unhappy fate in those lofty strains, addressed to M. Antony, by whose order he was put to death: "You have taken from Cicero old age, and a life more miserable than death under your government; but his fame, and the glory of his actions and words, you have been so far from destroying, that you have increased them. He lives, and will live in the memory of all ages; and while this system of nature, however constituted, shall remain (which scarce any Roman but himself conceived in his mind, comprehended by his genius, and illustrated with his eloquence), the praise of Cicero shall accompany all posterity, while it admires his writings against you, will curse your treatment of him; and sooner shall mankind be lost to the world than his name." It was a noble reply of Porus the Indian king, when, after his defeat by Alexander, being brought before him, and asked How he expected to be treated? he answered, Like a king. And Valerius Maximus, speaking of Pompey's treatment of Tigranes king of Armenia after he had vanquished him, expresses it in a manner suited to the dignity and beneficence of the action, when he says, "He restored him to his former fortune, esteeming it as glorious to make kings as to conquer them."

But the true sublime is consistent with the greatest plainness and simplicity of expression. And, generally speaking, the more plain and natural the images appear, the more they surprise us. How succinct, and yet how majestic, is that expression of Cæsar upon his victory over Pharnaces? I came, I saw, I conquered. But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Mosaic. "The legislator of the Jews (says he), no ordinary person, having a just notion of the power and majesty of the Deity, has expressed it in the beginning of his laws in the following words: And God said, Let there be light; and there was light. Let the earth be made; and it was made." This instance from the divine writer, and the character here given of him by that excellent critic, is the more remarkable, as he was himself a Pagan. And certainly no laboured description could raise in the mind a higher conception of the infinite power of the Deity, than this plain and short narration. To command nature itself into being by a word, represents it at once altogether boundless and unlimited.

It sometimes very much contributes to heighten the image of a thing, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bounds to fix to the thought. Of this kind is that of Cicero, when he first raises an objection against the necessity of an acquaintance with polite literature in order to form a great man, and then answers it. The objection is founded upon the examples of several great and excellent persons among the Romans, who had raised themselves to the highest pitch of honour and dignity, and been very serviceable to their country, by the help of a good genius, without the advantage of much learning. In reply to which, he allows, that, where these are not united, nature or genius is of itself much preferable, and will carry a person further in the pursuit of great and noble designs, then learning without a genius; but that both are necessary to complete and perfect a truly great man. But we shall give what he says himself on this head, by which that property of a sublime thought we are now endeavouring to explain, will appear from his manner of expression: "I acknowledge (says he) that many persons of an exalted mind and virtue have, from a divine temper, without instruction, become moderate and grave; and I add likewise, that nature, without the assistance of learning, has frequently more contributed to honour and virtue, than learning where a genius has been wanting: But yet I must say, that where the direction and improvement of learning is added to a great and excellent genius, it is wont to produce something admirable and singular which I know not how to describe." He knew very well, that by leaving the minds of his hearers thus in suspense, they would form to themselves higher conceptions of what be intended, than from any idea he could convey to them in words. We may add to this another example from the same great orator, where he says, "Truly, if the mind had no views to posterity, and all its thoughts were terminated by those bounds in which the space of life is confined, it would neither fatigue itself with so great labours, nor be disfigured with so many cares and watchings, nor so often expose itself to death. But there is a certain active principle in every good man, which constantly excites his mind by motives of glory; and reminds him, that the remembrance of his name is not to end with his life, but extend itself to all posterity." Of the like nature is that of Milton, when he describes Satan as flying from hell in quest of our earth, then newly formed. For having represented that his wings failed him in the vast vacuity, he thus describes his fall:
Those words, by which his fall is expressed,

And to this hour,

leave the mind in suspense, and unable to fix any bounds to the vacancy; and by that means raise a greater and more surprising idea of its space than any direct expression could have done. This image is very beautiful where it stands; but so much out of the common way of thinking, as to suit better with an epic poem than the discourse of an orator.

§ 2. The Sublime, with regard to Language.

What we have to offer upon this subject will come under the three heads of Elegance, Composition, and Dignity; which comprehend all the properties of style.

I. Elegance. Those words and expressions chiefly contribute to form the sublime, which are most sombre, and have the greatest splendour, force, and dignity. And they are principally such as these. Long words, when equally expressive, are rather to be chosen than short ones, and especially monosyllables. So to conquer or vanquish an enemy, carries it in a fuller and grander sound, than to beat an enemy. For which reason, likewise, compound words are often preferable to simple ones. So if we say, Caesar’s army, when he was present, was always invincible; this manner of expression has more of sublimity in it, than should we say, Caesar’s army, when he was present, could never be conquered. But the ancient languages have much the advantage of ours in both these respects; for their words are generally longer, and they are abundantly more happy in their compositions. The use of proper epithets does also in a particular manner contribute to this character. For as they denote the qualities and modes of things, they are as it were short descriptions; so that being joined to their subjects, they often greatly enlarge and heighten their image. Thus when the character of divine poet is given to Homer or Virgil, or prince of orators to Demosthenes or Cicero, it conveys to the mind a more sublime idea of them, than the bare mention of their name.

II. Composition: The force of which, as Longinus observes, is so great, that sometimes it ceases a kind of sublimity where the thoughts themselves are but mean, and gives a certain appearance of grandeur to that which otherwise would seem but common. But composition consists of several parts; the first of which, in the order we have hitherto considered them, is period. And here the case is much the same as with animal bodies, which owe their chief excellency to the union and just proportion of their parts. The several members, when separated from each other, lose both beauty and force, which they have when joined together in a complete body. In like manner, sublimity arises from the several parts of a period so connected, as to give force, as well as beauty, to the whole. The periods therefore in this character should be of a proper length. If they are too short, they lose their just weight and grandeur, and are gone almost before they reach the ear; as, on the contrary, when they are too prolix, they become heavy and unwieldy, and by that means lose their force. But more especially, nothing superfluous ought to be admitted, which very much enervates the force of a sentence. We shall exemplify this in a passage from Herodotus, where he is giving an account of the famous battle at Thermopylae between the Persians and Lacedaemonians. “Diocles (says he) the Spartan, being told by a Trachinian, before the engagement with the Medes, that when the barbarians came to shoot their arrows, they would fly so thick as to obscure the light of the sun; he was so far from being terrified at this, that, despising their number, he replied, he “was pleased with what his friend told him, since if the sun was obscured, they should fight in the shade, and not in the sun.” The sense here is great and noble, but the sublimity of expression is spoiled in a great measure by those last words, and not in the sun, which are wholly superfluous. Cicero was sensible of this, and therefore he omits that member in relating the same story, and says only: “A Spartan, hearing that one of the Persians should say in an insulting manner, that when they came to engage, they should not be able to see the sun, for the multitude of their darts and arrows, replies, Then we shall fight in the shade.” By stopping here, he gives the sentence much more life and emphasis. The next thing to be considered in composition, is the order and disposition of the several words and members of a sentence. The different placing of one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. “This public act (says Demosthenes) dispelled the danger which at that time, like a cloud, hung over the city.” Let us vary the order a little, and read it thus: “This public act dispelled the danger, which like a cloud hung over the city at that time.” What a different turn does the expression receive for the worse! The spirit and majesty of it are entirely lost. And in placing the several parts or members, they ought to be so disposed, that what is most weighty and important should stand last. So Tully says of Catiline, “We ought to return thanks to heaven, that we have so often escaped so odious, so frightful, so dangerous a plague of the state.” A thing may be odious and frightful, and yet not dangerous; therefore he puts this in the last place, to give it the greater force, and make the deeper impression. Another thing to be attended to in composition, is the connection of the words with regard to the sound; that the pronunciation, in passing from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. And as this is generally something grand and magnificent, such a contexture of them as will give the greatest force and energy to the expression is most proper for the sublime. Soft and languid sounds are very unsuitable to this character. They soothe and please the ear; but rather sink and depress the mind, than excite it to things great and noble. In this respect, therefore, our tongue, by its multitude of consonants, is more suitable for sublime discourses than some other modern languages, which abound with vowels.

III. The last head to be considered, is the proper use of tropes and figures, which is here so necessary, that the title of dignity seems to have been given to this part of elocution, from the assistance it more especially affords to this character. For if, as has been observed from Longinus, compositions will sometimes create
ORATORY.

Part III.

Elocution. a sort of sublimity; this much oftener happens from the force and efficacy of some lively tropes and strong figures.

And as to tropes, bright metaphors are peculiarly suited to raise and animate the style. This is manifest from the nature of them, as they consist of contrived similies, reduced to a single word; which, if taken from things lofty and grand, must of consequence give a sublimity to the style. What can suggest to us a greater idea of the valor of Ajax, than Homer's calling him the "bulwark of the Greeks;" or of the Scipios, than when they are styled by Virgil, the "two thunderbolts of war." A number of those, well chosen, contributes no less to the grandeur than to the beauty of discourse. Hyperbole sometimes gives the same force to an expression, if cautiously used; and so as not to exceed all appearance of truth. But the chief use of it is, where proper words will not express the just idea of the thing designed to be conveyed; and it may seem rather the off-spring of necessity than choice. Of this nature is that of Herodotus, when speaking of the Lacedemonians at Thermopylae, he says, "They defended themselves with the swords they had left, and even with their hands and teeth, till the barbarians buried them under their arrows." It cannot be supposed strictly true, that so many arrows were thrown at them as to bury them; but having in the former part of the sentence represented their resolute defence in the strongest terms, by saying, that naked and without arms, they engaged armed men with their hands and teeth, the following hyperbole seems not unnatural, and to intimate nothing more than what was necessary to quell such obstinate resolution and courage.

As to figures, whether verbal or those which consist in the sense, the nature of this character will easily direct to such as are most proper. But with respect to the latter, poets take greater liberties in the use of them than would be allowed in an orator. As their images are often formed for pleasure and delight, so they carry in them more of rapture and transport. But the orator's use of them being to set things in a stronger and clearer light, they are more sedate and moderate. Besides, an orator scarce ever has occasion for such fictitious images as we often meet with in poetry; though he ought to appear as natural, and its passing as strong and lively. We shall just mention some of the chief of those figures which seem best suited for this purpose; though they are no less suited to the middle style, as has been shown already, when taken from subjects of an inferior nature.

1. Description. Of this Justin gives us a fine instance, in a speech of King Philip of Macedon, where, in he represents the necessity of falling upon the Romans, who at that time were engaged in a war with Hannibal. "I behold (says he) a cloud of a most dreadful and bloody war rising in Italy. I see a storm of thunder and lightning from the west, which will overspread all places with a vast shower of blood, into whatever country the tempest of victory shall drive it." Greece has undergone many violent shocks in the Persian, Carthaginian, and Macedonian wars but these would all be found unworthy of regard, if the armies now engaged in Italy should march out of that country. I view the terrible and cruel wars which involve those nations through the courage of their forces, and skill of their generals. This rage and fury cannot cease by the destruction of one party, without the ruin of their neighbours. Indeed, Macedon has less reason to dread the savage conquerors than Greece; because more prepared, and better able to defend itself; but I am sensible, those who attack each other so impetuously will not confine their victories within those bounds, and that it will be our lot to engage the conquerors." So lively a picture of imminent and threatening danger must needs alarm the most timorous, and excite them to a resolution to defend their country, and all that was dear to them. Such images give life and vigour to a discourse, and being artfully interwoven with proper arguments, influence the mind, and carry it away by an irresistible force, so that the hearer is not barely left to conclude the certainty of the thing, but moved by it, as it were, from ocular demonstration. The images therefore of the orator ought to be drawn from real things, or at least such as are probable; for if they are wholly fictitious and incredible, as many poetical images are, they may give pleasure, but will not convince the mind, nor sway the passions.

2. Enumeration has some affinity with the former figure; by which, if the several parts have each something grand in them, the whole, when brought together, and disposed in a just order, very much contributes to the sublimity. We shall produce an example of this from an English writer, containing a description of our globe, upon a survey of it after the general conflagration, which he represents in this strong light: "Such is the vanity and transient glory of this habitable world! By the force of one element breaking loose upon the rest, all the varieties of nature, all the works of art, all the labours of man, are reduced to nothing; all that we admired and loved before, as great and magnificent, is obliterated and vanished, and another form and face of things, plain, simple, and everywhere the same, overspreads the whole earth. Where are now the great empires of the world, and their great imperial cities? their pillars, trophies, and monuments of glory? Show me where they stood, read the inscription, tell me the victor's name. What remains, what impressions, what difference or distinction, do you see in this mass of fire? Rome herself, eternal Rome, the greatest city, the empress of the world, whose dominion was superition, ancient or modern, make a great part of the history of the earth, what is become of her now? She laid her foundations deep, and her palaces were strong and impenetrable; she glorified herself, and lived deliciously, and said in her heart I sit a queen, and shall see no sorrow: but her hour is come, she is wiped away from the face of the earth, and buried in everlasting oblivion. But it is not cities only, and the works of men's hands; the everlasting hills, the mountains and rocks of the earth, are melted as wax before the sun, and their place is nowhere found. Here stood the Alps, the load of the earth, that covered many countries, and reached their arms from the ocean to the Black sea. This huge mass of stone is softened and dissolved, as a tender cloud into rain. Here stood the African mountains, and Atlas with his top above the clouds. There was frozen Caucasus, and Taurus, and Ida, and the mountains of Asia; and yonder, towards the north, stood the Skbroian hills, dressed in ice and snow; all these are vanished, dropped away as the snow upon their
Part III.

ORATORY.

Eloquence, their heads. These particulars considered separately are all truly great and noble, and every way suited to the nature of the subject; but as they are here disposed, and rise in order, they both enlarge the idea, and heighten the image of that grand catastrophe.

3. Similitude: which serves very much for beauty and ornament; and, when taken from great and sublime objects, adds a grandeur and magnificence to the things illustrated by it. We need no farther for an example of this, than to the great critic so often mentioned already, who has treated upon the sublime in a style every way equal to the subject. He, then, comparing those two great works of Homer, his Iliad and Odyssey, thus describes them: “Homer composed his Iliad when his mind was in its full strength and vigour: the whole body of the poem is dramatic, and full of action: whereas the best part of the Odyssey is taken up in narrations, which seem to be the genius of old age. So that one may compare him in this latter work to the setting sun, which still appears with the same magnificence, but has no longer the same heat and force.” And soon after, speaking of the Odyssey, he says: “That too may be called the reflux of his genius, which like the ocean ebbs, and deserts its shore.” What nobler idea could possibly have been given of that great poet, than by those two similitudes of the sun and the ocean? And elsewhere, comparing those two great orators Demosthenes and Cicero, he shows the like sublimity of thought. “Demosthenes (says he) is sublime, in that he is close and concise; Cicero, in that he is diffuse and extensive. The former, by reason of the violence, rapidity, strength, and fury, with which he rages and bears all before him, may be compared to a tempest, and thunder; but the latter, like a great conflagration, devours and consumes all he meets, with a fire that is never extinguished, but wherever it advances continually gathers new strength.”

4. Antithesis, or a sentence consisting of opposite parts, has often the same effect; as in the following instance of Cicero: where his view is to represent Pompey as a most consummate general. “Who (says he) ever was, or need be more knowing than this man? who from his childhood, and instruction at school, went into the army of his father, and learned the military art, in a very great war against the fiercest enemies: who, while yet a boy, became a soldier under the greatest general; and when but a youth was himself commander of a very great army: who has oftener engaged with the enemy in battle, than any other person with his adversary in private contests: has waged more wars than others have read, and conquered more provinces than others have wished to govern: whose youth has been spent in acquiring the art of war, not by the precepts of others, but his own commands; not by defeats, but victories; not by campaigns but triumphs.”

5. Apostrophe. Among the articles charged against Demosthenes by his great adversary and rival Aeschines, one was, that he had advised the Athenians to engage in a war against King Philip, wherein they had received a very great defeat. When Demosthenes comes to answer that part of the charge, he does not say, as he might, “You have not been misled, my fellow-citizens, in exposing your lives for the liberties and safety of Greece; you are not without the most illustrious examples of such conduct; for who can say these great men were misled, who fought for the same cause in the plains of Marathon?” But instead of expressing himself thus, he gives theatter quite a different turn; and in a sort of rapture, appealing to those brave defenders of their country, says, “No, my fellow-citizens, you have not done wrong, you have not; I protest by the ghosts of those great men who fought for the same cause in the plains of Marathon.” By this appeal to those ancient worthies whose memories were in the highest esteem at Athens, that it was the cause, and not the success, which rendered their actions so glorious, he artfully corroborates his assertion in a way which he knew must have the greatest weight with his audience.

As the proper subjects of this character are either divine things, or such as are in the highest esteem and regard among mankind, which often require laudatory discourses, or panegyric; these naturally admit of all the ornaments and assistance of eloquence. Which, however, must be used with discretion; for when the mind is wrappt up in thought, and stretched to the utmost of its powers in the pursuit of some noble and sublime idea, it cannot attend to all the lesser fineries and niceties of language; but from its own vigour, and lively conception of things, will be led to express them in terms the most emphatical, and best suited to their nature. In such cases, therefore, the sublimity must appear rather from the elevation of the thought, attended with a simplicity of expression, than from the ornaments and dress of the language. These things seem more natural when the mind is relaxed, and employed upon lower objects. Though, upon the whole, grandeur and majesty of expression is the proper mark of this character with relation to the language, as beauty and splendour is of the middle style.

CHAP. VIII. Of the Style of an Orator.

The style of an orator comprehends all the character already explained, of low, middle, and sublime, middle, and as they are applied by him in the different parts of his province. For that the language must be suited to the nature of the subject, we have had occasion often to observe already; and the different view of the speaker or writer necessarily occasions a variety in the manner of expression. Now an orator has three things in his view, to prove what he asserts, to represent it in an agreeable light, and to move the passions. These are all necessary, we do not mean in the order wherein we have now mentioned them, but that the discourse may upon the whole have its desired effect upon the audience. For unless the mind be convinced of the truth of what is offered by solid and cogent arguments, neither will the most eloquent discourse afford a lasting pleasure, nor the most passionate long influence the affections. Though, on the other hand, the hearers expect to be entertained at the same time they are informed; and, therefore, unless the language be agreeable to their taste, they will soon call off their attention, and think but mealy of the speaker. And unless both these are warmed and animated by a becoming pathos, the speaker may very probably miss of his end in bringing his audience over.
ORATORY. Part III.

Elocution, over to his sentiments. For bare conviction is not sufficient with many persons to excite them to action. They will acquiesce in the truth of a thing which they cannot contradict, or will not give themselves the trouble to examine; and at the same time remain un Concerned to prosecute it. And the pleasure of a florid discourse will of itself soon vanish, like the harmony of music, or the charms of a fine poem. And therefore to captivate his audience, secure them in his interest, and push them upon action, it is necessary for the orator to engage their affections; these are, as it were, the springs of the soul, which, managed by a skilful hand, move and direct it at pleasure. Now each of these parts of an orator’s province requires a different style. The low style is most proper for proof and information; because he has no other view here but to represent things to the mind in the plainest light, as they really are in themselves, without colouring or ornament. The middle style is most suited for pleasure and entertainment, because it consists of smooth and well-turned periods, harmonious numbers, with florid and bright figures. But the sublime is necessary in order to sway and influence the passions. Here the orator calls in all the assistance both of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

But as an orator has frequently each of these views in the same discourse, we shall first give a summary description of the several characters of style, which we have formerly discoursed on more at large; that, by placing them together in one view, the difference between them may be more plain and obvious: and then we shall proceed to show to what particular parts of a discourse each of them is more especially to be applied.

I. First, then, as shorter periods are proper in the low style, so less care is necessary in their turn and cadency. If a sentence now and then drop unexpectedly and disappoint the ear, or has something rough and harsh in its composition, it is no blemish in this character. For as it is suited to the manner of common discourse, an appearance of regard to the subject rather than the form of expression, is more becoming than any beauties of art. But the words should be well chosen and proper, suited to the ideas they are designed to convey; the expressions plain and clear, and the artificial ornaments few and modest. By artificial ornaments, are here meant tropes and figures; and they are called artificial, because they vary from the natural dress of language, either in the words or manner of expression: though they are often used by those who are wholly unacquainted with the rules of art; and particularly metaphors, which persons who have the least command of language frequently run into through mere necessity, for want of a sufficient stock of proper words to convey their ideas. The low style therefore admits of these: but care should be taken to choose such as have been rendered familiar by use, or at least where the similitude is very plain and evident. Bold or lofty metaphors, or where the allusion is dark and remote, ought to be avoided. Nor is the moderate use of the other tropes wholly disagreeable to this style. And the same thing is to be said with respect to verbal figures, or such as consist in the particular disposition of the sentence, so that if the form of it be changed, the figure is lost. Of these, such as come Elocution, nearest to the natural way of expression are most proper for this style; and therefore those which consist in a jingle of words, arising from the same or like sound, are to be avoided, as carrying in them too much the appearance of art. Those likewise which consist in a repetition of the same word have often too great a force and vehemence for this mild and gentle character. And as to figures of sentences, which do not depend on the construction of words, but lie in the sense, many of them are too gay and sprightly, and others too rapid and impetuous, for the simplicity of the low style; so that only the more moderate and sedate ones are to be allowed a place here. It is therefore no wonder if persons are often mistaken in their notions of this character: the beauty of which consisting in a certain plainness and simplicity, without any thing in it but what seems natural and common, every one is apt to imagine he can readily be master of it, till by experience he finds the contrary. For the case is much the same here, as in persons of fashion and good breeding, whose behaviour and address is attended with that agreeable freedom and seeming negligence, which in appearance is very easy to express, but in reality is scarce imitable by others.

As the middle style is more adapted for pleasure and delight, it admits of all those beauties and ornaments which soothe and entertain the mind. It has more force and energy than the low style, but less than the sublime. Smooth and harmonious numbers, well turned periods, of a just length, delightful cadency, and accurate disposition of the words, are suited to this style. The most beautiful and shining tropes, which strike the fancy, and all those verbal figures which, by a repetition, similitude, or proportion of sounds, please and gratify the ear, help to form this character. The like is to be said as to figures of sentences: The most florid and beautiful, such as enumeration, description, similitude, and the like, are here the most proper.

But it is the sublime style which perfects the orator. This requires the most forcible and emphatical words, the boldest metaphors and strongest figures. In verbal figures, repetitions, synonyms, gradations, contraries, with others of a like force and energy, are chiefly employed here. But figures of sentences are the most considerable, and principally contribute to make up this character. Among these are similes taken from lofty subjects, prosopopoeia, apostrophe, exclamation, epiphonema, aspoeiosis, and others of a like nature. But due care must likewise be taken of the form, construction, and harmony of the periods; which seem best disposed, when long and short ones are intermixed. For though round and swelling periods carry in them something grand and majestic, yet many times they move too slow to strike the passions; whereas short ones are more acute and pungent, and by returning quick, awaken the mind, and raise the passion. But to render it complete, it must be supported with strong reason, grandeur of thought, and sentiments every way equal to the expression; without which it will be very liable to swell into bombast, and end barely in amusement of the listeners.

II. Having given a short sketch of this part of the orator’s furniture, we shall now go on to show where, and in what manner, he is to make use of it. This will
with the sedateness of a philosopher; and where any part of his argument appears doubtful or obscure, he endeavours with the same even temper to explain and clear it up. But frequently he intermixes with his proofs all the arts of persuasion, and embellishes his reasons with the greatest ornaments and beauties of eloquence.

Confirmation is usually followed by conjunction, in which the orator endeavours to enervate and overthrow all that has been advanced in favour of the opposite side of the question. But as the style is much the same here as in the former part, what has been said upon that may be sufficient for this likewise.

The last part above mentioned is the conclusion. This consists of two branches, recapitulation, and address. Recapitulation is a short recital of the several arguments, at the least the chief of them, which were before advanced in support of the cause; that, being brought together into a narrow compass, they may appear in a stronger light. Wherefore the language here ought rather to be forcible and strong than florid, because brevity and conciseness is a necessary quality. The other branch of the conclusion consists in an address to the passions, and is wholly persuasive; for which the speaker is now entirely at leisure. Indeed, this is often done occasionally in other parts of the discourse, particularly in the introduction and confirmation: But, as in the former of these, his view is principally to secure the good opinion of the hearers, and excite their attention; and in the latter to defend his own side of the question by reason and argument; when these two points are gained, he has nothing left but to prevail with them to fall in with his design, and declare for him. And the best way to attain this, by engaging their passions in his interest. Hence, then, to use Quintilian's words, "All the springs of eloquence are to be opened. Now we are past the rocks and shallows, all the sails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here?"

All the variety above mentioned, however, is not always necessary. Regard must be had to the nature of the subject, the time, place, persons, and other circumstances; by all which the style is to be regulated. To discourse in a lofty and grand way upon a common topic, or in a low and flat manner upon a sublime argument, are both equally injudicious: Cicero refers to some discourses of his own, as instances of each kind. His oration for Cæcina, he says, is written in the low style, that for the Manilian law in the middle style, and that for Rutilius in the sublime; and his Actions against Verres, with some others, are patterns of the variety here mentioned. And he gives us a very comprehensive description of a perfect orator in very few words, when he says, "He is one who can speak upon a low subject acutely, upon a lofty subject with sublimity, and upon a moderate subject temporarily." By which he means no more, than one who is master of the three characters here described, and knows when and how to use them. But although he mentions several among the Greeks, and some few among the Romans, who excelled in one or other of these different kinds; yet one who excelled in them all, he supposes never to have existed, except in the imagination. The reason...
PART IV. OF PRONUNCIATION.

CHAP. I. *Of Pronunciation in general.*

PRONUNCIATION is also called *Action* by some of the ancients. Though, if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. But if we consider them as synonymous terms, in this large sense pronunciation or action may be said to be a suitable conformity of the voice, and the several motions of the body, in speaking, to the subject matter of the discourse.

The best judges among the ancients have represented this as the principal part of an orator’s province, from whence he is chiefly to expect success in the art of persuasion. When Cicero, in the person of Crassus, has largely and elegantly discoursed upon all the other parts of oratory, coming at last to speak of this, he says: “All the former have their effect as they are pronounced. It is the action alone that governs in speaking; without which the best orator is of no value, and is often defeated by one in other respects much his inferior.” And he lets us know, that Demosthenes was of the same opinion, who, when he was asked what was the principal thing in oratory, replied, action; and being asked again a second and a third time, what was next considerable, he still made the same answer. By which he seemed to intimate, that he thought the whole art did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would scarce have taken so much pains in correcting those natural defects, under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly by pronouncing long periods as he walked up hill; both of which methods contributed to the strengthening of his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he less careful in endeavouring to gain the habit of a becoming and decent gesture; for which purpose he used to pronounce his discourses alone before a large mirror. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a sword, which hung over him with the point downward. Such pains did this prince of the Grecian orators take to remove those difficulties, which would have been sufficient to discourage an inferior and less aspiring genius. And to how great a perfection he arrived in his action, under all these disadvantages, by his indefatigable diligence and application, is evident from the confession of his great adversary and rival in oratory, *Aeschines.* Who, when he could not bear the disgrace of being worsted by Demosthenes in the cause of Ctesiphon, retired to Rhodes. And being desired by the inhabitants to recite to them his own oration upon that occasion, which accordingly he did; the next day they requested of him to let them hear that of Demosthenes; which having pronounced in a most graceful manner, to the admiration of all who were present, “How much more (says he) would you have wondered if you had heard him speak it himself!” By which he plainly gave Demosthenes the preference in that respect. We might add to these authorities the judgment of Quintilian, who says, that “it is not of so much moment what our compositions are, as how they are pronounced; since it is the manner of the delivery by which the audience is moved.” And therefore he ventures to assert, that “an indifferent discourse, assisted by a lively and graceful action, will have greater efficacy than the finest harangue which wants that advantage.”

The truth of this sentiment of the ancients concerning the power and efficacy of pronunciation, might be proved from many instances; but one or two may here suffice. Hortensius, a contemporary with Cicero, and while living next to him in reputation as an orator, was highly applauded for his action. But his orations after his death, as Quintilian tells us (for we have none of them now remaining), did not appear answerable to his character; from whence he justly concludes, there must have been something pleasing when he spoke by which he gained his character, which was lost in reading them. But perhaps there is scarce a more considerable instance of this than in Cicero himself. After the death of Pompey, when Caesar got the government into his own hands, many of his acquaintance interceded with him in behalf of their relations and friends, who had been of the contrary party in the late wars. Among others, Cicero solicited for his friend Ligarius; which Tubero understanding, who owed Ligarius a grudge, he opposed it, and undertook to represent him to Caesar as unworthy of his mercy. Caesar himself was prejudiced against Ligarius; and therefore, when the cause was to come before him, he said, “We may venture to hear Cicero display his eloquence; for I know the person he pleads for to be an ill man, and my enemy.” But, however, in the course of his oration, Cicero so worked upon his passions, that by the frequent alteration of his countenance, the emotions of his mind were very conspicuous. And when he came to touch upon the battle of Pharsalia, which had given Caesar the empire of the world, he represented it in that moving and lively a manner, that Caesar could no longer contain himself, but was thrown into such a fit of shivering, that he dropped the papers which
Part IV.

ORATORY.

which he held in his hand. This was the more remarkable, because Caesar was himself one of the greatest orators of that age, knew all the arts of address, and avowed to the passions, and consequently was better prepared to guard against them. But neither his skill, nor resolution of mind, was of sufficient force against the power of oratory; but the conqueror of the world became a conqueror to the charms of Cicero's eloquence; so that, contrary to his intention, he gave into his plea, and pardoned Ligarius. Now that oration is still extant, and appears exceedingly well calculated to touch the soft and tender passions and springs of the soul; but we believe it can scarce be discernible to any in reading it, how it should have had so surprising an effect; which must therefore have been chiefly owing to the wonderful address and conduct of the speaker.

The more natural the pronunciation is, the will of consequence be the more moving, since the perfection of art consists in its nearest resemblance to nature. And therefore it is not without good reason, that the ancients made it one qualification of an orator, that he be a good man; because a man of this character will make the cause he espouses his own, and the more sensibly he is touched with it himself, his action will be the more natural, and by that means the more easily affect others in the same manner. Cicero, speaking upon this subject, says, "It is certain that truth (by which he means nature) in every thing excels imitation; but if that was sufficient of itself in action, we should have no occasion for art." In his opinion therefore (and who was ever a better judge), art in this case as well as in many others, if well managed, will assist and improve nature. But that is not all; for sometimes we find the force of it so great and powerful, that, where it is only counterfeit, it will for the time work the same effect as if it was founded in truth. This is well known to those who have been conversant with the representations of the theatre. In tragedies, though we are sensible that everything we see and hear is feigned and counterfeit, yet such is the power of action, that we are oftentimes affected by it in the same manner as if they were all realities. Anger and resentment at the appearance of enmity, concern and solicitude for distressed virtue, rise in our breasts; and tears are extorted from us for oppressed innocence, though at the same time, perhaps, we are ready to laugh at ourselves for being thus deceived. If art then has so great an influence upon us, when supported only by fancy and imagination, how powerful must be the effect of a just and lively representation of what we know to be true and real?

How agreeable it is both to nature and reason, that a warmth of expression and vehemency of motion should rise in proportion to the importance of the subject and concern of the speaker, will further appear, by looking back a little into the more early and simple ages of the world. For the higher we go, the more we shall find of both. We shall give the observation of a very great man upon this head, in his own words. "The Romans (says he) had a very great talent this way, and the Greeks a greater. The eastern nations excelled in it, and particularly the Hebrews. Nothing can equal the strength and vividness of the figures they employed in their discourse: and the very actions they used to express their sentiments, such as putting ashes on their heads, and tearing their garments, and covering them-
ORATORY.

Part IV.

Pronunciation, both in distinguishing the several parts of the same sentence, and in separating one sentence from another; likewise when to raise or sink their voice, or give it a proper inflection; to be slower or faster, more vehement or sedate, as the nature of the things may require; and that the tone of their voice be always mild and grave, but at the same time mixed with an agreeable sweetnecness. "These things may perhaps appear in themselves small; but if duly attended to, they will be found of considerable service in bringing us to a just and proper pronunciation. For in everything that is to be attained by practice, it is a great advantage to set out right at first.

The ancients likewise had persons whom they called phonasici, whose proper business it was to teach them how to regulate and manage their voice; and others, who instructed them in the whole art of pronunciation, both as to their voice and gestures. These latter were generally taken from the theatre, being some eminent experienced actors. So Quintilian, treating of the province of these persons, says, "The comedian ought to teach them how to relate facts, with what authority to advise, with what vehemence to express anger, and with what softness compassion." And speaking of gestures, he says, "He should admonish them to raise their countenance, not distort their lips, or stretch their mouths." With several other directions of the like kind. And we are told concerning the emperor M. Antonius, usually called the philosopher, that his first masters were Euphorus the grammarian, and Gemius the comician.

But though they made use of actors to instruct their youth in forming their speech and gestures, yet the action of an orator was much different from that of the theatre. Cicero very plainly represents this distinction in the words of Crassus, when speaking of orators, he says, "The motions of the body ought to be suited to the expressions, not in a theatrical way, mimicking the words by particular gesticulations, but in a manner expressive of the general sense, with a sedate and many inflection of the sides; not taken from the stage and actors, but from the exercise of arms and the palestra." And Quintilian says to the same purpose, "Every gesture and motion of the comedians is not to be imitated, nor to the same degree." They thought the action of the theatre too light and extravagant for the imitation of an orator; and, therefore, though they employed actors to inform young persons in the first rudiments, yet they were afterwards sent to the palestra, or schools designed on purpose, to teach them a decent and graceful management of their bodies. And such schools, as Quintilian informs us, were in use both among the Greeks and Romans: Just as of later ages children learn to dance, in some measure with the same intention.

Being thus far prepared, they were afterwards sent to the schools of the rhetoricians. And here, as their business was to cultivate their style, and gain the whole art of eloquence; so particularly to acquire a just and accurate pronunciation by those exercises, in which for that end they were constantly employed. And as the Greeks were most celebrated for their skill in all the polite arts, and especially oratory; the Roman gentility and nobility generally sent their sons abroad, and placed them under the tuition of some Grecian master, to instruct them in the art of speaking, and by that means to fit them for the service of their country, either in the courts of judicature or the senate. Thus Cicero was sent to Rhodes, to study under the famous Molo, and Brutus under Panmenes; Caesar was going to the same place when taken by pirates; and Augustus afterwards studied there under Apollodorus.

Nor, after all this pains and industry, did they yet think themselves sufficiently qualified to take upon them the character of orators. But it was their constant custom to get together some of their friends and acquaintance who were proper judges of such performances, and declaim before them in private. The business of these persons was to make observations both on their language and pronunciation. And they were allowed the greatest freedom to take notice of anything they thought amiss, either as to inaccuracy of method, impropriety of style, or indecency of their voice or actions. This gave them an opportunity to correct any such defects at first, before they became habitual. What effects might not justly be expected from such an institution! Persons trained up in this manner, with all those advantages, joined to a good natural genius, could not fail of making very complete orators. Though even after they came to appear in public, they did not lay aside the custom of declaiming. For Quintilian tells us, that C. Corbo used to practice it daily in his tent. And Augustus is reported to have continued it during the war of Mutina against M. Antony. Nor is it to be supposed, that so constant an attendance to this practice was only serviceable to them in their public performances; but it must necessarily affect their whole conduct, give them a freedom of speech, easiness of address and behaviour, and render them in all respects fine gentlemen as well as excellent orators. And from hence, perhaps, we may see less reason to wonder at the surprising effects of some of their discourses, when we consider what pains they took to arrive at those abilities.

Having thus far treated on pronunciation in general, we shall now proceed to consider the parts of it separately; which are voice and gesture.

CHAP. II. Of the Voice.

VOICE is one kind of sounds. Now the influence of voice, or sounds, either to rouse or allay our passions, is evident kind of from music. And certainly the harmony of a fine discourse, well and gracefully pronounced, is as capable to move us, if not in a way so violent and ecstatic, yet not less powerful, and more agreeable to our rational faculties. As the business of this chapter is to offer some either by considerations for the just and decent management of the voice, it may not be improper in the first place to observe in general what nature does when free and unconstrained. As persons are differently affected when they speak; so they naturally alter the tone of their voice, though they do not attend to it. It rises, sinks, and has various inflections given it, according to the present state and disposition of the mind. When the mind is calm and sedate, the voice is moderate and even; when the former is depressed with sorrow, the latter is languid; and when that is inflamed by passion, it is raised and elevated. It is the orator's business, therefore, to follow nature, and to endeavour that the tone of his voice appear natural and unaffected. And for this
this end, he must take care to suit it to the nature of
the subject; but still so as to be always grave and de-
cent. Some persons continue a discourse in such a
low and drawling manner, that they can scarce be
heard by their audience. Others again hurry on in
so loud and boisterous a manner, as if they imagined
their bearers were deaf. But all the music and har-
mony of speech lies in the proper temperament of the
voice between these extremes. In order to set this
matter in a just light, it will be necessary to consider
the principal affections or properties of the voice, and
how they are to be regulated by an orator. Now these
may all be referred either to quantity or quality.

The quantity of the voice consists in its highness or
lowness, swiftness or slowness, and the intermediate
degrees between them.

Every person who speaks in public should endeavour,
if he can, to fill the place where he speaks. But still
he ought to be careful not to exceed the natural key of
his voice. If he does, it will neither be soft nor agreeable,
but either harsh and rough, or too shrill and
squeaking. Besides, he will not be able to give every
syllable its full and distinct sound; which will render
what he says obscure, and difficult to be understood.
He should therefore take care to keep his voice within
reach, so as to have it under management, that he may
raise or sink it, or give it any inflection he thinks pro-
per: which it will not be in his power to do if he put a
force upon it, and strain it beyond its natural tone.

The like caution is to be used against the contrary
extreme, that the voice be not dropped, and suffered
to sink too low. This will give the speaker pain in raising
it again to its proper pitch, and be no less offensive to
the hearers. For though the music of speech consists
in the variations of the voice, yet they must be gradual
to render them pleasant. Such sudden and great
changes at once are rather to be esteemed chasms in speak-
ing than variations. Besides, as they often prevent
the hearers from taking in the sense of what is said,
it gives them no small uneasiness that they are obliged
to stretch their attention. Many persons are too apt
to be guilty of this, especially at the end of a sentence,
by dropping the last word; which ought, in a particu-
ar manner, to be expressed distinctly, because the
meaning of the whole sentence often depends upon it.

The medium between these two is a moderate and
even voice. But this is not the same in all; that which
is moderate in one would be high in another. Every
person, therefore, must regulate it by the natural key of
his own voice. A calm and sedate voice is generally
best; as a moderate sound is most pleasing to the ear, if
it be clear and distinct. But this equality of the voice
must also be accompanied with a variety of other
things; for there can be no harmony; since all harmony consists in vari-
ety. Nothing is less pleasing than a discourse pronounced
throughout in one continued tone of the voice,
without any change or alteration. Besides, a variation
of the voice is an ease to the speaker; as the body is
relieved by shifting its posture. The equality, there-
fore, we are here speaking of admits a variety of inflec-
tions and changes within the same pitch. And when
that is altered, the gradations, whether higher or lower,
should be so gentle and regular as to preserve a due pro-
portion of the parts and harmony of the whole, which
cannot be done when the voice is suddenly varied
with too great a distinction. And therefore it should move
from one key to another, so as rather to glide like a
gentle stream, than pour down like a rapid torrent,
as an ingenious writer has well expressed it. An
even voice is best fitted to keep the mind to close
attention. And therefore, in subjects designed only
for instruction, without any address to the passions,
there is little room for a variety of voice. For the
voice ought to agree with the style; and as upon such
subjects this should be equal, moderate, and smooth, so
should the other. Every thing, as we say, is beautiful
in its season; and there is a certain propriety in things
which ought always to be regarded. And, therefore,
that variety, ill-placed, is as disagreeable to a
judicious audience as the want of it, where the subject
requires it. We may find some persons, in pronouncing,
a grave and plain discourse affect as many different tones,
changes, and variations of their voice, as if they were
acting a comedy; which is doubtless a very great im-
propriety. But the orator's province is not barely to
apply to the mind, but likewise to the passions; which
require a great variety of the voice, high, or low, ve-
hement or languid, according to the nature of the passions
he designs to affect. So that for an orator always to
use the same tone or degree of his voice, and expect to
answer all his views by it, would be much the same
thing as if a physician should propose to cure all distem-
pers by one medicine. From hence it is evident, that
although various inflections and tones of the voice are
requisite to make it harmonious and pleasing to the ear;
yet the degree of it should differ according to the nature
of the subject, and design of the speaker. And, as a
perfect monotony is always unpleasant, so it can never
be necessary in any discourse.

The next property of the voice above mentioned was
swiftness. That some expressions ought to be pronounced
faster and swifter than others, is very manifest.
Gay and sprightly ideas should not only be expressed
louder, but also faster, than such as are sad and melan-
choly. And when we press an adversary, the voice
should be brisk and quick. But to hurry on in a precip-
tant manner, without pausing till stop for want of
breath, is certainly a very great fault. This destroys,
not only the necessary distinction between sentence and
sentence, but likewise between the several words of the
same sentence; nay, and often occasions us to express
our words by halves, while one is thrown so fast upon
another, that we are not able to give each its full and
just sound. By this means all the grace of speaking is
lost, and in a great measure the advantage of bearing.
For when the ears of the bearers cannot keep pace
with the volubility of the speaker's tongue, they will be
naturally more short of breath; and the better for what he
says. Besides, by not commanding his voice, and easing his breath at the
proper pause and points of distinction, he is often obli-
ged to stop in the middle of a sentence; and so dis-
vides what should be continued, and joins what should
be separated; which must necessarily destroy the sense,
and confound his discourse. Young persons are very
liable to this, especially at first setting out. And it
often arises from diffidence. They are jealous of their
performances, and the success they may have in speaking,
which gives them a pain till it is over; and this puts
them into a hurry of mind, which incapacitates them
from governing their voice, and keeping it under that

Vol. XV. Part I.

3 D
in itself, yet all the other virtues of a good pronunciation are deficient without it."

Hitherto we have considered such properties of the voice as respect quantity, we come now to speak of its qualities. And the chief of these are strength or weakness, clearness or obscurity, fulness or smallness, smoothness or roughness. Now, one half of these is what every one would willingly choose, as he would wish to be free from the others. But it is not in our power to give ourselves what qualities of the voice we please; but only to make the best use we can of what nature has bestowed upon us. However, several defects of the voice are capable of being helped by care and proper means; as, on the other hand, the best voice may be greatly hurt by ill management and indiscretion. Temperance is a great preservative of the voice, and all excess is highly prejudicial to it. The voice must necessarily suffer, if the organs of speech have not their proper tone. And in order to their having this, they must be kept in due temperature; that is, they must neither be too moist nor too dry. If they abound with fluids, these will obstruct the clearness of the voice, and render it obscure and confused; and if they are parched with drought, the voice will be harsh and rough. Now all excesses, as well as some bodily indispositions, are apt to affect the organs one or other of these ways.

A strong voice is very serviceable to an orator, because if it want some other advantages, it is, however, capable to make himself heard. And if at any time he is forced to strain it, he is in less danger of its failing him before he has finished his discourse. But he who has a weak voice, should be very careful not to strain it, especially at first. He ought to begin low and rise gradually to such a pitch as the key of his voice will well carry him, without being obliged to sink again afterwards. Frequent inflections of the voice will likewise be some assistance to him. But especially he should take care to speak deliberately, and ease his voice, by allowing due time for respiration at all the proper pauses. It is an extreme much less inconvenient for such a person rather to speak too slow, than too fast. But this defect of a weak voice is sometimes capable of being helped by the use of proper methods; as is evident from the instance of Demosthenes, before mentioned.

A voice is said to be clear, when the organs of speech are suited to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is very pleasing and agreeable to the hearers; and no less an happiness to the speaker, as it saves him a great expense of spirits. For a moderate voice, if clear, will be as distinct and heard, as one much louder, if thick and obscure. Which is a great advantage to the speaker, because he can better keep his voice under command, and modulate it at pleasure, as the several parts and circumstances of his discourse may require. On the contrary, an obscure and confused voice is not always occasioned from a deficiency in the organ; but many times is the effect of custom and a bad habit. Some persons, either from want of due care in their education at first, or from inadvertency and negligence afterwards, run into a very irregular and confused manner of expressing their words; either by misplacing the accent, confounding the sound of the letters,
Part IV.

PRONUNCIATION.

A full voice is not the same as a strong or a loud voice. It fills the ear but it is often not pleasant. And therefore to render it so, as well as audible, it should be frequently varied. However, this seems better suited to the character of an orator than a small and shrill voice; because it has something in it more grave and manly. And those who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden compression of the organ is apt to occasion a squeaking and very disagreeable sound.

A soft and smooth voice is of all the most musical, especially if it be flexible. And, on the contrary, nothing is less harmonious than a voice that is harsh and rough. For the one produces as disagreeably upon the ear as on the other gives it pleasure and delight.

From the consideration of these several properties of the voice, we may conclude that to the best, and fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and withal easily flexible to the several degrees and variations of sound which every part of the discourse may require.

CHAP. III. Of Gesture.

By this is meant, a suitable conformity of the motions of the countenance, and several parts of the body, in speaking, to the subject-matter of the discourse. The word gesture is here used in a larger sense than is ordinarily done in common language. For we rarely make use of that word to denote the motions of the countenance, or any part of it; but as these make a considerable part of our present subject, they must here be comprehended under this term.

It is not within the province of the learned, whether voice or gesture has the greater influence upon us. But as the latter affects us by the eye, as the former does by the ear, gesture in the nature of it seems to have this advantage, that it conveys the impression more speedily to the mind; for the sight is the quickest of all our senses. Nor is its influence less upon our passions; nay, in some instances it appears to act more powerfully. A cast of the eye shall express desire in as moving a manner as the softest language; and a different motion of it, resentment. To wring the hands, tear the hair, or strike the breast, are all strong indications of sorrow. And he who claps his hand to his sword, throws us into a greater panic than one who only threatens to kill us. Nor is it in some respects less various and extensive than language. Cicero tells us, he often diverted himself by trying this with Roscius the comedian; who could express a sentence as many ways by his gestures, as he himself by words. And some drams, called pantomimes, have been carried on wholly by move, who have performed every part by gestures only, without words, in a way very intelligent, as well as entertaining to the spectators.

Well, therefore, might Ciceror call action (or gesture) the language of the body, since it is capable in so lively a manner to convey both our ideas and passions. But with respect to oratory, gesture may very properly be called the second part of pronunciation; in which, as the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should arise therefore in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

But as gesture is very different and various as to the manner of it, which depends upon the decent conduct of several parts of the body; it will not be amiss to consider more particularly the proper management of each of those parts. Now all gesture is either natural, or from imitation. By natural gesture we mean such actions and motions of the body, as naturally accompany our words, as these do the impressions of our minds. And these, either respect the whole body, or some particular part of it. But before we enter upon this, let us just to observe, that it has been customary in all ages and countries, in making a set discourse before an assembly, to do it standing. Thus we read, that Abraham stood up, and spoke unto the children of Heth. And it seems as if he sat down when he had ended his speech, because, immediately after the account of their answer, it is said again, that Abraham stood up and bowed himself to the people of the land, the children of Heth. In like manner Homer represents the Grecian princes, as standing up, when they made a speech, either to the army, or in their councils. So when Achilles had assembled the army, to inquire into the reason of the great plague which at that time raged among them, he rises up before he begins to speak, and sits down again when he has done. After him the prophet Calchas rises, and charges it upon Agamemnon; who, rising up in a passion, does not refuse to comply with what Calchas proposed, but expresses his resentment at him for saying it. And after both Agamemnon and Nestor do the same in council. And Cicero acquaints us, that when Lentulus had been charged in the senate as an associate with Catilina, he stood up to make his defence. Nor does the advantage of being better heard, seem to have been the only reason for so general an agreement in this posture; but it appears likewise to have been chosen, as the most decent and respectful. Sitting carries in it an air of authority, and is therefore a posture scarce used upon such occasions, unless perhaps where that is designed to be expressed by it. Wherefore it was a thing very much resented, that when Caesar after he had got the power into his hands, once addressed the senate, either refused to rise, as some say, or as others, one of his friends held him down by his gown.

But though standing appears to be the most proper posture for speaking in public, yet it is very unbecoming for the body to be entirely without any motion like a statue. It should not long continue in the same position, but be constantly changing, though the motion be very moderate. There ought to be no appearance of stiffness, but a certain ease and pliability, naturally suiting itself to every expression.
which means, when a greater degree of motion is necessary, it will appear less sudden and vehement:

For as the raising, sinking, and various inflections of the voice must be gradual; so likewise should the motion of the body. It is only on some particular occasions that a hasty vehemence and impetuousity is proper in either case.

As to the several parts of the body, the head is the most considerable. To lift it up too high has the air of arrogance and pride; to stretch it out too far, or throw it back, looks clownish and unmannerly; to hang it downwards on the breast, shows an unmannerly bashfulness and want of spirit; and to suffer it to lean on either shoulder, argues both sloth and indolence. Wherefore in calm and sedate discourse it ought to keep its natural state, an upright posture. However, it should not long without motion, nor yet always moving; but gently turn sometimes on one side, and sometimes on the other, as occasion requires, that the voice may be heard by all who are present; and then return again to its natural position. It should always accompany the other actions of the body, and turn on the same side with them; except when aversion to any thing is expressed, which is done by stretching out the right hand, and turning the head to the left. The ancients erected a statue of Venus in this posture, who was called by the Greeks \\textit{arrogenta}, and by the Latins \\textit{Verticordia}, and in English may be termed the \\textit{forbidding Venus}. But nothing is more indelicate than violent motions and agitations of the head. And therefore when a witty writer, who is well known among us, would convey the most ridiculous idea of a pretender to knowledge, he expresses it thus:

\begin{quote}
For having three times shook his head
To stir his wit up, thus he said. \textit{Hudibras}.
\end{quote}

But it is the countenance that chiefly represents both the passions and disposition of the mind. By this we express love, hatred, joy, sorrow, modesty, and confidence: by this we supplicate, threaten, soothe, invite, forbid, consent, or refuse; and all this without speaking. Nay, from hence we form a judgment not only of a person’s present temper, but of his capacity and natural disposition. And therefore it is common to say, \textit{such an one has a promising countenance, or that he promises little by his countenance}. It is true, this is no certain rule of judging; nor is it in the power of any one to alter the natural make of his countenance; however, it may put us upon endeavouring to gain the most pleasing aspect we can; since it is so natural for mankind to draw such conclusions from it: and some persons are so unhappy, as to render their countenance more disagreeable, than otherwise it would be, by ill habits.

But the several parts of the face bear their part, and contribute to the proper and decent motion of the whole. In a calm and sedate discourse, all the features retain their natural state and situation. In sorrow, the forehead and eyebrows lower, and the cheeks hang down. But in expressions of joy and cheerfulness, the forehead and eyebrows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips. And terror elevates both the brows and forehead.

As these are the natural signs of such passions, the orator should endeavour to conform to them.

But as the eyes are most active and significant, it is the advice of Cicero that the greatest care should be taken in their management. And he gives this reason for it, \textit{Because other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes, by so many different actions, which cannot possibly be represented by any gestures of the body, if the eyes are kept in a fixed posture. Common experience does in a great measure confirm the truth of this observation. We readily guess at a person’s intention, or how he is affected to us, by his eyes. And any sudden change or emotion of the mind is presently followed by an alteration in the look. In speaking therefore upon pleasant and delightful subjects, the eyes are brisk and cheerful; as on the contrary, they sink and are languid in delivering any thing melancholy and sorrowful. This is so agreeable to nature, that before a person speaks, we are prepared with the expectation of one or the other from his different aspect. So likewise in anger, a certain vehemence and intensity appears in the eyes, which, for want of proper words to express it by, we endeavour to represent by metaphors taken from fire, the most violent and rapid element, and say, in such cases, the eyes sparkle, burn, or are inflamed. In expressions of hatred or detestation, it is natural to alter the look, either by turning the eyes aside, or downwards. Virgil has very justly observed this: for when he describes \\textit{Aeneas} meeting with Dido in the Elysian shades, and addressing her, he represents her disregard of him, by saying,}

\begin{quote}
Disdainfully she look’d; then turning round,
Still fix’d her eyes unmov’d upon the ground.
\end{quote}

She showed her resentment for his former treatment of her, by not vouchsafing to look on him. Indeed, the eyes are sometimes turned downwards upon other occasions, as to express modesty. And if at any time a particular object be addressed to, whatever it be, the eyes should be turned that way. And therefore Philostratus very deservedly ridicules a certain rhetorician as guilty of a solemnism in gesture, who, upon saying, \textit{O Jupiter!} turned his eyes downward; and when he said, \textit{O Earth!} looked upward. A staring look has the appearance of godliness and want of thought; and to contract the eyes, gives suspicion of craft and design. A fixed look may be occasioned from intemperance of thought, but at the same time shows a disregard to the audience; and a too quick and wandering motion of the eyes denotes levity and wantonness. A gentle and moderate motion of the eyes is therefore in common most suitable, always directed to some of the audience, and gradually turning from side to side with an air of respect and modesty, and looking them decently in the face, as in a common discourse: Such a behaviour will of course draw an attention.

As in conversation, when a person addresses us in an handsome and becoming manner, we presently put ourselves in a posture to give what he says a proper reception. But as all the passions are in the most lively manner expressed in the eyes, their motions ought to vary according to the different nature of those passions they are suited both to discover in the speaker, and convey to his hearers; since, as the quickest access to the mind is by the sight, a proper well-timed look will sometimes
Part IV.

ORATORY.

Sometimes sooner effect this than it can be done by words; as in discharging a cannon we are struck with the light before we hear the sound.

As to the other parts of the body distinct from the head, the shoulders ought not to be elevated; for this is not only itself indecent, but it likewise contracts the neck, and hinders the proper motion of the head. Nor, on the other hand, should they be drawn down, and depressed; because this occasions a stiffness both to the neck and the whole body. Their natural posture therefore is best, as being most easy and graceful. To shrug the shoulders has an abject and servile air; and frequently to have them upwards and downwards is a very disagreeable sight.

A continued motion of the arms any way is, by all means to be avoided. Their action should generally be very moderate, and follow that of the hands, unless in very pathetic expressions, where it may be proper to give them a more lively spring.

The hands need never be idle. Quintilian seems to think them as necessary and powerful in action, as Cicero does the eyes. "The hands (says he), without which all gesture is lame and weak, have a greater variety of motions than can well be expressed; and are almost equal to our words. Do not we desire with them, promise, call, dismiss, threaten, beseech, detest, fear, inquire, deny? Do not they express joy, sorrow, dole, confession, penitence, measure, plenty, number, and time? Do not they excite, restrain, prove, admire, and shame? In so great a variety of speech among all nations and countries, this seems to me the common language of all mankind." Thus far Quintilian. Now, all bodily motion is either upward or downward, to the right or left, forward or backward, or else circular. The hands are employed by the orator in all these, except the last. And as they ought to correspond with our expressions, so they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right. In denouncing, addressing, and sometimes occassions, they must be stretched out; and in threatening, sometimes thrown back. But when the orator speaks of himself, his right hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as the breast, so as to make near a right angle with the arm. This is not only graceful, but likewise the most easy posture, and gives the least strain to the muscles. They should never be suffered to hang down, nor to fall upon the cushion or bar. The left hand should never move alone, but accommodate itself to the motions of the right. In motions to the left side, the right hand should not be carried beyond the left shoulder. In promises and expressions of compliment, the motion of the hands should be gentle and slow; but in exhortations and applause move swiftly. The hands should generally be open; but in expressions of compunction and anger they may be closed. All fiscial and trifling actions of the fingers ought to be avoided; nor should they be stretched out and expanded in a stiff and rigid posture, but kept easy and pliable.

Neither the breast nor the belly should be thrust out; which in itself looks ungainly, and hinders the free motion of the trunk; which ought not to be kept too stiff and upright, but easy and flexible, always suiting itself to the motions of the head and hands. The feet should continue steady, and not give the body a wavering and giddy motion by frequently shifting; though some persons fall into that habit without moving their feet. Curi, a Roman orator, as Cicero tells us, was addicted to this; which occasioned a friend of his once to pass a joke upon him, by saying, Who that was talking out of a boat? The jest is too plain to need explication; for everyone knows the waving of a boat will give the body such a motion.

The gestures we have hitherto discoursed of, are such as naturally accompany our expressions. And we believe those we have mentioned, if only attended to, will be found sufficient to answer all the purposes of our modern pronunciation. The ancients, indeed, used several more vehement actions and gestures than we are accustomed to; as we have formerly shown. Philip the Roman orator, as Cicero informs us, did not use to prepare his discourses, but spoke, as we say, off-hand. And he was wont to tell his friends, "He was never fit to talk till he had warmed his arm." He doubtless, therefore, used a method of his own; he warmed his arms and hands than is common with us. And Cicero calls the arm projected the orator's weapon. Indeed, to extend or brandish the arm, carries in it an air of command and authority, which was not unbecoming the character of Philip, who was a person of the highest rank and quality. And therefore young orators, both among the Greeks and Romans, for a time used no motion of the arm, but kept it confined in their garment, as an argument of modesty, till age and experience allowed them to use greater freedom. Nor was it uncommon for the ancient orators to express the excess of their passions by tears. They thought nothing unbecoming that was natural; and judged it agreeable to the characters even of the bravest men, to be touched with a sense of humanity in great calamities: And therefore we find both Homer and Virgil make their greatest heroes shed tears on some occasions.

The other sort of gestures above mentioned are such as those of imitation; as when the orator describes some action, or personates another speaking. But here great care is to be taken not to overact his part, by running into any ludicrous or theatrical mimicry. It is sufficient for him so to represent things of this nature, as may best convey the image of them in a lively manner to the minds of the hearers; without any such change - either of his actions or voice as are not suitable to his own character.

CHAP. IV. Some particular Rules for the Voice and Gesture.

The subject of pronunciation is of so great importance to an orator, that it can neither be too clearly the voice laid down, nor too strongly inculcated. If we inquire into the causes of that surprising power it has over us, and by what means it so strongly affects us, this may in some measure appear by reflecting on the frame and constitution of human nature. For our infinitely wise and great Maker has so formed us, that not only the actions of the body are subject to the direction of the mind, but we are likewise endowed with various passions.
ORATORY.

Part IV.

Pronunciation.

Passions and affections, that excite us to pursue those things which make for our happiness, and avoid others which are hurtful to us. And as we are made for society, we are also furnished with speech, which enables us to converse with one another. And such is the contrivance of our make, and influence of our minds upon the mechanism of our bodies, that we can not only communicate our thoughts to each other, but likewise our passions. For, as Cicero well observes, "Every motion of the mind has naturally its peculiar countenance, voice, and gesture; and the whole body, every position of the face, and sound of the voice, like the strings of an instrument, act agreeably to the impression they receive from the mind." Nor is this all: but as every one is differently affected himself, he is capable to make the like impressions upon others, and excite them to the same motions which he feels in himself. As when two instruments are set to the same pitch, the strings of the one being touched, produce in the other the like sound. This common sympathy in the human frame shows how necessary it is that an orator should not only in general be well acquainted with the rules of pronunciation, but likewise know how to use them as occasion requires; for a general knowledge of the rules of art is not of itself sufficient to perfect an artist, without a further acquaintance with the particular application of them to their several cases and circumstances. Thus, for instance, it is not enough for an orator to understand all the beauties and ornaments of language, and which of them are suited to form the several kinds of style, unless he can likewise accommodate each of those characters to their proper subject. And so likewise in pronunciation, he ought not only to know the several qualities of the voice, and proper gestures of the body, but also when and where to make use of them. For not only different subjects, but also different parts of the same discourse, and even particular expressions, often require a difference in the manner of pronunciation, both as to the voice and gesture. Having therefore treated on both these parts of pronunciation in general, it may not be amiss now to consider how they are to be applied in each of the two respects last mentioned.

We shall begin with the parts of a discourse, and treat of them in their natural order. And here the view and design of the speaker in each of them will easily help us to see the proper manner of pronunciation.

Let us suppose then a person presenting himself before an assembly, in order to make a discourse to them. It cannot be decent immediately to begin to speak so soon as ever he makes his appearance. He will first settle himself, compose his countenance, and take a respectful view of his audience. This prepares them for silence and attention. To begin presently, and hurry on, without first allowing either himself or his hearers time to compose themselves, looks as if he was neglecting a task so important. He will always separate the person and speech; which will be very apt to make them as uneasy till he has done, as he seems to be himself. Persons commonly form some opinion of a speaker from their first view of him, which prejudices them either in his favour, or otherwise, as to what he says afterwards. A grave and sedate aspect inclines them to think him serious; that he has considered his subject, and may have something to offer worth their attention. A haughty and forbidding air occasions distaste, as it looks like disrespect. A wandering giddy countenance argues levity. A dejected drooping appearance is apt to raise contempt, unless where the subject is melancholy. And a cheerful aspect is a proper prelude to a pleasant and agreeable argument.

To speak low at first has the appearance of modesty, and is best for the voice; which, by rising gradually, will with more ease be carried to any pitch that may be afterwards necessary, without straining it. However, some variation of the voice is always proper to give it an harmony. Nay, and sometimes it is not improper for an orator to set out with a considerable degree of warmth, expressed by such an elevation of the voice, and gestures of the body, as are suited to represent the emotions of his mind. But this is not ordinarily the case. We have some few instances of this in Cicero; as in his oration for Roscius Amerinus, where the heaviness of the charge could not but excite his indignation against the accusers. And so likewise in that against Piso, and the two first against Catiline, which begin in the same manner, from the resentment he had conceived against their persons and conduct.

In the narration, the voice ought to be raised to somewhat an higher pitch. Matters of fact should be related in a very plain and distinct manner, with a proper stress and emphasis laid upon each circumstance, accompanied with a suitable address and motions of the body, to engage the attention of the hearers. For there is a certain grace in telling a story, by which those who are masters of it seldom fail to recommend themselves in conversation. The beauty of it consists in an easy and familiar manner of expression, attended with such actions and gestures as are suited to the nature of the things related, and help to enliven each particular circumstance and part of the discourse.

The proposition, or subject of the discourse, should be delivered with a very clear and audible voice. For if this be not plainly heard, all that follows in proof of it cannot well be understood. And for the same reason, if it be divided into several parts or branches, they should each be expressed very deliberately and distinctly. But as the design here is only information, there can be little room for gesture.

The confirmation admits of great variety both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in painting out the images of things, the orator should so endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands as may best help the imagination of his hearers. Where he introduces another person speaking, or addresses to an absent person, it should be with some degree of imitation. And in dialogues the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In conflation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, that the speaker may not seem to conceal, or avoid the force of them, unless they appear trifling and
and unworthy of a serious answer; and then a face-
tious manner, both of expression and gesture, may be
the properest way to confute them. For to attempt
to answer in a grave and serious manner, what is in it-
self empty and ludicrous, is apt to create a suspicion
of its having more in it than it really has. So when
Tubero, in his accusation of Ligarius before Caesar,
had made it part of his charge, that Ligarius was in
Africa during some part of the civil war between Ce-
sar and Pompey; Cicero, in his answer, not thinking
it deserved a serious reply, contents himself with bare-
ly mentioning it ironically. For he begins his
defence of Ligarius: "Cesar, my kinman Tubero
has laid before ye, a new crime, and till this day un-
heard of, that Q. Ligarius was in Africa." Every
one must easily perceive, by the manner in which these
words were pronounced, that the design of them was
to make the charge appear ridiculous. But caution
should be used not to represent any argument of weight
in a ludicrous way, lest by so doing the speaker should
more expose himself than his adversary.

In the conclusion, both the voice and gesture should
be brisk and sprightly, which may seem to arise from
a sense of the speaker's opinion of the goodness of his
cause, and that he has offered nothing but what is agree-
able to reason and truth; as likewise from his assurance
that the audience agree with him in the same sentiments.
In every undertaking that requires care and thought, per-
sons are apt at first to be sedate and moderate; but when
it is drawing to an end, and is near finished, it is very
natural to appear more gay. If an enumeration of the
principal arguments of the discourse be convenient, as it
sometimes is, where they are pretty numerous, or the
discourse is long, they ought to be expressed in the most
clear and forcible manner. And if there be an address
to the passions, both the voice and gesture must be
suited to the nature of them, of which more will be said
presently.

We proceed now to the consideration of particular
expressions. And what we shall offer here, will be first
in relation to single words, then sentences, and lastly
the passions.

I. Even in those sentences which are expressed in
the most even and sedate manner, there is often one
or more words which require an emphasis and distinct-
tion of the voice. Pronouns are often of this kind;
as, This is the man; and such are many words that
denote the circumstances and qualities of things. Such
as heighten or magnify the idea of the thing to which
they are joined, elevate the voice; as noble, admirable,
majestic, greatly, and the like. On the contrary, those
which lessen the idea, or debase it, depress the voice,
or at least protract the tone; of which sort are the
words little, meanly, poorly, contemptible, with many others.
Some tropes likewise, as metaphors and verbal figures
which consist in the repetition of a single word, should
have a particular emphasis. As when Virgil says of
the river Araxes, It disdain'd a bridge. And Nisus
himself in the same poet, I, I am the man; where the
repeated word is loudest. This distinction of words,
and giving them their proper emphasis, does not only
render the expression more clear and intelligible, but
very much contributes to the variation of the voice, and
the preventing a monotony. And the different pronun-
ciation of these words will also require a peculiar ges-
ture.

II. In sentences, regard should be had to their
length, and the number of their parts, in order to di-
stinguish them by proper pauses. The frame and struc-
ture of the period ought likewise to be considered, that
the voice may be so managed as to give it the most
musical accent. Unless there be some special reason for
the contrary, it should end louder than it begins. And
this difference of tone between the end of the former
sentence and the beginning of the next, not only helps to
distinguish the sense, but adds to the harmony of the
voice. And that the last syllables of a sentence might
become more audible and distinct, was doubtless one
reason why the ancient rhetoricians dislike short feet at
the end of a period. In an antithesis, or a sentence
consisting of opposite parts, one contrary must be louder
than the other. As, "He is gone, but by a gainful
remove, from painful labour to quiet rest; from un-
quiet desires to happy contentment; from sorrow to
joy; and from transitory time to immortality." In a cli-
max or gradation, the voice should rise with it. So,
"There is no enjoyment of property without govern-
ment; no government without a magistrate; no magis-
trate without obedience; no obedience where every one
acts as he pleases." And so in other gradations of a
different form. As, "Since concord ever was lost, friend-
ship was lost, fidelity was lost, liberty was lost, all was lost."
And again, "You would pardon him whom the senate
hath condemned, whom the people of Rome have con-
demned, whom all mankind have condemned." We
might mention several other figurative expressions,
which require a particular conformation and manage-
ment of the voice; but these, we presume, with some
others we shall have occasion to name presently when
we come to the passions, may be sufficient to guide us
in the rest. But that it may appear more evidently
how necessary a different inflection and variation of the
voice is in most sentences, give us leave to show how
Quintilian illustrates it, by a passage which he takes
from Cicero. The place is the beginning of Cicero's
defence for Mile, and the words are these: "Although
I am apprehensive it may seem base to discover fear
when I enter upon the defence of a most courageous man,
and it may appear very indecent, when Mile discovers
more concern for the public safety than for his own,
not to show a greatness of mind equal to his cause, yet
this new form of the court terrifies my eyes, which
cannot discern the ancient manner of the forum, and for-
mer custom of trials, whatever way they look: your
bench is not surrounded with its usual attendants." This
sentence consists of four members. And Quin-
tilian supposes, that though these words are the be-
ginning of a speech, and were accordingly expressed
in an am and submissive manner, yea, that the oder
used a great deal of variety in the pronunciation of
their several parts. In the first member (as he ima-
gines) his voice was more elevated in expressing the
word, a most courageous man, than in those other parts
of it, I am apprehensive it may seem base, and, to disco-
very fear. In the second member he rose higher, in saying,
when Mile discovers more concern for the public safety
than for his own; and then again, as it were, checked
himself in what follows, not to show a greatness of mind:
equal:
equal to his cause. The beginning of the third member carrying a reflection in it, was spoke with a different tone of the voice, this new form of the court terrifies my eyes; and the other part of it more loud and distinctly, which cannot discern the ancient manner of the forum, and former custom of trials. And the last member was still more raised and audible, your bench is not surrounded with its usual attendants. And it must be supposed, that while he was saying this, he cast his eyes round the assembly, and viewed the soldiers whom Pompey had placed there, which renders the expression still more grave and solemn. If this was the manner of the ancient orators, and they were so exact and accurate in expressing their periods, and the several parts of them, as we have reason to believe they were, it must have given a very great force, as well as beauty to their pronunciation.

III. That the passions have each of them both a different voice and action, is evident from hence; that we know in what manner a person is affected, by the tone of his voice, though we do not understand the sense of what he says, or many times so much as see him: and we can often make the same judgment from his countenance and gestures. Love and esteem are expressed in a smooth and cheerful tone: but anger and resentment, with a rough, harsh, and interrupted voice; for when the spirits are disturbed and ruffled, the organs are moved unequally. Joy raises and dilates the voice, as sorrow sinks and contracts it. Cicero takes notice of a passage in an oration of Gracchus, wherein he bewails the death of his brother, who was killed by Scaevio, which in his time was thought very moving: "Unhappy man (says he,) whether shall I betake myself? where shall I go? Into the capitol? that flows with my brother's blood. Shall I go home; and behold my unhappy mother all in tears and despair?" Though Gracchus had a very ill design in that speech, and his view was to excite the populace against their governors, yet (as Cicero tells us) when he came to this passage, he expressed himself in such moving accents and gestures, that he extorted tears even from his enemies. Fear occasions a tremor and hesitation of the voice, and assurance gives it strength and firmness. Admiration elevates the voice, and should be expressed with pomp and magnificence: O surprising clemency, worthy of the highest praise and greatest encomiums, and fit to be perpetuated in lasting monuments! This is Cicero's compliment to Caesar when he thought it for his purpose. And oftentimes this passion is accompanied with an elevation both of the eyes and hands. On the contrary, contempt sinks and protracts the voice. In the dispute between Cicero and Cælius, which of them should accuse Verres, Cicero puts this contemptuous question to him: "How are you qualified, Cælius, for such an undertaking? I will not ask, when you ever gave a proof of it, but when you so much as attempted? Do you consider the difficulty of managing a public cause? with much more to the same purpose. Though such kind of expressions require little gesture, yet sometimes a motion of the hand may not be improper, to signify censure or aversion. We may suppose Cicero to have acted thus in his defence of Babirius. For to show his assurance of his client's cause, having used this expression in a very audible manner, "I wish I had it to say, that Babirius had with his own hand killed Saturninus, who was an enemy to the Roman state," some persons in the crowd began to raise a clamour, just as of later times hissing has been practised on the like occasions. Upon which Cicero immediately replies, "This noise does not disturb me, but please me, since it shows, though there are some weak persons, yet they are but few." Then presently after follows the expression we refer to: "Why do not you cease your clamour, since it only discovers your folly, and the smallness of your number?" All exclamations should be violent. When we address to inanimate things, the voice should be higher than when to animated beings; and appeals to heaven must be made in a louder tone than those to men.

These few hints for expressing the principal passions must, if duly attended to, suffice to direct our practice in others. Though, after all, it is impossible to gain a just and decent pronunciation of voice and gesture merely from rules, without practice and an imitation of the best examples. Which shows the wisdom of the ancients, in training up their youth to it, by the assistance of masters, to form both their speech and actions.

But there is one thing which ought always to be attended to; namely, that persons should well consider their own make and genius, especially with respect to the passions. We seldom find, that any actor can excel in all characters; but if he performs one well, he is deficient in another: And therefore they are commonly so prudent as to confine themselves to such as best suit them. The case is the same in an orator; who should therefore keep within those bounds which nature seems to have prescribed for him. Some are better fitted for action than others, and most for some particular actions rather than others; and what fits well upon one would appear very awkward in another. Every one, therefore, should first endeavour to know himself, and manage accordingly. Though in most cases nature may be much assisted and improved by art and exercise. See Professor Ward's System of Oratory.

**ORB**

Oratory, among the Romanists, a closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotions.

ORB, in Astronomy, denotes a hollow globe or sphere.

ORB, in tactics, is the disposing of a number of soldiers in circular form of defence. The orb has been thought of consequence enough to employ the attention of the famous Marshal de Ruysegur in his Art of War, who prefers this position to throw a body of infantry in an open country, to resist cavalry, or even a superior force of infantry; because it is regular, and equally strong,
strong, and gives an enemy no reason to expect better success by attacking one place than another. Caesar drew his whole army in this form, when he fought against Labienus. The whole army of the Gauls was formed into an orb, under the command of Sabinus and Cotta, when fighting against the Romans. The orb was generally formed six deep.

ORBIT, in Astronomy, the path of a planet or comet, or the curve that it describes in its revolution around its central body; thus, the earth's orbit is the curve which it describes in its annual course around the sun, and usually called the ecliptic. See Astronomy, passim.

ORCades, the Orkney Islands. See Orkney.

ORCHARD, a garden department, consigned entirely to the growth of standard fruit-trees, for furnishing a large supply of the most useful kinds of fruit. For the particular management of the orchard, see Gardening.

In the orchard you may have, as standards, all sorts of apple-trees, most sorts of pears and plums, and all sorts of cherries: which four species are the capital orchard fruits; each of them comprising numerous valuable varieties. But to have a complete orchard, you may also have quinces, medlars, mulberries, service-trees, filberts, Spanish nuts, berberries; likewise walnuts and chestnuts; which two latter are particularly applicable for the boundaries of orchards, to screen the other trees from the insulit and impetuous winds and cold blasts. All the trees ought to be arranged in rows from 20 to 30 feet distance, as hereafter directed.

But sometimes orchards consist entirely of apple-trees, particularly in the eyder-making counties, where they are cultivated in very great quantities in large fields, and in hedge rows, for the fruit to make eyder for public supply.

And sometimes whole orchards of very considerable extent are entirely of cherry-trees. But in this case, it is when the fruit is designed for sale in some great city, as London, &c. for the supply of which city, great numbers of large cherry orchards are in some of the adjacent counties, but more particularly in Kent, which is famous for very extensive cherry-orchards; many of which are entirely of that sort called Kentish cherry, as being generally a great bearer; others are stored with all the principal sorts of cultivated cherries, from the earliest to the latest kinds.

A general orchard, however, composed of all the before-mentioned fruit-trees, should consist of a double portion of apple-trees or more, because they are considerably the most useful fruit, and may be continued for use the year round.

The utility of a general orchard, both for private use and profit, stored with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: In spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the different species arriving to perfection, in regular succession, from May or June, until the end of October, must afford exceeding delight, as well as great profit.

Of the Extent, Situation, and Soil for the Orchard.—

VOL. XV. Part II.

As to the proper extent of ground for an orchard, this must be proportioned, in some measure, to the extent of land you have to work on, and the quantity of fruit required either for private use or for public supply; so that an orchard may be from half an acre to 20 or more in extent.

With respect to the situation and aspect for an orchard, we may observe very thriving orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good: we should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit trees will prosper, nor the fruit be fine: but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an orchard, unless particularly compensated by the peculiar temperament or good quality of the soil.

And as for soil, any common field or pasture that produces good crops of corn, grass, or kitchen-garden vegetables, is suitable for an orchard; if it should prove of a loamy nature, it will be a particular advantage: any soil, however, of a good quality, not too light and dry, or too heavy, stubborn, or wet, but of a medium nature, of a soft, pliant temperature, not less than one spade deep of good staple, will be proper for this purpose.

Preparation of the ground.—The preparation of the ground for the reception of trees, is by trenching; or, if for very considerable orchards, by deep ploughing; but trench-digging, or one or two spades, as the soil will admit, is the most eligible, either wholly, or only for the present in the places where the lines of trees are to stand, a space of six or eight feet wide, all the way in each row, especially if it be grass-ground, and intended to be kept in the sward; or if any under-crops are designed to be raised, the ground may be wholly trench-ed at first: in either case trench the ground in the usual way to the depth of the natural soil; and if in grass, turn the sward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting orchards, however, on grass-grounds, some only dig pits for each tree, capacious enough for the reception of the roots, loosening the bottom well, without the labour of digging any other part of the ground.

The ground must be fenced securely against cattle, &c. either with a good ditch and hedge, or with a paling-fence, as may be most convenient.

Method of planting the Trees.—The best season for planting all the sorts of fruit-trees is autumn, soon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

Choose principally full standards, with straight clean stems, six feet high; each with a branchy well-formed head, of from two or three to four or five years growth; and let several varieties of each particular species be chosen, that ripen their fruit at different times, from the earliest to the latest, according to the nature of the dif-

ferent species.
Orchard. Different sorts, that there may be a proper supply of every sort regularly during their proper season. Of apples and pears in particular, choose a much greater quantity of the autumnal and late ripening kinds than of the early sorts, but most of all for apples; for the summer-ripening fruit is but of short duration, only proper for temporary service; but the late ripening kinds keep sound for considerable time for autumnal use; and the latest sorts that ripen in October, continue in perfection for various uses all winter, and several sorts until the season of apples come again.

Having made choice of the proper sorts, and marked them, let them be taken up with the utmost care, so as to preserve all their roots as entire as possible; and when so taken up, prune off any broken or bruised parts of the roots, and just tip the ends of the principal roots, in general, with the knife on the under side with a kind of slope outward.

If the trees have been already headed, or so trained as to have branched out into regular shoots to form each a proper head, they must be planted with the said heads entire, only retrenching or shortening any irregular or ill-placed shoot that takes an awkward direction, or grows across its neighbours, or such as may run considerably longer than all the rest, &c.

The arrangement of the trees in the orchard must be in rows, each kind separate, at distances according to the nature of the growth of the different sorts; but for the larger growing kinds, such as apples, pears, plums, cherries, &c. they should stand from 25 to 30 or 40 feet every way at least, though 25 or 30 feet at most is a reasonable distance for all these kinds.

Each species and its varieties should generally be in rows by themselves, the better to suit their respective modes of growth: though for variety there may be some rows of apples and pears arranged alternately, as also of plumbs and cherries; and towards the boundaries there may be ranges of lesser growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut-trees, and some chestnuts, set pretty close to defend the other trees from violent winds.

According to the above distances, proceed to stake out the ground for making the holes for the reception of the trees, which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the sun’s influence, more effectually.

But in planting very extensive orchards, some divide the ground into large squares or quarters, of different dimensions, with intervals of 50 feet wide between; serving both as walks, and for admitting a greater currency of air; in different quarters planting different sorts of fruit, as apples in one, pears in another, plumbs and cherries in others, &c. and thus it may be repeated to as many quarters for each species and its varieties as may be convenient.

As to the mode of planting the trees: A wide hole must be dug for each tree, capacious enough to receive all the roots freely every way without touching the sides. When the holes are all ready, proceed to planting, one tree in each hole, a person holding the stem erect, whilst another trims in the earth, previously breaking it small, and casting it in equally all about the roots, frequently shaking the tree to cause the mould to settle in close about all the smaller roots and fibres, and so as to raise the tree gradually up, that the crown of the roots may be but two or three inches below the general surface; and when the hole is filled up, tread it gently, first round the outside, then near the stem of the tree, forming the surface a little hollow; and then, if on the top of all be laid some inverted turf to the width of the hole, forming it with a sort of circular band, these or four inches wide; it will support the tree, and guard the roots from drying winds and the summer’s drought: observing that each tree stand perfectly upright, and that they range exactly in their proper rows.

Method of improving the Fruit.—The following method is said to have been successfully employed, by a German clergyman, in promoting the growth of young trees, and increasing the size and flavour of the fruit in orchards. Having planted several young plum trees in an orchard, he covered the ground, for some years, around the trunks, as far as the roots extended, with flax-shows, or the refuse of flax when it is scathed or heckled; by which means these trees, though in a grass-field, increased in a wonderful manner, and far excelled others planted in cultivated ground. As far as the shows reached, the grass and weeds were choked; and the soil under them was so tender and soft, that no better would have been wished for by a florist.

When he observed that the ground with the same substance, as far as the roots extended, around an old plum-tree, which appeared to be in a languishing state, and which stood in a grass-field. The consequences were, that it acquired a strong new bark, produced larger and better tasted fruit, and that those young shoots, which before grew up around the stem, and which it was every year necessary to destroy, were prevented from sprouting forth, as the covering of flax-shows impeded the free access of air at the bottom of the trunk.

In the year 1793, he transplanted, from seed-beds, into the nursery, several fruit-trees; the ground around some of which he covered, as above, with flax-shows. Notwithstanding the great heat of the summer, none of those trees where the earth was covered with shows died or decayed, because the shows prevented the earth under them from being dried by the sun. Of those trees, around which the ground was not covered as before mentioned, the fourth part miscarried; and those that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may also be employed for covering the ground in like manner; but stones, or logs of wood must be laid on them, to prevent their being dispersed by the wind. In grass land, a small trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax-shows are used, this is not necessary; they lie on the surface of the ground so fast as to resist the force of the most violent storm. The leaves which our author found most effectual in promoting the growth and fertility of fruit trees, are those of the walnut-tree. Whether it is, that, on account of their containing a greater abundance of saline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmosphere; or that, by both these means, they tend to nourish the tree both above and below.

Those who are desirous of raising tender exotic trees from the seed, in order to accustom them to our climate, may.
ords easy, when they transplant them, employ flax shows with great advantage. This covering will prevent the frost from making its way to the roots; and rats and mice, on account of the sharp prickly points of the flax shows, will not be able to shelter themselves under them.

Orchestra, in the Grecian theatres, was that part of the proscenium or stage where the chorus used to dance. In the middle of it was placed the Aegaeon or pulpit. The orchestra was semicircular, and surrounded with seats. In the Roman theatres it made no part of the scene, but answered pretty nearly to the pit in our playhouses, being taken up with seats for senators, magistrates, vestals, and other persons of distinction. The actors never went down into it. See Theatre.

Orchis, instituted by Orchius the tribune in the year of Rome 566. Its intention was to limit the number of guests that were to be admitted in an entertainment; and it is also enforced, that during supper, which was the chief meal among the Romans, the doors of every house should be left open.

Orchis, Foolstones; a genus of plants belonging to the gynandra class, and in the natural method giving name to the seventh order Orchidaceae. See Botany Index.

Orcus, god of the infernal regions, the same with Pluto, so called from the Greek word Ορθρας, signifying a "tomb or sepulchre," or from ορχης, "an oath by the river Styx." The ancients gave this name to all the divinities of the infernal regions, even to Cerberus. There was a river of the same name in Thebes, which took its rise from the marshes of the Styx, and the waters of which were so thick, that they floated like oil upon the surface of the river Peneus, into which they discharged themselves. This river probably suggested to the poets the idea of the infernal abodes, which they denominated Orcus. This deity has been confounded with Charon. He had temple at Rome.

Ordeal, an ancient form of trial. See Trial.

It was an appeal to the immediate interposition of divine power, and was particularly distinguished by the appellation of justice of Dei; and sometimes vulgaris purgatio, to distinguish it from the canonical purgation, which was by the oath of the party. There were two sorts of it more common than the rest, at least in Europe; fire-ordeal, and water-ordeal. The former was confined to persons of higher rank, the latter to the common people. Both these might be performed by

Ordeal; but the principal was to answer for the success of the trial; the deputy only venturing some corporal pain, for hire or perhaps for friendship.

That the purgation by ordeal, of some kind or other, is very ancient, admits not of a doubt; and that it was very universal in the times of superstition and barbarity, is equally certain. It seems even to have been known to the ancient Greeks; for in the Antigone of Sophocles, a person suspected by Creon of a misdeemour, declares himself ready to handle hot iron and to walk over fire to manifest his innocence; which the scholar tells us was then a very usual purgation. And Croesus gives us many instances of water-ordeal in Bithynia, Sardinia, and other places. It seems, however, to be carried to a greater height among the Hindoos, than ever it has been in any nation or among any people, however rude or barbarous; for in a paper of the Asiatic Researches communicated by Warren Hastings, Esq. we find that the trial by ordeal among them is conducted in nine different ways: first by the balance; secondly, by fire; thirdly, by water; fourthly, by poison; fifthly, by the Cosa, or water in which an idol has been washed; sixthly, by rice; seventhly, by boiling oil; eighthly, by red-hot iron; ninethly, by images.

I. Ordeal by the balance is thus performed. The beam having been previously adjusted, the cord fixed, and both scales made perfectly even, the person accused and a Pandit fast a whole day; then, after the accused has been bathed in saared water, the homo, or oblation, presented to fire, and the deities worshipped, he is carefully weighed; and when he is taken out of the scale, the Pandits prostrate themselves before it, pronounce a certain mensa or incantation, agreeably to the Sutras, and, having written the substance of the accusation on a piece of paper, bind it on his head. Six minutes after, they place him again in the scale; and, if he weighs more than before, he is held guilty; if less, innocent; if exactly the same, he must be weighed a third time; when, as it is written in the Mitaschera, there will certainly be a difference in his weight. Should the balance, though well fixed break down, this would be considered as a proof of his guilt.

II. For the fire-ordeal, an excavation, nine hands long, two spans broad, and one span deep, is made in the ground, and filled with a fire of pipal wood: into this the person accused must walk barefooted; and, if his foot be unhurt, they hold him blameless; if burned, guilty (A).

(A) In Europe fire-ordeal was performed either by taking up in the hand, unhurt, a piece of red-hot iron, of one, two, or three pounds weight; or else by walking, barefoot and blindfold, over nine red-hot plough-shares, laid lengthwise at unequal distances; and if the party escaped being hurt, he was adjudged innocent; but if it happened otherwise, as without collusion it usually did, he was then condemned as guilty. However, by this latter method Queen Emma, the mother of Edward the Confessor, is mentioned to have cleared her character, when suspected of familiarity with Alwyn bishop of Winchester. The first account we have of Christians appealing to the fire-ordeal, as a proof of their innocence, is that of Simplicius, bishop of Autun, who lived in the fourth century. This prelate, as the story is related, before his promotion to the episcopal order, had married a wife, who loved him tenderly, and who, unwilling to quit him after his advancement continued to sleep in the same chamber with him. The sanctity of Simplicius suffered, at least in the voice of fame, by the constancy of his wife's affection; and it was rumoured about, that the holy man, though a bishop, persisted, in opposition to the ecclesiastical canons, to taste the sweets of matrimony: upon which his wife, in the presence of a great concourse of people, took up a considerable quantity of burning coals, which she held in her clothes, and applied to her breasts, without the least hurt to her person or her garments, as the legend says; and her example being followed by her husband with the
III. Water-ordeal is performed by causing the person accused to stand in a sufficient depth of water, either flowing or stagnant, to reach his navel; but care should be taken that no ravenous animal be in it, and that it be not moved by much air; a brahman is then directed to go into the water, holding a staff in his hand; and a soldier shoots three arrows on dry ground from a bow of cane; a man is next despatched to bring the arrow which has been shot farthest; and, after he has taken it up, another is ordered to run from the edge of the water; at which instant the person accused is told to grasp the foot or the staff of the brahman, who stands near him in the water, and immediately to dive into it. He must remain under water, till the two men who went to fetch the arrows are returned; for, if he raise his head or body above the surface before the arrows are brought back, his guilt is considered as fully proved. In the villages near Benares, it is the practice for the person who is to be tried by this kind of ordeal, to stand in water up to his navel, and then, holding the foot of a brahman, to dive under it as long as a man can walk 50 paces very gently; if, before the man has walked thus far, the accused rises above the water, he is condemned; if not, acquitted.

IV. There are two sorts of trial by poison; first, the pandits having performed their aum, and the person accused his ablution, two retis and a half, or seven barley-corns of visshanaga, a poisonous root, or of sanc'hya, that is, white azemic, are mixed in eight mashas; or 64 retis, of clarified butter, which the accused must eat from the hand of a brahman: if the poison produce no visible effect, he is absolved; otherwise condemned. Secondly, the hooded snake, called naga, is thrown into a deep earthen pot, into which is dropped a ring, a seal, or a coin; this the person accused is ordered to take out with his hand; and, if the serpent bite him, he is pronounced guilty; if not, innocent.

V. Trial by the cosha is as follows: the accused is made to drink three draughts of the water, in which the images of the sun, of Devi, and other deities, have been washed for that purpose; and if, within 14 days, he has any sickness or indisposition, his crime is considered as proved.

VI. When several persons are suspected of theft, some dry-rice is weighed with the sacred stone called solgram, or certain alokas are read over it; after which the suspected persons are severally ordered to chew a quantity of it: as soon as they have chewed it, they are to throw it on some leaves of pippal, or, if none be at hand, on some b'furja patra, or bark of a tree, from Nepal or Cashmir. The man, from whose mouth the rice comes dry or stained with blood, is held guilty; the rest is acquitted.

VII. The ordeal by hot oil is very simple: when it is heated sufficiently, the accused thrusts his hand into it; and, if he be not burned, is held innocent.

VIII. like success, the silly multitude admired the miracle, and proclaimed the innocence of the loving pair. A similar trick was played by St. Brice, in the fifth century. Musc. Eccl. Hist. vol. ii.

(b) A very peculiar species of water-ordeal is said to prevail among the Indians on the coast of Malabar. A person accused of an enormous crime is obliged to swim over a large river abounding with crocodiles; and if he escapes unhurt, he is esteemed innocent.

At Siam, besides the usual methods of fire and water-ordeal, both parties are sometimes exposed to the fury of a tiger let loose for that purpose; and if the beast sparest either, that person is accounted innocent; if neither, both are held to be guilty; but if he spares both, the trial is incomplete, and they proceed to a more certain criterion.

In Europe water-ordeal was performed, either by plunging the bare arm up to the elbow in boiling-water, and escaping unhurt thereby, or by casting the person suspected into a river or pond of cold water; and if he floated therein without any action of swimming, it was deemed an evidence of his guilt; but if he sunk, he was acquitted. It is easy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity still practised in many countries to discover witches, by casting them into a pool of water, and drowning them to prove their innocence. And in the eastern empire the fira-ordeal was used for the same purpose by the emperor Theodore Lascaris; who, attributing his sickness to magic, caused all those whom he suspected to handle the hot iron: thus joining (as has been well remarked) to the most dubious crime in the world, the most dubious proof of innocence.

(c) This species of trial by ordeal is thus performed: The ground appointed for the trial is cleared and rubbed with cow-dung, and the next day at sunrise the Pandit worships Ganesa or the Hindoo Janus, presents his oblations, and pays adoration to other deities, conformably to the Sàstra: then having read the incantation prescribed, he places a round pan of gold, silver, copper, iron, or clay, with a diameter of sixteen fingers, and four fingers deep, and throws into it one sèr, or eighty sissa weight, of clarified butter or oil of sesamum. After this a ring of gold, or silver, or iron, is cleaned and washed, and cast into the oil; which they proceed to heat, and when it is very hot put into it a fresh leaf of pippala, or of bita: when the leaf is burned, the oil is known to be sufficiently hot. Then, having pronounced a mentra over the oil, they order the party accused to take the ring out of the pan; and if he take it out without being burned, or without a blister in his hand, his innocence is considered as proved; if not, his guilt. It is reported that this custom, with some slight variations, still prevails among the Indians on the coast of Malabar. The process there is said to begin after the accused person has been thoroughly washed in the presence of the prince of the country, the priests, &c. — the pot is filled with boiling lead; and the accused must take the ring out three times successively. On the Malabar coast, this ordeal seems only to be used when the person is accused of a capital crime; for after the process the arm is bound with cloth and sealed; and after several days, being brought out publicly, and the arm inspected, if it is found burnt he is instantly put to death; if not, his accuser undergoes the same trial, and being burnt, forfeits his life.
VIII. In the same manner they make an iron ball, or the head of a lance, red hot, and place it in the hands of the person accused; who, if it burn him not, is judged guiltless.

IX. To perform the ordeal by dharmach, which is the name of the stica appropriated to this mode of trial, either an image, named Dharma, or the genius of justice, is made of silver, and another, called Adharma, of clay or iron, both of which are thrown into a large earthen jar; and the accused having thrust his hand into it, is acquitted if he bring out the silver image, but condemned if he draw forth the iron; or, the figure of a deity is painted on white cloth, and another on black; the first of which they name dharma, and the second adharma: these are severally rolled up in cow-dung, and thrown into a large jar without having ever been shown to the accused; who must put his hand into the jar, and is acquitted or convicted as he draws out the figure on white or on black cloth.

Though we have proceeded thus far, we have not exhausted Mr. Hastings’s communication. He goes on to show (to greater extent than our limits permit us to follow) the manner in which each ordeal above mentioned was executed, giving examples, and unfolding other particulars of some importance in developing the nature of these barbarous customs. For these particulars, however, we must refer to the book itself. But as this subject unquestionably occupies an important department in the history of human superstition, we shall give the Indian law of ordeal from the same paper; when we shall introduce some further particulars concerning this extraordinary custom, which are not to be found in the above account, but which deserve to be noticed.

1. The balance, fire, water, poison, the idol—these are the ordeals used here below for the proof of innocence, when the accusations are heavy, and when the accuser offers to hazard a mulet, (if he should fail):

2. Or one party may be tried, if he please, by ordeal, and the other must then risk an amercement; but the trial may take place even without any wager, if the crime committed be injurious to the prince.

3. The sovereign having summoned the accused while his clothes are yet moist from bathing, at sunrise, before he has broken his fast, shall cause all trials by ordeal to be conducted in the presence of Brahmanas.

4. The balance is for women, children, old men, the blind, the lame, Brahmanas, and the sick; for the Sādhu, fire or water, or seven barley-coras of poison.

5. Unless the loss of the accuser amount to a thousand pieces of silver, the accused must not be tried by the red-hot ball, nor by poison, nor by the scales; but if the offence be against the king, or if the crime be heinous, he must acquit himself by one of those trials in all cases.

6. He who has recourse to the balance must be attended by persons experienced in weighing, and go down into one scale, with an equal weight placed on the other, and a groove (with water in it) marked on the beam.

7. Thou, O balance, art the mansion of truth; thou wast anciently contrived by deities: declare the truth, therefore, O giver of success, and clear me from all suspicion.

8. If I am guilty, O venerable as my own mother, then sink me down, but if innocent raise me aloft. Thus shall he address the balance.

9. If he sink he is convicted, or if the scales be broken: but if the string be not broken, and he rise aloft, he must be acquitted.

10. On the trial by fire, let both hands of the accused be rubbed with rice in the husk, and well examined: then let seven leaves of the Aravatta (the religious fig-tree) be placed on them, and bound with seven threads.

11. Thou, O fire, pervadest all beings: O cause of purity, who givest evidence of virtue and of sin, declare the truth in this my band.

12. When he has pronounced this, the priest shall place in both his hands an iron ball, red-hot, and weighing fifty palas (b).

13. Having taken it, he shall step gradually into seven circles, each with a diameter of sixteen fingers, and separated from the next by the same space.

14. If, having cast away the hot ball, he shall again have his hands rubbed with rice in the husk, and shall show them unburned, he will prove his innocence. Should the iron fall during the trial, or should a doubt arise (on the regularity of the proceedings), he must be tried again.

15. Preserve me, O Varuna, by declaring the truth. Thus having invoked the god of waters, the accused shall plunge his head into the river or pool, and hold both thighs of a man, who shall stand in it up to his navel:

16. A swift runner shall then hasten to fetch an arrow shot at the moment of his plunging; and if, while the runner is gone, the priest shall see the head of the accused under water, he must be discharged as innocent.

17. Thou, O poison, art the child of Brahman, steadfast in justice and in truth: clear me then from this heavy charge, and if I have spoken truly, become nectar to me.

18. Saying this, he shall swallow the poison Sāranga, from the tree which grows on the mountain Himalaya; and if he digests it without any inflammation, the prince shall pronounce him guiltless.

19. Or the priest shall perform rites to the image of some tremendous deity; and, having bathed the idol, shall make the accused to drink three handfuls of the water that has dropped from it.

20. If in fourteen days after he suffers no dreadful calamity from the act of the deity or of the king, he must indubitably be acquitted.

The superstitious weakness of mankind, when left to themselves, is astonishing. There is indeed nothing so absurd but they may be made most firmly to believe, nor so impious but they will do. Nor can a more notorious instance of the truth of this assertion

(b) A pal is four carshas, and a carsha eighty raticas or seeds of the gungd creeper, each weighing above a grain and a quarter, or correctly, 1 1/8 gr.
ord

be possibly given than that of the trial by ordeal. The gross absurdity as well as impiety of pronouncing a man guilty unless he was cleared by a miracle, and of expecting that all the powers of nature should be suspended by an immediate interposition of Providence to save the innocent, when it was even presumptuously required, is self-evident. Yet the origin of it may be traced as well to necessity as to superstition. At the time in which it originated in Europe, it was no easy matter for an innocent person, when accused of guilt, to get himself cleared by the then established mode of trial. (See Trial.)

It was therefore natural for superstition to fly to Heaven for those testimonies of innocence which the absurdity of human laws often prevented men from obtaining in the ordinary way; and, in this way doubtless did the trial by ordeal commence: and thus began by necessitous superstition, it was fostered by impious priesthood and unjust power. There was during all the processes great room for collusion and deceit; and there can be no question but it was often practised: it could not therefore on any account, or in any case, be a sign of innocence or of guilt.

We may call these particular methods of trial which we have already mentioned, 'there were some few more common in European countries; as the judicial combat — the ordeal of the cross — the ordeal of the corned.

The judicial combat was well suited to the genius and spirit of fierce anti-warlike nations, and was, as we may reasonably expect, one of the most ancient and universal modes of trial. We know that it was exceedingly common in Germany in very remote ages. It was also used in some countries on the continent at pretty early periods: it is not, however, mentioned in any of the Anglo-Saxon laws; and it does not appear to have been much used in England till after the Conquest. There are, however, two remarkable instances of it upon record, which we shall give in the words of Dr Henry: "Henry de Essex, hereditary standard-bearer of England; sold from a battle in Wales, A. D. 1158, threw from him the royal standard, and cried out, with others, that the king was slain. Some time after, he was accused with having done this with a treasonable intention, by Robert de Montfort, another great baron, who offered to prove the truth of his accusation by combat. Henry de Essex denied the charge, and accepted the challenge. When all preliminaries were adjusted, this combat was accordingly fought, in the presence of Henry II. and all his court. Essex was defeated, and expected to be carried out to immediate execution. But the king, who was no friend to this kind of trial, spared his life, and contented himself with confiscating his estate, and making him a monk in the abbey of Reading.

"The priory of Tintonmouth, in Northumberland, was a cell of the abbey of St Alban's. One Simon of Tintonmouth claimed a right to two corodies, or the maintenance of two persons in the priory, which the prior and monks denied. This cause was brought before the abbot of St Alban's and his court-baron, who appointed it to be tried by combat on a certain day, before him and his barons. Ralf Gubion, prior of Tintonmouth, appeared at the time and place appointed, attended by his champion, one William Pegun, a man of gigantic stature. The combat was fought, Pegun was defeated, and the prior lost his cause; at which he was so much chagrined, that he immediately resigned his office. This judicial combat is the more remarkable, that it was fought in the court of a spiritual baron, and that one of the parties was a priest."

We need scarcely add, that this detestable form of trial was the foundation of the no less detestable crime of duelling, which so much disgraces our age and nation; which is defended only by ignorance, false honour, and injustice; which is a relic of barbarous superstition; and which was absolutely unknown to those brave and generous nations, the Greeks and Romans, which it is so much the fashion to admire, and who in this particular so well merit our imitation. See Duel.

It was so much the custom in the middle ages of Christianity, to respect the cross even to superstition, that it would have been indeed wonderful if the same ignorant bigotry had not converted it into an ordeal; accordingly we find it used for this purpose, in so many different ways as almost to preclude description. We shall, however, transcribe, for the satisfaction of our readers, Dr Henry's account of it, and of the corned: "In criminal trials, the judgment of the cross was commonly thus conducted. When the prisoner had declared his innocence upon oath, and appealed to the judgment of the cross, two sticks were prepared exactly like one another: the figure of the cross was cut on one of these sticks, and nothing on the other: each of them was then wrapped up in a quantity of fine white wool, and laid on the altar, or on the relics of the saints; after which a solemn prayer was put up to God, that he would be pleased to discover, by evident signs, whether the prisoner was innocent or guilty. These solemnities being finished, a priest approached the altar, and took up one of the sticks, which was uncovered with much anxiety. If it was the stick marked with the cross, the prisoner was pronounced innocent: if it was the other, he was declared guilty. When the judgment of the cross was appealed to in civil causes, the trial was conducted in this manner: The judges, parties, and all concerned, being assembled in a church, each of the parties chose a priest, the youngest and stoutest that he could find, to be his representative in the trial. These representatives were then placed one on each side of some famous crucifix; and, at a signal given, they both at once stretched their arms at full length, so as to form a cross with their body. In this painful posture they continued to stand while divine service was performing; and the party whose representative dropped his arms first lost his cause.

"The corned, or the consecrated bread and cheese, was the ordeal to which the clergy commonly appealed when they were accused of any crimes; in which they acted a very prudent part, as it was attended with no danger or inconveniency. This ordeal was performed in this manner: A piece of barley bread, and a piece of cheese, were laid upon the altar, over which a priest pronounced certain conjurations, and prayed with great fervency, that if the person accused was guilty, God would send his angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. These prayers being ended, the culprit approached the altar,
There were besides these a variety of other ordeals practised in Christian countries, many of which retain the same names as among Pagans, and differ only in the mode of execution. In all nations of Christians where these trials were used, we find the clergy engaged in them. Indeed, in England, as late as King John's time, we find grants to the bishops and clergy to use the judicium ferrī, aquae, et ignis. And, both in England and Sweden, the clergy presided at this trial, and it was only performed in the churches or in other consecrated grounds: for which Steinhorn gives the reason, Non defuit illis operae et laboris pretium; semper enim ab ejusmodi judicio aliquid lucrī sacerdotibus obtinebat. But, to give it its due praise, we find the canon law very early declaring against trial by ordeal, or vulgatus purgator, as being the fabric of the devil, cum sit contra praeceptum Domini, Non tentabis Dominum Deum tuum. Upon this authority, though the canons themselves were of no validity in England, it was thought proper (as had been done in Denmark above a century before) to disuse and abolish this trial entirely in our courts of justice, by an act of Parliament in 3 Hen. III. according to Sir Edward Coke, or rather by an order of the king in council. It may still perhaps be a postulatum with some of our readers how the effects of these trials were evaded, and how it was possible to appear to do what we know could not be really done, without material injury to the persons concerned: on this subject the learned historian whom we have already quoted, observes with regard to the ordeals in ancient Britain, which, mutatis mutandis, will answer for others, that, "If we suppose few or none escaped conviction who exposed themselves to those fiery trials, we shall be very much mistaken. For the histories of those times contain innumerable examples of persons plunging their naked arms into boiling water, handling red-hot balls of iron, and walking upon burning ploughshares, without receiving the least injury. Many learned men have been much puzzled to account for this, and disposed to think that Providence graciously interposed, in a miraculous manner, for the preservation of injured innocence. But if we examine every circumstance of those fiery ordeals with due attention, we shall see sufficient reason to suspect that the whole was a gross imposition on the credulity of mankind. The accused person was committed wholly to the priest who was to perform the ceremony, three days before the trial, in which he had time enough to bargain with him for his deliverance, and give him instrucctions how to act his part. On the day of trial, no person was permitted to enter the church but the priest and the accused till after the iron was heated, when twelve friends of the accuser, and twelve of the accused, and no more, were admitted, and ranged along the wall on each side of the church, at a respectful distance. After the iron was taken out of the fire, several prayers were said; the accused drank a cup of holy water, and sprinkled his hand with it, which might take a considerable time if the priest was indulgent. The space of nine feet was measured by the accused himself with his own feet, and he would probably give but scanty measure. He was obliged only to touch one of the marks with the toe of his right foot, and allowed to stretch the other foot as far towards the other mark as he could, so that the conveyance was almost instantaneous. His hand was not immediately examined, but wrapped in a cloth prepared for that purpose three days. May we not then, from all these precautions, suppose these ordeals were in possession of some secret that secured the hand from the impressions of such a momentary touch of hot iron, or removed all appearance of these impressions in three days; and that they made use of this secret when they saw reason? Such readers as are curious in matters of this kind may find two different directions for making ointments that will have this effect, in the work here quoted. What greatly strengthens these suspicions is, that we meet with no example of any champion of the church who suffered the least injury from the touch of hot iron in this ordeal: but when any one was so fool-hardy as to appeal to it, or to that of hot water, with a view to deprive the church of any of her possessions, he never failed to burn his fingers, and lose his cause."

To this we shall add what the learned Beckmann has said concerning the imposition that was probably practised in the ordeal by fire. "I am not acquainted with everything that concerns the trial by ordeal, when persons accused were obliged to prove their innocence by holding in their hands red-hot iron; but I am almost convinced that this was also a juggling trick of the popes, which they employed as might best suit their views. It is well known that this mode of exculpation was allowed only to weak persons, who were unfit to wield arms, and particularly to monks and ecclesiastics, to whom, for the sake of their security, that by single combat was forbidden. The trial itself took place in the church, entirely under the inspection of the clergy; masses was celebrated at the same time: the defendant and the iron were consecrated by being sprinkled with holy-water; the clergy made the iron hot themselves; and they used all these preparatives, as jugglers do many motions, only to divert the attention of the spectators. It was necessary that the accused person should remain at least three days and three nights under their immediate care, and continue as long after. They covered his hands both before and after the proof; sealed and unsealed the covering: The former, as they pretended, to prevent the hands from being prepared any how by art; the latter, to see if they were burnt. Some artificial preparation was therefore known, else no precautions would have been necessary. It is highly probable, that during the three first days the preventive was applied to those persons whom they wished to appear innocent; and that the three days after the trial were requisite to let the hands resume their natural state. The sacred sealing secured them from the examination of presumptuous unbelievers; for to determine whether the hands were burnt, the three last days were certainly not wanted. When the ordeal was abolished, and this art rendered useless, the clergy no longer kept it a secret. In the 13th century, an account of it was published by Albertus Magnus, a Dominican monk..."
ORD

ORDERS, by way of eminence, or Holy Orders, denote a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See Ordination.

This the Romanists make their sixth sacrament. In no reformed church are there more than three orders; viz. bishops, priests, and deacons. In the Romish church there are seven, exclusive of the episcopate, all which the council of Trent enjoins to be received, and believed, on pain of anathema.

They are distinguished into petty, or secular orders; and major, or sacred orders.

ORDERS, the petty, or minor, are for; viz. those of doorkeeper, exorcist, reader, and acolyth.

Those in petty orders may marry without any dispensation; in effect, the petty orders are looked on as little other than formalities, and as degrees necessary to arrive at the higher orders. Yet the council of Trent is very serious about them; enjoins that none be admitted into them without understanding Latin; and recommends it to the bishops, to observe the intervals of conferring them, that the persons may have a sufficient time to exercise the function of each order; but it leaves the bishops a power of dispensing with those rules; so that the four orders are usually conferred the same day, and only make the first part of the ceremony of ordination.

The Greeks disavow these petty orders, and pass immediately to the subdeaconate; and the reformed to the deaconate.

Their first rise Fleury dates in the time of the emperor Justinian. There is no call nor benefit required for the four petty orders; and even a bastard may enjoy them without any dispensation; nor does a second marriage disqualify.

ORDERS, sacred, or major, we have already observed, are three; viz. those of deacon, priest, and bishop.

The council of Trent, retrieving the ancient discipline, forbids any person being admitted to the major orders, unless he be in peaceable possession of a benefice sufficient for a decent subsistence; allowing no ordinances on patronages or pensions, except where the bishop judges it for the service of the church.

A person is said to be promoted to orders per saltum, when he has not before passed the inferior orders. The council of Constantinople forbids any bishop being ordained without passing all the degrees; yet church-history furnishes us with instances of bishops consecrated, without having passed the order of priesthood; and Panormus still thinks such an ordination valid.

Military Orders, are companies of knights, instituted by kings and princes, either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

Religious Orders, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit. Religious orders.

In the French jurisprudence, ordinances are such laws as are established by the king's authority alone. All ordinances begin with, à tous présens, et à venir salut.

ORDINARY, in general, signifies common, usual; thus, an ambassador, or envoy in ordinary, is one sent to reside stately, and for a number of years, in the court of some foreign prince or state, in order to keep up a good understanding, and watch over the interest of his own nation. This term is also applied to several officers in the king's household, who attended on common occasions. Thus we say, physician in ordinary, &c.

ORDINARY, in naval language, denotes the establishment of the persons employed by government to take charge of the ships of war, which are laid up in the several harbours adjacent to the royal dock-yards. These are principally composed of the warrant officers of the said ships, as the gunner, boatswain, carpenter, deputy-purser, and cook, and three servants. There is besides a crew of labourers enrolled in the list of the ordinary, who pass from ship to ship occasionally, to pump, moor, remove, or clean them, whenever it is necessary.

The term ordinary is also applied sometimes to the ships themselves; it is likewise used to distinguish the inferior sailors from the most expert and diligent. The latter are rated able on the navy books, and have higher pay than those who are rated ordinary.

ORDINARY, in common or canon law, means one who has ordinary or immediate jurisdiction in matters ecclesiastical, in any place. In this sense archdeacons are ordinaries, but the appellation is most frequently applied to the bishop of the diocese, who has of course the ordinary ecclesiastical jurisdiction, and the collation to benefices within such diocese. There are some chapels, chapters, abbeys, &c. exempted from the jurisdiction of the ordinary. The archbishop is ordinary of the whole province, to visit, and receive appeals from the inferior judicatures.

The Romish writers on canon law call the pope by way of eminence ordinary of ordinaries, since by the Lateran council he has usurped the right of collating, by probation, to all benefices; in exclusion of the common collators.

ORDINARY of Assizes and Sessions, was a deputy of the bishop of the diocese, anciently appointed to give malefactors their neck-verse, and judge whether they read or not: also to perform divine service for them, and assist in preparing them for death. So the ordinary of Newgate, is one who is attendant in ordinary upon the condemned malefactors in that prison, to prepare them for death; and he records the behaviour of such persons.

ORDINARY, or Honourable Ordinary, in Heraldry, a denomination given to certain charges properly belonging to that art. See Heraldry, Chap. III. sect. i.

ORDINATES, in Geometry and Conics, are lines drawn from any point of the circumference of an ellipse, or other conic section, perpendicularly across the axis, to the other side. See Conic-Sections.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

Ordination has always been esteemed a principal prerogative of bishops, and they still retain the function.
ORD

Ordination, as a mark of spiritual sovereignty in their diocese.

Ordinance. Without ordination, no person can receive any benefice, parsonage, vicarage, &c. A person must be 23 years of age, or near it, before he can be ordained deacon, or have any share in the ministry; and full 24 before he can be ordained priest, and by that means be permitted to administer the holy communion. A bishop, on the ordination of clergy, men, is to examine them in the presence of the ministers, who in the ordination of priests, but not of deacons, assist him at the imposition of hands; but this is only done as a mark of assent, not because it is thought necessary. In case any crime, as drunkenness, perjury, forgery, &c. be alleged against any one that is to be ordained, either priest or deacon, the bishop ought to desist from ordaining him. The person to be ordained is to bring a testimonial of his life and doctrine to the bishop, and to give account of his faith in Latin; and both priests and deacons are obliged to subscribe the 39 articles.

The ordination of bishops is more properly and more commonly called consecration.

In the ancient discipline there was no such thing as a vague and absolute ordination; but every one was to have a church, whereof he was to be ordained clerk, or priest. In the twelfth century they grow more remiss, and ordained without any title or benifice.

The Council of Trent restored the ancient discipline, and appointed that none should be ordained but those who were provided of a benefice sufficient to subsist them. Which practice still obtains in England.

The council of Rome, in 944, ordered, that no ordinations shall be held, except on the first, fourth, seventh, and tenth months. In England, by can. 31, ordination days are the four Sundays immediately following the Ember-weeks; being the second Sunday in Lent, Trinity-Sunday, and the Sundays following the first Wednesday after September the 14th, and December the 23d. These are the stated times; but ordinations may take place at any other time, according to the discretion of the bishop or circumstances of the case.

Pope Alexander II. condemns ordination per saltum, as they call it; i.e. the leaping to a superior order without passing through the inferior.

Ordination is one of the sacraments of the church of Rome.

In the establishment of Scotland, where there are no bishops, the power of ordination is lodged in the presbytery, and by the Independents in the suffrage of the people. See Episcopacy, Presbyterian, and Independents.

ORDNANCE, a general name for all sorts of great guns used in war. See Gunnery.

Boring of Ordinance. Till within these 20 years, iron ordnance were cast with a cylindrical cavity, nearly of the dimension of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel cutters fixed into the dog-head of a boring-bar-iron. Three side cutters equidistant were requisite to preserve the caliber straight and cylindrical; and a single cutter was used at the end of the bar to smooth the breech of the piece. In boring ordnance cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring-bar, of a sufficient length to reach up to the breach of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water wheel being set a-going, the bar and cutters are turned round, and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of casting guns hollow, and widening the calibers by these boring bars. For the body of iron of the hollow-gun, being, at casting, in contact with the core that made the caliber within-side, and with the mould without-side, began to consolidate towards these sides in the first place, sooner than in the intermediate space, where of course the contraction of the iron takes place; by which means, all guns cast hollow become more or less spongy where they ought to have been most compact; and numberless cavities also were created round the cores, from stagnated air generated in them, which were too deep to be cut out by the boring.

To remedy these defects, iron ordnance is now universally cast solid, by which means the column of iron is greatly enlarged, and the grain more compressed; and the contraction of the iron becomes in the heart of the column, and consequently is cut out by the perforation for the caliber.

Guns are bored out of the solid reversely from the hollow method. The piece A is placed upon two standards BB, by means of two journeys, turned round by the water wheel C, the breech D being introduced into the centre of the wheel, with the muzzle towards the sliding carriage E, which is pressed forwards by a ratchet F, and weights, in the same way as the gun-carriage was in the hollow-boring. Upon this sliding carriage is fixed, truly horizontal and centrical to the gun, the drill bar G, to the end of which is fixed a carp's tongue drill or cutter H; which, being pressed forward upon the piece whilst it is turning round, perforates the bore, which is afterwards finished with borers and cutters as the hollow guns were. The principal difficulty of perforating solid guns truly centrical, arises from the contraction of the iron above mentioned; which, resisting the drill unequally, tends to throw it out of the centrical line.

Office of Ordinance, an office kept within the Tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land, in all the magazines, garrisons, and forts, in Great Britain. We have the following copious account of this establishment in Beaton's Political Index. In ancient times, before the invention of guns, this office was supplied by officers under the following names: the bouyer, the cross bouyer, the galeator or purveyor of helmets, the armourer, and the keeper of the tents; and in this state it continued till Henry VIII. placed it under the management of a master, a lieutenant, surveyor, &c. &c.

Some improvements have been since made; and this very important branch is now under the direction of the master general of the ordnance, having under him a lieutenant general, a surveyor general, a clerk, a storekeeper, a clerk of the deliveries, and a treasurer, with a very great number of inferior officers, employed

ORDANCE

in the Tower of London, at Woolwich, and in almost all the forts, garrisons, and principal ports in his majesty’s dominions. The office of ordnance is divided into two distinct branches, the civil and the military; the latter being subordinate, and under the authority of the former. For the better understanding the business of the different officers, they shall be distinctly treated of, beginning with the principal one, viz.

Master General of the Ordnance is deemed the principal officer in the civil branch of the ordnance; yet he is always chosen from amongst the first generals in his majesty’s service. His trust is very great, as in him is vested the sole power of storing all the military magazines in the King’s dominions with proper munitions of war, and likewise to supply the royal navy with what they may need in his department, the parliament granting money in the most liberal manner for this purpose. He is colonel in chief of the royal regiment of artillery, at present consisting of four battalions, and he is invested with a peculiar jurisdiction over all his majesty’s engineers employed in the several fortifications in his majesty’s dominions; and to him they are all accountable for their proceedings, and from him they receive their particular orders and instructions, according to the directions and commands given by his majesty in council.

As master general of the ordnance he has the appointment of almost all the inferior officers and servants. He has a secretary, and an under-secretary; and besides there is a secretary and a counsel to the board of ordnance.

Lieutenant General of the Ordnance receives all orders and warrants signed by the master-general, and from the other principal officers, and sees them duly executed, issues orders as the occasions of the state require, and gives directions for discharging the artillery when required at coronations, birth days, signal victories, and other solemn occasions. It is also his peculiar office to see the train of artillery, and all its equipment, fitted for motion, when ordered to be drawn into the field, or sent upon any particular service. He is colonel in second of the royal regiment of artillery, and has a secretary and several inferior officers and clerks under him.

Surveyor General of the Ordnance inspects the stores and provisions of war in the custody of the storekeeper, and sees that they are ranged and placed in such order as is most proper for their preservation. He allows all bills of debt, and keeps a check upon all labourers and artificers work; sees that the stores received be good and serviceable, duly proved and marked, as they ought to be, with the king’s mark, taking to his assistance the rest of the officers and proof-masters. To assist him in the business of his office, he has under him the proof-master of England, and clerks, and other inferior officers.

Clerk of the Ordnance, an officer whose function is to record all orders and instructions given for the government of the office; all patents and grants; the names of all officers, clerks, artificers, gunners, labourers, &c. who enjoy those grants, or any other fee for the same; to draw all estimates for provisions and supplies to be made, and all letters, instructions, commissions, deputations, and contracts for his majesty’s service; to make all bills of imprest and debentures, for the payment and satisfaction of work done and provisions received in the said office; and all quarter books for the salaries and allowances of all officers, clerks, &c. belonging to the office; and to keep journals and ledgers of the receipts and returns of his majesty’s stores, to serve as a check between the two accountants of the office, the one for money, and the other for stores.

Storekeeper of the Ordnance takes into his custody all his majesty’s ordnance, munitions and stores belonging thereto, and indents and puts them in legal security, after they have been surveyed by the surveyor-general, any part of which he must not deliver without a warrant signed by the proper officers; nor must he receive back any stores formerly issued till they have been reviewed by the surveyor, and registered by the clerk of the ordnance in the book of remains; and he must take care that whatever is under his custody be kept safe, and in such readiness as to be fit for service upon the most peremptory demand.

Clerk of the Deliveries of the Ordnance draws all orders for delivery of any stores, and sees them duly executed; charges by indenture the particular receiver of the stores delivered; and, in order to discharge the store-keeper, registers the copies of all warrants for the deliveries, as well as the proportions delivered.

Treasurer and Paymaster of the Ordnance receives and pays all moneys, both salaries and debentures in and belonging to this office. In his office are several clerks, ordinary and extraordinary, for the dispatch of business.

Office of Ordnance. Besides the principal officers already mentioned, there belong to this office two proofmasters; a clerk of the works; a purveyor for the land, and a purveyor for the sea; an architect; an astronomical observer; and other officers. The other part of this office, which is termed the military branch of the ordnance, is a chief engineer, who has under him two directors, four sub-directors, with an unlimited number of engineers in ordinary, engineers extraordinary, sub-engineers, and practitioner engineers.

ORDNANCE Bills, commonly called ordnance debentures, are bills issued by the board of ordnance on the treasurer of that office, for the payment of stores, &c. These are not payable at any certain time, and do not bear any interest, so that the discount upon them is often very high; but they are seldom much above two years in arrears.

ORDONNANCE, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole and to one another; or, as Mr. Evelyn expresses it, determining the measure of what is assigned to the several apartments. Thus ordonnance is the judicious contrivance of the plan or mould; as when the court, hall, lodgings, &c. are neither too large nor too small, but the court affords convenient light to the apartments about it; the hall is of fit capacity to receive company; and the bed-chambers, &c. of a proper size. When those divisions are either too great or too small, with respect to the whole, as where there is a large court to a little house, or a small hall to a magnificent palace, the fault is in the ordonnance. See Architecture.

ORDONNANCE, in Painting, is used for the disposition of the parts of a picture, either with regard to the whole piece, or to the several parts, as the groups, masses, contrasts, &c. See Painting.

ORDOVICES, ancient Britons, of whom we have the following account in Henry’s History of Great Britain. They lived in that country which is now called...
ORES, REDUCTION AND ANALYSIS OF.

IN the treatment of metallic ores, it has been already hinted, that two objects are in view: the one is to obtain a knowledge of the nature and proportions of their component parts; and the other is to be acquainted with the best methods of separating the metals which they contain, that they may be applied in their pure or uncombined state to useful purposes. In the following treatise, therefore, we shall keep in view the same objects: and under each of the metals we shall first detail the most improved methods of analysing its different ores; and, secondly, give a short account of the best and most approved processes that are employed in their reduction. The last object, however, refers only to some of the metals; others not being found in sufficient quantity, or not being applicable to useful purposes.

In this treatise we shall consider the metals in the same order in which they have been described under Mineralogy, and to each metal we shall devote a particular chapter.

CHAP. I. Of the Ores of Plutina.

Plutina, on account of its insusceptibility, density, and indestructibility, is one of the most important and useful of the metals yet known, and particularly for different chemical instruments and utensils, because there are few chemical agents whose effects it cannot resist. Plutina is only found in the state of alloy, with rhodium and palladium, two of the newly discovered metals; and it is accompanied also with another alloy, iridium and osmium, also newly discovered metals, as well as with particles of iron, gold and some other substances. The discovery of these metals, and the importance of plutina itself, have rendered the ores of this metal peculiarly interesting. We shall therefore in the present chapter, give a pretty full detail of the methods of analysing the ore, and of working it for the purposes of manufacture. These subjects will occupy the following sections.

SECT. I. Of the Analysis of the Ores of Plutina.

The whole of the plutina which is brought to Europe, has been previously subjected to the process of amalgamation in South America; and hence it happens, that a small quantity of mercury remains in it, sometimes in very small distinct particles, but more commonly in a state of combination with gold, in the form of an amalgam. In treating the ores of plutina, therefore, the first object is to separate the mercury, and the easiest process is to drive it off by means of heat, either in an open ladle, if it be not intended to collect the mercury, or in an earthen retort, if the object of the operator be to retain that metal. The plutina remaining after the mercury is thus driven off, appears much yellower, because the particles of gold dispersed through it exhibit their peculiar colour. The ore is next to be spread out thin on a smooth table, and by means of a pair of common bellows, the lighter particles may be separated with tolerable
The lighter particles being separated by mechanical action, the heavier particles are to be treated with a small quantity of slightly diluted nitro-muriatic acid, and by this means the whole of the gold is taken up, with a portion of iron, and a small quantity of platina and other ingredients. The gold may be thrown down from this solution by adding green sulphate of iron, and it may be purified by mixing it with nitre and borax. If the quantity of platina to be purified be considerable, it is an object worth the attention of the chemist, to separate and collect the gold, because the proportion of the latter contained in crude platina is small. Proust obtained seven ounces of gold from a quantity of platina consisting of 100 ounces, and from another quantity of the same weight he separated not less than 13 ounces of gold.* It may be observed that the platina which is whitest, is found to be the richest in the gold, and that the black varieties scarcely contain any at all.

The gold being separated, the platina is next to be digested in nitro-muriatic acid, and excepting a black matter, the whole is dissolved. This black matter, when first observed, was supposed to be plumbago; but it appears from the discovery of Mr. Tennant, to be a compound of two new metals, to which he has given the names of osmium and iridium. By adding muriate of ammonia to the nitro-muriatic solution, almost the whole of the platina is precipitated in the form of a yellow powder. This powder is a muriate of ammonia and platina, and it is nearly insoluble. The solution being next treated with zinc, the whole of its metallic contents, excepting the iron, are thrown down. The precipitate thus obtained is to be washed and digested in nitric acid much diluted. By this means the copper and lead with which crude platina is usually contaminated, are separated. The remainder is to be dissolved in nitro-muriatic acid; to the latter solution add common salt, and evaporate the whole to dryness; the salt remaining contains the muriates of soda and of platina, palladium and rhodium; and as the salt of rhodium is found to be insoluble in alcohol, it may, by means of it, be separated from the former. The platina and palladium now remain in the alcoholic solution, and from this the greater part of the platina may be separated by means of muriate of ammonia; and after diluting the solution by adding prussiate of potash, a deep orange precipitate is obtained, which is palladium. By concentrating the remaining liquor, the platina may be precipitated by means of muriate of ammonia.

Sect. II. Of the Methods of working Platina.

Platina, on account of its peculiar properties in resisting great degrees of heat and the action of many of the most powerful chemical agents, is by far the most important and valuable of the metals yet known for the purposes of constructing various instruments and utensils which are found highly useful in chemical analysis. But the refractory nature of this metal has presented many difficulties, and has greatly exercised the ingenuity and skill of chemists and artists to render it malleable and capable of assuming the requisite forms. It has been observed that the largest and whitest grains picked out from crude platina have a considerable degree of malleability even when cold; but when they are heated, this property appears in greater perfection: and if two of these grains be brought into contact, and subjected to the highest degree of white heat, the stroke of a hammer will make them adhere more or less perfectly. In this way, a small mass of metal may be obtained by the union of a few grains. But it is obvious that the patience and dexterity required in this slow and tedious process will prevent it from being practically useful.

In the progress of experiments made on platina it was discovered that arsenic combined readily with that metal, and formed an alloy of easy fusibility. The great volatility of the arsenic, particularly when in contact with charcoal, gave reason to hope that the whole of it, by proper management, might be burnt off, leaving the platina behind in a mass, and retaining its character and characteristic properties. In this way different chemists succeeded in forming, of this alloy, crucibles and other chemical utensils, which were found to be less fusible than silver, and were capable of resisting many of the common chemical agents. The most successful method of rendering platina malleable, and working it by means of this alloy, was discovered by Jeanet, a Parisian silversmith, who long directed his attention to this object. An account of his method has been given by Berthollet and Pelletier, of which the following is an abstract.*

The crude platina being first ground in water, and washed for the purpose of separating the earthy matters, three half pounds of the metal, three pounds of white arsenic, and one pound of pearl ashes, are to be well mixed together. A crucible, capable of holding 20 pounds of this mixture, is then to be placed in a furnace of any convenient construction. When the crucible is thoroughly red hot, introduce one-third of the mixture, and continue stirring it with a rod of platina till it comes to a state of quiet fusion; then add another one-third, stirring it in the same manner till the fusion is completed, and afterwards add the remaining one-third, and apply a strong heat, so that the whole may become very fluid. Then withdraw the crucible, and when it has cooled gradually, break it up; a well formed metallic button will be found in it, covered by blackish brown scoriæ, which has a considerable action on the magnetic needle. The button, which is very brittle, being broken to pieces, is to be fused again with white arsenic and pearl ashes as before, and the metallic mass obtained from this second fusion is generally found to have no effect on the magnetic needle; but if this should not be the case, a third fusion in the same way becomes necessary.

The first step of the process is now completed. A flat-bottomed cylindrical crucible, about three inches and a half in diameter, is to be made thoroughly hot in a furnace, and charged with one pound and a half of the arsenicated platina, mixed with a equal weight of white arsenic, and one half pound of potash; and when this mixture...
mixtures has been completely fluid, the crucible is to be removed from the fire, and allowed to cool in a horizontal position, that the thickness of the cake of metal may be uniform. When the crucible is cold, it is to be carefully broken, and the scoriz being removed, a cake of metal is obtained, well-formed and sonorous, weighing three ounces more than the arsenicated platina employed. The metal is now quite saturated with arsenic. It has been observed, that there is no inconvenience from incorporating too much arsenic, for it would appear that the full success and rapidity of the purification of the platina, are exactly in proportion to the quantity of arsenic with which it has been previously combined.

The mass of metal thus obtained, is placed in a muffle, and the heat is gradually increased, till the evaporation of the arsenic commences; after which the temperature is to be kept up as nearly as possible at the same degree, for the space of six hours, carefully watching not to increase it, lest the cake should be brought to a state of fusion. At the end of the six hours, the cake has become considerably porous; it is then to be withdrawn, and extinguished in common oil; after which it is returned to the muffle, by which means a further quantity of arsenic is drawn off; and this alternate heating and application of oil are to be continued till the arsenic no longer makes its appearance. In proportion as the arsenic is driven off, the fusibility of the mass diminishes, so that a greater degree of heat may be applied in the latter stage of the process. After having carefully burnt off at a high degree of heat the whole of the charcoal which is produced by the decomposition of the oil, the spongy cake of metal is to be digested in nitrous acid, and then edulcorated by repeated boiling in water. Three or more of the cakes are then to be placed in a crucible, and exposed to the highest degree of heat in a powerful furnace, and while they are thus rendered soft, an iron pestle let down upon them, will make them cohere; and being withdrawn from the crucible, they are to be heated to the utmost in a smith's fire, and carefully forged like iron on the anvil, into compact bars.

The cheapness of the process now detailed is the only advantage which it holds out, for the platina does not require to be previously dissolved in nitricum acid; but it is to be observed, that the metal by this treatment is by no means perfectly pure; a small portion of arsenic and iron still adhering to it, and probably some lead and copper, which may have been accidentally mixed with the ore, while it contains the whole of the palladium, osmum, iridium, and rhodium; and thus contaminated, it is obvious, that it must be less capable of resisting the action of alkalies, and high degrees of heat without injury, than when it is brought to a state of greater purity. Accordingly, other processes for the purification of this valuable metal, have been contrived and practised.

The following is the processes proposed by Count Moussin Poushkin, to render platina malleable. 1. Precipitate the platina from its solution by muriate of ammonia, and wash the precipitate with a little cold water.

2. Reduce it in a convenient crucible to the well-known spongy metallic texture, which wash two or three times with boiling water to carry off any portion of saline matter which may have escaped the action of the fire.

3. Boil it for about half an hour in as much water, mixed with one-tenth part of muriatic acid, as will cover the mass to the depth of about half an inch, in a convenient glass vessel. This will carry off any quantity of iron that might still exist in the metal.

4. Decant the acid water, and edulcorate or strongly ignite the platina.

5. To one part of this metal take two parts of mercury, and amalgamate in a glass or porphyry mortar. This amalgamation takes place very readily. The proper method of conducting it is to take about two drams of mercury to three drams of platina, and amalgamate them together; and to this amalgam may be added alternate small quantities of platina and mercury till the whole of the two metals are combined. Several pounds may be thus amalgamated in a few hours, and in the large way a proper mill might shorten the operation.

6. After the amalgam is completely produced, it must be quickly moulded in bars or plates, or any other forms that may be preferred; taking care that these moulded pieces should at least be half an inch in thickness, and of a proper length to manage them afterwards in the fire; it is also requisite that the mould should be perfectly even and smooth. Half an hour after the pieces are formed they begin to harden by the oxidation of the mercury, and change their brilliant metallic colour for a dull leaden one.

7. As soon as the pieces have acquired a proper degree of hardness to be handled without danger of breaking, which commonly takes place in a little more than an hour, place them in a proper furnace, and keep them ignited under a muffle or in a small reverberatory. No other precaution is necessary in this operation, but that of not breaking the pieces during their transport. The mercury flies off during the heat, and the platina remains perfectly solid; so that, after being strongly ignited two or three times before the bellows, it may be forged, or laminated in the same manner as gold or silver; care being taken, at the commencement of the forging, or of passing it between rollers, not to apply too great a force till the metal has acquired all its density. It is almost superfluous to add, that in evaporating the mercury from large quantities of amalgam, a proper apparatus, such as in the silver amalgamation, must be employed, to receive the volatilized mercury; but for small quantities, where the loss of this metal is of no consequence, the furnace must have a proper chimney to carry off the metallic vapours. When the platina comes out of the first fire, its dimensions are about two thirteenth parts smaller every way than the original amalgam from the mould. The whole of this operation seems to be governed by the pressure of the atmosphere and the laws of cohesive attraction: for the air is driven out from between the molecules of the platina, which by their solution in mercury are most probably in their primitive and consequently uniform figure. It is very visible, and at the same time a very amusing phenomenon to observe, (during the process of ignition, which is performed in four or five minutes), how the platina contracts every way into itself, as if pressed by some external force."

The count then adds, "that, as soon as my amalgam of mercury is made, I compress the same in tubes of wood, by the pressure of an iron screw upon a cylinder of wood, adapted to the bore of the tube. This forces out the superabundant mercury from the amalgam, and renders
Chap. I.

ORE S, &c.

Platina.

renders it solid. After two or three hours I burn upon the coals, or in a crucible lined with charcoal, the sheath in which the amalgam is contained, and urge the fire to a white heat; after which I take out the platina in a very solid state, fit to be forged *.”

A simpler method for rendering platina malleable, at the same time not less effectual, has been proposed by Mr. Knight. The following is an account of this method in the words of the author.

"To a given quantity of crude platina, I add fifteen times its weight of nitro-muriatic acid (composed of equal parts of nitric and muriatic acid) in a tubulated glass retort, with a tubulated receiver adapted to it. It is then boiled, by means of an Argand's lamp, till the acid has assumed a deep saffron colour; it is then poured off; and if any platina remain undissolved, more acid is added, and it is again boiled until the whole is taken up. The liquor, being suffered to rest till quite clear, is again decanted: a solution of sal-ammoniac is then added, by little and little, till it no longer gives a cloudiness. By this means the platina is thrown down in the form of a lemon-coloured precipitate, which having subsided, the liquor is poured off, and the precipitate repeatedly washed with distilled water till it ceases to give an acid taste; (too much water is injurious, the precipitate being in a certain degree soluble in that liquid); the water is then poured off, and the precipitate evaporated to dryness.

"So far my process is in a great measure similar to that which some others have also followed; but my method of managing the subsequent, and which are indeed the principal manipulations, will be found to possess many advantages over any that has yet been made public. The best process hitherto followed has been, to give the precipitate a white heat in a crucible, which in some measure agglutinates the particles; and then to throw the mass into a red-hot mortar, or any similar implement, and endeavour to unite them by using a pestle or rammer. But the mass is so spongy that it is hardly possible to get a single stroke applied to it before the welding heat is gone; and though by peculiar dexterity and address some have in this way succeeded, it has been found to require such innumerable beatings and hammerings, that most of those who have attempted it, have either failed entirely, or given it up as being too laborious and expensive. I have succeeded in obviating all these difficulties by adopting the following simple, easy, and expeditious method:—

"A strong, hollow, inverted cone of crucible earth being procured, with a corresponding stopper to fit it, made of the same materials, the point of the latter is cut off about three-fourths from the base. The platina, now in the state of a light yellow powder, is pressed tight into the cone, and a cover being fixed slightly on, it is placed in an air furnace, and the fire raised gradually to a strong white heat. In the mean time the conical stopper, fixed in a pair of iron tongs suitable for the purpose, is brought to a red or to a bright red heat. The cover being then removed from the cone, the tongs with the heated stopper is introduced through a hole in the cover of the furnace, and pressed at first gently on the platina, at this time in a state nearly as soft as dough, till it at length acquires a more solid consistence. It is then repeatedly struck with the stopper, as hard as the nature of the materials will admit, till it appears to receive no farther impression. The cone is then removed from the furnace, and being struck lightly with a hammer, the platina falls out in a metallic button, from which state it may be drawn, by repeatedly heating and gently hammering, into a bar fit for flattening, drawing into wire, planishing, &c.

"Besides the comparative facility of this process, it has the further advantage of rendering the platina much purer than when red-hot iron is obliged to be laid recourse to; for platina, when of a white heat, has a strong affinity for iron, and, with whatever care it may have been previously separated from that metal, will be found to have taken up a portion of it, when it is employed of a red heat, to serve to unite the particles of the platina. To the superior purity of platina, rendered malleable by the process before described, I attribute the greater specific gravity which I find it to possess, than that prepared by other methods. Having taken the specific gravity of about ten pennyweights of it, which I had previously passed repeatedly through a flattening mill, I found it to be 22.267.

Another method, which has been successfully practised, was contrived by Mr. Cock. The following is an account of his process. After the solution of the platina in nitro-muriatic acid, the liquor is filtered through clean sand, for the purpose of separating the black powder which floats in it. The clear solution is then decomposed by means of sal-ammoniac; the yellow precipitate being collected, is to be moderately well washed in warm water and dried; and being distributed into saucers placed in a small oven, constructed for the purpose, in which they are to be exposed for a short time to a low red heat, that the platina may be brought to the metallic state, and the greater part of the sal ammoniac may be sublimed. When the platina, after this treatment, is withdrawn, it is in the form of a grey coloured, spongy mass; and in this state half an ounce of it is to be put into a strong iron mould, one inch and a half wide, and two and a half long. It is then to be compressed as strongly as possible, by striking with a mallet upon a wooden pestle accurately cut to fit the mould; another half ounce is then added, and treated in the same manner, till six ounces have been forced into the mould; a loose iron cover, just capable of sliding down the mould, is then laid upon the platina. This part of the process requires particular care; for if any material quantity of air be left in the mass, the bar into which it is formed is extremely apt to scale and be full of flaws in the subsequent operations. The pressure being properly made, the mould is to be taken to pieces, and the platina will be found in the form of a dense compact parallelopiped. It is next to be placed in a forge fire of charcoal, and heated to the most intense white heat, in order to drive off the muriate of ammonia which remains: this being done, it is to be quickly placed on a clear bright anvil, and gently hammered in every direction by a clean hammer. This is several times to be repeated, at the end of which the mass will be perfectly compact, and fit to be laminated or wrought in any other manner at the pleasure of the artist. It is to be observed, that while the platina is heating, it must be loose in the fire, for if it were held by the tongs, they would infallibly become welded to the platina, and by this means greatly damage it. When the platina is thus drawn down to a compact bar, it will be covered by a semivitreous crust, somewhat
Gold.

somewhat reddish, chiefly proceeding from particles of the ashes melted down upon it, and extended by the hammer over its surface. To remove this, the bar, after being made red hot, is to be sprinkled over with glass of borax reduced to powder, and then kept at a white heat for a few minutes; it is to be plunged into diluted muriatic acid when moderately cool, by which the borax and other vitreous matters will be dissolved, and the platina with a perfectly clean white surface left behind.

CHAP. II. Of the Ores of Gold.

GOLD exists in nature only in the metallic state; but it is scarcely ever found perfectly pure, for it is alloyed in different proportions with silver, copper, tellurium, and some other metals. When it is alloyed with silver or copper, or even with both, the gold retains its ductility; but when combined with tellurium, its distinctive characters entirely disappear.

Sect. I. Of the Analysis of the Ores of Gold.

The method of analysing gold ores is very simple. The principal difficulty with which it is attended arises from the small proportion of this metal contained in the greater part, even of those ores which are considered as very rich. Native gold contains invariably, but generally in small proportion, silver or copper, and sometimes both, and the gangue is often a very hard quartz. In this case the following is an approved mode of proceeding. Reduce the ore to fine powder, mix it with six times its weight of carbonate of soda, or, what answers better, with four parts of carbonate of soda, and one of glass of borax: put the mixture into an earthen crucible, and melt it. Pour out the fused mass on a stone slab, and detach the small portion remaining in the crucible by means of a little diluted muriatic acid. Reduce the mass to coarse powder; put it into a flask with the muriatic solution; add strong muriatic acid, and apply a gentle heat. Continue the digestion, adding from time to time a little nitrous acid, till no farther action is produced, and the undissolved residue becomes of a pure white colour. Then pour off the liquor, wash the residue, and add the washings to the liquor.

1. After the insoluble residue is dried, expose it to the sun, and if it contain any muriate of silver, it will assume a purplish colour. When this is the case, let it be mixed with three times its weight of pearl-ash, and fused in an earthen crucible for five minutes. The silver will thus be reduced to metallic globules, and will be obtained pure by digesting it in muriatic acid, which combines with the earth and alkali, but does not act on the silver.

2. The nitro-muriatic solution is now to be carefully neutralized by means of soda or of potash; and a solution of green sulphate of iron is to be added, as long as any precipitate is formed. The precipitate thus obtained is gold, and this being carefully collected, is to be fused in a small crucible with nitre just in sufficient quantity to cover its surface.

3. The residual liquor, after being decomposed by the carbonate of an alkali, and the precipitate being well washed, is to be digested in liquid ammoniac, to dissolve the copper. The ammoniacal solution being slightly super-
saturated with muriatic acid, a rod of zinc being introduced, will precipitate the copper in the metallic state.

Auriferous pyrites. It appears that iron pyrites of a bronze yellow colour in masses, or in stratified cubes, and hepatic pyrites, which are found in veins in primitive mountains, contain a quantity of pure gold, or of gold alloyed with silver, which is worth the trouble and expense of extracting it. A considerable proportion, not only of the American, but also of the Hungarian gold, is obtained from ore of this kind. The produce of the latter sometimes does not exceed a few grains of gold in the quintal, but occasionally the auriferous pyrites of the Hungarian mines yield not less than 450 ounces of gold in the quintal of the ore.

The following is the method of analysis to be followed in ores of this kind. The pyrites being reduced to powder, is digested in muriatic acid, occasionally adding a small portion of nitric acid, till every thing soluble is taken up. The residue, after being well washed and dried, is to be weighed, and exposed to a heat which is just sufficient to burn off the sulphur, the quantity of which is indicated by the loss of weight. The residue is again to be digested in nitro-muriatic acid, and this solution is to be added to the first. The earthy residue, which contains the silver in the state of muriate, is then to be fused with an equal weight of glass of borax, and three times the quantity of pearl ashes. By this process the silver is reduced, and may be separated from the alkali and the earth by means of muriatic acid very much diluted. The nitro-muriatic solution is to be neutralized by a fixed alkali, and if it be afterwards treated with nitrate of mercury prepared in the cold, the gold will be thrown down in the state of a brown powder. It may be reduced to the metallic state by fusing it with nitre. The oxide of iron which remains in solution, may be obtained in the usual way in the state of magnetic oxide.

Auriferous galena.—Galena, or the native sulphuret of lead, almost always contains a small portion of silver, and very often it is in such quantity as to be worth the trouble of extracting it. Galena sometimes has also combined with it a little gold as well as silver, and it is worked as one of the ores of gold. This is the case with some of the galena of Hungary, as that of Boicza yields 2½ oz. of alloy in the quintal, of which 31 parts are silver, and one of gold.

The analysis of auriferous galena is to be conducted nearly in the same way as the auriferous pyrites. The pulverised ore being digested in nitro-muriatic acid, the gold and the lead, and, if any are present, the iron and antimony, are taken up; leaving behind the earthy matter, as well as the sulphur and silver, which may be separated according to the method employed in the former process. By gradually evaporating the nitro-muriatic solution, a crystallized muriate of lead is obtained; and by again diluting the solution with water, the gold may be separated by adding nitrate of mercury.

The analysis of the ores of gold containing tellurium, will be given under the head of that metal.

Sect. II. Reduction of the Ores of Gold.

Many of the most profitable veins of gold are of trifling magnitude, but at the same time yield ample returns to the miner, although they are mixed with so large
large a proportion of stony matter and other impurities as would render the working of any other metal altogether unprofitable. This obviously arises from the great commercial importance of gold compared with other metals, which no doubt is owing as well to its rarity as to its peculiar properties. In the Hungarian gold mines, which are the richest yet known in the old continent, the attention of the miner is not merely limited to the strigils of ore, but to the whole contents of the vein, which are usually extracted and raised to the surface in large masses. These masses are distributed to the workmen, who break them down, first with large hammers, and afterwards with smaller ones, till they are reduced to pieces of the size of a walnut. In the course of this process, every piece is carefully examined, and arranged according to its value. The smallest visible grain of native gold is separated from the quartz in which it is chiefly imbedded, and put by itself. The auriferous pyrites and galena are also put into separate heaps; even the small splinters that are detached in breaking down the masses, and the sand and mud of the mine, are all collected, washed, and sifted, and ranged according to their apparent richness. What has been rejected in the first examination, is re-examined by boys, whose labour is not of great value, and who pick out almost the whole that has been overlooked by the men, and arrange it in the same manner.

The native gold with the matrix attached to it, is again to be broken by hand into still smaller pieces, by which means other impurities and stony matters are separated. The ore is then introduced into a wooden box floored with cast-iron plates; and by the action of two or more heavy spars of oak, which are shod with iron and alternately worked like the common stamping mill, it is reduced to a fine powder. This powder, which is called flour, is then removed into a vessel like a large bason, and is mixed with such a quantity of salt and water as will render it damp. The workman then takes a thin porous leather bag, introduces a quantity of mercury into it, and by a regular and continued pressure forces the mercury in very minute drops through the leather. In this divided state it falls upon the pulverized ore, and is immediately kneaded up with it, till the requisite quantity, which depends on the proportion of gold, has been added. After completing this part of the process, the next object is to incorporate the mercury and the gold. This is effected by rubbing the mixture together for some time by means of a wooden pestle. The mixture is then heated in a proper vessel, and subjected for three or four days, to the temperature of boiling water; and, lastly, the mixture is to be carefully washed by small parcels at a time, so that the earthy particles may be carried off by the water. The mercury combined with the gold, only remains behind, in the form of amalgam. A portion of this mercury is then separated by pressure in a leathern bag, and the remainder is driven off by distillation, leaving behind the gold, and silver with which it may be alloyed.

But a more complicated process is requisite in separating that portion of the gold which is invisibly dispersed in the pyrites, in galena, and other metallic substances, as well as the stony parts of the matrix. In the treatment and sorting already described, those ores are separated, not only according to their apparent richness, but they are arranged also according to the degrees of hardness. They are then carried to the stamping mill, of which the principal parts are, 1. The coffers or cisterns, in which the ore is reduced to powder, and through which a stream of water continually passes, and so managed as to be increased or diminished at pleasure: 2. The stampers, or vertical beams, which are shod with iron; and, 3. The axle, which is fixed horizontally, and one end of which works in a pivot, while the other is riveted into the centre of a large water wheel. The mode of action of this apparatus is obvious. A stream of water falls upon the wheel, and turns it round, as well as the axle to which it is attached. The cogs, which are fastened to the axle, alternately raise the stampers to a given height, and then let them fall upon the ore placed in the coffers.

And as the ore is sufficiently broken, it is carried by the stream of water continually passing through, out at the sides of the coffers into the labyrinths, where the stony and metallic contents of the ore are deposited, according to their specific gravity, nearer to or at a greater distance from the aperture. The coffer is a rectangular hole sunk below the level of the ground, and it is about five feet in length, two feet and sometimes less in width, and four feet deep. Five stampers are employed; they are strong oaken beams shod with iron, and weighing about 200 pounds each. They are placed side by side, at the distance of about 2½ inches from each other.

When the ore is to be pounded, the first thing is to cover the bottom of the coffer with a flooring or pavement, composed of large pieces of the hardest and poorest part of the vein. These pieces are to be close set together, and a floor of this kind is found to answer better than an iron floor. The thickness of the floor is to be proportioned according to the degree of hardness of the ore to be pounded; for it is obvious that the higher the floor is, the smaller will be the space through which the stampers fall; and their momentum will therefore be proportionally diminished. One precaution must be invariably observed, that the part of the floor immediately under the middle stamper be about two inches lower than that below the stamper on each side, and that this again be an inch lower than that beneath the two outermost stampers.

After the coffer is thus prepared, the machinery is set in motion, a small stream of water being allowed to flow into the coffer. The ore is to be carefully thrown in, just below the middle stamper, or the proper quantity is supplied by means of a hopper. The ore being thus broken down by the middle stamper, is gradually delivered to the stampers on each side, where it is still further reduced to powder, and from them it passes on to the two outermost stampers, where it is reduced to such a degree of fineness as to be for a time suspended in the water, and carried along with the stream through the openings at the ends of the coffer.

In stamping the ores of gold and silver, great attention is necessary, that no pieces of ore be subjected to the process that can be conveniently separated from the gangue by the hand; and that the ore be reduced to a coarse or fine powder, according to its nature. When native gold is dispersed in minute particles, in a hard siliceous matrix, it is found impossible to separate the whole of the metal, unless it be very finely pulverized; and in this case the ore may be reduced to fine powder, both on account of the great difference of the specific gravity of the two ingredients of the ore, and also because the siliceous particles, however minute, acquire no degree of tenacity, so as to adhere to the particles of gold. In
ORE

Gold

stamping ores of this kind, therefore, the coffers may be set very low, that the stampers may have the greater power, and a small stream of water only may be let in, that the current which passes out may carry with it only the smaller particles. But when the gold is dispersed in an indurated ochre clay, or in calcareous spar; if the ore in this case be not finely pulverized, a great proportion of the metal will be retained in the earthy matrix; and if the stamping be continued too long, the whole will be brought to a fluid mud, which will prevent the subsidence of the particles of gold. In the management of this part of the process, no small degree of skill and experience is requisite, to obtain the greatest produce of gold.

The reduction of the ore to grains of a uniform size, greatly facilitates the washing which follows the stamping, and yields a greater product of metal. This is effected by taking care that the ore, when first introduced into the coffer, shall fall under the middle stamper, and also by the velocity of the water wheel being properly regulated. When the motion of the stampers is too slow, loss of sol·ime is the only consequence; but when the motion is greatly accelerated, the water is violently thrown about, carrying with it to the apertures at the end of the coffer, pieces of the ore that are not sufficiently comminuted.

The ore being reduced to particles of a sufficient degree of fineness to be carried by the force of the water out of the coffer, passes into shallow channels of different dimensions. These channels or troughs, the whole series of which is called a labyrinth, are constructed of wood or stone, and communicate with each other at the extremities. The various parts of the ore are deposited in these channels, according to their specific gravities; the heaviest particles are detained in the first, and the lightest are carried along, and subside in the last and lowest. Each of the channels has a groove at its lowest extremity, and thus admits of being closed at pleasure by pieces of wood about an inch in height, which slide down upon each other. By varying the rapidity of the current through the channels, the heavy particles can be more accurately separated from the lighter ones, which is done by diminishing the slope, and increasing the width and length of the channels.

But it is of whatever care the first operation of the washing may be conducted, it is by no means sufficient to separate the whole of the sand from the ore. A second washing on tables, as they are called, is requisite. These tables are long wooden planes, which are considerably inclined, and are crossed at regular distances by narrow shallow grooves. A long wicker basket, or perforated wooden trough, filled with the washed ore, is fixed to the upper extremity of the table, and a small stream of water is admitted, which passing between the twigs of the basket, carries with it particles of the ore. These particles are either carried by the current off the table, or are deposited, according to their specific gravity, in the grooves, the heaviest particles subsiding with the first. In this way the auriferous ores of iron and copper pyrites, galena, &c. are sufficiently separated from the quartz and other stony matter, to be fit for the furnace; but for the ores of native gold, a third washing is necessary. This is performed in small quantities at a time, in a wooden vessel resembling in shape a common fire-shovel, without a handle, but having the sides more elevated, and being furnished with two ears, by which it is held during the operation. The ore is put into this vessel, which is gently immersed in water, and a circular motion is communicated to it by a peculiar dexterity, which can only be acquired by practice. By this motion in the water the lighter particles are gradually thrown out of the vessel, and scarcely any thing remains behind but the gold, which is either amalgamated or fused with the addition of a little nitre, in an earthen crucible. Here it may be added, that the separation of the gold which is found in alluvial soil, or in the sands of rivers, is conducted precisely in the same way, only that it is not necessary to be subjected to the process of stamping previous to washing.

The produce of the proper auriferous ores is seldom of sufficient value to admit of the same attention in washing as native gold; and therefore it is always found, after this operation, mixed with a considerable proportion of earthy matters. When the metallic part is composed of pyrites, which is frequently the case, it may be useful, previous to the fusion of the ore, to give it a moderate roasting, for the purpose of expelling the greater part of the sulphur; but it must be observed, that this process is to be regulated by the quantity, and refractory nature of the stony part of the ore; because the sulphur in the subsequent fusion acts the part of a flux, and therefore the cleaner the ore, the more perfectly it may be roasted. This part of the process being completed, a little quicklime, as a flux, is added, and carefully mixed with the ore, and a portion of galena, according to the proportion of gold and silver contained in the pyrites, previously discovered by assaying it. This mixture is next to be introduced into a reverberatory furnace, which is to be raised to a red heat; and when the mixture begins to clot together, it is to be stirred from time to time, and kept at a temperature inferior to that of fusion, till part of the sulphur is expelled; and when this is accomplished, the fire is to be increased, so that the whole may be brought to a state of thin fusion, after which it is let out in the usual way, and received in a mould of sand. During the process of fusion, the iron having a very strong affinity for sulphur, recombines with that portion of which it had been deprived by the roasting, in consequence of the decomposition of the sulphurets of lead and copper with which it is mixed; and these metals, by their specific gravity, fall down through the vitreous ferruginous scoria, and carry with them the gold and silver, with which they unite at the bottom into a dense mass of metal. Thus it happens that the pig formed in the mould consists of two parts, which adhere to each other, but may be easily separated by the hammer. The superior and larger portion, is a cellular mass of scorification, and the lower is a black, heavy, compact mass, containing the gold and silver, along with lead, copper, and a portion of sulphur and iron. It is again broken into pieces, and roasted and fused once or twice, till the whole of the sulphur and other impurities are separated, and nothing remains but the metallic substances.

In the further treatment of the ores of gold, the object of the refiner is to separate it from the metallic substances with which it is alloyed. We shall now mention the different methods which are followed in separating the metals from gold with which it is usually alloyed.

1. Separation.
1. Separation of gold from platain.—As platain, like gold itself, is not susceptible of oxidation by exposure to heat and air, it cannot be separated by the process of cupellation; and platain having as little affinity for sulphur as gold itself, that substance, or the sulphurised metals, cannot be successfully employed for this purpose. It has been found that mercury combines more readily with gold than with platain, and from the knowledge of this circumstance a method has been devised of separating these metals. When the proportion of platain is so large, that the mass is brittle, it must be reduced to powder in a mortar; but if it be ductile, it may be reduced to small pieces by granulation. A quantity of mercury equal to seven or eight times the weight of the alloy, is then to be heated in an iron crucible, and raised to the boiling point. The alloy being first made red hot, is to be dropped in, and the whole kept for half an hour nearly at the same temperature. The mixture is then emptied into an iron mortar, and being covered with hot water, is to be carefully triturated for some hours, the water being renewed from time to time. In this way the gold combines with the mercury, and a considerable proportion of the platain will rise to the surface of the amalgam in the state of a black powder, which may be easily scraped off. In this way the alloy is to be purified as much as possible, and the superfluous mercury may be separated by straining through leather, and the amalgam is deprived of the remaining mercury by the process of distillation. The gold, which still holds a small quantity of platain, is now to be melted with three times the weight of silver; and the mixture being granulated, is to be parted by means of nitrous acid. It has been found (although it be a singular circumstance) that pure platain, or even when mixed with gold, is perfectly insoluble in this acid; but, when combined with a large proportion of silver, it is readily dissolved, and the solution is of a dark yellowish brown colour; and, therefore, by digesting this triple alloy of gold, platain, and silver, in nitrous acid, the silver and platain are dissolved, and the gold remains behind. But it may be necessary to ascertain whether the whole of the platain be separated. This is done by melting a few grains of the gold, after careful washing, with three times their weight of silver, and treating it as before with nitrous acid. If it contain one half per cent. or even a smaller proportion of platain, the acid will be perceptibly coloured, and this being the case, the process must be repeated again on the whole mass. But this is rarely necessary when the previous trituration with mercury has been carefully performed. By adding to the remaining nitrous solution, a solution of common salt, the silver will be precipitated, leaving the platain in the solution.

By the following method, which is still more copious, gold may be separated from platain. The alloy is dissolved in nitro-muriatic acid, and the gold is precipitated by means of carbonate of soda, or a large quantity of green sulphate of iron, neither of which has the effect of decomposing the solution of platain. The precipitated gold being dried, and mixed with a little borax and nitre, is subjected to fusion, after which it will be found in a state of perfect purity.

2. Separation of gold from silver.—In ores in which the proportion of gold is small, the silver may be conveniently separated by means of sulphur. The alloy is first melted, and granulated, by pouring it into cold water, which is kept in constant agitation with a rod or wicker brush. From an eighth to a fifth of the granulated metal is reserved, and the remainder is carefully mixed with about one-eighth of its weight of powdered sulphur, which adheres readily to the moist grains. The mixture is introduced into a covered crucible, and kept for some time at a gentle heat, that the metal may be completely penetrated by the sulphur, after which the heat is increased till the whole mass is brought into fusion. This sulphuret of silver becomes a tough viscous fluid, which retains the particles of gold, and prevents them from subsiding. The mass being kept in fusion for about an hour, that the union of the sulphur and silver may be completed, and any excess may be burnt off, a third part of the reserved silver in grains is to be added, and when it is melted, is to be stirred with a wooden rod, that it may be accurately mixed with the other materials, and brought into contact with the gold, with which it immediately enters into combination. The fusion being continued another hour, a similar quantity of grained silver is to be added, and after a third hour has elapsed, the remaining third is introduced, and treated in the same manner. The crucible, which is now to be kept carefully covered, is to be exposed to a high temperature for three hours, while the melted mass is stirred from the bottom every half hour. At the end of this time the surface of the mass, instead of being dark brown, becomes whitish as the sulphur escapes, and some bright white drops of melted silver, about the size of peas, make their appearance. The fused mass is now to be poured into a greased cone; and when it is cold, it will be found to be composed of a mass of sulphuret of silver, resting upon a white metallic button, which is nearly equal in weight to the added silver, and contains the whole of the gold that originally existed in the entire mass. If it appears that any of the gold remains among the sulphuret of silver, it may be separated by fusion in an open crucible. By this process part of the sulphur is burnt off, and a corresponding quantity of silver is reduced to the metallic state, which being carefully mixed with the remainder, and repeatedly stirred with a piece of stick, the whole of the gold remaining in the silver, which is still sulphurated, will be attracted; and by being poured into a cone, will be collected at the bottom in a mass.

The silver containing the gold, which is collected in these two operations, being melted and granulated, is subjected to one or more repetitions of the same process, till the silver that remains is found to contain a sufficient proportion of gold, to render it worth while to proceed to the process of parting by means of aquafortis. The whole of the silver may be separated by means of sulphur; but when the proportion of gold is considerable, the sulphuret of silver always takes up a part of it, which cannot again be entirely separated without repeated fusions; and therefore, when the gold is equal to \( \frac{1}{7} \)th of the silver, a further purification by means of sulphur, will scarcely be found advantageous.

An ingenious and economical method of separating the gold from old gilt silver lace or wire, has been extensively practised in Saxony. This method proceeds on the principle, that the affinity of gold for copper, and of silver for lead, is much greater than the affinity which subsists between gold and silver; and it is con-
Gold. 

O R E S, 

Chap. II.

Gold.

The alloyed metal is first granulated, and \( \frac{5}{9} \) of it is mixed with \( \frac{5}{9} \) its weight of litharge, and \( \frac{5}{9} \) of sandiver. This is called the precipitating mixture. The next is mixed with \( \frac{5}{9} \) of powdered sulphur, and is brought into fusion, which being complete, as will appear from the flashing at the surface, \( \frac{5}{9} \) of the precipitating mixture is added at three different times, allowing an interval of five minutes between each time; and the fusion is then continued for ten minutes longer.

Part of the sulphurated silver is taken out with a small crucible made red hot, and the remainder being poured into the melting cone, a quantity of metallic silver combined with the greatest part of the gold, subsides to the bottom. The sulphuret of silver is again melted, and the remaining part of the precipitating mixture is added as at first, and thus a second portion of gold alloyed with silver is obtained. But as the sulphuret still retains a small portion of gold, it is to be fused a third time; and a precipitating mixture, equal in weight to the former, but consisting of an alloy of equal parts of copper and lead, is to be added, and thus a third precipitate of gold holding silver is obtained, and the sulphuret is now deprived of the whole of its gold.

The different metallic masses thus obtained, are melted with \( \frac{5}{9} \) of lead, then granulated, and treated in the same way as at first, with sulphur and the precipitating mixtures. The silver thus obtained being rich in gold, is first to be granulated, then mixed with \( \frac{5}{9} \) of sulphur, and kept in fusion for about half an hour without any addition; and being poured into a cone, the sulphuret is separated from the metal, and this last is treated two or three times more with sulphur, in a similar manner. The metallic button obtained, which now appears of a yellow colour, is to be melted with one sixteenth of copper, then granulated, and mixed with one sixteenth of sulphur; and the mixture being first gently heated in a covered crucible, and kept in fusion for about a quarter of an hour, is poured into a cone, at the bottom of which the gold is collected of a brass colour, and about eighteen carats fine. The purification is afterwards completed by means of sulphuret of antimony, a process which will be afterwards described.

3. Parting operation.—When the proportion of the gold and silver, alloyed together, is such, that the former is not much less than one sixteenth, or greater than one fourth of the whole mass, the operation of parting may be followed. In this method the gold is separated from the silver by means of diluted nitric acid, or, as it is termed by manufacturers, aquafortis, which dissolves the silver, and leaves the gold untouched. The button of gold and silver is prepared for this process by flattening with the hammer, again heating it red hot, and slowly cooling to anneal it for the purpose of increasing its malleability. It is then to be extended into a small plate as thin as a wafer, by passing it between rollers of polished steel, again heated, but only to redness, and last of all rolled up in the form of a small loose coil or spiral, called a cornet. The annealing is useful in allowing the metal to be rolled up without cracking, and at the same time the freer action of the acid, in consequence of the texture of the metal being somewhat opened.

The cornet thus prepared is introduced into a pear-formed matras, called a parting-glass, and three or four times its weight of pure nitric acid of 1.25 specific gravity are added; the mouth being slightly covered to keep out the dust, the glass is set on a sand bath, or over charcoal, to boil. As soon as it becomes warm, the acid begins to act on the silver, and dissolves it with the evolution of nitrous fumes. During the whole action of the acid, the cornet appears all over studded with minute bubbles, and when these discontinue, or run into one another, forming a few large ones, the action of the acid is nearly over. The process is usually completed in about fifteen or twenty minutes from the time that the acid begins to boil. The cornet now appears corroded throughout, and has lost during the solution the whole of the silver; and the remaining gold which is slender and brittle, retains the same spiral form. Indeed it is of considerable importance that it should not be broken, for much of the accuracy of the operation depends on having the gold in one piece and not in fragments.

The acid solution of silver, while yet hot, is next to be carefully poured off, and a portion of fresh acid, somewhat stronger, is to be added, to separate all the remains of silver; the boiling is to be repeated as before, but only for five or six minutes; it is then poured off, and added to the former solution, and the parting-glass is filled with hot distilled water, to wash off the remains of the solution.

The cornet, which is now of a brown colour and spongy texture, and has little of the metallic appearance, is taken out in the following manner. A small crucible is inverted over the mouth of the parting-glass, while it is yet filled with the distilled water, and the latter being rapidly inverted upon the crucible, the cornet falls softly through the water down the neck of the glass into the crucible, where it is deposited, and the water is carefully poured off. The crucible after being dried is next heated to redness under a muffle. The cornet contracts greatly in all directions, becomes a firm texture, and resumes its metallic lustre; and after being brought to a red heat and cooled, it exhibits the appearance of a cornet of pure gold, having all the splendour, softness, and flexibility of this precious metal. By accurate weighing, the amount of the product is precisely ascertained, and thus the operation of parting is completed.

But if the proportion of gold amount to one third of the mass, it combines with part of the silver, and protects the latter by its insolubility from being acted on by the acid, so that in the process of parting, too great a proportion of gold in the alloy must be avoided; and farther, as the acid is expensive, unless the silver be rich in gold, this process, which is in many respects convenient, will not be found economical. In reducing the fineness of the alloy which is too rich in gold to be advantageously parted by itself, it will be the object of the refiner not to employ pure silver, but such as contains a small portion of gold; and at the same time it will be his study to save the quantity of acid.

The following is the usual method of conducting the process of parting. After selecting a proper quantity of rich and poor ingots of mixed metal, the whole is to be fused in an iron crucible; and being well mixed by frequent stirring, it is to be removed by a clean iron ladle, and granulated in cold water. The parting-glasses, which are nearly of the form of a truncated cone with a rounded bottom, are about twelve inches high and seven inches wide at the lower extremity, and they should be of equal thickness, well annealed, and free from any kind of flaws. About forty ounces of metal are introduced into each glass, and the nitrous acid, half saturat-

exceed the gold, or be equal to it, the copper and lead may be entirely separated, while the gold and silver remain behind. From a knowledge of these facts, the refiners, in separating the base metals from gold, by the process of cupellation, add to the mixture a considerable proportion of silver. When the gold is alloyed with tin, cupellation with lead alone will not succeed, because the tin, with part of the lead, forms a spongy and refractory oxide, and floats on the surface of the fluid metal, and at the same time retains part of the gold. But as iron is found to combine with tin into an alloy that may be scorified by lead, the addition of iron filings during the process removes the difficulty.

The following table shows the quantity of gold which is got from the different countries of the old and new world, taken on an average, between the years 1790 and 1802.

**Chap. III. Of the Ores of Mercury.**

The ores of mercury present less variety than those of many other metals; and on account of its peculiar properties, the management of its ores, whether for the purposes of analysis or reduction, is less complicated and difficult.

**Sect. I. Of the Analysis of the Ores of Mercury.**

To analyze the ore of native mercury, or native amalgam, it is to be digested in nitric acid of moderate strength; the mercury and silver, and bismuth, will be dissolved, and if the ore should contain a minute portion of gold, it will remain untouched in the form of a brown powder at the bottom of the solution. The nitrous solution is next to be gently evaporated till it is so far concentrated as to be on the point of crystallizing. It is then to be poured into a large quantity of pure water, by which means the most part of the bismuth will be separated, and a solution of common salt, or any other neutral muriate, being added to the filtered liquor, the silver and mercury will be precipitated in the form of muriate. After this is separated, add to the clear liquor some carbonated alkali, while any precipitation takes place; then boil the liquor, and separate the precipitate by filtration. The muriatic precipitate is next to be digested in nitro-muriatic acid moderately diluted, which takes up everything excepting the muriate of silver, from which, after being washed and dried, the proportion of silver in the ore may be easily ascertained. The nitro-muriatic solution is now to be decomposed at a boiling heat, by a carbonated alkali, and the white precipitate thus obtained being added to the former carbonated precipitate, mix them with a little oil, or what answers better, sugar, and distil in a small coated glass retort. Raise it gradually to a red heat, and continue at that temperature while any mercury comes over. The residue in the retort consists of a little metallic bismuth and charcoal.

**Native amalgam.**—With the view of ascertaining the proportion of mercury and silver in this ore, Klapproth examined some of the garnet-like crystals from the quicksilver mines of Deux Ponts. Some pure crystals weighing 33½ grains were introduced into a barometer tube of a larger diameter than usual, and closed at the lower end. This end was placed in sand, within a small crucible; heat was applied, and its intensity gradually increased to the degree of ignition. After cooling, he cut off the lower end of the tube, and found that it contained the silver, which had undergone ignition in its former crystalline form, and weighing 12 grains. On collecting the mercury which had been sublimed in the tube, he obtained 21 grains. Therefore since the deficiency of one third of a grain may be reckoned as a loss of quicksilver, the following will be the proportion of the parts in 100 of this crystallized amalgam of silver.

</tbody>
</table>

**Cinnabar.**—The analysis of cinnabar may be conducted in the following manner. The ore being reduced to a fine powder, is repeatedly digested in a mixture of 1 part of nitric acid, and 3 of muriatic, moderately diluted, by which everything in the ore is dissolved excepting the silicious earth and the sulphur. The residue being washed, dried, and weighed, is subjected to a red heat, and the remaining silice being deducted, the difference of weight shews the amount of the sulphur. The nitro-muriatic solution is next to be decomposed at a boiling heat, by carbonated alkali, and the precipitate obtained being mixed with a little lamp-black, and distilled, the mercury passes over in the metallic form. The residue in the retort consists of magnetic oxide of iron, and any accidental earth excepting silice that is contained in the ore, together with a little charcoal, which may be separated in the usual way.

**Hepatic ores.**—The hepatic ores of mercury, and such as contain bituminous substances, may be treated in the same way; but these ores are sometimes combined with a little silver, and therefore the matter which remains undissolved in nitro-muriatic acid, may be muriate of silver, as well as sulphur and silice. When the sulphur is burnt off, the residue is to be mixed with twice its weight of pearl-ash, and being strongly ignited in an earthen crucible, diluted muriatic acid is added, by which the alkali and the earth will be taken up, and the
Chap. III.

Mercury. The silver will remain behind in the form of small metallic grains.

Cerous ore of mercury.—To analyze this species of mercurial ore, let it be digested in a little distilled vinegar, by which the native mercury which is dispersed though the ore will be left behind. Add to the clear solution nitrate of barytes, by which the sulphuric acid will be separated in the state of sulphate of barytes; and this being removed, drop in nitrate of silver, by which the muriatic acid will be separated in the form of muriate of silver. The mercury now remains in solution in the state of nitrate, and being precipitated by means of iron, it is afterwards washed in muriatic acid, and thus appears in the metallic state. It may also be reduced to the metallic state by precipitating by carbonated alkali, and distilling the precipitate with a little lamp black.

A simple and easy process is followed in assaying the ore of mercury in the dry way. The ore to be examined is first to be reduced to powder, and carefully mixed with one-fourth of its weight of quicklime, and an equal portion of iron filings. It is then to be exposed to a red heat in an iron or earthen retort, as long as any mercury passes over into the receiver.

Sect. II. Of the Reduction of the Ores of Mercury.

A very simple process is followed for reducing the ores of mercury. The following is the method practised at the celebrated mines of Almaden in Spain. The pieces of pure cinnabar are first selected and separated from the ore, to be sold to painters and manufacturers of sealing-wax. The rest is sorted into three parts, of which the first is the richest, and is broken into pieces of a moderate size; the second, containing a smaller proportion of metal, is broken into smaller pieces; and the third consists of the dust and smaller fragments of the other two. These are kneaded up with clay, and being formed into bricks, are carefully dried in the sun. The furnace which is used for extracting the mercury is built in an oblong form, and is divided horizontally by an iron grate, into an upper and lower compartment, and near its top it communicates with a series of aludels. In charging the furnace, a stratum of flat rough stones is placed on the grate, intervals between each of the stones being left for the passage of the fire. A bed of ore of the second quality is laid on the stratum of stones, and then a stratum of the ore of the first quality, after which another of the second kind, and last of all a stratum of the third kind, which has been made up into bricks. A few faggots are then thrown into the lower cavity of the furnace, and lighted up; and a gentle fire is to be kept up by occasionally adding faggots for eight or twelve hours, according to the previous state of the ore with regard to moisture. After the moisture is separated, which is known by the vapour ceasing to be exhaled, the fire-place is filled again with faggots, and by the time they are consumed, a sufficient heat will be communicated to the ore, to allow the combustion to go on, by means of the sulphur which it contains, without requiring any more fuel. In the course of the next two days, while the sulphur burns slowly away, the mercury rises in the state of vapour, and passes into the aludels, where it is condensed. When the whole of the metal is extracted, the scoria is taken out of the furnace, and the aludels are emptied of their contents. But besides the mercury, they are found to contain a quantity of black matter like soot. This matter is easily separated by spreading the whole about on an inclined table, so that the mercury may run to the lower extremity, where it is collected in a channel, and the impure sooty matter remains behind.

The method of extracting mercury from its ores now described, is advantageous, on account of the simplicity of the apparatus, and the smaller expence of fuel; but it would appear that a portion of the mercury remaining in the ore is lost. There is besides a considerable loss in throwing away the soot, after separating the running mercury on the tables, not only because many of the globules of the metal itself are thrown away, but also the calomel, and cinnabar, which are found to be in considerable proportion, are wasted. Hence it has been recommended as a more profitable method, 1. To separate the sulphate of ammonia, which, according to the examination of Prout, forms part of the matter deposited in the aludels, and then by mixing what remains, with 12 or 15 per cent. of quicklime, distil it in an iron retort, by which means the whole of the running mercury would be obtained, as well as that which is produced by the decomposition of the calomel and cinnabar.

A more improved process is practised at the mines of Deux Ponts, and Idria. The ore, as it is brought out of the mine, is carefully sorted by hand, and these parts that seem destitute of metal, are rejected. This process, although tedious and expensive, is found to be more advantageous than the other method of separating the cinnabar by washing, in which there is a great loss of metal. The ore being thus sorted, it is reduced to powder, and accurately mixed with one-fifth of quicklime, which has fallen to powder by exposing it to the air; but it ought to be observed that the quantity of quick lime is to be regulated by the proportion of cinnabar contained in the ore. The mixture being thus prepared, is introduced into iron retorts, which are capable of holding about 60lbs. weight. The retorts, to the number of 40 or 50, are fixed in a long furnace, and a glass receiver is attached to each, but it is not luted. A moderate heat is then applied for the purpose of driving off the whole of the moisture; and when this is done, the joinings of the vessels are to be closely stop with tempered clay, and a full red heat is to be applied, and continued for seven or eight hours, at the end of which time the whole of the mercury will be volatilized, and condensed in the receiver. By this process it is found, that 100lb. of the ore yield from 6 oz. to 10 oz. of metal.

Chap. IV. Of the Ores of Silver.

The ores of silver present a considerable variety. Sometimes it is found in the metallic state in masses of from 30lbs. to 40lbs. weight, but it is often combined with sulphur in the state of sulphuret; with other metals, especially antimony, arsenic, iron, copper, lead, and bismuth; or with acids, as the carbonate and the muriatic, forming the carbonate and muriate of silver. The analysis and reduction of these different ores, it is scarcely necessary to observe, must be conducted according to
Sect. I. Of the Analysis of the Ores of Silver.

When a silver ore is to be examined, and the only object in view is to ascertain the proportion of silver it contains, the operation is usually conducted in the dry way. The ore is first roasted and reduced to powder; it is then mixed with litharge in proportion to the earthy matter combined with the ore, and quickly vitrified. The mass thus obtained is again reduced to powder, and being mixed with black flux, is to be fused in a crucible, with a sufficient degree of heat. By this process the lead of the litharge is revived, and collected at the bottom of the crucible, carrying with it the whole of the silver, as well as some of the other metals which may be combined with the ore. The button thus obtained is to be subjected to the process of cupellation, with the requisite quantity of pure lead, and in this way the base metals are scorified, and the silver remains behind in a state of purity, or combined only with the gold, which many of the ores of silver contain in small proportion. The gold is to be separated by some of the methods which we have already described, in treating of the ores of gold. This operation, in which the object only is to ascertain, as in this case, the quantity of silver, is called assaying. In the examination of ores in this view, more assays than one should always be performed, that an accurate and nearly invariable result may be obtained.

But in examining metallic ores, it is always more satisfactory to ascertain the whole of the ingredients of which they are composed. We shall therefore proceed to give an account of the best conducted analysis of the ores of silver.

Conesous silver ore.—The following is the analysis of this ore by Klaproth.

"Upon 200 grains of the cornesous silver ore I poured three times their weight of pure nitric acid; but no action took place, either in the cold or in the heat of boiling; only a subtle brown red iron-oxide was separated, which, being washed off from the remaining ore, and dried, amounted to four grains. Caustic ammonia, added to the nitric acid employed, precipitated five grains more of iron. When it was afterwards mixed with muriatic acid, only a pale milky colour was produced, but no real cornesous silver ore deposited. It followed from this, that neither any free native silver, nor any portion of it mineralized by sulphur, had been contained in that ore. The born-silver, after treatment with nitric acid, was reduced by twice its weight of salt of tartar, and yielded 133 grains of reguleine silver.

1. For the purpose of finding out, more accurately, its constituent parts, I mixed 200 grains with 600 grains of the purest alkali prepared from tartar, and brought the mixture into the state of fusion in a glass retort, applying the necessary degree of heat. After refrigeration, I broke off the upper half of the retort, softened the fused mass, which was of a light-brown colour, with hot distilled water, filtered the whole, and edulcorated the residue.

2. This residue was then dissolved in nitric acid. The solution acquired a brown tinge, and the scum floating upon the liquor assumed the colour of bricks. When the argentous parts were completely dissolved, there remained 8\(\frac{1}{2}\) grains of a brown-red powder, which imparted a golden yellow colour to the aqua regia, with which it was digested, and left a white residue behind. This last consisted of born-silver, mingled with a slight portion of the gange, or matrix of the ore, and afforded, on reduction, two grains more of silver. Caustic ammonia precipitated from the yellow solution seven grains of oxided iron.

3. The nitric solution of the silver was precipitated by common salt; and the muriate of silver thus obtained weighed, after reduction by means of soda, 134\(\frac{1}{2}\) grains of reguline silver.

4. The fluid, left after the separation of the born-silver, had a pale-yellow colour, owing to a portion of iron; which, precipitated by pure ammonia, weighed five grains.

5. After this, I proceeded to examine the saline mass, dissolved in distilled water, and separated from the silver, after the cornesous ore had been fused with pure alkali. On saturating this mass with distilled vinegar, the solution was rendered turbid, and a loose white earth deposited, which, collected and dried, amounted to three grains and a half of argilaceous earth.

6. The alumina being separated, the solution was reduced to a dry salt by evaporation, and the alcohol, affused upon it, took up the acetate of pot ash. The neutral salt, which was left behind by this process, and which consisted of the mineralizing muriatic acid and the alkali employed, I dissolved in water, and obtained from it, by repeated evaporation and crystallization, 117\(\frac{1}{2}\) grains of muriate of potash.

7. In order to learn whether and in what proportion sulphuric acid, by some writers has been mentioned as one of the constituent parts of the cornesous silver ore, were really present in it, I again dissolved that salt in distilled water, and dropped into it liquid muriate of barytes. The mixture became turbid, exhibiting that appearance which indicates the presence of only a slight quantity of sulphuric acid. I continued to add the barytes, until no more turbidity appeared. The weight of the precipitate thus obtained was three grains: but, as in these three grains of sulphated barytes the acid cannot properly be estimated to be more than half a grain, I think this quantity is too trifling to be considered as one of the essential constituent parts of the cornesous silver ore. But if that half grain of sulphuric acid be estimated equal to 1\(\frac{1}{6}\) grain of sulphur of potash, and be subtracted from the above 117\(\frac{1}{2}\) grains of digestive salt, or muriate of potash, there will remain of the latter only 116 grains, in which the concentrated muriatic acid amounts to 42 grains. Therefore,

One hundred parts of this cornesous ore contain

96.75"
Upon 500 grains of bright, crystalline, red silver ore, most finely pulverized, I poured six times their quantity of a mixture of equal parts of nitric acid of 1.350 specific gravity and distilled water. The phial was kept for several hours in a low digesting heat, so that the agency of the acid would be but moderate. I then diluted the solution with water; caused it to boil; and, after the residuum had subsided to the bottom, I decanted the clear solution. Upon the remaining pulvulent ore, a quantity of nitric acid and water, equal to the preceding, was again added; and, in the same manner, proceeded with as at first. The ore appeared now to have been effectually decomposed; and for this reason the solutions, together with the residuum, were put on the filter, and the latter properly washed.

The filtered nitric solution had no colour at all, having been very much diluted by the water by which the residue had been edulcorated. I subjected it to evaporation to ¼th part, and found the bottom of the evaporating glass vessel, after cooling, covered with copious finely granular, resplendent, and heavy crystals of a gray white. To ascertain their nature, I proceeded, by a separate process, a quantity of a solution of the same red silver-ore, sufficient for this enquiry, and found that they were sulphate of silver. Being assured of this, I dissolved that sulphate by a proportionate quantity of water, assisted by heat, added it again to the nitric solution, and combined this last with muriatic acid, as long as any muriate of silver would precipitate; which, when collected, edulcorated, and dried, was found to weigh 39½ grains.

The fluid, from which the born-silver had been thus separated, was then reduced to a smaller bulk, by distillation from a retort. This concentrated fluid became turbid, and left another grain of muriated silver on the filter. At this time it contained no other foreign substance, except a considerable portion of sulphuric acid.

What remained undissolved by the nitric acid, consisted of an ash-gray, pretty loose, or flocculent powder, of 203 grains in weight. When this had been gently digested for half an hour, with a mixture of five parts of muriatic acid, mixed with one part of the nitric, and then diluted with half its quantity of water, there remained, after filtering, careful edulcoration, and drying, 65 grains; which were the sulphenuous contents of the ore. When this residue had been gently heated, the sulphur deflagrated, leaving 64 grains of muriated silver behind. This sulphur, therefore, consisted of 58½ grains.

After the filtered solution had been evaporated in part, it was poured into a large quantity of water. By management, a white precipitate immediately ensued, which being separated by the filter, edulcorated, and dried, and lastly heated in a porcelain cup, gave 133 grains in weight. But I could not find the least trace of arsenic in it, though I had subjected it to all the trials deemed proper for discovering its presence. On the contrary, it was manifest, that this precipitate wholly consisted of oxide of antimony, quite of the same nature with that which is produced when muriatic solutions of antimony are precipitated by water. On exposing it to heat, a small portion of moisture still evaporated, attended with a muriatic smell, which was hardly perceptible. When again put on a test, and mingled with a third part of charcoal dust, the coaly powder was slowly consumed, by burning, without any arsenical smell, and left behind it the metallic oxide, possessed of a gray colour, and partly blended, partly covered, with a quantity of fine, gray-white, shining, acicular crystals, or the flowers of antimony, as they are called. But when it was fused in a covered crucible with tartar and powdered charcoal, it was completely revived into reguline antimony, which being blown off with the bellows, a bead of silver was left, weighing half a grain.

The liquor also, from which the antimonial oxide was separated, contained free sulphuric acid. On this account, I put it into a retort, together with the nitric acid, from which the silver had been precipitated in the state of born-silver, by means of muriatic acid, and continued the distillation until, at this temperature, nothing more would pass over; but, on raising the heat, thick white vapours had begun to rise. The fluid left behind in the retort was found upon trial, to be concentrated sulphuric acid. Upon diluting this last with water, and subsequent affusion of muriated barytes, the sulphate of barytes from thence produced, amounted, after edulcoration and desiccation, to 194 grains.

Consequently, the constituent parts discovered by these researches are, silver, antimony, sulphur, and sulphuric acid.

Vitreous silver ore.—This has been also analyzed by Klaproth, according to the following method.

1. If ductile vitreous silver ore be fused upon a piece of charcoal, by the assistance of the blow-pipe, its sulphur is quickly volatilized, and a button of pure silver remains. But it is otherwise with the brittle ore: for the bead left after the evaporation of the sulphur is brittle, and cannot be purified by the addition of borax. However, if a little nitrate of potash be added to the red-hot bead, it will destroy the portion of baser metal which it contains, and then the borate of soda causes it to yield a pure button of silver.

2. One hundred grains of ore, previously levigated, were gently boiled in a sufficient quantity of nitric acid, diluted with an equal quantity of water. This operation was repeatedly performed, till the black colour of the powdered ore disappeared, and the insoluble portion had become of a loose texture, and had acquired a gray-yellow colour. When filtered and dried, this residue weighed 26 grains.

3. On adding a solution of common salt to the above filtered solution, which had assumed a pale-greenish colour, a copious precipitate of born-silver ensued, which, edulcorated and dried, gave 88½ grains. Four parts of this afforded three of silver, by fusion with soda.

4. The remaining solution was next combined with sulphate of soda; but neither any turbidness, nor any indication of the presence of lead, appeared. Upon this, caustic ammonia was affused to excess, and the gray precipitate, which then fell down, and which the volatile alkali could not again render soluble, weighed five grains. Urged by heat, it melted into a consistency like sap, at the same time that a weak arsenical smell was perceived. After this precipitate had been once more dissolved in nitric acid, the addition of soda caused it to yield a whitish yellow, alkaline sulphuret a dirty brown, and Prussian alkali a deep blue precipitate, liable to the attraction of the lodestone, after ignition. Therefore, it consisted of iron, with a slight trace of arsenic.
ORES, &c.

Chap. IV.

5. The proportion of copper, indicated by a blue colour, in consequence of the addition of ammonia, and which still remained in the solution, was but slight. For, after the solution had been saturated with sulphuric acid, polished iron immersed in it, was invected with so slight a coppery crust, that no copper to any amount could be collected.

6. Those 26 grains, which continued insoluble in the nitric acid (2), were digested in nitro-muriatic acid, till nothing appeared to remain but the mere sulphur. Its weight amounted to 13 grains; but after deflagration, it left behind it about one grain of quartzose matter of the mine.

7. From this it is obvious, that 13 grains, or one-half of the above 26 grains, were held in solution by the nitro-muriatic acid; and these were precipitated entirely in the form of a white powder, upon the affusion of 20 parts of water. When ignited, this precipitate assumed a yellowish colour; but there was nothing either of arsenic, or any other volatile substance, perceptible. By combination with soda, it became reduced to pure regulne antimony; which, as such, admitted of being blown off, without leaving any residue, in its usual form of a thick white smoke, adhering to the contiguous bodies in the form of needle-shaped flowers (oxide) of antimony. Those 13 grains of oxidized antimony are equivalent to ten grains of that matter in the regulne state.

For the analysis of some of the other ores of silver, we must refer our readers to the ingenious and elaborate Essays of the sagacious Klaproth, from which we have extracted what is given above on this subject.

SECT. II. Reduction of the Ores of Silver.

Although the ores of silver contain a larger proportion of extraneous matters than the ores of some other metals, the value of that metal being greater than that of many others, admits of greater expense in the processes employed for their reduction. The ores of silver are reduced either by fusion, or amalgamation.

Reduction of silver ores by fusion.—Native sulphuret of lead, or galena, commonly contains a portion of silver, and often in such quantity, as to make its separation from the lead a profitable undertaking. The proportion of silver contained in lead is very variable. The greatest produce of silver, which we have heard of, was got from the lead ore of Craven in Yorkshire, which amounted to 230 ounces of silver in the ton of lead. The mines of Cardiganshire yielded formerly 80 ounces per ton; the Durham and Westmoreland mines afford lead, from which 17 ounces of silver are obtained upon an average per ton. The lead procured from the mines of Islay, one of the Western islands of Scotland, yielded, we have been informed, 40 ounces per ton; and the average produce of lead at the refinery at Poullaonen, in Brittany in France, is above 39 ounces of silver per ton. The following is the process carried on at the latter establishment, for separating the silver from the lead.

After the lead has been extracted from the ore, the object of the refiner is to obtain the silver in a separate state, which is dispersed through the mass of lead. This is performed by the process of cupellation on a large scale, or refining, as it is usually termed. The floor of the reverberatory furnace, in which the process is conducted, is horizontal, and it is lined with wood ashes and sand mixed together, and well beaten, and formed into a shallow basin, which is the cupel. There is an aperture at one side of the cupel, which forms a right angle with the flue by which the flame from the fireplace passes into the cavity of the furnace. Through this aperture the lead, brought to the state of litharge, runs; and opposite to it there is another aperture by which a blast of air is admitted. The top of the furnace has a circular aperture directly above, and corresponds in extent with the cupel, which may be shut up with a frame work of iron filled with bricks. When the furnace is ready, the cupel is lined with hay, and is then charged with about 177 quintals of lead, in bars or pigs, through the circular aperture, and the cover being put on, the fire is lighted up. In the course of six hours, the whole of the lead being melted, and brought to a red heat, a blast of air is directed upon the surface of the lead, and the ashes of the hay, and other impurities are removed with a wooden rake. The blast being continued for half an hour more, the surface of the lead begins to be covered with a thick crust of oxide, which is scraped off, and is soon succeeded by another, but it is not till the surface has been cleared five or six times that the true litharge appears. When this is the case, the temperature is raised to a cherry red, and by the action of the blast, with the occasional aid of the workman, the litharge flows out through the aperture mentioned above. The intense heat volatilizes a considerable portion of lead, and so fills the interior of the furnace with vapour, that a person of experience only can discover what is going on in the cupel. At the end of 38 or 40 hours from the time that the fire is lighted, the contents of the cupel are reduced to about six quintals, and the litharge which comes over at this time is kept separate, because it contains a small portion of silver. At last the litharge ceases to flow, and the surface of the melted metal appears covered only by a thin pellicle. It then becomes gradually convex at the edges; the pellicle breaks up, and the surface of the metal appears quite bright. The blast is now to be turned off, the fire damped, and an aperture in the furnace, previously stopped with clay, is opened to admit a tin plate tube, through which a stream of water is poured into the cupel, in order to cool the metal rapidly, but it may be prevented from springing, which would be the case, if this precaution were not observed at the moment of congelation. But the silver thus obtained is still contaminated with a portion of lead, from which it is freed by a second cupellation, which is performed in a moveable cupel containing about 700 or 800 ounces, and is placed in a small reverberatory furnace, which being heated about three hours, is charged with silver of the first cupellation. After the fusion of the silver, a proper working heat is kept up for four or five hours, when the refining is usually completed. The loss of lead by volatilization during the refining process is estimated at about eight per cent. When the quantity of litharge produced is large, it is recovered into lead, by being returned into the reverberatory furnace, and treated in the same manner as the ore. This forms lead of the best and softest quality, because it is in a state of the greatest purity. And besides, the worrie that remain after the reduction of the ore, and the litharge, along...

ORES, &c.

427

Siver.

along with the old cupels, and the metallic soot which is deposited in the chimney of the furnace, are treated in a common blast furnace, and a considerable portion of lead is thus obtained.

A different practice is followed in the English refineries. A common reverberatory furnace, having the area perforated with a large oval hole to receive the cupel, is employed. The cupel is formed of six parts of well burnt bone ashes, and one of good fern ashes, mixed together, and moistened to a proper consistence. A quantity of this mixture is stirred to the depth of about two inches in an iron frame, which consists of a raised elliptical rim, with five broad bars rivetted to its bottom, so as to occupy nearly one-half of its area. The ashes are rammed down very close with a wooden beater, and particularly within the bars of the frame, as it is laid on a flat floor. More ashes are then added, and beaten carefully in, till the frame is quite full. By means of a sharp-edged spade, five inches square, a cavity is formed in the test for containing the melted metal, and at one end of the frame a semi-elliptical hole is cut through the breast, which latter is to be left of sufficient solidity and thickness. The test is now to be turned on its side, and dressed from all superfluous ashes adhering to the bottom, taking care that none shall be left flush with the bottom of the frame or cross bars, otherwise the test might be bulged, by fixing it at the bottom of the furnace. The rim being plastered with slaty or moistened ashes, the test is placed upon the supporting cross bars, and fixed firmly with wedges against the bottom of the furnace, the breast being next to the feeding hole. A moderate heat is now applied, and gradually increased till the test be red hot; and when it ceases to emit steam from the under side, it is sufficiently dry. This previous preparation being completed, the following is the method of operation as it is described by Mr. Snelter.

Lead previously melted in an iron pot is ladled into the test until the hollow part be nearly filled, the operator closes the feeding aperture, and increases the heat of the furnace until the surface of the lead is well covered with litharge; he then removes the door from the feeding hole, and with an iron rod, which has one end bent down at right angles about three inches, and made flat or chisel-shaped, scrapes the small gutter or channel until the litharge just flows into it; the blast from a pair of double bellows is then directed from the back part over the surface of the test, the litharge is urged forward, and flows from the gutter upon the floor of the refinery; the operation now goes forward, gradually adding lead as the escape of litharge makes it necessary, until the gutter is so worn down that the test does not contain more than an inch in depth of lead, the blast is then taken off, the gutter filled up with moistened ashes, and a fresh one made on the other side the breast; the test is again filled, though not so full as at first, and the operation carried on until this gutter also is worn down and the test contain from about 50 to 70 pounds of alloy. This quantity is run into an iron pot, and set by until a sufficient number of pieces have been collected to make it worth while to take off a plate of pure silver from them.

The quantity of alloy left in the working off each test must depend in a great measure upon the quantity of silver which by estimation it is supposed to contain. A sufficient quantity of lead should always be left in the alloy to make it fuse easily in the iron pot.

When the test is removed from the furnace and broken up, the litharge will be found to have penetrated to an inconsiderable but an equal depth in the ashes; that part not impregnated with litharge may be pulverized, mixed with fresh ashes, and again used for another test.

The operation of taking off the silver pure differs in no respect from the foregoing, only more care is observed in the working, not to suffer the escape of any metallic particles with the litharge, as that would occasion considerable waste of silver. As the process advances, and the proportion of silver to lead increases, the litharge assumes a darker colour, a greater heat becomes necessary, and at last the brightening takes place; the interior of the furnace, which during the whole of the process had been very obscure and misty, clears up. When the operator observes the surface of the silver to be free from litharge, he removes the blast of the bellows, and suffers the furnace to cool gradually; as the silver cools many protuberances arise on the surface, and fluid silver is ejected from them with considerable force, which falling again on the plate, spots it very fantastically with small globules.

The latter portions of litharge bring over a considerable quantity of silver with them; this is generally reduced by itself and again refined.

The litharge as it falls upon the floor of the refinery is occasionally removed; it is in clots at first, but after a short time as it cools it falls for the most part like slaked lime, and appears in the brilliant scales it is met with in commerce: if it is intended as an article for sale, nothing more is necessary than to sift it from the clots which have not fallen, and pack it in barrels.

If, on the contrary, it is intended to be manufactured into pure lead, it is placed in a reverberatory furnace, mixed with clean small-coal, and exposed to a heat just sufficient to fuse the litharge. The metal as it is reduced flows through an aperture into an iron pot, and is cast into pigs for sale. During the reducing, care is taken to keep the whole surface of the litharge in the furnace covered with small-coal.

In some smelt works, instead of a reverberatory furnace for reducing, a blast furnace is made use of, on account of the greater produce, but the lead so reduced is never so pure as that made in the wind furnace. The oxides of the metals, which require a greater heat to reduce than the lead, are in the blast furnace generally reduced with it.

The volatile oxides, as zinc, antimony, and arsenic, are mostly carried off by evaporation during refining; a considerable portion of the oxide of lead itself is carried off by evaporation, making the interior of the furnace so misty and obscure that a person unused to refining cannot see more than a few inches into it.

A considerable portion of these oxides is driven by the blast of the bellows through the feeding aperture, and would be dissipated in the refining-house, to the great injury of the workmen's healths; to prevent their ill effects, the arch or dome over the feeding hole is erected to carry the fume into the stack of the furnace.

We shall now describe the method of treating the
proper ores of silver, as it is conducted by Schreiber at
Allemont in France. These ores are native silver, and
the sulphuric of silver mixed with arsenical cobalt, py-
rites, iron ochre, clay, calcareous spar, and some other
earthy minerals. The silver being dispersed in very mi-
minute grains through the gangue, cannot be separated
from the stony parts by washing. After the ore is picked
by the hand, it is pounded dry in the stamping mill, and is
reduced to the consistence of coarse sand. Roasting,
previous to fusion, is not required; but the ore being
refractory, it is found necessary to employ a flux com-
posed of quicklime, scorice from a preceding fusion, and
slag from the iron forgies. To supply the proper quan-
tity of lead, powdered galena, with the litharge and
scorice furnished by the refinery, and with old cupels
ground to powder, is added to the ore in such propor-
tions that the lead, which is obtained by the fusion,
may contain two per cent. of silver, allowing 20 per
cent. of the lead at least to be lost by evaporation, or
combining with the scorice. After being properly mix-
ed, the materials are subjected to the heat of a powerful
blast-furnace, with alternate charges of charcoal.

The products of the fusion are lead combined with silver, a
black, compact, sulphureous, semi-metallic substance
which is called matt, and some scorice. The scorice
thus obtained is neglected, excepting a certain propor-
tion, which is reserved as a flux for the next parcel of
ore. But the matt, which is tolerably rich in silver, is
again melted with litharge, and the lead carries with it
almost the whole of the silver; and although this second
matt contain a portion of silver, it is not found worth
while to subject it to a second fusion. After refining the
lead procured by these operations, it is found to yield
about two per cent. of silver. The process of cupella-
tion is performed at a higher heat than usual, which it
is supposed is necessary by the presence of a small por-
tion of iron; but the consequence of employing this high
temperature is to increase the waste of the metal by eva-
poration; for instead of seven or eight per cent. it a-
mounts to no less than 20 per cent. And as every pound
avoided of the lead thus volatilized, contains from
six to ten grains of silver, the loss in this process is very
great. Perhaps it might be diminished by mixing a larger proportion of lead with the silver ore.

But other silver ores afford both lead and copper, and in
this case a more complicated operation becomes re-
quisite. In the first part of the process the poorest kinds
of silver ore, or such as contain but a small proportion of
copper and lead, and a great deal of stony matter,
are to be mixed with the poorer pyritic ores, or such
as contain little silver and copper, and a great deal of
sulphur and iron. A portion of scorice obtained from a
former process, and containing the oxides of lead and
copper, with some silver, is added to this mixture by
way of flux. The materials thus prepared being ex-
posed to heat in a blast-furnace, re-act on each other,
and enter into fusion. The stony matter is dissolved,
and the melted mass separates into two distinct parts, of
which the heaviest occupying the bottom of the furnace
forms about one-fourth of the whole mass. This is
called matt, and contains all the silver, with the greater
part of the copper, most of the lead, iron, and sulphur,
and generally zinc and arsenic. The slag which swims
on the surface, as being the lighter portion, consists of
the greater part of the sulphur, oxide of iron, and earthly

S, &c.  Chap. IV.

matte; the small proportion of lead and copper is not
worth the trouble of extraction.

To drive off part of the sulphur and other volatile
impurities, the crude matt obtained in the preceding
operation is roasted, and being mixed with one and a
half times its weight of a richer kind of silver ore, and
twice its weight of lead scorice, by way of flux, it is
again fused, and thus a rich matt is procured, which
may contain from nine to ten pounds of lead, from three
to four pounds of copper, and from six to seven ounces
of silver in the quintal, besides a quantity of scorice
which holds a little silver, and which may therefore be
successfully employed as a flux in subsequent fusions.
This rich matt being roasted, is mixed with half its
weight of litharge and scorice, in equal proportions, and
again subjected to fusion. The product of this fusion is
a quantity of metallic lead, containing from six to eight
ounces of silver in the quintal; a similar quantity of
copper matt, which contains from 30 to 40 pounds of
copper, and about four ounces of silver in the quintal;
and lastly a quantity of scorice, which contains from six
to 10 pounds of lead, and about 40 grains of silver in
the quintal.

The copper matt of the above operation is next roas-
ted, and fused with a quantity of lead and copper scor-
ice, and the product obtained is black copper, which
contains from 60 to 80 pounds of copper, and from five
to ten ounces of silver in the quintal. This black cop-

pe being melted with litharge and scorice, the most
part of the silver combines with the lead, and after one
or two fusions, the copper is entirely freed, not only
from the lead and silver, but also from the sulphur, iron,
and other impurities.

Liquation.—The affinity between lead and silver is
much stronger than the affinity between lead and cop-

per. In consequence of this affinity, lead and silver are
easily separated from copper, by being exposed to a
moderate heat. This process is called liquation or eli-

gation. When the black unrefined copper, or copper matt,
contains the proper proportion of silver for this opera-
tion, it is first used with lead or litharge, or with a
mixture of the two, and an alloy consisting of copper,
lead, and silver, is thus obtained. This is cast into
lumps, so that the metallic product shall be in the
form of round masses or loaves, which being set in a
furnace on an inclined plane of iron, with a small chan-
nel grooved out, are exposed to a moderate red heat.
By this process the lead melts, or, as it were, sweats
out of the loaf, and carrying the silver along with it,
on account of its stronger affinity for this metal, runs
down the groove, while the copper remains behind as a
dark red spongy mass. The lead containing the silver
being subjected to the process of cupellation, the latter
is obtained separate. But, in adopting this process, the
proportion of the three metals must be attended to. The
lead should not be more than four times the weight
of the copper, otherwise the alloy becomes so fusible, that
part of the copper will be melted and carried along
with the lead and silver; or, if too great a degree of
heat is applied, the whole loaf of liquation will be fused,
and the process must again be repeated. The pro-
portion of lead should at least be 2 to 3 times the quantity
of copper, otherwise a considerable proportion of it, and
also part of the silver, will remain in the loaf after heat-

ing. But as this process is now more rarely followed,
Chap. IV.

ORES, &c.

Silver.

we shall not enter into any further detail of the particulars connected with it.

Reduction of silver ores by amalgamation.—This process, by which silver ores are reduced, and which is now pretty generally followed in different parts of Europe, was first practised by the Spaniards in South America. The ores which are subjected to amalgamation, are such as contain only a small quantity of lead or copper; but it is of some importance that there should be a certain proportion of iron pyrites, and if this proportion be not naturally mixed with the ore, it is a good practice to supply the deficiency, by adding what is wanting to the dressed ore, so that the pyritical contents may, as nearly as possible, be in a certain proportion to the quantity of silver, which is to be ascertained by previously assaying a portion of the ore.

The ore being reduced to the consistence of coarse sand, is carefully mixed with common salt, in the proportion of eight or nine per cent. when the silver in the ore amounts to eight ounces per quintal; and when the latter amounts to 12 ounces, or even a greater proportion, from 10 to 12 per cent. of salt is to be added.

The next process is roasting the ore, in which about three quintals are spread on the floor of a reverberatory furnace, and subjected to a moderate red heat. During the roasting the ore is to be turned twice or thrice, that every part of it may be equally exposed to the heat. The first charge being withdrawn, an experienced workman knows by its appearance whether the proportion of salt be too little or too much, and, as may be required, more salt or ore is added to the unroasted parcel. When the whole of the ore is roasted, it is ground in a mill, passed through sieves, by which it is made as fine as meal, and is then prepared for the proper process of amalgamation. This is performed in the following manner. A number of small barrels, which are made to revolve rapidly on their axes by means of machinery, or fixed tubs, either open or covered, having in the centre of each an instrument resembling a chocolate mill, which may be turned rapidly by similar machinery. The tubs or barrels are filled about one-third with water, and afterwards a sufficient quantity of roasted ore and mercury, in nearly equal proportions, is introduced, so that the whole may be of the consistence of thin mud. The machinery is put in motion, and continued without interruption for 30 or 48 hours, according to the nature of the ore, when the amalgamation is completed. About a quarter of an hour after the agitation of the matter in the barrels has ceased, the greater part of it falls to the bottom, and is withdrawn by opening a hole made for the purpose. The earthy residue is carefully washed by small portions at a time, and thus a good deal of the amalgam which, from being very minutely divided, could not sink through and mix with the rest, is recovered. The earth, however, if originally rich in silver, still retains a small proportion. It is therefore dried, and being mixed with about 3 per cent. of salt, is again roasted, but at a higher temperature than at first; and the process of amalgamation being again repeated, the whole of the silver is extracted. The fluid amalgam is strained through a closely woven bag, and is thus separated into nearly pure mercury and a stiff amalgam; and the latter being subjected to distillation, the mercury is driven over, and the silver remains behind. The copper, which is combined with the silver, is separated by cupellation.

The process of amalgamation is thus explained. The greater part of the sulphur of the silver and pyrites is, by roasting, burnt off, and converted into sulphurous acid, which latter, as soon as it is formed, and assisted also by the affinity of the silver for muriatic acid, decomposes the common salt, forming a sulphate or sulphite of soda, while the muriatic acid combining with the silver, forms muriate of silver. In the amalgamation which follows, the mercury, being in great proportion, decomposes the muriate of silver, and is partly converted into calomel. Hence it appears, that the loss of mercury, which is sometimes very considerable in this process, arises, first, from the conversion of part of it into calomel; and, secondly, from the extremely minute division of another part, so that it is carried off in washing the earthy residue; but the proportion of the latter depends much on management.

By the following method silver may be separated from copper, according to Napion, without the expensive and complicated process of liquation. The mixed metal is melted; a quantity of sulphur is sprinkled over its surface, while the whole is stirred about with a stick by an assistant, so that the sulphur may combine with the copper into a matt, which floats above the metal, and is to be removed with a pair of tongs, previously moistening its surface with water, to make it solid. Another portion of sulphur is next to be stirred in, and, the second matt produced is to be removed in the same manner. This process being repeated a sufficient number of times, the greater part of the copper is converted into matt, holding a small proportion of silver, while the remaining copper, which retains the most of the silver, originally diffused through the whole mass, becomes rich enough to be sent immediately to the refinery. In treating the matt, it is first to be reduced to powder, mixed with common salt and quicklime, in the proportion of 12 per cent. of each, roasted for 10 hours, amalgamated as before; and after three successive roastings and amalgamations, the whole of the silver may be extracted.

Table of the quantity of Silver introduced into Commerce, taken at an average between the years 1799. and 1802.

CHAP.
ORES, &c.

Chap. V. Of the Ores of Copper.

The ores of copper are very various. This metal is found native, in the state of oxide, in the state of sulphuret, and in that of salt, combined with carbo nic, muriatic, phosphoric, and arsenic acids.

Sect. I. Of the Analysis of the Ores of Copper.

The analysis of the ores of copper, it is obvious, must vary, according to the nature of the substances with which they are combined; but as a great proportion of the ores of that metal are combined with sulphur or arsenic, when they are to be treated in the dry way, they are first roasted, for the purpose of expelling those substances. To effect this, the ore is mixed with about one half its bulk of charcoal powder, or fine saw-dust, and then subjected to a low red heat, on a flat tile or muffle, on which it should be thinly spread. The sulphur or the arsenic rises in fumes; and to accelerate the separation of these substances, the mixture should be frequently stirred, observing at the same time not to increase the heat to such a degree as to make the ore clot together, which is one of the objects in the use of the saw-dust or charcoal. When it appears that the fumes cease to rise, and the whole of the charcoal is burnt off, the part of the ore remaining is now in the state of oxide, but mixed with a quantity of sulphur or arsenic, which cannot be entirely separated by roasting, and with the earthy matters with which the ore was originally combined.

The next object is to reduce the oxides, thus obtained, to the metallic state; and in this process of reduction the oxide is exposed to a high temperature, in contact with some carbonaceous matter, and seceded from the air. It has been a common practice to add some alkaline matters by way of flux, to promote the fusion of the extraneous matter combined with the ore; but the experience and observation of more enlightened chemists have proved, that a portion of the metallic oxide is always dissolved by saline fluxes, so that by assays in the dry way with saline fluxes, a less proportion of metal than the ore really contains, is obtained from it. The loss, according to Klaproth, between the treatment of a copper ore in the dry way, and the same ore, in the moist way, amounted to no less than 9 per cent. To obviate this inconvenience, a flux is employed by some, composed of fusible glass, into which a large proportion of alkali and silica enters, without any metallic matter; or flour spar, lime, and particularly borax. By the latter, a thinner fusion of the vitrifying mixture, than by an equal quantity of any other substance, is produced, so that a smaller proportion of borax than of the alkaline matters answers all the purposes of a flux; and thus the loss of the metallic oxide, by solution, is less.

But in reducing the pure oxides, or the carbonated oxides of copper, the method which is attended with scarcely any loss, is by subjecting them in contact with charcoal, in a covered crucible, to an intense heat. It is indeed in this way that the reduction of roasted copper ores is conducted on a large scale; but as these latter contain sulphur, arsenic, iron, and other impurities, the process must be many times repeated before the copper is brought to a malleable state.

In reducing the sulphurated ores of copper, a button of metal, of considerable purity, may be sometimes obtained by means of a single operation. The tedious process of roasting is avoided by adding to the ore two or three times its weight of nitre, and projecting it into a hot crucible. When thrown into the crucible, a deflagration takes place, in which the sulphur is burnt, and converted into sulphuric acid, which unites with the potash of the decomposed nitre. The metal being now freed from the sulphur, is in a state of complete oxidation by the nitric acid, and may be reduced by adding a flux of tartar and pitch, or other similar matters, and applying a strong heat for a sufficient length of time. But it seems to be more advisable to separate the metallic oxide after deflagration. This may be done by washing the mixture, after which the oxide is to be reduced by the proper flux.

In the analysis of copper ores in the moist way, the metal is obtained separate in three states; either in the metallic state, in the state of black oxide, or in that of green carbonate. If a polished piece of iron be introduced into an acid solution of copper, it is immediately covered with a coating of shining metallic copper, which is owing to a part of the iron being dissolved by the acid, and a corresponding portion of copper being separated from the solution. The whole of the copper may be precipitated in this way, and at last the solution contains only iron. The precipitate, which is in the form of ragged filaments, may be washed, dried, and weighed, so that the proportion of the metal in the ore examined may be ascertained. It may be added, that the precipitation is greatly promoted, by boiling for a short time, especially towards the end of the process, which produces the separation of the last portions of the copper; and it should be farther observed, that a perfect separation of copper from iron is obtained only when the solution is made in sulphuric or muriatic acid, and not in nitric acid. The method of separating copper from silver has been already mentioned. It may be separated from lead, by adding sulphate of silver to the solution, by which an insoluble sulphate of lead is obtained, and the copper remains behind. To separate copper from antimony, the oxides of copper and antimony are digested with nitric acid; the copper is dissolved, and the antimony is left. By immersing a piece of metallic tin in the solution, copper may be separated from tin; for by this means the copper only is precipitated. Arsenic is separated from copper by dissolving in nitrous acid, and adding acetate or nitrate of lead, which produces an insoluble arseniate of lead, and leaves the copper behind. In case there should be an excess of lead, the addition of sulphate of soda will throw it down in the form of insoluble sulphate. When nickel is combined with copper, it is usually conjoined with iron. Ammonia precipitates all the three metals; but, when added in excess, redissolves the nickel and copper. To obtain the latter separate, supersaturate with muriatic acid, and introduce a poached piece of iron, by which the copper is precipitated, and the nickel remains in the solution.

To ascertain the quantity of precipitated copper obtained from the examination of an ore, it is to be washed and dried, put into a small crucible, moistened with a drop or two of oil, and covered with borax. Thus prepared, it is subjected to strong heat for a few minutes,
Chap. V.

ores, and a solid button of malleable copper is produced, which may be accurately weighed. But if the product of the analysis be in the state of green carbonate, which is obtained by adding carbonate of potash or soda to a solution of copper, the green precipitate, thus formed, is to be washed and dried at the temperature of boiling water. An hundred and eighty parts of this carbonate are equivalent to 100 of metallic copper. The quantity of copper obtained by analysis may be estimated also in the state of black oxide. If the green carbonate be boiled for a few moments in caustic potash, it shrinks and becomes a deep brownish black fine powder, which is a pure oxide of copper in its highest state of oxidation. One hundred parts of this oxide, after being well washed, and dried in a low red heat, for a minute or two, are constantly found to contain 80 parts of pure metallic copper.

We shall now give a few examples of the analyses of particular ores of copper.

Vitreous copper ore, or sulphuret of copper from Siberia.—The following is the mode of analysis of vitreous copper ore by Klaproth.

1. Upon 200 grains of the ore, coarsely powdered, moderately strong nitric acid was affused, which attacked and dissolved them with frothing and extraction of red vapours. The solution was clear, and the sulphur alone in the ore was left behind, floating in the fluid, in gray, loose flocculi, without any other residue; which indicated that no antimony was present. The sulphur collected on the filter was heated in a small crucible to inflammation, and it burned with its peculiar colour, without any trace of arsenic; yet leaving a slight portion of oxidised iron and siliceous earth.

2. The solution, which had a pure blue colour, was treated first with muriate, and then with sulphate of soda. But none of these, nor any other salt, rendered it turbid, or produced any other alteration; by which it appears, that this ore contains neither silver nor lead.

3. To determine, with proper accuracy, the proportion of the constituent parts, I repeated the examination in the following manner. Two hundred grains of the powdered ore were combined and heated with muriatic acid, to the degree of boiling. But as this alone manifested no action on it, I added nitric acid gradually, by drops, which exerted a strong attack in each instance. When the solution of the ore had been accomplished, I separated the fluid from the sulphur floating on the surface; and digested this last once more with a fresh quantity of muriatic acid, dropping into it some nitric acid, after which I collected it upon the filter. This sulphur, washed and desiccated, weighed 35.4 grs. out of which, after its combustion, 10 grain of siliceous earth remained; so that the true amount of sulphur was 37 grains.

4. The solution exhibited a glass-green colour. I divided it into two parts. Into one half polished iron was immersed, upon which the copper precipitated of a dendritical form, and pure metallic brilliancy. It weighed 78.4 grains, when washed, and immediately desiccated, in a moderate temperature.

5. In order to ascertain the proportion of iron contained in the ore, I combined the other half of the solution with caustic ammonia added to excess of saturation. The precipitated iron remained behind, in the form of a subtle brown mud, which, collected on the filter, desiccated and ignited, weighed three grains. But as the iron is contained in the mixture of the ore, not in this calciform state, but in the reguline, which last is to the first in the proportion of 3 to 4, these three grains of oxidated iron give 24 of metallic iron to be added in the computation.

Therefore, an hundred parts of the Siberian vitreous copper ore consist of:

Variegated copper ore.—This ore was analysed by Klaproth, in the following manner.

1. One hundred grains of the pulverized ore were subjected to gentle digestion with nitric acid, whose action upon it was but moderate. From the residue, the sulphur was driven out by combustion. This residue, when a second time digested with nitric acid, dissolved in it, leaving only a slight portion of a red oxide of iron. On examining the solution, first by common salt, and then by Glauber salt, it continued limpid and unchanged.

2. Upon 200 grains of the powdered ore, muriatic acid was affused, the mixture heated, and then combined in small portions with nitric acid. The solution, which was thus performed, had a brown colour while concentrated; but as soon as it was diluted with water, it acquired a green. The remaining sulphur was gray, tenacious, and spongy, and weighed 72 grains when dry. By slow combustion it left 35 grains, of which, after extraction by muriatic acid, five grains still remained behind. These lost one grain more of sulphur by burning, and the remaining four grains dissolved entirely in muriatic acid. Whence the quantity of sulphur amounted to 38 grains.

3. The muriatic solution was divided into two equal parts; and the copper was precipitated from one of them by means of iron. It amounted to 60.5 grains.

4. The other half was supersaturated with caustic ammonia, and the oxide of iron which fell down was collected. This, when moistened with linseed oil, and exposed to a low red heat, weighed 10 grains; which are equal to 74 grains of metallic or reguline iron.

Thus, in 100 parts of this variegated copper ore from Norway were found,:

In supplying the deficiency in the sum of weights of the copper, iron, and sulphur, from the hundred, by putting oxygen in the account, I mean to characterize this last as a constant constituent part of variegated copper ore, producing in it those variegated colours: in the same manner, as in steel, in copper pyrites, and other
other metallic substances, the beginning of their oxidation is indicated by a similar diversity of colours.

In the last-mentioned substances, however, the changeable colours are only owing to external causes; for which reason they present themselves only on the surface, when long exposed to air. On the contrary, the variegated copper ore is penetrated throughout its whole mass by the oxidizing principle. This corresponds with the deficiency of weight to make up the sum of the fixed constituent parts of the ore here analysed; whereas no such loss is observable in the vitreous copper ore, treated and decomposed by the same method. It is on this account also, that the action of the nitric acid is less strong, and the disengagement of nitrous gas is less copious, in the variegated than in the vitreous copper ore.*

Malachite, or carbonate of copper.—Klaproth analysed a Siberian ore of this species, according to the following process.

1. One thousand grains of compact reniform malachite, from the Turjim mines, on the Ural, were reduced to powder, and heated to complete redness in a small glass retort, connected with the pneumatic apparatus. Much carbonic acid gas was disengaged in this process, to the amount of 252 cubic inches, without reckoning that part which was absorbed by the water of the apparatus. This gas was entirely absorbed by lime water, at the same time that a proportionate quantity of carbonate or crude calcareous earth was produced. In the intermediate small receiver a moisture collected, weighing 78 grains, which, upon trial, proved to be pure water.

2. The pulverulent residue taken out of the retort appeared of a black colour, and weighed 716 grains. To serve for the following experiments, it was divided into four parts, at 179 grains each; and hence corresponding to 250 grains of rough malachite.

3. One hundred and seventy-nine grains of ignited malachite, combined with three times its quantity of black flux, were put into an assay crucible, without lining it, and covered with muriated soda. In this situation it was committed to the fire of the blast furnace, and when the coals had become red hot without the action of the bellows, it was kept melting for the space of 20 minutes. After cooling, it was observed that, in the broken retort, the whole mixture, under the covering of common salt, had run into an uniform, compact, and opaque mass, of the bright red colour of ordinary sealing-wax, and that no metallic button had been formed.

It follows from this, that there was not carbone enough present to take up entirely the oxygen of the metallic oxide. Therefore the copper has, by means of this small remainder of oxygen still united with it, been brought into the state of red oxide of copper; and, as such, it has diffused itself uniformly through the alkaline salt.

5. One hundred and seventy-nine grains of ignited malachite were mingled with three times their quantity of black flux, and one-tenth of powdered charcoal. When fused in this state, during 20 minutes, under a stratum of common salt, in an assay crucible not lined in the inside, they afforded a button of reguline copper, which had run well together, and weighed 1364 grains.

5. Another 179 grains of ignited malachite, mixed with thrice as many grains of black flux, and one-fifth part of their weight of colophony, and likewise fused for 20 minutes, under a cover of muriate of soda, in a crucible not secured by lining, yielded a well-melted button of reguline copper, weighing 138 grains.

6. The remaining 179 grains of ignited malachite were, like the preceding, melted during the time of 20 minutes, under a cover of common salt. But the assay crucible had previously been lined with powdered charcoal, and the malachite mingled with an equal weight of calcined borax, with half its quantity of white glass, and one-fourth part of colophony, or boil turpentine. By this process I obtained, indeed, a well-fused button of reguline copper; but with a considerable loss, as it weighed only 105 3/4 grains.

In order to discover more accurately the constituent parts of the malachite, I performed the following experiments.

7. One hundred grains of malachite, reduced to powder by trituration, were dissolved in nitric acid; which was effected without leaving any residue. The solution had a bright-blue colour, and was saturated to excess with caustic of ammonia; but the precipitate produced was entirely, and without turbidity, redisolved by the excess of the alkali. This shewed that the malachite here examined was perfectly free from iron, and similar admixtures.

8. I combined 100 grains of triturated malachite with a sufficient quantity of sulphuric acid, previously diluted with five parts of water, and accurately weighed together with the vessel. After the malachite had been wholly dissolved, which was effected gradually, and with a moderately strong effervescence, the loss of weight, occasioned by the carbonic acid gas that was extricated, was found to consist of 18 grains.

9. One hundred grains of the same powdered malachite were ignited, at a moderate heat, in a covered crucible. The black residue had lost 29 1/2 grains in weight. If from these be subtracted 18 grains for the carbonic acid, the remaining 11 1/2 grains of loss will consist of water.

10. And lastly, 100 grains, which had been dissolved in diluted sulphuric acid, and precipitated by zinc, yielded 58 grains of pure copper.

In consequence of these experiments, the Siberian malachite consists, in the 100, of,

| Copper       | 58 |
| Carbonic acid | 18 |
| Oxygen       | 12.10 |
| Water        | 11.50 |

106.00*

Muriate of copper.—This ore, when exposed upon charcoal to the action of the blow-pipe, gave to the flame a blue and green colour; the muriatic acid was soon driven off, and a metallic button of pure copper remained.

This ore of copper was examined and analyzed by Klaproth in the following manner. A portion of the ore being reduced to powder, and boiled with water, communicated no colour to the solution; and, with the addition of a solution of nitrate of silver, afforded a small quantity of a white precipitate which blackened

* Ibid. i

520

4
Chap. V.

ORES, &c.

Copper. in the day light. This experiment shows, that the proportion of muriatic acid is too small to give a compound soluble in water.

1. One hundred grains of the elutriated mineral dissolved readily and quietly in nitric acid assayed in the cold. The solution possessed a pure blue colour, and deposited a little of a brown iron ochre which, separated by filtering, weighed a grain and a half. It was then diluted with water, and treated with a nitric solution of silver. The precipitated muriate of silver, when edesulcorated, dried, and melted at a moderate degree of heat, in a silver pan, weighed 64½ grains.

One hundred parts of metallic silver yield by such combination 133 parts of muriated silver. But as this metal, to be rendered soluble in acids, takes up 12 per cent. of oxygen, these must be subtracted; so that of this increase of weight by 33 parts, there remain 20½ for the muriatic acid.

These principles being laid down, the above 64½ grains of muriated silver will fix the proportion of the muriatic acid, contained in 100 parts of the ore, very nearly to 10 grains.

2. That I might be sure of having completely separated the muriatic acid from the nitric solution of this copper ore, I added the nitrated silver in a small degree of excess; and this silver I afterwards threw down with muriatic acid, and filtered it off. Which done, the copper was precipitated in the metallic state, by means of a piece of polished iron immersed in the solution. It amounted to 57½ grains when collected and carefully dried.

The copper, however, is contained in the ore as an oxide. In this state its weight is increased 25 per cent. by the oxygen; which, for those 57.50 grains of metallic copper, just now mentioned, gives, by calculation, 14.38 grains.

Now, since what is deficient from the first weight of the ore employed is to be considered for the greatest part as its water of crystallization, and since those 1½ grains of ferrous oxide do not belong to the composition of the ore, the constiuent parts of the muriated ore of copper may be said to be in the 100 as follows:

| Oxide of copper | 73 |
| Muriatic acid | 10.1 |
| Water of crystallization | 16.9 |
| Total | 100.0 |

Phosphate of copper.—The following is the method of analysis adopted by Klaproth, in the examination of this ore.

1. Because this ore is very much intermixed with its quartzose matrix, I pulverized a portion of it, previously freed as much as possible from the stone matter, and ascertained the weight of quartz still united with it, by solution in nitric acid. The quartz amounted to 16 parts in 100 of the purified ore.

On this consideration, I weighed 116 grains of the powdered ore, and poured nitric acid upon it. The mixture became of itself moderately warm. When the solution, assisted by a little heat, was thoroughly brought about, and by means of filtration freed from the undisolved quartzy matrix, it showed by its pure sky-blue colour, that it contained no iron.

| Vol. XV. Part II. | 31 |

2. After the small portion of the predominant acid had been saturated with potash, I added to the solution dissolved acetate of lead, until no further precipitation took place. The precipitate was at first drenched for a while with weak acetic acid, then elixivated with water, and at last perfectly dried in a low heat. It weighed 138 grains.

That this precipitate was a combination of lead with phosphoric acid, of this I had myself assured by a previous experiment, made with another portion of the same fossil. It exhibited the phenomenon, which is peculiar to phosphated lead; namely, that under the blow-pipe it runs into a pearl, which in the very moment of fixation, rapidly assumes a garnet-like form with shining surfaces.

Upon another portion of that precipitate, half its weight of sulphuric acid, sufficiently weakened with water, was poured and digested with it. The clear fluid, which had been filtered off from the generated sulphate of lead, and contained free phosphoric acid, was first half saturated with soda, and, upon this perfectly neutralized with ammonia. By crystallization, it yielded microcosmic salt, or phosphate of soda and ammonia.

3. In order to discover the proportion of the phosphoric acid combined with those 138 grains of the precipitate mentioned before, I proceeded to the following experiment.

I burned pure phosphorus under a large glass-bell, dissolved the obtained dry phosphoric acid in water, passed it through the filter, and reduced it by evaporation, in a sand heat, to a smaller volume. When towards the end of this process, flames of phosphorated hydrogen gas appeared, I added nitric acid by drops till no longer any red vapours were disengaged.

Of this perfectly oxygenated unctuous liquid phosphoric acid, I diluted 100 grains with water, and neutralized the liquor with finely powdered white marble; of which 324 grains were employed. The mixture was evaporated to dryness, and the dry mass kept in a moderate red heat for half an hour. This ignited phosphate of lime weighed 256½ grains. In the 324 grains of marble employed in this experiment, the portion of lime, or pure calcareous earth, amounted to 198.20 grains, which, if subtracted from the above 256.50 grains, determine the quantity of the phosphoric acid in that calcareous phosphate to be 78.30 grains.

From these data, taken together, it now was rendered evident, that in those 138 grains of phosphated lead, which have been produced by the combination of lead with the phosphoric acid, constituting a component principle of the portion of the ore examined,—the concrete phosphoric acid amounts to 30.95 grains.

4. The remaining part of the solution, which yet contained the cuprous part of the ore, was first treated with sulphate of soda, to separate the small portion of lead it still held dissolved from a slight excess of acetated lead added in the process (2). Which done, it was mixed with a little of uncombined sulphuric acid, and a piece of polished iron put into it to precipitate the copper, which I found to weigh 54.50 grains. But as this metal is contained in the ore in an oxidized state, which requires 25 per cent. of oxygen; there must 68.13 grains be reckoned for the oxide of copper.

One
Arseniate of copper, or needle-shaped copper ore.—

This ore was examined by Klaproth, according to the following process.

"1. Under the blow-pipe, upon charcoal, this ore detonates, emits a white arsenical smoke, and runs into small reddish-gray globules, which, when again fluxed with borax, yield a pure regulus of copper.

2. A pure, massive specimen of this ore, weighing 50 minutes, in a moderate red heat. Its figure was not altered by the fire: but its dark olive colour was changed into a bright grass green, inclining to that of the asinik. Its weight was diminished by 1/34 grain.

3. Nitric acid dissolves it quietly in the cold, and the solution possesses an undefiled blue colour. By the addition of nitrate of silver, the mixture is not in the least rendered turbid. Acetate of barytes produces a precipitate which entirely disappears upon dilution with water. The effusion of dissolved acetate of lead, forms with this solution a white precipitate, which upon the charcoal emits arsenical vapours, and is reduced to metallic lead, when combined with an excess of ammonia, the precipitate falling down at first, is directly dissolved, no cloudiness left behind, and the deep-blue colour is restored to the liquor.

4. Also by the acetic acid this ore is gradually dissolved. Upon the evaporation of the solvent, a dark-green salt of a dendritic form remains behind.

5. One hundred grains of the accicular olive copper ore, which had previously been freed, by means of elutriation, from the admixed reddish iron ochre, soon dissolved in nitric acid, and without the application of heat. The solution, being accurately neutralized with carbonated potash, was combined with dissolved acetate of lead, until all precipitation ceased. The obtained precipitate, when edulcorated and dried in a raised temperature, weighed 133.4 grains.

6. To be more convinced that this precipitate was an arsenated lead, I drenched it with water, and digested it with half its weight of sulphuric acid. The liquor, separated by filtration, contained uncombined arsenic acid. I neutralized it with soda, and treated part of it with a solution of nitrate of silver. This produced a copious precipitate of arsenated silver, which possessed the brick-red colour peculiar to it, emitted arsenical vapours upon the charcoal, and was readily reduced to pure silver. The remaining part of the solution, when mixed with liquid nitrate of iron, afforded the common whitish precipitate of arsenated iron.

Now in order to ascertain, by means of a comparative experiment, the proportion of the acid of arsenic combined with the 133.4 grains of the above precipitate (.), I dissolved in water 100 grains of solid arsenic acid, and added to it a solution of acetated lead in small portions so long as any precipitate would appear. The arsenated lead then obtained weighed 297 grains after edulcoration and drying in a warm place. Hence it followed, that the quantity of concrusted acid of arsenic combined with those 133.4 grains of the precipitate, which the acid of arsenic contained in the ore had produced, must be estimated at 45 grains.

And to be more assured that all the arsenical acid had been separated from the nitric solution of the ore, I added a little more of acetated lead than would have been absolutely requisite. This was afterwards again precipitated as sulphate of lead, by adding sulphated soda, and filtered off. To the solution, thus freed from the last precipitate, I added uncombined sulphuric acid, and precipitated the copper, now disengaged from its mineralizing acid, by means of a polished piece of iron, in the metallic state. Thus I obtained of it 40.4 grains.

But since in the composition of the olive copper ore the copper is contained in the state of an oxide, it yet remained to discover the proportion of oxygen. To attain this end, I dissolved 200 grains of pure copper in nitric acid, diluted the solution with a sufficient quantity of water, and again precipitated the metal with a lixivium of caustic potash. The precipitate had a light blue colour; but after the mixture had stood a couple of days in a moderately warm place, that blue colour was changed into a brown. When separated by filtration, washed with a large quantity of water, and desiccated in a low heat, this precipitate amounted to 269 grains. Upon ignition it weighed only 250 grains, and appeared in the form of a very subtle, fully-black powder.

Therefore, because according to this experiment, copper acquires an increase of 25 per cent. of weight by combining with oxygen, it is obvious, that for the above 40.4 grains of metallic copper, we must put in the account 50.62 grains of oxidized copper.

In consequence of this decomposition, 100 parts of the olive copper ore contain,

| Oxid of copper | - 50.62 |
| Acid of arsenic | - 45. |
| Water of crystallization | - 3.50 |
| * 99.12 | * Ibid ii. 150 |

SECT. II. Of the Reduction of the Ores of Copper.

The processes employed for the reduction of copper ores in the large way are extremely simple. It scarcely ever happens, it has been remarked, that the same order in conducting the different reducing processes, even in cases where the quality of the ore is found to be the same, is observed at two works. The same remark, however, might probably be made with regard to other manufactories, where the same practical management being long established, and attended with ordinary success, its inconveniences or advantages are rarely investigated, with regard to the abridgement of labour, or the diminution of expense. We shall now describe the processes for the reduction of copper ores, which are followed in different places, by which our readers, who are interested in the subject, will be enabled to appreciate the advantages of each, or to suggest improvements of which they are susceptible; and with this view, we shall describe the operations for reducing copper ores which are followed in Cornwall, and in Anglesea.
Chap. V.

ORES, &c. 435

Copper. Method of reducing copper ores in Cornwall.—The ore is first broken to pieces, of the size of a hazel nut. This operation is known by the name of cobbet. The richer pieces of ore are then picked out by the hand. The next operation is roasting, which is performed in large reverberatory furnaces, 16 feet long, and 14 feet broad. The bottom of the furnace is composed of fire bricks, covered with sand, two feet thick. This sand becomes a semivitrified mass by the intense heat. The height of the chimney is from 40 to 50 feet, the draught of which is so strong, that the sulphur and arsenic, separated during the roasting, are carried almost entirely through it. The ore is introduced through a kind of funnel, and spread to the thickness of a foot over the bottom of the furnace. The fuel is placed at the anterior part of the furnace, so that the flame must pass over the surface of the ore as it is directed by the current of air towards the chimney. The ore is roasted in this furnace with a dull red heat for 12 hours, and is frequently stirred with an iron rake, to expose fresh surfaces to the flame.

The ore being sufficiently roasted, is carried to another furnace, nine feet long by six wide, where it is exposed to a fusing heat, without addition, except that of a little calcareous sand, when the slag does not rise freely. It is raked out at the end of every four hours, when it is of the consistence of soft dough, and is introduced into oblong moulds, a little water being sprinkled upon it, to make it sink down. The slag being raked off, a fresh quantity of calcined ore is introduced into the furnace, and the copper is tapped off by a hole in its side, which had been stopped up with wet clay mixed with one-fourth part of new coal, which prevents the clay from becoming so hard as to render it difficult to open the hole by means of an iron pick. As the rough copper flows from the furnace, it is conducted by a gutter into a large bucket, suspended by chains in a well, through which a stream of water is passing. The metal, as it falls into the water, is granulated, without explosion or danger, and is afterwards taken out by raising the bucket.

But in this state the copper is very impure, being quite brittle, and mixed with arsenic and sulphur, which can only be separated by other processes. For this purpose it is again melted, and granulated two or three times. Each time a slag is thrown up in the furnace; but as it contains some copper, it is not, like the first slag, rejected, but worked over and over again with new charges of calcined ore. The nature of the ore must determine the number of fusions and granulations. After the granulation, the mass is melted and cast into pigs, which have a blistered appearance on the surface. These are again broken up, and melted and roasted several times, by which the metal becomes purer, and is then cast into iron moulds, after which it is carried to the refining furnace; and being again melted with the addition of some charcoal, it is brought to such a degree of purity as to bear the hammer, and be fit for the market. In this way, by repeated calcination and fusion, the common ores of copper are freed from arsenic, sulphur, and earthy matters, and brought to the metallic state. Here it is proper to add, that where there is variety of ores, no small degree of judgment is requisite in sorting and distributing them for the furnace, that the more fusible ores being mixed with such as are more refractory, will render the poorer ores, by the addition of a portion of the richer, worth the working.

Method of reducing copper ores in Anglesea.—The ore, which is the sulphuret of copper, is broken into small pieces, and exposed to heat in a kiln, which is close covered. A little fire is applied to the mass of ore in different places, by which the whole is gradually kindled. The kiln is furnished with flues, which open into a long, close, pent-house gallery, for the purpose of collecting the sulphur, which rises in the state of vapour to the top of the kiln, passes through the flues into the long gallery, where it is slowly condensed, is afterwards taken out, and farther prepared for sale. The mass of ore, after it is once kindled, burns of itself for about six months, and in this time the sulphur chamber is four times cleared out. The improved sulphur chambers are constructed in the form of lime kilns, having the ore at the bottom, and the sulphur subliming at the top. The richer part of the roasted ore is exported without being subjected to any other preparation, but the poorest part is melted on the spot, and contains, besides a great deal of sulphur, many other impurities. The smelting houses consist of a range of large reverberatory furnaces, having chimneys above 40 feet high, thus producing a very strong current of air. Thirty one of these furnaces are arranged side by side under the same roof. The fuel, which is coal, is burnt on a grate at the anterior part of the furnace, and the flame is carried over the ore placed on the bottom of it, by the draught of air. Twelve hundred weight of roasted ore is introduced into the furnace, mixed with a small portion of coal dust. Here the ore is melted, and brought to an impure regulus, and when it is sufficiently fused, it is drawn off into earthen moulds. Each charge of the furnace is worked off in about five hours, and yields about half a hundred weight of rough copper, which after being farther purified, affords about 50 per cent. of pure metal.

In reducing copper ores at Neusol in Hungary, lead is employed in the refining part of the process. The rough copper is spread out on the rough bed of a furnace, and after being six hours in fusion, a quantity of lead, in the proportion of from six to eight per cent. of the copper, is thrown in. This immediately begins to vitrify, and form a thick scoria, along with the impurities of the copper. The scoriae are successively removed, till the whole is separated, and the copper is purified. The scorize retain a portion of the copper, and are employed in a future operation. The process continues from ten to twelve hours, with fifty quintals of raw copper.

Some of the fine copper ores contain such a proportion of silver as to render it worth while to extract the metal. In the different roasting and fusions which are employed to bring the copper to a state of purity, the silver always remains combined with it, so that it must be separated by another process. The method of separating silver from copper has been already described, in treating of the reduction of the ores of silver.

The springs which are found in copper mines, or flow from rocks which afford copper ores, are often so strongly impregnated with blue vitriol or native sulphate of copper, as to yield a considerable quantity of this metal. It is obtained by the following process. Large, square open pits, are formed of rammed clay, two or three...
three feet deep. Into these pits the vitriol water is pumped; a quantity of refuse iron is thrown in, which being allowed to remain for a considerable time, the iron is dissolved by its stronger affinity for the acid, and the copper being separated, is precipitated in the form of brown mud. After the water appears to be exhausted of the copper, the oxides of copper collected at the bottom is raked out, and being dried in the sun, may be reduced in the usual way. This material which is the richest employ'd in obtaining metallic copper, yielding fifty per cent. although contaminated with some iron and clay, is rarely smelted, excepting along with the poorer ores, some of which do not afford more than five per cent. of pure metal.

The plates of copper of a fine red colour, usually known by the name of rouette copper, are made by a particular management. When the metal is found to be in a state of sufficient purity, the surface while in fusion is well scummed, and allowed to cool till it is just ready to fix. At this time the workman brushes it over with a wet broom, by which the surface is immediately fixed, and a thin plate is separated from the metal below, which is still in a fluid state. The plate thus produced is taken off and thrown into water, where it becomes of a high red colour. The same operation is repeated and continued successively till the whole of the fluid metal is converted into thin irregular plates of the above description.

Chap. VI. Of the Ores of Iron.

The ores of iron, which present a considerable variety, are reduced, on account of the refractory nature of this metal, with no small difficulty. The most powerful agents must be employed for this purpose. And as the construction of furnaces is a matter of the greatest importance in the smelting of iron ores, we were led, when treating of that subject, to enter into a pretty full account of the processes themselves; to this account the reader is referred for information on the methods followed in the reduction of these ores. The present chapter therefore will be only occupied in giving an abridged view of their analysis.

Sect. I. Of the Analysis of Iron Ores.

Native Iron.—In analysing this ore, it may be dissolved in diluted nitric acid; the lead may be separated by adding sulphate of soda, thus forming an insoluble sulphate of lead; the oxides of iron and copper may be precipitated by means of caustic fixed alkali at a boiling heat; the addition of caustic ammonia will dissolve the copper, and the iron will remain behind.

Pyrites.—Iron pyrites is either magnetic, or is destitute of this property. When the ore is magnetic, it may be either proper magnetical pyrites, or common pyrites with a mixture of magnetic iron, either in the metallic state, or in that of black oxide. If the magnetism be owing to black oxide mixed with common pyrites, no hydrogen gas will be produced by digesting it in muriatic acid; and if metallic iron and pyrites be combined together, the gas obtained will be hydrogen gas: but if the ore examined be magnetic pyrites, the gas evolved by muriatic acid will be sulphurated hydrogen. The following analysis is applicable to both species of pyrites. 1. After reducing the pyrites to a very fine powder, let it be digested in nitric acid of moderate strength, and boiled almost to dryness; then add a fresh portion of acid, and repeat this process till the whole sulphur is converted into sulphuric acid. 2. Pour off the liquor, edulcorate the undissolved residue, and add the washings to the liquor. 3. Add to this carboxate of soda to a slight excess, and separate the precipitate, if any take place. 4. After neutralising the residual liquor by a little nitrous acid, it may be decomposed by muriate of barytes, which is to be added while any precipitate takes place. A hundred parts of this precipitate indicated 14.5 of sulphur in the ore. 5. The insoluble residue (2.) is next to be digested with caustic soda, and being evaporated to dryness and slightly ignited, the precipitate (3.) is to be added, and the whole dissolved in muriatic acid, and boiled nearly to dryness. By the addition of water the silica will be left in the state of a white insoluble powder. 6. Mix the muriatic solution with ammonia in slight excess, and the aluminas and oxide of iron will be precipitated together, leaving the lime, if there should be any, in the solution, from which it may be obtained in the state of carbonate, by a mild alkali. 7. The iron and alumina may be separated by boiling in nitric acid, which leaves the metallic oxide untouched, or by digestion in caustic potash or soda, which produces a similar effect.

Magnetic Iron Ore, Specula Iron Ore, and Red Iron Ore—are composed chiefly of oxide of iron, with an accidental quantity of silica and alumina. These ores are with difficulty acted on by acids alone. In conducting the analysis, therefore, 1. The ore is to be reduced to a fine powder, and heated in a silver crucible, with caustic soda in solution. When the whole moisture is evaporated, the remaining matter is to be ignited to a low degree for a few minutes; next dissolve the whole contents of the crucible in diluted muriatic acid; evaporate the solution nearly to dryness, and boil the residue in distilled water, acidulated with a little muriatic acid, and the silica will remain behind undissolved. 2. The solution being considerably reduced by evaporation, add caustic soda to a slight excess; and boil it upon the precipitate which is thus obtained. This precipitate, after being edulcorated, is pure oxide of iron, and being heated with a little wax, it may be brought to the state of magnetic oxide, one hundred parts of which indicate seventy-three of metallic iron. In this way the quantity of iron in the ore may be estimated. 3. The alkaline solution contains the alumina, which may be separated by muriate of ammonia, and after being washed and ignited, its quantity may be ascertained.

Black Iron Ore, and Brown Iron Ore.—Besides the ingredients contained in the former species, these ores are combined with a portion of manganese; the precipitate obtained, therefore, is a mixture of the oxides of iron and manganese. These oxides may be separated by dissolving them in muriatic acid, and adding to the hot solution caustic soda, drop by drop, till the liquor becomes colourless, or till the precipitate thrown down at each addition of the alkali begins to be white. In this way the oxide of iron is precipitated, while that of the manganese remains in solution. The iron being removed, the oxide of manganese may be obtained, by continuing the addition of soda till no further precipitate is produced. The two oxides may also be separated by adding succinate
Chap. VI.

Succinite of soda to the muriatic solution, by which means the iron is precipitated, and the manganese remains in solution.

1. Digest the ore, being twice or thrice digested in muriatic acid. The muriatic solutions and washings, being mixed together, are to be concentrated by evaporation, and decomposed at a boiling heat, by adding caustic soda in excess. 4. Boil the precipitate and supernatant fluid together for a short time, the alumina only will be dissolved. 5. The insoluble portion is next to be washed and ignited, and being once abstracted with nitric acid, the lime, barites, and magnesia, will be dissolved, leaving behind the oxides of iron and manganese. 6. To separate the oxides, digest the mixture with a gentle heat in diluted nitric acid, with the addition of a small bit of sugar; the manganese is dissolved, and the remaining oxide of iron may be brought to the magnetic state, by heating it with wax. 7. The nitrate of manganese may be precipitated by carbonate of soda, and after washing and drying it at a heat below redness, pure carbonate of manganese is obtained, one hundred parts of which indicate fifty-five of metallic manganese. 8. To the nitric solution (4.), a good deal diluted with water, add sulphuric acid as long as any precipitate is formed. The sulphate of barites thus obtained being removed, the other earths may be thrown down by means of the carbonate of an alkali; they are again dissolved in diluted sulphuric acid, and the sulphates of lime and magnesia thus produced; being precipitated by alcohol, may be separated from each other by cold water. In this way the sulphate of magnesia is dissolved, with only a very inconsiderable quantity of the sulphate of lime.

Argillaceous iron ore, bog iron ore, blue earthy and green earthy iron ores, are chiefly composed of the oxides of iron and manganese, phosphate of iron, silica, alumina, and lime. The analysis of these ores may be conducted according to the following process. 1. After the ore is reduced to powder, and ignited, abstract it two or three times with nitric acid; pour off the acid, and wash the residue with a small portion of strong nitric acid. 2. Add the acids together, evaporate nearly to dryness, wash the residue with cold water; the phosphate of iron remains behind. 3. Ignite the insoluble residue (1.) with caustic soda, and separate the silica as in a former analysis, by muriatic acid. 4. Mix the nitric and muriatic liquors, boil them with an excess of caustic soda, and the alumina will be dissolved, while the metallic oxides and lime are precipitated. 5. After ignition, abstract the compound precipitate with nitric acid; the lime is now dissolved, and nothing remains but the oxides of iron and manganese, which may be separated according to the preceding analysis.

Arseniate of Iron. — This ore is found to contain oxides of iron and copper, with arsenic acid, besides a portion of silica, and sometimes lime. It was analyzed by Mr. Chenevix, according to the following process. Being reduced to powder, and subjected to less than a red heat, the water of crystallization is driven off; the residue is next boiled with caustic potash, and the alkaline solution being separated by filtration, is to be neutralized with nitric acid. The addition of nitrate of lead affords a precipitate of arseniate of lead, one hundred parts of which indicate thirty-three of arsenic acid. Muriatic acid is next to be added to the residue, which is insoluble in potash; the iron and copper are thus dissolved, and the silica remains behind. By supersaturating the muriatic solution with ammonia, the oxide of iron will be precipitated, and the oxide of copper will remain in solution by the alkali.

But, for practical purposes, we shall give a short view of the simpler methods of assaying the ores of iron, which are chiefly employed in manufacture, with the view of ascertaining the quantity of metal to be obtained from them, when treated in the large way. Among the older metallurgists it was usual to employ active saline fluxes in assaying the ores of iron; but as the metallic part of the ore can only be brought into fusion at a very high temperature, the same degree of heat effects the vitrification of the earthy matters, which, aided by lime and bottle glass, so that the use of borax, or alkaline salts, which are more expensive, may be dispensed with.

To assay the richer varieties of magnetic iron ore, particularly iron sand, reduce them to a fine powder, add one-twelfth of charcoal, or double the quantity of fine saw dust, and expose the mixture in a covered crucible for an hour to the heat of a powerful wind furnace. After this the iron will be found at the bottom of the crucible, in the form of an irregular button, and covered with a small portion of cellular scoriae. This process will be sufficient where the quantity of earthy matter is small; but as the common magnetic iron ore contains a considerable portion of silica, a flux of the following materials may be necessary. For every eight parts of ore take eight of bottle glass, six of limestone or chalk, and one of charcoal; mix the whole carefully together with the ore, and expose the mixture to heat, as in the former case. If the operation have succeeded, a button of iron will be found at the bottom of the crucible, covered by a compact, vitreous, greenish slag.

As the specular iron ore generally contains a portion of sulphur, from the admixture of pyrites, it must be roasted at a moderate red heat, till the sulphureous odour is no longer perceptible; then to eight parts of the ore, add eight of bottle glass, six of chalk, and one-twelfth of charcoal, and treat the mixture as before. The red, brown, and black iron ores, may be assayed in the same way.

Sparry iron ore may be assayed without roasting, by reducing it to powder, and placing it in a crucible lined with a mixture of charcoal and clay, and then covering it with about one-fourth of its weight of calcined borax.

In assaying argillaceous and bog ores of iron, they are first to be roasted, and then mixed with eight parts of bottle glass, seven of charcoal, and one and a half of charcoal, to eight parts of ore, and subjected to fusion in an unlined crucible. It is scarcely necessary to observe, that the proportion of chalk may be diminished in treating...
O R E

S, &c.

Lead.

To assay galena in the dry way, it is to be mixed after roasting with three times its weight of black flux, covered with salt, and melted. A button of lead will be found at the bottom of the crucible, but the silver and other metals which existed in the ore, are still combined with the metallic lead.

Sulphuric of lead, antimony and copper.—An ore of this kind was analysed by Mr Hatchett, by the following process. Two hundred grains of the ore were heated in a matras, with two ounces of muriatic acid, and nitric acid was very slowly added, till the whole exhibited a moderate effervescence. Being gently heated for an hour, the solution assumed a green colour, and a quantity of sulphur which floated on the surface, being collected, digested separately with a little muriatic acid, and washed and dried, weighed thirty-four grains; and as it burnt entirely away without any residuum, in a red earthen cup, it was perfectly pure. The solution with the muriatic acid, in which the sulphur had been washed, was first boiled, and afterwards mixed with six pints of boiling distilled water, to which it communicated a milky appearance. It was filtered while hot, and the filter washed with another portion of boiling water. The white precipitate, which was oxide of antimony, was dried in a sand bath, and weighed sixty-three grains.

When the liquor with the washings-cooled, some crystals of muriate of lead were deposited. The liquor was afterwards evaporated nearly to dryness, and a few drops of sulphuric acid were added, to separate the lead which remained in solution. The residue being again dissolved in boiling water, was entirely decomposed by sulphate of soda, and the sulphate of lead thus obtained being added to the former portion, was washed and dried on a sand bath. It weighed 120 grains.

The liquor, which was now bluish green, assumed a deep blue colour by the addition of ammonia; a small portion of the oxide of iron was separated, which, when dried and heated with wax, became magnetic, and amounted to 2.4 grains. The liquor, after being evaporated nearly to dryness, was boiled with a strong solution of potash, till it was nearly dry, and the residue being washed with water, a black oxide of copper remained; which, after being dried, weighed thirty-two grains.

White lead ore, or carbonate of lead.—The white tabular lead ore, from Leadhills in Scotland, was analysed by Klaproth, according to the following process.

1. One hundred grains of it, in pure specimens, and previously triturated to a powder, were by small portions introduced into a mixture of 200 of nitric acid with 300 grains of water, and put in equilibrium upon the balance. The ore dissolved readily, and with a strong effervescence, without leaving any residuum. By the carbonic acid that escaped, there was a loss of 12 grains of weight.

2. The solution, which was clear and colourless, was diluted with water, and a cylinder of zinc put into it. After 24 hours, the whole of the lead had shot into beautiful metallic lamine, which collected, washed, and both quickly and carefully dried, to the end that no oxidation might take place, afforded 77 grains of lead in the regulus state, which correspond with 82 grains of oxidated lead.

Consequently, the constituent parts of this tabular

ORE

Lead.

and carbonated white lead ore, bear to each other the following proportion:

Oxide of lead, - 82.
Carbonic acid, - 16.
Water, - - 2.

† Essays,
i. 131.

Green lead ore, or phosphate of lead.—The following is an example of the method of analysing this species of ore, adopted by Klaproth.

1. An hundred grains of this ore, in very pure specimens, left on solution in dilute nitric acid one half grain of the quartzose matrix behind; which I separated and replaced by an equal quantity of pure ore. The colourless solution, treated with nitrate of silver, yielded 10 grains of muriated silver: which indicates 1.54 of concrete muriatic acid, contained in 100 of the ore.

2. In the next instance, the ingredient lead was separated by means of sulphuric acid. The collected sulphate of lead, after gentle ignition, weighed 104 grains; for which 77.10 grains of oxidated lead must be put in the account.

3. When after this the nitric solution had been freed, by nitratated barytes, from the portion of sulphuric acid added to excess, and subsequently treated with ammonia so far, that the acid still predominated; I continued adding a solution of acetated lead, till no more turbidity was effected. The generated phosphate of lead, when collected and exposed to a gentle red heat, proved to weigh 85 grains; and consequently, the proportion of the phosphoric acid must have been 19 grains.

4. The remaining fluid was mixed with muriatic acid, the mixture evaporated to dryness, and extracted with ardent spirit. The residue, after completely evaporating the spirit, was again dissolved in water, and treated with Prussian alkali. A precipitation of prussiated iron ensued, which indicated the amount of oxide of iron 10 grains.

From the results of this decomposition it follows, that the constituent parts of green lead ore, and their proportion to each other, are:

Oxide of lead, - 77.10
Phosphoric acid, - 19.
Muriatic acid, - 1.54
Oxide of iron, - 0.10

† Ibid.
i. 125.

Red lead ore, or chromate of lead.—In analysing this ore, Vauquelin adopted the following simple process. Equal weights of the ore reduced to fine powder, strong muriatic acid, and distilled water, were digested together at a moderate temperature, and stirred from time to time. The chromate of lead is thus decomposed, and converted, for the most part, to muriate of lead, which is of a white colour. When the acid has ceased to act, pour off the liquor, add fresh muriatic acid, diluted as before with an equal quantity of water, and to the amount of about one fourth of the former quantity, and digest till the whole of the orange-coloured particles among the white muriate disappear. This liquor is to be added to the former, along with the washings;

the whole is to be heated, and placed in a cool place for a few days, that the small portion of muriate of lead which it holds in solution, may be deposited; and this being removed, add very gradually oxide of silver, precipitated from its solution in nitric acid by caustic potash, till the last portions assume a red purple colour. In this way the whole of the muriatic acid is separated, and the liquors contain only chromic acid, which is deposited by slow evaporation in the form of small, prismatic, ruby red crystals. The quantity of muriate of lead obtained by this process being ascertained, will show the quantity of metallic lead contained in the ore.

Yellow lead ore, or molybdate of lead.—Klaproth analysed this ore in the following manner.

1. A hundred grains of the crystals were carefully freed from the adhering calcareous earth and ochre of iron, and then finely pulverized. They were then dissolved in muriatic acid, assisted by heat, alternately affusion upon them the acid, and a large quantity of water. In this instance a trace of siliceous earth, though scarcely discernible, appeared.

2. The greatest part of muriate of lead, generated in the process, was deposited in fine needles, even before the solution had completely grown cold. The supernatant clear fluid was then poured off, reduced to a smaller volume by evaporation, and freed from the muriated lead, which still separated. The muriated metal, collected with care, and briskly desiccated, weighed 74 grains. By dissolving it in hot water, and steeping into the solution a polished piece of iron, the lead precipitated upon this last fine lamellae, and in the metallic state.

3. But in order to find more accurately what proportion this muriated lead might bear to pure oxide of lead, I made the following experiments.

Two hundred grains of lead, cut into shreds, were dissolved in 300 grains of nitric acid, diluted with 10 ounces of water, and, with the assistance of digestion, in a boiling heat. The solution was then divided into two parts.

a. Into one half I dropped muriated acid, as long as it produced any turbidity; evaporating afterwards the mixture to the most perfect dryness of the residue. The muriate of lead here produced weighed 133 grains.

b. From the second half of the nitric solution I precipitated the oxide of lead by dissolved caustic potash. This oxide, when desiccated and briskly dried till it began to turn yellowish, amounted to 115 grains.

From this it followed that those 74\(\frac{1}{2}\) grains of muriated lead, obtained from 100 grains of the yellow molybdate of lead (a) are equal to 64.43 grains of pure oxide of lead.

4. The concentrated muriatic solution of molybdena, which had a blue colour, was mixed with nitric acid, and lodged in a sand bath for farther evaporation. Being thus circumstances, it was again divided of its blue colour, and a yellow oxide of molybdena separated. But when the evaporation had been carried on to complete dryness, I collected and weighed the remaining lemon-yellow oxide of molybdena; and found it amount to 34\(\frac{1}{2}\) grains.

Wherefore, one hundred parts of the purest crystals of the yellow lead ore, from Carinthia, contain, Oxide.
Sulphate of lead.—This ore of lead was analysed by Klaproth according to the following process.

"1. One hundred grains of tabular sulphate of lead from Wanlockhead, in select pure specimens, lost 2 ½ grains, by being heated in a covered crucible. When finely pulverized and ignited in a platinum crucible with 400 grains of carbonate of potash, they yielded a brownish yellow, moderately concrete mass. Upon this substance, previously triturated, water was affused and heat applied to promote the solution of the soluble parts. As in the case of the preceding fossil, so in this, an oxide of lead deposited from the liquor, which, when washed, dried, and moderately ignited, weighed 70 ¼ grains. Diluted nitric-acid took the whole of it up, without the assistance of heat, and afforded a clear solution, from which the lead has been precipitated in the reguline state, by means of zinc. The metallic lead, thus obtained, when collected, washed and quickly dried, amounted to 65 ½ grains.

"2. In order to ascertain the quantity of sulphuric acid contained in the alkaline solution, it was combined with nitric acid added to super-saturation in some degree, and, in the next instance, treated with acetate of barytes. By this management sulphate of barytes was formed and precipitated, to the amount of 76 grains, after being heated to redness, which indicates 2 ½ grains of concrete sulphuric acid.

"According to this decomposition, an hundred parts of this tabular sulphate of lead consist of,

- Oxide of lead, 70.50
- Sulphuric acid, 25.75
- Water of crystallization, 2.25

"Ibid.

SECT. II. Of the Reduction of the Ores of Lead.

Galena is by far the most abundant ore of lead, and indeed almost the only ore which is subjected to the process of reduction. The treatment of this ore of lead in this way is very simple. The first object in dressing the ore, is to separate the extraneous matters or impurities, such as iron pyrites, blende, calcareous spar, quartz, &c. The purer part of the ore is broken to pieces about the size of a hazel nut, and washed from any earthy matters which adhere to it, and then it is ready to be smelted. A ton, or a greater quantity, of the ore, is spread on the floor of a common reverberatory furnace with a low arch, and with the flame of pit coal it is quickly brought to a red heat; being, during this time, occasionally stirred with iron rakes, to expose fresh surfaces to the action of the heat. When it begins to assume the consistence of paste, the heat is lowered, and kept at a dull red, till the whole of the sulphur is nearly driven off; when the heat is increased, and the ore brought to perfect fusion. The mass consists of two fluids the upper being a vitreous slag, and the lower metallic lead. The fire is now damped, and a few spadefuls of quicklime thrown in, by which the scorie become sud-

denly solid, and are removed to the side of the furnace. The tap hole is now opened, and the lead runs into moulds, in which oblong masses or pigs, about 60 pounds each, are formed. After the lead has run out of the furnace, the hole is again closed, the scorie are replaced in the bed; and the heat being raised to a glowing red, they are soon melted. The greater part of the lead separates from the slag, and collects in a mass at the bottom. The scorie become solid with the addition of a little lime, and the lead is let off into the mould. The second scorie still contain a portion of lead, from six to eight per cent.; but as it is not worth the expense of extracting, it is thrown away. It is found that the first running of lead is the best; the second, which is obtained from the scorie, being considerably harder, on account of a greater proportion of iron combined with it.

The process which is followed, at least in most parts of Scotland, is somewhat different from that now described, particularly in the previous preparation of the ore. The masses of ore, as it is brought from the mine, being separated from any adhering impurities, are reduced to small pieces, well washed, and then pulverised. In this state it is ready for the smelting process, which till of late was usually performed in an open furnace.

In some mining countries there is a considerable proportion of white lead ore mixed with the galena; doubts have been entertained whether it be profitable to retain this ore, even although it contain a large proportion of metal, because in the reverberatory furnace it is vitrified immediately on the application of the heat, and acting as a powerful flux, the whole is brought into fusion before the sulphur be entirely separated; so that the proportion of scorie in this case is greatly augmented, with very little increase in the produce of lead.

CHAP. VIII. Of the Ores of Tin.

There is no great variety of the ores of tin. It is usually found in the state of oxide, or in that of sulphur, when it is also combined with copper, and a small proportion of iron.

SECT. I. Analysis of the Ores of Tin.

Before treating of the analysis of the ore of tin, we shall first describe a very simple process for assaying it. The ore is first reduced to the consistence of coarse sand, and separated from the stony matters by washing. If it appear, by subjecting a grain or two to the action of the blow-pipe, that it contains arsenic, 200 grains of the ore mixed with a little charcoal, are to be roasted in a calcining test at a low red heat, till the whole of the arsenic is driven off. The residue is withdrawn, mixed with a little pitch and fine saw-dust, introduced into a crucible lined with charcoal, and after a cover is luted on, placed in a large furnace, whose heat is to be raised to a bright red. In about 20 minutes the reduction is completed, the crucible is removed, and a button of metallic tin is found at the bottom, covered with a little scorie. But if the ore should contain no arsenic, the previous process of roasting is unnecessary.

Tin-stone.—The best method of analysing the ores of tin, is that contrived by Klaproth, by means of the fixed alkalies, which was conducted according to the following process.
Chap. VIII.

ORES.

1. One hundred grains of tin-stone from Alternum, in Cornwall, previously ground to a subtile powder, were mixed in a silver vessel with a lixivium containing 620 grains of caustic potash. This mixture was evaporated to dryness in a sand heat, and then moderately ignited for half an hour. When the gray-white mass, thus obtained, had been softened while yet warm, with boiling water, it left on the filter 11 grains of an undissolved residue.

2. These 11 grains, again ignited with six times their weight of caustic potash, and dissolved in boiling water, left now only 11/2 grains of a fine yellowish-gray powder behind.

3. The alkaline solution (1. and 2.), which was in some degree colourless, was saturated with muriatic acid. A brilliant white, tender oxide of tin was thrown down, giving to the mixture a milky appearance. This precipitate, re-dissolved by an additional quantity of muriatic acid, was precipitated afresh by means of carbonated soda. When lixiviated and dried in a gentle heat, it acquired the form of bright yellowish transparent lumps, having in their fracture a vitreous lustre.

4. This precipitate, being finally powdered, soon and entirely dissolved in muriatic acid, assisted by a gentle heat. Into the colourless solution, previously diluted with from two to three parts of water, I put a stick of zinc; and the oxide of tin, thus reduced, gathered around it in delicate dendritie laminae of a metallic lustre. These, when collected, washed, and fused, under a cover of tallow, in a capsule placed upon charcoal, yielded a button of pure metallic tin, weighing 77 grains.

5. The above-mentioned residue of 11/2 grains, left by the treatment with caustic potash (2.), afforded with muriatic acid a yellowish solution; from which, by means of a little piece of zinc introduced into it, one half grain of tin was still deposited. Prussian alkali, added to the remainder of the solution, produced a small portion of a light-blue precipitate; of which, after subtracting the oxide of tin now combined with it, hardly one-fourth of a grain remained, to be put to the account of the iron contained in the tin-stone, here examined.

In these experiments, (excepting only a slight indication of silic, amounting to about three-fourths of a grain), no trace has appeared, either of tungstenic oxide, which some mineralogists have supposed to be one of the constituent parts of tin-stone, or of any other fixed substance. Therefore, what is deficient in the sum, to make up the original weight of the fossil analysed, must be ascribed to the loss of oxygen; and thus the constituent parts of pure tin-stone from Alternum are to each other in the following proportion:

<table>

The analysis of grained tin ore, or wood tin, may be conducted in the same way as the former.

Tin pyrites.—The following is the process which Klaproth adopted in the analysis of this species of tin ore.

Vol. XV. Part II.
Sect. II. Of the Reduction of the Ores of Tin.

Tin stone, or vein tin, as it is called in Cornwall, contains a large proportion of stony matters. It is first broken by hammers into pieces of the size of a hen's egg, when it is ready for the operation of stamping, which is performed in the way already described for the ores of gold, excepting that there are only three stampers. A tin plate about a foot square, and pierced with holes, and covered with a moderate sized knapping-needle, is inserted in front of the trough, and that surface of the plate with the rough extremities of the holes is on the inside, by which the holes are prevented from being plugged up with the ore. As the ore is reduced to the proper fineness, it passes with the water through the holes into the labyrinth, where it is collected, and after being washed on a wooden table, when it is ready for roasting. In this state it has a considerable proportion of copper and iron pyrites, and is called black tin. After being calcined at a low red heat for several hours, in a large reverberatory furnace, the ore comes out of a bright ochre red colour, owing to the decomposition and oxidation of some of the metallic substances; but the oxide of tin, when the operation is properly conducted, remains unaltered. The ore is washed a second time, to separate the remaining impurities; and the water which is impregnated with sulphate of copper, is retained and decomposed by means of old iron.

The reduction of the ore is the next step in the process. Seven cwt. of roasted ore, with one fifth of its bulk of small coal, are introduced into a reverberatory furnace, which is about seven feet long, and 3½ feet wide. No lime, or indeed flux of any kind is required. A brisk heat is kept up for about six hours; the tin sinking down as it is reduced, and covered with black scorice. The furnace is now tapt, and the metal flows into a shallow pit. When the whole of the metal has run out, the scorice are removed from the furnace, and a fresh charge is made. The metal in the pit throws up a slag, rich in metal, which is immediately returned to the furnace; and after the melted tin has cooled a little, it is taken out with iron ladles, and poured into granite moulds. Each charge affords on an average from four to five cwt. of metal; but as the first scorice are not entirely free from metal, they are again stamped and washed, and mixed with a new parcel of roasted ore. The pigs of tin are next put into a small reverberatory furnace; where, without any addition, they are subjected to a very gentle heat; the purest part of the tin melts first, and is drawn off, forming what is called common grained tin; the other part contains some copper, arsenic and iron, which is brought to a state of fusion, and cast into pigs, forming common tin.

Stream tin ore, which is peculiar to Cornwall, is prepared for the furnace by reducing it to powder, and passing it through wire sieves, which have 16 meshes in the square inch. A blast furnace is employed, which is about seven feet high, and is supplied with air from two cylinders washed by an overshot water wheel. The method of managing the furnace, after being fully heated, is the following. Three or four shovels full of ore, and two or three half bushels of charcoal, without any kind of flux, form a charge with which the furnace is fed at short intervals. There is a small channel at the bottom of the furnace, through which the reduced tin is constantly flowing into a pit below, and the slag which accompanies it is removed from time to time, and returned into the furnace. When the pit is full, the melted metal is removed into an iron boiler three feet in diameter, having a small fire under it, to keep the metal in fusion. Two or three large pieces of charcoal are then placed upon the tin, and forced to the bottom by means of an iron instrument resembling a wheel, with a long handle fixed in the axle. This produces a violent ebullition, and a little slag, before mixed with the metal, flies up to the surface, and is removed. In a minute or two the metal is tried, as it is called, by taking up a ladleful, and returning it again into the mass; when, if it assume a bright silver-like appearance, and a uniform consistence, the purification is complete. When cool to the proper degree, it is removed into the moulds, where it is formed into pigs of two or three cwt. Stream tin ore yields from 65 to 75 per cent. of the best and poorest tin.

Chap. IX. Of the Ores of Bismuth.

Bismuth is found in the metallic state, accompanied by native silver, blende, and galena, some other metals, and earthy substances. It is also met with in the state of oxide, and also in the state of sulphuret.

Sect. I. Of the Analysis of the Ores of Bismuth.

In conducting the analysis of the ores of bismuth, previous roasting is not requisite. The native bismuth, or oxide of bismuth, dissolves readily in nitrous acid, diluted with about one third of water, and either in the cold, or with a moderate heat; but boiling is necessary for the sulphuret, to precipitate the sulphur, and dissolve the bismuth. The greater part of the nitrate of bismuth may be precipitated from the solution, and separated from the metals with which it is usually alloyed, by adding a large quantity of water. But to separate the bismuth totally, evaporate the clear liquor which remains over the precipitated oxide to a small bulk, so as to retain in solution the nitrates of the other metals. Add muriatic acid by drops, as long as any white cloud is formed. This last precipitate consists of the remaining portion of the oxide of bismuth, mixed with muriate of silver, if the ore examined contain any of that metal. Then add a few drops of strong nitric acid, which dissolves the bismuth, and leaves the silver; and to this portion of the nitrate of bismuth add water, which separates the whole by precipitation. To ascertain whether the solution contains any silver, expose the precipitate by muriatic acid to the light, which will become of a bluish or slaty colour, if any silver has been dissolved; but if not, the pure white colour remains unaltered. As the oxide of bismuth is composed of 81.3 per cent. of metal, and 18.7 of oxygen, the proportion of metal in the ore may be precisely ascertained by weighing it. The other metals held in solution by the nitrous acid, which are chiefly lead, iron, copper and cobalt, may be separated in the usual way.

Sect. II. Of the Reduction of the Ores of Bismuth.

The low degree of heat at which bismuth is fusible, renders
Chap. X.

O R E S, &c.

renders the reduction of the ores of this metal a very simple process. In the treatment of the native metal, and the oxide, the weight of the ore of black flux is put into a crucible along with it, covered with salt, to about a finger’s breadth, and melted for 5 minutes with a brisk fire; when it is cold, the bismuth is found in a clean button. The flux employed by others is one part of borax, and the same quantity of powdered glass, to two of the ore, and the fusion is effected in a crucible lined with charcoal. With the oxide, a little oil, rosin, or charcoal, should also be mixed. Previous roasting is necessary in the treatment of the sulphuret of bismuth, to separate the sulphur; the other part of the treatment is the same with that now described.

But in the large way, the ores of bismuth are reduced merely by heating them along with burning fuel. Sometimes a shallow hole is made in the ground, and filled loosely with pieces of wood and bushes, and after the fire is kindled, the ore reduced to small pieces is thrown in, and sometimes the stump of a hollow pine tree is filled with wood and ore alternately, and set on fire; the bismuth separates from its matrix, and collects in a mass at the bottom.

CHAP. X. Of the Ores of Zinc.

The ores of zinc are, the native carbonate, or common calamine, the oxide of zinc, and the sulphuret.

SECT. I. Analysis of the Ores of Zinc.

On account of the great volatility of zinc, it cannot be examined in the dry way, or subjected to assay, without particular precaution. In assaying blend, or the sulphuret of zinc, the ore, after being bruised, is to be carefully separated from particles of galena, or other impurities. It is then to be roasted, and the sulphur being driven off, to be reduced to fine powder, mixed with half weight of charcoal, introduced into an earthy retort, to which a tube is fitted. The retort being exposed to a strong heat in a wind furnace, for three quarters of an hour, is to be gradually cooled, and on breaking it, the zinc is found in the neck, in metallic drops. The object may be accomplished in another way. Prepare the ore as before, and having mixed it with charcoal, let it be straitened in a crucible, with its own weight of copper clippings; and having luted on a perforated cover, subject it for nearly an hour to a low white heat. Allow it to cool, and examine and wash the contents. The globules of brass formed are thus easily separated from the other impurities, and the excess of weight of the brass above the copper, indicates the quantity of zinc given out by the ore.

Blende, or sulphuret of zinc.—This ore is found to contain not only zinc and sulphur, but sometimes iron, lead, copper, and arsenic, with silica, alumina, and a portion of water. It may be analyzed by the following process:

1. Introduce into a small coated glass retort, 200 grains of ore reduced to powder, and let it be gently ignited for a quarter of an hour. The fluid collected in the receiver will be found to be water.

2. Digest another portion of ore in repeated quantities of diluted nitric acid, till every thing soluble is taken up; wash the residue; weigh and ignite it; the loss of weight indicates the quantity of sulphur which is burnt off.

3. Digest the residue in a little nitro-muriatic acid, till the insoluble portion becomes quite white, which is pure silica.

4. Add to the nitric solution (2.) a few drops of sulphate of soda; evaporate gently, and continue to add sulphate of soda while a precipitate is formed, and after being evaporated nearly to dryness, digest in diluted muriatic acid; the sulphate of lead remains behind.

5. Add together the nitro-muriatic solutions (3, 4.); decompose by carbonate of soda, and digest the precipitate in caustic ammonia; the zinc and copper are thus dissolved.

6. Let the ammoniacal solution (5.) be saturated with muriatic acid; boil it, and add caustic soda, while a precipitate takes place: this is the brown oxide of copper.

7. Oxide of zinc now only remains in the soda solution, which is to be saturated with muriatic acid, and decomposed by carbonate of soda. The precipitate obtained after ignition is oxide of zinc.

8. The residue which was insoluble in ammonia (5), is to be treated repeatedly with nitric acid, and digested in caustic soda. Oxide of iron, contaminated slightly with arsenic, remains insoluble.

9. Having saturated the soda solution (8.) with nitric acid, add nitrate of lead, till no farther precipitate is formed; the precipitate is arseniate of lead.

10. And to the residual liquor, add first, sulphate of soda, to separate any nitrate of lead that may remain; filter the liquor, decompose it by carbonate of ammonia; the precipitate, washed and ignited, is pure alumina.

Calamine, or carbonate of zinc.—The ores of this species contain, besides the carbonate of zinc, the carbonates of lead, iron, and lime. The following is the mode of analysis:

1. The ore reduced to powder is to be dissolved in diluted nitric acid; the loss of weight during the solution indicates the quantity of carbonic acid. Neutralize the solution with caustic soda, evaporate gently, and add from time to time a few drops of sulphate of soda while any precipitate is formed.

2. Having thus cautiously brought it nearly to dryness, digest it in highly rectified alcohol, and afterwards in a little cold water, which will take up everything but the sulphates of lead and lime.

3. These may then be separated by digestion in sulphuric acid very much diluted, which will take up the sulphate of lime, leaving the sulphate of lead pure.

4. Neutralize the muriatic solution by soda, and evaporate nearly to dryness; then add alcohol to the residuum, which will throw down the sulphate of lime with a little sulphate of soda, which latter may then be washed away by a little cold water.

5. The alcoholic solution (2.) after evaporation to dryness, may be digested in caustic ammonia, which will take up the oxide of zinc, and leave behind the oxide of iron.

6. The alkaline solution, after being slightly supersaturated with muriatic acid, is to be decomposed by a perfectly carbonated alkali, by which the zinc is procured.
SECT. I. Of the Analysis of the Ores of Antimony.

Gray ore of antimony, or sulphuret of antimony.—As the sulphurets of antimony are the principal ores of this metal, we shall only describe the process by which the analysis of these ores may be conducted.

1. Take half a pound being reduced to fine powder, and then rinse it with water, let the loss of weight be noted; then add together the losses by ignition and solution; deduct from the sum the known weight of the carbonate, and the residue is water.

SECT. II. Of the Reduction of the Ores of Zinc.

The ore being reduced to small pieces, and the different impurities being separated, it is next calcined in a reverberatory furnace at a moderate red heat, and if the ore be calamine, the carbonic acid is driven off, and if blende, it is deprived of its sulphur. After this it is washed, and the metallic oxide being separated from the earthy parts, it is dried, and carefully mixed with about one-sixth of its weight of charcoal, by grinding the ingredients together in a mill, and is now ready for the smelting process. This is performed in a circular furnace, in which are fixed six large earthen pots, about four feet high and nearly of the shape of oil jars. An iron tube is inserted into the bottom of each pot, and, passing through the arched floor of the furnace, terminates in a vessel of water placed beneath, while the other end of the tube rises within the crucible to a few inches of the top. The crucibles are then filled with the mixture of the ore and charcoal, to the level of the tube, the cover of each is carefully luted on, and an intense heat is to be kept up for several hours. The zinc, as the process of reduction goes on, rises in the form of vapour to the top of the pot; but as it cannot escape, it descends through the iron tube, passes into the water, and is condensed in small drops. The globules are afterwards fused, and cast into the form of ingots, when it is fit for the market.

But as common zinc contains a little of other metals, as copper, lead, arsenic, iron, and manganese, which impair its quality, these impurities are partially separated by melting the zinc in a crucible, and stirring into it, with a stick or earthen rod, a mixture of sulphur and fat; by the latter the zinc is preserved from oxidation, and the sulphur combines with all the other metals except the zinc, and converting them into sulphurets, they rise to the top in the form of scorial, which may be removed. This process is to be repeated as long as any scorial appear. The method of purifying zinc proposed by Proust, is simple distillation in an earthen retort. The zinc passes over, and the oxides of the other metals remain behind. But it is supposed that the arsenic or lead cannot be separated in this way.

CHAP. XI. Of the Ores of Antimony.

Native antimony is a very rare production; the most common ore of antimony is the sulphuret; but it is also sometimes found in the state of oxide.
Chap. XI.

ORES, &c.

Antimony. Earthy parts floating on the surface, are removed with a rake. The melted mass is cast into the form of large cakes, and is the crude antimony of the shops.

The metal is obtained in a state of purity from the crude antimony, or sulphuret, by different processes. The following is recommended as one of the best, and most frequently practiced. The sulphuret being reduced to small pieces, is strewed thinly on the floor of a reverberatory furnace, to drive off the sulphur. The heat at first must not exceed that of the melting point of tin; otherwise the antimony will melt. A lambent blue flame is observed over the surface of the ore, which proceeds from the combustion of the sulphur; the metal is deprived of its lustre, and is converted into a grayish oxide. In the course of some hours, by carefully stirring the ore, and cautiously increasing the temperature, as the fusibility diminishes, it last ceases to give out sulphurous vapours, and can bear a moderate red heat without melting. After the roasting, the ore is removed from the fire, and is found changed into an ashy gray oxide, weighing from 30 to 36 per cent. less than the sulphuret, but it is not yet entirely free from sulphur. To reduce the oxide, mix it with half its weight of crude tartar, and subject to a full red heat in a covered crucible. The oxide is decomposed by the carbonaceous part of the tartar, and the antimony, reduced to the metallic form, is collected at the bottom of the crucible. A small proportion, however, still remains, dissolved by the sulphuret of potash, formed by the alkaline base of the tartar and the sulphur of the oxide. The quantity of metal which is thus obtained in the large way, amounts to 66 or 70 per cent. of the oxide employed. The loss, however, would be greater, if the ore has not been properly roasted.

The reduction is effected also by another process, which is supposed to be more economical. The roasted oxide is mixed with oil or fat, and a little powdered charcoal, and then introduced into a crucible; and as the metal begins to appear, powdered niter, in the proportion of an ounce to a pound of oxide, is gradually injected, after which the whole mass is brought to thin fusion, affording a pure metal, and in greater proportion than in the usual way.

The only other process which we shall mention, for reducing sulphuret of antimony, is that by means of some of the other metals, for which the sulphur has a greater affinity than for the antimony. Proceeding on this principle, iron, copper, lead, silver, and tin, may be employed in the process; but as iron is not only more effectual, but also cheaper, it is preferred. The antimony obtained by this process, was formerly called martial regula, not only on account of the iron being used in the preparation, but, not improperly, on account of a small portion of that metal which still adheres to it. The proportions recommended are the following: Eight ounces of small iron nails are heated in a crucible almost to whiteness; 16 ounces of crude or roasted sulphuret of antimony, coarsely pounded, are then added: the crucible is covered, and the fire kept up; and in a few minutes, when the whole is melted, three ounces of niter are to be added: after a slight detonation has taken place, the whole is brought to perfect fusion. It is then put into an iron cone previously heated and greased, and as the mass becomes solid, the sides of the cone are struck, to promote the precipitation of the metal. When cold and weighed, a mass of antimony is obtained, equal to about 20 ounces of the sulphuret employed, covered with alkaline ferruginous scoriae, from which it is easily separated by a blow of the hammer.

But the metal is not yet entirely free from iron and sulphur; to purify it still farther, therefore, it is to be remelted, two ounces of crude antimony, and three of niter being added; and when the detonation has ceased, it is poured into a cone, and the metal is separated as before, from the scoriae. Fuse the metal again; project upon it three ounces of niter; separate the purified metal from the scoriae; remelt with a strong heat, projecting gradually three ounces of niter, and immediately pour it into a cone. About eight ounces of a beautiful stellated regular, covered with yellowish white scoriae, are thus obtained.

Chap. XII. Of the Ores of Cobalt.

COBALT exists usually in a state of combination with arsenic and sulphur, or in the state of oxide. Scarcely any of its ores are free from arsenic and iron. Nickel is also sometimes abundantly mixed with the ores of cobalt, and occasionally a little manganese and copper.

Sect. I. Of the Analysis of the Ores of Cobalt.

White and gray cobalt ores, consisting chiefly of arsenic and cobalt, may be examined in the dry way, according to the following process, which, however, is not to be considered as very perfect. The ore is to be mixed with charcoal or saw-dust, and roasted to drive off the arsenic. The oxide after calcination is mixed with four times its weight of an equal mixture of carbonate of potash and tartar, and heated intensely, at the temperature which is required for melting cast-iron. A button of metallic cobalt is found beneath the scoriae, which are always of a deep blue, or nearly black colour, owing to the combination of part of the oxide of cobalt. A hundred grains of this ore, treated by Klaproth according to this process, yielded 44 grains of metallic cobalt; but if the ore contained iron, copper, or nickel, it must have been alloyed with these metals, and perhaps not entirely free from arsenic.

But the analysis may be conducted with more accuracy according to the following process by Tasmert:—Ann. de l'Acad. de.

1. With a view to ascertain the quantity of arsenic, be digested 100 parts of cobalt ore with diluted nitric acid. The whole was dissolved in a few hours, and deposited on cooling, white crystalline grains. By evaporation more crystals were deposited; the whole collected and dried, weighed 56 parts, and, excepting three parts, the whole was sublimed. These 53 parts are oxide of arsenic, and indicate 49 per cent. of metal in the ore.

2. Three hundred parts of the ore digested with four times as much nitric acid, afforded a rose-coloured solution. After partial evaporation, and with the addition of water and heat, a pale-red precipitate (1) was formed, leaving a rose-coloured solution. The solution being boiled with an excess of potash, afforded an oxide of cobalt, which was rose coloured, and then green, and when dried in a red heat, black. The amount was 85 parts.

3. These.
Preparation of Saffire—This substance is chiefly prepared in the large town, in different parts of Germany, but particularly in Saxony, and the following is the method of its preparation. The furnace employed is somewhat like a baker's oven, and is so constructed, that the flame of wood may be reverberated on all sides. The cobalt ore is placed on the hearth of the furnace, and by the action of the flame soon becomes red hot; a dense arsenical vapour arises, which is conducted through a horizontal wooden square trough or chimney, some times 100 fathoms long. In this chimney the arsenic is chiefly condensed, yet it is said, that some of the vapours, on account of their great volatility, escape. The calcination is continued till the exhalation of vapours nearly ceases: the ore is then reduced to powder, calcined a second time, again ground, and passed through a fine sieve. The powder is then mixed with two parts of powdered flint or quartz, after which it is moistened, and packed into barrels, where it acquires a great degree of hardness. This is the saffire of commerce, in the state in which it is exported; the exportation of the simple coloured oxide being prohibited under heavy penalties, it is said that the flints are added with a view to conceal the real nature of the substance.

Preparation of Smallt.—This is also sometimes called saffire, and when reduced to a very fine powder, it is called auro blue. It is prepared with about equal parts of calcined cobalt ore, potash, and ground flints. This mixture is first fritted, and afterwards made into glass, in pots like those of the glass-house. Eight or ten hours are required for its fusion. When the blue colour is perfect, the fused matter is taken out with iron ladles, and dropped into cold water, which makes it crack in all directions, so that it is easily reduced to fine powder. This operation is performed in a mill of very hard stone, enclosed in a wooden case. In the preparation of the smalt by the above process, a portion of bismuth, which usually accompanies the ores of cobalt, is found. Above it there is also a mixed alloy of iron, copper, and arsenic.

CHAP. XIII. Of the Ores of Nickel.

Nickel, as it is found in the state of ore, is usually combined with arsenic and sulphur, copper and iron, or with oxygen, in the form of oxide.

SECT. I. Of the Analysis of the Ores of Nickel.

When the ore contains, beside nickel, arsenic, sulphur, copper, and iron, with which it is usually accompanied, cobalt, silver, and bismuth, with some earthy matters, the analysis may be conducted according to the following process.

1. The ore being reduced to an impalpable powder, is to be two or three times digested in nitric acid, considerably diluted, after which every thing soluble will be taken up. During the process, nitrous gas is given off.
2. The insoluble part consists mostly of sulphur and silica, which after being dried, weighed and heated, the sulphur burns off, and the difference of weight before and after ignition, indicates its amount. The residue, after boiling in a little nitrous acid, is pure silica.
3. Saturate the two nitrous solutions (1. and 2.) with pure...
Chap. XIV. ORE

Pure soda, evaporate considerably, and pour the solution into cold distilled water; the oxide of bismuth is precipitated.

4. Add muriate of soda by drops to the filtered solution, while any precipitate is formed, which is the muriate of silver.

5. Evaporate the solution nearly to dryness, boil it with strong nitric acid while nitrous gas is given out; red oxide of iron is precipitated during the process.

6. Remove the oxide of iron, saturate the liquor with soda, and add nitrate of lead while any precipitate takes place. This is the arseniate of lead, which may be separated by filtration.

7. Decompose the nitrous solution by carbonate of soda: digest the washed precipitate in liquid ammonia; the oxide of iron mixed with alumina, is left behind, and may be separated by caustic fixed alkali.

Let the ammoniacal solution be slightly supersaturated with nitric acid, and a polished bar of iron introduced; in this way the copper will be separated: then decompose the liquid by carbonate of soda, and digest the precipitate in ammonia, and the iron employed in separating the copper will be removed.

9. The solution now contains only nickel and cobalt. Let it be evaporated till the excess of ammonia be expelled. This is the case when the vapour ceases to discolor moist turmeric paper. Then add pure potash or soda to the solution largely diluted, while any precipitation takes place. The precipitate is the oxide of nickel. The cobalt now only remaining in the solution, may be separated in the usual way. To reduce the oxide of nickel, mix it with glass of borax and a small quantity of carbonaceous matter, and then subject it in a crucible to the most powerful furnace heat. A button of pure nickel is thus produced.

As the ores of nickel are not very abundant, and as this metal is little employed for purposes of manufacture, the reduction of its ores does not extend beyond chemical analysis, which we have now detailed.

Chap. XIV. Of the Ores of Manganese.

Manganese usually exists in the state of oxide, combined with a small proportion of iron, or in the state of carbonate, and sometimes in that of sulphuret.

Sect. I. Of the Analysis of the Ores of Manganese.

Radiated gray ore of manganese.—This ore was analysed by Kilpalooff according to the following process:

"Two hundred grains of the ore, in grossly broken crystals, were heated to a thorough redness in a small coated glass retort, connected with the pneumatic apparatus. The gas collected amounted only to nine grains, upon deducting the common air of the apparatus; but showed by the lively combustion of an iron wire confined in it, that it was pure oxygen gas.

"2. In the small intermediate hollow glass sphere of the apparatus, a considerable quantity of moisture has condensed, which weighed 14 grains, and was pure water.

"3. The manganese, having sustained that ignition, weighed 181 grains. The external lustre of the crystals was very much diminished, and their gray colour turned blackish.

S, &c.

"One hundred parts of this ore have, consequently, been decomposed into,

| Black oxide of manganese | 92.50 |
| Water | 7. |
| Oxygen gas | 2.25 |

99.75 † Emerse. ll. 245.

As manganese is chiefly employed for economical purposes, in the state of oxide, the reduction of its ores forms no object of manufacture.

Chap. XV. Of the Ores of Molybdena.

For an account of the treatment of the ores of molybdena, which exists in the state of sulphuret and in that of oxide only, see Chemistry; see also the analysis of the molybdate of lead, in the chapter on lead, in this article.

Chap. XVI. Of the Ores of Arsenic.

Arsenic is found native, when it is alloyed with a small portion of iron, and sometimes also with a little gold or silver; in the state of sulphuret, or in the state of oxide.

Sect. I. Of the Analysis of the Ores of Arsenic.

The method of analysing the ores of arsenic by Bergman, has been already given under Arsenic in the article Chemistry, as well as the method of subliming the metal in close vessels, to obtain it in a state of purity. The following is recommended as a successful process for preparing this metal for nice chemical purposes.

Mix a quantity of arseniate of potash with about 5 parts of charcoal, and let it be sublimed in a close glass vessel, slowly heated to redness. The metallic arsenic thus obtained is in the form of beautiful brilliant crystals.

Sect. II. Preparation of White Arsenic and Orpiment.

White arsenic.—In the large way, this is prepared, by roasting the arsenical ores, previously ground to powder, and mixed with charcoal or saw dust, at a low red heat for several hours. The roasted ore is then subjected to a second sublimation, according to the following method; which is practised in Bohemia. The vessels in which the sublimation is performed, are strong square boxes of cast iron furnished with conical heads, which are closely luted with clay. These boxes are arranged in a spacious brick area, which is heated by flues proceeding from two furnaces, placed a little below them. When the impure arsenic has become red hot, it is removed into the boxes by 13 pounds at a time, where it is brought into fusion, and about an hour after begins to sublime into the conical head. When the arsenic ceases to rise, another quantity is introduced into the vessel, and treated in the same way. These additions are continued till about 150 pounds of arsenic have been thus treated in each vessel; a period of about 12 hours is requisite for the sublimation of the whole quantity. When the vessels are cold, the conical head is taken off, and the sublimed arsenic is broken off with hammers, at the same time any impurities that adhere to it are separated, for a second operation.

Orpiment.—
very small quantity, the reduction of their ores is not an object of much importance. A short account of the method of analysing them will be found under Chemistry, and the characters of the ores, with their constituent parts, will be found under Mineralogy. See also Assaying, Chemistry, and Decomposition Chemical, in the Supplement.

For the account of an elaborate analysis of the ores of tellurium, see Klaproth's Essays, ii. 1.

ORE

Orellana

ORELLANA, Francis, the first European, as is commonly thought, who discovered the river of the Amazons. In 1539, he embarked near Quito, upon the river Coca, which farther down takes the name of Napo. From this he fell into another large river; and, leaving himself entirely to the direction of the current, he arrived at Cape North, on the coast of Guiana, after sailing nearly 1800 leagues. Orellana perished 10 years after, with three vessels which had been intrusted to him in Spain, without being able to find again the mouth of this river.

In sailing down the river, he met with some armed women, against whom an Indian cacique had told him to be on his guard; and he thence named it the river of the Amazons.

ORENSE, an ancient town of Spain, in the kingdom of Galicia, with a bishop's see, famous for its hot baths, is seated at the foot of a mountain, on the river Minho, over which there is a handsome bridge of one arch. W. Long. 7. 27. N.Lat. 42. 16.

ORESTES, in Ancient History, a son of Agamemnon and Clytemnestra. When his father was cruelly murdered by Clytemnestra and Ægisthus, young Orestes was saved from his mother's dagger by means of his sister Elektra, called by Homer Laodicea, having been privately conveyed to the house of Strophius, who was king of Phocis, and who had married a sister of Agamemnon. He was tenderly treated by Strophius, who carefully educated him with his son Pylades. The two young princes soon became acquainted, and from their familiarity arose the most inviolable attachment and friendship. When Orestes came to years of discretion, he visited Mycenæ, and avenged his father's death by assassinating his mother Clytemnestra and her adulterer Ægisthus. Various accounts are given of the way in which these murders were committed. After their commission, however, he was acknowledged king of Mycenæ; but being tormented by the Furies, a punishment which the ancients always thought followed parricide, he exiled himself to Argos, where he was still pursued by the vengeful goddesses. Apollo, however, purified him, and he was acquitted by the unanimous opinion of the Areopagites, whom Minerva herself instituted on this occasion, according to the narration of the poet Æschylus, who flatters the Athenians in his tragical story, by representing them as passing judgment even upon the gods themselves. According to Pausanias, Orestes was purified of the murder, not at Delphi, but at Træzene, where still was seen a large stone at the entrance of Diana's temple, upon which the ceremonies of purification had been performed by nine of the principal citizens of the place. There was also at Megalopolis, in Arcadia, a temple dedicated to the Furies, near which Orestes cut off one of his fingers with his teeth in a fit of insanity. These different traditions are confuted by Euripides, who says that Orestes, after the murder of his mother, consulted the oracle of Apollo at Delphi, where he was informed that nothing could deliver him from the persecutions of the Furies, if he did not bring into Greece Diana's statue, which was in the Taurica Chersonesus, and which, as it is reported by some, had fallen down from heaven. This was an arduous enterprise. The king of Chersonesus always sacrificed on the altar of the goddess all such as entered the borders of his country. Orestes and his friend were therefore both carried before Thoas the king of the place, and they were doomed to be sacrificed. Iphigenia, Orestes's sister, was then priestess of Diana's temple, and it was her office to immolate these strangers. The intelligence that they were Grecians delayed the preparations, and Iphigenia was anxious to learn something about a country which had given her birth. She even interested herself in their misfortunes, and offered to spare the life of one of them, provided he would convey letters to Greece from her hand. This was a difficult trial: never was friendship more truly displayed, according to the words of Ovid, ex Pont. 3. ci. 2.

Ite iubet Pylades carum moriturus Orestae.

Hic negat; inque vicem pugnat uterque mori.

At last, however, Pylades gave way to the pressing in treaty of his friend, and consented to carry the letters of Iphigenia to Greece. These were addressed to Orestes himself; and therefore these circumstances soon led to a discovery of the connections of the priestess with the man whom she was going to immolate. Iphigenia was convinced that he was her brother Orestes; and when the cause of their journey had been explained, she herself resolved with the two friends to fly from Chersonesus, and to carry away the statue of Diana. Their flight was discovered, and Thoas prepared to pursue them; but Minerva interfered, and told him that all had been done by the will and with the approbation of the gods. Some imagine that Orestes came to Cappadocia from Chersonesus, and that there he left the statue of Diana at Comata. Others contradict this tradition; and Pausanias thinks that the statue of Diana Orthia was the same as that which had been carried away from the Chersonesus. Some again suppose that Orestes brought it to Arcia in Italy, where Diana's worship was established. It was after this that Orestes ascended the throne of Argos, where he reigned in perfect security, married Hermione the daughter of Menelaus, and gave his sister
not be any communication between it and any neighbouring room. Orffyreus however was so incensed, or pretended to be so, that he broke the machine in pieces, and wrote on the wall, that it was the impertinent curiosity of Professor Gravesande, which made him take this step. The prince of Hesse, who had seen the interior parts of this wheel, but sworn to secrecy, being asked by Gravesande, whether, after it had been in motion for some time, there was any change observable in it, and whether it contained any pieces that indicated fraud or deception, answered both questions in the negative, and declared that the machine was of a very simple construction.

ORFORD, a town of Suffolk in England, 88 miles from London, situated between two channels, where the river Ore, after having joined the Ald, falls into the sea. It was once a populous town, with a castle; of which, and of a nunnery near the quay, there are still some ruins. The towers of the castle and its church are a sea-mark for colliers, coasters, and ships that come from Holland. There is a light-house at Orford-Nesse, which is also of great use to seamen, and is a shelter for them when a north-east wind blows hard upon the shore. The town was incorporated by Henry III. has a mayor, 18 portmen, 12 chief burgesses, a recorder, a town-clerk, and two serjeants at arms. Though it sent members to parliament, in the 26th of Edward I. yet it had no more elections till the reign of Edward IV. It still sends two members to parliament, and has the title of an earldom. There are still remaining the ruins of a holy house, where the seamen’s wives used to pray for the safety of their husbands. By the withdrawing of the sea, it has been deprived of its chief advantage, for it now gives not the name of a harbour. It had the honour to give title of earl to the brave admiral Russell, which, after being many years extinct, was revived in the person of Sir Robert Walpole. The population in 1811 amounted to 737. E. Long. 1. 40. N. Lat. 52. 15.

ORGAL, among dyers, denotes the lees of wine dricd.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation; in which sense the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called organs.

Organ, in Music, denotes the largest and most harmonious of all wind-instruments; on which account it is called the organ, organum, the instrument, by way of excellence; chiefly used for playing a thorough bass, with all its accompaniments.

That organs are the invention of remote antiquity has been argued, and seems now to be generally allowed; but the particular time and country in which the discovery was made appears to be lost amidst the ruins of time. In ancient authors there are a variety of passages where mention is made of the organ, but it is at least possible that an instrument is not very different from that which now goes by the same name. From St Augustine’s commentary on the 4th verse of the 150th Psalm we learn, that the Greeks had another name for those instruments in which bellows were employed; that the name organ was appropriated to this particular instrument merely from the usage of the Latin tongue; and that it was indifferently given to all instruments used to accompany the voice in concert. We mention this, not because we doubt of the
antiquity of the organ, but merely to show that the time of its invention cannot be determined by the era of the authors where its name occurs. As the following observation, extracted from a periodical work which has long been in deserved esteem with the public, are intended to ascertain its early use, we submit them, without commentary, to the judgment of our readers. Cassiodorus has described our organ in a few words, lib. i. Epis. 45. Praising that art, which makes **Organa extranea vocibus insanare, et peregrini portae complectere, ut musica possit arte cantere.** And the emperor Julian has given an exact description of it in an epigram which may be found in the **Antithetis,** b. i. ch. 86. In his time these instruments were in such request, that Ammianus Marcellinus, b. xiv. ch. 6. complains that they occasioned the study of the sciences to be abandoned. However, those musical instruments whose melody is produced by wind, had been known at Rome long before. Witness that agreeable poem of Capo, which for its elegance has been ascribed to Virgil, where we find that the musician introduces the wind into his pipes by means of a pair of bellows, which she holds under her arms and blows. In the hydraulic organ, the water moves the air, instead of bellows. Cornelius Severus, in his *Enea,* has given an exact description of it (A). And though there were two kinds of hydraulic and pneumatic instruments, the first of which played by the inspiration and action of bellows, and the other by the action of water, it is certain, nevertheless, that both of them were pneumatic, being inspired by the wind. And Heron of Alexandria, in his **Pneumatica,** has treated of Hydraulics as belonging to pneumatica. This Heron lived in the time of Ptolemy Euergetes, king of Egypt. When Svetonius says, that Nero **Organa hydraulica novi et ignoti generis circumdavit,** he did not mean that they were unknown to Rome before Nero, but that those of Nero were of a new construction. Those were the hydraulics of a new fabric, which he exhibited to the people at the public games, as Svetonius relates a little after. Heliodorus, one of the worthy successors of Nero, like him was fond of these hydraulica; and Alexander Severus, his cousin and successor, had the same inclination. Claudian, who lived some time after, has left us this elegant description of them:

*Et qui magna levi detta corda murmurans*
*Innumerarum voces segetis moderatur aenea;*
*Intuet errante digito, pentesine trabalis*
*Vектe laborantes in carmina carminis munias.*

This very construction which is observed in the pipes of an organ, gradually decreasing in magnitude, has been represented in an epigram of Optatumus Porphyrius, who lived in the time of Constantine. This epigram, which is quoted in Pithon’s collection of ancient epigrams, is composed of verses of an unequal length, successively increasing. This corresponds with those words of the old schoolman on Juvenal, sat. 8. ver. 275: **Tunici Galli utantur in sacris in modum organi utrinque decrescentibus virgilis purpuris.**

On the whole, then, the antiquity of organs, or of instruments of a very similar nature, can scarcely be disputed; but nothing very particular respecting the time, place, or manner, of the invention can possibly be determined from those incidental observations which occur in the writings of the ancients (B). It appears indeed to have been borrowed by the Latins from the Greeks, but not to have been in general use till the eighth century; and it has been affirmed, that, in France, it was not known till the time of Louis le Debonair, i.e. A.D. 815, when an Italian priest taught the use and construction of it, which he himself had learned at Constantinople. By some, however, it has been carried as far back as Charlemagne, and by others as far as Pepin. Bellarmine says that the organ began to be used in the service of the church about the year 666, as Plutarch relates out of the Pontifical: for when Pope Vitalian reformed the singing of the Roman church, he added to it organs in order to support and embellish it. Ammonius thinks, however, that this happened after the year 820, in the time of Louis the Pious. Perhaps the learned Bingham is our surest guide in determining this point. He positively asserts that there were no such things as **organs**

---

(A) Which is thus translated by Mr Jabez Hughes:

As in an organ *²*, first the rushing air
A mass of waters does before it bear;
And then the waters, in their turn, we find
Drive through the hollow pipes the vanquish’d wind;
Which strongly from its strait confinement sent,
Comes loudly rattling through the narrow vent:
Still as the waters press, the spirits sound,
And spread the bubbling symphony around.
So air and water meet, &c.

It is by no means certain that Cornelia Severus was the author of this poem, though it is published under his name by Le Clerc. Seneca’s authority, on which the Younger Scaliger founds his opinion, enforces no such conclusion. He only says, that “Severus was not discouraged from writing on this subject, by its having been already treated by Ovid and Virgil.” Barthius, in his notes on Claudian, refers it to Manilius, and in his *Adversaria* to some Christian writer. By others it has been ascribed to Virgil, and by Scaliger, the father, to Quintilius Varus. But though it is less clear and methodical than Virgil, and though it has been much mutilated by time, it certainly was penned by a masterly and truly poetical hand.

(B) Vitruvius describes an organ in his 10th book; and St Jerome mentions one with 12 pair of bellows, which might be heard a thousand paces, or a mile; and another at Jerusalem which might be heard at the Mount of Olives.
Organs in use in the ancient church; and that though church-music was as old as the apostles, instrumental music was not so. He also says that it was the general opinion of the learned in his days, that organs were not introduced into churches till after the time of Thomas Aquinas, A.D. 1250; and for this opinion, as far as the authority of Aquinas will go, we have a positive proof; for in his sermons we find these words: "Our church does not use musical instruments, as harps and psalteries, to praise God withal, that she may not seem to Judeza (c)." From hence it has reasonably been concluded, particularly by the learned Gregory, that they were not used in churches in his time. Yet Wharton has also observed that Marinus Sanusus (who flourished A.D. 1200) first introduced wind organs into churches; from this circumstance he derived the name Torcelus, the name for organ in the Italian language. About the same time Durandus in his Rationale speaks of them as generally received in the church; and he, in Mr Gregory's opinion, is the first author who takes notice of it. These authorities are strong, and the opinions founded on them by the learned render them still more convincing: it appears, however, from the testimony of Gervas the monk of Canterbury, who flourished A.D. 1190, that organs were introduced upwards of 100 years even before that time; for in his description of Lanfranc's church, as it was before the fire in 1174, he has these words, "Crux australis supra fornix organa gestore solebat." We do not say that this invalidates the reasoning of the learned Bingham; of that our readers are to judge; and in forming their judgments they will be determined by the credit of the testimonies which are here opposed to each other. If we suppose that of Gervas the strongest, and in opposition to the other conclude from it, that organs were introduced into England long before the 13th century, it will give some countenance to an opinion which prevails pretty generally, viz. that in Italy, Germany, and England, they became frequent about the 13th century. See Music, p. 493. But however we are disposed to determine this matter (which is in itself but of little consequence), it is certain that the use of the organ was very common in the latter ages of the church, and the propriety of it was undisputed. In the last century, however, during the civil wars, organs were removed from the churches in England; and so generally reproved, that, at the Restoration, there could scarce be found either organists, organ builders, or singers (d).

The organs in Germany (says Dr Burney) in mag-

nitude, and the organists in abilities, seem unrivalled in any other part of Europe, particularly in the use of pedals. In Marpurg's Essays, vol. iii., there is a minute account of a variety of organs in Germany; of which the longest pipe of the manuals is 16 feet long, and of the pedals 32. One of the largest organs in Germany, which but Marpurg has omitted in his list, is at Grolitz in Upper Lusatia. It would be to no purpose to enlarge our article with a more minute account of the state of organic music in different parts of the world; in various parts of the article Music, observations connected with this subject will be found, and to that we must refer. We may particularly notice, for the perusal of those who wish for further information on this subject, the observations which have been made on organs in the History of Music, at p. 493. We need scarcely refer to the life of Handel, which all our readers who are fond of music of any kind, particularly sacred, have undoubtedly perused.

The church organ consists of two parts; the main body, called the great organ; and the positive or little organ, which forms a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32 feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high and 28 broad: its largest pipe is 13 inches diameter, and it has 16 pair of bellows.

The several parts of the church-organ are as follows: HHH is the sound-board; which is composed of two parts, the upper board or cover HHH, and the under board HH, which is much thicker than the other; each of these consists of several slabs laid with their edges to each other, and joined very close together. In the under side of the lower board there are made several channels, which run in the direction LL, MM, &c. and are continued as far as there are stops in the organ, and come almost to the edge HK. These channels are covered over very close with parchment or leather all the way, except a hole that is commonly at the fore end next HK, upon which a valve or stop is placed. These channels are called partitions. When this valve or flap is shut, it keeps out the air, and admits it when open. On the upper side of the lower board there are likewise cut several broad square channels, lying cross the former, but not so deep as to reach them; these lie in the direction LN, PQ, &c. To fit these channels, there are the same number of wooden sliders or registers f, f, f, &c. running the whole

(c) The lawfulness of using organs in churches, has, however, been ably defended by an appeal to the use which the Jews made of instruments of music in divine service; and with much reason; for were the use criminal in us, as was asserted by many well meaning men of the last century, and as it is still thought by some in this, it would unquestionably have been equally unlawful for the Jews. The Christians in Aquinas's time, however, acted wisely in avoiding the use of them, if by so doing they would have given offence to their weaker brethren. For though they are highly ornamental, and in some churches may be productive of good effects, yet the use of them is far from being essential, and may be easily dispensed with.

(d) Organs have never yet been used in the establishment of Scotland, since that became Presbyterian; but they are used in Holland, where that form of church-government also obtains. Bishop Horne, in a sermon which he preached at the opening of the new organ at Canterbury in 1784, says that he believes some Presbyterian dissenters in England have adopted it in their places of worship. See his Sermon, p. 8.
whole length; and these may be drawn out or thrust in at pleasure. The number of these is the same as that of the stops in the organ.

IKKK is the wind-chest, which is a square box fitted close to the under side of the lower board, and made air-tight, so that no air can get out but what goes through the valves along the partitions.

VV are the valves or puffs which open into the wind-chest; they are all inclosed in it, and may be placed in any part of it, as occasion shall require. One of these valves, with the spring that shuts it, and the wire that opens it, is represented by fig. 2.

C, D, E, F, &c. are the keys on which the fingers are placed when the organ is played: these keys lie over the horizontal bar of wood W, in which are stuck an equal number of wire-pins z, z, on which keys are fixed; and the keys move up and down on the bar, as on a centre. There is another bar, against which the keys fall when put down, and which is here marked 3; on this also are several wires, which go through the keys, to guide them; and on this bar a list is fastened to hinder the keys from knocking against the wood.

The keys are made to communicate with the valves several ways, as we shall now describe. First, a, a, a, are the key-rollers, moving on the pivots, t, t: these rollers lie horizontally, one above another, and are of such length as to reach from the valve to the key: b, b, b, are arms or levers fixed to the key-rollers; c, c, are the wire-wires fixed to the arms a, a, and to the valves V, and go through the holes h, h, in the bottom of the wind-chest: d, d, d, are likewise arms fixed to the key-rollers: e, e, are the key-wires, fixed to the arms b, b, and to the keys C, D, E. Now, when the end of any one of the keys C, D, E, is put down, it pulls down the arm b, by the wire d, which turns about the roller c with the arm a, that pulls down the wire e, which opens the valve that is shut by the spring as soon as the pressure is taken off the key. In this construction there must be a worm spring fastened to the key, and to the bar W on the other side, to keep down the end 5 of the key.

Another method of opening the valves is thus: x, x, x, y, y, are slender levers, moveable on the centres 1, 1; z, z, z, are wires going from the further ends of the keys to the ends 6 of the levers; y, y, y, are other wires, reaching from the ends 7 of the levers, through the holes h, h, to the valves V. So that putting down the key C, D, &c. raises the end 5, which thrusts up the end 6 of the lever, by the wire z, z; this depresses the end 7 of the lever, which pulls down the wire y, and opens the valve V.

A third way of opening the valve is this: At the end of the key 5, is a lever, 8, 9, moving in the centre 7. This makes, with the key, a compound lever. From the end 9, a wire goes to the valve. Now the putting down the end 9 of the key, raises the end 8, which depresses the end 9 of the lever 8, 9, pulls down the wire, and opens the valve. There is only one of these drawn in the scheme, and but a few of the others, to avoid confusion.

R, R, are the rollers, to move the sliders, by help of the arms c, c, c, which are fixed horizontally in these rollers: k, k, c, are also levers fixed in the rollers; l, l, are the handles, which lie horizontally, and pass through the holes II; they are fastened to the lever 8, being moveable about a joint at e.

Now, any handle i, being drawn out, pulls the end e towards i, which turns about R, k, along with the arm c, c; and the end f pulls out the slider g, g; and when p is thrust in, the arm f likewise thrusts in the slider g.

Upon the several rows of holes which appear on the top of the upper board, there are set up an equal number of rows of pipes. The pipes of an organ are of two kinds: the one has a mouth like a flute, the other with reeds. The first, called pipes of mutation, consist, (1.) of a foot AABB (fig. 3.), which is a hollow Fig. 3. cone, that receives the wind that is to sound the pipe: (2.) To this foot is fastened the body of the pipe BBDD. Between the foot and the body of the pipe is a diaphragm or partition FEF, that has a long but narrow aperture, by which the wind comes out; over this aperture is the mouth BBC, whose upper lip C, being level, cuts the wind as it comes out.

The pipes are of pewter, of lead mixed with a twelfth part of tin, and of wood. Those of pewter are always open at their extremities: their diameter is very small, and their sound very clear and shrill. Those of lead mixed with tin are larger; the shortest are open, the longest quite stopped; those of a mean size are partly stopped, and have beside a little ear on each side the mouth, to be drawn closer or set further asunder, in order to raise or lower the sound. The wooden pipes are square, and their extremity is stopped with a valve or tampon of leather. The sound of the wooden and leaden pipes is very soft; the large ones stopped are commonly of wood, the small ones of lead. The longest pipes give the greatest sound, and the shortest the most acute: their lengths and widths are determined by a fixed proportion to their sounds; and their divisions are regulated by a rule, which is called the disposition. The longest has commonly 16 feet; but in very large organs it has 32 feet. The lead pipes are always open, though made of wood and lead. Whatever note any open pipe sounds, when its mouth is stopped, it will sound an octave lower; and a pipe of twice its capacity will likewise sound an octave lower.

A reed-pipe consists of a foot AABB (fig. 4.), that carries the wind into the shallot or reed CD, which is a hollow demi-cylinder, fitted at its extremity D, into a sort of mould, by a wooden tampon G. The shallot is covered with a plate of copper KKL, L, fitted at its extremity II, into the mould, by the same wooden tampon. Its other extremity KK is at liberty: so that the air entering the shallot makes it tremble or shake against the reed; and the longer that part of the tongue IL, which is at liberty, is made, the deeper is the sound. The mould II, that serves to fix the shallot or reed, the tongue, tampon, &c. serves also to stop the foot of the pipe, and make the wind go out wholly at the reed. Lastly, in the mould is soldered the tube HH, whose inward opening is a continuation of that of the reed: the form of this tube is different in different ranks of pipes. The degree of acuteness or gravity in the sound of a reed pipe, depends on the length of the tongue, and that of the pipe G, K, taken from the extremity of the shallot to the extremity of the tube. The quantity or intonation of the sound depends on the width of the reed, the
the tongue, and the tube; as also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To diversify the sounds of the pipes, a valve is added to the port-vent, which makes the wind go out in fits or shakes. In fig. 1. x represents a flute-pipe of wood, Z a flute-pipe of metal, Y a trumpet-pipe of metal. The pipes, to prevent them from falling, pass through holes made in boards, placed upon the upper board.

The pipes are made to communicate with the wind-chest in the following manner. There are holes bored that go through the upper and lower boards, and through the slider (when it is drawn out), into the partition below; so that any pipes placed upon those holes will then communicate with the partition, which by its valve, communicates with the wind-chest. But when the slider is thrust in, its holes do not answer to those in the upper and lower boards; therefore, the communication is stopped, so that no wind can get to the pipe.

To every large organ there must be at least two pair of bellows, which are marked in fig. 1. by TU, TU. O, O, are the handles, moving upon the axis u, u. Each of these bellows consists of two boards, the lowest of which is immovable, and in this there is a valve v, v, opening upwards, and a tube leading to it, called the convolving tube. There is also a hole in this under board, from which a tube leads to the port-vent, which is a square tube marked a, rising upward, and inserted into the under side of the wind-chest at b. In the tube leading to the port-vent, there is a valve that opens towards the port-vent, and suffers the air to go up the port-vent, but not to return. Now the handle Θ being pulled down, raises the upper board T, and the air enters through the valve v; and when the handle is let go, the weight of the upper board, which carries three or four pounds to every square foot, continually descending, drives the air through the port-vent to the sound-board: and as the bellows work alternately, one pair is constantly descending, which occasions a continual blast through the port vent. In chamber organs there is but one pair of bellows; but they are formed of three boards, in the manner of a smith's bellows, and so have a continual blast. All the internal structure of the organ is concealed from the sight by the front of the instrument, which stands upon the part between the numbers 3 and 6 (fig. 1).

In every organ, the number of partitions LL, MM, &c. there are in the sound-board (fig. 1.), that of the valve VS, that of the rollers s s, or of the levers y y or 8 9 and their wires, and that of the keys ABC, &c. must be always equal. Large organs have commonly four or five sets of keys, besides those that belong to the pedals or large pipes, the stops to which are played by the feet; said to be the invention of Bernard, a German, about the year 1400. These command certain pipes, which, to increase the harmony, are tuned below the diapason. The keys of an organ are usually divided into four octaves; which are, the first sub-octave, second sub-octave, middle octave, and first octave. Each octave is divided into 12 stops or frets, of which seven are black and five white: the former mark the natural notes, and the latter the artificial notes, that is, flats and sharps. The number of keys, therefore, when there are four octaves, must be 48. Some organists add one or more stops to the first and second sub-octaves. The pedals have two or three octaves, at the option of the organist; so that the number of stops is indeterminate. The keys are placed between GG (fig. 1.), but the scheme could not contain them all. There are also as many handles i i, &c. rollers RR, &c. slides j j, &c. as there are stops upon the organ; and it must be observed, that between the slides j j, &c. there are as many sliders on the right hand, and the same number of handles and rollers, and other rows of pipes placed between LN, PQ, which could not be expressed in the figure.

The least pipes and partitions are placed toward the middle of the organ, and the greatest on the outside. The stops of an organ have various denominations, according to the sounds they are to produce; some of which are diapason, principal, fifteenth, twelfth, treble, cornet, trumpet, French horn, vox humana, flute, bassoon, cromossa, &c. The foreign organs, especially those of Germany, have many more: particularly that in the abbey church of Weingarten, a town in the Upper Palatinate, which has 66 stops, and contains no fewer than 6666 pipes. The organ at Haarlem is said to have 60 stops, many of them but little known to the English workmen, and distinguished by names that express the sound which they produce.

When this magnificent instrument is played, the handle O of the bellows is first put down, which raises the upper board T, and gives room for the air to enter by the valve r. Then the other handle O is put down: In the meantime the board T, belonging to the first handle, descending, and shutting the valve r, drives the air through the other valve, up the port-vent, and into the wind-chest. Then drawing out any handle, as that of the flute-stop p l, which draws out the slider f g, all the pipes in the set LN are ready to play, as soon as the keys C, D, E, &c. are put down: therefore if the key D be put down, it opens the corresponding valve m v, through which the air enters into the pipe X, and makes it sound. In the same manner any other pipe in the set LN, will sound when its key is put down: but no pipe, in any other set, will sound till the slider be drawn out by its corresponding handle.

Among the modern improvements of the organ, the most remarkable are the swell and the tremulant: the former, invented by an English artist, consists in a number of pipes placed in a remote part of the instrument, and inclosed in a kind of box, which being gradually opened by the pressure of the foot, increases the sound as the wind does the sound of a peal of bells, or suppresses it in like manner by the contrary action. The tremulant is a contrivance by means of a valve in the port-vent, or passage from the wind-chest, to check the wind, and admit it only by starts; so that the notes seem to stammer, and the whole instrument to sob, in a manner very offensive to the ear. There is a tremulant in the organ at the German chapel in the Savoy. See Hawkins' History of Music, and Burney.

Hydraulic Organ, denotes a musical machine that plays by water instead of wind. Of these there are several in Italy, in the grottoes of vineyards: Ctesebes of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have invented organs that played by compressing the air with water, as is still practised. Archi-
ORIBASUS, a celebrated physician, greatly esteem-
ed by the emperor Julian, in whose reign he flourished. 
He abridged the works of Galen, and of all the most 
respectable writers on physic. This was done at the 
request of the emperor. He accompanied Julian into the 
est, but his skill proved ineffectual in attempting to 
cure the fatal wound which his benefactor had received. 
After Julian's death he fell into the hands of the 
barbarians.

ORICHALCUM, or AURICHALCUM, a metallic 
substance resembling gold in colour, but very inferior 
in value. It was well known to the old Romans, who 
often took advantage of its resemblance to gold; for 
some sacrilegious characters, who could not resist the 
temptation of taking gold from temples and other pub-
lic places, chose to conceal their guilt by replacing it 
with orichalcum. It was thus that Julius Caesar acted 
when he robbed the capitol of 3000 pounds weight of 
gold; in which he was followed by Vitellius, who de-
spoiled the temples of their gifts and ornaments, and 
replaced them with this inferior metal. It has been a 
matter of dispute with philosophers and others, what 
this metal could be, or how it was procured or made; 
it is probable at least that it was greatly analogous to 
our brass, if not wholly the same with it (See Brass). 
The value of our brass is much less than that of gold, 
and the resemblance of brass to gold, in colour, is ob-
vious at first sight. Both brass and gold, indeed, are 
susceptible of a variety of shades of yellow; and, if 
very pale brass be compared with gold, mixed with 
much copper, such as the foreign goldsmiths, especial-
ly, use in their toys, a disparity may be seen; but the 
nearness of the resemblance is sufficiently ascertained 
in general, from observing that substances gilded with 
brass, or as it is commonly called Dutch leaf, are not 
easily distinguished from such as are gilded with gold 
leaf.

The Romans were not only in possession of a metallic 
substance, called by them orichalcum, and resembling 
gold in colour, but they knew also the manner of making 
it, and the materials from which they made it were the 
very same from which we make brass. There are, in-
deed, authors of great repute who think very differently; 
and who consider the art of making brass as an in-
vention wholly modern. Thus M. Cronstedt does not 
think it just to conclude from old coins and other an-
tiquities, that it is evidently proved that the making 
of brass was known in the most ancient times; and the 
authors of the French Encyclopédie assure us, that our 
brass is a very recent invention (A). It appears, how-
ever, from Pliny's Nat. Hist. lib. xxxiv. § 2. and from 
the concurring testimony of other writers, that orichal-
cum was not a pure or original metal; but that its basis 
was copper, which the Romans changed into orichalcum 
by means of cadmia, a species of earth which they threw 
upon the copper, and which it absorbed. It has indeed 
been contended, that the cadmia of Pliny was native 
arsenic; an opinion which scarcely merits confutation, 
but which must appear extremely groundless, when we 
reflect

(A) Art. Orichalque.—"The vessels here called brazen, after ancient authors, cannot have been of the ma-
terials our present brass is composed of; the art of making it is a modern discovery." See Laughton's History 
of Ancient Egypt, p. 58.
reflect that it is impossible to make either brass or copper from arsenic, and that Pliny expressly calls it a stone from which brass was made. The testimony of Ambrose bishop of Milan, in the 4th century, and of Primasius bishop of Adrumetum, in Africa, in the 6th, and of Isidorus bishop of Seville in the 7th, all seem to confirm Pliny's account. We may therefore safely conclude that the Romans knew the method of making brass by mixing cadmia or calamine with copper; yet it is probable they were not the inventors of this art; but that they borrowed it from some other country. It appears from a variety of testimonies that brass was made in Asia, in a manner very similar to that at Rome; and a variety of places are mentioned in that extensive country where it was commonly made; and it is supposed by some that in India, as well as in other parts of Asia, it was made in the remotest ages.

With respect to orichalcum, it is generally supposed that there were two sorts of it, one factitious, the other natural. The factitious, whether we consider its qualities or composition, appears to have been the same with our brass. As to the natural orichalcum, there is no impossibility in supposing, that copper ore may be so intimately blended with an ore of zinc, or of some other metallic substance, that the compound, when smelted, may yield a mixed metal of a paler hue than copper, and resembling the colour of either gold or silver. In Du Halde's history of China, we meet with the following account of the Chinese white copper. "The most extraordinary copper is called de-tong, or white copper; it is white when dug out of the mine, and still more white within without it. It appears by a vast number of experiments made at Pekin, that its colour is owing to no mixture; on the contrary all mixtures diminish its beauty; for, when it is rightly managed, it looks exactly like silver: and were there not a necessity of mixing a little tien-tong, or some such metal with it, to soften it and prevent its brittleness, it would be so much the more extraordinary, as this sort of copper is perhaps to be met with nowhere but in China, and that only in the province of Yung-nan. Notwithstanding what is here said, of the colour of this copper being owing to no mixture, it is certain that the Chinese white copper, as brought to us, is a mixed metal; so that the ore from which it is extracted must consist of various metallic substances, and from some such ore it is possible that the natural orichalcum, if ever it existed, may have been made. But, notwithstanding that the existence of natural orichalcum cannot be shown to be impossible, yet there is some reason to doubt whether it ever had a real existence or not.

We know of no country in which it is found at present; nor was it anywhere found in the age of Pliny; nor does he seem to have known the country where it ever had been found. He admits, indeed, its having been formerly dug out of the earth; but it is remarkable, that in the very passage where he is mentioning by name the countries most celebrated for the production of different kinds of copper, he only says in general concerning orichalcum, that he had been found in other countries, without specifying any particular country. Plato acknowledges, that orichalcum was a thing only talked of even in his time; it was nowhere then to be met with, though in the island of Atlantis it had been formerly extracted from its mine. The Greeks were in possession of a metallic substance, called orichalcum, before the foundation of Rome; for it is mentioned by Homer and by Hesiod; and by both of them in such a manner as shows that it was then held in great esteem. Other ancient writers have expressed themselves in similar terms of commendation; and it is principally from the circumstance of the high reputed value of orichalcum that authors are induced to suppose the ancient orichalcum to have been a natural substance, and very different from the factitious one in use at Rome, and probably in Asia, and which it has been shown was nothing different from our brass.

But this conclusion cannot be validly drawn from their encomiums upon it; for at whatever time the method of making it was first discovered, both its novelty and scarceness, joined to its utility, would enhance its value, at least there can be no absurdity in supposing, that when first introduced it was greatly prized, even though it be granted that it possessed no other properties than such as appertain to brass.

Respecting the etymology of the word there is great diversity of opinions. Those who write it aurichalcum think it is composed of the Latin word aurum, "gold," and the Greek χαλκός, "brass or copper." The most general opinion is, however, that it is composed of ἀραί, "a mountain," and χαλκός, alluding perhaps to its being found in mountains or mountainous countries. The above account is chiefly extracted from a paper in the second volume of Memoirs of the Literary and Philosophical Society of Manchester, written by the present bishop of Landaff, Dr Watson, and communicated by Dr Percival. To this paper then we refer our readers who desire a more copious account of it. To the above two etymological meanings of the word we shall subjoin the following, mentioned by the learned bishop, and which, in our opinion, is equally well founded, and certainly as ingenious, as the other two.

The Hebrew word Or, Aur, signifies light, fire, flame; the Latin terms urus, "to burn," and aurum, "gold," are derived from it, in as much as gold resembles the colour of flame: and hence it is not improbable, that orichalcum may be composed of an Hebrew and Greek term, and that it is rightly rendered, flame-coloured copper. In confirmation of this, it may be observed, that the Latin epithet lucidum, and the Greek one χαλκός, are both applied to orichalcum by the ancients. See also Beckmann, Hist. of Inven. iii. 71.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORIGINUM, ORIGANY or Marjoram, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 42d order, Verticillatae. See Botany Index.

ORIENT, a town and harbour of France, in the department of Morbihan, in the bottom of the bay of St Louis. Since the year 1720, a handsome town has been built here, where the French East India Company had large magazines. It was formerly a free port. The number of inhabitants in 1850 was 19,022. The English attempted to become masters of it in 1746, but miscarried. W. Long. 3. 16. N. Lat. 47. 45.

ORIENTAL PHILOSOPHY. See Philosophy.

ORIGEN, one of the most celebrated ecclesiastical writers, greatest geniuses, and most learned men of the
Ori. the primitive church, during the third century, was
born at Alexandria in the year 185; and was sur-
named Adamantius, either from his indefatigable applica-
tion to study, or from the firmness he discovered amidst
the torments he suffered for the faith. Leonidas, his
father, trained him at home with great care, and made
him apply to the study of the Holy Scriptures from his
infancy, in which he made surprising progress. The
son’s inclination and turn suited exactly with the
father’s design; for he pursued his studies with a most
extraordinary zeal and arduour: and, being ended
with a quick apprehension and a strong imagination,
did not content himself with that sense which at first
presented itself, but farther endeavoured to dive into
mysterious and allegorical explications of the sacred
books. He would sometimes even puzzle his father,
by too much soliciting him for reconciante meanings;
which obliged the good man to reprehend him a little,
and wish to advise him not to attempt to penetrate
too far in the study of the Holy Scriptures, but to
content himself with their most clear, obvious, and
natural sense. Hence it appears, how early he was
seized with that furore allegoricis, as a learned modern
calls it, that rage of expounding the Scriptures alle-
gorically, which grew up afterwards to be a most
distemper, and carried him to excesses—which cannot be
excused (A). He had afterwards in philosophy Ammonius
the celebrated Christian philosopher, and St
Clement of Alexandria for his master in divinity. At 18
years of age he succeeded that great man in the office
of catechist; an important employment, which consisted
in teaching divinity, and expounding the Scriptures.
Leonidas his father had suffered martyrdom the year
before, during the persecution of Severus in 202; and
Ori gen had shown such eagerness to follow his father
to martyrdom, that his mother was obliged to hide
his clothes to prevent his going abroad. Ori gen
had a great concourse of auditors who attended his school,
some of whom were of the faithful, and the others
pagans. He confirmed and strengthened the first in their
faiths, and converted most of the others; and there were
such a number of martyrs amongst his disciples, that it
might be said, ‘that he kept rather a school of martyr-
dom than of divinity. He taught the doctrines of
Christianity to the girls, and women as well as to the men;
and taking in a too literal sense what Christ says of be-
coming voluntary eunuchs, castrated himself to prevent
his deserving or suffering scandal. He took a voyage
to Rome in 211, in the beginning of Caracalla’s reign,
under the pontificate of Zephyrinus. At his return he
published many works, by which he acquired an extra-
ordinary reputation, that drew to him a great number of
readers. But Demetrius, bishop of Alexandria, con-
ceiving a jealousy of him, endeavoured by various pre-
tences to injure him. At length Ori gen went to An-
tioch, whether the empessa Mammeza had sent for him
to hear him discourse on the Christian religion. He did
not however stay long there, but returned to Alexandria,
where he continued to teach till the year 228, when
he left the city, and travelled into Achaia. In that
journey he went into Palestine, and was ordained
by the bishops of that province at 42 years of age. His
being ordained by foreign bishops, without the per-
mission of Demetrius, renewed that praelate’s resent-
ment against him; on which Ori gen hastily returned
to Alexandria, to endeavour to mollify him: but De-
metrius drove him from thence in 231, and caused
him to be excommunicated, and even deposed in a
council held in Egypt. Ori gen then retired to Ces-
area in Palestine, where he raised a celebrated school,
and had St Gregory Thaumaturgus, and a great
number of other persons who were illustrious for their
virtue and learning, for his disciples. He afterwards
travelled to Athens; and then, at the desire of Firmi-
lianus, stayed some time at Cesarea in Cappadocia;
whence he was invited into Arabia, to convince and
bring back to the truth Beryllus bishop of Bostra; who
maintained that the Word had no existence before his
incarnation. Ori gen had the happiness to make him
sensible of his mistake; and some years after was sent
for into Arabia by an assembly of bishops, to dispute
against the Arabians, who maintained that the souls
of the dead remained in a state of insensibility till the
general resurrection. At length the seven persecu-
tions of the Christians began in the reign of Decius,
and none were used with greater severity than Ori gen.
He supported with incredible constancy the dreadful
torments which the persecutors of the Christians in-
vanted against them; torments that were the most
incurable, as they were made to continue a long
time, and as they took the greatest care to prevent his
expiring in the midst of his tortures: but in the midst
of the most excruciating torments, he discovered an
hercule courage, and suffered nothing to escape him
that was unworthy a disciple of Jesus Christ. He
died at Tyre in 254, aged 69. He was the author of
a great number of excellent works. The principal
of those which have been handed down to us are, 1. A
Treatise against Celsus, of which Spencer has given
a good edition in Greek and Latin, with notes: this
learned treatise has been translated into French by Elias
Boubereau, a protestant minister, born at Rochelle.
2. A great number of Homilies, with Commentaries
on the Holy Scriptures. 3. Philoeca, and several other

(A) He is the first Christian (whose notions on this subject have come down to us) who believed in the re-
stitution of all things. This is his sixth distinguishing tenet; to which is added this singular notion, that as
Christ had been crucified in this world to save mankind, he is to be crucified in the next to save the devil.
The other obnoxious tenets of Ori gen are these five: viz. 1. That in the Trinity the Father is greater than
the Son, and the Son than the Holy Ghost. 2. The pre-existence of souls, which Ori gen considered as sent
into mortal bodies for the punishment of sins committed in a former state of being. 3. That the soul of Christ was
united to the word before the incarnation. 4. That the sun, moon, and stars, &c. were animated and en-
dowed with rational souls. 5. That after the resurrection, all bodies will be of a round figure. It is probable
that the mystic theology of the modern Quakers and other such sects is derived from Ori gen. See Moser.
Ecc. Hist. vol. 1st,
other treatises. 4. Fragments of his Hexaples, collected by Father Montfacon, in two volumes folio. Of all Origen's books, the loss of the Hexaples is most to be regretted. This work was thus named from its containing six columns; in the first of which was the Hebrew text of the Bible; in the second, the same text in Greek characters; in the third, the Greek version of the Septuagint; in the fourth, that of Aquila; in the fifth, that of Symmachus; and in the sixth, that of Theodotion. This work gave the first hint for our Polyglot Bibles. 5. The book of Principles; of which we have only an incorrect Latin version. In all his writings he discovers a surprising degree of modesty, candour, and humility; a noble and sublime genius, profound learning, and vast erudition. His manners were extremely pure, and he had a warm zeal for spreading the truths and morals of the Gospel.

Much has been written both for and against this celebrated father, both by his contemporaries and others: he has indeed suffered great abuse, which he did not deserve, and which we shall not retail; contenting ourselves with the following account of his character by Dupin, and some remarks on it by Dr Jortin. "Origen (says Dupin) had very quick parts, a very strong and enlarged imagination; but he relied too much on the vivacity of his genius, and often lost himself, out of too great earnestness to fathom and subtilize every thing. He had a very happy invention, and a more happy delivery of what he invented; but he had not that exactness in his inventions, nor that gracefulness of delivery as might be wished. He carried on his works with so great a ease, that he is said to have dictated to seven or eight persons at a time; and he was so ready in expressing himself, that he made the greatest part of his homilies extempore: upon which account his style was not very correct or coherent. He had a vast memory, but often trusted too much to it. He was a person of most profound learning: he particularly studied Plato's philosophy, and was indeed too much addicted to it for a Christian. He understood likewise the doctrines of other philosophers. He applied himself mightily to the study of human learning. He was neither ignorant of history nor mythology; and he had as great a knowledge in all the profane sciences, as those who studied nothing else. But he particularly excelled in the knowledge of the Holy Scriptures, which he learned all by heart; and that he might neglect nothing for attaining a right understanding of the letter thereof, he carefully examined all the versions of the Bible, and compared them all together with the Hebrew text, subjoining a literal commentary upon the most difficult places. He was not very well skilled in the Hebrew; yet he knew enough of it to understand it, and to observe the difference of the text and the translations. Nevertheless, he did not adhere to the literal explication of the Bible, but thought it necessary, for the sake of gaining it credit with the heathens, who despised its plainness and simplicity, and of rendering it more useful to the world, to give mystical and allegorical interpretations of every thing in it."

Dr Jortin tells us, "That Origen was very learned and ingenious, and indefatigably industrious. His whole life from his early years was spent in examining, teaching, and explaining the Scriptures; to which he joined the study of philosophy and of all polite literature. He was humble, modest, and patient, under great injuries and cruel treatment, which he received from Christians and Pagans: for though he ever had a considerable number of friends and admirers, on account of his amiable qualities and useful accomplishiments, he was persecuted and calumniated by men, who had neither his learning nor his virtue, degraded from the order of presbyters, driven from his home, and excommunicated by one Demetrius bishop of Alexandria, who envied him, says Eusebius, for the reputation which he had gained. His inquisitive genius, and his mixing philosophy with Christianity, led him perhaps into some learned singularities and ingenious reversion; but he was by temper far from dogmatizing in such points, from fomenting schisms, and setting up himself for the head of a party. He lived in times when Christians were not so shocked with systems and determinations as they were afterwards, nor so much exposed to disingenuous and illiberal objections; and had more liberty to pursue their inquiries and to speak their mind. He was ever extremely sober and exemplary, practising what he preached to others; and he lived and died poor, and destitute even of common conveniences."

The most complete edition of his works is that of Father Delarue, a Benedictine, in Greek and Latin. The celebrated Montfacon likewise published, in 2 vols folio, some remains and fragments of his Hexapla.

He ought not to be confounded with another Origen, a Platonic philosopher, and the disciple and friend of Porphyry, who studied philosophy under Ammonius; perhaps this Origen was the founder of the Origenians.

ORIGENIANS (Origeniani), ancient heretics, who even surpassed the abominations of the Gnostics. Epiphanius speaks of them as subsisting in his time; but their numbers, he says, were inconsiderable. He seems to fix their rise about the time of the great Origen; but does not say that they derived their name from him. On the contrary, he distinguishes them from the Origenists, whom he derives from Origen Adamantius; adding, indeed, that they first took their name from one Origen; by which he intimates, that it was not the great Origen. And St Augustine expressly asserts, that it was another. Their doctrines were shameful: they rejected marriage; they used several apocryphal books, as the acts of St Andrew, &c. and endeavoured to excuse their open crimes, by saying, that the Catholics did the same in private.

ORIGENISTS, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state: that they were holy intelligences, and had sinned in heaven before the body was created: that Christ is only the Son of God by adoption; that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues one after another; that, in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

ORIGINAL, a first draught or design of any thing, which serves as a model to be imitated or copied.
ORIGINAL SINE, the crime of eating the forbidden fruit, of which, it is said, all mankind are guilty at their conception, by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human race; and that, on his sinning, all that were to spring from him partook of his crimes. See THEOLOGY, &c.

ORIGUELÁ, a town of Valencia in Spain. It is situated between the mountains, on the banks of the river Segura, in a place fortified by nature, and in a fertile plain abounding in all things, especially corn. It contains 21,000 inhabitants, and has a university and a bishop's see. It is defended by an old castle; and is the capital of a government independent of Valencia, whose jurisdiction extends 30 miles in length and 15 in breadth.

W. Long. o. 56. N. Lat. 38. 22.

ORILLON, in Fortification, is a small rounding of earth, faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See FORTIFICATION.

ORIOLUS, or Oriole, a genus of birds belonging to the order of Passeriflora. See AVANTHILOGY INDEX.

ORION, a fabulous hero, was the son of Jupiter, Neptune, and Mercury. For as these gods were visiting the earth, they entered the house of Hyrieus, a native of Tanagra, in Boeotia, under the character of hightoned.Yers, on account of his being famed for hospitality to strangers. Hyrieus treated them in the best manner in his power; and even killed an ox, the only one he had, for their entertainment. At which the gods were so pleased, that they offered the old man whatever he would ask; who letting them know that he desired nothing so much as a son, they, to gratify his wish, caused the ox's hide to be brought before them, in which, having deposited their urine, they bade him keep it under ground for nine months. He then dug for the skin, and found it in a beautiful child, whom he called Orion, ab urina. The name was afterwards changed into Orion by the corruption of one letter, as Ovid observes: Perditio antiquorum litera prima somnus. The name was taken from among her attendants, and even became deeply enamoured of him. His gigantic stature, however, displeased Oenopion king of Chios, whose daughter Hero or Merope he requested in marriage. The king, not willing to deny him openly, promised to make him his son-in-law as soon as he delivered his island from wild beasts. This task, which Oenopion supposed to be impracticable, was soon performed by Orion, who eagerly demanded his reward. Oenopion, on pretence of complying, intoxicated his illustrious guest, and put out his eyes on the sea-shore, where he had laid himself down to sleep. Orion found himself blind when he awoke. He went, directed by the sound, to a neighbouring forge, where he placed one of the workmen on his back, and by his directions went to a place where the rising sun was seen with the greatest advantage. Here he turned his face towards the luminaries, and, according to report, he immediately recovered his eyesight, and hastened to punish the perfidious cruelty of Oenopion. Orion was reported to be an excellent workman in iron, and to have fabricated a subterraneous palace for Vulcan.

Aurora, whose Venus had inspired with love, carried him away into the island of Delos, that she might enjoy his company with greater security, but Diana, who was jealous of this, destroyed him with her arrows. Some say, that Orion had provoked Diana's resentment, by offering violence to Opis, one of her female attendants; or, as others say, because he had attempted the virtue of the goddess herself. According to Ovid, Orion died of the bite of a scorpion, which the earth produced to punish his vanity, in boasting that no animal on earth could conquer him. Some say that Orion was son of Neptune and Euryale, and that he had received from his father the privilege and power of walking over the sea without wetting his feet. Others assert, that he was a son of Terra, like the rest of the giants. He had married a nymph called Sida, before his connection with the family of Oenopion; but Sida was the cause of her own death, by boasting herself better than Juno. DIDOUS says, that Orion was a celebrated hunter, superior to the rest of mankind, by his strength and uncommon stature. He built the port of Zancle, and fortified the coast of Sicily against the frequent inundations of the sea, by hoisting a mound of earth called Polyx, as a temple to the gods of the sea. After death Orion was placed in heaven, where one of the constellations still bears his name. The constellation of Orion was placed near the feet of the bull. It was composed of 17 stars in the form of a man, holding a sword; for which reason the poets often speak of Orion's sword. As the constellation of Orion, which rises about the 9th day of March, and sets about the 21st of June, is generally supposed to be accompanied at its rising with great rains and storms, it has acquired the epithet of aquarius; given it by Virgil. Orion was buried in the island of Delos; and the monument which the people of Tanagra in Boeotia showed, as containing his remains, was nothing but a cenotaph. The daughters of Orion distinguished themselves as much as their father; and when the oracle had declared that Boeotia should not be delivered from a dreadful pestilence before two of Jupiter's children were immolated on the altars, they joyfully accepted the offer, and voluntarily sacrificed themselves for the good of their country. Their names were Hero and Metioche. They had been carefully educated by Diana; and Venus and Minerva had made them very rich and valuable presents. The deities of hell were struck at the patriotism of these two females; and instantly two stars were observed to arise from the earth, which still smoked with their blood, and were placed in the heavens in the form of a crown. According to Ovid, their bodies were burned by the Thesani, and from their ashes arose two persons, whom the gods soon after changed into constellations.

ORION, in Astronomy, one of the constellations of the southern hemisphere. The word is formed from the Greek ορίων, "to make water;" the ancients supposing that it raised tempests at its rising and setting. The stars in the constellation Orion, in Ptolemy's catalogue are 37, in Tycho's 62, in the Britannic catalogue 80.

Orestiagni, an ancient town of the island of Sardinia, with an archbishop's see. It is pretty large and well fortified; but thinly inhabited, on account of the unhealthy air; it is seated on the western coast,
ORKNEY ISLANDS, called Orcades by the ancients, certain islands on the north of Scotland (A), from which they are separated by a frith 20 miles in length and 10 in breadth.

As writing seems to have been unknown in the northern islands, during those periods which the antiquarian would call the most curious and important, the chief part of our information respecting the ancient state of the Orkneys must be derived from tradition and conjecture. Their mountainous situation, and natural jealousy of strangers, obstructed the progress both of knowledge and religion: for instead of receiving either from their southern neighbours, we are certain that they derived their knowledge of Christianity from Norway, during the expeditions undertaken by that nation (in the end of the 10th or beginning of the 11th century) to make settlements in the Orkneys and on the coast of Caithness (B). The best (because it is in all probability

(A) The northern isles of Scotland have been often mentioned by ancient authors, and called by different names from those they now go by; so that it is sometimes difficult to know which of them are meant. The ancient name, however, of the islands are the subject of this article, has never been disputed. The Ebudes, it is agreed, are the modern Hebrides; and there is no doubt of the ancient Orcades being the same with the Orkneys. Of Thule, however, we are not so certain; and whether it means the Shetland Isles, or Iceland, remains undetermined. Pythis, a Massilian, pretends to have visited these islands, and particularly Thule; but he does not mention the Orcades. The geographer Mela, who was contemporary with the emperor Claudius, is the next writer who describes the northern islands. Of the Orkneys he gives a remarkably just account, and says they were thirty in number, with narrow channels between them; but he is less accurate with respect to the rest. Pliny the Elder is the third who mentions the northern islands. He makes the number of the Orkneys to be forty, and of the Hebrides to be thirty. Solinus, the supposed contemporary with Agricola, is the next after Pliny. In his time, and according to his account, these islands had not a single inhabitant, and were overgrown with rushy grass. It seems on the whole to be pretty generally allowed, that Julius Agricola, who first sailed round Britain, discovered the Orkneys, till then unknown, and subdued them. The Romans, never that we know, visited these islands again but once, which was probably after Honorianus had defeated the Saxons in the seas of Orkney. Claudius was so far from reducing them (as is asserted by Jerome in his Chronicle), that Juvenal has these lines in Hadrian's time:

Arma quid ultra
Littora Juverne promovimus et modo captas
Orcades, et minima contentos noce Britannos.

In vain, O Rome, thou dost this conquest boast
Beyond the Orcades' short-nighned coast.

DRYDEN.

Tacitus informs us, that before the completion of the first century, the Roman fleets sailed round Scotland, and landed in the Orcades to refresh.

(B) It has been asserted, that the Orkneys, as well as the isles of Shetland, were originally peopled from Norway, in the ninth, tenth, or eleventh century. Others again imagine, with as much probability, that the Picts were the original inhabitants, and call Orkney the ancient kingdom of the Picts. Certain singular houses, now overgrown with earth, are called Picta houses; and the Pentland Frith (formerly Pictland or Pictland) is supposed to retain their name. Claudian's lines, cited by Mr. Camden, prove, that the Picts, with some other German colony, particularly the Saxons, were at that time in possession of these isles; and so Ninims expressly says. Many of the present inhabitants use the Norse language, which differs but little from the Teutonic or Pictish language, and was in general use to the last century, but except on Foula, where a few words are still known by that aged people, it is quite lost. The English tongue, with a Norwegian accent, is that of these islands; but the appearance of the people, in their manners and genius, evidently shows their northern origin. Ninims. c. 5, puts their arrival at Orkney not less than 900 years after the coming of Brutus into Britain, which he says was in the time of Eli the Jewish high priest. The ancient surnames are of German original. Some date the first settlement of the Picts here A. M. 4867; when, emigrating from their native country, they planted a colony in Orkney, and thence crossing Pictland frith, and traversing Caithness, Ross, Murray, Mar, and Angus, settled in Fife and Lothian; thence called by our writers Pictlandia. Others think they did not settle here till the time of Reuther king of Scotland, when the Picts, joining with a party of the Scots, were repulsed, with the loss of their king Gethus, and many of the Picts and Scottish nobility, with great slaughter; but the invasions of the Britons, at the same time, constrained the Picts to fly to Orkney, where they chose for king Gothus their deceased sovereign's brother,
Delays were not permitted; Christianity was forced upon 

him and his subjects; and on the departure of Olau, he 
carried the son of Sigurd as an hostage for what he had 
engaged; which was to give honourable protection to all 
those holy men who might choose to reside in those parts 
for the purpose of instructing the people in the nature 
of the Christian doctrines; for many of the more inteli-
gent and religious men who had come from 

Norway with Olau, remained in the Orcades and in the north 
of Scotland, to fulfill their pious resolution of spread-
ing the light of the gospel there. Olau, with the rest of 
his followers, sailed on another expedition towards 
the faith of Moray. The death of Kindus's son, 
which happened soon after Olau's return to Norway, 
released Sigurd from his engagements with him; 
and he entered into one with Malcolm II. one of whose 
dughters he had in marriage, and by whom he had a 
son, Torphinus. Torphinus's bravery, magnificence, 
generosity, and hospitality, endeared him to the inha-
bibants; and he ruled without control for many years, 
till Ronald, a grandson of Sigurdus, who had lived in 
Norway, and who was esteemed the rightful heir of 
the earldom of Orkney, made a successful descent up 
on it. Torphinus wished to give him battle; and in a 
sea-fight, with the assistance of some ships from Ar-
ninus, a man who had filled some of the first places in 
Norway, he totally defeated him. By courting the 
friendship of that court, his dominions remained quiet 
for the greater part of his life; the latter part of which 
was no less eminent for establishing salutary laws, 
and encouraging the arts of industry, than the former 
had been distinguished for military fame and success in 
the exploits of war. He lived to an advanced age, 
until after Malcolm III. had ascended the throne of 
Scotland. Torphinus had built a sumptuous church 
in Byrsa, where the first bishop of Orkney resided. 

In the decline of life he retired to that island, and, 
finishing his days with exemplary piety, was with much 
solemnity interred in the temple which he had raised. 

His country long lamented the loss of so celebrated 
a ruler, who had established security in it, through 
the influence of his laws, and had taught it to enjoy the 
arts and blessings of peace. He left two sons, Paul 
and Erland, who through the whole of their lives 
amicably shared both in the honours and administra-
tion of their father's extensive domain. During this 
period, the northern counties are said to have arrived 
at a very superior degree of cultivation and improve-
ment, which became equally conspicuous in the rich-
ness of their lands, and in the mildness of their dispo-
sitions. Their sons, however, did not both inherit their 
father's virtues. Magnus, the son of Erland, was pious 

and 

brother, till they were able to return to Lothian, and drive out the Britons. After this they flourished here, and 
were governed by kings of their own. There still remains a place called Cunninggwa, the dwelling place of the 
minister of Sandwich, whose name and form bespeak it the residence of some of them. But no traces of their 
history remain, except the name of Belsus, in ancient characters, on a stone in the church of Birsay, where still is to 
be seen one of the principal palaces. This government probably subsisted till the subversion of the Pictish king-
dom in Scotland, A. D. 839, by Kenneth II. king of Scotland. On the whole, however, the time of the discovery 
and population of the Orkneys is certainly unknown. Probably it was very early; for we are told that they owe 
their name to the Greeks.

Orcades has memorant dictas a nomine Graeco. Claudián.
ORK [ 461 ]

Orkney, and peaceful; a great promoter of religion, and anxious in patronizing the Roman missionaries, and in protecting the establishments of Christianity: but Hacon, the heir of Paul, was vehement, wild, and impatient of restraint. He saw how Magnus was revered, and envy drove him to revenge; for, by the most deliberate and deceitful villany, he got Magnus into his power, and murdered him without mercy. The latter part of his life was spent in penance, and in improving his dominions.

Magnus's singular piety, and the manner of his unfortunate death, were so well represented at the court of Rome, that he was canonized. Hacon left two sons, Paul the Silent, and Harold the Orator. Caithness came to Harold, and the Orkneys were governed by Paul.

Ronald, a descendant of St Magnus, an elegant and accomplished youth, appeared at the court of Norway, and was supported in a plea upon the Orkney as the heir of the canonized martyr. He sent messengers to Paul, and offered to share the government with him; but this proposal was refused, and the ambassadors were treated with great contempt. They, however, found persons of power disposed to second their master's views; who soon after their return set out, and vowed, if he succeeded, to build a magnificent church, and to dedicate it to St Magnus. All seemed satisfied with the enterprise; and, full of hope, the fleet set sail. Paul in the mean time put himself in a state of defence. By very artful manoeuvres, however, Ronald obtained his purpose, and willingly shared his sovereignty with Harold, the legal heir of Paul. They lived amicably together; and on the assassination of Ronald, which was accomplished by a proud chief, who thought himself insulted, he was buried with great pomp. Harold now fully possessed the unrivalled sovereignty of the north, and lived long to enjoy it. We find that in 1296 he was able to bring 7000 men to the field, and a body of cavalry, against William, king of the West Inns, but was immediately defeated. In the next year, the Caithnessians rebelled again, headed by one Roderick, and Torphinus, son to Harold. The king met and defeated them near Inverness. Roderick was slain; and William seizing on Harold in the extremity of Caithness, detained him till Torphinus surrendered himself as a hostage; but on some new treasons of the father, the king, according to the barbarity of the times, caused the eyes of the unhappy youth to be put out; and had him emasculated, of which he soon perished in prison. Harold died in the 73rd year of his age; and with him ended, in its early, the independent sovereignty of the north of Scotland. The Norwegians seem to have been in possession of these isles as late as 1266; for then Magnus IV. king of Norway, being worsted in war with the Scots, yielded them to Alexander III. king of Scotland by treaty, and Haquin king of Norway confirmed the possession of them to King Robert Bruce in the year 1312. Lastly, in 1464, Christian I. king of Norway and Denmark, when he gave his daughter in marriage to James III. king of Scotland, transferred all his right to them to his son-in-law and his successors; to which more binding the Pope's confirmation was obtained. We are told by some, that Magnus sold them to Alexander for the sum of 4000 marks sterling, and a yearly acknowledgement of 100 marks.

They are about 30 in number; but many of them are uninhabited, the greater part being small, and producing only pasturage for cattle. The principal islands are denominated by the names of Mainland, South Ronaldshay, Swinna, Flatta, Copinshe, Strupenshe, Stronsa, Sunda, &c. the terminations in a, or ha, being generally given in the Teutonic to such places as are surrounded by water. The currents and tides flowing between the islands are extremely rapid and dangerous. Near an island called Swinna, are two great whirlpools, called the wells of Swinna, which are counted dangerous by mariners, especially in a calm. When sailors find themselves sucked into the vortex, it is said they throw out a barrel, or some bulky substance, which smooths the water till it is sucked down and thrown up at a considerable distance, during which time the ship passes over in safety. But when there is a break of wind, these whirlpools may be crossed without any danger. The largest of these islands is called Pomona, in length 33, and in breadth 9 miles, containing 9 parish-churches, and 4 excellent harbours.

The air of these islands is moist, on account of the neighbourhood of the sea; and frost and snow do not continue long. In some places the soil is bare and mountainous, and in others sandy and barren; however, many of the islands produce large crops of barley and oats, but no wheat or other grain excepting what is inclosed in gardens. These, when duly cultivated, produce all kinds of kitchen herbs and roots, bringing even fruit-trees to maturity; but out of them, in the open country, there is scarce a tree or shrub to be seen, except juniper, wild myrtle, heath, and the cyrus-bodou: yet this deficiency cannot be imputed to the poverty of the soil, or the nature of the climate: for the trunks of large oaks are frequently dug up in the marshes. This is likewise the case in the most southern parts of the Highlands of Scotland, where not a shrub is to be seen above the surface of the earth; nay, the inhabitants frequently find, deep in the earth, the roots of large trees, evidently exhibiting marks of the axe by which they were felled; so that these northern parts must have undergone some strange revolutions. The Orkneys produce great variety of herbs and berries, grass and corn, which last is exported as far as Edinburgh. In some of the islands, the natives have discovered mines of tin, lead, and silver, though none of them are wrought to any advantage; in others, we find abundance of marble and alabaster. When the wind ranges to any violence, the sea throws in plenty of timber, torn from other countries; and, not unfrequently, the people find large pieces of ambergrise. The fresh water in these islands is very pure and limpid; and though there are no large rivers in the Orkneys, the ground is well watered with lakes and pleasant rivulets, that not only serve to turn their mills, but also abound with trout of the most delicate flavour.

Besides the abundance of little horses, black cattle, sheep, swine, and rabbits, the inhabitants of the Orkneys rear all sorts of domestic animals and tame poultry. Their heaths and commons yield plenty of red deer,
Of the Orkneys are civilized, polite, and hospitable; and live like those of Scotland, from whom they are chiefly descended. They live comfortably, are remarkably courteous to strangers, and drink a great quantity of wine, with which their cellars are generally well stored. Indeed the inhabitants of the Orkneys may be now justly deemed a Scotch colony. They speak the language, profess the religion, follow the fashions, and are subject to the laws, of that people. They are frugal, excusable, circumspect, religious, and hospitable. The mariners are remarkably bold, active, dexterous, and hardy. Many surprising instances of longevity occur here, as well as in Shetland, of persons living to the age of 140. The Orkney women are generally handsome, and well shaped, and bring forth children at a very advanced age. In the Orkneys, some particular lands are held by a tenure called Udalt Right, from Ulcinius, or Ulans, king of Norway, who farmed the lands, on condition of receiving one-third of the produce; and this right devolved in succession, without any charter granted by the sovereign. The inhabitants of Orkney, instead of measuring their corn, weigh it in pismores or pounders. Their least denomination is a mark, consisting of 18 ounces, and 24 marks make a lispound, which is a Danish quantity. The poorer sort of people in the Orkneys appear very meanly habited, with a piece of seal skin, instead of shoes; and living chiefly on salt fish, are subject to the scurvy. They are much addicted to superstitious rites; in particular, interpreting dreams and omens, and believing in the force of idle charms. The islands of Orkney, we have already observed, produce very bold, able, and hardy mariners. The common people, in general, are insured to fatigue, and remarkably adventurous, both in fishing during rough weather, and in climbing the rocks for the flesh, eggs, and down of sea-fowl. Formerly, while they were exposed to the invasions of the Norvegians, or western islanders, every village was obliged to equip a large boat well manned; and all the feasible men appeared in arms, when the alarm was given by the beacons lighted on the tops of the rocks and highest mountains. These beacons, known by the name of ward-hills, are still to be seen in every island. Their corn land they inclose with mud or stone walls, to preserve it from the ravages of their sheep, swine, and cattle, which wander about at random, without being attended by herdsmen: their ordinary manure, especially near the sea-coast, is sea-weed, which they carefully gather and divide into equal portions. Their sheep are marked on the ears and nose; but so wild, that when they have occasion to shear them in the month of May, they are obliged to hunt every individual, with dogs trained for that purpose. Their manner of catching sea-fowl is curious and particular. Under the rock, where these fowls build they row their boat, provided with a large net, to the upper corners of which are fastened two ropes, lowered down from the top of the mountain by men placed in that station. These hoisting up the net, until it be spread opposite to the cliffs in which the fowls are sitting, the boatmen below make a noise with a rattle, by which the fowls being frightened, fly forwards into the bottom of the net, in which they are immediately enclosed and lowered down into the boat; others practise the method used in Iceland and Norway, and are lowered down by a single rope from the summit of the mountain; this is the constant way of robbing the hawk's nest. See Bird-Catching. In these islands some strange effects are produced by thunder and lightning. In the year 1680, the lightning entered a cow-house, in which 12 cows stood in a row, and killed every second beast as she stood, and left the rest untouched. The tempests that prevail mostly in the Orkneys are aques, consumptions, scurvy, and itch. The aques, which abound in the spring, the natives cure with a diet drink of Bitters and antiscorbutics infused in ale; for phthisical complaints they use the plant arby, and the caryophyllus marinus boiled with sweet milk.

The isles of Orkney and Shetland compose one stew-
testant religion prevails in the isles of Orkney, according
to the rites and discipline of the kirk; these, and
the isles of Shetland, constituting one presbytery, which
assemblies at Kirkwall. The country is divided into
18 parishes, containing 31 churches, and above 100
chapels.

The trade of the Orkneys is not very considerable,
though it might be extended to great advantage. They
supply with fresh provisions, for ready money, the ships
and vessels that touch upon the coast in the course of
northern voyages, or in their passage from the East
Indies, when they go north about Ireland and Scotland,
in time of war, to avoid the privates of the enemy.
They are also visited by those engaged in the herring-
fishery, though there is not such a resort on this account
to these islands as to the isles of Shetland. Nevertheless
a good number of boats from the western parts of
Scotland, as well as from Londonerry, Belfast, and
other parts of Ireland, fish for herring as far north as
the Leuze, and supply the Orkneys with tobacco, wine,
brandy, and other spirituous liquors, clothes, and divers
manufactures. These they change for fish, and oil
extracted from porpoises, seals, and other sea animals.
The people of Orkney export annually great numbers
of black cattle, swine, and sheep; together with large
quantities of corn, butter, tallow, salt, and stuffs made
in the country, over and above the skins of seals, oters,
lambs, and rabbits, down, feathers, writing-quills,
hams, and wool; yet all these articles would, in point of
profit, fall infinitely short of their herring fishery,
were it prosecuted with industry, economy, and vigour.

The most valuable of their manufactures is kelp, and
indeed the staple commodity was first introduced in
1722, by Mr. James Pet, of Whitehall, in Shetland,
since which period it has been gradually on the increase.
From 1763 to 1778, there was manufactured, on an
average, 1820 tons annually at four guineas per ton;
from 1778 to 1792, the annual average produce was
3000 at 6l. per ton; from 1792 to 1794, above 4000
tons. Thus, from 1722 to 1794, a period of 72 years,
the produce of the kelp was 251,976l. sterling, or more
than the value of all the Orkney islands, even at the
rate of 36 years purchase; the annual rent, exclusive
of the kelp and fisheries, not exceeding 8000l. sterling.

As there are no merchants in the Orkneys at present
who export fish on their own account, what herring are
taken are used to sell to the Dutch or Scotch dealers
in and about Inverness. They generally fish for herring
on the west side of the Orkneys; and are therefore more
remote from markets than those who are employed in
the same manner on the coast of Shetland. In the Ork-
ney islands they see to read at midnight in June and Ju-
y; and during four of the summer months they have
frequent communications, both for business and soci-
ity, with each other, and with the continent: the rest of
the year, however, they are almost inaccessible,
through fogs, darkness, and storms. It is a certain fact,
that a Scotch fisherman was imprisoned in May for
publishing the account of the prince and princess of
Orange being raised to the throne of England the pre-
ceding November; and he would probably have been
hanged, had not the news been confirmed by the arrival
of a ship.

We may reckon among the curiosity of the Ork-
Orkney. Considering the art that must have been used to bring such unwieldy masses together in this order. They were probably temples and places of sacrifice used in times of pagan superstition; and seem to bear a great affinity with the celebrated monument called Stonehenge on Salisbury Plain in England. In one of the mounts, at the north end of the causeway, the natives found nine fibulae, or clasps of silver, formed into a circle, and resembling a horse-shoe. In many different places of the Orkneys we find rude obelisks or single stones of a great height, set up either as a memorial of battles, treaties, or the decease of remarkable personages. In Rousay, between two high mountains, there is a place which the natives distinguish by the appellation of the camp of Jupiter Fring; but the meaning of this name, handed down by tradition, is not yet known. At the west end of the Mainland, near Skeal, we find a surprising causeway, above a quarter of a mile in length, on the summit of high hills, composed of reddish stones of different magnitudes, impressed with various figures both on the under and upper surface. Some gentlemen in the neighborhood have carried off the most beautiful of these stones, to be set in their chimneys by way of ornament, like the painted kilns of Holland. This country produces many sepulchers of different nations. In the neighborhood or links of Skeal, the sand being blown away from the surface of the ground, several square catacombs appear, built of stones well cemented together, containing some parcels of black earth, and each secured by a large stone at the mouth. Sepulchers of the same kind are found at Rossum on Stronsa; which is likewise remarkable for a different kind of monument, consisting of one entire stone cylinder hollowed, with a bottom like that of a barrel, and a round stone to fill up the entrance; above, the stone was sharpened into an edge; within were found some burnt bones and red clay; and over it was placed a large flat stone for the preservation of the whole. These, in all probability, were Roman catacombs. In Westra divers Danish graves have been discovered: in one of these appeared the skeleton of a man, with a sword on one side and a Danish axe on the other. Some have been found buried with dogs, combs, knives, and other utensils. In many places of the country we find round hillocks or barrows, here known by the name of brooch, signifying in the Teutonic language, burying place, supposed to have been the cemeteries of the ancient Saxons. In different parts of these islands we see the remains of great buildings, believed to have been fortresses erected by the Danes or Norwegians when they possessed the country. One of these, in the isle of Wyre, called the castle of Coppi-row, signifying a town of security, is surrounded by a fosse, and the first floor still remains above ground, a perfect square of stone wall, very thick, strongly built, and cemented with lime, the area within not exceeding ten feet in length. Of this Coppi-row the common people relate many idle fables. In the chapel of Clet, in the isle of Sands, there is a grave 10 feet long, in which was found part of a man's back bone larger than that of a horse. Human bones of nearly the same size, have been dug up in Westra; and indeed this country is remarkable for producing men of a gigantic stature. Within the ancient fabric of Lady Kirk in South Ronaldshay, there is a stone four feet long and two feet broad, on which the prints of two feet are engraven, supposed to be the place where, in times of popery, penitents stood to do public penance. The cathedral of Kirkwall, the capital of the Orkneys, is a fine Gothic building, dedicated to St Magnus, but now converted into a parish church. Its roof is supported by 14 pillars on each side; and its steeple, in which is a good ring of bells, by four large pillars. The three gates of the church are chequered with red and white polished stones, embossed and elegantly flowered.

Campbell, in his Political Survey, suggests two improvements in the Orkneys: 1. The erecting an university; of which he recapitulates the probable advantages arising from their centrical situation: And, 2. Allowing the East India Company to erect a spacious magazine in one of these islands; where also a collector, and a sufficient number of king's officers, should reside, to receive the duties of such East India commodities as might be taken off by British subjects. These he proposes for the Orkneys in particular, and in addition to improvements proposed for the whole islands in general.

The following table exhibits a view of the population of the parishes of Orkney and Shetland, at two periods.

Increase 4648
In 1801, according to the returns made to Parliament, the population of Orkney was 24,445, and that of Shetland was 22,379, and in 1811 the population of both was 46,153. For a fuller account of Orkney, see Barry's History of the Orkney Islands, 4to. 1805.

ORLE, ORLET, or Orlo, in Architecture, a pillet under the ovo, or quarter round, of a capital. When it is at the top or bottom of a shaft, it is called cincture. Palladio uses the word orlo for the plentiful of the basis of the columns.

ORLE, in Heraldry. See HERALDRY.

OLEANOS, a province of France, now forming the three departments of Loiret, Loire et Cher, Eure et Loir.

ORLEANS, the chief town of the department of Loiret, and formerly the capital of the government of Orleans. It was anciently called Gernabum, or Cer- naunum; and afterwards denominated Aurelia, Aurelia, and Aurelianum, by the emperor Aurelian, who considerably enlarged it. In Julius Caesar's time it was the capital of the Carnutes. It stands about 20 leagues south of Paris, on the northern bank of the Loire; across which Mr. Wraxall says there is an elegant bridge of nine arches, the entrance by which is exceedingly noble and striking, the street which leads from it being composed of most elegant modern buildings. In general, however, excepting this street, it is very meanly built; the streets are narrow, and the inhabitants in general poor. It is surrounded with walls, and fortified with 40 towers. The streets almost all terminate at the gates for the convenience of trade. It is the seat of several courts of justice, and in 1809 contained 36,000 inhabitants. It is a bishop's see; and the cathedral is a most superb Gothic structure, and had the finest steeple in France till it was damaged in the time of the civil wars. There were 22 parishes in it, and a great number of churches. There are manufactures of cloth, serges, coverlets, printed calicoes, cotton thread, painted paper, refined sugar, &c. By the canal of the Loire it carries on a considerable trade in corn, wines, brandies, vinegar, timber, fire-wood, wool, &c. The canal begins about two miles above the city; is near 18 leagues in length; and terminates on the Loing, which falls into the Seine. The environs of Orleans, more especially in the province of Sologne, to the south of the Loire, are very agreeable. It is in general a level country, covered with corn and vines. To the north of the city is a forest, the largest in the whole kingdom. Before the revolution it belonged to the duke of Orleans; to whom the timber felled in it, one year with another, brought about 100,000 livres. Louis XIV. gave the dukedom of Orleans to his own brother Philip, who began and finished the canal; which, by the duties paid by vessels going up and down, brought in, one year with another, 150,000 livres. The bishop was suffragan to the archbishop of Paris, and had a revenue of 24,000 livres, out of which his tax to Rome was 2000 florins. A new bishop, it is said, on the first day of his entering, had the privilege of releasing all the prisoners in it, except those committed for treason. In the street leading from the bridge stands the celebrated monument where Charles VII. and Joan of Arc the Maid of Orleans, are represented on their knees before the body of our Saviour, who lies extended on the lap of the Virgin. It was erected by order of that monarch in 1458, to perpetuate his victories over the English, and their expulsion from his dominions. All the figures are in iron. The king appears bareheaded, and by him lies his helmet surmounted with a crown. Opposite to him is the Maid herself in the same attitude of grateful devotion to Heaven. It is a most precious and invaluable historical monument.

"In the Hotel de Ville (says Wraxall) is a portrait of the same immortal woman, which I studied long and attentively. Though it was not done till 1581, which was near 130 years after her decease, it is yet the oldest and best picture of her now existing. The painter seems undoubtedly to have drawn a flattering resemblance of her, and to have given his heroine imaginary charms. Her face, though long, is of exceeding beauty, heightened by an expression of intelligence and grandeur rarely united. Her hair falls loosely down her back, and she wears on her head a small bonnet enriched with pearls, and shaded with white plumes, tied under her chin with a string. About her neck is a little collar, and lower down, upon her bosom, a necklace composed of small links. Her dress, which is that of a woman, I find it difficult exactly to describe. It sits close to the body, and is cut or slashed at the arms and elbows. Round her waist is an embroidered girdle, and in her right hand she holds the sword with which she expelled the enemies of her sovereign and her country. I am not surprised at the animated and enthusiastic attachment which the French still cherish for her memory. The critical and desperate emergency in which she appeared; her sex, youth, and even the obscurity of her birth; the unparalleled success which crowned her enterprise; the crouel and detestable sentence by which she was put to death; the air of the marvellous spread over the whole narration, increased and strengthened by that veneration which time affixes to every great event—all these united causes conspired to place her above mortality. Rome and Athens would undoubtedly have ranked her among their tutelary deities, and have erected temples to her honour; nor can I help being amazed, that amidst the almost infinite number of modern saints who crowd and disgrace their churches, no altar has yet been dedicated to the Maid of Orleans." See FRANCE, No. 101.

The bridge was new built in the 18th century, and opened in 1760; and the French esteem it the finest in the world. E. Long. i. 59. N. Lat. 47. 54.

ORLEANS, New, the capital of the state of Louisiana in North America. It is situated on the left side of the Mississippi river, 105 miles from its mouth. This place was founded by the French in 1718; and since it was ceded to the United States with the rest of Louisiana in 1803, its growth has been rapid beyond example. In 1817 it was estimated to contain 30,000 inhabitants, about one third only of whom speak English. It is the great depot of trade for all the countries watered by the Mississippi, Missouri, and Ohio, and must in progress of time become one of the first trading cities in the world. The exports in 1817 amounted to 9,024,812 dollars. The low situation of the town exposes it sometimes to inundation, though it is protected by an embankment; and the extensive marshes all round render it unhealthy. The streets are
ORM

Ornithology.

ORMUS, a small island of Asia, at the bottom of the gulf of the same name, at the entrance of the gulf of Persia. It is about two leagues from the main land, and about six leagues in circuit. They catch excellent oysters about the island; and it yields plenty of fine white salt; also a kind of shining black sand, which is used for dusting writings, and is transported in considerable quantity to Europe. There is neither sweet water nor grass upon it, the soil being of a salt sulphureous nature. It was taken by the Portuguese in 1507, who fortified it; and it was afterwards frequented by a vast number of merchants, who were extremely rich. In 1623 the Persians, by the assistance of the English, conquered this place, and demolished the houses, which were 4000 in number, containing 40,000 inhabitants. Some time after, the Persians rebuilt the fort, and placed a garrison in it; but they could never bring it to be a place of trade as before: however, it is the key of the Persian gulf, as well on account of the importance of the place, as the commodiousness of the harbour. It is now almost deserted, for it produces nothing but salt, which sometimes is two inches deep upon the surface of the earth.

E. Long. 56. 25. N. Lat. 27. 20.

ORNE, a department of France, including part of ci-devant Normandy and Perche. The soil is low and moist, but being well adapted for pasture, great numbers of cattle and horses are raised. There are some considerable woods, and some productive mines of iron. The trade consists chiefly in grain, cider, cattle, horses, hemp, and in serge, woolen cloths, lace, and linens, of which there are manufactures. The territorial extent of this department is 1,265,000 acres, or 2400 square English miles. The population in 1800 was 397,931 persons. The contributions for the year 1802 amounted to 3,666,903 francs. Alençon is the chief town.

ORNITHLÆ, a name given by the ancients to certain winds, which usually blew in the spring, at the time when the birds of passage came over to them. Pliny says, that these winds blew from the west, and that by some the Etesian winds were called by this name. Others suppose that they blew from the north, or north-west.

ORNITHOGALLUM, Star of Bethlehem; a genus of plants belonging to the hexandria class; and in the natural method ranking under the 10th order, Coronaria. See Botany Index.
INTRODUCTION.

The term Ornithology is derived from the Greek ὄρνιθη, a bird, and λόγος, discourse, and denotes that part of Zoolgy which treats of birds.

Birds are two-footed animals, covered with feathers, and furnished with wings. Like quadrupeds and the cetaceous tribe, they have warm blood, a heart with two ventricles, and two auricles, and lungs for the purpose of respiration; but they are distinguished from both by their feet, feathers, wings, and horny bill, as well as by the circumstance of their females being oviparous.

The elegant and beautiful colouring of many of the feathered race, the graceful ease of their flight, their various music, their tender solicitude for their offspring, their engaging instincts, their susceptibility of domestication, and their subservience to the sustenance of man, have, in all ages, contributed to interest the latter in the study of their history.

Of the naturalists, however, whose writings have descended to us from antiquity, Aristotle and Pliny are the only two who appear to have entered into any details on a subject so inviting and important. Though the former composed no particular treatise on birds, he brings them under review in different parts of his History of Animals. In the third chapter of the eighth book, for instance, he enumerates the different kinds of nourishment adapted to different species, and their various modes of feeding. The ninth book contains his very imperfect nomenclature, his remarks on the diversified modes of nidification, and some valuable observations on the family of eagles. His notion of the organization and habits of birds is interspersed in the body of the work, and introduced in the way of comparative reference to the structure and manners of other animals. Pliny's enumeration of the feathered species, is extended over most part of his tenth book, but is destitute of precise description, and encumbered with absurdity and fable.

Of the numerous ornithologists of more modern date, some have chiefly directed their labours to method and classification, others have been more solicitous to describe and delineate; some have treated of the whole class, others of particular portions of it; while, lastly, some have been contented to define and describe, and others have illustrated and enhanced their text by more or less accurate designs from living or prepared specimens. This combination of the pen and the pencil, which has so eminently contributed, in our day, to the acquisition and diffusion of knowledge, seems to have been unknown to the ancients.

Although the unavoidable limitation of our plan precludes a minute and critical report of the works to which we have just alluded, we shall briefly advert to a few of the most conspicuous. Among the first who excited, on the continent, a taste for the study of ornithology, and for a methodical distribution of that portion of science, we may mention Belon. Aware that nature Belon is most successfully contemplated in her own works, he travelled from the laudable desire of collecting information, and communicated to the world the results of his enquiries. His History of Birds, a thin folio volume, divided into seven books, or parts, and illustrated by wooden cuts, was published at Paris, in 1555. His principle of classification being chiefly founded on the circumstances of habitation and food, and only occasionally on external forms and characters, is obviously very defective; his descriptions, though tolerably accurate, are, for the most part, too concise; and many of his plates are very inadequate representations of their originals. It must, at the same time, be allowed, that he frequently suggests judicious views of his subject; that he notes with ingenuity, the points of resemblance between the human skeleton and that of birds; that he has penned several passages which may still be perused with interest and instruction; that the nature of his manner is always pleasing, and that when we reflect on the period in which he flourished, he is entitled to no ordinary praise.

The celebrated Conrad Gessner, physician and professor at Zurich, and contemporary with Belon, has devoted the third volume of his History of Animals to the department of ornithology. It is an erudite, but ponderous tome, exhibiting alphabetical tables of the names of birds, in Hebrew, Chaldee, Arabic, Greek, Latin, and most of the spoken languages of Europe. His descriptions are compiled abridgements; but his references, at the close of each article, are very numerous; for if any author of his acquaintance happen to mention a bird, his name and the passage are duly commerated. Gessner's arrangement differs in no respect from that of any common dictionary; and few of his engravings are executed with correctness. The curious reader will probably be gratified with the perusal of his account of the art of rearing birds for falconry, the diseases to which they are liable, and the remedies which the learned doctor prescribes.

The same topics are discussed by Aldrovandus, a physician of Bologna, who availing himself of the writings of the two preceding naturalists, added to their indigested stores, and compiled three folios, divided into 20 books, and illustrated by wooden plates. His catalogue, however, scarcely comprises any birds but such as are natives of Europe, and by no means all even of these. He too implicitly adopts the vague distinctions of Belon; and on various occasions, not only copies Aristotle with servility, but overloads his borrowed materials with a mass of dark commentary. The motley complexion of the whole production, in fact, betrays the desire of accumulation rather than the exercise of taste and judgement.

Johnston, who published in 1657 a folio volume of Johnson, 760 pages, did little else than greatly condense the heavy complements of Gessner and Aldrovandus. He divides the whole class into land and water birds, and deduces his subordinate divisions from the nature of their aliment.
ORNITHOLOGY.

The next writer of eminence in this department, who merits particular quotation, is Francis Willoughby, Esq. an Englishman gentleman, who laid the foundation of a more accurate arrangement. His work, which appeared in 1676, was revised and edited by his friend the celebrated Ray. It is divided into three books, of which the first is allotted to general views of the subject, and an explanation of the author's method. The first chapter treats of the form and external structure of birds, the second of their organization and internal structure. The sixth includes 24 queries, the answers to which, if founded on fact, would greatly contribute to the advancement of ornithology. Mr. Willoughby formally recognizes the grand division of terrestrial and aquatic, comprising under the former those who live at a distance from water, and under the second, those which live on the margin or surface of that element. He then institutes his leading distinctions from the form of the bill and feet, and would doubtless have accomplished a more complete arrangement, had he uniformly adhered to the same principle; but in compliance with the prejudices of his time, he assumes the different kinds of food, the varieties of size, the nature of the flesh, and even moral qualities, as the grounds of subdivisions. At all events, however, he has the credit of having opened a career, which others have successfully pursued. His second and third books contain the description and history of the species, distributed according to the rules laid down in the first. To the exposition of each genus are prefixed two chapters of general observations; the first including the vague or fabulous accounts of the ancients, and the second such common properties as pertain to the genus. The author then proceeds to the specific details, stating the most important particulars with precision and neatness, and concluding with an account of peculiar habits.

Ray, in his Synopsis Avium, follows, with a few exceptions, the method of his friend, referring at the same time to the tail feathers, and some parts of the internal conformation. The latter, we need scarcely remark, cannot with any propriety be adopted as generic or specific characters.

The new method of classing birds proposed by Monsieur Barrere in 1745, implies either a total ignorance or blamable neglect of the writings of Willoughby and Ray. As its only tendency was to confuse and perplex, we forbear noticing its details. Suffice it to remark, that it includes the peacock and man of war bird in the same family, and ranks the yellow hammer between the bustard and the ostrich. In his Essay on the Natural History of Guiana, the same author enumerates the birds in alphabetical order; but his catalogue has been more than doubled by subsequent travellers.

Jacob Theodore Klein, member of several learned academies, published at Lubeck in 1759 a quarto volume, entitled, Historie Avium Prodromus, cum gravitatione de ordine et numero in generi. In this work he divides birds into families, orders, and species. His eight families are distinguished by the conformation of the feet, his orders by the form of the bill, and his tribes, sometimes by the form and proportions of the head, sometimes by accidental differences of the bill, introduced sometimes by the author's own fanciful ideas. From too great an anxiety to simplify, this naturalist is generally too brief, and adds to his obscurity by an affection of learned phraseology.

This last-mentioned quality likewise disfigure the Marshing scientific catalogue of Marshing, physician to the prince of Anhalt, which appeared in 1752. His classes, orders, and genera, are founded on the formation of the feet and bill; and his descriptions of birds examined by himself, are usually accurate; but he is often misled by the errors of others, and the method which he proposes is complex and incommodeous.

In this summary of celebrated systematic ornithologists, Linneanists, we may assign to Linnaeus the date of 1766, when he published the 12th edition of his Systema Naturae. In so far as that astonishing body of arrangement respects the feathered tribes, it certainly manifests at once the extent and minuteness of the author's discriminating powers. As the same nomenclature and divisions are still the most familiar to British naturalists, we purpose to be chiefly regulated by them in the sequel, and consequently shall, for the present, wave any explanation of the Linnaean arrangement.

M. Salerne physician at Orleans, left behind him a Salerne MS. treatise on Ornithology, which was published by his friends in 1767. His method is that of Ray. The historical part is from the pen of Salerne himself; but the body of the text is a promiscuous and clumsy compilation. The typography is executed with neatness and elegance, and the plates, which are 31 in number, are engraved with uncommon skill; though the larger birds are for the most part represented on too small a scale.

M. Brison of the Royal Academy of Sciences, published, in 1769, A System of Ornithology, in Latin and French, in six quarto volumes. He distributes birds into 26 orders, instituted from the form of the feet, bill, &c. 315 genera, which are determined by the peculiarities of the bill or mandibles, and about 3200 species. Each article is preceded by a numerous and accurate list of references and figures; many species, till then undescribed, are particularized; and the work is illustrated by upwards of 220 excellent engravings. The principal merit of Brison's plan consists in the adoption of external and permanent characters, which enable the student to assign the name and station of a bird which he sees for the first time. The descriptions are equally accurate with those of Willoughby, and more copious. Though not exempt from errors and defects, this work still holds a respectable rank in the library of the ornithologist.

The Natural History of Birds, by the Comte de Buffon and his learned associates, is too generally known to require our analysis or criticism. It's great defect is want of scientific arrangement, a want which is scarcely redeemed even by the popular, luminous, and elegant style of the descriptions, combined with the highly finished execution of the coloured plates. With the exception, however, to which we have just alluded, we feel no hesitation in adopting the language of the English translator.

"The history of birds possesses every quality that could recommend it to the public: it exhibits a clear and comprehensive view of the knowledge acquired in ornithology, scattered through a multiplicity of volumes, and..."
ORNITHOLOGY.

in various languages, it discusses and elucidates with critical accuracy, the numerous controverted points; it reduces the whole to simplicity, order, and elegance; and, by large additions of valuable matter, it greatly extends the bounds of the science." "M. de Buffon was not to be deterred by the difficulty and extent of the undertaking. The correspondents of the king's cabinet continued to transmit numerous communications, and specimens from all parts of the world. Above eighty artists were, under the direction of the younger M. Daubenton, employed five years in the drawing, engraving, and colouring, of upwards of a thousand birds. But the commencement of the work which these were intended to illustrate was delayed two years, by reason of a severe and tedious indisposition, which during that space afflicted the excellent naturalist. And after he had recovered his health, he reflected that at his advanced period of life he could not reasonably expect to be able to accomplish the history of birds, and also that of minerals, in which he had already made some advances. He judged it expedient therefore to have recourse to the assistance of his friends; and he was peculiarly fortunate in the choice of the learned and eloquent M. Gueneau de Montbeillard, who cheerfully undertook the laborious task, and composed the greatest part of the two first volumes of the History of Birds, which appeared in 1771, under the name however of M. de Buffon. In his composition of thought and mode of expression, M. de Montbeillard followed so closely his illustrious associate, that the public could not perceive any change. It was now proper to throw off the mask; and in the publication of the four subsequent volumes, each author prefixed his name to his own articles. The third volume was nearly printed when new assistance was received from the communications of James Bruce, Esq. of Kinnaird. That accomplished and adventurous traveller, in his return from Abyssinia, passed some days with M. de Buffon at Paris. The count was filled with admiration on seeing the numerous and elegant drawings which Mr Bruce had made of natural objects; and on several occasions he mentions the explorer of the source of the Nile in terms the most flattering and respectful. After the publication of the sixth volume in 1783, M. de Montbeillard was desirous of devoting the whole of his leisure in composing the History of Insects, which had become his favourite study. The three remaining volumes were therefore written by M. de Buffon himself; though he acknowledged that the Abbé Berthot had collected the nomenclature, formed most of the descriptions, and communicated several important hints. The work was completed in 1783; and as only a few copies of the illuminated plates were on sale, and these extremely costly, a small set of engravings were made, to accommodate ordinary purchasers.

Sonini's recent edition of Buffon's Natural History contains many valuable additions; and forms, perhaps, one of the most complete works of the kind that has yet appeared. In the department of ornithology, it presents us with descriptions and figures of every bird to which the editors could have access, either in the living or preserved state, or of which they could be favoured with drawings.

Mauduit's Dictionary of Ornithology, which makes part of the Encyclopédie Méthodique, deserves to be particularly quoted, on account of the preliminary discourses, the accuracy of the descriptions and references, and the correct execution of the plates. The whole forms an excellent collection of the most important particulars which lay within the author's reach; and we have occasionally availed ourselves of his labours in the completion of the present article.

A series of splendid plates was executed at Florence, Gerrini in illustration of Gerrini's Ornithology; but they betray, in general, a disregard of nature, and are, in many instances, merely copies from imperfect drawings or inaccurate engravings. Gerrini's nomenclature is likewise very faulty, and too frequently confounds species and varieties.

In 1773, the ingenious and indefatigable Mr. Pennant published a small volume, entitled Genera of Birds. In his preface, he enters into a minute account of the external parts of birds, their feathers, flight, nidification, &c. In his selection of systematic arrangement, he gives the preference to that of Ray, whose plan appears to him to be so judicious, that it is scarcely possible to make any change is it for the better. At the same time, he admits, that latter discoveries have made a few improvements on his labours. "My candid friend, Linnaeus," adds Mr. Pennant, "will not take it amiss, that I in part, neglect his example; for I permit the land-fowl to follow one another, undivided by the water-fowl with pinnated feet, placing between the waders and cloven-footed water-fowl, and the web-footed. The ostrich, and land-birds with wings useless for flight, I place as a distinct order. The trumpeter (Psophia Linnet) and the bustard, I place at the end of the gallinaceous tribe. All are land-birds. The first multi-porous, like the generality of the gallinaceous tribe; the last granivorous, swift runners, avoiders of wet places; and both have bills somewhat arched. It must be confessed, that both have legs naked above the knees, and the last, like the waders, lay but few eggs. They seem ambiguous birds, that have affinity with each other; and it is hoped, that each naturalist may be indulged the toleration of placing them as suits his own opinion." Mr. Pennant's grand divisions, then, are into land-birds and water-fowl. The first he distributes into the six following orders. 1. Rapacious, 2. Pirs, 3. Gallinaceous, 4. Columbine, 5. Passerine, and 6. Struthious. The second comprehends, 7. Cloven-footed, or Waders, 8. those with Pinnated feet, and 9. the Web-footed.

In 1781, Dr. Latham commenced his General Synop-Lathamisia of Birds, a work of much accurate detail, and extending to three double quarto volumes, with two of supplement. Admitting the primary division of Ray, he adheres, with a few exceptions, to the Linnaean genera, which, as well as the species, his opportunities of research enabled him to multiply to a very considerable amount. Each genus is illustrated by one coloured copper-plate at least, usually of some rare species. Of these plates, however, the execution is sometimes coarse or meagre; and candour will not permit us to compliment the author on the purity or correctness of his style. His volumes, nevertheless, constitute a precious repository of descriptions and facts, and must always hold a distinguished place in the library of the ornithologist. Dr. Latham is likewise the author of the Ornithologica, which forms a convenient compass of his larger work, being comprised in two quarto volumes.
ORNITHOLOGY.

About two years ago, Sebastian Gérardin de Mirécourt published an "Elementary View of Ornithology, or the Natural History of those Birds which usually occur in France," &c. This gentleman appears to have been born and bred in the department of the Vôges, in which he discharged the duties of professor of natural history, and which is known to contain a greater diversity of the feathered race than almost any province in Europe. His preliminary discourse explains the general topics of ornithology in language at once succinct and perspicuous. The five chapters of which it consists were submitted to the notice of the estimable Daudin, whose premature death his friends and science will long deplore. The arrangement of the work, which is limited to two octavo volumes, and a thin quarto volume of plates, has been chiefly regulated by that of Cuvier, in his Sketch of the Natural History of Animals; but M. Gérardin has ventured to introduce a few occasional alterations, which were suggested in the course of his teaching in the central school, and which he conceived would facilitate the progress of his pupils. His synonymy is that of Linnaeus and Brisson; and his descriptions are generally minute, distinct, and accurate. On the whole, however, the reader is entitled to expect more copious information relative to the manners and habits of many of the species, than will be found in these results of thirty years application to the subject, combined with many favourable opportunities. We have also remarked a want of uniformity and precision in some of the author's statements. The engravings are chiefly valuable on account of the correctness of their outlines.

Hernandez.

Of the numerous writers who have treated of the birds of particular countries, we may observe, that Hernandez, a Spanish physician, has described those of Mexico. His work consists of 229 chapters, each of which, generally, treats of a single species. As they are, however, designed only by their Mexican names, and described with too much brevity, their precise stations in the Linnaean arrangement are with difficulty ascertained. Similar objections apply to the work of Nieremberg, who has described the birds of the same country. From both we may infer, that the feathered tribes in Mexico are numerous, and diversified with the most brilliant colouring; and that the natives had made considerable progress in the study of their history.

Maregravo.

Brazil presents a still more rich and splendid field to the researches of the ornithologist; but Maregravo, who professes to delineate its natural history, and allots his fifth book to the birds, is not less defective than the two writers whom we have just mentioned. His plates are not only wretchedly executed, but frequently do not correspond with the descriptions.

Sir Hans Sloane, in his History of Jamaica, has represented 44 species of birds, in 18 plates, annexed to the second volume; but it is seldom that the reader can rely on the accuracy of his delineations.

To Mr Catesby of the Royal Society, we are indebted for an excellent account of the birds of Carolina, Florida, and the Bahama islands, in two volumes imperial folio, in French and English. The first volume, and part of the appendix in the second, are devoted to the birds. The descriptions are concise and perspicuous, and accompanied with some interesting notices relative to the manners and habits of the species described. The plates, which are numerous, are generally faithful representations of the originals, and admirably well coloured. The method followed in these splendid volumes, approaches somewhat to that of Willoughby.

Schwenckel a physician, who published in 1603 "Scheren," the natural history of Siberia, in two quarto volumes, includes the birds in his fourth book. His enumeration and description of the parts which belong to birds in common with other animals, and of the appropriate parts of the organization of the former, are neat and accurate. His differences, founded on habituation, food, &c. are less valuable. The introduction is followed by the enumeration of birds, in alphabetical order, according to their Latin names. The descriptions, though accurate, are, for the most part, too short; and though adequate to recall a bird already known, are not sufficient to convey a precise notion of those which are described for the first time. The historical portion is too much condensed; and with facts which are calculated to excite interest, the author often blends such as are superfluous, or improbable.

M. Brunni published in 1764, an account of the Brunni birds of Denmark, and the neighbouring islands and provinces. In most instances he follows the Linnaean nomenclature, and sometimes the synonymy of Brisson. He chiefly dwells on the rare and non-descript species, but even then seldom enters sufficiently into detail, to enable the student to ascertain the species in question.

M. Sonnerat, corresponding member of the Royal Someret Academy of Sciences of Paris, published, in 1776, an account of his voyage to New Guinea, the Molucca and Philippine islands, the isle of France, and some other islands, in the Indian ocean; and in 1783, he favoured the world with a relation of his second voyage, to several parts of the East Indies and China. Though this zealous and learned naturalist was prevented by want of time, from forming very extensive collections, his descriptions and designs manifest both accuracy and taste. Besides correcting the errors of former travellers and voyagers, he has noticed a considerable number of birds for the first time, and most of them remarkable either for their singularity or beauty. His account of the wild cock and hen, the origin of our common domestic fowl, will be perused with peculiar interest.

The splendid work of Frisch, a German naturalist, chiefly consists of coloured plates of the birds of Europe, arranged in 12 classes according to distinctions which are sometimes vague and incommodious. The figures are, for the most part, accurate and lively representations from nature, though in some instances, they are larger than the life. The author has bestowed particular attention on the different colourings of the two sexes of the same species.

M. le Vaillant, author of a voyage to the Cape of Good Hope, and of the natural history of the birds of Africa, is eminently distinguished by the ardour and acuteness with which he has prosecuted his ornithological researches, and has availed himself with laudable diligence of his rare opportunities of collecting accurate details relative to every species which he undertakes to illustrate. His natural history of the birds of paradise, rollers, promeropoeus, toucans, and sparrows, is perhaps the most highly finished and sumptuous publication that has appeared in any of the departments of ornithology. The figures, about one hundred in number, are engraved by Péres, from the drawings of Barrand, coloured by Langlois,
ORNITHOLOGY.

Introduction.

Isanglois, and retouched by the pencil of the original designer; while the elder Didot has executed the typography, in his best style, on vellum paper. Each figure is as large as life, and is usually drawn from a specimen in the highest state of preservation; and in many cases, an exact representation of the female bird has also been obtained. Though the pre-eminent merit of the work consists in the figures and descriptions, it is in a few instances agreeably diversified by traits of character, which the author remarked in the living bird, and by some interesting hints of a more general complexion, which his accurate and extensive observation enabled him to collect. We cannot, however, refrain from expressing a wish, that he had been more liberal of his synonyms and references, and that he had treated systematic writers with a little more respect. We should not forget, that methodical nomenclature, though the result of art, and liable to many errors, is entitled at least to subordinate regard, and as an unspeakable aid to the memory. Even if we should concede to our innovating author the propriety of those more fanciful arrangements to which he manifests a predilection, it would still admit of doubt, whether, on the whole, they would more accord with gradations unequivocally indicated by nature. Are we certain that, amid her countless productions, nature recognizes a single line of demarcation? or, that the study of ornithology would be essentially promoted by classing the sibbet with the jays, or every individual furnished with parade feathers among birds of paradise?

Desmarest. The natural history of tangiers, todies, and manakin by Angeline Gaëtan Desmarest, with coloured engravings, from drawings by Pauline de Courcelles, pupil of Barraband, is another of those recent and splendid productions of the Parisian press, which reflect so much honour on the zeal, industry, and taste of the French naturalists. The paper, type, and figures, all bespeak the excellence of the respective artists who have produced them, as well as the love of chaste and elegant embellishment which has presided over the undertaking. The ornamental style of the work, however, is not its sole passport to our favourable notice. The exposition of the three genera mentioned in the title, is a subject which calls for much critical research and laborious investigation. M. Desmarest, without presuming to extricate the whole nomenclature, lays down many important distinctions, and proceeds with circumspection, so far as his opportunities have enabled him to advance. "Before we enter," says he, "on the details of the species, it may be proper to mention, that we shall limit our descriptions to those which we have seen, and of which we have been enabled to exhibit figures. We shall, moreover, endeavour to analyse, and, if possible, to unravel the references of authors. Should success thus far attend us, we conceive that we shall have duly performed the part of zealous naturalists." Besides descriptions and plates of the male, the author has also, not unfrequently, represented the female, or young of the same species, or an individual as it appears in the molting state. His pages will afford least entertainment to those, who delight to observe the instincts and economy of the feathered race; and who shrink from the minute adjustment of classification and synonymy. It ought, however, to be remembered that few authentic facts have been collected relative to the history of these foreign birds; and that though future travellers may increase the scanty stock of interesting notices, the exertions of the present author may not a little contribute to systematize and facilitate their observations.

The Natural History of Birds, by George Edwards, in four quarto volumes, without any reference to country or method, contains many excellent coloured designs and correct descriptions; and the same remark applies to his Gleanings of Natural History, the most considerable portion of which relates to birds.

Several of his countrymen have expounded or delineated the birds of our own island with more or less felicitous manner. The ornithological part of Pennant's British Zoology, Hayne's Natural History of British Birds, with their portraits accurately drawn, and beautifully coloured from nature; Lord's Natural History of British Birds, Lewin's Birds of Great Britain, with their eggs, in three volumes quarto, Walcott's Synopsis of British Birds, two volumes 4to, Bewick's History of British Birds, with figures engraved on wood, &c. &c. are all entitled to critical notice; but the limitation of our plan forbids us to dwell on them. We shall, therefore, close this portion of our introduction by pointing to a work which seems not yet to have procured its due share of the public favour; we mean the Ornithological Montagu Dictionary, or Alphabetical Synopsis of British Birds, by George Montagu, F. L. S. &c. in two small octavo volumes. We are acquainted with few publications of the kind that contain a larger quantity of accurate and important information within such a narrow compass. As a book of reference and consultation, it is well calculated to suit the occasions of ordinary readers, and even to convey instruction to the learned student. The synopsis and specific descriptions evince much diligence and accuracy; and various articles are enriched by the result of personal observation and extensive travel. Sufficiently aware of the fallible indications of plumage, the writer is more solicitous to reduce than to multiply distinctions; and in doubtful cases, has sometimes had recourse to the unequivocal test of dissection. A few of the articles, however, are dismissed with too much brevity, and the style is very deficient in polish and correctness.

If any of our readers are desirous of procuring a more complete catalogue of works published on ornithology prior to the year 1765, they will find it in Gronovius's Bibliotheca regni animalis atque lapidei, or recensio auctorum et librorum qui de regno animali et lapideo, methodie, physice, &c. tractant. The structure of the feathered tribes, and their habits of life, are wonderfully adapted to the various functions which they are destined to perform. The pointed beak, the long and pliant neck, the gently swelling shoulder, the expansive wings, the tapering tail, conforming the light and bony feet, are all wisely calculated to assist and accelerate their motion through the yielding air. Every part of their frame is formed for lightness and buoyancy; their bodies are covered with a soft and delicate plumage, so disposed as to protect them from the intense cold of the atmosphere through which they pass; their wings are made of the lightest materials, and yet the force with which they strike the air is so great, as to impel their bodies forward with astonishing rapidity, while the tail serves the purpose of a rudder to direct them to the different objects of their pursuit. The internal structure of birds is no less wisely adapted to the
ORNITHOLOGY.

Grainorous birds partake much of the nature and disposition of herbivorous quadrupeds, agreeing with them in the number of their stomachs, the comparative length and capacity of the intestines, the quality of their food, and the gentleness of their manners. Contented with the seeds of plants, with fruits, insects, and worms, their principal attention is directed to procuring food, hatching and rearing their offspring, and eluding the snares of men and the attacks of predaceous animals. As they are generally tractable and easily domesticated, man has selected for his own advantage those which are most prolific and profitable. Of these the hen, goose, turkey, and duck, are the most considerable, and form a valuable store of rich, wholesome, and nutritious food.

Carnivorous birds are provided with wings of great length, the muscles which move them being proportionally large and strong, so that they are enabled to keep long on the wing, in search of their prey. They are, besides, armed with strong hooked bills, and sharp and formidable claws. They have large heads, short necks, strong and brawny thighs, and a sight so acute and piercing, as to enable them to view their prey from the greatest heights in the air, and to dart down on it with incredible swiftness and undeviating aim. Their stomachs are smaller than those of the grainorous kind; and their intestines are much shorter. The analogy between carnivorous birds and quadrupeds, is too obvious to escape the notice of even the superficial observer. Both of them are provided with weapons which indicate destruction and rapine, their manners are fierce and unsocial, and they seldom congregate, like the inoffensive grainorous tribes; but when not on the wing, retire to the tops of sequestered rocks, or to the depths of extensive forests, where they conceal themselves in sullen and gloomy solitude. Such of them as feed on carrion, have the sense of smelling so acute, that they can scent carcases at astonishing distances.

Without the means of conveying themselves with great swiftness from one place to another, birds could not easily subsist, the food which nature has provided for them being so irregularly distributed, that they are obliged to take long journeys to distant parts in order to procure the necessary supplies. Hence one cause of those migrations which are so peculiar to the feathered race. Besides the want of food, however, two other causes may be assigned, namely, the want of a proper temperature of air, and of a convenient situation for the important work of breeding and rearing their young. Such birds as migrate to great distances, are alone denominated birds of passage; but most species are more or less so, although they do not move to places remote from their former habitations. At particular periods of the year, most birds remove from one country to another, or from the more inland districts towards the shores, or vice versa. The seasons of these migrations are observed with the most astonishing order and punctuality; but the secrecy with which immense flocks take their departure, and the suddenness with which they reappear, are not easily explained. We are also apt to suppose, that, during long flights over immense tracts of water, the means of subsistence would inevitably fail, without reflecting on the superior velocity with which birds are carried forward in the air, and the ease with which they continue their exertions for a much longer
ORNITHOLOGY.

Our swiftest horses are supposed to go at the rate of a mile in somewhat less than two minutes; and there is one instance on record of a horse that went at the rate of nearly a mile in one minute, but only for one second of time. In such cases an uncommon degree of exertion has been attended with its usual consequences, debility, and a total want of power to continue that exertion; but the motions of birds are not impeded by similar causes, and they not only glide through the air with a quickness superior to that of the swiftest quadrupeds, but can continue on the wing with equal speed for a considerable length of time. Now, if we can suppose a bird to go at the rate of only half a mile in a minute, for the space of 24 hours, it will, in that time, have gone over an extent of more than 700 miles; which is sufficient to account for almost the longest migration; and, as it is a favourite current of air, there is reason to believe, that it will perform the same journey in a much shorter space of time.

The wings of birds are so constructed, that, in striking down wards, they expand very considerably, and, except that they are somewhat hallow on the under side, they form, in this act, almost two planes. The muscles that move the wings downwards are very large, and have been estimated, in some instances, at not less than the sixth part of the weight of the whole body. When a bird is on the ground, and intends to fly, it takes a leap, stretches its wings from the body, and strikes them downwards with great force. By this stroke, they are put into an oblique direction, partly upwards, and partly horizontally forwards. That part of the force which tends upwards is destroyed by the weight of the bird, while the horizontal impulse serves to carry it forwards. The stroke being completed, it moves its wings; and they, being contracted, and having their edges turned upwards, meet with very little resistance from the air. When they are sufficiently elevated, it makes a second stroke downwards, and the impulse of the air again moves it forward. These successive strokes act as so many leaps taken in the air. When the bird wants to turn to the right or left, it strikes strongly with the opposite wing, so as to Impel the body to the proper side. If it wants to rise, it raises its tail, and if to fall, depresses it. When in a horizontal position, the tail keeps the body steady. A bird, by spreading its wings, can continue to move horizontally in the air for some time, without striking, because it has acquired a sufficient velocity; and the wings, being parallel to the horizon, meet with but small resistance. On alighting, it expands its wings and tail full against the air, that they may meet with all possible resistance. The centre of gravity in birds is somewhat behind the wings; and, to counterbalance it, most of them may be observed to thrust out their head and neck in flying. This is very apparent in the flight of ducks, geese, and several species of water-fowl, whose centre of gravity is farther backwards than in the land birds. In the heron, on the contrary, whose long head and neck, although folded up in flight, overbalance the rest of the body, the long legs are extended, in order to give the proper counterpoise, and to supply what is wanting in the shortness of the tail.

The feathers of birds would constantly imbibe the moisture of the atmosphere; and, during rain absorb so much wet, as would almost, if not wholly, impede their flight, had not the wise economy of nature obviated this by a most effectual expedient. They are furnished on the rump with two glands, in which a quantity of unctuous matter is constantly secreting. This is occasionally pressed out by means of the bill, and used for the lubrication of the feathers. The birds which share, as it were, the habitations of man, and live principally under cover, do not require so large a supply of this fluid, and, consequently, are not provided with such a large stock of it as those that rove abroad, and reside in the open element. Hence poultry, when wet, assume a ruffled and uncomfortable appearance.

As birds are continually passing among hedges and Nictitating thicket, their eyes are protected from external injuries, as well as from too much light, when flying in opposition to the sun's rays, by a nictitating or winking membrane, which can at pleasure be drawn over the whole eye like a curtain. This covering is neither opaque, nor wholly pellucid, but somewhat transparent. By means of it, the eagle is said to gaze at the sun.

It appears from observations, founded on numerous experiments, that the peculiar notes, or song, of the different species of birds, are altogether acquired, and are no more innate than language is in man. The attempt of a nesting to sing, may be compared with the imperfect endeavour of a child to talk. The first essay seems not to possess the slightest rudiments of the future song; but, as the bird grows older and stronger, it is not difficult to perceive its aim. While the scholar is thus endeavouring to form his song, when he is once sure of a passage, he commonly raises his tone, which he drops again when he is not equal to what he is attempting. A common sparrow, taken from the nest when very young, and placed near a linnet and goldfinch, though in a wild state it would only have chirped, adopted a song that was a mixture of these two. Three nestling linnet were educated, one under a sky-lark, another under a wood-lark, and a third under a tit-lark; and, instead of the song peculiar to their own species, they adhered entirely to that of their respective instructors. A linnet, taken from the nest, when but two or three days old, and brought up in the house of an apothecary at Kensington, from want of other sounds to imitate, almost articulated the words "pretty boy," as well as some other short sentences. These and other well-authenticated facts seem to prove, that birds have no innate notes, but that the language of those whose care they are committed at birth, will be the language which they adopt in after life. It may, however, appear somewhat unaccountable why, in a wild state they adhere so steadfastly to the song of their own species only, when so many others are to be heard around them. This arises from the attention paid by the nestling bird to the instructions of its own parent only, generally disregarding the notes of all the rest. Persons, however, who have an accurate ear, and have studied the notes of different birds, can very often distinguish some that have a song mixed with those of another species; but these are in general so trilling as scarcely to be reckoned any thing more than mere varieties of provincial dialects.

All birds are oviparous, or produce eggs, from which, after the process of incubation, the young are extruded. These eggs differ in different species, in respect of number, figure and colour. They contain the rudiments
ORNITHOLOGY.

Introduc— The nests of birds are, in general, constructed with astonishing art, and with a degree of skill and neatness that often defies the efforts of the human hands. Both the male and female generally assist in this interesting concern. They each bring materials to the place, as sticks, moss, straw, &c. for the foundation and exterior; and hair, wool, or the down of animals or plants, to form a soft and commodious bed for their eggs, and for the tender bodies of their young when hatched. The outside of the nest usually bears so great a resemblance in colour to the surrounding foliage or branches, as not easily to be discovered even by persons who are in search of them.

ORNITHOLOGY.

17. Subulatum, Subulated or awl-shaped,—applied to a bill that is straight and slender, in the form of an awl.

18. Pes ambulatorius,—all the toes divided to the bottom.

19. Pes gressorius,—the outer toe more or less united to the middle one, particularly conspicuous in the feet of the king's fisher.

20. Pes scansorius,—formed for climbing, like the foot of the woodpecker.

21. Pes lobatus,—furred, or lobed, like those of the grebes.

22. Pes pinnatus,—pinnated, or scoloped. The webs indented in the sides, as in coots and sandpipers.

23. Pes tridactylus, or curvorus,—wanting the back toe.

24. Pes didactylus,—composed of only two toes, as in the ostrich.

25. Pes semi-palmatus, Semi-palmated,—when the webs reach only half the length of the toes.

26. Ungue postico sessili,—when the hind claw adheres to the leg without any toe, as in the pelicans.

27. Digites quattuor omnibus palmatis,—all the four toes connected by webs, as in the corvus.

28. Rostrum cultratum,—when the edges of the bill are very sharp, as in that of the crow.

29. Unguiculatum,—said of a bill furnished with a nail at the end, as those of ducks and goosanders.

30. Lingua culata,—a tongue edged with fine bristles, like that of the duck.

31. Incurva,—plain, or even.

32. Lumbriciformis,—when the tongue is long, round, and slender, like a worm, as that of the woodpecker.

33. Pedes compedes,—when the legs are placed so far behind as to make the bird walk with difficulty, or as in gulls, of which we have examples in the auks, grebes, and divers.

34. Nares lineares,—when the nostrils are very narrow, as in sea gulls.

35. Emarginata,—with a rim round the nostril, as in the stork.

36. Iris, is that part which surrounds the pupil of the eye.

37. Mandibles, denote the upper and under parts of the bill.

38. Compressa,—vertically flattened at the sides.

39. Depressa,—horizontally flattened.

40. Carunculata,—a fleshy excrescence on the head.

41. Hypochondria,—the hinder sides of the breast and abdomen.

42. Occellata,—with roundish concentric spots, of different colours.

43. Phalanges,—the articulations of the toes.

SYSTEMATIC EXPOSITION OF THE CLASS.

ACCORDING to the Linnæan method, the class of Aves, or Birds, is distributed into six Orders, denominated Accipitres, Picae, Anseres, Grallae, Gallinæ, and Passeres.

ORDER I. ACCIPITRES.

This natural order includes birds of prey, that have the bill somewhat hooked downwards, the upper mandible dilated near the point, or armed with a tooth, the nostrils wide, the feet short and strong, with four toes, three of which are placed forwards, and one behind; toes warty under the joints; claws hooked and sharp-pointed. They live on other animals alive or dead, and are themselves not eatable. They are monogamous, or live in pairs. The females are larger and more beautiful than the males, and generally lay about four eggs. This order includes vultur, falco, strix, and lamia.

Gen. I. Vultur, Vulture.

Bill straight, hooked at the point; head bare of feathers.

Birds of this genus are distinguished from eagles and hawks, by being gregarious, by the comparative heaviness of their flight, and by their living on carrion. The females, too, are hardly larger than the males. Unless pressed by hunger, they seldom attack living animals; they fly slowly, unless when very high in the air, and have an exquisite sense of smell. The tongue is large and fleshy; the legs and feet are strong, and mostly covered with scales; and the wings are lined, on the inside, with down.

Grifeus.

Condor, conur, or curur.—Very large, with a caruncle on the crown of the head, the whole of its length; the throat naked. Quills of the wings two feet and a half long, and an inch and a half thick; body black, back white; neck ruffled with long white feathers; throat red; head brown, and woolly; eyes black, irides chesnut; bill black, but tip with white; feet black; claws straightish; tail small.—The female differs from the male, in having a tuft on the neck, in its brown colour, and in having no ruff. Brisson, however, has properly remarked, that the plumage of this species varies in colour, a circumstance which will, in some measure, account for the discordant descriptions of different authors. At the same time, we must regret, that the history of this enormous bird is so imperfectly known. Its extent of wing is variously stated, from nine to eighteen feet; and, while Fresier ascribes to it sufficient strength to carry off sheep, and boys of ten years old, Marco Paulo sturdily affirms, that it can lift an elephant from the ground high enough to kill it by the fall. Though very rare, Buffon suspects it is not confined to South America, and that it does not essentially differ from the roc of the eastern nations, so famous in the Arabian tales; nor from the laemmer geyer of the German Alps. A preserved specimen in the Leverian Museum measured ten feet, from the tip of one wing to that of the other. It is described and figured in the second supplement to Latham's Synopsis. In Chili, the condors make their nests among the most inaccessible rocks, and lay two white eggs bigger than those of a turkey. They feed on dead carcases, and sometimes prey on sheep, goats, or even young calves, when they stray far from their dams, falling on them in flocks, plucking out their eyes, and tearing them in pieces. The country people
ORNITHOLOGY.

King vulture, or king of the vultures.—Caruncles on the nostrils; crown of the head and neck bare of feathers. The extreme length of the body does not exceed two feet three inches, and it is not thicker than the hen turkey. Its wings are short in proportion to the other vultures. The bill is thick and short, and begins its curvature only at the point; in some individuals it is entirely red, in others only red at the extremity, and black in the middle. In the cere, which is broad and orange-coloured, are placed the nostrils; and between them the skin projects like a loose jagged comb, falling indifferently on either side, according as the bird moves its head. Under the naked part of the neck is a collar, or ruff, composed of pretty long soft feathers of a deep ashy colour, and so broad, that when the bird contracts itself, it can conceal the neck and part of the head like a cowl, whence some naturalists have given it the name of monk. The feathers on the breast, belly, thighs, legs, and under the surface of the tail, are white, slightly tinged with yellow; those of the rump and upper surface of the tail, are black in some individuals, and white in others. The other feathers of the tail are always black, and so are the great feathers of the wings, which are commonly edged with grey. The king of the vultures is a native of South America and the West Indies, and lives on carrion, rats, lizards, snakes, and excrements of all kinds, from which circumstance it has a most offensive odour.

Carrion vulture, or turkey buzzard (carrion crow of Jamaica).—Body grey brown; quill feathers black; bill white; the sides of the head warded; legs flesh-coloured.
—Common in the W. Indies, and in N. and S. America. Somewhat larger than the black eagle. It is protected in America for its use in decoyng dead carcasses and serpents, which it does, along with dogs, in the greatest harmony. It will seize meat from the shambles, breathes a most fetid odour, and, when taken, vomits up an intolerably stinking matter. Roosts by night, in flocks, on the highest branches of trees. They are generally very tame in their wild state, probably owing to their being more ascermed than molested by man.

White, ash-coloured, or Angola vulture.—Body snowy; quill and tail feathers black; collar white; head and lower part of the neck covered with white down; middle toe covered with 11 distinct scales; claws black. About the size of a female turkey. The female excels the male in size, and differs chiefly in being less tinged with ash.

A. Bill hooked only at the point, bearded at the base with extended bristles.

Snake-eater, or secretary vulture.—Body black; head crested; tail feathers white at the tips, the two middle ones longest; legs very long. Bill black, cere white; orbits orange, and naked; irides pale cinereous; tail rounded; legs brownish; claws short, black, hooked, not very sharp; crest capable of being erected or depressed.—In seizing its prey, this bird makes use of its wings, with which it inflicts violent blows by means of a bony protuberance at the bend of the wing. It is also by its wings that it defends itself against the bites of venomous snakes, until the latter, tired with their efforts, or nearly bruised to death, are easily dispatched. This species likewise preys on turtles, lizards, and even grasshoppers and other insects. When in a domesticated state scarcely any kind of food comes amiss to it; and, if young birds are presented to it, it will take them by the bill foremost, and swallow them whole. One of those which Le Vaillant killed, had 21 young turtles, 17 small lizards, and three snakes, in his stomach. Like other birds of prey, it is observed to bring up the undigested parts of its food, in the form of round pellets. In pairing time, two males will often be found engaged in a violent contest for a female. The secretary vulture

... of Pennant, and the rachamah of Bruce. "When, Accipitr...
ORNITHOLOGY.

Accipiter, is three feet high, remarkable for the length of its legs, and inhabits interior Africa and the Philippine islands. These birds make a flat nest, like that of the eagle, full three feet in diameter, lined with wool and feathers, in some high tuft of trees, and usually concealed from observation.

Crested or Oroonoko eagle.—Head crested with long feathers; body beneath variegated; eyes with a nictitating membrane. Under the crop, white feathers, which, when the bird is irritated, fall to the ground. Erects the crest in the form of a coronet; is said to be able to cleave a man's skull at a stroke. Inhabits Mexico, Brazil, and other parts of South America, and is as large as a sheep.

Cinereus or white-tailed eagle: crene of the Scots.—Cere and feet yellow; tail feathers white, the middle ones tipped with black; head and neck pale cinereus; irides and bill pale yellow; nostrils, and the space between the eyes, bluish, with a few bristles; body and wings cinereus, mixed with brown; tail white, black, below the knees, downy, glossy yellow; claws black.

Size of a turkey, feeds on birds and fish. Inhabits Europe, and is frequently found in Scotland and the Orkney islands.

B. Feet generally feathered, of a large size.

Black eagle.—Cere yellow; feet yellow, and somewhat downy; body rusty black, with yellow streaks; bill horn colour, verging on blue; irides chestnut; externo part of the tail white, with blackish spots, tippets, whitish; legs dirty white, toes yellow, claws black. Two feet ten inches long. Inhabits Europe and America.

Osprey or sea eagle.—Cere and legs yellow; feet half covered with down; body of a rusty colour; inner vases of the tail feathers white. It is distinguished by the colour and figure of its nails, which are of a shining black, and form an entire semicircle; by its legs, which are naked below, and covered with small yellow scales; and by the beak of feathers which hangs from the chin, and which has occasioned its receiving the name of the bearded eagle. It measures from the end of the bill to the point of the nails, three feet and a half, and its wings expand to between six and seven feet. It loves to haunt the sea shore, and often frequents inland tracts, near lakes, marshes, or rivers that are stocked with fish; but, though it preys on the finny tribe, it also attacks game, and, being large and strong, seizes and carries off geese and hares, and sometimes even lambs and kids. It catches fish even during the night, when the noise of its plunging into the water is heard at a great distance. In attempting to lay hold of overgrown fish, it is sometimes dragged under water, being unable to disengage its talons. It inhabits Europe and North America, and was found by Captain Cook, in Botany island. It is not uncommon in Scotland and Ireland. "From the astonishing height (saya Mr Montagu), these and some other birds fly, we are led to believe they are capable of living in a much lighter air than other animals. From the top of some of the highest mountains in Scotland we have seen several soaring together so great a distance as to appear scarcely larger than a swallow." The female sea eagle seldom lays more than two eggs, and sometimes produces only a single young one.

Golden eagle.—Cere yellow; feet downy, and rusty-coloured; body dark brown, irregularly barred; tail black, and covered with ash-coloured bars. It greatly resembles the preceding, but is distinguished from it chiefly by its legs, which are yellow, short, strong, and covered with feathers to the feet. The general length of this species is about three feet and a half; the breadth eight feet; and it usually weighs about twelve pounds. It breeds in the most inaccessible rocks, and lays three or four white eggs. It inhabits Europe and Siberia, and is said to be not unfrequent in the mountainous parts of Scotland, Ireland and Wales, though it has been frequently confounded with the sea eagle. It feeds on lambs, kids, and all kinds of game, and has been known to carry off infants to its nest. It is remarkable for its longevity and abstinence from food; some having been kept in menageries for upwards of a century; and Pennant records an instance of one which lived twenty-one days without any sustenance whatever. It flies high, during serene weather, and descends nearer the earth in storms.

Ring-tailed, white-tailed, black, or common eagle.—Fulvan. Cere yellow; feet downy, and of a rusty brown colour; back brown; tail with a white transverse band. In the bill, cere, irides, and legs, it resembles the preceding, to which it is also nearly equal in size; but the plumage is rather darker, and the tail is white for two-thirds of its length. It inhabits Europe, Asia, and America; and is trained by the Tartars to hunt hares, antelopes, and foxes. In Scotland, it is very destructive to deer, which it will seize between the horns; and, by incessantly beating it with its wings, soon makes a prey of the harassed animal. It likewise makes great havoc among the white hares and ptarmigans. It builds in high precipices and cliffs; and the nest of a pair has been observed in the same spot, in the Orkney islands, beyond the memory of man. Willoughby describes a nest of this species found in the Peak of Derbyshire, as composed of large sticks, lined with two layers of rushes, between which was one of heath. It contained one young, and an addle egg, and by them a lamb, a lafe, and three heath pouts. There is a variety, with a white tail, tipp'd with brown.

White eagle.—Entirely white. Inhabits the Alps; of which the size of the golden eagle.

Fierce eagle.—Cere green; body brown above; back, Forez, belly, and tail coverters snowly, variegated with chestnut spots; tail feathers equal, brown, with four paler bands; bill leaden black; cyclids blue; irides yellow; head and neck ferruginous, mixed with whitish; quill feathers twenty-six, black above, white beneath, tipp'd with grey; tail feathers twelve, white beneath; claws sharp; upwards of two feet long; very rapacious; inhabits Russia; was found frequent near Astrakan in the winter of 1769; will not touch dead animals.

Kite.—Cere yellow; tail forked; body brown; head whitish or grey; back and wing coverters dusky, edged with ferruginous, the under parts more or less ferruginous, streaked with dusky, and lightest in the breast; quill feathers dusky black, with bars more or less obscure; tail bright ferruginous; legs yellow; claws black. But there are several varieties. The female is somewhat larger than the male, measuring in length two feet four inches, and five feet six inches of outstretched wing. It is readily distinguished by its remarkable forking of its tail, and by its smooth and even flight, which resembles a sailing or gliding through the air.
ORNITHOLOGY.

Accipitres. air, without any apparent motion of its wings. It frequently, however, soars very high, and, though beyond the reach of human vision, will distinctly perceive its prey, and dart down on it with irresistible force. Its attacks are confined to such animals as are found on the ground, such as young rabbits, hares, game of all kinds, poultry, and young birds incapable of flying. It will also destroy young lambs, and feed greedily on carrion; but in default of these, will readily devour mice, rats, worms, and even snakes.—The kite occurs as far north as Greenland, and as far south as Guinea and Senegal. It is common in England, where it continues the whole year; but from the more northerly latitudes, it retires to Egypt before winter, and is said to breed there, and returns in April to Europe, where it breeds a second time, contrary to the nature of rapacious birds in general. The nest is composed of sticks, and lined with wool, the inner bark of a tree, hair, and other soft materials, and is usually made in the fork of some large tree. The eggs are generally three, rarely four, somewhat larger than those of a hen, of a dirty white, with a few rusty spots at the larger end.

Balneotes. 70

Bald buzzard, osprey, fishing hawk, &c.—Cere and feet blue; body brownish above, white below; head whitish; a brown bar descends from each eye by the sides of the neck to the wings; legs naked, short, strong; claws remarkably long, hooked, and black. Inhabits Europe, Siberia, and America, frequenting marshy places, and the neighbourhood of large rivers and lakes, pouncing on fish with great rapidity and dexterity, and carrying them off in its talons to a small distance to feed on them. It builds its nest on the ground among reeds, and lays three or four eggs of an elliptical form, rather less than those of a hen. Mr Montagu found the nest of this bird on the top of a chimney of a ruin in one of the islands of Loch Lomond. The usual length of the bald buzzard is two feet, and its extent of wing five. The species is now rarely met with in England, but may be frequently seen near the lake of Killarney in Ireland. There are several varieties, among which may be included those of Carolina and Cayenne. Some of the ancient writers, and even Linnaeus, have very erroneously alleged, that the left foot of the bald buzzard is subpalmatum.

C. Legs naked, of a smaller size.

Buteo. 71

Bussard, or Patrick.—Cere and feet yellow; body brown; belly pale, with brown spots. Scarce any two individuals of this well-known species are precisely alike. The ordinary length of the body is twenty inches, and the extent of wing four feet and a half. The buzzard is one of our most common species of falcon. It is remarkable for its sluggish, inactive disposition, seldom remaining long on wing, except in the breeding season, when it ascends spirally to a great height. It makes its nest in the fork of a tree, of large sticks, and lines it with wool, hair and other substances, and sometimes takes possession of a deserted crow's nest, which it accommodates to its purposes. The eggs are two or three, rather larger than a hen's, of a dirty white, and, for the most part, with rust-coloured spots at the larger end. It feeds and tends its young with great assiduity; and Ray affirms, that, if the female be killed, the male takes charge of them, and patiently rears them till they are able to provide for themselves. This bird will continue for many hours perched on a tree or eminence, Accipitres. whence it darts on such birds, small quadrupeds, reptiles, or insects, as come within its reach.

Honny buzzard.—Cere black; feet half naked, and Apivora; yellow; head ash-coloured; tail with cinereous bands, and tipp with white; of nearly the same size as the preceding, and, like it, subject to considerable varieties in its markings. Its nest in respect of form and materials, is similar to that of the buzzard, and it sometimes occupies that of other birds. Its eggs are of an ash-colour, with small brown spots. Mr White of Selborne found only one egg in the nest, smaller, and not so round as that of the buzzard. The same seems to have been given it from its feeding on the larvae of wasps; but it is also fond of various other insects and of field mice, frogs, and lizards. It occurs in all the northern parts of Europe, and in the open tracts of Russia and Siberia, but is far from common in England. Buffon observes, that it is frequently caught in the winter, when it is fat and delicious eating.

Moor buzzard, duck hawk, or white-headed harpy.—Erebus. 73

Cere green; body brownish; crown of the head, throat, auricula, and feet, yellow. The colouring, however, is subject to considerable variety. Length twenty-one inches; weight twenty ounces. Preys on rabbits, young wild ducks, and other water fowl; and likewise feeds on fish, frogs, reptiles, and even insects; making its haunts in hedges and bushes near pools, marshes, and rivers. The nest is most frequently made on the ground, among short wood, furze, or fern, and sometimes though rarely, in the fork of a tree. It is composed of sticks and rushes, or coarse grass. The moor buzzard is not a bird of rapid flight, but pounces its prey on the ground, and is generally seen skimming over the surface; but, in the breeding season, the male will sometimes soar to a considerable height, and remain suspended on wing for a great length of time. Inhabits Europe.

Goehawk.—Cere black; feet yellow; body brown; Palumbus; tail feathers barred with pale bands, a white line over each eye; bill blue, black at the tip; iris yellow; head brown; body beneath white, waved with black; tail long, cinereous, and white at the tip; claws black. The wing, when closed, does not reach near the end of the tail; of an elegant slender shape, twenty-two inches long. Inhabits Europe, Tartary, and America; is rarely found in England, but is not uncommon in the more woody districts of Scotland, where it breeds, and is a great destroyer of game. It feeds on small birds and mice, and eagerly devours raw flesh. It tears birds to pieces before it eats them, but swallows the pieces entire, and frequently disorges the hair and feathers, rolled up in small pellets. This species was formerly much prized in the sports of falconry, being used not only for partridge and pheasant, but also larger fowl, as geese and cranes, and sometimes for rabbits.

Gentil falcon.—Cere and feet yellow; body ash-coloured, with brown spots; tail with four blackish bands; somewhat larger than the preceding, though some ornithologists reckon it only a variety. It inhabits the Alps of Europe and North America. In the days of falconry, 75 observes the author of "Elements of Natural History," this species was in high esteem as a bold and spirited bird. It inhabits the north of Scotland. The king's falconer was anciently obliged to supply the court with hawks; and to this day the office is kept up in
ORNITHOLOGY.

Acipiter in Scotland; a nest of young birds being annually presented by the falconer to the barons of exchequer, who generally give them away in presents."

Peregrinus. Perigrine falcon—Cere and feet yellow; body ash-coloured above with brownish bands, reddish white beneath, with blackish bands; tail spotted with white. Weights between two and three pounds, is a bold and powerful bird, and inhabits Europe, and the north of Asia and America. It is not uncommon on most of our rocky coasts, usually frequenting such high cliffs as the guillemot and razorbill resort to for breeding. One that eloped from its master in the county of Forfar, on the 24th September 1772, with four heavy bells on its feet, was killed on the morning of the 26th of the same month, at Mostyn in Flintshire.

Vesicolus. Spotted falcon—Cere yellow; head and body above, white, with pale reddish spots, white beneath; breast a little spotted with ferruginous. Size of the buzzard. Inhabits England; but its history is little known.

Crissus. Grey falcon—Cere and legs yellow; body dusky gray above with white and oblong black spots beneath; tail feathers long, the two middle ones uniform, the rest spotted. Bill blueish; irides red; head dusky brown before, white behind; sides and chin buff; quill-feathers spotted with white. Inhabits England; but is very rare, and by some esteemed only a variety.

Cancrota. Jer-falcon, gyr-falcon, Iceland falcon, white jer-falcon, &c.—Cere and feet of a greenish ash-colour; body white, spotted with brown. Bill blueish-ash, black at the tip; claws lead colour. Larger than the goshawk, and subject to variety, from age, sex, and climate, some in the northern latitudes being found quite white, others brown above, white beneath, spotted with brown, and the tail gray, with transverse brown lines. Inhabit the north of Scotland, is a very bold bird, and in the days of falconry, was used for the larger species of game, as cranes and herons.

Cacoctera. Laughing falcon—Cere and legs yellow; eye-brows white; body varied with brown and whitish; crown white, with a black ring. Back, wings, and rump brown; neck, chin, breast, belly, and under parts of the wings white; tail with yellow and black bands. Inhabits South America, and is said to laugh, when looked at.

Lanarius. Lower—Cere dull yellow; bill and feet blue; body marked with black longitudinal spots underneath. A white stripe over each eye; breast yellowish white, with brown spots; legs short; primary quill-feathers and tail dusky, with rusty oval spots; but graceful and vary. Either less than the buzzard, has its name from teasing its prey into small pieces with its bill. The latter is very bold, and was formerly used in falconry. It is found in many parts of Europe; inhabits Iceland and the Faroe islands, Denmark, Sweden, and the Tartarian deserts. It is rare in England, and among the low-trees and shrubs in the deserts about Astracan.

Hen-harrier.—Cere white; legs tawny; body hoary-blue; edges of the eye-lids yellow, with an arched line surrounding the throat; bill black; irides yellow; hind part of the head white, with pale brown spots; breast and belly white, the former streaked with dusky; two middle tail-feathers gray on both sides, the rest gray above, white beneath, and all streaked with dusky. These characters, however, are far from constant.

This species, in its most perfect state, weighs about thirteen ounces, and is eighteen inches and a half in length. It feeds on birds, lizards, and other reptiles, and is particularly destructive to poultry. It flies low, skimming along the surface in quest of prey. The female nests on the ground, and lays four eggs of reddish colour, with a few white spots. Inhabit Europe and Africa. Wallis, in his Natural History of Northumberland, remarks, that it breeds annually on the Cheviot hills, and on the shady precipices under the Roman wall, near Cragglye. Dr Latham and other eminent ornithologists have supposed that this and the following are male and female; but the repeated instances of hen-harriers of both sexes having been seen, leave it beyond all doubt that they constitute two distinct species.

Ring-tail, ring-tail hawk, white-rumped bay falcon, Pygargus. &c.—Cere and legs yellow; body cinereous; belly pale, with oblong rufous spots; orbits of the eyes white. Bill pale; irides yellow; tail longish, banded with dusky, and dotted with white, the male marked with transverse, and the female with longitudinal, spots beneath. Length 18 or 20 inches. Inhabit Europe, and the temperate parts of Siberia. Flies higher than the preceding, and sometimes perches on trees. Its eggs are white, much freckled with red.

Kestrel, kestrel, stone-gall, &c.—Cere and legs yellow; back purplish-red, with black spots; breast with brown streaks; tail rounded. Crown of the head of a fine cinereous gray; greater quill-feathers black, very slightly tipped with whitish. Bill lead colour, irides dusky and large. The male weighs about seven ounces, and measures 13 inches in length. The female is considerably larger, and distinguished from the other sex by the head and tail being of the same colour as the back, which is not so bright a red brown as the male. Feeds principally on mice, in search of which it is frequently seen hovering in the air and stationary for a great length of time. Preys also on small birds and insects, and was formerly used for catching game. Inhabit Europe, Siberia, and the more temperate parts of North America.

One of our most common birds of prey, especially among the rocks and cliffs of the coast, which favour its breeding. The nest is of sticks, and lined with wool and other soft materials; but it sometimes builds on trees, or is contented with the deserted nest of a magpie or crow. The eggs are usually four or five, of a dirty white, blotched with rust colour, of various shades. It is a handsome bird, whose sight is acute, and whose flight is easy and graceful. It includes two or three varieties.

Fishing falcon.—Legs brown; head ferruginous, with Piscator long feathers; body cinereous above, pale yellowish white beneath; tail pale brown above, blueish-ash beneath. Bill and irides yellow; margin of the upper feathers rusty brown; the under spotted in the middle with brown. Inhabit Senegal, where it is called tomaz; preying chiefly on fish, which it takes out of the water, and retires to a convenient place to eat them piecemeal.

Sparrow hawk.—Cere green; feet yellow; belly Nime white, waved with grey; tail with black bands. The weight of the male of this species is about five ounces, that of the female nine: the former measures in length about 12 inches, the latter 13. The male is inclined to rust colour on the breast, the female to whitish. On the back of the head, in both sexes, is an obscure broken patch of white. The quill feathers are dusky, barred...
ORNITHOLOGY.

Acipiter. — Red with black on the outer webs, and spotted with white at the base of the inner. The legs are long, slender, and yellow. In some the back is spotted with white, and others have the body entirely of that colour. The sparrow-hawk is very common in our wooded and inclosed districts, but is less frequent in the mountainous parts. The female sometimes builds her nest in hollow trees, high rocks, or lofty ruins, but more frequently takes possession of that which has been deserted by a crow, laying four or five eggs, of a dirty white or bluish tinge, blotched at one of the ends with rust colour. It is very widely diffused over the world, from Russia to the Cape of Good Hope. It is bold and spirited, making great destruction among pigeons, young poultry, and small birds of all kinds, which it will attack and carry off in the most daring manner; at the same time, that it is obedient and docile, and can be easily trained to hunt partridges, quails, larks, &c.

Hobby. — Ceres and feet yellow; back brown; neck white; belly pale, with oblong brown spots. Bill blue; orbits yellow; irides generally chestnut; lateral tail-feathers with blackish bars; primary quill-feathers with oval reddish spots; claws black. The male weighs about seven ounces, and the female nine, or more. Inhabits Europe and Siberia, breeds in Britain, but leaves us the latter end of October. It builds in trees, and sometimes takes possession of a deserted crow’s nest, laying three or four eggs, which are said to be white. Though small, it is inferior to none of the falcon tribe in courage, and will frequently pounce a partridge; but its favourite prey is the lark, which it terrifies to such a degree, that it sometimes flies to man for protection, and will allow a net to be thrown over it.

Merlin. — Ceres and feet yellow; head rusty; body above, of a blueish ash, with spots and rusty streaks; beneath, yellowish-white, with oblong spots. Bill blue; irides dusky; tail alternately streaked with dusky and reddish; claws black; egg brown red. There are several varieties. The merlin is a small species of falcon, being scarcely larger than the blackbird, but is very rapid on wing, and was esteemed for its courage in hawking. It flies low, and is generally seen skimming along the side of a hedge, or over the surface of the ground, in pursuit of small birds. Inhabits Europe; visits the south of England in October, about the time the hobby retires, but has never been observed to breed farther south than Cumberland, where it has been found more than once, with four young ones, placed on the ground.

Minute falcon. — Ceres brown; legs yellow; body white beneath; tail feathers brown, branded with black. About 11 inches long. Inhabit Maltese, and occurs, though rarely, in England.

Puffin. — Ors yellow; body brown-ash; beneath whitish, with blackish bars; crown whitish. Hardly six inches long. Inhabit Cayenne.

Gen. 3. STRIX, Owl.

Bill hooked; no cere; nostrils oblong, covered with brightly recumbent feathers; head, eyes, and ears large; tongue bifid.

These are nocturnal birds, with the organs of vision so constructed as to see in the dark. Their sense of hearing is very acute; by means of a particular membrane at the opening of the external ear. They can move the outermost toe either backwards or forwards. They feed on carrion, living small birds, hares, mice, field-mice, lizards, &c. When they venture abroad in day light, they are chased, and insulted by smaller birds, especially by the crow. In their manner of life, round head, &c. they have some affinity to cats. During the winter, they live retired, fasting, or sleeping in towers and old walls.

A. Eared.

Great owl, great eared owl, great horned owl, &c.- Bubo.

Body of a reddish or tawny colour; irides yellow; head and body variegated with black, brown, ash, and rusty spots and lines; claws large, much hooked, and dusty. Liable to considerable varieties. Nearly the size of an eagle, and very strong, preying on hares, rabbits, moles, rats, mice, and sometimes bats and reptiles. Inhabits Europe, Calmac Tartary, and South America, haunting mountainous rocks and caverns. Its nest is nearly three feet in diameter, and composed of sticks bound together by fibrous roots, and lined with leaves. It generally lays two eggs, somewhat larger than those of a hen, and variegated, like the bird itself. The young are very voracious, and are plentifully supplied with food by the parents. This bird is by no means common in Great Britain, though it has been occasionally shot both in England and Scotland. It endures day light better than most of the genus, flies low in the day, but sometimes soars very high during the night.

Pacifogroso eagle owl.- Size of the common eagle owl; feathers larger, raise above the base of the bill which is black; irides golden yellow; upper part of the body brown, variegated with slender rufous and cinereous lines; under part pale-ash, transversely striped with brown; throat white; lower part of the neck and sides of the breast orange brown, spotted with darker brown; quills and tail banded with brown; legs and half the toes covered with cinereous feathers; claws horn colour. Inhabits America, Kamtchaka, and Astracan. Is a little smaller than the great horned owl, and is supposed by some to be only a variety.

Ceylonese eagle owl.—Bill horn colour; irides yellow; Zeylanon. upper part of the body pale reddish brown, under part yellowish white; ears short, pointed; first quills and tail barred with black, white, and pale red; legs naked to the knees. Length 23 inches; weight two pounds and near 10 ounces. Native of Ceylon.

Long-eared or horned owl.—Ears with six feathers. Ears Ovis. black and yellow; irides yellow; back and wing covert dusky brown, gray, and yellowish-rusty; breast and belly pale yellow, with brown longitudinal lines; tail barred with ash-colour, and dusky; legs and feet feathered to the claws. About 14 inches long; but there is a variety that is much smaller, and another which is distinguished by the greater darkness of the body. Diffused over the four quarters of the globe, frequenting forests and wooded tracts, and manifesting a particular taste for fox, box, or holly plantations, where it more readily conceals itself by day among the ever-green foliage. Its principal food is mice, and sometimes small birds taken at roost. It remains with us the whole year, and is frequently taken; yet little is known of its habits.

Short-eared owl, hawk owl, mouse hawk, &c.- Brachyotus.

Ears short; body above brown, feathers-edged with yellow; beneath pale yellow, with longitudinal dusky streaks.
ORNITHOLOGY.

Specimen from Jamaica, which differed in no respect from our common owl. The white owl is very susceptible of domestication, when taken young.

Towny or brown owl, common brown or ivy owl, Strix aluco, black owl, houlet, wood owl, &c.—Body ash-coloured, the third flag-feather the longest; plumage marked above with dusky spots and points; breast and belly yellowish, mixed with white; beneath with dusky streaks; irides dusky; tail with pale brown and black spots and lines. Fourteen inches long; stretch of wing two feet eight inches; weight of the female 19 ounces. Inhabits Europe and Tartary. This is another very common species. It resides chiefly in woods and plantations of fir; concealing itself in the thickest recesses; sometimes it settles on the ground, but if molested, takes shelter in a neighbouring tree. It is rarely seen on wing by day, except forced from its haunts, the light dazzling it to such a degree that boys hunt it down with sticks and stones. It breeds in the hollows of trees, and sometimes in barns, where it is protected by the farmer, as it is an excellent mouser. It lays two or three eggs of a roundish form, and dull white colour. It is the only species known to hoot, besides which, it makes a disagreeable screaming noise. It is a great enemy to young pigeons, leversets, young rats, &c. but chiefly subsists on mice.—"We have taken this bird," says Mr. Montagu, "in its natural state, as well as young, and found no difficulty in either case of preserving them alive. They were never observed to drink; and indeed for many months together had no water offered them."—The ulula of Linneus is now esteemed only a smaller variety of the strigula.

Little owl.—With white spots arranged in five rows Passerina on the flag-feathers; bill whitish brown; irides pale yellow; head, back, and wing coverta pale brown, with white spots; breast whitish, variegated with rusty. Scarcely larger than a blackbird, but varies considerably both in respect of size and markings. Inhabits Europe, North America, and the West Indies. Is very rare in England, though it has sometimes been found in Yorkshire, Flintshire, and the neighbourhood of London. It is said to frequent ruined edifices in France, and to build in chimneys, in Carniola; but it frequently nests in the holes of rocks and walls, and lays five or six eggs, spotted with yellowish and white. It can fly by day, and give chase to swallows and other small birds on wing, but mice are its principal food.

White-fronted owl.—Body rusty brown, paler beneath; forehead white; quill feathers barred with black and white. Only five inches long. Native of North America.

Gen. 4. Lanius, Shrike.

Bill nearly straight, with a dent on each mandible, characters near the end, naked at the base; tongue jagged at the point.

The birds of this genus form a connecting link between the falcons and pies, and have been differently classed by different ornithologists. Though comparatively small, they are very courageous, will attack birds much larger than themselves, and are called butcher birds, because they frequently kill several, before they begin to feed. They fix on their victims with their talons, split the skull with their bill, and then feed on them at leisure.
ORNITHOLOGY.

482

Accipitres. Collared shrike, canary biter, or fiscal.—Tail wedge-shaped; body black, white beneath; first quill feather white at the base; bill and head blackish; tail feathers, except the four middle ones, white at the tips. Very common at the Cape of Good Hope, also found in Senegal, and in the interior parts of Africa. Twelve inches long. Feeds on beetles, grasshoppers, and other insects, which it not only catches with great dexterity; but when it cannot consume them all, will stick them on the pales of farm yards, till it has occasion for them. It also seizes on sparrows and canary birds, of which it devours only the brains.

Excidor. Cinereous shrike, great cinereous shrike, greater butcher bird, mattingless, night jar, &c.—Tail somewhat cuneiform, white on the edges; back gray; wings black, with a white spot; bill black, with bristles at the base; upper parts of the plumage of a pale blue ash, the under parts white; legs black. The female differs chiefly in the under parts, which are of a dirty white, marked with numerous semicircular brown lines. There is a variety, with the body white, legs yellowish, and bill and claws blackish; and another with lesser wing coverts and reddish shoulders. Inhabits Europe and North America. It is rather a scarce bird in England, but is said to breed among some of our mountainous situations; coming in May, and departing in September. It makes a nest of heath and moss, lined with wool and gossamer, and lays six eggs, of a dull olive green, spotted with black at the larger end. According to Buffon, it is common in France, where it continues all the year; it kills rats, mice, and small birds, affixing its prey to a sharp thorn, and tearing it in pieces with its bill; it is also said to imitate the notes of some other birds, by way of decoying them to their destruction. Mr Pennant observes, that when kept in a cage, it sticks its food against the wires before it will eat it.

Red-backed shrike, lesser butcher-bird, or slasher.—Tail somewhat wedge-shaped; back hoary; four innermost tail-feathers of one colour; bill of a leaden hue. Irides hazel; head and lower part of the back of a light gray, upper part of the back and wing coverts of a bright rusty red; breast, belly, and sides, of a fine pale rose, or bloom colour; a black streak passes from the bill through the eyes; legs black. Length about seven inches; weight eight drams. The female weighs two drams more, and has all the upper parts of a ferruginous brown. The manners of this species are similar to those of the last. It kills small birds by piercing the skull with its bill, and insects by transfixing them on the thorn of the sloe-bush. It tears off the body of the chaffer, and leaves the elytra, wings, and head behind. It imitates the song of many of the sparrow tribe, and thus entices them within its reach. It chiefly haunts inclosed moist situations, makes its nest in some thick hedge, composing it very skillfully of moss and fibrous roots put together with wool and lined with hair, and lays five or six eggs of a bluish-white colour, with a circle of brown near the broad end. It inhabits Europe and Africa, visits Britain in May, and departs to some warmer climate in September. Among its varieties Gmelin includes laminus rutilus of Latham, or woodchat, which is very rare in this country.

Tyrant shrike.—Body cinereous, white beneath; crown of the head black, with a longitudinal tawny streak. Eight inches long. There are several varieties, all natives of America and the West Indies, and of a fierce and audacious disposition, fixing on the backs of other predacious birds, and making a continual chattering noise, till they force them to retire.

ORDER II. PICÆ.

The distinguishing marks of this order are, a bill Caruncled, somewhat compressed, more or less crooked, and always convex; toes divided, and adapted either for climbing (scensorial) or, for stepping, (gessorial). Some feed on insects, worms, and the flesh and offal of other animals, and some on the seeds and juices of plants. During the breeding season, they are monogamous, and make their nests on trees; and during incubation, the female is often fed by the male. There are a few genera, however, which do not exactly correspond with these characters.

Gen. 5. PIITACUS, Parrot.

Bill hooked; upper mandible moveable, and, for the most part, covered with a case; nostrils rounded, and placed in the base of the bill; tongue fleshy, obtuse, entire; feet scensorial.

This very numerous genus, which contains upwards of 140 species, is peculiar to the warmer regions of both worlds. The birds which belong to it, resemble the accipitres in the form of the bill, but in their manners coincide with the other genera of this order. They feed on the seeds and fruits of various plants; are very docile, and by means of their obtuse tongue, may be taught to imitate human speech. They climb easily, assisting themselves with their bill. They associate in pairs, and attain to a great age. Some species equal the domestic fowl in size, while others are no larger than a sparrow. In Europe, they sometimes lay eggs, but seldom sit on them. In their native climes, the male and female sit on them alternately.

A. Tail long, and wedge-shaped.

Red and blue macaw.—Quill-feathers blue above, fuscous beneath, scapulars varied with blue and green; cheek naked, wrinkled. Body scarlet; upper mandible white, lower black; temples white; wing-coverts generally yellow; tail long and red; feathers blue at the sides. Two feet seven inches in length, size of a capon. Inhabits Brazil, Guiana, and other regions of South America, affecting moist palm woods, and living on the fruit of the trees. When driven by hunger to feed on the manchineel apple, its flesh is poisonous, though the bird itself receives no injury. Makes its nest in decayed trees, enlarging the hole, if necessary, with its bill, and lining the inside with feathers. The female lays two eggs at a time, about the size of those of a pigeon, and spotted like those of a partridge. Breeds twice a year, the male and female sitting on the nest alternately, and reciprocally nursing and feeding the young birds. The latter are tamed with great ease, and may even be taught to speak, but the old birds are clamorous and unreasonable. Though the flesh is hard, black, and unsavoury, it makes good soup, and furnishes a great part of the food of the inhabitants of Cayenne, as well as other parts of South America. Like other parrots it is subject to fits when kept tame. The strength of its
ORNITHOLOGY.

its bill is sufficient to break a peach-stone with great ease.

Red and yellow macaw.—Pale scarlet; scapulars yellow, tigt with green; quill-feathers blue above, rufous beneath; cheeks naked and wrinkled. Size of the preceding. Inhabits Guiana, Brazil, and Jamaica.

Tabuan parrot.—Head, neck, breast, and belly, purple; back and wing-coverts green; crown terminated by a lunular blue mark; first quill-feathers and greater part of the tail blue. Length, 19 inches. A beautiful species, found at Tonga Taboo, and the other Friendly isles in the South seas. The green variety, with the head, neck, breast, and belly, scarlet, occurs in New South Wales.

Beautiful parrot.—Head, neck, and body, red beneath, brown above; interscapulars pale blue, mixed with red; tail greenish-brown, tigt with white. Varies, with the wings, tail, and body green above. From 12 to 15 inches long. Inhabits the Molucca islands.

Pennantian parrot.—Scarlet; fore part of the back black, waved with scarlet; sides and throat blue; quill-feathers each with a white spot. There is a variety with a pale band in the middle of each wing. The female has the upper parts of the neck and body greenish, top of the head red, and a patch of the same colour under each eye; chin and throat blue; lower part of the neck and breast, as also the rump and vent, red; middle of the belly dusky green; tail dark blue, fringed with chestnut; shoulders blue, and the rest of the wing the same, but darker. Fifteen inches long. Inhabit New South Wales.

Splendid parrot.—Bright blood-red; back feathers edged with black; chin, wing, and tail blue. Sixteen inches long. Inhabits New Holland.

Orange-billed parrot, or long parrakeet.—Of a yellowish green colour; the hind part of the head, the throat, and breast red; crown of the head and ears blue, with ash-coloured orbits. Eight inches long. Inhabits India. Like other small species with long tails, is not easily taught to speak.

Grey-breasted parrakeet.—Olive; face, chin, and breast mouse-colour, quill-feathers green. Bill and legs gray; tail five inches long. About the size of a thrush. Tame and gentle, and easily taught to articulate. Common at Monte Video.

Carnivora.

Horned parrot.—Green; head scarlet, with two long feathers standing out like horns; collar and rump straw-colour; outer edge of the quill and tail feathers blue. Bill and legs black blue; temples orange; irises golden, wing-coverts at the tips and within dusky; tail black beneath. Length 11 inches, size of a small dove. Inhabits New Caledonia. Figured in Latham's Synopsis.

Ground parrot, New Wales parrot, or black-spotted parrakeet of Von Dienten's Land. Green; four middle tail feathers barred with green and black, the rest with black and yellow; bill and legs black; tail much wedged. This is a most elegant and beautiful species, about 12 inches long, inhabiting New South Wales, and other parts of New Holland, where it is known by the name of gooligaang. It is rarely seen, except on the ground, particularly in moist places. It is not known to perch on trees like other parrots, but rises from among the grass, and immediately alights in it again. The legs and toes are more slender than usual in this genus, and the claws more straight.

Otaheite parrakeet.—Blue; feathers of the head long; chin and throat white; bill and legs red. Tongue fringed at the end; only five inches long; inhabits Otaheite, and feeds on the fruit of the banana.

B. Tails short, and even at the ends.

Banksian cockatoo.—Splendid black; crest small; head and wing coverts dotted with buff; outer tail-feathers scarlet in the middle, barred and tigt with black. Nearly three feet long, but varies both in size and markings. Inhabits New Holland, and was brought to England by Sir Joseph Banks. Figured in Latham's first Supplement.

Great white cockatoo, or yellow-crested cockatoo.—Crested; crested folding, and yellow. Bill, cere, irides, legs and claws black; orbits naked and white; quill and lateral tail-feathers, from the base to the middle, sulphureous on the inside; feathers of the neck loosely flowing; crest five inches long, and erectable. Length 18 inches; size of a dome-tic ordinary fowl. This, and several other species, frequently repeat the word cockatoo. Inhabit the Molucca islands.

Ash-coloured or hoary parrot.—Bluish-gray; tem-

Erythraeuma ples naked and white; tail scarlet. Bill black; cere white; irides yellowish white; legs cinereous; claws black. Subject to several varieties. About 23 inches long. Loquacious, and easily taught to speak. Inhabit Africa, and is sometimes called jaco from the sound which it commonly utters.

Ceram or purple parrot, Ceram lory, &c.—Red; or-Caraxus bits ash-coloured; cheeks and wings green; hinder parts of the tail-feathers blue. There are three or four varieties. Size of a dove. Inhabits Ceram, and the other Molucca islands.

Purple or blue-cap lory.—Red; cap violet; wings green; shoulders and cheeks blue; orbits brown. There is a variety with a blue cap, black orbits, and yellow collar. According to some writers, these are male and female. They inhabit the East Indies, and are remarkable for speaking distinctly, and quickly learning their lesson. They are in general scarce, and fetch a high price.

Violet cap, or black-capped lory.—Purple; cap violet; Lory. wings green; breast, cheeks, and tail blue; orbits pale flesh-colour. Upwards of 10 inches long; inhabit the Philippine islands, particularly Yolo. It is so familiar and playful, that it is much to be regretted that its duration of life proves so short in these colder regions.

Yellow-winged parrot, or yellow-headed creatin.—Ochro-

Green; front and orbits whitisht; crown, cheeks, chin, piervs, throat, and remoter wing-coverts, yellow. Thirteen inches long. Inhabit South America. A friend of the count de Buffon had one of this species alive, which seemed much attached to its master, and yet of a very capricious temper, expecting a return for every demonstration of civility. In its wantonness, it would sometimes bite a little too hard, and laugh heartily, as if pleased with the act; but if chastised for the offence, it became the more refractory, and could be reclaimed only by gentle treatment. It took great delight in tearing every thing to pieces, was dull and silent if confined
ORNITHOLOGY.

Sapphire parrot, or sapphire-crowned parrotet. — Pica Green; rump and breast scarlet, crown (of the male) blue. It sometimes occurs with the head yellowish blue, a transverse orange bar behind, and the front and under part of the throat and tail-covers red. Five inches long. Inhabits the Philippine islands. Sleeps suspended by one foot, and is very fond of the fresh juice of the cocoa-nut tree. "If this is put in a cage (says Oeseck), it whistles very seldom, and commonly grows quite silent; it hangs itself with its feet so, that the back is turned towards the earth, and seldom changes this situation: it is fed with boiled rice; in which manner in the year 1752, one was brought to Gottenburg. — We observed that their nests were remarkable for their exceeding fine texture; but we did not see the birds. If they had a different construction, the monkeys would be very mischievous to them; but now, before they can get to the opening, the lowest part, as the weakest, breaks in pieces, and the visitor falls to the ground, without any danger to the birds."

Gen. 6. RAMPHASTOS, Toucan.

Bill large, hollow, convex, and serrated at the margins; both mandibles incurved at the tips; nostrils behind the base of the bill long and narrow; tongue feathered at the edges; feet mostly scansional.

The birds of this genus seem to be limited to the tropical regions of South America, and are very impatient of cold. They feed on fruit, especially that of the palm trees. They are generally met with in small flocks of eight or ten, moving from place to place in quest of food, and advancing northward or southward as the fruits ripen, though they are not properly migratory. They make their nests in the hollows of trees abandoned by the woodpeckers, and not formed by themselves, the structure of their bill not allowing of the efforts necessary to make, or even enlarge a hole in the most tender wood, as it yields to the least pressure of the finger. They lay two eggs, and probably breed more than once in the year, as they are pretty numerous. If brought up young they are easily tam'd, and become very familiar.

Green toucan. — Green, belly yellow, rump red. Up. virides, per mandible yellow, with red sides and a black line in the middle, the lower black; the base and space round the nostrils red, the teeth in both white, irides and orbits yellow, legs lead colour, claws black, tail wedged and inclining to ash beneath; head, chin, and throat in the male, black, in the female, bay, terminated by a black, narrow, transverse band. Fourteen inches long. Inhabits Cayenne. Its extraordinary large bill gives it a very singular appearance.

Peachick toucan. — Green, feathers sprinkled with red spots. Bill variegated with yellow and black, legs and claw black. Seventeen inches long. Inhabits the coast of New Spain, and is said to feed on fish. This last circumstance, however, may admit of doubt. Most of the species will eat fish, and even flesh, in a state of confinement; but their frequent proximity to the water in their natural state, is probably occasioned by the situation of their favourite fruit.

Bra. il toucan, or B. cielien pie. — Blackish, abdominal band and vent red, rump white. Twenty-one inches long.
Gen. 7. MOMOTUS, Motmot.

Characters. Bill strong, slightly curved, serrated at the edges; nostrils feathered, tongue feathered, tail wedged, feet gessoarial.

Brazilian motmot, or Brazilian saw-billed roller.—Green, front bluish-green, hind part of the head violet, crown black. Variegated with green, tawney, blue and cinereous. Body olive-green above, rusty beneath; head large, bill black, legs black, claws hooked. About a foot and half in length, and nearly equal to a magpie in size. Inhabits Brasil, Cayenne, Mexico, and other parts of South America. It is a solitary bird, frequenting thick forests; chiefly seen on the ground, or on some low branch of a tree, taking short flights when disturbed, and pronouncing the word hontou. It makes a nest of dry grass and stalks on the ground, frequently in some hole deserted by an armadillo or other quadruped, and laying for the most part two eggs. It feeds on insects and raw flesh, the fragments of which it macerates in water. When taken, it strikes violently with its bill. Its voice is extremely harsh, weak, and tremulous.

Gen. 8. SCYTHROPS, Channel-bill.

Characters. Bill large, convex, cultrated, spurred or channelled on the sides, with the tip bent; nostrils round, naked, placed at the base of the bill; tongue cartilaginous and bifid at the end; toes placed two before and two behind; tail consisting of ten feathers.

New Holland channel-bill, psittaceous or anomalous horn-bill.—Bill pale brown, tip with yellowish, convex, keeled; nostrils surrounded with a red wrinkled skin; orbits naked; head, neck, and under parts of the body pale bluish-gray; back, wings, and tail cinereous, the feathers mostly with dusky blackish tips; tail long, wedge-shaped, its feathers barred with black near the end, and tip with white; legs short, scaly, and with the hooked claws black. Size nearly that of a crow, and the total length 27 inches. Inhabits New Holland, though not plentifully, and is seldom seen unless in the morning and evening, sometimes in small groups of eight or ten, but frequently in pairs, appearing about Fort Jackson in October, and departing in January, but to what country is not known. Both on the wing, and when perched, they make a strange, loud, screaming noise, not unlike that of the common cock and hen, when they perceive a hawk or other bird of prey hovering over them. They are supposed to feed principally on the seeds of the red gum and peppermint trees, which they swallow whole. The tail is sometimes displayed like a fan, which gives the bird a majestic appearance.

Gen. 9. BUCEROS, Horn-bill.

Bill convex, curved, sharp-edged, large, serrated at the margins, with a horny protuberance on the upper mandible near the base; nostrils behind the base of the bill; tongue short, sharp-pointed; feet gessoarial.

The birds of this genus are all inhabitants of the warmer regions of Asia and Africa, and seem to correspond to the toucans of the New World. According to Latham, the circumstance of their feeding on fish requires confirmation.

Philippine horn-bill.—Front bony, flat, and two bicorne horned at the fore part. Varies with vermilion bill, black belly, and the back and rump brown. Body black above, white beneath; quill feathers with a white spot; tail longish and black; legs greenish. Size of a common fowl; inhabits the Philippine islands, and has a cry like the grunting of a hog. It lives in the woods, and feeds on fruits, such as the Indian fig, pistachio, &c., which it swallows entire; and after digesting the pulp, brings up the stones whole, and still fit for vegetation. The Gentoos rank it among their gods.

Abyssinian horn-bill.—Black; bony protuberance on the fore part; orbits, chin, and part of the cul. throat naked, and irides brown. Greater quill feathers white. Total length, three feet ten inches; extent of wing, six feet. On the neck are several protuberances, as in the turkey cock, of a light blue colour, changing to red on various occasions. Occurs in Abyssinia, generally among the fields of taff, feeding on green beetles, which frequent that plant. It has a putrid smell, which has occasioned a suppression of its feeding on carrion. It has been seen with eighteen young ones, and usually runs on the ground; but when raised, flies both strong and far. It builds in large thick trees, and when it can, near churches; has a covered nest, like that of a magpie, but four metres as large as an eagle's, placed firm on the trunk, at no great height from the ground, and the entry always on the east side.

Indian horn-bill.—Protuberance flattened forwards, belly tawney, neck with a white collar. Two feet four inches long, rather bigger than a cock. Inhabits the Moluccas, and feeds chiefly on nutmegs, from which circumstance its flesh is very delicate, and has a fine aromatic flavour. In its native places, it is frequently tamed for the purposes of destroying rats and mice.

Rhinoceros horn-bill, rhinoceros-bird, or horned Indian Rhinoceros-raven.—The horny process on the upper mandible recurved. Inhabits India. Three feet long, and nearly as big as a turkey. Feeds on flesh and carrion, and follows the hunters for the purpose of feeding on the entrails of the beasts which they kill. It is also said to feed on rats and mice, and after pressing them flat with its bill, to toss them up in the air, and swallow them whole, immediately on their descent.

Panayan horn-bill.—Greenish black; under part of Panayan Plate C. C. C. C. fig. 2.

body dusky red; the prominence of the upper mandible acute above and plane at the sides; bill very long, arched, dusky, having the sides marked transversely with orange-coloured furrows. Size of the raven. Native of the isle of Panay.
Gen. 10. Buphaga, Beef-eater.

Bill straight, squarish; mandible gibbous, entire, more gibbous at the margins; feet gressorial.

Characters.

African beef-eater.—Upper parts of the body gray-brown, under parts and rump yellowish; bill hardly an inch long, sometimes yellowish, tipp'd with red, sometimes black; tail wedged; legs and claws black. Eight inches and a half long. Inhabits Senegal, and other districts of Africa. Resembles the starling in its manners, appearing in small troops of a dozen or more. Alights on the backs of oxen, antelopes, and other quadrupeds, and by pressing the elevated part of the animal's hide, which contains the larva of the cestrus, forces it out, and relishes on it. It is also said to feed on various kinds of insects. It has a sharp kind of cry, in no respect approaching to a song.

Gen. 11. Crotophaga, Ani.

Bill compressed, semi-oval, arched, carinated on the back; upper mandible angular at each edge; nostrils perrous, or going from one side of the bill to the other.

Lesser ani.—Blackish-violet; feet scensorial. Body black; tail long, and wedged; upper mandible incurved at the tip; nostrils oval; tongue fleshy, and entire; legs black. Length thirteen inches and a half; size of a blackbird; and sometimes known by the names of the razor-billed blackbird, or great blackbird. Inhabits South America and several of the West India islands. This species is gregarious to such a degree, that many females lay their eggs in the same nest, to make which they all unite in concert, and after depositing their eggs, sit on them close to each other, in order to hatch them, each striving to do the most for the general good. When the young are hatched, the parents exert themselves to feed the whole flock. It is still more remarkable, that as soon as the female has laid her eggs, she covers them with leaves, and repeats this operation as often as she is obliged to leave the nest for food. It generally breeds twice a year; and the eggs are about the size of those of a pigeon, of a sea-green colour, and spotted at the ends. The lesser ani feeds on worms, insects, fruits, and grain, according to the season. The other species resemble this in appearance and manners, but vary somewhat in size and colouring.

Bill strong, triangular, the upper mandible at the base elevated above the crown, both mandibyles dentated on edges; nostrils in the middle of the bill; tongue entire and stout; toes placed three before and one behind.

Violet plantain-eater.—Bill one inch and a half; the upper mandible nearly triangular, losing its attachment at the back part, and hanging over the crown; colour of the bill yellow, and reddish towards the end; irides brown; top of the head purple; neck, breast, body and wings violet; legs dusky-black, and very strong. This beautiful and rare bird is found on plains near the borders of rivers, in the province of Agra, in Guiana, and is said to live principally on the fruit of the plantain.

Its total length is nineteen inches, of which the tail is six inches and one-third. It is described and figured in Latham's second supplement.

Bill incurved, arched, the lower mandible shortest, with a caruncle below at the base; nostrils depressed; character half covered with a membrane nearly cartilaginous, cut at the point, and fringed; feet gressorial.

Cinerous wattle-bird.—Body, bill, and legs black; caruncle first blue, then orange; irides blue, and very large; tail long and wedged; legs long; hind claws longer than the rest. Fifteen inches long; about the size of a jay. Inhabits New Zealand, where it is often seen walking on the ground, and sometimes, though more rarely, perching on trees. It feeds on various kinds of berries and insects, and even, according to some, on small birds. Its note approaches to whistling, and sometimes to a sort of murmuring that is unpleasant. Its flesh is edible, and by some esteemed savoury.

Bill strong, upper mandible a little convex, edges cut, and in most species, slightly notched near the tip; nostrils covered with bristles reflected over them; tongue divided at the end; toes, three forward, one backward, the middle one joined to the outer as far as the first joint.

The greater number of this tribe are found in every climate. They are prolific, social, and elegant; building on trees; laying six eggs; and living on grain, seeds, insects, &c. Some of them are apparently hurtful to agriculture; but their use in diminishing noxious vermin more than counterbalances the waste which they occasion.

Raven.—Black; back of a blueish-black; tail nearly rounded. Two feet two inches long. Varies with a few scattered white feathers, or is black and white, or entirely white. A well-known bird, a native of Europe, Asia, and America. It is hardy, cunning, voracious, and yet patient of hunger. Preys on young ducks and chickens, and even destroys young lambs and sickly sheep, by first picking out their eyes. Smells carrion at a great distance; gluts itself when an opportunity offers, retires to digest, and returns again to feed. Though easily domesticated, and taught to speak, it has a mischievous trick of purloining anything glittering, and concealing it. "We have been assured (says Mr Montagu), by a gentleman of veracity, that his butler having missed a great many silver spoons and other articles, without being able to detect the thief for some time, at last observed a tame raven with one in his mouth, and watched him to his hiding place, where he found more than a dozen." The raven usually makes choice of the forks of the largest trees to build in; but many of them likewise breed on rocky coasts, and nestle in the most inaccessible parts of them. At this time they are very bold, and will not allow even the falcon to approach their nest with impunity. The male and female pair for life, and drive their young from their haunt, as soon as they are able to provide for themselves. The female lays five or six eggs of a bluish-green.
is green colour, blotched and spotted with brown and
ash-colour, and somewhat larger than those of a crow.

Carroon crow.—Bluish-black; tail rounded; tail
feathers acute. Varied with speckles of white, or en-
tirely white; bill black, iridescent dusky, legs black. Di-
stinguished from the rook by the bill, which is rather
more convex towards the end, and by the reflected
bristles at the base being always perfect. These marks,
however, are obvious only in adults, and in young birds,
the note is the only criterion, which in this is much
more hoarse than that of the rook. This species weighs
about nineteen ounces, and is eighteen inches long.
It feeds on flesh, insects, and grain, but is particularly
fond of carrion. It frequently attacks the eyes of dy-
ing animals, destroys weakly lambs, and when pressed
with hunger, will even pursue birds on wing. It also
makes havoc among young game and poultry. It will
frequently hide its food till hunger becomes more
urgent. With the lesser species of hawks it wages con-
tent war; nor will it suffer the kite, the buzzard, or
the raven, to approach its nest with impunity. Carrion
crows keep in pairs all the year, and seldom congregate
but to regale on some carcass, or to roost in winter.
They build in woods, on the branches of trees, making
a nest of sticks, plastered with earth, and lined with
some soft materials, as wool and hair. The eggs are
four or five in number, of a greenish colour, spotted
with dusky and ash.

Rook.—Black; fore part of the head cinerous; tail
somewhat rounded. Very like the preceding; but differ-
s in its manners, being content with feeding on the
insect tribe and grain. It is particularly fond of what
is commonly called the grub-worm, which is the larva
of the chaffer. The rook is gregarious at all seasons,
resorting every spring to breed on the same trees, where
their nests may be seen crowded one over another, on
the upper branches. It lays four or five eggs, much
like those of the crow. After their young have taken
wing, they will forsake their nest-trees, but return to them
again in October, to roost. On the approach of winter,
they usually seek some more sheltered situation at night,
but generally assemble first in the usual place, and then
fly off together. Rookeries are sometimes the scene of
violent contests between the old and new inhabitants.
An unfortunate couple of strangers will sometimes have
their half-built nests torn in pieces, and be compelled
to begin their work anew in some more undisturbed situa-
tion. Of this (says Mr Bewick) we had a remark-
able instance in Newcastle. In the year 1783, a pair
of rooks, after an unsuccessful attempt to establish
themselves in a rookery at a great distance from the
exchange, were compelled to abandon the attempt.
They took refuge on the spire of that building, and al-
though constantly interrupted by other rooks, built their
nest on the top of the vane, and brought forth their young,
undisturbed by the noise of the populace below them;
the nest and its inhabitants turning about with every
change of the wind. They returned and built their nest
every year on the same place till 1793, soon after which
the spire was taken down. In England,
rooks remain during the whole year; but both in
France and Spain they migrate. It is a singular cir-
cumstance, that the island of Jersey should be entirely
without rooks; particularly when we know that they
frequently fly over from Britain to France. The young
birds, when skinned, and made into pies, are much in
request at some tables, but are nevertheless coarse eat-
ing.

Hooded crow, or royston crow.—Ash-coloured; head,
throat, wings, and tail black. Length twenty-one
inches. Visits the south of England in October, and
retires north to breed, in the beginning of April. In
the Hebrides, and some parts of Scotland and Ireland,
it is resident throughout the year. In open champaign
districts, it feeds on grain, worms, and carrion; but it
often resorts to the neighbourhood of the sea coast,
where the various animal matters thrown up by the tide,
afford a constant supply of food. It not only picks out
the eyes of lambs and diseased sheep, but of horses,
when entangled in bogs. The nest and eggs are simi-
lar to those of the common crow. It is not uncommon
in many parts of Europe and Siberia.

Jackdaw.—Brownish black; hind part of the head
hoary; front, wings, and tail, black. Its varieties are,
a white collar round the neck; white, with a yellowish
bill; bright black, and eyes surrounded with white
dots; black, with bill and legs red; wings white, bill
somewhat curved; brownish, with white shoulders, &c.
Weighs about nine ounces; length near thirteen inches.
This very common bird frequents old towers, ruined
buildings, and high cliffs, where it builds, as well as in
holes of trees. The nest is made of sticks, and lined
with wool and other soft materials; the eggs are five or
six, and bluish, spotted with black. The jackdaw is
gregarious, frequently rooks with rooks, and like the
latter, feeds on grain and insects, is fond of cherries,
and will devour carrion in severe weather. It is frequently
seen to perch on the back of sheep, not only to rob that
animal of its wool, as a lining to its nest, but also to
pick out the ticks with which it is infested. Though
easily made tame, and taught to speak, it is mischievous,
and full of tricks.

Jay.—Wing-coverts blue, with white and black trans-
verse lines; body variegated with purple and gray. This
beautiful bird is very common in Great Britain, and in
various parts of Europe and Siberia; frequenting wooded
tracts, but not in flocks. It weighs seven ounces,
and measures nearly thirteen inches in length. The
nest, which is commonly built in high coppice wood, or
hedges, and sometimes against the sides of a scrubby tree,
is formed of sticks, lined with fibrous roots, and contains
five or six eggs, of a light brown colour, not very un-
like those of the partridge, but smaller, and obscurely
marked with a darker shade of brown. The jay is a
great devourer of fruit and grain, particularly acores,
peas, and cherries; will frequently plunder the nests of
smaller birds of their eggs and young, and sometimes
pounce on the old birds, on which it preys, as well as on
mice. Its common notes are various, but harsh, and
manifest a singular propensity to imitation and mimicry,
counterfeiting the bleating of a lamb, the meowing of a
cat, the cry of a kite or buzzard, the hooting of an owl,
the neighing of a horse, &c. It has even been known
to imitate very exactly the sound made by the action of
a saw.

Blue jay.—Blue; collar black; wing-coverts with
transverse black lines; crest blue; cheeks, chin,
and belly, white; breast pale red; back pale purple;
tail long, wedged, with black and blue lines, and tippd
with white; legs black. Eleven inches long; inhabits
North
ORNITHOLOGY.

Gen. 15. Coracias, Roller.

Bill sharp-edged, bent in at the point, base naked of feathers; tongue cartilaginous, and bifid; legs short; feet gressorial; toes three before, and one behind; characters divided to their origin.

This genus is not confined to any particular region of the globe, as one or other of the different species may be met with in each of the four quarters of the world.

Common or gargules roller.—Blue; back red; flag; Coracias. feathers black.—The only species that has ever been met with in England, and that very rarely. Length twelve inches and a half; size of a jay. Vies with some of the parrots, in its shades of blue and green, mixed with white, heightened by the contrast of graver colours. It is wider than the jay; frequents the thickest woods, and builds its nest chiefly on birch trees. It is plentiful in Germany, Sicily, and Malta, where they are sold in the markets and poulterers shops. It feeds on frogs, beetles, acorns, grain, and fruit, and in cases of necessity will even eat carrion. It is remarkable for making a chattering kind of noise. Its flesh tastes like that of a turtle.

Long-tailed roller.—Bill blackish, one inch and a half long; hind parts of the head green; upper parts of the back and scapulars fulvous glossed with green; lower part of the back, rump, and wing coverta, fine blue; upper tail coverts blue green; two middle feathers of the tail deep green, rest blue green; outer ones on each side twice the length of the others, and the projecting part deep blue; the shafts of all black; legs grey; claws blackish. Inhabits Angola.

Dorcile or tame roller.—White, interspersed with Diociles. reddish, bay beneath; legs yellow; tail feathers black, tip with white; bill yellow; claws flesh-colour. Size of a jaydaw. Inhabits Persia; and has obtained its name from imitating the words and actions of those around it.

Noisy roller.—Black; patch on the wings; vent, striepe base, and tip of the tail white. This species is very numerous at Norfolk island; and is very clamorous, especially at night. It is a very foolish bird; running after any person, and allowing itself to be knocked down with a stick. It is about nineteen inches long, and rather bigger than a jaydaw.

Gen. 16. Oriolus, Oriole.

Bill conical, convex, very acute and straight; upper characters manible somewhat longer than the under, and slightly margined; tongue bifid and acute; feet gressorial.

The birds of this genus are gregarious, noisy, numerous, voracious, and great devourers of corn. They chiefly inhabit America, and often build pendulous nests. The only European species, which also inhabits Asia and Africa, is the

Golden oriole, or golden thrush.—Pale yellow, lores Cassidea; limbs black; outer tail feathers yellow on the hind part; bill and irides yellow; legs plumbeous. Nine inches and a half long. Inhabits Europe, Asia, and Africa; and is incident to several varieties. It is by no means uncommon in France, where it summers and breeds. Its nest is in the shape of a purse, fastened to the extreme diversations
ORNITHOLOGY.

divarications of the outmost twigs of tall trees, and composed of fibres of hemp, or straw, mixed with fine dry stalks of grass, and lined within with moss and lichens. The female lays four or five eggs of a dirty white, marked with small brown spots. She sits three weeks, and will not unfrequently suffer herself to be taken with the eggs and nest, and continue to sit upon them in a cage, till she dies. The golden oriole is partial to grapes, figs, cherries, berries, and insects. It has a loud cry. Its flesh is reckoned good eating.

Climbing oriole.—Tawny; head, neck, and breast spotted with white; tail rounded; bill yellowish grey; legs blackish. Seven inches long. Inhabits Guiana, among trees, which it climbs like a pie, and picks out insects from under the bark.

Icteris oriole.—Tawny; head, throat, back, quill, and tail feathers, black; wings with a white spot; bill mostly black, with a brown base; irides yellowish; legs sometimes black and sometimes light coloured, or gray white. Nine inches and a half long. Inhabits the warmer parts of America and the Caribbee islands. Domesticated for the purpose of killing insects. In its wild state it is very agile and bold. It builds a large cylindrical nest, suspended to the end of a twig of a tree, with a view to defend its young from the attacks of snakes and other animals. Of these nests several may sometimes be seen near to one another, and not far from houses.

Red-winged oriole.—Black; wing covets tawny. Size of a starling; length from eight to nine inches. Occurs in Mexico, the Carolinas, Virginia, and as far as New York. Builds a thick pensile nest among reeds, or between the forks of trees, three or four feet from the ground, along with other birds, in the swamps, which are seldom accessible by man. In Louisiana these birds appear only in winter, and sometimes in immense flocks, that three hundred or more are taken at one draught of the net. These nets are spread on some bare smooth path, at the side of a wood, with rice strewn to decoy the birds. To secure the multitudes that are caught, it is often necessary to knock most of them on the head upon the spot. Their common name in America is maïse-thief, which they have acquired from the circumstance of their pecking a hole in the plant when green, and so destroying it.

Red-breasted oriole, or mocking-bird of Guiana.—Black; chin, throat, breast, and upper corner of the wings red. Seven inches long, less than a blackbird. Inhabits Guiana and Cayenne; sings pleasantly, and imitates the notes of many other birds. The nest, which is built of hay, &c. is long, cylindrical, twelve or fifteen inches in circumference, and hangs from the high branches of the tallest trees.

Black and yellow oriole.—Black; bind part of the back, spot on the wing-covers, and base of the tail feathers, yellow. There are, however, several varieties. Bigger than a blackbird. Inhabits South America; forms a pendent nest, shaped like an alembic: four hundred of which may sometimes be seen together, hanging from the extreme branches of trees. The eggs are dirty white, with small pale brown spots.

Baltimore oriole, or Baltimore bird.—Blackish; the under parts of the body, and band on the wings tawny; bill lead colour; greater wing covets black, vol. XV. part II.
ORNITHOLOGY.

hhabitats various parts of the East Indies; is very fond of cherries and grapes; and can easily trained to whistle, sing, or speak.

Boat-tailed grale.—Grayish; shoulders blue; quill feathers green on the outside. Size of a cuckoo, nearly thirteen inches long. The folding up of the tail feathers, instead of forming a plane surface at top, sinks into a hollow, like a deep gutter, the singularity of which is manifest only when the bird is flying, or perched, for when on the ground, it always carries its tail expanded. It inhabits Jamaica and North America, keeping company with the maize-thief and red-winged oriole. It feeds on maize, the fruit of the banana, &c. as well as on beetles and other insects.

Purple grale.—Violet black; tail rounded. upwards of thirteen inches long, though the female measures only eleven and a half. Habits Mexico, the warm parts of America, and Jamaica; sings sweetly; feeds on all kinds of grain, and makes great havoc in the maize plantations. It lays five or six bluish eggs, with black stripes and spots.

Gen. 18. PARADISEA, Bird of Paradise.

Bill covered with a belt of downy feathers at the base; feathers of the sides very long; two of the tail feathers naked. Legs and feet very large and strong; three toes forward, one backward, the middle connected to the outer one as far as the first joint.

The birds of this genus, till lately, were very imperfectly known, and had given rise to various idle tales, such as their never alighting on the ground from their birth to their death; their living entirely on dew; their being produced without legs, &c. The circumstance which led to the last-mentioned error, was merely accidental; the legs and coarser parts of the wings having been pulled off in the course of preparing the birds for an ornamental article of dress. Though the birds of paradise occur in Japan, China, Persia, and various parts of India, they are believed to be properly natives of New Guinea, where they breed. The Dutch get them chiefly from Banda, where the story of their want of legs has been propagated, in order to enhance their value.

Great bird of Paradise.—Feathers of the hypochondria longer than the body; the two intermediate tail feathers long and setaceous; the size of the body scarcely exceeds that of a thrush, though the plumage would indicate a bird as large as a pigeon; the length from the end of the bill to that of the tail is twelve inches and a half; the bill is greenish yellow, and an inch and a half long; the eyes are very small; the head, which is also small in proportion to the bird, as well as the throat and neck are covered with very short, dense, stiff feathers, of which those on the head and hind part of the neck are of a pale gold colour; the base of the bill is surrounded with black feathers, appearing like velvet, and changing in different lights to green; the fore part of the neck is golden green; the lower part of the neck behind the back, wings, and tail, are chestnut; the breast is of a deep chestnut, verging to purple; from under the wings proceeds a great quantity of feathers, with the webs so loose, as to appear like a herring-bone, some of them nearly eighteen inches long, some chestnut and purplish, others yellowish, and a few almost white; from the rump arise two feathers without webs, except for four inches next the base, and the same at the tips; the legs are stout and of a brown colour. These birds are found in the Molucca islands, and those surrounding New Guinea, particularly in Arto, where they arrive with the westerly or dry monsoon, and whence they return to New Guinea, when the easterly or wet monsoon sets in. They are seen going and returning in flights of thirty or forty, conducted by a leader, which flies higher than the rest. During this flight they vire like starlings. By a sudden shifting of the wind, their long scapular feathers are sometimes so dishevelled as to preclude flying, when they fall to the ground, or are lost in the water. In the former case they cannot rise again into the air, without gaining an eminence, and are secured by the natives, and killed on the spot, as they cannot be preserved alive by art. They are likewise caught with bird-lime, or shot with blunt arrows, or intoxicated with the berries of menispermum cocculus put into the water which they are accustomed to drink. Their real food is not known with certainty. According to some, they feed on the red berries of the waringa tree (ficus benjamin), according to others, they are particularly fond of nutmegs; some assert that they live on large butterflies, and others, that they chase and devour small birds. It is only for ornament that they are coveted by such of the inhabitants of the east as are able to purchase them, the chiefs of the country wearing them constantly in their turbans. The grandees of Persia, Surat, and the East Indies, use them as sigarettes, and even adorn their horses with them. There is a lesser variety of this species, found in the Papuan islands.

King's bird of Paradise, or king's bird.—Chestnut brown purple, whitish beneath; two middle tail-feathers filiform, feathered, and semilunar at the tips; breast bluish; cirri of the tail very long; feathers under the wings longer than the rest; tail short, truncate; from five to seven inches long, and about the size of a lark. It is said not to associate with any others of the bird of paradise, but shifts solitary from bush to bush in quest of red berries, and never gets on tall trees. It occurs in the islands of the Indian ocean, and returns to New Guinea in the rainy season, but is much more scarce than the preceding.

Magnificent bird of Paradise.—Chestnut brown above; magnifica, chin green, with golden lunules; crown with a tuft of yellow feathers; first quill-feathers brown, secondary deep yellow; middle tail-feathers very long, with a very short fringe; legs and bill yellow, and the latter black at the tip and base. A singular and beautiful species, figured in Latham's Synopsis.

Gorget bird of Paradise.—Black, slight green below; neck, head, nap, crown, and band on the middle of the belly fine green, a splendid gold-coloured crescent under the chin; tail feathers 12, unequal, the outer ones five inches long, and the two in the middle 22. Twenty-eight inches long. Figured in Latham's Synopsis.

Superb bird of Paradise.—Crested; head, crown, and superb, belly green; chin violet, silky; wings black; tail with a shade of green; bill black; legs brown; under the wings a tuft of loose, black, silky feathers, as long as the wings when folded. Eight inches and eight lines long. Native of the northern parts of New Guinea.
ORNITHOLOGY.

White bird of Paradise.—Entirely white. Inhabits the Papuan islands, and is very rare.

Bill shorter than the head, sharp-edged, hooked; mandibles serrated at the edge; feet scansional; body long; nostrils covered with bristles; feet short, woolly; tail very long, consisting of 12 feathers.

The birds of this genus are all inhabitants of the tropical regions, and mostly inhabit South America. They live solitary, in the thickest recesses of moist woods, sitting and building on the lower branches of trees. They take but a short flight, and feed on insects and fruit. As they differ much in appearance, in different stages of life, a considerable degree of confusion has prevailed in the illustration of the species. They have the name of curucu from their note.

Red-bellied curucu.—Of a greenish-gold colour, tawney beneath; throat black; lateral tail feathers, with white and black bars, the middle ones tipped with black. Somewhat less than a magpie; length 10 inches and a half. Inhabits Mexico, Brazil, and Peru. There are two or three varieties. At pairing time, only two or three are found together; and the male has a kind of melancholy note, by which their haunts are discovered. They begin to pair in April, and build in the hole of a rotten tree, laying three or four white eggs, about as big as those of a pigeon, on the bare rotten dust. During the incubation of the female, the male takes care to provide food for her, and to beguile the time by his song. The parents feed the young with small worms, caterpillars, and insects; and, when their nurseries are able to shift for themselves, they forsake them, and return to their solitary haunts, till nature prompts them to produce their second brood in August or September. Various attempts have been made, but without effect, to domesticate this species, as it obstinately refuses food, when in confinement.

Gen. 20. Bucco, Barbet.
Bill cultrate, compressed laterally; apex emarginate on both sides, and incurved, gap reaching below the eyes; nostrils covered with recumbent feathers; feet scansional; bill strong, somewhat straight, almost covered with bristles; tail feathers usually ten.

The birds of this genus are all inhabitants of Africa, and the warmer parts of Asia and America, and are a dull and stupid race.

Tamatia. Spotted-bellied barbet.—Tawney brown, tawney white, spotted with black beneath; chin tawney; neck with a tawney lumule varied with black, a black spot behind the eyes; head very large; bill black; crown and front tawneyish; legs black. This bird occurs both at Cayenne and Brazil. It is clumsy, solitary, silent, and pensive, affecting only such places as are farthest from habitations, generally in the woods, where it chooses some low branch, well covered with twigs and foliage, on which it perches, with its large head resting between its shoulders for a long time together, allowing itself to be shot at several times before it makes its escape. It feeds on insects, particularly large beetles.

Beautiful barbet.—Green; head and chin red, edged with blue; quill feathers brown, throat and breast yellow, the latter spotted with red; belly yellow, spotted with green; bill, legs, and claws cinereous, the latter tipped with yellow; a blue streak on each side of the mouth; tail wedged; quill feathers edged with green. Size of a sparrow, nearly six inches long. Inhabits the country of Maynas, on the borders of the Amazon, and is the most beautiful and active of the tribe.

Gen. 21. Cuculus, Cuckoo.
Bill smooth, weak, a little curved; nostrils bounded by Character a small rim; tongue arrowed, short, and pointed; feet scansional.

Of upwards of 50 species belonging to this genus, the first mentioned only is a native of Great Britain; and very few of the others are natives of Europe.

Common cuckoo.—Cinereous, whitish beneath, trans. Cuculus. Versely streaked with brown; tail rounded, blackish, dotted with white; edges of the eyelids, opening of the mouth and palate saffron; when young, the whole body is brownish, the feathers edged with white; the upper part of the body is sometimes varied with reddish. It likewise occurs with wavings of grey; a double row of white dots on the middle tail feathers, and the bill, or bits, and legs of a sulphur colour. Size of the turtle dove; 14 inches long, and weighs about four ounces and a half. The female is rather less, and, in general, differs from the other sex, in the neck and breast being of a tawneyish brown, barred with dusky, and the wing coverets marked with light ferruginous spots. Inhabits Europe, Asia, and Africa. This well-known bird comes to us early in the spring, and almost invariably leaves us by the first of July, though the females may sometimes remain a little later, till they have deposited all their eggs. Such as are seen about the latter end of September or beginning of October, are the young of that year, or stragglers which have been wounded. The singular note of the male has given rise to the name of this bird, in most languages; the female is in silence, or makes only a chattering note. Cuckoos build no nest, and what is more extraordinary, the female deposits her solitary egg in the nest of another bird, by which it is hatched. The nest which she selects for this purpose is usually that of the hedge sparrow, though sometimes also that of the water wagtail, tit-lark, yellow hammer, green linnet, &c. Dr Jenner, in his valuable communication to the Royal Society, published in the second part of the 7th volume of their Transactions, observes, that while the hedge sparrow is laying her eggs, which generally takes up four or five days, the cuckoo contrives to deposit her egg among the rest, leaving the future care of it entirely to the hedge sparrow. This intrusion often occasions some discomposure, for the old hedge sparrow at intervals, while she is sitting, not only throws out some of her own eggs, but sometimes injures them in such a way, that they become addle; so that it frequently happens that not more than two or three of the parent bird’s eggs are hatched with that of the cuckoo; and, what is very remarkable, it has never been observed, that the hedge sparrow has either thrown out or injured the egg of the cuckoo. When the hedge sparrow has sat her usual time, and has disgorged the young cuckoo and some of her own offspring from the shell, her own young ones, and any of her eggs that remain unhatched, are soon turned out; the young
ORNITHOLOGY.

young cuckoo then remains in full possession of the nest, and is the sole object of the future care of its foster-parent. "The mode of accomplishing this (says the ingenious and interesting inquirer, in reporting his observations on a particular case), was curious: the little animal, with the assistance of its rump and wings, contrived to get the bird upon its back, and making a lodgement for its burden, by elevating its elbows, clambered backwards with it up the side of the nest until it reached the top, where, resting for a moment, it threw off its load with a jerk, and quite disengaged it from the nest. After remaining a short time in this situation, and feeling about with the extremities of its wings, as if to be convinced that the business was properly executed, it dropped into the nest again." Dr Jenner made several experiments in different nests, by repeatedly putting in an egg to the young cuckoo, which he always found to be disposed of in the same manner. But we are reluctantly compelled to withhold various other interesting details relative to this subject, and to refer our readers to the original communication. The young birds are observed to be helpless and foolish for a great length of time, but are capable of being tamed, and, when in confinement, will eat bread and milk, fruits, insects, eggs, and flesh, either cooked or raw; but, in a state of nature, they live chiefly on caterpillars and insects.

Long-billed rain cuckoo.—Tail wedged; body brownish, testaceous beneath; eyelids red. Rather bigger than a blackbird. Inhabits woods and shrubries in Jamaica, is easily tamed, flies short, sings before rain, and feeds on grubs, insects, worms, small serpents, frogs, lizards, and small birds.

Rain cuckoo.—Olive ash, rufous beneath; chin and throat white; outer tail-feathers edged with white. From 16 to 17 inches long, like the preceding. Inhabits Jamaica, and sings before rain. Both species are familiarly known by the names of old man, and rain bird.

Laughing cuckoo.—Tawney, chin, throat, and breast cinnamon; belly, thighs, and lower tail-coverts black; bill bluish black; irides white; tail half as long as the body. Sixteen inches long. Inhabits New Spain; has a voice like a man laughing, on which account it is dreaded by the Indians as ominous.

Coronadel crested cuckoo.—Upper parts of the body black; under part white; a white spot on the edge of the wing; tail wedge-shaped and tipped with white; head crested; bill black; legs brown. Length eleven inches. Inhabits the coast of Coromandel.

Pisan cuckoo.—Tail wedged; body above varied with white and black, white beneath; head black and crested; chin and breast rufous. Rather larger than the common species, and has its name from having been once caught in Pisa.

Bee cuckoo, honey-guide, moroc, &c.—Rusty gray, white beneath; eyelids naked, black; shoulders with a yellow spot; tail wedged, rusty; bill brown at the base, and surrounded with bristles, yellow at the tip; feathers of the thighs white, with a longitudinal black streak; quill-feathers brown above, gray brown beneath; first tail-feathers very narrow, rusty; the next sooty, the inner edge whitish; the rest brown at the tip on the inner web. Somewhat larger than the common sparrow. Native of the interior parts of Africa. This bird is very fond of honey and bee maggots; but being unable, by its own efforts, to procure them from the hollow of trees, it points out to man and to the animal called ratel, the nests of wild bees. The morning and the evening are its principal meal times; at least it is then that it shews the greatest inclination to come forth, and with a grating cry of cherr, cherr, cherr, to excite the attention of the ratel, as well as of the Hotentots and colonists. Somebody then generally repairs to the place whence the sound proceeds, when the bird, continually repeating its cry, flies on slowly and by degrees to the quarter where the bees have taken up their abode. The persons thus invited, follow accordingly, taking great care, at the same time, not to frighten their guide by any unusual noise; but rather to answer it now and then with a very soft and gentle whistle, by way of letting the bird know, that its call is attended to. When the bees nest is at some distance, the bird often makes long stages, or flights, waiting for its sporting companions between each flight, and calling to them again to come on; but it flies to shorter distances, and repeats its cry more frequently, and with greater earnestness, in proportion as they approach nearer the nest. When the bird has sometimes, in consequence of its impatience, got too far a-head of its companions, but particularly when, on account of the unevenness of the ground, they have not been able to keep pace with it, it will fly back to meet them, and, with redoubled cries, denoting still greater impatience, upbraid them, as it were, for being so tardy. When it arrives at the nest, whether the latter is built in the cleft of a rock, or in a hollow tree, or in some cavity of the earth, it hovers over the spot for a few seconds, then sits in silence, and for the most part concealed, in some neighbouring tree or bush, in expectation of the result, and with a view of receiving its share of the booty. Nor is it disappointed; the hunters, by way of acknowledgement, leaving it a considerable portion of that part of the comb in which the bees are hatching. Mr Barrow corroborates these details, and adds, that the moroc intimates to the inhabitants, with equal certainty, the dens of lions, tigers, hyenas, and other beasts of prey, and noxious animals. Le Vaillant mentions that the Hotentots are very partial to this bird on account of its services, and that once when he was on the point of shooting one, they intreated him to spare its life. Mr Bruce, by confounding this species with another peculiar to Abyssinia, has indulged in some very misplaced strictures on the accounts of Spinman and Lobo.

Gen. 22. Yunx.

Bill smoothish, cylindrical, pointed, a little curved; nostrils concave, naked; tongue very long, smooth, worm-shaped, armed at the point; tail feathers 10, flexible; feet scansional.

This genus consists of only one species, and has, by most authors, been held distinct; for, though allied to some other genera, it perfectly coincides with none. The tongue and disposition of the toes correspond to those of the woodpecker; but the weakness of the bill distinguishes it from that family. It seems also to be nearly related to the cuckoo, did not its length of tongue form a marked distinction.

Wryneck.—Gray, varied with brown, and blackish; belly reddish, with blackish spots; tail-feathers waved with
ORNITHOLOGY.

with black spots, streaks, and bars. Description, however, is very inadequate to convey an accurate idea of the elegant markings of this little bird. Its name seems to have been given it from the manner of turning its head over its shoulder and perpetually looking about, when the black line on the back of the neck gives it a twisted appearance. The weight of this beautiful bird is about ten grams, and its length seven inches. It inhabits Europe, Asia, and Africa, appearing in Britain about the same time with the cuckoo, and chiefly frequenting woods, or thickly inclosed countries, where trees or orchards abound. Its food principally consists of ants and other insects, of which it finds great abundance lodged in the bark and crevices of trees, and which it secures by a bony substance at the end of its long tongue. It likewise frequents ant hills, into which it darts its tongue and draws out its prey. It is never seen with any other society than that of its female, and as soon as the domestic union is dissolved, which is in September, they retire and migrate by themselves. It makes an artless nest of dry grass, on dusty rotten wood, in holes of trees, and lays nine or ten eggs, which are white and transparent. If surprised in its nest, it stretches itself at full length; and erecting the feathers on the crown of its head, suddenly rises, making, at the same time, a short hissing noise, like that of a turkay cock. In the beginning of spring, it very frequently repeats a noise like that of the smaller species of hawks.

Bill angular, straight, wedged at the tip; nostrils covered with recumbent setaceous feathers; tongue round, worm-shaped, very long, bony, missile, daggere, beset at the point with reflexed bristles; tail feathers ten, hard, rigid, pointed; feet scamorial.

The birds of this genus climb trees, particularly those that are decaying or dead, in search of insects and their larvae. The bone of their tongue terminates in two long slender cartilages, which proceed from below upwards, and from behind forwards, over the whole skull, under the skin, and are attached to the forehead near the base of the bill. By means of those elastic cartilages, the woodpeckers thrust out their filiform tongue to catch insects. The feet are formed for climbing, their tail is fitted for resistance and support, and their sharp-pointed and barbed tongue enables them to extract insects from their lurking places in trees. They are therefore unjustly persecuted and driven from plantations. They make their nests in hollows of trees. They have a membranous stomach, and want the accom.

Great black woodpecker.—Black, cap vermilion. In the female the hind head only is red; length 17 inches and a half. Size of a jacksaw; bill nearly two inches and a half long, of a dark ash colour, and whitish on the sides; irides pale yellow. Has all the habits of the green woodpecker, and is a great destroyer of bees. Makes its nest deep in some tree, which it has excavated for the purpose, and lays two or three white eggs; a circumstance which seems peculiar to most of the genus. Occurs in Europe, Siberia, and Chili; but rarely visits England.

Red-headed woodpecker.—Head wholly red; wings and tail black; belly white. Eight inches and three quarters long, and weighs two or three ounces. This species inhabits Virginia, Carolina, Canada; &c.; but on the approach of winter, migrates more or less to the southward, according to the severity of the season, from which circumstance the North Americans foretell the rigour or clemency of the ensuing winter. The red-headed woodpeckers are very destructive to maize fields and orchards, and are fond of scorns. During the winter, they are very tame, and sometimes come into houses, as the redbreast in Geron. They are found chiefly in old trees; and the noise that they make with their bills may sometimes be heard at a mile’s distance.

Gold-winged woodpecker.—Striated transversely with black and gray; chin and breast black; nape red; rump white. Chin of the female cinereous; length 11 inches; weight five ounces. Inhabits North America; is almost continually on the ground; feeds on worms and insects; and, in default of these, on berries and grass. When fat, it is esteemed good eating.

Green woodpecker.—Green; crown of the head crimson; bill dusky, two inches long; inner circle of the irides reddish; outer white; temples blackish; quill feathers dusky, with whitish spots; tail blackish, obscurely barred with green, and tipt with white; legs greenish ash. Weighs about six ounces, and is thirteen inches long. Inhabits Europe, and is by no means uncommon in the wooded parts of England. It feeds on insects, and is particularly fond of bees. It is frequently seen climbing up a tree, or on the ground, in the neighbourhood of an ant hill. The hole which they make is as perfect a circle as if it had been described by a pair of compasses. It is curious to observe them try every part of a dead limb of a tree, till they have discovered the most sonorous, and then the strokes are reiterated with such velocity, that the head is scarcely perceived to move. The softer wood, such as the elm, ash, and asp, are, for the most part, attacked, for the purpose of nidification, and are perforated only where they exhibit symptoms of decay. The excavations are often deep, to give security to the eggs, which are generally four or five, and placed on the rotten wood without any nest.

Downy woodpecker.—Back longitudinally downy; outer tail feathers white, with four black spots. Weighs an ounce and a half, and measures only five inches and a half in length. Inhabits Carolina, Virginia, New Jersey, &c. and is a daring bird, and dangerous to orchards. As soon as it has pecked one hole in a tree, it makes another close to the first, in a horizontal direction, proceeding till it has made a circle of holes quite round the trunk, so that the tree frequently dries up and decays.

Hairy woodpecker.—Back somewhat downy, in a Villous longitudinal direction; outer tail feathers entirely white. From nine to twelve inches long. Like the former, is the pest of orchards. Inhabits North America, from Hudson’s Bay to Carolina; and likewise occurs in the north of England.

Greater spotted woodpecker.—Variegated with black Major and white; hind head and vent red. Female, without red on the hind head. The weight of this species is about two ounces and three quarters, and the length nine inches. The bill is dusky, and an inch and a quarter long; the irides are reddish brown. Inhabits Europe, North America and Siberia. It is less frequent in England than the green species, to which it is nearly allied.
ORNITHOLOGY.

Middle spotted woodpecker.—Variegated with white and black; vent and cap red; cheeks white; three lateral tail feathers, tippet with white. Supposed by some to be only the young of the preceding species.

Minor. Lesser spotted woodpecker.—Variegated with white and black; crown red; vent testaceous or brick-coloured. There are two or three varieties. The weight of this small species is not quite five drams; and the length is about five inches and a half. Inhabits Europe and Asia, and has the habits of the major; but is of more rare occurrence.

Minute woodpecker.—Chesnut gray; whitish, waved with brown beneath; crown red; hind head black, spotted with white. Only three inches and a half long, the least of its tribe. Inhabits Cayonne.

Cardinal. Cardinal woodpecker.—Black; under part of the body white, spotted with black; crown and back part of the head red; wings spotted with white; legs and bill blackish. Inhabits the Isle of Luzon.

Characters. Bill subulate, somewhat depressed, obtuse, straight, covered at the base with bristles; nostrils small, oval; feet gressorial.

These mostly inhabit the warmer regions of America, and are nearly related to the family of fly-catchers; but are distinguished from them by having the middle and outer toe much connected, which, in the fly-catchers, are divided to the base.

Green tody.—Green; yellowish rosy beneath; breast chestnut; wings spotted with a red spot; legs and claws gray. The male, according to Buffon, has the upper part of the body of a pale blue, the belly white, the breast and sides rose colour. This pretty species, which is about the size of a wren, and four inches long, occurs not only in the warmer parts of the American continent, but also in St Domingo, Jamaica, and other islands of the West Indies. The females are not uncommon in Jamaica. It is supposed to feed on soft insects, and is of a shy solitary disposition, frequenting the lower parts of moist tracts of country, where it is observed to sit all of a heap, its head drawn in between its shoulders, and so stupid as almost to allow itself to be taken by the hand.

White-headed tody.—Black; subcrescented head and chin white; bill blackish; the lower mandible white, tippet with blackish; wings short; tail even. Less than the redstart. Inhabits America. Figured in Latham’s Synopsia.

Obscure tody.—Olive brown, yellowish-white beneath; crown, quill, and tail feathers blackish. Size of the hedge sparrow. Inhabits North America, where it feeds on insects. Frequent the decayed parts of trees, and has all the actions of the fly-catcher. It has an agreeable note, two or three times repeated, but not what can be called a song.

King tody.—Blackish brown, reddish beneath; crest chestnut, spotted with white at the tip; chin and eyelids white; bill dusky brown; breast with transverse blackish lines; legs flesh colour. This singular and beautiful species...
ORNITHOLOGY.

Species measures seven inches in length. Inhabits Cayenne, and is very rare.

Broad-billed tody.—Yellowish-brown, yellow beneath; chin and spot on the crown white; wings and tail brown; bill very large and broad. Size of the nightingale. Figured by Latham.

Crested tody.—Crest scarlet; body brown, spotted with white; wings covets spotted with white; feathers of the crest tipped with black. Native of Guinea.

Gen. 26. ACEDO, King’s-fisher.

Characters. Bill triangular, thick, straight, long, and acuminate; the tongue fleshy, very short, flat, and acute; feet, for the most part, gressorial.

The birds of this genus are dispersed over the whole globe; though it is supposed that only one species inhabits Europe. Most of them frequent rivers and the vicinity of waters, and live on fish, which they catch with singular art and dexterity. Sometimes they hover over the water, where a shoal of small fishes is seen playing near the surface; at other times, they wait with attention on some low branch, hanging over the water, for the approach of a single one, which is so unlucky as to swim that way. In either case they drop like a stone, or rather dart with rapidity on their prey. They seize the latter crossways in their bill, retire to a resting place to feed on it, devour it piecemeal, bones and all; and afterwards bring up the indigestible parts in pellets. The wings of most of this genus are very short; yet the birds fly rapidly, and with great strength. In their colours, blue of different shades predominates. Their nostrils are small, and generally covered.

Crested king’s-fisher.—Bill black; an inch and a half long; crown feathers long, forming a crest, of a greenish colour, and barred with black; a fine blue stripe on each side of the neck; upper part of the body bright blue; upper wing covets violet, and each feather tipped with a bright blue spot; legs and claws reddish; length nearly five inches. Inhabits Ambayona and the Philippines.

Splendid king’s-fisher.—Tail short; body yellowish-green; shoulders, throat, and rump yellow; wings and crown of the head blue; bill yellowish-brown colour; head with a bright yellow stripe on each side; smaller wing covets edged with yellow; legs reddish-brown. A beautiful species, which inhabits South America.

Common king’s-fisher.—Tail short; body blue above, orange-coloured beneath; lores red; bill black; crown and wing covets green, with blue spots; tail of a beautiful blue; irides red and black. In the female the bill is not so long as in the other sex. Frequently running streams and rivers, in the banks of which it generally takes possession of a rat’s hole to deposit its eggs. This hole is ascending, and generally two or three feet in the bank; at the end is scooped a hollow, at the bottom of which is a quantity of small fish bones, nearly half an inch thick, mixed with the earth, and which are probably the castings of the parent bird, as they are found even before they have eggs. On this disgorge matter the female lays to the number of seven eggs, which are perfectly white and transparent, and of a short oval form. Before the young are able to fly, the hole becomes extremely fetid by the fæces of the brood, which cannot be carried away by the parent birds, as is common with most of the smaller species. As the old birds have nothing in their bill, when they go in to feed their young, it has been inferred, that they eject from the stomach for that purpose. When the young are nearly full feathered, they are extremely voracious, and may be discovered by their constant chirping. This species is reckoned the most beautiful of all the British birds, weighs one ounce and a quarter, and measures seven inches in length. It inhabits Europe, Asia, and Africa. It was formerly believed, that if the body of this bird was suspended by a thread, some magnetic influence always turned its breast to the north. This, however, is as fabulous as the tradition, that its stuffed skin will preserve woolen cloth from the depredations of moths. There is a variety found in Senegal, about six inches and a half long, blue-green varied with brown above, tawny beneath, and chin yellowish.

Belted king’s-fisher.—Tail long, crested, bluish; Alceo, belly white; breast ferruginous; a white spot before and behind the eyes; bill black; chin white; breast with a ferruginous band on the fore part; thighs rusty; shanks very short; legs brown; outer toe connected with the middle toe. Eleven inches long. Inhabits Carolina, and feeds on lizards and fish. It is subject to several permanent varieties, which occur in different parts of America.

Amazonian king’s-fisher.—Glossy green; under parts Amazonus, of the body and lunule on the neck white; sides variegated with green; tail spotted with white; bill and legs black. Thirteen inches long. Inhabits Cayenne.

Respected king’s-fisher.—Tail long; body olive above; Tatra, white beneath; eye-brows white; collar greenish black. Bill black; lower mandible white. Legs black. Eight inches and a half long. Native of the Society islands, where it is held sacred by the inhabitants, as are the species denominated venter and sacra.

Great brown king’s-fisher.—Crested, olive above, Pascua, whitish and obscurely striated beneath; temples and hind head dirty white; tail rounded with rusty and steel-blue lines, and tip with white. The female has no crest. Eighteen inches long. Inhabits New Guinea.

Crab-eating king’s-fisher.—Tail long; body blue-green, Camara, yellowish-tawney beneath; band through the eyes; wings ovate, covets and tips of the quill feathers black. Twelve inches long. Inhabits New Guinea, and feeds on crabs.

Egyptian king’s-fisher.—Brown, with rusty spots; Egypt, whitish, with cinereous spots beneath. Size of the Rossen crow. Inhabits Lower Egypt, about Cairo; builds in sycamore and date trees, and feeds on frogs, insects, and small fish, which last it meets with in the fields when they are flooded. Its cry approaches to that of the common crow.

Gen. 27. GALBULA, Jacamar.

Bill straight, very long, quadrangular, pointed; nostrils Characters. Oval, at the base of the bill; tongue short, sharpened; thighs downy on the fore part; feet scissorial.

This is much allied to the preceding; but the toes are differently placed, namely, two before and two behind. The food of the jacamar is likewise different, as it feeds on insects alone; and, for that purpose, frequents moist woods.

Galbula.
ORNITHOLOGY

Great jacamar.—Copper gold above, ferruginous beneath; head and limbs green gold; tail wedged, and longer than the body. Size of the green woodpecker. Native country unknown.

Paradise jacamar.—Two middle tail feathers very long; body golden green; throat and wings white beneath; bill and legs black; head violet brown; tail much wedged. Inhabits Cayenne and Surinam; is 11 inches and a half long; flies in pairs; is less solitary than its congener, and feeds on insects.

Common bee-eater.—Back ferruginous; belly and tail bluish-green; two of the tail feathers longer than the others; chin pale yellow; bill black; irides red; front blue green; crown, hind head, and neck, bay; a black streak from the bill to the hind head; tail wedged, the feathers edged inwardly with cinereous; legs brownish; claws reddish black. A variety sometimes occurs with the bill convex and uncariated, and the toes unconnected at the last joint. The common bee-eater measures 10 inches from bill to tail. It inhabits various parts of Europe, Asia, and Africa; and is very plentiful in the southern parts of Russia, particularly about the rivers Don and Wolga. In the third volume of the Linnæan Transactions an account is given of one of this species having been shot, for the first time, in Britain, near Mattishall, in Norfolk, in July 1794. A flight of about 20 was seen in June; and the same flight, as was supposed, much diminished in number, was observed passing over the same spot in October following. They feed, on the wing, upon bees, gnats, flies, and other insects; or, in defect of these, upon seeds. Their nest is composed of moss, and the eggs, from five to seven, are perfectly white, and about the size of those of a starling. They are gregarious and migratory, quitting the colder latitudes, in great flocks, in autumn. When the sun shines on them, in their flight, they are a pleasing object, as they appear gilded. Kolben remarks, that they guide the Hottentots to the honey, which the bees lay up in the crevices of the rocks. Legs brown. There are several varieties. Eight inches and a half long. Inhabits India.

Superb bee-eater.—Red; front, throat, and rump, blue; two middle tail feathers longer than the others. Nine inches long.

Wattled or New Holland bee-eater.—Brown; belly yellow; wattles carunculated; tail wedged, tip with white; bill black; nostrils pervious, and half covered with a membrane; crown blackish; a silvery stripe at the angle of the mouth; a long, orange, pendent caruncle behind the base of the lower mandible; legs brownish, the outer toe connected at the base to the middle one. Fourteen inches and a half long. Inhabits New Holland; is pretty numerous on the shores of that country; chatters incessantly; is very bold; feeds on insects, and sucks the honey from the different sorts of Banksia.

Horned or knob-fronted bee-eater.—Brown; head somewhat naked; under parts of the body and tips of the tail feathers whitish; a blunt short Eminence, like the rudiment of a horn, on the fore head. Size of a missel thrush. This singular species also inhabits New Holland, and is well figured in White's Journal.

Red-winged bee-eater.—Under part of the body of an olive or dirty-white colour; throat yellow; wings and tail red, tip with black; bill one inch long, black; legs black. Six inches long. Inhabits Senegal.

Gen. 29. Urupa, Hoop, or Hoopoe.

Bill arched, long, slender, convex, a little compressed, somewhat obtuse; nostrils small, at the base of the bill; tongue obtuse, entire, triangular, very short; feet gregarious.

Of the species included under this genus, the first only is found in Britain. They feed on insects, haunt dunghills, and are, in general, uncleanly in their manners.

Common hoop.—Variegated with blackish and rufous white, beneath; crest pale orange, tip with black; tail black, with a white band; bill and legs black; irides hazel; back and wings with black and white lines; neck reddish-brown; crest of a double row of feathers; tail feathers 10. The weight of this beautiful bird is about three ounces, and the length 12 inches. Inhabits Europe, Asia, and Africa; but only visits this country, occasionally, in autumn, and is very seldom known to breed with us. The female is said to have two or three broods in the year. Seldom makes a nest; but lays her eggs, which are generally four or five, bluish-white, and marked with pale brown spots, in the hollow of a tree, and sometimes in a hole of a wall, or even on the ground. Its food consists chiefly of insects of the beetle tribe. It is a solitary bird, two of them being seldom seen together. In Egypt, where they abound, they are seen only in small flocks. Its crest usually falls behind on its neck, except when it is surprised or irritated, and then it stands erect; the tail, too, being, in that case, usually erected, and spread like a fan.

Grand hoop, or grand promouropa.—Black; head, neck, back, breast, glossy green; scapular and lateral tail feathers faded; tail very long. The greatest extraordinary and beautiful bird (observes Dr Latham), is near four feet in length, from the top of the bill to the end of the tail; the body is the size only of a middling pigeon, though much elongated in shape. The bill is three inches long, pretty much curved, and black; the head, hind part of the neck, and upper part of the belly, are of a shining green; the fore part of the neck, and lower part of the belly, without gloss; the scapular feathers are of a singular construction; the webs on one side of the shaft being exceeding short, and on the other of a great length; the shape of them failform: they
they are of a purplish black colour, with the ends, for
three quarters of an inch, of a most brilliant gilded glossy
green, though some of them, in a different light, re-
fect a blue gloss; beneath each wing arises a thick tuft of
feathers, eight inches and a half in length, and of a
texture resembling the herring-bone ones in the great-
er bird of Paradise; and, besides these, on each side of
the tail are five or six falceform feathers, with unequal
webs, as the scapulars, though not half so much curved;
the colour half dusky, half greenish brown; the last di-
vided from the other colour, on each feather, in an ob-
lique manner; the tail consists of 12 feathers, and is of
an enormous length, the middle ones measuring no less
than 28 inches; but each of the others shortens as it
proceeds outwards, to the outer one of all, which is on-
ly five inches in length; the colour of all of them is
blue black, with a polished steel gloss in some lights;
the legs are black." Dr Latham has annexed a colour-
drawn figure. Little else is known of this remarkable spe-
cies, except that it inhabits New Guinea.

Red-billed hoop.—Black green; belly black; tail
wedge; six first quill and lateral tail feathers spotted with
bill and legs red; feathers of the head and neck silky, and somewhat downy. Fifteen inches long. Inhabits Asia and Africa. Figured by Latham.

Character. Bill arched, slender, somewhat triangular, pointed;
tongue various, though generally pointed; feet form-
ed for walking.

The birds of this genus are spread over the globe.
They live chiefly on insects; their nostrils are small;
their tail is composed of 12 feathers; their feet are large,
with a large back toe; their claws are long and hooked.
Most of them have an acute tongue; though in some it
is flattened at the point, in others ciliated, in a few tu-
bular. There are a considerable number of species, of
which only one is a native of Britain.

Familiaris.

Common creeper.—Gray; white beneath; quill fea-
thers brown, ten of them with a white spot; head and
neck brown, with black streaks; rump tawney; wing
coverts varied brown and black; quill feathers dusky,
tipped with white, edged and barred with tawney; breast
and belly silvery; tail long, tawney, the feathers sloping
off to a point. Weighs about two drams; length five
inches. Inhabits Europe, Asia, and America. Runs
with great facility on all sides of small branches of trees,
in search of insects and their eggs, which constitute its
food. Except the crested wren, it is the smallest of
British birds; and though pretty common, is not seen
without difficulty, from the ease with which on the ap-
pearance of any one, it escapes to the opposite side of
the tree. Its nest is composed of dry grass and the in-
nner bark of wood, loosely put together, and lined with
small feathers; and it is usually constructed in some
hole, or behind the bark of a decayed tree. The eggs
are from six to eight, white, and minutely speckled with
bright rust colour. During incubation, the female is
fed by the other sex. The note of the common creeper
is weak, monotonous, and deliberately uttered, but rare-
ly heard in winter.—In North America, is found a va-
rity of a considerably larger size.

Hook-billed red creeper.—Scarlet; wings and tail
black; bill longer than the head, bent like a scimitar,
Vol. XV. Part II.
ORNITHOLOGY.

Topaz humming bird.—Red; middle tail feathers very long; head brown; chin gold-green; rump green; bill, head, and neck black; breast rosy; back and wing coverts orange red; quill and middle tail feathers purplish green; the rest orange. Female almost entirely green. Six inches long. Inhabits Surinam.

Mango humming bird.—Glossy green; tail nearly equal, and ferruginous; belly black, bill and legs black; a blue line dividing the colors of the back and belly; vent white; two middle tail feathers black. Four inches long. Inhabit Mexico, Brazil, and St Domingo. According to Albinus, it is also found in Jamaica, building its nest of cotton in the physic-nut-tree, and laying two white eggs as big as peas. There are several varieties. Under this species, Dr Latham relates the following interesting particulars.

"We have before related a circumstance of the possibility of keeping humming birds alive for some time, by means of sugar and water; but this was in their own country and climate. In addition to this, we have been informed, on undoubted veracity, of the following fact: A young gentleman, a few days before he set sail from Jamaica to England, was fortunate enough to meet with a female humming bird, sitting on the nest and eggs; when, cutting off the twig, he brought all together on board the ship; the female became sufficiently tame, so as to suffer itself to be fed with honey, and during the passage hatched two young ones; however, the mother did not survive long, but the young were brought to England, and continued alive for some time in the possession of Lady Hammond. Sir H. Englefield, Baronet, and Colonel Sloane, both witnesses of the circumstance, informed me that these little creatures readily took honey from the lips of Lady Hammond, with their bills: one of them did not live long, but the other survived at least two months from the time of its arrival."

B. Bill straight.

Red-throated humming bird.—Green gold; tail feathers black, the three lateral ones ferruginous, tip with white; chin flame colour; bill black; chin scarlet, with a beautiful gold gloss. The female brown above, white beneath; tail subequal; wings are red, and white. Three inches and one-fourth long. Inhabit America, as far north as Canada. This beautiful little creature flies so swiftly, that the eye is incapable of pursuing it, and the motion of its wings is so rapid as to be imperceptible to the nicest observer. It never feeds on the wing, suspended over the flower from which it extracts its nourishment. Like the bee, having exhausted the honeyed juice of one flower, it wanders to the next, in search of new sweets. It is most partial to those flowers which have the deepest nectaries: and, in the countries which these birds inhabit, whoever sets plants of this description before his window, may depend on being visited by multitudes of them. It is very entertaining to see them swarming around the flowers, and trying every tube by thrusting in their bills. If they find that their companions have anticipated them, and rubbed the flower of its honey, they will frequently, in a fit of rage, pluck it off, and throw it on the ground, or even tear it in pieces. Numbers will sometimes contend very fiercely for the possession of the same flower. During the conflict, they frequently pursue the fugitives into the apartments of these houses whose windows are
ORNITHOLOGY.

Order III. Anseres.

Bill somewhat obtuse, covered with a skin, gibbous at the base; mouth toothed; tongue fleshy; feet palmated, and formed for swimming.

Most of the birds belonging to this order dwell much in the water. Their feet and legs are short, concealed under the feathers, and placed more behind than in other birds. Their toes are short, and generally compressed, so that they easily cleave the water, and by means of their membranes or webs, form, as it were, broad oars. Their plumage is thicker, closer, and better furnished with down than that of other birds. The gland which all birds have at the rump, and from which they express an oily matter to preserve their feathers moist, is most considerable in the anseres, which strive to make their plumage impermeable to water. They feed on fish, aquatic animals, and plants. In general they are polygamous, and make their nests among reeds, or in moist places. They are soon able to seek their own food; yet the mother leads and protects them for some time, and the male frequently kills them. For the most part they lay many eggs; and the flesh of many is eatable, though it frequently savours of oil, or of fish.

Gen. 32. Anas.

This is a very numerous genus, and includes swans, geese, and ducks.

A. Bill gibbous at the base.

Wild swan, hooper, elk, whistling swan, &c.

Semicylindrical, and black; cere yellow; body white; eyelids naked, yellow; legs black; ribs eleven. This is obviously a distinct species from the common or mute swan, being of a smaller size, and having the windpipe differently constructed. It weighs from fifteen to twenty-five pounds, and measures nearly five feet in length. It inhabits Europe, Asia, and America, affecting chiefly the northern regions of the globe, and seldom appearing in England, except in hard winters. On the approach of spring, they quit their southern stations, and again retire northward to breed. A few indeed drop short, and perform that office by the way, halting in some of the Hebrides, Orkneys, Shetland, or some solitary island. But the great bodies of this species occur on the large rivers and lakes near Hudson's bay, and those of Kamtschatka, Lapland, and Iceland. They are said to return to the latter place in flocks of about a hundred at a time, in spring; and also to pour in on that island from the north, in nearly the same manner, on their way southward, toward the close of autumn, flying very high in the air, and in such a compact body, that the bill of one touches the tail of another. The young, which are
ORNITHOLOGY.

Anseres. are bred there, remain throughout the first year; and in August, when they lose their feathers, and are unable to fly, the natives kill them with clubs, shoot, and hunt them down with dogs, by which they are easily caught. The flesh is highly esteemed, as are the eggs, which are gathered in the spring. The Icelanders, Kantschatkades, and other inhabitants of the north, covering their skins with the down on them, sew them together, and convert them into various sorts of garments. The northern American Indians have recourse to the same expedient for clothing themselves, and sometimes weave the down as barbers do the caws for wigs, and then manufacture it into ornamental dresses for the women of rank, while the larger feathers are formed into caps and plumes, to decorate the heads of their chieftains and warriors. They likewise gather the feathers and down in large quantities, and barter or sell them to the inhabitants of more civilized nations. Notwithstanding the fabulous accounts and poetical descriptions of the song of the dying swan, its voice is shrill, harsh, and piercing, not unlike the sound of a clarionet, when blown by a novice in music. It is asserted, however, by those who have heard the united and varied voices of a numerous assemblage of them, that they produce a more harmonious effect, particularly when softened by the murmur of the waters. At the setting of a frosty weather, wild swans are said to associate in prodigious multitudes, and, thus united, to use every effort to prevent the water from freezing; which they are enabled to accomplish for a considerable length of time, by constantly stirring and dashing it with their extended wings. The wild swan has been styled "the peaceful monarch of the lake," because, conscious of his superior strength, he fears no enemy, nor suffers any bird, however powerful, to molest him, at the same time that he preys on the feathers of the feathered tribe. His vigorous wing shields him against the attacks even of the eagle, and his blows from it are so powerful, as to stun or kill the fiercest of his foes. His food consists of the grasses and weeds, and the seeds and roots of plants which grow on the margins of the water, and of the myriads of insects which skim over or float on its surface; occasionally, too, of the slimy inhabitants within its bosom. The female makes her nest of the withered leaves and stalks of reeds and rushes, and commonly lays six or seven thick shelled, white eggs. The incubation is said to last six weeks. Both male and female are very attentive to their young, and will suffer no enemy to approach them.

Tund swan.—Bill semicylindrical, black; cere black; body white. The plumage of this species is of the same snowy whiteness as that of the preceding, and the bird is covered next the body with the same kind of fine soft down; but it is of a larger size, and is furnished with a projecting, callous, black tubercle, or knob, at the base of the upper mandible. But the most remarkable distinction consists in the conformation of the windpipe, which, in the present species, enters at once into the lungs, so that the utmost noise the bird can utter, is a mere hiss: whereas, in the wild species, the windpipe first enters the chest a little way, is then reflected in the form of a trumpet; after which it enters a second time, when, dividing into two branches, it goes on to join the lungs. The manners and habits of both species in the wild state are very similar. The beauty, graceful motion, and majesty of this bird, when it is wafted along a piece of water, attract the admiration of every beholder: but, out of the liquid element, the elegance of its form in a great measure disappears. While the male and female are employed with the cares of the young brood, it is not safe to approach them; for they will fly on a stranger, and sometimes beat him to the ground by repeated blows. Notwithstanding, however, their great strength of wing, a slight blow on the head will compass their destruction. Multitudes of this species are found in Russia and Siberia, as well as farther southward, in a wild state. They occur, without an owner, on the Trent, on the inlet of the sea near Abbebourne in Dorsetshire, and on some other rivers and lakes, in different parts of the British isles. Those on the Thames have, for ages, been protected as royal property; and it is still reckoned felony to steal their eggs. In former times great numbers were reared for the table: but they are now reckoned by most a coarse kind of food. A fattened cygnet, however, is still accounted a great delicacy, and usually fetches upwards of a guinea in the poultry market. It is generally believed that the swan lives to a great age, though the term of three centuries, assigned to it by some authors, is certainly much exaggerated. The female nestles among the rough herbage near the water's edge, lays six to eight large white eggs, and sits on them about as many weeks before they are hatched. The young do not acquire their full plumage till the second year. If kept out of the water, and confined to a court-yard, the swan soon becomes dirty, dull, and spiritless. Its usual food consists of fish and water plants.

Black swan.—Black; wings edged with white; bill red; upper mandible blackish at the tip, a yellow spot near the lip; legs black; feet paler. Extent of wing four feet eight inches. Inhabits various parts of New Holland; but little is known respecting its manners.

Snow goose.—Body snow-white; front yellowish; ten highest first quill feathers black; bill and legs red. Size of a red goose; length two feet eight inches; extent of wing three feet and a half; weight between five and six pounds. Great numbers of this species occur about Hudson's bay; visit Severn river in May, and stay a fortnight, but go farther north to breed. They return to Severn Fort about the beginning of September, and stay till the middle of October, when they depart for the south, and are observed in immense flocks attended by their young. At this time many snowgeese are killed by the inhabitants, who pluck and eviscerate them, and put them into holes in the earth, where they are preserved quite sweet by frost, throughout the severe season. These birds seem also to occupy the west side of America and Kantschatka. In the summer months they are plentiful on the arctic coast of Siberia; but never migrate beyond 130° of longitude. They are supposed to pass the winter in more moderate climes, as they have been seen flying over Silesia; probably on their passage to some other country, as it does not appear that they continue there. Those of America, in like manner, winter in Carolina. The Siberians decoy them by a person covered with a white skin, and crawling on all fours, whom they are stupid enough to mistake for their leader, and whom they follow, when driven by men in their rear, till he entangles them in nets, or leads them into a sort of pond prepared for the purpose.

Antarctic goose.—Snowy; bill black; legs yellow. The
ORNITHOLOGY.

The female has the tail flesh-coloured, and the body brown, with transverse white lines. From twenty-four to twenty-six inches long. Inhabits Falkland islands.

_Bustard goose._—White; two middle tail feathers, primary quill feathers, and greater wing coverts, black; nape, and upper part of the back, with numerous black lines; wings with a blunt spine at the flexure, and a dusky green spot; greater wing coverts tipped with white; secondary quill feathers half black, half white; legs black. This is the _sea-goose_ of Gray, and the white-winged antarctic goose of Brown. It measures from thirty-two to forty inches in length, stands pretty high on its legs, walks and flies with great ease, and has not that disagreeable cackling cry peculiar to the rest of its kind. It generally lays six eggs; and its flesh is reckoned wholesome, nourishing, and palatable. Inhabits the Falkland islands.

_Loggerhead goose, or racehorse duck._—Cinereous; dusky beneath; vent white; wings and tail short and black; bill, irides, and tubercle on the wings and legs, yellow. Length thirty-two inches; weighs from twenty to thirty pounds. Observed on Falkland islands, Staats Land, &c.; mostly in pairs, though sometimes in large flocks. From the shortness of their wings, they were unable to fly, but used them in the water as oars, and swam so rapidly, that it was very difficult to shoot them when on that element. In order to catch them, the sailors would surround a flock with boats and drive them on shore, where, unable to raise themselves from the ground, they ran very fast; but soon growing tired, and squatting down to rest, were easily overtaken and knocked on the head. Their flesh, however, was not much relished, being rank and fishy.

_Sheldrake, or burrow duck._—Bill turning up at the point; forehead compressed; head greenish black; body white and variegated; bill and legs red; head and neck violet; collar white; back white; breast brown; belly white, with a black line; first quill feathers black; the next violet, inner ones ferruginous, the last white; tail white, tipped with black. The female has less vivid colours. This elegant species of duck weighs about two pounds and a half, and measures about two feet three inches. It inhabits Europe and Asia, and is not uncommon in many parts of our coasts, remaining all the year. The female makes choice of a rabbit burrow, wherein to deposit her eggs, which are numerous, amounting sometimes to sixteen, and which she covers with down from her own body. The nest is generally near the water, whither the female leads her young soon after they are hatched. This species is rarely met with remote from salt water; out if the eggs are taken and hatched under a hen, the young become tame, and may be kept in ponds. They very seldom breed when in a state of confinement. Their principal food consists of sea-weeds, small shell-fish, and marine insects. The flesh is rancid.

_Velvet duck._—Blackish; lower eyelid and spot on the wings, white; bill yellow, black in the middle, gibbous at the base; legs red. Female without the gibbosity on the bill, and body blackish. From 20 to 22 inches long. Inhabits Europe and South America. It is sometimes, though not often, seen on our coasts in winter. Frequent Hudson's bay, where it breeds in summer; and is not uncommon in Russia and Siberia. Lives on foci and shell-fish. The female makes its nest of grass, and lays from four to ten white eggs. The catching of this species is a favourite diversion of the Tungusi, who dwell on the river Ochota, and who chase great numbers of these birds, during the moulting season, into shallow water, and then knock them down with clubs. They take many of them alive, and, thrusting a needle through their eyes, carry fifty or more on a string. It is alleged that the birds, thus treated, will live for two or even thirty days.

_Scooter, or black diver._—Body quite black; bill gib. Nigrum at the base; head and neck sprinkled with purple; tail somewhat wedged. Female of a browner hue, and without the protuberance at the base of the bill. Length 22 inches; feeds on grass and shell-fish, and tastes rancid. These birds inhabit Europe and North America, and mostly reside at sea, distant from the shore. With us they are seen only in the winter season, when they are plentiful on some parts of the coast of France. They are great divers, and abound in most of the northern regions of the world. They want the horny nail at the end of the bill, which is common to the rest of the genus. As they taste strongly of fish, they are allowed by the Roman church to be eaten in Lent.

_White fronted or laughing goose._—Brown; white, Albifrons, spotted with black beneath; front and rump white; bill and legs flame colour. Breast cinereous; tail dusky, edged with white. Two feet four inches long. Inhabits Europe, Asia, and America. And visits the feney parts of England, in small flocks in winter. During severe weather it is killed on the coast as well as on rivers, and not uncommonly brought to market and sold for the common wild goose. It leaves us in the earliest spring, none being seen after the middle of March.

B. Bill equal at the base.

_Scapg duck._—Black; shoulders waved with ash co-Melted; belly and spot on the wings white; bill broad, bluish ash; irides yellow; head and neck greenish black; back and wing coverts waved with black, and cinereous; legs and primary quill-feathers dusky; secondary white, tip with black; tail coverts, and vent, black. Female brown; bill black, surrounded with a circle of white feathers; neck rusty; belly, and bar on the wings, white; legs black. From 18 to 20 inches long; feeds on shell-fish, and inhabits Europe, northern Asia, and America. It is found in Iceland, Lapland, Sweden, Norway, Russia, and Siberia, and as high as Hudson's bay in America. In England, it appears in the winter season, in small flocks, and is frequently observed in fresh waters. In October it begins to emigrate southward in flocks. It also frequently lives in holes under ground.

_Grey leg goose, or wild goose._—Bill semicylindrical; Amer. body cinereous above, paler beneath; neck striated; bill flesh-coloured and tip with white; rump and vent white; legs flesh-coloured; claws black, wants the wing spot. Weighs eight or nine pounds, and is about 33 inches long. Varies much in colour by domestication, in which state it is our common tame goose. Inhabits in flocks the northern parts of Europe, Asia, and America; resides the whole year in the Lincolnshire fens, where it breeds, laying eight or nine eggs which are hatched in 28 or 30 days. Frequent lakes and rivers, and lives to a great age. The domestic goose is well known. It is bred in great multitudes in the fens of Lincolnshire, both on account of its flesh and feathers. The geese are there attended by a person called
ORNITHOLOGY.

Anseres. a gossward, who drives them to feed and water. They are plucked five times a year, once for quills and feathers, and four times for feathers only. If the season prove cold, many of them die by this cruel operation. Tame geese have been known to live for 80 years. They generally retain the white rump and vent feathers of their original stock. They feed on water insects, worms, and plants; and by means of two rows of strong sharp teeth within their bills, they crop the herbage in meadows, and do much injury to young corn.

Buiicollas. Red-breasted goose.—Black; white beneath; bill small, conical; neck rufous; spot between the bill and eyes white. Length 21 inches; weight about three pounds. Inhabits Russia and the northern parts of Siberia, but is very rarely found in England. In winter it migrates towards Persia. It is a beautiful species, and its flesh is in high request.

Scelligm. Bean goose.—Cinereous; dirty white beneath; bill compressed at the base; tail-coverts white; legs saffron; bill reddish in the middle, black at the base and tip; head and neck inclined to ferruginous; quill-feathers edged with black; tail with white; claws white. Measures from two feet and a half to three feet in length, and weighs from five to seven pounds. Inhabits Hudson’s bay and the Hebrides, particularly the isle of Lewis, where it remains all summer and breeds. These birds migrate to England in autumn, and leave it again in May, lighting, on their passage, on corn fields, and feeding on the green wheat. In their migration they fly at a great height, sometimes in a straight line, and sometimes in the form of a wedge, cackling as they advance. This species is often killed, and sold for the common wild goose, with which it has been long confounded.

Bencalis. Garlond duck.—Bill narrow; head green; breast and belly white. Inhabits the len of Iceland, but is very rare.

Erythr. Ash-coloured; front white; body waved with black and white above; neck black; belly white; bill short, black, with a flesh-coloured spot on each side, a black spot between the bill and eye; tail white beneath; legs blackish. Twenty-five inches long. Inhabits the north of Europe and Hudson’s bay, and appears in large flocks on the north-west coasts of Britain during winter. They are then very wild and shy; but, on being taken, become quite familiar in a few days. In February they quit our shores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed. In the darker ages this species was seriously believed to be produced from the lepas anatifera, a shell which is often found adhering by a pedicle to logs of wood that have lain long in the sea, from which circumstance it obtained the name of tree-goose and elakis.

Barnacle. Brent or brand goose.—Brown; head, neck, and breast, black; collar white; bill, wings, tail and legs, black; broad spot on each side of the neck; tail-coverts and vent white; belly and shoulders cinereous; flanks streaked with white; considerably smaller than the preceding. Inhabits Europe, Asia, and North America. These birds appear on our coasts, particularly in the west of England, during winter, and in Shetland are called herra geese. But they are most plentiful in Ireland, where they are taken in nets placed across the rivers, especially in those which empty themselves into the northern parts of the Irish channel. Sometimes they appear in vast flocks on the coast of Picardy, destroying all the corn near the sea. They migrate northward in summer, and return south in autumn, flying high in wedge-shaped flocks. They feed on polygonum viviparum, emetrum migrum, and other plants, but chiefly on aquatic plants and marine vermes. They are easily tamed, and reckoned good for the table.

Eider, elder, or Cathubt duck.—Bill cylindrical; cere wrinkled, and bifid on the hind part; bills, legs, front, ocular band, breast, lower part of the back and belly black; middle of the head, upper part of the back, shoulders, and wing coverts white; a green blotch beneath the hind head. The female almost wholly ob- scurely ferruginous, with black lines; tail and primary quill-feathers dusky. The young are not mature in plumage till the third, or perhaps the fourth year. This species is nearly double the size of the common duck, and about 22 inches long. It inhabits the high latitudes of Europe, Asia, and America, and feeds chiefly on testaceous animals. It is rarely, if ever, seen in the south of England, but breeds in the north of Scotland, particularly on the Western isles, as also on the Fara islands, on the coast of Northumberland, in June and July. The nest is made on the ground, composed of marine plants, and lined with down of exquisite fineness, which the female plucks from her own body. The eggs are usually five, and of a greenish colour. In Iceland the elder ducks generally build their nests on small islands not far from the shore, and sometimes even near the dwellings of the natives, who treat them with so much attention and kindness as to render them nearly tame. Two females will sometimes lay their eggs in the same nest, in which case they always agree remarkably well. As long as the female is sitting, the male continues on watch near the shore, but as soon as the young are hatched, he leaves them. The mother, however, remains with them a considerable time afterwards; and it is curious to observe her attention in leading them out of the nest almost as soon as they creep from the eggs. Having conducted them to the water’s edge, she takes them on her back and swims a few yards with them, when she dives, and leaves them on the surface to take care of themselves. They are seldom afterwards seen on land. When the natives come to the nest, they carefully remove the female, and take away the superfluous down and eggs. They then replace the mother, and she begins to lay afresh, covering the eggs with new down; and when she can afford no more, the male comes to her assistance, and covers the eggs with his down, which is white. When the young ones leave the nest, which is about an hour after they are hatched, it is once more plundered. The best down, and most eggs, are got during the first three weeks of their laying; and it has generally been observed that they lay the greatest number of eggs in rainy weather. One female, during the time of laying, usually yields half a pound of down, which, however, is reduced one half after it is cleaned. When pure, it is sold in Lapland at the rate of two dollars a pound. It is extremely soft and warm, and so light and elastic, that a couple of handfuls, squeezed together, are sufficient to fill a covering like a feather bed, which is used in those cold countries instead of a common quilt or blanket. The Iceland company at Copenhagen, generally export every year...
ORNITHOLOGY.

American year from 1500 to 2000 pounds weight of down, cleaned and uncleaned, exclusive of what is privately exported by foreigners. The Greenlanders kill these birds with darts, pursuing them in their little boats, watching their course by the air-bubbles when they dive, and always striking at them when they rise near to the surface. Their flesh is valued as food, and their skins are made into warm and comfortable under garments.

Muscovy-duck.—Face naked, with red caruncles; legs and ovaries naked, and with the bill red; tip of the bill and space round the nostrils black; crown black; temple, chin, and throat white, varied with black; breast and lower part of the belly brown, mixed with white; back and rump brown, with a green gloss; upper part of the belly white; three first quill feathers white, the rest brown; tail feathers twenty, the outer white, the rest green. Two feet long: native of Brazil, and is domesticated in Europe. Has its name, not as vulgarly alleged, from the country of Muscovy, but from the circumstances of its smelling of musk, which arises from the liquor secreted in the gland of the rump. Like other domesticated fowls they are subject to great varieties. They are a thriving and prolific species, and not only associate, but sometimes breed with the common duck. Their flesh is much esteemed. Mr. Pennant says they are met with wild about Lake Baikal in Asia; by, that they are natives of Louisiana; Marcgrave, that they reside in Brazil; and Buffon, that they occur in the overflowed savannahs of Guiana, where they feed in the day time on the wild rice, and return in the evening to the sea. He adds, that they nestle on the trunks of rotten trees, and that after the young are hatched, the mother takes them one after another, by the bill, and throws them into the water. Great numbers of the young brood are said to be destroyed by the alligators.

Clapper-duck./Extremity of the bill dilated, rounded, with an incurved nail; bill black; irides yellow; head and neck violet green; breast white, and lunulated; back, wings, and wedged tail brown; belly-chestnut; vent white; first and second wing covers pale blue, greater brown, tift with white, the rest edged with white; legs tawney. The female has a considerable resemblance to the common duck, but both sexes are very apt to vary in their colouring. This species inhabits Europe, Asia, and North America, but is by no means common in Britain. A few remain in France during the breeding season, making a nest of rushes, in which they lay 10 or 12 rufous-coloured eggs.

Red-breasted Shoveler.—Brown; chin and breast chestnut; wings tipt with gray, wing-spot purple, edged with white; tail short, white; bill broad, brownish yellow; head large; eyes small; irides yellow; legs small, slender and bay. Size of a tame duck. Sometimes found in the fens of Lincolnshire, but is rare, and little known.

Ural duck.—Waved with cinereous and yellowish, and spotted with brown; brown, speckled with gray beneath; throat brown-yellow, waved with black; tail long, black, wedged. Rather bigger than the common teal. Is not infrequent in the greater lakes of the Ural mountains, and the rivers Oby and Irtsch. Is not seen on the ground, being, from the situation of its legs, unable to walk; but it swims well and quickly, with the tail immersed in the water as far as the rump, and serves as a rudder, contrary to the common method of a duck's swimming. The nest is formed of reeds.

Godwits, or gray.—Wing-spot rufous, black, and white; bill flat, black; legs tawny; rump black; back brown, waved with paler; breast and belly gray, varied with white. Nineteen inches long. Inhabits Europe and Northern Asia. Visits Britain in winter, but not in great numbers. Supposed to breed in Sweden, and probably in Russia and Siberia. It is said to be a great diver, and to feed chiefly by night, concealing itself among the reeds and rushes during the day. It makes a noise not unlike that of the mallard, but louder. Its flesh is savoury.

Golden eye.—Black and white; head turned; violet; a large white spot at each corner of the mouth; bill black; irides golden; lower part of the neck, breast, and belly; white; back and rump black; legs red. The markings of the female are, head red brown; neck gray; breast and belly white; wing coverts varied with dusky and cinereous; middle quill feathers white; the rest and tail black; legs dusky. About 19 inches in length. Inhabits Europe, Asia, and North America.

Birds of this species do not assemble in large flocks, nor are they numerous on the British shores or on the lakes in the interior. They are late in taking their departure northward in the spring, and in their flight they make the air whistle with the vigorous quick strokes of their wings. They are excellent divers, and seldom set foot on shore; on which, it is said, they walk with great apparent difficulty, and, except in the breeding season, only repair to it for the purpose of taking their reposum. They build in the hollows of trees, and prey on shell-fish, mice, fish, and frogs.

The anas glacian, or mossion, seems to be only a variety of the golden eye in one stage of its plumage, before it arrives at maturity.

Bimaculated or clucking duck.—Subcrest; brown, waved with black; head green; a ferruginous spot before and behind the eyes; breast with black spots; wing-spot green, edged with white. Length 20 inches; occurs along the Lena, and about Lake Baikal, and has been taken in a decoy in England. Has a singular note, somewhat like clucking.

Wigeon, whoever, or whin.—Tail pointed; vent feathers black; head bay; front white; back waved with black and white; bill plumbeous, with a black nail; head and upper part of the neck red, with blackish spots; breast claret; body above waved with cinereous and blackish; wing-spot blue green; black before and behind; wing-coverts varied brown and white; belly white; legs lead colour. Female waved with brown; breast paler. Twenty inches long. Inhabits Europe, Asia, and Africa. Visits England in autumn, when great numbers are taken in decoys, being esteemed an excellent food. It likewise frequents our rivers and salt-water inlets in small flocks. It is remarkable for uttering a whistling or piping noise, which is frequently heard as it flies during the night. It lives on frogs, worms, insects, and water plants, and is sometimes domesticated. There is a variety with a silvery wing-spot, and the throat waved with ash-colour.

Pin-tailed duck.—Tail pointed, long, black beneath; head with a white line on each side; back waved with cinereous; bill black, bluish at the sides; head ferruginous; throat white, a little spotted; body white beneath;
ORNITHOLOGY.

Anseres.

346

Ferrugineous duck.—Reddish-brown; bill dilated and rounded at the base; feet pale blue. Weight 20 ounces. Inhabits Denmark and Sweden, but very rarely occurs in this country.

Glacialis.

347

Long-tailed duck.—Tail pointed, long; body black, white beneath; bill black, orange in the middle; head on the fore part and sides reddish-gray; hind part, breast, and belly, white; scapulars long and white; sides of the neck with a black spot; lower part of the breast, back, wings, and tail, chocolate; four middle tail-feathers black, two middle ones longer, the rest white; legs dusky-red, or blackish. The female has the tail shorter and wedged; the body varied with blackish, rufous, and gray; the back black; collar and lower part of the belly white. Of the size of a wigeon. Inhabits Europe, Asia, and America, frequenting both the interior lakes and the sea shores of these quarters of the world. The birds of this species do not, in the winter, like many of the other tribes, entirely quit their northern haunts, but considerable numbers remain there, enduring the rigours of the season, and enjoying, in summer, the perpetual day of an unsetting sun. Numerous flocks, however, spread themselves southward in the winter, from Greenland and Hudson's Bay, as far as New York in America, and from Iceland and Spitzbergen over Lapland, the Russian dominions, Sweden, Norway, and the northern parts of the British isles in Europe. The flocks which visit the Orkney isles appear in October, and continue there till April. About sunset they are seen in large companies going to and returning from the bays, in which they frequently pass the night, making such a noise, as in frosty weather may be heard some miles. They are rather scarce in England, to which they resort only in very hard winters, and even then in small straggling parties. They fly swiftly, but seldom to a great distance, making a loud and singular cry. They are expert divers, and supposed to live chiefly on shell-fish. The female makes her nest among the grass near the water, and, like the eider duck, lines it with the fine down of her own body. According to Latham, she lays five eggs, which are of a bluish white colour, and about the size of those of a pullet.

Pochard, or red-headed wigeon.—Waved with ash-colour; head brown; pectoral band; vent and rump black; bill broad, blue, tip with black; irides tawney; head and neck bay; breast and upper part of the back black; scapulars and inner wing-coverts undulated with black and white; belly whitish, with dusky lines at the sides; legs plumbeous. Female darker; head pale reddish-brown; wing-coverts and belly cinereous. Nineteen inches long; weight 28 ounces. Inhabits Europe, Asia and America. This species is frequently caught in the decoys in England, though it is not known to breed there. In some counties it is called poket, plum-bird, or great-headed wigeon. It is of a plump round shape, walks with a waddling and ungraceful step, but flies rapidly, and in flocks of from 20 to 40, commonly in a compact body. It is much in request for the table, but is not easily domesticated. The male has a labyrinth, or enlargement of the trachea, near the junction with the lungs, a singular conformation peculiar to the male of several species of the duck tribe, but the use of which is still unknown. In winter the pochard migrates southward, as far, it is said, as Egypt.

Garganey.—Wing-spot green; a white line above the eyes; bill lead colour; crown dusky, with oblong dark streaks; cheeks and neck purple, with white streaks; breast light brown, with semicircular black bars; belly white, lower part and vent speckled; first quill-feathers cinereous, outer webs of the middle ones green; scapulars long, narrow, striped with white, ash colour and black; tail dusky; legs lead-colour. Female, with an obscure white mark over the eye; plumage brownish; wings without the green spot. Length 17 inches. Inhabits Europe and Asia. By some called pied wigeon, or summer teal. Frequent only the fresh waters, feeding on seeds and aquatic plants. Is not common in Britain, and is said to be impatient of cold.

Teal.—Wing-spot green; a white line above and beneath the eyes; bill black; irides hazel; head and neck bright bay; a broad green band behind the eyes to the nape, and terminating beneath in a white line; body whitish, with transverse blackish lines above; fore part of the neck and breast with round black spots; wing-spot green, edged beneath with white, obliterated black above; vent black in the middle. The female is distinguished by the head and neck varied with whitish and brown, and the vent totally white. There are two permanent varieties, of which the first is the wing-spot varying in colour; the body brownish above, rufous-white beneath, and black spots on the belly. The second has the cheek, chin, and under parts of the body white-rufous, and the wing-spot without black. Weight about 12 ounces; length 14 inches and a half. The smallest of the duck tribe, and in high request at the table. Inhabits Europe and Asia; visits us in winter, and frequents our fresh waters in small flocks. Many are caught in the decoys, and a few breed in Woburn Forest, in the morasses about Carlisle, &c. The female makes a large nest composed of soft dried grasses lined with feathers, and cunningly concealed in a hole among the roots of reeds and bulrushes, near the edge of the water. The eggs are of the size of those of a pigeon, from six to ten in number, and of a dull white colour marked with small brownish spots. The male has a bony labyrinth in the lower part of the windpipe.

Malard, or wild duck.—Cinereous; middle tail feathers (of the male) recurved; bill straight; collar white; bill greenish-yellow; head and neck glossy-green; scapulars white, with waved brown lines; back brown; vent black-green; breast chestnut; belly gray; wing-spot violet-green, edged above with a black and white line; two middle tail feathers dark-green, and recurved. Female reddish-brown, spotted with black. Very subject to vary, especially by domestication, when it is our common tame duck. About 23 inches long. Weight about two pounds and a half. Inhabits Europe, Asia, and America; is very common in marshy places in many
ORNITHOLOGY.

Gen. 33. MERGUS.

Bill toothed, slender, cylindrical, hooked at the point; character. nostrils small, oval, in the middle of the bill; feet four-toed, outer toe longest.

The birds of this genus live on fish, and are very destructive in ponds.

Crested merganser.—Crest globular, white on each side; body brown above, white beneath; bill and legs black; irides golden; crest larger than the head, edged with black. Female brown; crest less and ferruginous. Length seventeen inches and a half; weight nearly 23 ounces. An elegant species, which inhabits North America, appearing at Hudson’s bay about the end of May, and building, close to the lakes, a nest composed of grass, lined with feathers from its own breast.

Gosander.—A longitudinal crest, somewhat erect; Merganser. the breast white, without spots; the tail feathers as coloured; shaft black; bill, legs, and irides red; greater quill-feathers black; lesser white. Weight about four pounds; length two feet four inches. Inhabits Europe, Asia, and America. Sometimes visits our rivers and lakes in severe winters, but retires to the more northern latitudes to breed. It has been known to build on trees, but more frequently among rocks or stones, and lays 4 eggs, which, with the bird itself, are eagerly devoured by the weasel. It swims with only the head above the surface of the water; dives deep; remains a long time below, and rises at a considerable distance. Its flesh is rancid and scarcely edible. In quest of fish, it dives with great celerity, and holds its slippery prey with great security by means of its toothed bill, so admirably adapted to the purpose.

Dum diver, or sparkling fowl.—Crested; cinereous; Castor. head and upper parts of the neck bay; chin, middle quill feathers, and belly white; bill and irides red; belly-somethings flesh colour. Weighs about 38 ounces.
ORNITHOLOGY.

Acarea.

 Brennan.

 Serrator.

 Plate 6. Fig. 2.

 Alca.

 Gen. 34. Alca, Auk.

 Character. Bill toothless, short, compressed, convex, often transversely furrowed; lower mandible gibbous near the base; nostrils linear; legs (in most cases) three-toed.

 The birds of this genus are mostly inhabitants of the Arctic seas; are accounted stupid, breed in holes, which they themselves often dig, and in the caverns and fissures of rock, where they rest during the night. In respect of colour, they are generally uniform, being black above, and white beneath. They are shaped like a duck, with their feet placed behind the centre of gravity; their bills are large, having the surfaces crossed with furrows, and ending in an acute point. They lay but one egg, which is very large, considering the size of the bird.

 Puffin. Bill compressed, two-edged with two grooves; orbits and temples white; upper eyelid daggered or furnished with a pointed callus; body black; cheeks, breast, and belly white; bill red, with a black base; legs red. Weighs between 12 and 13 ounces; length upwards of 12 inches. Inhabits the northern seas of Europe, Asia, and America, in vast flocks. Appears on many parts of our rocky coast about the middle of April, and begins to breed about the middle of May.

 On the Dover cliffs, and other such places, they deposit their single egg in the holes and crevices: in other places they burrow like rabbits, if the soil is light, but more frequently take possession of rabbit burrows, and lay their egg some feet under ground. On St Margaret’s island, off St David’s, the fishermen put their hands into the holes, and the puffins seize them so ostentatiously, that they allow themselves to be drawn out. In other places they are caught with ferrets, and the young are taken and pickled. About the latter end of August they retire from our coasts, and have all migrated by the beginning of September. Their principal food is small fish, particularly sprats, with which they feed their young.

 Great auk, or penguin. Bill compressed, edged; oval spot on each side before the eyes. Bill black, with eight or ten grooves; wings short and imperfect; secondary quill feathers tipt with white; legs black. Three feet long. Inhabits Europe and America; occurs in the most northern parts of Britain, and breeds in the isle of St Kilda, appearing about the beginning of May, and retiring about the middle of June. The shortness of its wings renders them useless for flight, but of singular service in diving under water, where they act as fins, and thus enable it to pursue its prey with great velocity. It lays an egg six inches long, white and marked with purple spots, close to the sea mark, being incapable of flying, and almost of walking.

 Razorbill. Bill with four grooves, and a white line on each side as far as the eyes. Bill black; the largest groove white; body black above, the under parts, from the middle of the throat, white; secondary quill feathers tipt with white; legs black. In the young bird the bill has but one groove, and, in the still younger, there is no line from the bill to the eyes. Eighteen inches long. Inhabits Europe and North America. The birds of this species associate with the guillemots, and also breed in the same places. About the beginning of May they take possession of the highest impending rocks, for the purpose of incubation, and on the ledges of these rocks they assemble in great numbers, sitting closely together, and often in a series of rows one above another. There they deposit their single large egg on the bare rock, and notwithstanding the multitudes of them which are thus mixed together, yet no confusion takes place; for each bird knows her own egg, and hatches it in that situation. The razorbill is provincially called awk, murre, falk, marrot, and so on.

 Dusky auk. Size of the murre thrush; the length 11 inches. Upper mandible of the bill bent at the point; colour yellow brown; the ridge white; irides white, and surrounded with a black circle; forehead covered with downy feathers, which are reflected, half one way, and half the other: behind the eyes a stripe of white; head and neck black; upper parts of the body black; legs livid; webs black. Inhabits Japan and Kamtschatka. Is sometimes seen at a great distance from land, when it is solitary, but on land is gregarious.

 Perroquet auk. Bill compressed, with a single groove in each mandible; a white spot on the upper eyelid, between and under the eyes. Inhabits the sea between Japan and Kamtschatka, and often intimates approaching land to mariners.

 Tufted auk. Entirely black; bill with three transverse grooves, 1½ inch in length, escacle; sides of the head,
ORNITHOLOGY.

Antestes. head, space round the eyes, and the angle of the throat, white; a yellow tuft of feathers rises from the upper eyebrow, and stretches to the neck; legs brownish orange; claws black; length 19 inches; female less; the tufts smaller, and the bill crossed only with two grooves. Inhabits Kamtschatka and the neighbouring islands.

Alca. Little auk, little black and white diver, Greenland dove, sea turtle, &c.—Bill without furrows and conical; the whole abdomen and tips of the flag feathers white; feet black. There is a variety that is totally white, and another with a rufous breast. Nine inches long. Inhabits Europe and America, particularly Spitzbergen, Greenland, and Newfoundland, where they are called ice birds; but they are rare visitors of the British isles.

Pygmaeus. Pigeon auk.—Bill carinated, depressed at the base; body black above, cinereous beneath. Seven inches long. Inhabits the islands between Asia and America.

Gen. 35. Aptenodytes, Penguin. Bill straight, a little compressed and sharp-edged; upper mandible longitudinally and obliquely grooved, the lower truncated at the tip; tongue with reflected prickles; wings fan-shaped, without quill feathers; feet placed behind, four-toed, and palmed.

The birds of this genus resemble those of the preceding in colour, food, habit, and apparent stupidity, as also in the situation of their feet, in their erect walk, in their nests, and in their eggs. They differ from them, however, in this, that they are all inhabitants of the South seas, from the equator to the Antarctic circle. They are quite incapable of flying, the feathers on their wings being so short as to resemble scales. They are fortified against cold by an abundance of fat; they swim very swiftly; on land they sit erect, in a singular manner and in vast multitudes, and they cackle like geese, only in a hoarser tone. Their nostrils are linear, and hidden in a furrow of the bill; their wings are covered with a strong dilated membrane, and their tail-teeth very rigid.

Crested penguin.—Bill reddish brown; legs reddish; frontal crest black, erect, auricular, sulphur colour, and shed on each side; body bluish black, white beneath; wings white beneath. Female with a yellowish stripe on the eyebrow. Twenty-three inches long. Inhabits the Falkland islands, and the southern parts of New Holland. Called hopping penguin and jumping jack, from its action of leaping quite out of the water, for three or four feet at least, on meeting with the least obstacle. Though more lively than its congeners, it is so foolish as to allow itself to be knocked on the head with a stick, or even to be taken by the hand. When irritated, it erects its crest in a beautiful manner. These birds make their nests among those of the pelican tribe, with which they live in tolerable harmony, and seldom lay more than one egg, which is white, and larger than that of a duck.

Patagonian penguin.—Bill and legs black; ears with a golden spot; lower mandible tawny at the base; irides hazel; head and bind part of the neck brown; back dark blue; breast, belly, and vent white. Four feet three inches long. Inhabits Falkland islands and New Guinea. M. Bougainville caught one, which soon became so tame as to follow and know the person who had the care of it; at first it fed on flesh, fish, and bread, but after some time, grew lean, pinied and died. This species is not only the largest, but the fattest of its genus; and its flesh, though not very palatable, is black.

Cape penguin.—Bill and legs black; eyeballs and pectoral band white. Size of a large duck; length 17 inches. Inhabits the Atlantic and Antarctic seas, chiefly round the Cape of Good Hope. Lays two white eggs, which are reckoned delicious eating. Like all the genus, swims and dives well, but hops and flutters in a strange awkward manner on land, and if hurried stumbles perpetually, or makes use of its wings instead of legs, till it can recover its upright posture, crying at the same time like a goose, but with a hoarser voice. There are two or three varieties.

Little penguin.—Bill black; legs white. Fifteen Minor. inches long. Inhabits New Zealand. Digs deep holes in the earth, in which it lays its eggs.

Gen. 36. Procellaria, Petrel. Bill toothless, a little compressed, hooked at the point; mandibles equal; nostrils cylindrical, tubular, truncated, lying on the base of the bill; feet palmed, hind claw sessile, and without a toe.

The birds of this genus all frequent the deep, where they endure the greatest storms, being hardly ever seen on shore, except at breeding time. They are, however, capable of walking, and their legs are bare of feathers a little above the knee. They feed on the fat of dead whales and fish, and have the faculty of spouting oil from their nostrils.

Pacific petrel.—Black, dusky beneath; legs spotted Pacific. with black; bill plumbeous and much hooked; nostrils elevated, oval, distinct, obliquely placed; feet pale. Twenty-two inches long. Inhabits, in vast flocks, the islands of the Pacific ocean. These flocks disappear at once, diving under water altogether, and then rise as suddenly.

Diving petrel.—Blackish brown; white beneath; br. Utricularis. and chin black; legs blue green, without the spur behind. Eight inches and a half long. Inhabits New Zealand in numerous flocks, and dives remarkably well, often rising at considerable distances, with surprising agility. They croak like frogs, and sometimes make a noise like the cackling of a hen.

Stormy petrel, storm finch, Mother Cary's chicken, &c. Petelius. —Black, with a white rump. This species is about the size of a swallow, and in its general appearance and flight, not unlike that bird. Length about six inches. The stormy petrel is rarely seen on our shores, except in the northern islands, where it breeds in the holes of rocks, or under loose stones, in the months of June and July. At all other seasons it keeps far out at sea. Multitudes of them are seen all over the vast Atlantic ocean, especially before stormy weather. They often skim with incredible velocity along the hollows of the waves, and sometimes on the summits, braving the utmost fury of the tempest. As they appear to run on the surface of the sea, they have their name from an allusion to Peter's walking on the water. The inhabitants of the Faroe isles draw a wick through the body of this bird, which is so fat as to burn when lighted, and serve the purpose of a candle. There is a variety with
ORNITHOLOGY.

Anseres. The body black; head and sides bluish; scrag green, and wing coverts and rump spotted with green. Both sorts are excellent divers, feed on small fishes, are mute during the day, and clamorous in the night.

Nivea. Snowy petrel. Snow white; shafts of the feathers and bill black; legs dusky blue. One foot long. Inhabits the colder parts of the Southern sea, especially in the neighborhood of ice, the masses of which they own haunt in considerable flocks.

Pulmar petrel, or pulmar. Whitish; back hoary; bill and legs yellowish; nostrils composed of two tubes, lodged in one sheath. About the size of the common gull, and 17 inches long. Inhabits the Northern and Southern seas; breeds in Greenland, Spitzbergen, St Kilda, &c. laying one large white egg. It is a bold and stupid bird, and very fat, living on fish, dead whales, and other carcasses and filth, in quest of which it often follows ships for a great way. Its flesh, though rancid, is eaten raw, dried or boiled, by the Kurile islanders, the Greenlanders and St Kildians, and the oil when expressed is used both for food and lamps. The young are in season about the beginning of August, when the inhabitants of St Kilda endeavour to surprise them in their nests, to prevent them from spouting out their oil, which they do by way of defence. This oil is there valued as a cathartic; and every young bird yields nearly an English pint of it, which is carefully preserved. When the thermometer is above 32 degrees, it is very pure, but at a lower temperature becomes turbid.

Gigantea. Glacial petrel. Monoporous petrel, or breakbones. Brownish, spotted with white; white beneath; shoulders, wings, and tail brown; bill and legs yellow; a naked, wrinkled, yellow membrane at the angles of the mouth. Bigger than a goose; length 40 inches; expansion of the wings seven feet. Common in the high southern latitudes, and sometimes found, though more rare, in the Northern seas. Is often seen sailing with the wings expanded, close to the surface of the water, but without appearing to move them. At Christmas harbour, Kerguelen's land, &c. they were so tame, that they suffered themselves to be knocked on the head with a stick, by our sailors, on the beach. Though their chief food is fish, they also feed on the carcasses of seals and birds. Many of the sailors confound them with the albatross, though such of them as are better informed, call them Mother Carey's goose. They are reckoned to be very good food. An individual of this species is figured in Latham's Synopsis.

Cetidea. Glacial petrel. Bluish-ash; back blackish; chin, throat, and breast, white; bill yellow; legs blue. Nineteen inches long. Inhabits the icy seas.

Capronis. Pintado, or pintado petrel. Variegated with white and brown, and sometimes with yellowish and brown; bill and legs black; temples white and black. Size of the kitiwake; length 14 inches. This is the pintado bird of Dampier, the white and black spotted petrel of Edwards, and the Cape pigeon of our sailors. It is seldom seen much to the north of 30 degrees, and is most frequent about the Cape of Good Hope, and the neighbouring regions. It flies in very numerous flocks, which almost sweep the surface of the water. Our voyagers have traced them to New Zealand, Falkland islands, and various regions of the southern hemisphere. The sailors often catch them with some tarred string, or a bit of hord on a fishing rod. Sometimes they appear in such immense numbers, that 700 have been taken in one night. They feed on fish, but more frequently on the carcasses of whales, &c.

Shearwater petrel, or shearwater. Black above; upper white beneath; legs rufous; bill yellow, tip with black; hind head whiteish ash; spurious wings spotted with black; first quill and tail feathers brown without and white within. Weight 17 ounces; is 15 inches long, and nearly the size of a pigeon. Inhabits the Southern and Arctic seas. Breeds in the isle of Man, and in the Orkneys, in the former of which it is called manks puffin, and in the latter fyre. It takes possession of a rabbit burrow or other hole, and lays one white egg, blunt at each end, which is hatched in August. Though the flesh is rank and fishy, it is much relished by some. Great numbers are killed and barreled with salt. These the inhabitants boil, and eat with potatoes. There is a variety that is cinnerose above, white beneath, and with a clear white tail.

Gen. 37. Diomedia, Albatross. Bill straight, upper mandible hooked at the point, lower truncated; nostrils oval, wide, prominent, lateral; tongue very small; toes three, all placed forwards.

Only four species are known to belong to this genus. Wandering Albatross, or man of war bird. White; back and wings with white lines; bill pale yellow; legs flesh colour; quill feathers black; tail rounded, and lead coloured; bill grooved, dirty yellow; nostrils remote from the base, and rising out of the forrow; tail feathers fourteen; thighs naked. From three feet and a half to four feet long; bigger than a swan; weighs from twelve to twenty-eight pounds; and extends its wings from ten to thirteen feet. Inhabits most seas, but chiefly occurs within the tropics. It is frequent about the Cape of Good Hope, and towards the end of July appears in great numbers in Kamtschatka, and the seas which separate that part of Asia from America. It is very voracious, feeding on the salmon, which are found in shoals in the mouths of rivers, on the flying-fish, when forced out of the water by the corphexa, and on other fishes, which it devours whole, and in such quantities, as to be prevented by their weight from rising, though in general it soars very high. It likewise preys on mollusca, and is itself attacked by the sea-eagles, and the larus cataractes. On the shore of South America, it builds about the end of September, a nest of earth on the ground, from one to three feet high, and lays a number of eggs, which are four inches and a half long, and eatable, though the white of them does not coagulate with heat. Its voice resembles the braying of an ass, and its flesh is dry and hard.

Chocolate albatross. Bill whitish; body deep chestnut-brown; belly pale; face and wings whitish beneath. Three feet long. Inhabits the Pacific ocean.

Yellow-nosed albatross. White; bill black; keel of upper mandible and base of the lower yellow; body above black-blue, white beneath. Three feet long. Occurs in the Southern hemisphere, from 30° to 60°, all round the pole. Flies five or six feet above the water.

Sooty albatross. Brown; head, bill, tail, quill feathers Puffinus; and claws sooty-brown; area of the eyes white. Three feet long. Inhabits the Southern ocean within the antarctic
ORNITHOLOGY.

Bill straight, bent at the point, and furnished with a nail; the nostrils form an almost obliterared slit; face somewhat naked; legs balancing the body equally; the four toes connected by a membrane.

The pelicans are gregarious, fond of fish, and in general remarkable for their extreme voracity. For the most part they keep out at sea, but some of them are likewise found in the interior parts of continents. They have all a long bill, in a lateral furrow of which lie the nostrils. Several of the tribe are rendered useful to mankind by being taught to fish.

A. Bill without teeth.

White or common pelican.—White; gullet pouch; bill from fifteen to sixteen inches long, red; upper mandible depressed and flat; lower forked; bag at the base of the mandible, membraneous, capable of great distension; irides hazel; gape of the mouth wide; head naked at the sides, covered with a flesh-coloured skin; hind-head somewhat crested; body faintly tinged with flesh colour; sparse wings and main quill feathers black; legs yellow colour. Larger than a swan, and about five feet long. Inhabits Asia, Africa, and South America. In fishing, this bird does not immediately swallow its prey, but fills its bag, and returns to the shore to devour at leisure the fruits of its industry. As it quickly digests its food, it has generally to fish more than once in the course of the day. At night it retires a little way on the shore to rest, with its head resting against its breast. In this attitude it remains almost motionless, till hunger calls it to break off its repose. It then flies from its resting-place, and raising itself thirty or forty feet above the surface of the sea, turns its head, with one eye downwards, and continues to fly in that posture till it sees a fish sufficiently near the surface, when it darts down with astonishing swiftness, seizes it with unerring certainty, and stores it up in its pouch. It then rises again, and continues the same manoeuvres, till it has procured a competent stock. Clavigero informs us, that some of the Americans, to procure a supply of fish without any trouble, cruelly break the wing of a live pelican, and after tying the bird to a tree, conceal themselves near the place. The screams of the wounded and confined bird attract others of its kind, which eject for it a portion of provisions from their pouches. As soon as the men observe this, they rush to the spot, and after leaving a small quantity for the bird, carry off the remainder. The female feeds her young with fish macerated for some time in her bag. The pelican is susceptible of domestication, and may even be trained to fish for its master. Faber mentions an individual of this species which was kept in the court of the duke of Bavaria above forty years, and which seemed to be fond of the company of mankind, and of vocal and instrumental music. When a number of pelicans and corvorsants are together, they are said to practise a singular method of taking fish. They spread into a large circle, at some distance from land; the pelicans floating on the surface of the water with their extensive wings, and the corvorsants diving beneath, till the fish contained within the circle, are driven before them towards the land; and as the circle contracts by the birds drawing closer together, the fish at last are brought into a small compass, when their pursuers find no difficulty in filling their bellies. In this exercise they often attend by various species of gulls, which likewise obtain a share of the spoil. The pelican generally builds in marshy and uncultivated places, particularly in islands and lakes, making its nest, which is deep, and a foot and a half in diameter, of carexes, and lining it with grass of a softer texture. It lays two or more white eggs, which, when persecuted, it sometimes hides in the water. When it builds in dry and desert places, it brings water to its young in its bag. It walks slowly, flies in flocks, and lives in society with other birds.

Rose-coloured pelican.—Rose; gullet pouch; line Rosell.; and legs black; area of the eyes naked; pouch yellow.

Size of a goose. Inhabits Manilla.

Frigate pelican, or frigate bird.—Tail forked; body Aquilina; and bills and orbis black; belly of the female white. Three feet long; extent of the wings fourteen feet. Inhabits within the tropics. This is the frigate bird of Dampier and other navigators. From its great expanse of wing, it is capable of flying very smoothly, and so high as to be scarcely visible, remaining much in the air, and remote from land. It feeds on fishes, particularly flying fish, on which it darts with the greatest velocity. It is not unfrequently likewise preyed on other piscivorous animals. It builds in trees or on rocks, and lays one or two eggs of a flesh colour, and spotted with red.

Lesser frigate pelican.—Tail forked; body ferruginous; and bills and orbis red. Resembles the last, but less.

Corvorsant.—Tail rounded; head somewhat crested; bill blackish; the base of the lower mandible covered with a yellowish skin, extending under the chin, and forming a pouch; irides green; chin white, surrounded with a yellowish arch; tail long and lax, consisting of fourteen feathers; thighs with a white spot, dotted with black; legs black. Three feet long; size of a goose, but more slender, and weighing about seven pounds. Inhabits Europe, Asia, and America. Common on many of our sea-coasts, building its nest on the highest parts of cliffs that hang over the sea, and laying three or more pale green eggs, about the size of those of a goose. In winter these birds disperse along the shores, and visit the fresh waters, where they commit great depredations among the fish. They are remarkably voracious, and have a very quick digestion. Though naturally extremely shy and wary, they are stupid and easily taken when glutted with food. Their smell, when alive, is more rank and offensive than that of any other bird, and their flesh is so disgusting, that even the Greenlanders will hardly taste it. It is not uncommon to see twenty of these birds together, on the rocks of the sea coast, with extended wings, drying themselves in the wind. In this attitude they sometimes remain for nearly an hour, without once closing their wings; and as soon as the latter are sufficiently dry to enable the feathers to imbibe the oil, they press this liquor from the receptacle on their rumps, and dress the feathers with it. It is only in one particular species that any matter can be spread on them, namely, when they are somewhat damp; and the instinct of the birds teaches them the proper moment. Corvorsants were formerly sometimes
ORNITHOLOGY.

403

Graculus.

Shag.—Tail rounded; body black, brown beneath; tail feathers twelve; head and neck black, with a green gloss; back and wing-coverts purple black, glossy at the edges; middle of the belly dusky; legs black. Weights about four pounds. Length twenty-nine inches. The female weighs about three pounds and a quart; and is only twenty-seven inches long. Inhabits the northern seas of Europe. Swims with its head erect, and the body under water. On perceiving the flash of a gun, dives instantaneously, and rises at considerable distance. Has the manners and habit of the preceding, and devours a prodigious quantity of fish. Near the Cape of Good Hope a variety occurs with a yellow chin, and wedged tail. Another, which frequents the coasts of Cayenne and the Carribbee islands, is blackish above, brown beneath; and has the feathers above edged with black.

Pygmarus.

Dwarf shag.—Tail wedged; feathers twelve; body black, with a few scattered white spots. Female brown, without spots. Size of the gannayeen. Inhabits the Caspian sea.

Cristatus.

Crested shag.—Shining green, dusky beneath; bill and legs dusky; head crested. From two to three feet long. Inhabits the northern seas of Europe, occurs on our own coasts, and both in appearance and manners, resembles the graculus.

B. Bill serrated.

Thagus.

Saw-billed pelican.—Brown; tail rounded; gullet pouchung, and covered with short cinerous feathers; bill one foot long; each mandible hooked; pouch very large; legs black. Size of a turkey; extent of wings nine feet. Inhabits Chili.

Bananus.

Gannet, or soland goose.—Tail wedged; body white; bill and quill feathers black; face blue; irides yellowish; tail feathers twelve; eyes surounded with a naked skin of fine blue; legs black, and greenish on the fore part. Three feet long. Weights seven pounds; and inhabits Europe and America. This species of pelican haunts the Bass island in the frith of Edinburgh, Ailsa, on the coast of Ayrshire, the island of St Kilda, and hardly any where else in Europe. It arrives at these spots in March, and continues till September. As it must let itself fall before it takes wing, it requires a steep and precipitious breeding station. It makes a rude nest of sticks, grass, sea-plants, &c. and lays one egg. While the female is occupied with incubation, the male brings her food, which consists almost entirely of herring and sprats. In the bag under their bill they are able to fetch four or five herrings at a time, and a great number of sprats, which the young bird extracts from the mouth of the old one, with its bill, as with pincers. The young begin to be taken in August, and by some are relished as an exquisite morsel; but the old ones are tough and rancid. The fowler who seizes the young, is let down by a rope from the top of a cliff, and is sometimes stationed on the slippery projection of a rock, with the perpendicular precipice of four hundred feet or more beneath him. The young are of a dark gray colour, and continue so for a year or more, when they gradually become white, except the tips of their wings, which are always black. In September and October, the old birds leave their breeding places, and migrate southward, following, as is alleged, the shoals of herrings. In December they are often seen off Lisbon plunging for sardines; but after that period it is not well known what becomes of them till March. They are common on the coasts of Norway and Iceland, and were said to be met with in great numbers about New Holland and New Zealand. They also breed on the coast of Newfoundland, and migrate southward along the American shores as far as South Carolina. Of this species there are two varieties. The first is brown, spotted with white, and white beneath, with naked and blackish. The second is brown, with triangular white spots, whitish, and spotted with brown beneath; the bill, wings, tail, and legs brown.

Lesser gannet.—Tail wedged; body whitish; all the Picosol.
quill feathers black; face red. Two feet and a half long. Inhabits the Chinese, Indian, and American seas.

Booby.—Tail wedged; body whitish; primary quill Sula feathers tipt with blackish; face red; bill gray; brownish at the base; irides pale ash; chin bald, yellowish; body white beneath; tail brownish at the tip; legs yellowish. Has its name from being so foolish as to alight on one's hand, if held out to it, when tired. Builds in places bare of trees, making its nest on the ground. Its flesh is black and rancid.

Fishing coot—Tailed Europe.—Tail rounded; body brown, bill white, and spotted with brown beneath; throat white; bill yellow; irides blue. Inhabitants China, where it is named for the purpose of catching fish.

Lesser booby.—Black, white beneath; face downy. Eighteen inches long. Inhabits Cayenne.

Chancellors.
Pruia.

Bill straight, pointed, toothed; nostrils an oblong slit near the base; face and chin naked; legs short; all the toes connected.

The birds of this genus have a small head, and long slender neck. They inhabit the southern and warmer latitudes, and live chiefly on fish, which they take by darting the head forwards, while the neck is contracted like the body of a serpent.

White-bellied darter.—Head smooth; belly white. Inhabits Brazil. Two feet ten inches long. Builds on trees, and is scarcely ever seen on the ground. When at rest, it sits with the neck drawn in between the shoulders. The flesh is oily and rancid.

Black-bellied darter.—Head smooth; belly black. About three feet long. Inhabitants Ceylon, Java, &c.

There are several varieties.

Surinam darter.—Head crested; belly white. Thirteen inches long. Inhabitants Surinam. Is domesticated and feeds on fish and insects, especially flies, which it catches with great dexterity.

Caribbean.

The
ORNITHOLOGY.

A. Feet three-toed. Guilleminot.

White guilleminot.—Snowy; bill and legs brownish and flesh-coloured. Size of the garganey. Inhabits the Netherlands.

Black guilleminot, spotted guilleminot, Greenland dove, sea turtle, &c.—Body black; wing-coverts white. But these general markings are incident to great variety. The more special characteristics are; bill black; inside of the mouth and legs red; upper wing-coverts in the middle, and lower part of the belly, white. Weighs fourteen ounces, and measures nearly the same number of inches in length. Inhabits Europe and America. Frequent the Faroe islands, the Bass, St Kilda, &c. visiting these places in March, making its nest far under ground, and laying one egg of a dirty white, blotched with pale rust colour. Except at breeding time, it keeps always at sea, lives on fish, flies low, and generally in pairs. It cannot, without much difficulty, rise from the ground. In the Orkney islands, it is called _tyate_. The Greenlanders eat its flesh, and use its skin for clothing, and its legs as a bait to their fishing lines.

B. Four-toed, and palmed. Diver.

Red-throated diver or loon.—A stigianous shield-like spot beneath the neck; body brown, with many white spots above, white beneath; bill black; head and chin cinereous, spotted with brown; neck with small white and brown lines above; legs dusky. Weighs about three pounds. Length near two feet and a half. Inhabits the north of Europe, Asia, and America, and is seldom seen far southward, except in very severe winters. In the breeding season it frequents the lakes, making a nest among the reeds and flags, and lays two eggs of an ash colour, marked with a few black spots. In Iceland it
ORNITHOLOGY.

431. **Black-throated diver.**—Head hoary; neck violet black and crown and back black and bill black; body black above, white beneath; sides of the neck white, spotted with black; shoulders and wing-coverts with white spots, the former square, the latter round; tail feathers dusky. Two feet long. Inhabit the northern parts of Europe, Asia, and America, frequenting both the sea and lakes. Before rain, it is restless and clamorous; occurs in Scotland, but is not common in England.

432. **Speckled diver or loon.**—White beneath; head and neck black and quill feathers dusky; throat pale ash; back, flanks, rump, and tail, spotted with white; bill horn colour; legs brown. The weight of this species is about four pounds, and the length 27 inches. It inhabits the north of Europe and America, and is among the most common of the diver tribe found in this country, being frequently seen in winter, in our bays and inlets, and sometimes in fresh-water rivers and lakes. From attending the sprats in the Thames, it is called sprat loon by the fishermen. In the northern regions it lays two eggs, the size of those of a goose, dusky, and with a few black spots; in the grases, the eggs closely resemble a smaller diver.

433. **Northern diver or greatest speckled diver.**—Head and neck purple black; chin and upper part of the neck with a white interrupting band; upper part of the body, bill, legs, and tail black; back with square white spots disposed in rows; wing-coverts with white dots. The largest of the genus; sometimes weighing fifteen or sixteen pounds, and measuring nearly three feet and a half in length. Inhabits the north seas, and breeds in the fresh waters, in Iceland, Greenland, &c. Frequent the seas about the Orkneys, all the year round, without breeding there. The skin, which is tough, and well covered with soft down, is dressed in some parts of Russia, &c. and used as clothing.

434. **Immer.**

Immer, omer; or emmer goose, or diver. Body blackish and waved with white above, white beneath; feathers of the back, wings, and tail edged with white. Two feet long. Inhabits the Arctic ocean, and also, it is said, the lake of Constance, where it is called flader. Unless in severe winters, it is rare in England, but is more common on the Scottish and Orkney coasts. It makes its nest on the water, among reeds and flags. It feeds on fish, latter which it dives with great celerity, and is sometimes taken under water by a bated hook.

436. **Crested grebe, gray or ash-coloured loon, &c.**—Head rufous; collar black; secondary quill feathers white; bill flesh-coloured, brown at the tip; lores and irides red; body brown above, white beneath; head perhaps, and varies in colour by age. During the first year, the bird has a smooth head, and a white spot on the wings; and during the second, a long downy tuft on each side of the throat. This is the largest of the grebes, weighing about two pounds and a half, and measuring twenty-one inches in length. It occurs in almost every lake in the northern parts of Europe, as far as Iceland, and southward to the Mediterranean, and is also found in various parts of America and Siberia. It is common in the seas and lakes in various parts of England, where it breeds. The female makes her nest of various kinds of dried fibres, stalks and leaves of water plants, as of the nymphia, potamogeton, bottonia, &c. and the roots of menyanthes trifoliata, and conceals it among the flags and reeds which grow in the water, and where it is erroneously said, that the young are fed on small eels. In some countries, ladies muff and other ornamental articles of dress are made of the skin of the belly of this species, which has a fine down of a dazzling whiteness. It requires five skins to make a muff, which sells at four or five guineas. The tippet grebe is the female or young of this species.

437. **Eared grebe, or dobchick.**—Blackish-brown above, white beneath; head black; ears created, and ferruginous; bill and legs black; lores and lores red; primary quill feathers dusky, secondary white. There is a smaller variety with a double crest, and the neck spotted with chestnut. This species is about twelve inches long, and inhabits the northern lakes of Europe and Siberia. It is also met with in southern climates, but is not numerous in England. According to Pennant, it breeds in the seas near Spalding in Lincolnshire, and the female makes a nest not unlike that of the preceding, laying four or five small white eggs.

438. **Horned grebe.**—Head glossy green; a yellow tufted band through the eyes; neck and breast tawny. Size of the preceding. Inhabit North America.

439. **Little grebe, or small dipper.**—Of a reddish brown above, white, with spots beneath; head smooth; feathers of the body edged with reddish; lower part of the belly gray; upper wing-coverts, and first and last quill feathers blackish, rest of the quill feathers white; bill blackish; base of the lower mandible reddish; legs blackish green. Inhabit Europe, North America, the Philippine isles, and the Delta in Egypt. The least of the grebe tribe, weighing only between six and seven ounces, and measuring from the tip of the bill to the rump, ten inches. It seldom quits the water, and its remarkable diver, feeding on fish, insects, and aquatic plants; constructing a large nest, a foot thick, of grass and the stalks of aquatic plants, in the midst of the waters which pervade it, and laying five or six whitish eggs, which it covers when it leaves the nest. In several parts of this country it is called didopper.

440. **Dusky grebe.**—Subcrested, brown; chin, cheeks, neck, and region of the ears cinereous; under part of the neck and breast rusty-red; belly, and secondary quill feathers white; bill black, the sides tawny at the base; irides tawny; legs dusky. Seventeen inches long; and weighs nearly nineteen ounces. Inhabit Europe, but is very rare in Britain.

441. **Black chin grebe.**—Head smooth; body blackish; chin black; throat ferruginous; belly cinereous, mixed with...
ORNITHOLOGY.

Gen. 42. Larus, Gull.

Character.

Bill straight, sharp edged, a little hooked at the tip, and without teeth; lower mandible gibbous below the point; nostrils linear, broadest on the fore part, and placed in the middle of the bill.

The birds of this genus have a light smooth body; long wings; a strong bill; the tongue somewhat cleft; the feet short; bare of feathers above the knee; with a small back toe. They inhabit the north; feed chiefly on fishes, and even on those that are dead. When harassed, they throw up or discharge their food. As the young are sometimes spotted to their third year, the excretion of this species is attended with doubt and difficulty.

A. Nostrils without a cere.

Tridactylus.

Tarrock, or kittiwake.—Whitish; the back greyish; tips of the tail feathers, except the outermost, black; three toes. In mature age, the characters are; back whitish hoary; quill feathers white; hind toe unarmèd. Ornithologists, in fact, seem now to be agreed, that L. tridactylus and L. rissa, are only varieties of the same species. A third variety occurs, distinguished by an oblique black band on the wing, and white chin. About the size of a pigeon; about fourteen inches long. Inhabits Europe, Asia, and America. Breeds on the cliffs about Flamborough-head, the Bass, isle of May, the rocks near Slains Castle, &c.; lays two eggs; feeds on fishes, and seek its food in company of seals and whales. It swims and flies rapidly, and is often clamorous. Its flesh is much relished by the Greenlanders, who also make clothing of its skin. One that was kept and tamed, knew its master's voice at a distance, and answered him with its hoarse piping note. It had a varicos appetite, and though plentifully fed on bread, would rob the poultry of its share.

Little gull.—Snowy; head and beginning of the neck black; back and wings russet; bill brown red; legs scarlet. Size of a thrush. Inhabits Russia and Siberia.

Common gull.—White; back hoary; primary quill feathers black at the ends, the fourth and fifth with a black spot at the tip, the outer one black without; bill yellow; irides hazel; legs greenish white. A variety is met with that has the head spotted with brown; neck brown above, and tail feathers white, with a black band. This is generally supposed to be the younger bird. Inhabits Europe and America. Seventeen inches long; of the size of a pigeon; and is seen in numerous flocks, continually screaming. Lives on fishes, vermes, and the larvae of insects; builds among rocks and stones, and is a foolish bird. The most common and numerous of all the British gulls, breeding on rocky cliffs, and laying two eggs, nearly the size of those of a common hen, of an olive brown colour, marked with dark-reddish blotches. At the mouths of the larger rivers they are seen in numbers, picking up the animal substances which are cast on shore, or come floating down with the ebb-tide. For this kind of food they watch with a quick eye, and it is curious to observe how such as are near the breakers will mount up the surface of the water, and run splashing towards the summit of the wave to catch the object of their pursuit. At particular seasons, this species also resorts to the inland parts of the country, to feed on worms, &c. Some persons who live near the sea, commonly eat this, as well as various other kinds of gulls, which they describe as being good food, when they have undergone a certain sweetening process before cooking; such as burying them in fresh mould for a day, or washing them in vinegar. This species breeds on the ledges of rocks, close to the sea shore, sometimes not far above the water. This bird is frequently seen in winter, at a considerable distance from the coast. It flicks with rooks in severe weather, and will follow the plough for the sake of the larvae of the chaffer.

Black-backed gull, or great black and white gull.—Larus marinus.

White; back black; bill yellow; lower mandible with a red spot near the tip and black in the middle; irides yellow; lower part of the back white; quill feathers black, tinged with white; legs flesh-coloured. The markings, however, vary considerably with the age of the bird. The weight of this species is four pounds and three quarters; and the length near thirty inches. It inhabits Europe and America. Though not very plentiful on our coasts, it is occasionally seen in small flocks of eight or ten, sometimes in pairs, but never associating with the other gulls. It cackles like a goose, lives chiefly on fish, but also infests the eider duck, and even lambs. It has been known to tear and devour the largest fish on the hooks, when left dry by the ebbing tide. It breeds on the steep holmes, and Lundy island, in the Bristol channel, makes a nest in the clefts of the highest rocks, and lays three eggs of a blackish grey colour, with dark purple spots, and eatable. Its skin is used for clothing by the Eskimaux and Greenlanders; and the young not only affords a fine down, but an article of food.

Herring gull.—White; back brown; legs yellow; bill yellow; irides straw-coloured; five first quill feathers black above. Weight about thirty-three ounces. Length twenty-three inches. Inhabits Europe, Asia, and North America, proceeding southward in winter as far as the Black and Caspian seas, Jamaica, and the islands on the shore of South Carolina. It lives on fish, especially herrings, which it seizes with great boldness, and the shoals of which it accompanies in flocks. It is sometimes observed to trample the soft sand, by moving its feet alternately in the same place, for the purpose, it is supposed, of forcing up sand eels, or some hidden prey. This species is very common on the British shores; makes its nest of dry grass on the projecting ledges of the rocks, and lays three eggs of a dull whitish colour, spotted with black. Fishermen describe it as the constant, bold, and intruding attendant on their nets, from which they find it difficult to drive it away.

Black-headed gull.—Whitish; head blackish; bill black; legs black. Eighteen inches long. Inhabits Europe and America. Flies about the shores in flocks, with a continual clamour; and builds in pine trees.

Laughing gull, or black-headed gull.—Whitish; head blackish; bill and legs pale red. Eyelids red; irides hazel; head and chin dusky brown; and in the full grown bird black; first ten quill-feathers white-edged, and tip with black; the rest cinereous, tip with white; claws black. This species has its name from its singular cry, which resembles a horse laugh. It is fifteen inches long; inhabits Europe, America, and the Bahama islands; and breeds in the pools and fens of England, making its nest on the ground, with rushes, dried grass, &c. and laying three greenish brown eggs, spotted with tawney.
ORNITHOLOGY.

Aneres. — Tawney. "In former times (says Mr Bewick), these birds were looked upon as valuable property by the owners of some of the fens and marshes in this kingdom, who every autumn caused the little islets or hafts in those wastes, to be cleared of the reeds and rushes, in order properly to prepare the spot for the reception of the old birds in the spring, to which places at that season they regularly returned in great flocks to breed. The young ones were then highly esteemed as excellent eating; and on that account were caught in great numbers before they were able to fly. Six or seven men, equipped for this business, waded through the pools, and with long staves drove them to the land, against nets placed upon the shores of these hafts, where they were easily caught by the hand, and put into pens ready prepared for their reception. The gentry assembled from all parts to see the sport." — "These were the sea-gulls of which we read as being so plentifully provided at the great feasts of the ancient nobility and bishops of this realm. Although the flesh of these birds is not now esteemed a dainty, and they are seldom sought after as an article of food, yet in the breeding season, where accommodation and protection are afforded them, they still regularly resort to the same old haunts, which have been occupied by their kind for a long time past."

B. Nostrils covered with a cere.

452. Parasiticus. Arctic gull. — Two middle tail feathers very long; bill and legs dusky; body black above; temples, front, and under parts of the body white; breast with a dusky band. Female brown beneath; twenty-one inches long. Inhabit Europe, Asia, and America. Breeds in the Hebrides and Orkneys, among the heath, making its nest of grass and moss, in some marshy place, and laying two eggs, the size of those of a hen, ash-coloured and spotted with black. It is very rapacious, and pursues the lesser gulls, not for their dung, as some have asserted, but to make them disgorge what they have lately eaten, which it dexterously catches and devours before it reaches the water. It is to be remarked, that all this tribe are voracious, and if chased by a hawk, or other bird that creates alarm, readily disgorge, in order to lighten themselves, and thus escape by flight. It is so uncommon a thing to see them bring up a large quantity of half digested food, when slightly wounded by shot; and tam gulls will do the same, if driven by a dog. It may also be observed, that gulls float highly on the surface of the water by reason of the quantity of feathers in proportion to their weight, and seem to be incapable of diving. If they should be wounded ever so slightly, and fall into the water, they never attempt to dive like other aquatic birds.

453. Crepidastus. Black-tailed gull. — Varied with dirty white and brown, paler beneath; two middle tail feathers a little longer; bill black; breast and belly white, with numerous dusky and yellowish lines; flanks and vent transversely black and white; wing-coverts and tail black, edged with white or brownish; legs bluish; toes and connecting membrane black. Weight about eleven ounces; length fifteen or sixteen inches. Inhabits Europe and America, but is not common on the British shores. Its habits nearly coincide with those of the preceding species. Its excrement is said to be red, from the circumstance of its feeding on the helix jamthina.

454. Hydracar. Skua gull. — Grayish; quill and tail feathers white at the base; tail nearly equal; bill dusky, much hooked, upper mandible covered half way with a black cere; body brown above, rusty-ash beneath; legs blackish, rough, warty; claws hooked, black; hind-toe short, with a sharp hooked claw; two feet long. Inhabits Europe and America. These fierce birds are met with by navigators in the high latitudes of both hemispheres, where they are much more common than in the warm or temperate parts of the globe. They are often mentioned in Captain Cook's Voyages, and, from their being numerous about Falkland islands, the seamen call them Port Egmont hena. They are also common in Norway, Iceland, the Shetland and Faroe isles, &c. They prey not only on fish, but also on the lesser sorts of water fowl, and are so courageous in defence of their own young, that they attack either man or beast, that dares to disturb their nest. They make their nests among the dry grass, and, when the young are reared, they disperse themselves commonly in pairs over the ocean. In the island of Foula, in Shetland, the skua gull is called bonxie, and is a privileged bird, there being a fine of 10l. Scotch for destroying its eggs, because it keeps off the eagle during the whole breeding season.

Gen. 43. Sterna, Tern.

455. Sterna. Bill subulate, somewhat straight, pointed, a little compressed, without teeth; nostrils linear; tongue pointed; wings very long; tail generally forked.

The birds of this genus are mostly inhabitants of the ocean, and feed on fishes. They are seldom afraid of man.

456. Sterna. Scapuligera. — Black above; upper parts of the body, cheeks, front and shafts of the quill and tail feathers white; sixteen inches long. Inhabits the Atlantic and Antarctic seas.

457. Sterna. Noddy. — Body black; front whitish; eye-brows black; bill and legs black; hind-head cinereous; fifteen inches long; found chiefly within the tropics; is clamorous, seldom goes far from shore, and always rests there during the night. It builds on the rocks, and its eggs are reckoned excellent food.

458. Sterna. Sandwich tern. — White; back and wings hoary; cap black; front with white spots; quill feathers blackish, with a white shaft; bill black, yellowish at the tip; legs black; wings longer than the tail; egg olive-brown, with purplish and crowded spots; eighteen inches long. Inhabits the Kentish coast, generally appearing about Romney, in the middle of April, and departing in the beginning of September. It is not uncommon about Sandwich, where it was first particularly noticed by Mr Boys. The circumstance of its breeding in England has not been perfectly ascertained. The havia of some authors, or the Kamtschatka tern of Pennant, appears to be only a variety, which is black, with paler colours above; white beneath; and bill and legs black.

459. Sterna. Common or greater tern. — Two outer tail feathers half black, and half white; bill and legs crimson; the former tipped with black; crown and area of the eyes black; rest of the head, neck, tail, and body, white beneath; back and wings cinereous; outer tail feathers black on the outer edge. There is a variety with black legs, and the outer tail feathers entirely white. The weight of this species is about four ounces and a quarter; and
ORNITHOLOGY.

Order IV. GRALLÆ.

Bill subcylindrical, and somewhat obtuse; tongue entire and fleshy; legs naked above the knees; the feet are commonly furnished with four toes, of which three stand forwards, and one backwards, sometimes wholly unconnected, and at other times half connected by a web. Some species, too, have only three toes; their legs are long, that they may seek their food in marshy and swampy places, for which reason they have also a long neck, and, for the most part, a long bill. Their bodies are oval, and somewhat compressed, and their tail is generally short. They build chiefly on the ground and in marshy places, and feed principally on fishes and water insects. They are all more or less migratory, and such as inhabit the more northern countries of Europe, universally leave them at the approach of winter.

Gen. 45. PHALacroPTeROS, Flamingo.

Bill bare, toothed and bent as if broken; nostrils linear; the feet four-toed and palmed, the membranes semicircular on the fore part; hind toe not connected.

The birds of this genus combine the answers with the grallæ. They have the neck and legs long; the bill strong and thick, the upper mandible carinated above, and denticulated at the margin, the under one compressed and transversely sulcate; the nostrils above covered with a thin membrane, and communicating with each other; the back-toe very small, and the web which connects the fore-toes reaching to the nails.

Red flamingo.—Flag feather black. This singular Ruber.

bird is scarcely so big as a goose, but has the neck and legs in a greater disproportion to the body than any other bird; the length from the end of the bill to that of the tail being four feet and two or three inches; but to the end of the claws, sometimes more than six feet; the bill is four inches and a quarter long, and of a structure different from that of any other bird, the upper mandible being very thin and flat, and somewhat movable, the under thick, and both bending downwards from the middle; the end, as far as the curvature, is black, and the rest reddish-yellow; a flesh coloured cere extends round the base of the bill to the eye; the neck is slender and of an immemorable length; the tongue, which is large and fleshy, fills the cavity of the bill, has a sharp cartilaginous tip, and is furnished with twelve or more hooked papillae on each side, which bend backwards. The bird, when in full plumage, which it does not acquire till the third year, is of a most beautiful deep scarlet, except the quills, which are black. The flamingo affects the warmer latitudes; and, in the old continent, is not often met with beyond the 40th degree north or south. It is met with everywhere on the African coast and adjacent isles to the Cape of Good Hope, and sometimes on the coast of Spain and Italy, and even on those of France that lie on the Mediterranean, having been found at Marseilles and for some way up the Rhone. It is seen also on the Persian side of the Caspian sea, and from thence along the western coast as far as the Wolga. They breed in the Cape de Verd isles, particularly in that of Sal, constructing a nest.
ORNITHOLOGY.

Grallæ of mud in the shape of a hillock, with a cavity at top, in which the female generally lays two white eggs, of the size of those of a goose, but more elongated. The hillock is of a sufficient height to admit the bird's sitting on it conveniently, or rather standing, as the legs are placed on each side at full length. Sometimes the female will deposit her eggs on the projecting part of a low rock, if otherwise adapted to the above-mentioned attitude. The young are not able to fly till they are grown, but they can previously run with amazing swiftness. In this immature state, they are sometimes caught and easily tamed. In five or six days, they became familiar, and even eat out of the hand, and drink a great quantity of sea water. It is, however, difficult to rear them, as they are very liable to pine from want of their natural subsistence, which chiefly consists of small fish and water insects. These they take by plunging the bill and part of the head into the water, and from time to time trampling the bottom with their feet, to disturb the mud, and raise up their prey. In feeding they are said to twist the neck in such a manner, that the upper part of their bill is applied to the ground. Except in the breeding season, flamingoes are generally observed in great flocks, and at a distance appear like a regiment of soldiers, being often ranged alongside of one another on the borders of rivers. When the Europeans first visited America, they found these birds on the shores tame and gentle, and no way distrustful of mankind. We learn from Catesby, that when the fowler had killed one, the rest of the flock, instead of attempting to fly, only regarded the fall of their companion in a kind of fixed astonishment; so that the whole flock were sometimes killed in detail, without one of them attempting to make its escape. They are now, however, extremely shy, and one of their number acts as sentinel, while the rest are feeding. The moment that this guard perceives the least danger, he gives a loud scream, like the sound of a trumpet, and instantly all are on the wing, and fill the air with their screams. The flamingo, when at rest, stands on one leg, the other being drawn up to the body, with the head placed under the wing on that side of the body on which it stands. Its flesh is esteemed tolerable eating, and that of the young has been compared to partridge. Pliny, Martial, and other writers of antiquity, have celebrated the tongue as a morsel of exquisite relish.

Chilimæs flamingo.—Quill feathers white; bill covered with a reddish skin; head suberected; measures five feet from the bill to the claws. Inhabits Chili; frequents only fresh waters, and is extremely shy.

Platalea Spoonbill.

Character. Bill long and thin; the tip dilated, orbicular and flat; nostrils small at the base of the bill; tongue short and pointed; feet four-toed and semipalmated.

White spoonbill.—Body white; chin black; bill head somewhat crested. Bill black, brown or spotted; tongue heart-shaped; irides gray; lores, orbits, and naked dilatable chin, black; quill feathers sometimes tint with black; legs black. This species admits of two varieties, of which the first has the wings varied with black and white, and the legs yellowish; and the second has the body all white, and the legs flesh coloured. The white or common spoonbill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Feroe isles to the Cape of Good Hope; but rarely occurs in England. It lives on grass, carices, the roots of reeds, serpents, frogs, muscles, and other shell-fish, but especially on fishes, which it often seizes from other birds. It makes its nest in high trees, near to the sea, and lays three or four white eggs, sprinkled with a few pale red spots. The flesh, especially of the young bird, tastes like that of goose.

ronsæn spoonbill.—Body rose-coloured; tail coverts tupa scarlet; bill cinereous white, with a furrow parallel with the edges; face and chin naked and whitish; legs gray. This species also frequently appears of a blood red hue; the neck white; collar black; and tail feathers scarlet. Two feet three inches long. Inhabits South America and Jamaica. Figured in Latham's Synopsis.

Dwarf spoonbill.—Body brown above; white below; feet four-toed; cleft, a very small membrane connecting the toes at the root.

Horrid sreamer.—Wings with two spines at the curved vulture, front horned; bill and legs black; irides golden; body blackish above, white beneath; wings reddish beneath; spine strong, sharp, horned, triangular, yellow; horn on the front recurved, round, whitish, three inches long; hind toe straight. Three feet four inches long. Inhabits the fenny parts of South America; making a large nest of mud, in the shape of an oven, on the ground, and laying two eggs the size of those of a goose. It is remarked, that they are always met with in pairs, and if one dies, the other mourns for death. On hearing the least noise, or seeing any one, even at a distance, they rise from the ground and make a loud screaming noise. They feed principally on herbs, seeds, and reptiles. The flesh of the old bird is tough and ill tasted; but that of the young, though very dark, is frequently eaten by the natives.

Crested sreamer.—Wings unarmed; front crested. Size of a heron. Inhabits Brazil.

Platalea Spoonbill.

Character. Bill long and thin; the tip dilated, orbicular and flat; nostrils small at the base of the bill; tongue short and pointed; feet four-toed and semipalmated.

White spoonbill.—Body white; chin black; bill head somewhat crested. Bill black, brown or spotted; tongue heart-shaped; irides gray; lores, orbits, and naked dilatable chin, black; quill feathers sometimes tint with black; legs black. This species admits of two varieties, of which the first has the wings varied with black and white, and the legs yellowish; and the second has the body all white, and the legs flesh coloured. The white or common spoonbill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Feroe isles to the Cape of Good Hope; but rarely occurs in England. It lives on grass, carices, the roots of reeds, serpents, frogs, muscles, and other shell-fish, but especially on fishes, which it often seizes from other birds. It makes its nest in high trees, near to the sea, and lays three or four white eggs, sprinkled with a few pale red spots. The flesh, especially of the young bird, tastes like that of goose.

ronsæn spoonbill.—Body rose-coloured; tail coverts tupa scarlet; bill cinereous white, with a furrow parallel with the edges; face and chin naked and whitish; legs gray. This species also frequently appears of a blood red hue; the neck white; collar black; and tail feathers scarlet. Two feet three inches long. Inhabits South America and Jamaica. Figured in Latham's Synopsis.

Dwarf spoonbill.—Body brown above; white below; feet four-toed; cleft, a very small membrane connecting the toes at the root.

Horrid sreamer.—Wings with two spines at the curved vulture, front horned; bill and legs black; irides golden; body blackish above, white beneath; wings reddish beneath; spine strong, sharp, horned, triangular, yellow; horn on the front recurved, round, whitish, three inches long; hind toe straight. Three feet four inches long. Inhabits the fenny parts of South America; making a large nest of mud, in the shape of an oven, on the ground, and laying two eggs the size of those of a goose. It is remarked, that they are always met with in pairs, and if one dies, the other mourns for death. On hearing the least noise, or seeing any one, even at a distance, they rise from the ground and make a loud screaming noise. They feed principally on herbs, seeds, and reptiles. The flesh of the old bird is tough and ill tasted; but that of the young, though very dark, is frequently eaten by the natives.

Crested sreamer.—Wings unarmed; front crested. Size of a heron. Inhabits Brazil.

Platalea Spoonbill.

Character. Bill long and thin; the tip dilated, orbicular and flat; nostrils small at the base of the bill; tongue short and pointed; feet four-toed and semipalmated.

White spoonbill.—Body white; chin black; bill head somewhat crested. Bill black, brown or spotted; tongue heart-shaped; irides gray; lores, orbits, and naked dilatable chin, black; quill feathers sometimes tint with black; legs black. This species admits of two varieties, of which the first has the wings varied with black and white, and the legs yellowish; and the second has the body all white, and the legs flesh coloured. The white or common spoonbill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Feroe isles to the Cape of Good Hope; but rarely occurs in England. It lives on grass, carices, the roots of reeds, serpents, frogs, muscles, and other shell-fish, but especially on fishes, which it often seizes from other birds. It makes its nest in high trees, near to the sea, and lays three or four white eggs, sprinkled with a few pale red spots. The flesh, especially of the young bird, tastes like that of goose.

ronsæn spoonbill.—Body rose-coloured; tail coverts tupa scarlet; bill cinereous white, with a furrow parallel with the edges; face and chin naked and whitish; legs gray. This species also frequently appears of a blood red hue; the neck white; collar black; and tail feathers scarlet. Two feet three inches long. Inhabits South America and Jamaica. Figured in Latham's Synopsis.

Dwarf spoonbill.—Body brown above; white below; feet four-toed; cleft, a very small membrane connecting the toes at the root.

Horrid sreamer.—Wings with two spines at the curved vulture, front horned; bill and legs black; irides golden; body blackish above, white beneath; wings reddish beneath; spine strong, sharp, horned, triangular, yellow; horn on the front recurved, round, whitish, three inches long; hind toe straight. Three feet four inches long. Inhabits the fenny parts of South America; making a large nest of mud, in the shape of an oven, on the ground, and laying two eggs the size of those of a goose. It is remarked, that they are always met with in pairs, and if one dies, the other mourns for death. On hearing the least noise, or seeing any one, even at a distance, they rise from the ground and make a loud screaming noise. They feed principally on herbs, seeds, and reptiles. The flesh of the old bird is tough and ill tasted; but that of the young, though very dark, is frequently eaten by the natives.

Crested sreamer.—Wings unarmed; front crested. Size of a heron. Inhabits Brazil.
ORNITHOLOGY.

Grall. blackish; upper mandible gibbous at the base; lower
tumid beneath; legs flesh-coloured. Inhabits India, and
feeds on shell-fish.

Neu Holland. Body purplish-green above,
under parts, neck and shoulders white; head purplish,
spotted with white; neck feathered; irides yellow; first
quill feathers white; tail black and white. Full
six feet long; is supposed to live chiefly on fish. Inhabits

Gen. 49. Cancroma, Boatbill.

Cancroma.

Characters. Bill gibbous, and shaped like an inverted boat; nostrils
small, and placed in a furrow; tongue small; toes
divided.

Cebitaria. Crested boatbill.—Crested; cinnereous; belly rufous;
crown and lunule on the neck black; bill brown; lore
naked and blackish; crest long, pendulous and pointed;
legs yellowish-brown; toes connected at the base. The
body is sometimes spotted with brown. Twenty-two
inches long. Inhabits South America; perches on trees
which overhang the water, and darts down on a fish
as they swim underneath. It likewise feeds on crabs.

Gen. 50. Scopus, Umbre.

Scopus.

Characters. Bill thick, compressed, long and straight; nostrils linear
and oblique; feet with four unconnected toes.

Fig. 4. Tufted umbre.—With a crest; bill brown, with a
longitudinal furrow on each side, in which are placed
the nostrils: lower mandible narrower towards the end,
and a little truncated; crest thick, tufted and lax; body
brown; tail obscurely barred; legs longish and brown.
Female not crested. Twenty inches long. Inhabits Africa.

Ardea.

Characters. Bill straight, pointed, long, somewhat compressed, with
a furrow from the nostrils towards the tip; nostrils
linear; tongue sharp; feet four-toed, cleft; toes
connected at the base.

The birds of this genus have long feet and
necks, and live on amphibious animals and fishes.

A. Crested, and bill scarcely longer than the head.

B. Crested, and bill longer than the head.

Crowned heron, or crown-bird.—Crest bristly and erect;
temples with two naked wattles; bill brownish;
irides gray; crown covered with short silky feathers;
crest circular, yellowish, tippd with black; temples
and wattles red; body bluish ash; wing-coverts white, the
greater ones reddish, those next the body blackish; tail
and greater quill feathers black, the secondary bar; legs
dusky. The female is black, where the male is bluish-
ash, has no wattles on the throat, and the long feathers
on the breast less conspicuous. This beautiful species,
the bauaric crane of Bay, and the crowned African
crane of Edwards, is two feet nine inches long; and
inhabits Africa, particularly the coast of Guinea, as far
as the Cape de Verd islands. At the latter it is said to
be very tame, and so familiar as to come into the court-yards
to feed with the poultry. It is supposed to feed chiefly on
worms and vegetables, often sleeps on one leg, runs very
fast, and not only flies well, but continues on wing for a
long time together. The flesh is said to be very tough.

Demoselie heron, demeselle of Numidia, or Numidian

crane.—A tuft of long, white, pendant feathers behind
each eye; bill yellowish; the base greenish, tip red;
irides red; head and tips of the primary quill feathers
black; feathers of the breast long and pendulous; crest
over the eyes turned back, and pendulous; body bluish-
ash; crown cinereous; head, neck, throat, breast and
legs black. The wind-pipe does not, as in the generality
of birds, go straight forwards into the lungs, but
first enters a cavity in the keel of the breast bone, for
about three inches, when it returns, after making a bend
forwards, and then passes into the chest. This elegant
species is about the size of the common crane; and three
feet three inches long. It is found in many parts of
Africa and Asia, but most plentifully about Bittgelerei,
the ancient Numidia, and Tripoli. It also occurs at
Aleppo, and in the southern plain, about the Black and
Caspian seas, and not unfrequently beyond Lake Baikal,
about the rivers Selenga and Argun, but never ventures
to the northward. It affects marshes and rivers, subsisting
chiefly on fish. In the Crimea it builds its nest in
open plains, generally in the vicinity of the salt lakes.
The young birds are brought to market by the Tartars,
and are so susceptible of domestication, that they even
afterwards breed in the farm yards. From the gentleness
of its manners and the elegance of its form, it is
often kept in menageries. In confinement, it often
assumes strange and uncouth attitudes, and seems occa-
sionally to imitate dancing; and Kayser mentions one
in the gallery at Florence, which had been taught to
dance to a certain tune, when played or sung to it.

B. Creases; head bold.

Common crane.—Hind head naked and papillous; cap
and quill-feathers black; body cinereous; innermost tail
feathers jagged; bill greenish-black; front covered with
black down; hind head red, with a few scattered hairs,
and a cinereous area beneath; temples and upper neck
white; legs black. There is a variety with the body
white; and the lower part of the neck and quill feathers
black; bill greenish black; front covered with black
don; hind head red, with a few scattered hairs, and a
cinereous area beneath; temples and upper neck white;
legs black. Weighs near 50 pounds; length five feet.
Inhabits Europe and Asia, and annually migrates in flocks
to the southern parts of Asia and Africa, in autumn.
The course of their flight is discovered by the loud noise
which they make; for they soar to such a height as to
be scarcely visible to the naked eye. Like the wild
goose, they form themselves into different figures,
describing a wedge, a triangle, or a circle. It is said
that formerly they visited the fens and marshes of England,
in great numbers; but they seem now, in a great mea-
sure, to have forsaken our island. They are seen in
France in the spring and autumn; but generally only as
passengers. They make their nests in marshes, and lay
two bluish eggs. They feed on reptiles of all kinds, and
on several sorts of vegetables, particularly green corn;
among which, if a flock slights, it makes great havoc.
Like other large birds, the crane has much difficulty in
commencing its flight.

Siberian crane.—White; temples and front naked, Gigantes.
red, wrinkled; ten first quill feathers shining black;
bill and legs red. Stands four feet and a half high.
Inhabits the marshy flats of Siberia, and feeds on reptiles,
worms, and small fish.

G. Storks;
ORNITHOLOGY.

C. Storks; orbits naked.

White stork.—White; orbits and quill feathers black; bill, legs and skin red; greater wing coverts black. Inhabits Europe, Asia, and Africa. Is about the size of a turkey; and measures three feet three inches in length. Feeds on fish and reptiles, and in several countries is protected for its use in destroying serpents. Vast numbers annually resort to some parts of Holland, and even as far north as Russia, to breed, but rarely visit England. They observe great exactness in the time of their autumnal departure from Europe to more favoured climes. They pass a second summer in Egypt, and the marshes of Barbary; pairing in the former country, and rearing a second brood. Before each of their migrations, they rendezvous in amazing numbers, and are for a while much in motion among themselves, till, after making several short excursions, as if to try their wings, they all on a sudden take flight with great silence, and with such speed, as in a moment to be out of sight. At Bagdad, hundreds of their nests are to be seen about the houses, walls, and trees; and at Persepolis, the remains of the pillars serve them to build on, every pillar having a nest on it. Shaw mentions flights of them leaving Egypt, and passing over Mount Carmel, each half a mile in breadth. The good-natured Hollanders provide boxes for them to build their nests in, on the tops of their houses, and resent any injury done to the birds as an offence committed against themselves. The stork is of a mild and affectionate disposition; and though it has a grave air, yet, when roused by example, is not averse from gaiety. "I saw," says Dr Hermann, "in a garden where children were playing at hide and seek, a tame stork join the party, run its turn when touched, and distinguish the child whose turn it was to pursue the rest, so well, as, along with the others, to be on its guard."—To this bird the ancients ascribed many of the moral virtues, as temperance, vigilance, conjugal fidelity, and filial and parental piety.

Black stork.—Brown; breast and belly white. Two feet nine inches long. Inhabits Europe and Asia. Feeds on fish and reptiles; is timid, and retires into thick woods and inaccessible spots.

D. Herons; middle claw inwardly serrated.

Gigantic heron.—Glaucous above; dirty white beneath; bill a little triangular. This is a large species, measuring from tip to tip of the wings, nearly 15 feet. The bill is of an enormous size, and 16 inches round at the base. The head and neck are naked, except a few straggling curled hairs. The feathers of the back and wings are of a bluish ash colour, and very stout; those of the breast long. The claw hangs down the fore part of the neck, like a pouch, thinly covered with down. The belly is covered with a dirty white down, and the upper part of the back and shoulders surrounded with the same. The legs and about half of the thighs are naked, and the naked parts are full three feet in length. The gigantic heron inhabits Bengal, and is sometimes found on the coast of Guinea. It arrives in the interior parts of Bengal before the period of the rains, and retires as soon as the dry season commences. Though its aspect is far from inviting, it is one of the most useful birds of these countries, in clearing them of snakes and noxious reptiles and insects. They sometimes feed on fish; and one of them will generally devour as much as would serve four men. On opening the body of an individual of this species, a land tortoise, 10 inches long, and a large black cat, were found entire within it, the former in the pouch and the latter in its stomach. Being, un daunted at the sight of mankind, they are soon rendered familiar; and when fish or other food is thrown to them they catch it very nimbly, and immediately swallow it entire. A young bird of this kind, about five feet in height, was brought up tame, and presented to the chief of the Bananas, where Mr Smeathman lived. It regularly attended the hall at dinner time, placing itself behind its master's chair, frequently before any of the guests entered. The servants were obliged to watch it carefully, and to defend the provisions by beating it off with sticks: yet notwithstanding every precaution, it would frequently snatch off something from the table, and one day purloined a whole boiled fowl, which it swallowed in an instant. It used to fly about the island, and roost very high among the silk cotton trees; from this station, at the distance of two or three miles, it could see when the dinner was carried across the court; when darting down, it would arrive early enough to enter with some of those who carried in the dishes. When sitting, it was observed always to rest itself on the whole length of the hind part of the leg. Sometimes it would stand in the room for half an hour after dinner, turning its head alternately as if listening to the conversation. These birds are found in companies, and when seen at a distance, near the mouths of rivers, advancing towards an observer, it is said that they may be easily mistaken for canoes on the surface of a smooth sea, and when on the sand banks, for men and women picking up shell-fish on the beach.—From their immense gape, they have obtained the name of large throats, and from their swallowing bones, that of bone eaters or bone takers.

Night heron.—Crest on the hind head white, horizontal, of three feathers; back black; belly yellowish. The female has the head smooth and brown; belly brownish and white beneath; and the first quill feathers with a white spot at the tip. About 20 inches long. Inhabits Europe, Asia, and America. Only one instance occurs of its having been met with in England. It is pretty common in Russia, particularly on the Don, where it builds in trees, and is also met with at Astrakan during summer. It is said to lay three or four white eggs, and sometimes to build among the rocks. It has a very uncouth and rough voice, like that of a person straining to romit.

Crested purple heron.—Hind head black; crest pendant, and composed of two long feathers; body olive above, purplish beneath. Two feet 10 inches long. Inhabits Asia.

African heron.—Crested; body cinereous; neck, breast and belly, ferruginous; chin white; neck with three black lines; bill and legs yellow; crest of three long feathers; feathers of the breast and rump mixed with ferruginous; a broad black line from the nape to the back, and another on each of the sides. About three feet long; and smaller than the common heron. Inhabits Asia and Africa, and has been twice found in England.

Common heron.—Hind head with a pendent crest; neck body ash coloured; line on the neck beneath and pectoral bar black. The female has the hind head smooth and black; back bluish and whitish beneath; and the
ORNITHOLOGY.

Blue heron.—Hind head crested; body blue; bill and lore green; legs green. In the female, the head and neck are dusky purple; the chin and middle of the throat white, and the back lead colour. There is a subcrested variety blue green, with the chin and throat white. Another is varied with brown, yellow, and cinereous; steel black above; white beneath; and wings and tail greenish. From to 18 inches long. Inhabits America. Found in Carolina in spring, and in Jamaica, and other islands of the West Indies, in winter. It has also been met with at Otahite, and other islands of the South seas, where it is much respected.

Squacco heron.—Ferruginous; white beneath; hind Comast. head with a long white pendent crest, edged with black. About 1.5 inches long. Inhabits Europe and Asia. A white variety, with a smooth head, the upper part, crown, breast, and back reddish, and which inhabits Coromandel. Has been once shot in England.

Bittern; in provincial English, bitter, bumpy cost, butler, butter bump, and miredrum. —Head smoothshiny; body testaceous, with a transverse band, paler beneath, with oblong brown spots. About two feet and a half long. Inhabits Europe, Asia, and America, affecting the more temperate regions in winter, and migrating northwards in summer. Though not a plentiful species in Britain, it is occasionally found in the breeding season, in the less frequented reedy marshes, and swampy moors, well clothed with rushes, where it forms a nest on some stumps, by collecting sedges or other coarse plants together. It lays four or five eggs of a light olive green colour, inclining to cinereous. At this season the male makes a singular bellowing noise, vulgarly supposed to be produced by the bird putting his bill into a reed. It is with difficulty roused from its lurking place, flies heavily, and frequently lights again at a small distance, so that it becomes an easy prey to the sportsman. About sunset, it sometimes soars to a great height in the air, with a spiral ascent, making at the same time a loud and singular noise. Its flesh is accounted a delicacy.

Greater bittern.—Head smoothshiny, black; body cinereous brown above; rufous beneath; lore and naked orbits yellow; throat white, streaked with black and reddish. Three feet nine inches long. Inhabits Italy.

Great white heron.—Head smooth; body white; bill tawney; legs black; bill six inches long; irides yellowish; lore green. Three feet six inches long. Inhabitants Europe, Asia, and America. Is rare in England.

Watteled heron.—Back, wings, legs and crown black—Cariocula blue; smooth head and neck white; body black beneath; bill and chin carunculated. Five feet long. Inhabitants Africa.

Minute bittern.—Smooth head and upper part of the body reddish-bay; white beneath; sides of the neck rufous; wings and tail black. Twelve feet and a half long. Inhabitants Jamaica.

Little bittern.—(Male). Head smooth; body brown; Minula. reddish beneath; tail feathers greenish black; lore yellowish; (Female). Body brown, edged with the feathers reddish; reddish beneath; crown, back, wings and tail black; bill yellow green; naked part of the face yellow; irides saffron; legs green brown. This beautiful species is scarcely larger than a fieldfare, and about inches long, from the tip of the bill to the end of the tail. The female lays four or five white eggs, of the size of those of the blackbird, and which are placed on a

breast with oblong black spots. Bill dusky; base yellowish beneath; area of the eyes naked and greenish; irides yellow; temples black; front, crown, and neck, white above; spurious wings and greater quill feathers black; scapulars and feathers of the throat long, lax, and narrow; body white beneath; legs dirty green. The weight of this species is about three pounds and a half; and the length about three feet four inches. Inhabits almost every where in fenny places, and is common in England. It is a great destroyer both of sea and fresh water fish, being enabled by the great length of its legs, to wade into some depth of water, where it stands motionless, till some of the finny tribe approach, when it darts its bill into them in an instant. Its digestion being as quick as its appetite is voracious, it commits great devastation in ponds and shallow waters. It will likewise eat frogs and vegetables. They are frequently observed to feed by moon light, when the fish come into the shoaler waters. In the breeding season, herons are gregarious, and make their nests very near one another. Permain mentions having seen eighty nests on one tree, and Mr. Montagu once saw a heronry on a small island in a lake, in the north of Scotland, on which there was but a single scabby oak, which not being sufficient to contain all the nests, many were placed on the ground. The nest is large and flat, made of sticks lined with wool and other soft materials. The eggs are four or five in number, of a greenish-blue, and about the size of those of a duck. Heronries were much prized in the days of falconry, and some are yet to be seen in several parts of the kingdom. In flying, this species hides its head between its shoulders, and its legs hang down. When it flies very high it presages a storm. If taken young, these birds may be tamed: but when the old birds are captured, they soon pine away, refusing every kind of nourishment. The body is very small and always lean, and the skin is scarcely thicker than membrane used by the gold beaters. Linen has made the two sexes indistinguishable, species, and others were long of the same opinion: but later observations have corrected the mistake.

Egret, or little egret.—Hind head crested; body black; bill black; lore and legs greenish; irides yellowish; crest consisting of some short, and two long feathers; face naked and green; claws black. Nearly a foot long, and weighs one pound. Inhabitants marshy places, in temperate regions, in the four quarters of the world. If we may judge from the bill of fare of the famous feast given by the archbishop Nevil, these birds were formerly plentiful in England; for no fewer than 1,000 were in that list. It is, however, now become a very rare bird in this kingdom. Its plumage were formerly used to decorate the helmets of warriors, but are now applied to ornament the head dresses of European ladies, and the turbans of the Persians and Turks. Its habits are analogous to those of the common heron.

Great egret.—Somewhat crested, white; legs black; feathers of the back and breast lax, narrow and very long. About two feet long. Inhabitants South America. Is shy and solitary, lying hid among the tall reeds, and feeding by night.

Great heron.—Hind head crested; body brown; thighs rufous; breast with oblong black spots. Above five feet long. Inhabits the lakes and rivers of Virginia, and feeds on lizards, frogs, and fish.
ORNITHOLOGY.

Gralle. — a few dried flags on the ground. Inhabits Europe and Asia, but is rare in England.

E. Bill gaping in the middle.

Pondherry heron.—Gray-ash; quill feathers long and black; middle claw not serrated; bill yellow, thick at the base, pointed at the tip, and a little bent in, gaping in the middle; space between the bill and eyes feathered; legs yellow. Fourteen inches and a half long. Inhabits India.

Coromandel heron.—White; back, wings and tail black; upper mandible serrated from the middle to the tip; bill yellow, thick at the base, and pointed at the tip; legs reddish-yellow; upper part of the head with black lines; lores and chin naked and black; irides red; toes connected at the base. Inhabits Coromandel, and feeds on fish and reptiles.

Scelopascus.—Brown; throat and breast streaked with white; chin and legs white; wings and tail copper-colour. Twenty-five inches long. Inhabits Cayenne.

Tantulus. — Gen. 52. Tantulus; ibis.

Character. — Bill long, subulated, roundish, somewhat arched; face naked; tongue short and broad; jugular pouch naked; nostrils oval; feet four-toed and palmed at the base.

Locatellus. — Wood ibis. — Face bluish; bill reddish; legs, quill and tail feathers black; body white; bill nine inches long, yellowish-brown; irides reddish. The male has the head and neck naked, wrinkled and black-blue; and the female has the neck gray and downy. Three feet long. Inhabits New Holland and the warmer parts of America. Is stupid and slow in flight, sitting on trees, and feeding on herbs, seeds, fruits, fish, and reptiles. The flesh is good. Of this species there are two varieties, the first having the head and neck white, blushed with yellow, the body black, and belly cinereous; and the second distinguished by white wing-coverts, with a black blotch in the middle.

Ignatius. — Head and neck black; legs green; body varied with glossy-blue, blackish, green and claret; dark rufous beneath; quill and tail feathers green-gold; bill green. Thirteen inches and a half long. Inhabits Russia, and was once shot in Cornwall.

Niger. — Black ibis. — Face, bill, and legs reds; body black.

Egyptian ibis. — Face red; bill pale yellow; quill feathers black; body reddish-white. This is a large bird, somewhat exceeding the stork, and measures from 30 to 40 inches in length. The bill is seven inches long, the colour yellow, growing reddish towards the tip, slightly curved, and ending in a blunt point. The fore part of the head, all round as far as the eyes, is naked and reddish. The skin under the throat, is also bare and dilatable; the plumage reddish white, most inclining to red on the head, wings; bills and tail black; the legs long; and the thighs bare for three parts of their length. Hasselquist adds that the irides are whitish, and the end of the bill and the legs black; and that it is found in Lower Egypt, in great plenty, in places just freed from the inundations of the Nile. It lives on frogs and insects, and is seen in gardens morning and evening, and sometimes so abundantly, that whole palm trees are covered with them. When at rest they sit quite erect, their tail touching their legs. The same author believes it to be the ibis of the ancients; first, because it is common in, and peculiar to Egypt; secondly, as it eats serpents; and, thirdly, because the urns which contain the remains of embalmed birds, found in the sepulchres along with the mummies, seem to contain birds of this size. Its figure represented Egypt, in the hieroglyphic writing of its inhabitants. In that country it is still called Pharaoh's bird, and builds in the palm trees.

Scarlet ibis. — Face, bill and legs red; body scarlet; irides wings tint with black. Twenty-one inches long. Inhabits South America. Sits on trees, but lays its greenish eggs on the ground. The young are at first black, then gray, whitish just before they fly, and afterwards grow, gradually red.

White ibis. — This species is 22 inches long, and about 8 inches, the size of the whimbrel; the face, bill and feet reddish; body white; tips of the wings green; the male and female nearly alike. Native of Brazil, but towards the end of summer migrates to the north, and is found in great numbers in the marshy lands of Carolina, feeding on fish and aquatic insects. Here they remain for about six weeks: the fat and flesh of the white ibis are said to be of a saffron-colour, but though not much esteemed, is sometimes eaten.

Character. — Bill short, straight, toothless; thighs longer than the body; feet four-toed, palmed; hind toe unconnected.

Italian courrier. — Ferruginous above; white beneath; bill two middle tail feathers white, tip with black; bill pale yellow, black at the end, with a large gap; irides a double circle of bay and white. Less than the curlew. Inhabits Italy, and runs swiftly.

Scolopax. — Gen. 54. Scolopax.

Bill roundish, obtuse, and longer than the head; nostril linear; face covered with feathers; feet four-toed; hind toe consisting of many joints.

The birds of this and of the succeeding genus are with difficulty ascertained, being subject to differ in appearance from sex and age, and their colours shading into one another. The markings of their feet, however, are pretty constant, and therefore afford one of the best criteria.

Pigmy curlew. — Arched bill, and legs black; body varied with ferruginous, brown, and white; beak beneath; rump white; quill and outer tail feathers edged with white. Size of a lark. Inhabits Europe, and is very rare in England.

Common curlew. — Bill arched, blackish; legs bluish; wings blackish, with snowy spots; lower mandible reddish at the base; body above, and breast, streaked with dusky brown; chin, rump, belly, and vent, white; quill feathers black, spotted with white within; legs bluish; toes flat and broad. This species is subject to vary considerably in size, weighing from 20 to upwards of 30 ounces; the length of the largest being about 25 inches. Inhabits the moist and fenny places of Europe, Asia, and Africa. A rufous and black variety, with a smaller body, and longer bill, occurs in America. The curlew
ORNITHOLOGY.

Carul. - Carul is common on most of our coasts, in winter, when it is gregarious, and feeds on small crabs, and other marine insects and worms. In the spring it retires inland, and commonly to the more northern parts of the kingdom, to breed, resorting to the most retired situations on the heath-covered mountains, or in extensive and unfrequented marshes. It makes no nest; but deposits among the heath, rushes, or long grass, four eggs, of a pale olive colour, marked with brownish spots. The young make use of their legs as soon as they are hatched, but cannot fly for a considerable time. The flesh of this species is eatable, but is best in summer, when the bird feeds on frogs, worms, and water insects. In winter it is rank and fishy.

519. Phoebus. - Bill arched, and black; legs bluish; back with rhomboid brown spots; rump white; lower mandible reddish at the base; body above, and breast brownish, with dusky brown streaks; chin, rump, belly, and vent, white; tail brown, with dusky bars; quill feathers black, spotted with white on the inside. About the same size as the preceding; but agreeing with it in appearance and habits. It is also more scarce in this country.

400. Nigra. - Black snipe. - Bill and legs red; body black. Inhabits the islands between Northern Asia and America.

Nodding snipe. - Bill black; legs greenish; body cinereous; crown and upper part of the back dusky red; and streaked; the lower white, spotted with black. Size of the common snipe. Inhabits Labrador, and is constantly nodding the head.

453. Reticula. - Woodcock. - Bill straight, reddish at the base; legs cinereous; thighs covered; head, with a black band on each side; upper mandible longer, reddish at the base; front cinereous; lower eyelid white; crown, neck above, back, and wing-coverts, ferruginous, mixed with black and gray; chin pale ash; throat yellowish, with small dusky spots; body whitish beneath, with dusky lines; quill feathers dusky, with triangular fuscous spots; tail rounded, cinereous at the tip; legs brownish. Length 13 inches; weight from 12 to 15 ounces. This is known as the woodcock, and is a species of woodcock, and inhabits the northern countries of Europe, Asia, and Africa, migrating in winter to the more temperate regions. In Britain it seldom appears in numbers till about the middle of November; but some occasionally appear as early as the latter end of September, or beginning of October. They generally come to us with northerly or easterly winds, when the more northern countries become frozen; and if the frost in those parts where they breed is suddenly severe, large flocks are sometimes met with on our coasts, where they remain for a day, to recruit their strength, and then disperse. In England they are not so plentiful as formerly, when the art of shooting flying was less practised. A great many, however, are yet to be found in the more uncultivated parts of Devonshire, Cornwall, and Wales, as well as in the north of Scotland; but they are nowhere so abundant as in the large tracts of woods in Ireland. In severe weather, they accumulate, from the moors and inland counties, to the woods in the west of England. It is one of the few winter birds that occasionally breed with us. It builds a nest of a few fibres, or dry leaves, on the ground, generally at the root of a tree, and lays four eggs, somewhat larger than those of a pigeon, of a yellowish white, spotted and botted with fuscous brown and ash colour. Its usual food is insects and worms, for which it bores with its bill into moist places, feeding principally at night, when its call resembles that of the snipe. In some countries the woodcock remains the whole year, only moving in the breeding season, from the plains to the mountains. In this country, it usually prepares for its departure about the middle of March, when flocks come down to the sea coast, and, if the wind is favourable, are soon out of sight; but if it be contrary, they linger till it change.

Little woodcock. - Bill straight; legs brownish; front cinereous; hind head black, with four transverse yellowish lines; chin white; body above black, waved with slight tawney; yellow beneath. Eleven inches and a half long. Inhabits America. Its flesh is reckoned exquisite.

Great snipe. - Legs and crown black, the latter with Majors, a pale divided line down the middle, a pale streak above, and beneath the eyes; body varied above, white beneath; bill like that of the woodcock; lower feathers of the body, except the middle of the belly, black; quill feathers dusky; tail feathers reddish, and, except the two middle ones, with black lines. Weighs about eight ounces; length 16 inches. Inhabits Siberia, and very rarely England.

545. Common snipe. - Bill straight, tuberculated; legs Gulligana, brown; body varied with blackish and tawney, white beneath; front with four brown lines; crown, bill,ocular band, and wings, black; chin pale rusty; tail-feathers black at the base; rump variegated. The weight of this species is about four ounces, and the length nearly 12 inches. It is met with in marshy situations, in almost every part of the world, and is very plentiful in our own island. In very wet times it resorts to the hills; but more generally frequents the marshes of the plains, where it can penetrate the earth with its bill, in quest of worms. Some few remain with us the whole year, and breed in the more extensive marshes and mountainous bogs. The nest is made of the materials around it, as coarse grass or heath, and placed on a dry spot, near a splash or swamp, under the eggs, like that of the lapwing, being much pointed, and invariably placed with their smaller ends inwards. In the breeding season the snipe changes its note entirely. The male will keep on the wing for an hour together, mounting like a lark, uttering a shrill piping noise, and then descend with great velocity, making a blowing sound, like that of an old goat, which is alternately repeated round the spot possessed by the female, especially while she is sitting on her nest. The young ones run off soon after they are freed from the shell; but they are attended by the parent birds, until their bills have acquired a sufficient firmness to enable them to provide for themselves. When undisturbed in its retreats, the snipe walks leisurely, with its head erect, and keeps moving the tail at short intervals. But it is rarely observed in this state of tranquillity, being extremely watchful, and perceiving the sportsman, or his dog, at a great distance, and either concealing itself among the variegated withered herbage, so similar in colour, edges to its own plumage, that it is almost impossible to discover it, or, as happens more frequently, springing and taking flight beyond the reach of the gun. When first disturbed it utters a kind of feeble whistle, and generally flies against the wind, turning nimbly in a zig-zag direction,
ORNITHOLOGY.

522

and sometimes soaring almost out of sight. From its vigilance and manner of flying, it is very difficult to shoot; but some sportsmen can draw it within range of their fowling-piece, by imitating its cries, and others are contented to catch it in the night by springers. The snipe is much esteemed as a delicious and well-flavoured dish; and though it is very fat, it rarely disagrees even with the weakest stomach.

546

Gallinula. _Swinhoei._—Bill black, flat, tuberculated; body variegated; legs greenish; lores brown; rump varied with olive; bill black; body variegated with testaceous, black, violet, and glossy green; head with pale yellow and black lines, reaching from the bill to the hind head; breast spotted; belly and vent white. Eight inches and a half long. Inhabits Europe, Asia, and America. Is found in the same places with the preceding, but is more solitary and rare. It will lie among quakes, or other thick covert, till in danger of being trampled on, and, when roused, seldom flies far. It comes to us later than the common snipe, and is never known to remain in this country during the breeding season. It is as much esteemed as the snipe, and is cooked in the same manner.

547

Gallinula. _Swinhoei._—Bill straight, the lower base red; body beneath snowy; legs greenish; bill black; the lower mandible bending a little upwards; eyelids and lower part of the back white; head, neck, and back, pale cinereous; shafts of the feathers spotted with brown; quill feathers dusky, spotted with white on the inside; tail white, with dusky lines; legs very long. Weight about six ounces; length four inches. Inhabits Europe, Asia, and America. Is sometimes seen, in small flocks, on our coasts, in winter; as also in the marshes and fens contiguous to the sea. Some few are supposed to remain with us all the summer, and to breed in our fens. The greater part, however, retire northward to breed, and are found in Sweden, Russia, and Siberia. Their flesh, like all the rest of this genus, is well flavoured, and reckoned good eating.

548

Gallinula. _Swinhoei._—Bill straight, red; legs scarlet; secondary quill feathers white; bill black towards the tip; irides reddish hazel; head and neck cinereous above; back and shoulders greenish-brown; wing-coverts cinereous, mixed with dusky and brown, and spotted with white; secondary quill feathers, except the two inner ones, white towards the tip; primary dusky, the four or five inner ones tipped with white; line over the eyes white; a dusky spot between the bill and eyes; short dusky streaks on the chin and throat; under part of the body and rump white, with small dusky spots; each of the tail feathers with 12 or 13 transverse black lines. Weighs about five ounces, and is 12 inches long. Inhabits Europe and America. Is not uncommon in some parts of England, residing the greater part of the year in the fen countries, where it breeds and rears its young. It lays four eggs, which are white, tinged with olive, and marked with irregular spots of black, chiefly on the thicker end. When disturbed it flies round its nest, making a noise like a lapwing. It is not so common on the sea shores as several of its congeners, and is of a solitary disposition, being mostly seen alone, or only in pairs.

549

Gallinula. _Swinhoei._—Blackish, with white spots; white beneath; hence on, the breast and bands on the lateral tail feathers blackish; legs red. Size of the greenshank. Inhabits Europe, frequented the banks of rivers, and feeding on the smaller shell-fish and other vermes. Seldom visits Britain.

Lesser godwit, jupiter's snipe, or stone plover.—Bill Linnaeus inclining a little upwards at the point, red at the base; body grey brown, varied with rufous; white beneath; quill feathers white at the base, the four first without spots; tail white at the base; sides whitish; cheeks reddish; back brown; quill feathers blackish; feathers round the bill reddish white. Seventeen inches long, and weighs nine ounces. Inhabits the north of Europe, and is gregarious; but seldom occurs in Britain.

Red godwit, or red-breasted godwit.—Bill a little recurved, yellowish; legs black; body reddish-nutty beneath; bill blackish at the tip; head, neck, breast and body, ferruginous above, and, except the neck, streaked with black; lower part of the back and rump rufous white; greater quill feathers black without, the base white within; secondary and tail feathers half black and half white. Weight about 12 ounces; length 18 inches. There is a variety with the head and neck cinereous, and the chin and belly white. Inhabits Europe and America, and is gregarious, but rarely seen with us.

Common or grey godwit.—Bill straight, reddish yellow; legs yellow; legs greenish; head and neck reddish; three of the quill feathers black, with a white base; a broad white streak from the bill to the eye; body reddish-brown above; feathers with a dusky spot in the middle. Subject to very considerable variety both in size and plumage. In general, it weighs from seven to twelve ounces, and measures from 1½ to 1½ inches. It inhabits Europe, Asia, and Africa; continues with us the whole year, and resorts to the fens in spring for breeding. In the winter it is found on our shores, particularly at the mouths of large rivers and inlets, where the mud and sand become bare at low water, and where it feeds on insects. It is much esteemed by epicures as a great delicacy, and sells very high. It is caught in nets, to which it is allured by a stole, or stuffed bird, in the same manner, and at the same season, as the rails and reeves.

Gallinula. _Linnaeus._—Brown, edged with whitish; neck whitish, with small brown spots; chin and belly white; quill feathers with black bands; bill a little turned up, brown, with a purple base; tail feathers white; the two middle ones wholly, the rest barred with brown on the outer side. Sixteen inches long. Inhabits Europe. Regarded by some ornithologists as only a variety of the argentea.

Cinereous godwit.—Legs long, cinereous; head, neck, and back varied with cinereous and white; chin and breast white, spotted with ash; bill thicker than in the greenshank; tail with cinereous lines. Size of the greenshank. Inhabits Lincolnshire; but is very rare, and seems to be imperfectly known.

Cambridge godwit.—Legs orange; bill red; body chestnut; brown ash above, white beneath; wing-coverts and tail feathers barred with black; lesser wing-coverts brown, edged with white and barred with black; quill feathers blackish, white within; the secondary barred with white. Larger than the redshank. Was shot near Cambridge, and first described by Pennant.

5
ORNITHOLOGY.

Gen. 55. Tringa, Sandpiper.

Characteristics.

The birds of this genus frequent the plains and shores, and hardly touch the ground with their back toe.

Ruff and reeve.—Bill and legs rufous; they lateral tail feathers without spots; face with flesh-coloured granulations; bill sometimes black or yellowish; irides hazel; back of the neck with a large tuft of feathers, which fall off in moulting season. Female pale brown; back spotted with black; tail brown; the middle feathers spotted with black; breast and belly white. The ruffs, or males, are so very variable in their markings, that two are seldom found alike. Buffon mentions that Klein compared above 100 ruffs together, and found only two that were similar. About one foot long. Inhabits Europe and Siberia. The male does not acquire the ornament of his neck till the second season, and, before that time, is not easily distinguished from the female, except by being larger. After moulting, at the end of June, he loses his ruff and the red tubercles of his face; and from that time, till the spring of the year, he again, in plumage, looks like his mate. These birds leave our island in the winter, and are then supposed to associate with other congeners of species. In the spring, as soon as they arrive again in England, and take up their abode in the fens where they were bred, each of the males (of which there appears to be a much greater number than of females) immediately fixes on a particular dry or grassy spot in the marsh, about which he runs round and round, until it is trodden bare, wishing, apparently, to invite the female to take joint possession, and become an inmate. As soon as a single female arrives, and is heard or observed by the males, her feeble cry seems to rouse them all to war; for they instantly begin to fight; and their combats are described as being both desperate and of long continuance, the female, at the end of the battle, remaining the prize of the victor. It is at the time of these battles, that they are caught in the greatest numbers in the nets of the fowlers. They are also at other times caught by dry nets, and are drawn together by means of a stuffed reeve, which is placed in some suitable spot for that purpose. The ruff is much prized as a delicious dish, and is sought after with great eagerness by the fowlers who live by catching them and other fowl birds, for the markets of the metropolis, &c. Before they are offered for sale, they are commonly put up to feed, for about a fortnight, on boiled wheat, and bread and milk, mixed with hemp-seed, to which sugar is sometimes added; in consequence of which mode of treatment they soon get very fat. In the beginning of May the female makes her nest in a dry tuft of grass, in the fens, and lays four white eggs, marked with rust spots.

Lapwing, petic, bastard plower, &c.—Legs red; crest pendent; breast black; bill black; irides hazel; crown shining black; crest on the hind head four inches long; cheeks and sides of the neck white; a black line beneath each eye; throat black; hind part of the neck mixed with white, ash-colour, and red; back and scapulars glossy green; some of the feathers with ferruginous tips; lesser wing-cover shining black, blue, and green; greater quill feathers black, the four first with a white spot at the end; lesser black on the upper half, white on the lower; belly white; vent and tail coverts orange; outer tail feathers white; the rest on the lower half black, tippets with dirty white; upper white. Weights between seven and eight ounces. Is found in most parts of Europe, as far north as Iceland; and in the winter is met with in Persia and Egypt. The chief food of the lapwings is worms, and sometimes they form flocks nearly over the low marshy grounds in search of these, which they draw with great dexterity from their holes. When the bird meets with one of those rolls of earth that are thrown out by the perforations of the worm, it first gently removes the mould from the mouth of the hole, then strikes the ground at the side with its foot, and steadily and attentively waits the issue; while the reptile, alarmed by the shock, emerges from its retreat, and is instantly seized. In the evening, the lapwings pursue a different plan, running along the grass, and feeling under their feet the worms, which now come forth, invited by the coolness of the air. They thus obtain a plentiful meal, and afterwards wash their bill and feet in the small pools or rivulets. They remain in this country the whole year. The female lays four olive-coloured eggs, spotted with black, on the dry ground, near some marsh, on a little bed of dry grass which she prepares. She sits about three weeks, and the young are able to run within two or three days after they are hatched. The parent exhibits the greatest attachment to them, and has recourse to every pleasing artifice to allure boys and dogs from approaching them. In place of waiting the arrival of the enemies at the nest, she boldly pushes out to meet them. When as near as she dare venture, she rises from the ground with a loud screaming voice, as if just flushed from butching, though, probably, at the same time, not within 100 yards of her nest. She then flies with great clamour and apparent anxiety, whining and screaming round the invaders, striking at them with her wings, and sometimes fluttering as if she was wounded. To complete the deception, she becomes still more clamorous as she retires from the nest. If very near, she appears altogether unconcerned; and her cries cease in proportion as her fears are increased. When approached by dogs, she flies heavily, at a little distance before them as if maimed, still clamorous and bold, but never offering to move towards the quarter where her young are stationed. The dogs pursue, in expectation every moment of seizing the parent, and by this means actually lose the young; for the cunning bird, having thus drawn them off to a proper distance, exerts her powers, and leaves her astonished pursuers to gaze at the rapidity of her flight. These birds, when tamed, clear gardens of worms and snails. Their flesh and eggs are both reckoned delicacies for the table. In winter they join in large flocks, but are then very shy.

Gamet, gamet sandpiper, or red-legged horseman.—Gametes.

Bill and legs red; body variegated with pale yellow, and cinereous; white beneath; bill tippet with black; irides yellowish green; wing-coverts and scapulars cinereous, and edged with yellow; first quill and tail feathers dusky, the latter edged with yellow. About the size of the greenshank. Inhabits the northern parts of Europe and America, but seldom occurs in France or England.
ORNITHOLOGY.

Welsh sandpiper.—Blackish-ash; chin and middle of the belly white; base of the bill and legs red. Eight inches and a half long. Habits Glamorganshire and Caermarthenshire.

Turnstone, Hebridalsandpiper, or sea-dotterel.—Legs red; body black, varied with white, and ferruginous; breast and belly white; bill black, a little turned up at the tip; cheeks and neck black above; tail black in the middle, and white at the ends. Female more dusky; head varied with brown and whitish; neck blackish above. Though these are the usual characteristics, the sub-species vary a great deal. About the size of a thrush; length nine inches and a half, and weight rather more than four ounces. Habits the sea coasts of Europe and America. Though not known to breed with us, it visits some of our shores in August, and departs in spring. The name has been given it from its manner of turning up the stones in search of worms and marine insects. It makes a slight nest on the dry ground or sand, and lays four olive-coloured eggs, spotted with black. This species is not uncommon in the north of Scotland.

Striated sandpiper.—Base of the bill and legs yellow; tail feathers white, barred with brown; most of the quill feathers white. Nearly 11 inches long. Habits Europe and North America. Feeds on shell-fish and mollusca, which it searches for at the ebb of the tides, and on insects which it catches, hanging over the water like a swallow.

Spotted sandpiper.—Base of the bill and legs flesh colour; all the body spotted; eye-brows and double band on the wings white; bill dusky; body above greenish-brown, white, with dusky spots beneath; two middle tail feathers greenish-brown, the rest white, with dusky lines. Female without spots beneath. About the size of a thrush, and eight inches long. Habits Europe and North America; is migratory, and is sometimes, though rarely, found in Britain.

Ash-coloured sandpiper.—Cinereous above, white beneath; legs dusky green; head spotted with black; neck with dusky streaks; back and wing-coverts with concentric black semicircles, varied with cinereous and white; tail coverts black and white; tail cinereous, edged with white; breast spotted with black; membrane surrounding the toes narrow and toothed. Length about 10 inches; weight from four ounces and a quarter to five and three quarters. This species, like most of the tribe, is subject to considerable variety. It inhabits Europe and America; visits some parts of our coasts, in large flocks, in winter, and departs about the latter end of March or beginning of April.

Brown sandpiper.—Pale brown, spotted with black above, white beneath; fore part of the neck streaked with black; tail cinereous; wing-coverts edged with whitish; bill and legs black. Size of a jack-snipe. Habits England, but is very scarce.

Black sandpiper.—White, varied with gray and brown spots above, with olbrown and black spots beneath; two middle tail feathers all black. Size of a thrush. Habits England, chiefly in Lincolnshire.

Gray phalarope, or great coot-footed tringa.—Bill subulate, and bent in at the tip; tail pinnate; breast waved with white; bill black; front white; crown dull; neck pale ash above; back, rump, and shoulders dove-colour, with dusky spots; wing-coverts and quill feathers brown; breast and belly white; tail dusky, edged with cinereous; legs black; membrane round the toes indented. Size of the common prure; weight one ounce. Habits Europe, Asia, and America. Congregates about the borders of the Caspian sea, and is not common in Britain. In stormy weather, it swims in numbers on lakes; but in fine weather, is solitary along the fens.

Red phalarope, or cock coot-footed tringa.—Bill subulate. Hypo- lighted, bent in at the tip; feet pinnate; breast cinerea, sides of the neck ferrugious; bill black; band through the eyes blackish; bill above the wings white; rump with blackish bands. The female is gray above, rufous beneath, with the eye-brows and base of the tail reddish, and the rump white; bill yellowish; band above the eyes reddish; bar on the wings white, and the rump spotted with blackish. Eight inches long. Habits northern Europe and America; but is rarely met with in our own country. These birds go in pairs, and catch insects in the water with their bill. They do not dive, and are but bad swimmers. The female makes her nest on dry ground, and lays four eggs.

Alpine sandpiper, or dunlin.—Brown testaceous; breast blackish; tail feathers whitish-ash; legs brownish; belly white; two middle tail-feathers a little longer. Weights from nine to eleven drams; length of the largest eight inches. Habits Europe, Asia, and America, and is not uncommon on our coasts during great part of the year. The female lays four eggs, of a dirty white, blotched with brown round the thicker end, and marked with a few small spots of the same colour on the smaller end.

Green or wood sandpiper.—Bill dotted at the tip; eye-brows legs greenish; back brown; green belly and outer tail feathers white; bill greenish; crown and hind head dusky ash; rump variegated; eye-brows white. Habits Europe, North America, and Siberia. This elegant species weighs about three ounces and a quarter; length full 10 inches. It is by no means plentiful in Britain, and, except in pairing time, lives solitary. It is never seen near the sea; but frequents rivers, lakes, and other fresh waters. It runs on the shores, or skims the surface of the water. It utters a cry as it rises, and sometimes dives when pursued by the buzzard. It feeds on the fry of small fishes and worms. Though its flesh tastes somewhat of musk, it is considered as a great delicacy. It comes to us about the middle of September, and leaves us as late as the end of April, when it departs northward to breed.

Shore sandpiper.—Smooth bill, and legs cinereous; Littleness feathers brown, the shaft of the first snowy. Near 11 inches long. Habits Europe; and is ranked by some ornithologists among British birds.

Greenshinch sandpiper.—Body varied above; neck cinereous beneath; belly, vent, and sides of the rump white; bill black; legs greenish; crown brown, streaked with black; neck ash-coloured beneath; back and wing-coverts brown ferruginous, edged with whiteness; hind part of the back, rump, and lesser wing-coverts cinereous; tail cinereous, the feathers waved towards the tip, which is pale rusty. Size of the preceding, but very rare. The circumstance of one having been shot near Greenwich, has given rise to the trivial name.

Sea or selinger sandpiper.—Varied above with gray Maritima and black, white beneath; legs yellow; middle of the back
ORNITHOLOGY.

523

Gralla.

back violet; throat and tail dusky; four outer tail feathers very short, and edged with white. Size of a star. Inhabits Norway and Iceland. A small flock of this species, consisting of 10 or 12, was once observed, several years ago, near Beshill, on the 8th of December.

Common sandpiper.—Bill smooth; legs livid; body cincereous, with black stripes, white beneath; bill brown; irides hazel; head brown, with black streaks; eyes brown; neck cinereous above; back and wings greenish-brown, with numerous, narrow, dusky lines; quill feathers brown, and, except the first, with a white spot within; tail rounded, and glossy-green brown. Weight about two ounces; length seven inches and a half. Inhabits Europe and America. Visits this country in the spring, chiefly frequenting our lakes and rivers, on the borders of which it makes a nest composed of moss and dried leaves, and most commonly placed in a hole in the bank. It lays four or five eggs of a dirty white, marked with dusky and cinereous spots, mostly at the larger end. When disturbed, it makes a piping noise as it flies; and, when running on the ground, the tail is constantly in motion. In autumn it is liable to be much infested with the hippobosca kirvinitis.

Knot.—Bill long; legs hazel colour; primary quill feathers serrated; outermost tail feather white, without spots; bill dusky ash; irides hazel; lores dusky; eye-brows and band on the wings white; body cinereous, white beneath; lower wing-coverts tip with white; chin and breast with minute spots; belly and vent with dusky lines; rump with brown semicircles. Nine inches long, and weighs four ounces and a half. Inhabits Europe and America. In Lincolnshire, and the other fenny districts of England, it is caught, in great numbers, by nets, into which it is decoyed by carved wooden figures to represent itself. It is also fattened for sale, and esteemed by many equal to the ruff in the delicacy of its flavour. The season for taking it is from August to November, after which the frost compels it to disappear. This bird is said to have been a favourite dish with Canute king of England; and Camden remarks that its name is derived from his.

Sint, purre, or sandinger.—Bill and legs black; lores white; body and rump grey and brown; head and neck cincereous above, with brown streaks; back and wing-coverts brownish, the greater tips with white; throat white, mixed with brown; breast and belly white; two middle tail feathers more dusky, the rest edged with white: the legs are sometimes brown. The country people frequently call it ox-bird, ox-eye, least snipe, sea-lark, or wagtail. It is nearly eight inches in length, and weighs about an ounce and three quarters. Inhabits Europe, Asia, and America. During winter it is found on all our coasts, appearing in vast flocks, and especially affecting the flat sandy shores and inlets. They leave us in April, though it is suspected that some remain with us all the year. These birds run nimbly near the edges of the flowing and retiring waves, and are almost perpetually wagging their tails, while they are, at the same time, busily employed in picking up their food, which consists chiefly of small worms and insects. On taking flight, they give a kind of scream, and skim along the surface of the water with great rapidity, as well as with great regularity, not flying directly forward, but performing their evolutions in large semicircles, alternately approaching the shore and the sea in their sweep, the curvature of their course being indicated by the flocks appearing suddenly and alternately in a dark or in a snowy white colour, as their backs or their bellies are turned to or from the spectator.

Little sandpiper.—Bill and legs brown; body reddish, beneath; outer tail feathers with a white shaft; rump variegated; bill tipt with black; greater wing-coverts and quill feathers brown, tipt with white; tail dusky; breast and belly white. About the size of a hedge-sparrow, and between five and six inches long. Inhabits Northern Europe and Nootka Sound; and has been once or twice killed in England.

Gray sandpiper.—Bill black; legs greenish; body squataropa. gray, white beneath; head, back, and wing-coverts, edged with greenish-ash; cheeks and chin with oblong dusky spots, and with the belly and rump white; tail barred with black and white. Weight about 7 ounces; length 12 inches. Inhabits Europe and America. Is not plentiful on our shores, seldom more than six or seven being seen in a flock, and all of them retiring northward to breed. In Siberia and Carolina, it is said to be found in great flocks.

Red or Aberdeen sandpiper.—Bill and legs brown; body ferruginous beneath; secondary quill feathers edged with white; body thickly sprinkled with black, and ferruginous above; wing-coverts white on the outer edge; rump and vent whitish, the former waved with black, and the latter with a few black streaks; quill feathers black, with white shafts; tail feathers cinereous, with white shafts. From eight to ten inches long. Inhabits the north of Europe and America. Sometimes appears in great flocks on the coasts of Essex and the north of Scotland. In summer it frequents the neighbourhood of the Caspian sea, and also the river Don. It is perpetually running up and down on the sandy banks, picking up insects and small worms, on which it feeds.

Gen. 56. CHARADRIUS, Plover.

Bill roundish, obtuse, straight; nostrils linear; feet formed for running, three-toed.

The birds of this genus frequent the mouths of rivers, and the neighbourhood of torrents, and seem to enjoy rainy weather. From this last circumstance is derived their French name pluvier, and the English plover.

Ring plover, ring dotterel, or sea lark.—Breast black; front blackish, with a white band; crown brown; legs yellow; upper half of the bill orange, lower black; irides hazel; body gray-brown above, white beneath; eggs bluish-white, with small round purplish spots. Of this species there is also a gray variety, with the collar and belly white; and another gray-ash, with the front and collar white, and the lower half of the tail black, tipt with rusty; the former inhabiting Spain, and the latter America. The more common sort is a native of both Europe and America, and is a well known visitant of our shores in summer; usually arriving in spring, and migrating in autumn, or at least retiring to the more inland parts of the country. It weighs about two ounces, and is between seven and eight inches long. It pairs early in May, and makes no nest, but lays four eggs in a small cavity in the sand, just above high tide. They are of a cinereous brown, marked all over with small black and ash-coloured spots. It is to be remar-
ORNITHOLOGY.

D'Orville, that these and other birds which lay invariably only four eggs on the ground, place them so as to occupy the least possible space, that is, with the small ends touching each other as a centre. The ringed plover is greatly attached to its young, and will practise various deceptions to save them from men and dogs; sometimes fluttering along the ground as if crippled, and sometimes seeming to tumble head over heels repeatedly, till it has enticed its enemy from a distance from its young, and then it flies off.

Noisy plover.—Bands on the breast, neck, front, and cheeks white; tail pale yellow, with a black bar; legs yellow. Between nine and ten inches long. Inhabits America. Is very restless and clamorous.

Dotterel.—Breast ferruginous; band over the eyes, and line on the breast white; legs black; bill black, depressed in the middle; front mixed with dusky and gray; hind head black, temples and chin white; upper part of the neck, back and wings, grey-brown; line across the breast white; middle of the belly black, red-brown above; greater quill feathers brown, and some of them edged with white; tail olive brown, with a dusky band near the end, and tip with white. The female is distinguished by a dusky band over the eyes, and brown crown. The crown of this species is sometimes varied with white, gray-brown, and yellowish; the body beneath yellowish, mixed with white; the two middle tail feathers brown, and the lateral ones white. Weight between four and five ounces; length nearly 10 inches. Inhabits Europe, and makes this island a resting station in its migratory flights to and from its breeding place. It is seen on some of our downs, heaths, and moors, from April to the beginning of June; returns again in September, and remains till November. On the Wiltshire downs, it resorts to the new sown corn or fallow-ground, for the sake of worms and beetles, its principal food. In the autumn it flies in flocks of five, six, or more. It is a stupid bird, and easily shot, but much esteemed for the delicacy of its flesh.

Long-legged plover, or long shanks.—White; back and rump black; bill black, longer than the head; legs red, and very long; bill black, slender, tapering to a sharp point; the upper mandible a little longer than, and bent over, the lower; irides red; neck dusky spots above. There is a variety with white and black wings, and the tail feathers white. This extraordinary species is certainly the longest legged bird, in proportion to its bulk, hitherto known; the length from the apex of the bill to the end of the tail being thirteen inches, and from that to the end of the toes, five inches more. It is rare in Britain, and in many parts of Europe, so that its manners are very imperfectly known. According to Latham, it is common in Egypt, being found there in the marshes in October. Its food is said to consist principally of fish. It is likewise plentiful about the salt lakes, and often seen on the shores of the Caspian sea, as well as by the rivers which empty themselves into it, and in the southern deserts of Independent Tartary. It is also often met with in the winter parts of America, and sometimes in Jamaica.

Bill depressed, subulated, recurved, pointed, flexible at the tip; feet palmed, four-toed, hind toe not connected, very short, and placed high up; nostrils narrow, pervious; tongue short.

Of this singular genus there are only three species, of which the first inhabits Europe.

Scooping avocet.—In provincial English, butter-lip, scooper, yelper, picornini, crooked bill, cobler's awl, &c. Variegated with white and black; bill three inches and a half long; irides hazel; crown black, a white spot behind and beneath the eyes; rest of the head, neck, back, exterior part of the wings, lesser quill feathers, tail, and under part of the body white; inner scapulars, and greater quill feathers without and at the tips black, legs bluish, and very long membrane connecting the toes indented. Resides in the neater parts of Europe, weighing thirteen ounces, and measuring, from the tip of the bill to the end of the tail, eighteen inches. It breeds in the fens of Lincolnshire, and on Romney Marsh, in Kent. The female lays two white eggs, tinged with green, and marked with large black spots. In winter these birds assemble in small flocks of six or seven, and frequent the shores, particularly the mouths of large rivers in search of worms and marine insects, which they scoop out of the mud or sand. They seem to be particularly fond of the cancer pilaeus, or locusta. By means of their long legs, they run over shores that are covered five or six inches with water. In their movements they are lively, alert, volatile, and difficult to catch. When the female is frightened off her nest, she counterfeits lameness; and, when a flock is disturbed, they fly with their necks stretched out, and their legs extended behind, over the head of the spectator, making a shrill noise, and uttering a yelping cry of tu-tu, tu-tu, all the time.

American avocet.—Head and neck reddish; back, black; white beneath. Fourteen inches long. Inhabits North America and New Holland.

White avocet.—White; lower wing covert brownish; bill orange; legs brown. Fourteen inches and a half long. Inhabits Hudson's bay.

Bill compressed, the tip an equal wedge; nostrils linear; tongue a third part as long as the bill; feet formed for running, three toed, left.

Sea pie, or pied oyster-catcher.—Bill, eyelids, and legs Orinova-red, the former sometimes tipt with black; irides scarlet; body sometimes totally black; frequently the head, neck, and body above black; white beneath; a small white spot under the eyes; breast with a white semicircular band; middle wing covert at the tips, and greater, entirely white; quill feathers spotted with white on the inside; tail from the middle to the base white, lower half black; claws black. Weight seventeen ounces, length sixteen inches. Inhabits almost every sea shore, but seems never to quit the coast. Congregates in small flocks in winter, and chiefly subsists on marine insects.
ORNITHOLOGY.

Glanis. sects and shell-fish, especially on oysters, which it seize
with great adroitness. It makes no nest, but deposits
its eggs on the bare ground, above high water mark.
The eggs are generally four, of an oliveaceous brown,
blotched with black, and somewhat larger than those of
the lapwing. The male is very watchful at the time
of incubation, and on the least alarm, flies off with a
loud scream, and the female instantly runs from her
eggs to some distance, and then takes wing. It is a
shy bird, but becomes bolder when the young are hatched.
The latter are capable of running as soon as they
quit the eggs, and are led by their parents to their pro-
per food. "The young are easily tamed.

Gen. 59. GLAREOLA. Pratincole.

Characters. Bill strong, short, straight, and hooked at the tip; no-
strils at the base of the bill, linear and oblique; gap
of the mouth large; feet four-toed, toes long, slen-
der, connected at the base by a membrane; tail fork-
ed, consisting of twelve feathers.

Austria. *Pratincola.*—Gray brown above; collar
black; chin and throat white, breast and belly reddish-
gray. Very subject to vary in its plumage. Inhabits
the heaths of southern Europe. About nine inches
long. Feeds on worms and aquatic insects; is very
restless and admonitory, and lays about seven eggs.

Senegal. *Pratincola.*—Bills, legs, and whole body brown.
Nine inches and a half long. Inhabits the Senegal,
and also Siberia.

N. America. *Spotted pratincola.*—Brown, spotted with white; lower
part of the belly and vent reddish-white, with black
spots; bill and legs black. Size of the Austria. In-
habits Germany.

Gen. 60. FULICA.

Characters. Bill convex; upper mandible arched over the lower at
the edge; lower gibbous near the tip; nostrils ob-
long; front bald; feet four-toed and sub-pinnated.

Birds of this tribe frequent waters, and feed on worms,
insects, and small fish. They have a compressed body,
the bill thick, and bent in towards the tip; the upper
mandible reaching far up the forehead, and the wings
and tail short. They are divided into gallinules or se-
ter hens, and coots. The former have the feet cleat;
the upper mandible membraneous at the base, and the
wings concave; while the latter have the toes surround-
ed by a scalloped membrane; the mandibles equal; no-
strils oval, narrow and short.

A. Feet cleat. Gallinule.

Common gallinule, or moor hen.—Front tawney;
bracelets red; body blackish; bill red, with a greenish
tip; irises red; body sooty above, mixed with olive;
cinereous beneath; outer edge of the wings and lower
tail-coverts white; legs greenish; toes flat and broadish.
Weighs from 14 to 16 ounces; length 14 inches. In-
habits Europe and America, and is a very common spe-
cies, being found in most seamy and slow rivers, or
streams of water, and frequently in ponds abounding in
weeds, where it can lie concealed. It feeds principally
on insects, seeds, and vegetable productions of various
sorts, in quest of which it frequently quits the water. It
runs fast, and is equally expert in swimming and diving,
but flies heavily, and with its legs hanging down. As
it runs or swims, it is continually flitting up the tail,
when the white underneath is very conspicuous. The
nest is made of flags or rushes, and placed near the sur-
fave of the water, on some branch of a tree or bush, and
sometimes on the stump of an old willow. The eggs are
commonly five or six, but sometimes nine or ten, of a
light yellowish brown, marked with rust-coloured spots.
The young are hatched in about three weeks, and in-
stantly take the water. This species breeds twice or
thrice in the course of a season. Its flesh is reckoned
delicious.

Purple gallinule.—Front red; bracelets many; body
green; violet beneath. Fifteen inches long. Common
in most temperate and warm countries. Is docile and
easily tamed. Stands on one leg, and lifts the food to
its mouth with the other. Feeds on fish, roots, fruits,
and seeds.

B. Feet pinnated. Coot.

Common, black, or bald coot.—Front flesh-coloured; Atra
bracelets greenish-yellow, body blackish; bill yellowish-
white; front, except in pairing time, white; legs yel-
lowish green; outer edge of the wings white. There
are several varieties. Length 18 inches; weight from
20 to 30 ounces. Inhabits Europe, Asia, and Ameri-
ca. It occurs in Great Britain at all seasons of the
year, and is not supposed to migrate to other countries,
but changes its stations, and to remove from the pools,
where the young have been reared to the larger lakes,
where flocks assemble in the winter. The female com-
monly builds her nest of a great quantity of coarse dried
weeds, well matted together, and lined within with softer
and finer grasses, in a bush of rushes surrounded by
the water. She lays from 12 to 15 eggs at a time, and
commonly hatches twice in a season. Her eggs are
about the size of those of a pullet, and of a pale brownish-
white colour, sprinkled with numerous small dark spots,
which, at the thicker end, seem as if they had run into
each other, and formed bigger blotches. As soon as
the young quit the shell, they plunge into the water,
dive, and swim about with great ease, but they still gath-
er about the mother, and take shelter under her
wings, and do not entirely leave her for some time.
They are first covered with a sooty-coloured down, and
are of a shapeless appearance; and, while in this state,
before they have learned by experience to shun their
enemies, they are often sacrificed to the rapacity of the
pike, the kite, moor-buzzard, &c. A female of this
species built her nest in Sir William Middleton's lake
at Belsay, in Northumberland, among the rushes, which
were afterwards loosened by the wind, so that the nest
was driven about, and floated on the surface of the wa-
ter; notwithstanding which, she continued to sit as
usual, and brought out her young on her moveable
habitation. The common coot swims and dives with
great ease, but is a bad traveller, and may be said not
to walk, but to splash and waddle between one pool
and another, with a laboured, ill-balanced, and awk-
ward gait. During the day it usually skulks among the
rushes or other water plants, rarely venturing abroad,
except in the dusk, or at night, in quest of herbage,
seeds, insects, and fishes. The sportsman and his dog
can seldom force it to spring from its retreat, as it
will rather bury itself in the mud than take wing, or,
ORNITHOLOGY.

if it be very closely pursued, and compelled to rise, it gets up with much flustering and apparent difficulty.

Greater coot.—Front white; bracelets red; body blackish. Has much the appearance and manners of the last, but is larger and blacker. It is found both in England and Scotland. The French eat it on measage days.

Crested coot.—Blue black; naked front and crown red; caruncle red, biffd, erect; bracelets red, green, and yellow; bill whitish, with a red base; legs dusky. Eighteen inches long. Inhabits China and Madagascar.

Gen. 61. VAGINALIS, Sheath-bill.

Bill strong, thick, conical, convex, and compressed; upper mandible covered above with a movable horn; nostrils small; placed before the beak; tongue round above, flattened beneath, and pointed at the tip; face naked and papillous; wings with an obtuse excrescence beneath the flexure; legs strong; four-toed; naked a little above the knees; toes rough beneath; claws grooved.

White sheath-bill.—Bill black at the base; sheath a horn yellow or black plate, nearly covering the nostrils; face naked; and in the adult bird, beset with white, or pale orange warts; a brown or blackish warts above the eyes, larger than the rest; feathers white; excrescences on the wings blackish; legs two inches long, and generally reddish. The only species of the genus; about the size of a pigeon. From 15 to 18 inches long; inhabits New Zealand and the South seas, and feeds on shell-fish and carcasses.

Gen. 62. PARRA, Jacana.

Bill tapering, somewhat obtuse; nostrils oval, in the middle of the bill; front covered with lobated ca
runcles; wings spinous.

Chilensis.  

Chilean jacana.—Claws moderate; legs brown; bill head subscerotced. Inhabits Chili. Size of a jay, but has longer legs; feeds on worms and insects; is noisy, and defends itself by the spurs on the wings. Builds in the grass, and lays four tawney eggs, speckled with black.

Jacomina.  

Chesnut jacana.—Hind claws very long; legs greenish. Ten inches long; inhabits watery places in South America, and utters, almost unceasingly, a shrill disagreeable cry.

Faithful jacana.—Toes long; legs tawney; hind head crested; bill dirty white; upper mandible like that of the dunghill cock; a red membrane on both sides of the base of the bill, extending to the temples, in the middle of which are the eyes; ridges brown; hind head with about 12 blackish feathers; three inches long, forming a pendant crest; rest of the neck covered with thick black down; body brown; wings and tail blackish; wing-spurs two or three, and half an inch long; belly light black; thighs half bare; toes so long as to entangle each other in walking. About the size of a cock, and stands a foot and a half from the ground. Inhabits the rivers and inundated places near Carthagena in America; feeds on herbs; has a clear and loud voice, a slow gait, and easy flight. The natives keep one of these birds tame to wander with the poultry, and defend them against birds of prey, which it does by means of the spurs on its wings. It never deserts the charge committed to its care, and brings them home at night. It will readily suffer itself to be handled by grown up persons, but not by children.

Gen. 63. RALLUS, Rail.

Bill thickish at the base; attenuated on the back towards the tip; compressed; a little incurved and pointed; tongue rough at the tip; body compressed; tail short; feet four-toed and cleft.

The birds of this genus have the bill a little inflected; small nostrils; tongue rough; and the tail very short.

Land rail, crake, corn-crake, daker-hen, &c.—Wings chestnut-rusty; bill and legs brown-ash; irides hazel; feathers of the body reddish-brown; the upper ones black in the middle; chin very pale; belly whitish-yellow. About nine inches and a half long. Inhabits the sedgy parts of Europe and Asia. From its appearing at the same time with the quail, and frequenting the same places, it is sometimes called the young quail. Its well known cry is first heard as soon as the grass becomes long enough to shelter it, and continues till the grass is cut; but the bird is seldom seen, as it skulks in the thickest parts of the herbage, and runs so nimbly through it, winding and doubling in every direction, that it is difficult to come near it. When hard pressed by the dog, it sometimes stops short and squats down, by which means it too eager pursuer overshoots the spot, and loses the trace. It seldom springs but when driven to extremity, and generally flies with its legs hanging down, but never to a great distance. As soon as it alights, it runs off, and before the Fowler has reached the spot, the bird is at a considerable distance. It is a migratory species, appearing with us about the latter end of April, and departing in October. On its first appearance, and till the female begins to sit, the male is frequently heard to make a singular kind of noise, much resembling that of a comb when the finger is drawn along the teeth of it, and which has been used as a decoy. When they first arrive, they are very lean, but before their departure, become excessively fat, and are much sought after for the delicacy of their flesh.

Water rail, brook ouzel, loicock, velvet runner, &c.—Wings gray, spotted with brown; flanks spotted with white; bill orange beneath; bill black, reddish at the base; irides red; feathers of the upper part of the body olive-brown, and black in the middle; the lower ones cinereous; those of the lower part of the belly and vent edged with rufous; quill feathers dusky; lower tail coverts white; tail feathers short, black; the two middle ones at the tip, the rest edged with ferruginous; legs dusky red. Length about 12 inches; weight four ounces. Inhabits watery places in Europe and Asia. Though not very plentiful, it is sometimes found in various parts of Great Britain, in low situations, about water courses and rivulets, where it seeks shelter among sedge-rushes, and reeds, and is seldom put to flight, depending chiefly on its legs for safety. When roused, it flies only a small distance, and then in a heavy and awkward manner, with its legs hanging down. It runs nimbly, and frequently flips up its tail. The nest is made

Gallin. and outer edge of the wings white. About the size of a pleasant; length 17 inches. Inhabits Southern Europe and Asia. A few instances are on record of its having been found in England. In France, it is frequently served at table as a delicacy, though the flesh be blackish. In June it lays from three to five eggs, of a glossy green, and the young are able to fly in August.

636

Afr. White-eared bustard.—Black; back cinereous; ears white; in the male the bill and legs are yellow; the crown is cinereous, and the wings are marked with a large white blotch, the neck behind, and thighs above the knees, have a white collar; the tail feathers 14; the female is cinereous, and the thighs and belly black. Length 22 inches. Native of the Cape of Good Hope.

637

Husbara. Ruffled bustard.—Yellowish, spotted with brown; feathers of the neck long, whitish, with black shafts; quill feathers black, with a white spot in the middle.

638

Oce. Size of a capon. Inhabits Africa and Arabia.

639

Strept. Thick-kneed bustard, stone curlew, or Norfolk plover.—Gray; two first quill feathers black, white in the middle; bill sharp pointed; feet cinereous; bill black; legs greenish-yellow; lower eyelid naked, pale yellow; a yellow line above and beneath the eyes; a brown line from the bill, under the eyes to the ears; knees thick, as if swollen; belly and thighs white. Weights about 17 ounces; length 18 inches. Inhabits Europe, Asia, and Africa. With us it is a migratory species, making its first appearance the latter end of April, or beginning of May, when the male is heard to make a very loud shrill noise, particularly in the dusk of the evening. It chiefly frequents large corn fields, beaths, or warrens, in open hilly situations; makes no nest, but lays two light-brown coloured eggs, blotched and streaked with dusky, on the ground. Its food chiefly consists of insects and worms, and sometimes also of mice, frogs, and toads. In the autumn, these birds assemble in small flocks preparatory to their departure, and are seldom seen after the beginning of October. When flying, they stretch out their feet straight behind, like the heron. The young are hardly to be distinguished from the stones in which they generally harbour.

640

Gen. 66. STRUTHIO.

Characters Bill subconical; nostrils oval; wings short, unfit for flight; feet formed for running.

641

Came. Black ostrich.—Feet with two toes; head small; bill horn-colour; irides hazel; eyelids fringed, head and greater part of the neck bald, flesh-coloured, with a few scattered hairs; feathers of the body lax, black, and decomposite; the webs on each side equal; quill and tail feathers snowy, waved, and long, with a sprinkling of black on the edge or tip; chest callous; wing spurs two, one at the end of the wing, and one on the spurious wing; thighs and flanks naked; feet strong, gray-brown; toes connected at the base, the outer very short, and unarmed. The ostrich stands so very high as to measure from seven to nine feet, from the top of the head to the ground; from the back, however, it is seldom more than three or four feet, the rest of its height being made up by its extremely long neck. In the sandy and burning deserts of Africa and Asia, the black ostriches are seen in such large flocks, as sometimes to have been mistaken for distant cavalry. Their strong jointed legs, and cloven hoofs, if we may use the expression, are well adapted both for speed and defence. Their wings and all their feathers are insufficient to raise them from the ground. Their voice is a kind of hollow mournful howling; and they graze on the plain with the quacha and the zebra. In the interior parts of southern Africa they frequently make great havock in the corn fields, destroying the ears of wheat so effectually, that in a large tract of land, it often happens that nothing but the bare straw is left behind. In running, they have a proud and haughty look, and even when closely pursued, never appear to be in great haste, especially when the wind is with them, and they can easily accelerate their progress by flapping their wings, so as to outstrip the swiftest horse. But if the weather be hot and calm, or if the birds have by any accident lost a wing, the difficulty of outrunning them is not so great. The ostrich is one of the few polygamous birds found in a state of nature, one male being generally seen with two or three, and frequently with five females. It has been commonly believed that the female, after depositing her eggs in the sand, and covering them up, allows them to be hatched by the heat of the climate, and leaves the young to shift for themselves. Recent travellers have, however, assured us, that no bird whatever has a stronger affection for her offspring, and that none watches her eggs with greater assiduity. It is true, that during the intense heat of the day, when incubation is less necessary, she sometimes forsakes them, but she always carefully broods over them by night. Kolben affirms that this species sit on their eggs like other birds, and that the males and females take this office by turns, as he had frequent opportunities of observing. Nor is it more true, that they forsake their young as soon as excluded from the shell. On the contrary, the old ones are very assiduous in supplying them with grass and water, are careful to defend them from harm, and will even themselves encounter every danger in their defence. All the females which are attached to one male, deposit their eggs in the same place, to the number of ten or twelve each, about the size of a child's head. These they hatch all together, the male also taking his turn of sitting on them. Thus from sixty to seventy eggs have sometimes been found in one nest, and Linneus erroneously assigned them to one female. The term of incubation is six weeks. The nest appears to be merely a hole in the ground, formed by the birds trampling the earth for some time with their feet. If the eggs are touched by any person in the absence of the parents, they immediately discover it by the scent, at their return, and not only desist from laying any more in the same place, but trample to pieces with their feet all those that have been left. On this account the Africans are very careful in taking part of the eggs away not to touch any of them with their hands, but always fetch them out of the nest with a long stick. Within the eggs are frequently discovered a number of small oval-shaped pebbles, of the size of a narrow flat pea, of a pale yellow colour, and exceedingly hard. These eggs are reckoned a great delicacy, and are prepared in various ways. From their large size, one of them is sufficient to serve two or three persons at a meal. The ostrich itself is chiefly valuable for its plumage; and the Arabs have reduced the chase of it to a kind of science. They hunt it,
ORNITHOLOGY.

Galinea. It we are told, on horseback, and begin their pursuit at a gentle gallop; for should they, at the outset, use the least rashness, the matchless speed of the game would immediately carry it out of their sight, and in a very short time, beyond their reach. But when they proceed gradually, it makes no particular effort to escape. As it does not go in a direct line, but runs first on one side, and then on the other, its pursuers save much ground by rushing directly onward. In a few days at most, the strength of the animal is exhausted, and it then either turns on the hunters, and fights with the fury of despair, or hides its head, and tames its fate. Frequently, also, the natives conceal themselves in ostrich skins, and thus are enabled to approach near enough to surprise them. Some persons breed up these birds in flocks, for they are tame with very little trouble, and may be rendered very useful in a domestic state. Besides the valuable feathers which they cast, the eggs which they lay, their skins, which are used by the Arabians as a substitute for leather, and their flesh, which many esteem excellent food, they are sometimes made to serve in place of horses. It is pleasant to observe with what dexterity they play and frisk about in a tame state, particularly in the heat of the day, when they will strut along the sunny side of a house, with great majesty, perpetually fanning themselves with their expanded wings, and seeming, at every turn, to admire and be enamoured of their own shadows. They are very tractable and familiar towards persons who are acquainted with them, but are often fierce towards strangers, whom they frequently attempt to push down by running furiously on them, and when they succeed thus far, they not only peck at their fallen foe with their bill, but strike at him violently with their feet. While thus engaged, they sometimes make a fierce hissing noise, and have their throat inflated, and mouth open; and at other times, make a kind of cackling noise. During the night they often utter a doleful or hideous cry, somewhat resembling the distant roaring of a lion, or the hoarse tone of a bear or an ox, as if they were in great agony. They will swallow with the utmost voracity large, or small, or stone, indiscriminately. "I saw one at Oran (says Dr Shaw), that swallowed, without any seeming uneasiness or inconvenience, several leaden bullets, as they were thrown upon the floor, scorching hot from the mould." Mr Adanson mentions two ostriches which afforded him a sight of a very extraordinary nature. They were so tame, that two little black dogs mounted both together on the back of the largest. No sooner did he feel their weight, than he began to run as fast as possible, and carried them several times round the village, as it was impossible to stop him otherwise than by obstructing the passage. To try their strength, he directed a full-grown negro to mount the smallest, and two others the largest. This burthen did not seem at all disproportioned to their strength. At first they went at a pretty sharp trot, but when they became heated a little, they expanded their wings, as if to catch the wind, and moved with such fleetness that they scarcely seemed to touch the ground. "Most people (observes M. Adanson) have, one time or other, seen a partridge run, and consequently must know that there is no man whatever able to keep up with it: and it is easy to imagine, that if this bird had a longer step, its speed would be considerably augmented. The ostrich moves like the partridge, with this advantage; and I am satisfied that those I am speaking of would have distanced the fleetest race horses that were ever bred in England. It is true, they would not hold out so long as a horse, but they would undoubtedly be able to over the space in less time. I have frequently beheld this sight, which is capable of giving one an idea of the prodigious strength of an ostrich, and of showing what use it might be of, had we but the method of breaking and managing it as we do a horse."

Emeu, or cassowary.—Feet three-toed; helmet and dewlaps naked; bill and legs black; gape very large; irides of the eyes nearly at the tip of the bill; eyes large; helmet horny, reaching from the base of the bill to the middle of the crown, three inches high, the fore part blackish, the hind part yellow; temples and neck banded, wrinkled, and reddish, with a blue or purple tinge, and covered with a few scattered hairs; two pendant caruncles, partly red and partly blue, on each side of the neck; chest on which it rests callous; feathers brownish-black, lax, generally two from one shaft; no tail; wings consisting of about five naked dusky shafts; claws straight. Five feet and a half long. Inhabits within the torrid zone in Asia; is a fierce and bold bird; kicks with its feet like a horse, grunts like a hog, feeds on vegetables, which it swallows whole; lays greenish eggs, more oblong than those of the black ostrich; runs very swiftly, and is incapable of flying.

New Holland cassowary.—Feet three-toed, crown New Holland flat; shanks serrated behind. Seven feet two inches long. Inhabits New Holland.

American ostrich.—Feet three-toed, and a round cal. Rhin. long. Nearly the height of a man. Inhabits South America; feeds on fruits, flesh, and flies, defends itself with its feet, and calls its young by a kind of hiss.

Didoa. Didus.

Bill narrowed in the middle, with two transverse characters. Wrinkles; each mandible bent in at the tip; nostrils oblique, near the edge of the middle of the bill; face naked beyond the eyes; legs short and thick; feet cleft; wings unfit for flight; no tail.

Hooded dodo.—Black, waved with whitish; head imbecus. Hooded; feet four-toed; bill strong, large, bluish, with a red spot; the upper mandible yellowish at the tip, the lower bulging near the tip; gape very large; irides whitish; plumage soft; belly whitish; head large, black, as if covered with a cap; feathers of the rump curled, inclining to yellow; legs yellowish; claws wanting. This uncouth species is rather bigger than a swan, and nearly three feet in length. It inhabits the islands of Mauritius and Bourbon in the Indian ocean. According to Helbert, it seldom weighs less than 50 pounds; has a slow pace; the body round and fat; and the stomach is so strong as to digest stones. It is, however, so seldom met with that its true history is little known.

Solitary dodo.—Varied with gray and brown; feet Solitarium. four-toed; eyes black; spurious wings, terminating in a round protuberance. The female with a white protuberance, resembling a teat, on each side of the breast. Size of a turkey. Inhabits the island of Rodrigue, where it is not uncommon, though seldom more than
ORNITHOLOGY.

Pavo.

Gen. 68. Pavo, Peacock.

Characters. Bill convex and strong; head with a crest of feathers turning forwards; nostrils large; rump feathers long, broad, expansive, and covered with eye-like spots.

Crested peacock.—Head with a compressed crest; spurs solitary. It is impossible to describe the beauties of this well-known species in adequate terms. Its matchless plumage, as Buffon observes, seems to combine all that delights the eye in the soft and delicate tints of the finest flowers, all that dazzles it in the sparkling lustre of the gems, and all that astonishes it in the grand display of the rainbow. Its head is adorned with a tuft, consisting of 24 feathers, whose slender points are furnished with webs only at the ends, painted with the most exquisite green, mixed with gold. The head, throat, neck, and breast, are of a deep blue, glossed with green and gold; the back of the same, tinged with bronze; the scapulars and lesser wing-coverts are of a reddish-carmine colour, variegated with black; the middle coverts deep blue, glossed with green and gold; the greater coverts and spurious wing are of reddish-brown, as are also the quills, some of which are variegated with black and green; the belly and vent are black, with a greenish line. But the distinguishing character of this bird is its train, which rises just above the tail, and when erected, forms a fan of the most resplendent hues. The two middle feathers are sometimes four feet and a half long, the others gradually diminishing on each side. The shafts, which are white, are furnished from their origin nearly to the end with parted filaments of varying colours, ending in a flat valve, which is decorated with what is called the eye. This is a brilliant spot, enamelled with the most enchanting colours, yellow, gilded with various shades, green, running into blue and bright violet, varying according to its different positions, the whole receiving additional lustre from the centre, which is a fine velvet black. When pleased or delighted, and in sight of his females, the peacock erects his tail, and displays all the majesty of his beauty, and he frequently turns it slowly round, as if to catch the sunbeams in every direction, accompanied with a hollow murmuring voice. His cry at other times is very disagreeable, and often repeated. The peahen is somewhat less than the cock, and though furnished both with a train and crest, is destitute of those dazzling beauties which distinguish the male. She lays five or six eggs of a whitish colour, in some secret spot, where she can conceal them from the male, who is apt to break them; and she sits from 25 to 30 days, according to the temperature of the climate and the warmth of the season. Peacocks were originally brought from the distant provinces of India, and thence have been diffused over every part of the world. They are sometimes found in a wild state in many parts of Asia and Africa. The largest and finest are said to be met with in the neighbouring of the Ganges, and on the fertile plains of India, where they grow to a great size. In colder climates, they require care in rearing; and do not acquire their full plumage till their third year. In former times they were considered as a delicacy, and made a part of the luxurious entertainment of the Roman voluptuaries. The females of this species, like the pheasant, have been known to assume the appearance of the male, by a total change of colour, which is said to take place, after they have done laying. A white variety of peacock occurs not unfrequently, in which the eyes of the train are barely visible, and may be traced by a different undulation of shade on the pure white of the tail.

Meleagris.

Gen. 69. Meleagris, Turkey.

Bill conical, and incurved; head covered with spongy caruncles; chin with a longitudinal membranaceous caruncle; tail broad, and expansive; legs spurred.

American or common turkey.—Front and chin ca. Gallina.

runcinated; breast of the male tufted. Female without a spur. Upwards of three feet and a half long. Inhabits America; and is very generally domesticated. In a wild state it lives in woods, and feeds on nuts, acorns, and insects. It roosts on the highest trees; is very irascible, and impatient of any thing red. The cock struts with an inflated breast, expanded tail, red face, and relaxed frontal caruncle, making a singular inward noise, which when it is uttered shakes the whole body. The eggs are numerous and white, with reddish or yellow spots. The females lay them in spring, generally in some retired or obscure place; for the cock, enraged at the loss of his mate while she is employed in hatching, is otherwise apt to break them. They sit on their eggs with so much perseverance, that if not taken away, they will almost perish with hunger before they will entirely leave the nest. In a wild state, turkeys are gregarious, and associate in flocks, sometimes of about five hundred. They are very swift runners, but fly awkwardly; and about the month of March they become so fat, and they cannot fly beyond three or four hundred yards, and are then easily run down by a horseman. The hunting of these birds forms one of the principal diversions of the Canadians. When the latter have discovered the retreats of the turkey, which in general are near fields of nettles, or where there is plenty of any kind of grain, they send a well-trained dog in the midst of the flock. The
ORNITHOLOGY.

The birds no sooner perceive their enemy than they run off at full speed, and with such swiftness that they leave the dog far behind; he, however, follows, and as they cannot go at this rate for any length of time, at last forces them to take shelter in a tree, where they sit, spent and fatigued, till the hunters come up, and with long poles, knock them down one after another. Turkey cocks, among themselves, are very fierce and pugnacious, and yet, against other animals, are usually weak and cowardly. The disposition of the female is in general much more mild and gentle than that of the male; and when leading out her young family to collect their food, though so large and apparently so powerful a bird, she gives them very little protection against any rapacious animal that comes in her way, but rather warns them to shift for themselves. It deserves to be remarked, that though this species is reared with some difficulty, yet in its wild state it is found in great plenty in the forests of Canada, that are covered with snow for more than three-fourths of the year. It is easily hurt by hunger or rain. They are bred in great numbers in Norfolk, Suffolk, and some other counties, from whence they are driven to the London markets in flocks of several hundreds. The drivers manage them with great facility, by means of a bit of red rag tied to the end of a long stick, which, from the antipathy that these birds bear to that colour, effectually answers the purposes of a scourge. We need scarcely notice, that the flesh of the turkey is reckoned a delicate food. The Indians make an elegant clothing of the feathers, by twisting the inner webs into a strong double string with hemp, or the inner bark of the mulberry-tree, and working it like matting, so that the whole appears rich and glossy, and as fine as silk shag. The natives of Louisiana make fans of the tail; and of four tails joined together the French used formerly to form a parasol.

655

Horned turkey.—Head with two horns: body red, with like spots: bill brown; nostrils, front, and area of the eye covered with black hair-like feathers: crown red: horns callous, blue, bent back; curuncle of the chin dilatable, blue, varied with rufous; legs whitish, spurred; tail feathers twenty. The female has the head covered with feathers, without horns or gular caruncle; feathers of the head and upper part of the neck black-blue, long, and decumbent; rest of the body, as in the male, red with eye-like spots; spurs more obtuse. Rather less than the preceding. Inhabits India.

656

Penelope.

Bill naked at the base; head covered with feathers; chin naked; tail with twelve feathers; legs without spurs.

657

Character.

Guam.—Head with a erect crest; temple violet. Two feet six inches long. Inhabits Brazil and Guiana, where it is frequently tamed, its flesh being reckoned very delicate. It frequently utters a sound like the word jacu.

658

Orbitalia.

Jacu or jacu.—Blackish; crest and first quill feathers white. Size of a hen turkey. Inhabits Cayeny and Guiana. It expands its crest, and cries in a mournful tone, like a young turkey. It builds on the ground, is easily tamed, and is often domesticated.

Marant turkey.—Greenish-black; naked orbits; and legs red; throat somewhat naked, speckled with white.

659

Cambodexia.

Marant.

660

Saggyvraa.

Bill strong and thick; the base of each mandible covered with a cere; nostrils in the middle of the cere; feathers covering the head, turned spirally forward; tail large, straight, and expansile.

Crested curassow.—(Male). Cere yellow; body black; belly white; bill black or horned; cere reaching from the middle of the bill behind the eyes; crest erect, black, and three inches long; tail black and roundish, eleven inches long, feathers fourteen; spurs none. (Female). Red; head bluish; crest white, tipped with black; bill cinereous; irides red; legs brown. Subject to much variety. Three feet long. Inhabits the mountainous woods of South America. Lives on fruits, roosts on trees, and is often domesticated on account of its white and delicate flesh. They are frequently kept tame in our menageries, and readily mix with other poultry, feeding on bread and grain, but they are unable to bear the dampness of the grass of our meadows, which renders their toes subject to rot off. Dr Latham mentions an instance in which the whole of one foot was gone, and but part of one toe left on the other, before the creature died.

Globosa curassow, or curassow bird.—Yellow; gibbosity of the nostrils globular; body blackish-blue, lower part of the belly white; bill yellow, tipped with cinereous; gibbosity yellow, and very hard; irides red; orbits white; crest black, tipped with white; legs pale ruddy. (Female). Bill and legs cinereous; head and crown black; crest black, with a white band; some of the feathers of the neck tipped with white; throat, breast, back, and wings brown; upper part of the belly white, and some of the feathers tipped with black; vent yellowish brown; tail black, with four transverse white bands. Size of the preceding. Inhabits Guiana.

663

Plate CCCC. fig. 4.

Gen. 70. Penelope.

Character.

Gen. 71. Crax, Curassow.

Bill strong and thick; the base of each mandible covered with a cere; nostrils in the middle of the cere; feathers covering the head, turned spirally forward; tail large, straight, and expansile.

Bill short and strong; cheeks covered with smooth naked skin; legs generally with spurs.

The females produce many young ones at a brood, Character. and take care of them for some time, leading them abroad, and pointing out food for them. The young are at first clad with a thick soft down. The nests of the whole tribe are formed on the ground.

Common.

Common.

Common.
ORNITHOLOGY.

Common cock, or wild cock.—Comb on the crown, and two wattles on the chin compressed; ears naked; tail compressed and erected; feathers of the neck linear, long, and membranaceous at the tips; body, when wild, less than the common cock; comb large, indented, shining red; temples and line from the crest to the eyes naked and flesh-coloured, a clay-coloured spot of the shape of a man's nail, and covered with short feathers, behind the eyes; feathers of the rest of the head and neck long, narrow, gray at the base, black in the middle, and tipt with white; feathers of the upper part of the body grayish, with a white and a black streak; breast red; third: greater wing-covers reddish-chesnut, with transverse black and white streaks; tail coverts glossy violet; middle tail feathers long and falcated; spurs large and curved. The female without comb and wattles; head and neck gray; cheeks and chin whitish; body more dusky, and varied with brown gray and rufous; and wants the spurs. Inhabits India in a wild state, is every where domesticated, and subject to innumerable varieties in size and colour. His beautiful plumage and undaunted spirit, as well as his great utility, have rendered him a favourite in all countries into which he has been introduced. The cock is the attendant, and keeps eye on his female, hard by, not losing sight of them. He leads, defends, and cherishes them, collects them together when they struggle, and seems to eat unwillingly till he sees them feeding around him. Whenever a strange cock appears within his domain, he immediately attacks the intruder, and, if possible, drives him away. The patience and perseverance of the hen in the hatching, are truly extraordinary, but are too familiar to most of our readers to require to be detailed. Though by nature timid, and apt to fly from the meanest assailant, yet, when marching at the head of her brood, she is fearless of danger, and will fly in the face of the fiercest animal that offers to annoy her. As the chickens reared by the hen bear no proportion to the number of eggs which she produces, many artificial schemes of rearing have been attempted. Chickens have long been hatched in Egypt by means of artificial heat. This is now chiefly practised by the inhabitants of a village called Berme, and by those who live at a little distance from it. Towards the beginning of each month these persons spread themselves all over the country, and each of them is ready to undertake the management of an oven. These ovens are of different sizes, each capable of containing from forty to eighty thousand eggs; and the number of ovens in different parts is about three hundred and eighty-six. They are usually kept in exercise for about six months; and as each brood takes up twenty-one days in hatching, it is easy in every one of them to produce eight different broods of chickens in the year. The ovens consist only of a low arched apartment of clay. Two rows of shelves are formed; and the eggs are placed on them in such a manner as not to touch each other. They are slightly moved five or six times in the course of twenty-four hours. All possible care is taken to diffuse the heat equally throughout, and there is but one aperture, just large enough to admit a man stooping. During the first eight days, the heat is rendered great, but during the last eight, it is gradually diminished, till at length, when the young brood are ready to come forth, it is reduced almost to the state of the natural atmosphere. Every keeper of an oven obliges himself to deliver to his employer only two thirds of as many chickens as there have been eggs entrusted to him; and he is a greater by this bargain, as it always happens, except from some unlucky accident, that many more than that proportion of the eggs are productive. In this way it has been calculated that the Egyptian ovens give life annually to near a hundred millions of chickens. This useful and advantageous mode of hatching eggs was introduced into France by the ingenious and indefatigable Monsieur de Reaumur, who, by a number of experiments, reduced the art to certain principles, and applied it to the production of all kinds of domestic fowls. The young brood are generally hatched a whole day before they taste food, and then a few crumbs of bread are given for a day or two, after which time they begin to pick up grain and insects for themselves. In order to save the trouble of attending them, capons are taught to watch them in the same manner as hens. M. de Reaumur informs us, that he has seen above two hundred chickens at once, all led about and defended by only three or four capons. It is asserted that even cocks may be taught to perform this office, which they will continue to do all their lives afterwards. Among the triumphs of this art, it is especially worthy of remark that he is unrivalled by those of any other nation for its invincible courage, and on that account is made use of as the instrument of the inhuman sport of cock-fighting. The Athenians allotted one day in the year to this barbarous pastime; and the Romans are said to have learned it from them, and to have introduced it into this island. Henry VIII. was so fond of the sport, that he caused a commodious house to be erected for that purpose, which, though now applied to a very different use, still retains the name of the cock-pit. The Chinese, the Sumatrians, and others in the eastern parts of the world, are so addicted to this savage diversion, that, in the paroxysms of their frenzy, they will sometimes risk not only the whole of their property, but their wives and children, on the issue of a battle. The cock, it is well known, is a watchful bird, and crows clapping its wings. The hen will lay eggs the whole year, provided she has plenty of food and cold water, gravel, and a warm place. After laying, she requires a peculiar note of attention. Her heat is increased while hatching, but if put into cold water, she ceases to sit.

Couaier pheasant.—Tawney white; tail long, and shining green; a few white spots at the base of the tail. Eighteen inches long. Inhabits New Spain; is slow in flight, but so swift on foot as to outrun the fleetest horses.

Common pheasant.—Rufous, head blue; tail wedged; cheeks papillous; bill pale, horn colour; sities yellow; cheeks red, speckled with black; in the old birds wrinkled and pendulous; a greenish-black feathered line from the nostrils to beneath the eyes; rest of the head and neck green-gold, with a gloss of violet and blue; lower part of the neck, breast, back, and rump, shining tawney; quill feathers brown, with ochreous spots; belly and vent white; tail feathers eighteen, with transverse black bars; legs dusky, armed with spurs. Female less, varied with brown, gray, rufous, and blackish; cheeks feathered; and, after she has done brooding, puts on the appearance of the male. There are several varieties. This beautiful bird is about nineteen inches long, and weighs from two pounds twelve ounces to three pounds four ounces. It is said to have been brought from the island of Colchis.
ORNITHOLOGY.

Gallinæ.—The Argonauts; a native of Africa, and very common in almost all the southern parts of the old continent, whence it was originally imported into Great Britain. Pleasants are much attached to the shelter of thickets and woods, where the grass is very long; but they also often breed in clover fields. They form their nests on the ground, and the females lay from twelve to fifteen eggs, which are smaller than those of the domestic fowl and are always deposited in a few large, almost spherical, nests made of a few leaves and grasses, put carelessly together, and the young follow the mother like chickens, as soon as they break the shell. The parents and their brood remain in the stubble and hedge rows, if undisturbed, for some time after the corn is ripe. If disturbed, they seek the woods, and only come forth in the mornings and evenings to feed in the stubble. Though very fond of corn, they are often obliged to content themselves with wild berries and acorns. In confinement, the female lays so many eggs, nor hatches and rears her brood with so much care and vigilance as in the fields. In a new she will very rarely dispose her eggs in a nest, or sit on them at all; and the domestic hen is usually entrusted with the charge of incubation and rearing the young. The wings of the pheasant are very short, and ill adapted for considerable flights. As the cold weather approaches, these birds begin to fly at sunset among the branches of oak trees for roosting during the night; and they do so more frequently as the winter advances, and the trees lose their foliage. The male birds at these times make a noise, which they repeat three or four times, and which the sportsmen call cocking. The hen on flying up utter one shrill whistle, and then are silent. Poachers avoid themselves of these notes, and, unless the woods are strictly watched, secure the birds with the greatest certainty.

The crowing of the males, which begins in the first week of March, may be heard at a considerable distance. During the breeding season, the cocks will sometimes intermix with the common hen, and produce a hybrid breed. The pheasant does not appear to pair, for the female carefully hides her nest from the male; and where they are in plenty, and food provided for them, the two sexes are said in general not to feed together. In a domestic state, they are sometimes more or less mixed with white, and sometimes wholly so. A variety with a white ring round the neck, and thence called the ring pheasant, is not uncommon in some parts of England. This species rarely occurs in Scotland.

Argus pheasant.—Pale yellow, spotted with black; face red; bind head crested, blue; bill yellowish; orbits and whiskers black; front, chin, and throat red; hindhead and nape blue; wings gray, with eye-like spots; tail wedged, the colour of the wings; two middle feathers three feet long, with large eye-spots at the shaft; feet armed; size of a turkey. Inhabits Chinese Tartary and Sumatra. This is a most beautiful bird, though its colours are not brilliant. It is with great difficulty kept alive for any time after it has been caught in the woods. It seems to have an antipathy to the light, being quite inanimate in the open day; but when kept in a dark place, it appears to be perfectly at ease, and sometimes makes its call, which is rather plaintive, and not harsh like that of the peacock. The flesh resembles that of the common pheasant.

Impeyan pheasant.—Crested, purple glossy green, black beneath; feathers of the neck with a changeable lustre of gold, copper, and green; tail entire, rufous; larger than a common fowl. Inhabits India, but not plentifully, being brought from the hills in the northern parts of Hindostan to Calcutta, as curiosities. Lady Impey attempted, with great probability of success, to bring over with her some of them to England; but after living in health on board the ship for two months, they caught a disorder from the rest of the poultry, and died to the smallpox, or scarlet fever, in the hold. They bear cold, but are impatient of heat. The cock was never observed to crow, but had a strong hoarse cackle, not unlike that of a pheasant. Described and figured by Latham.

Crested pheasant.—Brown above; beneath reddish white; vent rufous; head crested; orbits red, naked; tail wedge-shaped, and tip with yellow; bill and unarmèd legs black; feathers of the crest whitish-brown; beneath black; feathers from the hind head to the lower part of the neck have a white streak down the middle; coverts of the wings at the tip and edge white; quill feathers rufous; tail ten inches long; length of the body 22 inches. Native of New Spain. Frequent trees in the neighbourhood of water, and feeds on worms, insects, and serpents.

Painted pheasant.—Crest yellow; breast scarlet; see Pictus. Secondary quill feathers blue; tail wedged; bill, irides, and armed legs, yellow; feathers of the crest silky, and hanging backwards; cheeks naked and flesh coloured; feathers of the hind head tawney, with black lines, and beneath these green ones; back and rump yellow; upper tail coverts long, narrow, and scarlet; wing-coverts varied by red and brown; scapulars blue; quill feathers brown, with yellowish spots; tail feathers varied bay and black, and 23 inches long. Female reddish brown; yellowish brown beneath; legs unarmèd; less than the common pheasants; length two feet nine inches and a half. The native country of this beautiful species is China, where it is called Kin-ki. It bears confinement well, and will breed readily in that state. The eggs are redder than those of the common pheasant, and somewhat resemble those of the Guinea fowl. An instance of their breeding with the common pheasant is mentioned by Buffon. Edwards informs us, that some females of this species, kept by Lady Essex, in the space of six years gradually gained the male feathers; and we are told, that it is not unusual for the hen birds, when about four or five years old, to be neglected by the cocks, and gradually to gain the plumage of the male.

Superb pheasant.—Unarmèd; rufous, varied with Superbus. Green and blue; caruncles of the front rounded; wattles awl-shaped; bill and body red; each side of the neck with long feathers turned back; crown green; the hind part with a folding blue crest; shoulders green, spotted with white; primary quill feathers blue; tail long, wedged, the feathers varied with blue and red; coverts declined, and of various mixed colours; legs yellow. Inhabits China.

Gen. 73. Numida. Pintado, or Guinea Fowl.

Bill strong and short; the base covered with a carunculated cere, receiving the nostrils; head horned, with a compressed coloured callus; tail short, bending down; body speckled.

Common
ORNITHOLOGY.

Common Guinea hen.—Caruncles at the gape double, and as gular fold; bill of a reddish horn colour; head blue; the crown with a conical, compressed, bluish red protuberance; upper part of the neck bluish ash, almost naked; lower feathered, verging to violet; body black, with round white spots; legs gray brown; gular caruncle of the male bluish; of the female red. There is a variety with the breast white, and another with the body entirely white; somewhat larger than the common hen. Inhabits Africa, and is domesticated in most parts of Europe, the West Indies, and America. It formed a part of the Roman banquets, and is now much esteemed as a delicacy, especially when young. The female lays a great number of eggs, which she frequently secretes till she has produced her young brood. The eggs are smaller than those of a common hen, and of a rounder shape, and are delicious eating. The Guinea hen is a restless and very clamorous bird, and has a harsh creaking note, which is peculiarly grating and unpleasant. Like the common domestic fowl it scapes the ground, and rolls in the stubble to feed itself from insects. During the night it perches on high places, and, if disturbed, alarms the neighbourhoood by its unceasing cry. In its natural state of freedom, it is said to prefer marshy places. It is easily tamed, but often abandons its young.

Tetrao.

Near the eyes, a spot which is either naked or papil- lous, or rarely covered with feathers.

The birds of this genus have a strong convex bill; grouse, partridges, and quails, agree in having a short convex bill. The grouse chiefly inhabits the colder regions, and is distinguished by small nostrils, hid under the feathers; an acute tongue; strong feet; and a pretty long tail. Partridges and quails are less in size; have a short tail; and their nostrils covered above with a cal- lous prominent margin. They inhabit the temperate and even the warmer climates. The tinamous are a tribe peculiar to Guiana, and approach the pheasant in manner. Their bill is longer and obtuse at the apex; the nostrils are placed in the middle; their gape is very wide; the throat thinly covered with feathers; the tail very short; the back-toe short, and useless for running. The female is larger than the male.

Grouse.

Wood grouse, cock of the wood, or capercailzie.—Tail rounded; ears pithy white; bill horn colour; spot above the eyes scarlet; irides hazel; nostrils covered with short feathers; feathers of the chin black, longer; head and neck cinereous, with fine transverse black lines; body bay with blackish lines above; breast blackish green; belly and vent black, variegated white; tail feathers 18, each side spotted with white; legs robust and brown; toes pectinated at the edge. Of the female the bill is dusky; chin red; body with alternate red and black transverse lines above; breast with a few white spots, the lower part orange; belly spotted with pale orange and black; the feathers tift with white; shoulders black, the feathers edged with black and pale brown, and tift with white; tail rusty, barred with black, and tift with white. In size, this species is little inferior to a turkey, and sometimes weighs 12 or 13, but more frequently seven or eight pounds. The male is two feet nine inches, and the female two feet two inches long. Inhabits the mountainous and woody parts of Europe and northern Asia. It is not uncommon in the pine-forests of Normandy, in Russia and Siberia, in Italy, and several parts of the Alps. In Scotland and Ireland it is nearly extinct. It feeds on the berries of the juniper and vaccinium, and on the seeds of the pine tribe and other trees. It is a solitary bird, except in the season of love, when, in the beginning of February, perched on the top of a tree, it calls the females about it with a loud voice, its tail expanded, its wings hanging down to its feet, its neck stretched out, and the fea- thers of its head erected. The female builds on the ground among mosses, and lays from eight to sixteen eggs. The flesh of this species is much esteemed, and its eggs are accounted preferable to those of every other bird. They are white, spotted with yellow, and larger than those of the common hen. The young follow the birds as soon as they are hatched, and sometimes with part of the shell attached to them.

Black game, black grouse, or black cock.—Violet black; tail forked; secondary quills feathers white towards the base; bill black; body shining glistening black; wing-coverts black brown; four first quills feathers black, the rest white at the base; tail feathers from 16 to 18, black, legs black brown; toes pectinated. Female less; the weight of an old cock is nearly four pounds, but that of the female is not often more than two. Length about 23 inches: there are several varieties. Inhabits mountainous and woody parts of Europe. In Britain it is chiefly confined to the northern parts of the kingdom, and especially to the Highlands of Scotland; population and culture having driven them from the south, except in a few of the more wild uncultivated parts, as in the New Forest in Hampshire, Dartmoor and Sedgemoor in Devonshire, and the heathy hills in Somersetshire contiguous to the latter. It also occurs in Staffordshire, North Wales, and the north of England. It feeds principally on the tops of heath and marsh, except when the mountain berries are ripe, at which time it devours bilberries and cranberries with the greatest voracity. In the month of April the male places himself on an eminence, at morning dawn, and invites the females by crouving and clapping his wings. The males are polygamous, and fight desperately for the females. They afterwards associate peaceably in small packs, are fond of wood, heathy, and mountainous situations; but occasionally visit the corn fields in autumn, retiring wholly to woods in the winter, and perching on trees. It is somewhat remarkable that they are killed by eating cherries or pears. The female forms an artless nest on the ground, and lays six or eight eggs, of a dull yellowish white colour, marked with numerous very small ferruginous specks, and with blotches of the same towards the smaller end. The young are hatched very late in summer. The young males quit their parent in the beginning of winter, and keep together in flocks of seven or eight till the spring. They do not acquire their male garb till towards the end of autumn, when the plumage gradually changes to a deeper colour, and assumes that of a bluish-black, which it afterwards retains.

Pomfret, white grouse, or white game.—Cinereous; toes downy; quill feathers white; tail feathers black,
ORNITHOLOGY.

Gallicus.

Tipt with white, the middle ones white; body, in summer, cinereous, varied with white and brown, in winter nearly all white; but in all seasons the lateral tail feathers are black, tipp with white; legs and toes covered with a thick wool like a hare's. From 14 to 15 inches long. Inhabits the Alpine parts of Europe and Siberia. In this country it is met with only on the summits of our highest hills, chiefly in the Highlands of Scotland, and sometimes, but rarely, on the lofty hills of Cumberland and Wales. As the snow melts on the sides of the mountains, it constantly ascends till it gains the summit, where it forms holes, and burrows in the snow. These birds pair at the same time with the red grouse; the female lays eight or ten white eggs, spotted with brown, not in any regular nest but on the ground. In winter they fly in flocks, and are so little accustomed to the sight of man, that they are easily shot, or taken in a snare. They are on the wild productions of the hills, as the buds of trees, the young shoots of pines, the heath, crow-berry, rhododenron, &c. They run swiftly, fly heavily, are impatient of the sun and wind, and are unsuspicious of domestication. The flesh of the young is a great delicacy. That of the full-grown birds has sometimes a bitter, but not unpleasant taste; it is also dark coloured, and, according to Buffon, approaches in flavour to that of the hare.

White grouse. Orange, varied with black bands and white blotches; toes down; tail feathers black, tipp with white; the middle ones entirely white; bill black; belly and legs white; claws broad and flat. Upwards of 16 inches long. Inhabits the woods of Europe and Asia, and, like the preceding, grows white in winter.

Pinnate grouse. Back of the neck with supplemental wings, which are wanting in the female. The male is smaller than a partridge. Inhabits North America; feeds chiefly on acorns; and at sunrise erects his neck and wings, and sings for the space of half an hour.

Hazel grouse. Tail feathers brown; spots black and a black band, except the two middle ones. Fourteen inches long. Inhabits the hazel woods of Europe; feeds on catkins; when terrified, erects the feathers of the crown.

Red grouse, or moorcock. Transversely streaked with rufous and blackish; six outer tail feathers blackish on each side; caruncle on the eyebrows lunated and scarlet; greater quill-feathers brown; tail feathers sixteen, the four middle ones the colour of the back, the rest blackish. Length fifteen inches; weight about nineteen ounces. This species is only to be met with in the extensive uncultivated wastes that are covered with heath, particularly the most mountainous situations, having been driven from the south by cultivation. It still occurs in the mountains of Wales, and in the moorlands of Yorkshire and the north of England, but is no where so plentiful as in the Highlands of Scotland, and in the waste moors of North Britain in general. It is also found in the Western islands, and in the mountains and bogs of Ireland; but seems to be unknown on the continent of Europe, those mentioned by Buffon as natives of France, Spain, Italy, &c. either forming a distinct species, or at least a variety. Linneus did not seem to be acquainted with it, and Gmelin gave it as a variety of the ptarmigan. The red grouse never resort to woods, but confines himself wholly to the open moors, feeding on the mountain and bog berries, and;

Vol. XV. Part II.

in defect of these, on the tops of the heath. They pair in the spring; and the female lays from 8 to 14 eggs, much like those of the black grouse, but smaller, on the ground. The young keep with the parent birds till towards winter, and are called a pack, or brood. In November they flock together in greater numbers, sometimes to the amount of thirty or forty, and are then extremely shy and difficult to be shot.

B. Orbits granulated; legs naked.

684 Album.

Gallus or red partridge. Bill and legs blood-red; Rufus.

685 Capito.

Chin white, surrounded with a black band, and spotted with white; feathers of the sides with a double black stripe; tail feathers fourteen, cinereous, the five outer rufous for the last half. Rather larger than the next species. Inhabits various parts of southern Europe, Asia, Africa, and the Greek islands. A variety, called the Guernsey or red-legged partridge, has sometimes been found on the Suffolk or Norfolk coasts. It is distinguished by a single black stripe on the feathers of the sides, and sixteen tail feathers, of which the five outer are rufous on each side. The red partridge frequently perches on a tree, and will breed in confinement, which the common one is never known to do.

686 Bonasia.

Common partridge. A naked scarlet spot under the eyes; tail ferruginous; breast brown; legs white; face yellowish; cap and neck waved ash; quill feathers brown, with ferruginous bands; tail feathers eighteen, lower part of the breast with two chestnut spots. Several varieties of this species are enumerated by ornithologists, but most of them appear to be accidental. Length about 15 inches; weight 15 ounces. Inhabits Europe and Asia, though chiefly in temperate regions; the extremes of heat and cold being equally unfavourable to it. They are nowhere in greater plenty than in this island, where, in their season, they are our most abundant entertainments. They haunt corn fields, and are never found at any distance from arable land. They pair early in the spring; and the female is very prolific, laying from 12 to 20 eggs. It makes no nest, but scatters a small hole in the ground, and throws into it a few contiguous fibres, on which to deposit the eggs. The old birds sit very close on the latter when near hatching. The incubation lasts three weeks, and the young birds learn to run as soon as hatched, frequently with part of the shell sticking to them. It is no uncommon thing to introduce partridges' eggs under the common hen, who hatches and rears them as her own: but, in this case, the young birds require to be fed with the larvae of ants, which are their favourite food, and without which it is almost impossible to rear them. They likewise eat insects, and, when full grown, feed on all kinds of grain and young plants. "The affection of the partridge for her young (says Mr Bewick), is peculiarly strong and lively; she is greatly assisted in the care of rearing them by her mate: they lead them out in common, call them together, point out to them their proper food, and assist them in finding it by scratching the ground with their feet; they frequently sit close by each other, covering the chickens with their wings like the hen. In this situation they are not easily flushed; the sportsman, who is attentive to the preservation of his game, will carefully avoid giving any disturbance to a
ORNITHOLOGY.

b. Legs without a spur. Quail.

Green quail.—Green; bill and legs reddish; wings chestnut, speckled with black; bill a little bent at the tip; bind toe unarmèd; tail and vent black. Between 11 and 12 inches long.

California quail.—Lead colour; crown with an upright crest; throat black, edged with white; belly yellowish brown, with black crescents. The female wants the black throat and whitish margin. Larger than the common quail. Inhabits California.

Noisy quail.—Varied with yellowish, rufous, black, and gray; bill longer than in others of the genus. A very clamorous bird, which inhabits the woods in Java.

Chinese quail.—Body spotted with gray; throat black, with a white arch. From four to six inches long. Inhabits China and the Philippine islands, and is carried alive by the Chinese, in the winter, between their hands, for the purpose of warming them.

Common quail.—Body spotted with gray; eyebrows white; tail feathers with a ferruginous edge and crescent; bill black; head black, varied with rufous; a yellow streak down the middle of the crown and neck; feathers of the neck rusty brown, varied with gray; the shafts with a longitudinal yellow streak; body beneath dirty ochreous; throat and breast reddish; quill feathers gray brown, with rufous bars on the outside; tail feathers white, with reddish and black lines; legs brownish. Seven inches and a half long. Inhabits Europe, Asia, and Africa. When these birds migrate to and from the north, they are found in prodigious quantities in all the islands of the Archipelago.

One hundred thousand, it is said, have been taken in one day on the west coast of the kingdom of Naples. A small portion only extend their flight to this country. With us they appear about the beginning of May, in our cultivated champagne districts, though not in such numbers as formerly. On their first arrival, the males are constantly uttering a whistling note, three successively repeated, which being imitated by a whistle or quail-call, they are easily enticed into a net. Before the revolution, great quantities used to be sent alive from France to the London market. In confinement they fatten, and seem to lose much of their fierce and pugnacious disposition. The female deposits eight or ten yellowish eggs, blotched, or spotted with dusky, on the bare ground, and usually with us among green wheat. The young birds follow the mother as soon as hatched, but do not continue long together; for they are scarcely grown up when they separate, or, if kept together, they fight obstinately, and frequently destroy one another.

From this quarrel-some disposition it was, that the Greeks and Romans used them as game cocks; and that the Chinese, and some of the Italians are, at this day, addicted to the diversion of quail-fighting. After feeding two quails very highly, they place them opposite to each other, and throw in a few grains of seed between them, when the birds rush on each other with the utmost fury, striking with their bills and heels till one of them yields.

C. Orbits with a few feathers; legs naked, four-toed, Tinamous.

Cayenne tinamous.—Bill and legs brown; back ash-brown, varied with blackish stripes; chin cinereous; belly pale orange. Eleven inches long. Inhabits Cayenne and Guiana.

Great tinamous.—Legs yellowish-brown; bill black; Major crown rufous; body olive; back and tail with black spots. Eighteen inches long. Inhabits the woods of South America; roots on the lower branches of trees; feeds on worms, insects, seeds and fruits; builds twice a year, at the root of a large tree, and lays from twelve to fifteen green eggs.

Little tinamous.—Bill and legs yellow; head and neck black; body brown above, rufous beneath; chin mixed with white; quill feathers brown. Nine inches long. Inhabits Guiana. Builds an hemispherical nest in the branches of trees.

ORDER VI. PASSERES.

BILL conical, pointed; nostrils oval, pervious, and na- Character ed.

The birds of this order have the feet formed for walking or hopping. They live, some at the time of breeding, and others constantly, in monogamy. Some which feed on the seeds of plants have a short bill, others that live on insects and worms are generally furnished with a longer bill. They nestle on trees, in bushes, in houses, and on the ground. They often build very artificial nests, and feed their young with their bill. This order includes all the singing birds; the males are the songstors. They are for the most part, eatable.

Gen. 75. COLUMBA, Pigeon.

Bill straight, descending towards the tip; nostrils ob- long, and half covered with a soft tumid membrane.

The birds of this genus have a weak and slender bill, short feet, and many of them red toes, divided to their origin. They extend their residence even to the arctic regions. They drink much, and not at intervals like other birds, but by continuous draughts like quadrupeds. Their note is plaintive or mournful. They form the connecting link between this and the preceding order; but are more nearly related to the passerine tribes, in being monogamous, in caressing each other by their bills, in the male and female alternately hatching, in both joining to feed the young, in laying but few eggs, and in their nidification. Of upwards of seventy species which belong to this genus, only five or six are natives of
ORNITHOLOGY.

Passers.

of Great Britain. The eggs of all the species are white.

A. Tail even and moderate.

765

Common or stock pigeon, or stock dove. — Bluish; neck above glossy green; double band on the wings, and tip of the tail blackish; throat and breast chestnut colour; claws black. Length 12 or 14 inches; weight 11 ounces. Inhabits Europe and Siberia; is wild in many places, but is kept in pigeon-houses everywhere where, and is the parent stock whence all the varieties of the domestic pigeon are derived, and is on that account called the stock-dove. It builds in towers, in caverns of rocks, and in cliffs in uninhabited islands. On the approach of winter, it migrates southward. It is gregarious; lays two eggs, and breeds several times in the year.

706

Domestica.

Domestic pigeon. — Cinereous; rump white; band on the wings, and tip of the tail blackish. The varieties are, however, very numerous, and not easily reducible to distinct descriptions. Some of the most remarkable are, the rock, Roman, Barbary, Jacobine, shaker, tumbling, coronet, horseman, and turner pigeons. From 14 to 15 inches long. Inhabit and is domesticated in almost every part of Europe and Asia, and lays from nine to 11 times a year. Though only two eggs are laid at a time, at the expiration of four years, the produce and descendants of a single pair may amount to nearly 15,000. A composition of loam, old rubbish, and salt, will not only entice birds of this species to remain in a required spot, but will even decry those belonging to other places, and is therefore prohibited by law. The carrier pigeon is easily distinguished from the other varieties, by a broad circle of naked white skin round the eyes, and by its dark blue or blackish colour. The bird is conveyed from its home to the place whence the information is intended to be sent; the letter is tied under its wing, and it is let loose. From the instant of its liberation, its flight is directed through the clouds, at an amazing height, to its home, and it darts onward in a straight line to the very spot from which it was taken, by virtue of some faculty or instinct which it is very difficult to explain. To measure their speed with some degree of exactness, a gentleman some years ago, on a trifling wager, sent a carrier pigeon from London, by the coach, to a friend at St. Edmund's-bury, and along with it a note, requesting that the pigeon, two days after its arrival there, might be thrown up precisely when the town-clock struck nine in the morning. This was accordingly done, and the pigeon arrived in London, and flew into the Bull Inn in Bishop's Gate Street, at half an hour past eleven o'clock of the same morning, having flown 72 miles in two hours and a half.

707

Columbata.

Great crowned Indian pigeon. — Bluish; cinerous above; orbits black; crest; shoulders ferruginous. Size of a turkey. Inhabits New Guinea.

708

Crissata.

Lesser crowned pigeon. — Eyelids white; hind head with a red gold crest; breast and belly violet; back, rump, and tail green; legs yellow; hind toe unarmed. Size of the common pigeon. Inhabits Malacca.

709

Palumbia.

Ring dove. — Cinereous; tail feathers black on the hind part; primary quill feathers whitish on the outer edge; neck white on each side; bill yellowish; cere red, and scarlet; irides yellowish; head, back, and wing-coverts bluish; rump and throat pale ash; breast chestnut colour; belly and vent whitish; neck above and at the sides green gold, with a white crescent on each side; feet rough as far as the toes. Weighs about 20 ounces; length eight inches. Inhabits Europe, and rarely Siberia. From its living in woods, and building in trees, it is not uncommonly called wood pigeon. It seems to be originally a native of this island, and probably migrates no farther than from the northern to the southern parts of it. Early in spring it begins to pair, at which time the male is observed to fly in a singular manner, alternately rising and falling in the air. It forms a nest of a few small sticks loosely put together. Its common food is grain and seeds of all kinds, acorns and beech-nuts, and in default of these, turnip-greens, and young clover, or even green corn, and ivy berries. Various attempts to domesticate this species have proved unsuccessful.

Turtle dove. — Tail feathers with white; back Turtur. 

711

gray; breast flesh-coloured; a spot of black feathers, tip with white, on each side of the neck; bill brown; irides yellow; crown olive-ash; front and chin nearly white; scapulars and coverts reddish-brown, spotted with black; throat and breast chestnut-coloured; belly and vent white; two middle tail feathers dusky-brown, the end and exterior side of the outermost feathers white. Subject to several varieties. About 12 inches long. Inhabits Europe, China, and India. Visits the southern parts of England in the spring, and leaves them in the beginning of September. Is very shy and retired, breeding in thick woods, and nesting on high trees. Is very destructive to fields of peas.

B. Tail long and wedge-shaped.

Passenger pigeon. — Orbits naked and sanguine; breast Migratorius. From 15 to 16 inches long. Inhabits North America, migrating southward in December in quest of food. The multitudes which pass in hard winters are truly astonishing, as they fly by millions in a flock, and literally intercept the light of the sun. As soon as one flock has passed, another succeeds; and these movements sometimes continue for three days without intermission. Their favourite food is acorns; but they not only eat the fruit of various kinds of trees, but also corn and rice, of which they are very unsparing in the course of their passage.

Margined turtle. — Breast red; tail feathers tipped with black, and edged with white; bill horn; irides ta- 

712

rugous; front and chin reddish brown; lores white; Plate Perris. 

714

MARGINA 

Margined. 

Marina; 

716

Bantam pigeon. — Orbits naked and flesh-coloured. Bantam- 

717

neck, breast, and flank, waved with black and white. 

size of the wry-neck. Inhabits Java.

Gen. 76. ALAUDA, Lark.

Bill cylindrical, subulate, straight; the mandibles Character equal, and a little gaping at the base; tongue bifid; kind-claw straight, and longer than the toe.

Field

3 Y 2
Field or sky lark.—Outer webs of the two middle tail feathers white, middle ones ferruginous on the inner side; body above varied with blackish, reddish-gray, and whitish; reddish-white beneath; bill and legs black; throat spotted with black. A variety sometimes occurs that is wholly white, another which is black-brown, and a third, which is found in Russia, and distinguished by its very long legs. This well-known species is about seven inches long, and inhabits Europe, Asia, and Africa. It is most common in the open and upland cultivated country in summer, and is rarely found on extended moors at a distance from arable land. The nest is placed on the ground, among grass or corn, and is formed of dry grass and other vegetable stalks, and lined with fine dry grass. The eggs are generally four, rather larger than those of a tit-lark, and of a dirty white, blotched and spotted with brown. The sky lark begins to breed in May, and will lay as late as September, if its first nests are destroyed. The incubation lasts a fortnight, and two broods are usually produced in the course of the year. When hatched, the mother watches over them with the most tender solicitude and affection. They are first fed with worms and insects; but after they are grown up, they live chiefly on seeds, herbage, and most other vegetable substances. They are easily tamed, and become so familiar as to eat off the table, and even alight on the hand. The lark becomes tuneful early in spring, and continues so during the summer. His song is chiefly heard in the morning and evening; and he is one of those few birds that chaunt their melodious music on the wing. We need scarcely remark, that he mounts almost perpendicularly, and by successive springs into the air, where he hovers at a great height, and whence he descends in an oblique direction, unless threatened by some ravenous bird of prey, or attracted by his mate, when he drops down to the ground like a stone. When he first leaves the earth, his notes are feeble and interrupted, but, as he rises, they gradually swell to their full tone. These birds cease their strains in winter, when they assemble in flocks, grow fat, and are taken in multitudes by the bird-catchers. Four thousand dozen have been taken in the neighbourhood of Dunstable, between September and February; and Kepler informs us, that the excuse on larks alone produces about 200l. a-year to the city of Leipzig, whose neighbourhood is celebrated for larks of a peculiarly delicate flavour.

Tit lark.—Greenish-brown, outer webs of the two outermost tail feathers white; eyebrows with a white line; bill black; body white beneath; breast ochreous yellow, with oblong black spots; legs yellowish. Length nearly five inches and three quarters. Inhabits Europe, and is very common in most parts of this island, though it seems partial to barren situations, and occurs both in mountainous and low swampy places. In Scotland, it is almost the only bird which frequents the extensive heath tracts on which it breeds. It has a fine note, and sings either sitting in trees, or on the ground.

Lesser field lark.—Reddish-brown, spotted beneath; chin and belly white; throat and breast obscure yellow; legs brownish; wing coverts edged with white; quill feathers dusky, the outer web of the first edged with white, the others with yellowish-green; hind claw short, and sometimes hooked. Somewhat larger than the preceding, with which it has been often confounded. It visits this country in spring, but is rarely seen till the beginning of May; is not plentiful, and chiefly affects enclosed situations. From the beginning of May till July, it may be seen mounting in the air in a fluttering manner, at the same time uttering a twittering note, and then descending to some neighbouring tree with motionless wing and the tail thrown up. It then sings sweetly, but never when rising. In generally nests in the high grass or green wheat, and lays four eggs of a deep bluish white, thickly blotched and spotted with purplish brown.

Wood lark.—Head surrounded by a white annular edent; body varied like the arvensis; legs flesh-coloured. Weighs about eight drams; length six inches. Inhabits Europe and Siberia, and is met with, though sparingly, in various parts of Britain. It sings delightfully on wing, but rarely when sitting on the ground, though sometimes when perched on a tree. Its song is much more melodious than that of the sky lark, but does not consist of so great a variety of notes; but then it frequently sings in the night, and through most of the year, except in the months of June and July. It does not ascend in the air perpendicularly, and continue hovering and singing in the same spot, like the sky lark, but will sometimes soar to a great height, and keep flying in large irregular circles, singing with little intermission; and will thus continue in the air for an hour together. It is an early breeder, the eggs being sometimes found in the nest in the beginning of April.

Red lark.—Brown or reddish white; two outermost tail feathers white. About the size of the sky lark. Inhabits North America, and is sometimes found near London.

Malabar lark.—Wings and tail dirty brown colour, reddish edges; bill black; crest long, brown and tipped with white; chin and belly reddish white, the feathers of the back, and coverts of the wings, brown; the edge reddish towards the tip, and marked with a white spot; legs reddish. Five inches and a half long. Native of Malabar.

Grasshopper lark, or grasshopper warbler.—Tail feathers brown, the outer one half white, the second with a white wedge tip; wings with two whitish lines; bill dusky; legs whitish; lores white; body greenish-brown above, feathers dusky in the middle, yellowish-white beneath; breast dirty white; tail longish, and somewhat wedge. Length five inches and a half; weight about three drams and a quarter. Inhabit Europe. Though not plentiful in Britain, it perhaps appears to be much less so from its extreme shyness, and its habit of concealing itself among furze and thick hedges. Its singular note resembles the chirping of the larger species of crickets.

Rock lark.—Olive brown, varied with blackish; yellow beneath; sides of the neck and breast with brownish spots; outermost tail feathers obliquely half whitish, second whitish at the tip. Upwards of seven inches long. In its song, manner of flying, and general habits, is much allied to the tit lark. Inhabits some of the rocky shores of England, and seems to subsist chiefly on marine insects.

Lesser crested lark.—Tail feathers black, the two outermost white on the outer edge; head crested; legs red; body pale brown. Inhabit Europe and Siberia, and
ORNITHOLOGY.

Passeres  

Calandra.  

Gen. 77. STURNUS, STARE, or STARLING.  

Character.  

Common star or starling.—Bill yellowish; body black, with white dots; quill feathers and tail dusky; the former edged with yellow on the outer side, the latter with dirty green; lesser coverts edged with yellow, and slightly glossed with green; legs reddish-brown. Male shining with purple, green, and gold. There are several varieties. Weight about three ounces; length eight inches and three quarters. Found in almost every part of the old continent. It breeds in the hollows of trees or rocks, among rubbish, or in old towers, and sometimes appropriates the nest of another bird. Myriads of this species breed among the rocks in the Orkney islands, and in the winter feed on the Cancer pulex. Their general food is insects, earth-worms, seeds, berries, &c. They migrate in flocks, and are very noisy. In confinement it may be taught to mimic various sounds, and even to speak. So attached are they to society, that they not only join those of their own species, but also birds of a different kind; and are frequently seen in company with redwings, fieldfares, and even with pigeons, jackdaws, and owls. They chatter much in the evening and morning, both when they assemble and disperse.  

Water ouzel, or corke.—Black; breast white; chin white; tail black; belly ferruginous; legs pale blue before, black behind. Length seven inches and a half. Inhabits Europe and northern Persia. Is shy and solitary, and rarely to be seen, except on the banks of rivers, and streams of water. It is not infrequent in the mountainous parts of Scotland and Wales, and in some districts in Devonshire. In these places it breeds, and continues the whole year. The nest is very large, formed externally of moss and water plants, and lined with dry oak leaves, resembling that of the wren, with a dome or covering. It is usually placed in some mossy bank, impeding on the water, and contains five or six eggs of a transparent white. "A pair of these birds, says Mr. Montagu, which had for many years built under a small wooden bridge in Caerphalhmashire, we found had made a nest early in May. It was taken, but had no eggs, although the bird flew out of it at the time. In a fortnight after they had completed another nest in the same place, containing five eggs, which was taken; and a month after we took a third nest under the same bridge, with four eggs; undoubtedly the work of the same birds, as no others were seen about that part. At the time the last was taken, the female was sitting, and the instant she quitted her nest, plunged into the water, and disappeared for a considerable time; at last she emerged at a great distance down the stream. At another time we found a nest of this bird in a steep projecting bank over a rivulet clothed with moss. The nest was so well adapted to the surrounding materials, that nothing but the old bird flying in with a fish in its bill would have led to a discovery. The young were nearly full feathered, but incapable of flight, and the moment the nest was disturbed, they fluttered out and dropped into the water, and to our astonishment, instantly vanished; but in a little time made their appearance at some distance down the stream; and it was with difficulty two out of five were taken, as they dived on being approached.—The aquatic habits of this bird have not escaped the notice of ornithologists, some of whom speak of their flying under water. If, indeed, the wings being in motion could be called flying, in certainly does; but this is no more than is common to all diving birds, which, in pursuit of fish, or to escape danger, always use their wings to accelerate their motion. In this case, however, the wings are not extended, for that would retard their progress; but it is effected by short jerks from the shoulder joint. Whether these birds can run at the bottom of the water, as some have asserted, is much to be doubted, as it is requisite all birds should use a considerable exertion to keep them under water, by reason of their specific gravity being so much less. It is certainly a most curious and singular circumstance, that a bird, not apparently in the least formed for diving, should pursue its prey under water, living chiefly on small fish and aquatic insects. It cannot, however, swim on the surface."  

Green stare.—Green above; bluish beneath; a tuft Vireo of black and white feathers on the front and chin. Inhabits China.  

Wattled Stare.—Bill and legs black; a pendent Caruncula—orange wattle at each angle of the mouth. Male black, with the back and wing-coverts ferruginous. Female rust-brown, with very small wattles. Ten inches long. Inhabits New Zealand.  

Collared Stare.—Blackish brown, spotted with brown; Collaris flanks rufous; chin white, spotted with brown. Size of the fieldfare. Inhabits Switzerland and Italy. Is solitary, wags its tail, feeds on seeds, sings with a very weak voice, and builds in the ground, or in clefts of rocks.  

Gen. 78. TURDUS, THRUSH.  

Turdus  

Character.  

Bill somewhat straight; upper mandible a little bending; and notched near the point; nostrils naked or half covered with a small membrane; mouth ciliated, with a few bristles at the corners; tongue jagged.  

Most of the numerous species of this genus feed on berries, especially those of the juniper; and many of them are excellent songsters.  

Missel thrush.—Back brown; neck spotted with Pica-pi—white; bill yellowish; body whitish-yellow beneath, with spots brown on the chin and white beneath; quill and tail feathers brown, with paler edges; the three outermost tipped with white; legs yellow; claws black. Weight near five ounces; length 11 inches. Inhabits the woods of Europe. It is by no means plentiful in Britain, and appears to be less so in winter. It begins to sing in January if the weather be mild, but ceases as soon as the thermometer sinks below 40 degrees. A
ORNITHOLOGY.

Passersa. — At the middle of March it makes a nest in the fork of some tree, especially if covered with lichen, and seems partial to the apple tree, frequenting orchards more than other situations in spring, and never building in a bush. The nest is made of mosses, lichens, and dry leaves, lined with withered grass, and fortified on the outside with small sticks. The eggs are four or five, rarely six; of a flesh colour, and marked with deep and light rust-coloured spots. The song of this bird is louder than that of the thrush, and superior to it. Perching on the uppermost branch of a tall tree, the missel thrush sings when its mate is making the nest, and during incubation; but becomes silent as soon as the young are hatched, and is no more heard till the beginning of the new year. If the young are taken, its song continues as before, and if the female is destroyed, it continues in song the whole summer. The missel is very bold during the breeding season, driving other birds from the neighbourhood of its nest, and on atta-cking the magpie and jay. Its food is insects and berries, particularly those of the misletoe, which are frequently propagated after passing through the digestive organs of this bird.

Filaris. — Fieldfare. — Tail feathers black, the outermost at the inner edge tispt with white; head and rump hoary; bill yellowish, tipp with black; crown and neck olive ash above; body bay above; quill feathers cinereous; throat and breast yellowish-rufose; belly and vent whitish; legs blackish. Subject to three or four varieties. Length 10 inches; weight four ounces. Habits Europe, Syria, and Siberia. Arrives in Britain, in large flocks, about Michaelmas, and leaves us in March. It feeds on the berries of the bolly, thorn, juniper, empertrum nigrotum, arbutus al-pina, &c. as well as on worms and insects. In very se-vere weather they migrate farther south, if not prevented by a sudden fall of snow. In 1758, when a heavy snow fell on the northern and eastern parts of England, prodigious flocks of fieldfairs appeared in the west, but as that part of the island also was soon covered with snow, which lay on the ground for a considerable time, they became too weak to advance farther south, and thousands were picked up, starved to death. Though it builds in trees, and sits on them in the day time, it al-ways roosts on the ground. When a person approaches a tree that is covered with them, they continue fearless, till one at the extremity of the bush, rising on its wings, utters a loud and peculiar note of alarm, when they all immediately fly, except one other, which remains till the person approaches still nearer, and then it also flies off, repeating the note of alarm. Fieldfairs were highly esteemed by the Roman epicures, who kept them in their aviaries, and fattened them with crumbs of bread, mixed with minced figs. According to Varro and Plutarch, the flesh was sometimes bitter.

Pilatus. — Redwing or wind thrush. — Wings ferruginous underneath; eyebrows whitish; bill blackish; legs pale gray; body gray-brown, whitish beneath, with brown spots; sides and inner coverts ferruginous; vent white. Weight nearly two ounces and a half; length eight inches and a half. Habits Europe, and is a winter guest with us, appearing a few days before the prece-ding, migrating in vast flocks. It breeds in Sweden, Norway, &c. where it inhabits the maple woods, and sings delightfully from their highest tops. It builds in hedges or thickets, and lays six bluish-green eggs, spot-ted with black. In the southern countries of Europe, it does great injury to the vineyards.

Muscri. — Thrush or song-thrush; mavis of the Scotch. — Quill feathers ferruginous at the inner base. Remembles the missel in colour, but the inner wing coverts are yellow, irides hazel, bill brown, and the mouth yellow within. Habits the woods in Europe. Weight about three ounces; length nine inches. This well-known species is generally admired for its song. Every wood and grove re-echoes with its notes, which sometimes vie with those of the missel. The thrush frequently sings as early as February, if the weather is mild, and in March the female makes its nest, composed of dried grass and green moss externally, and plastered within with rotten wood, mixed with cow dung or clay, and so compactly as to hold water, a circumstance which, in a rainy season, sometimes proves fatal to the egg. The latter are four or five, of a blue colour, and spotted with black at the larger end. The nest is sometimes placed on the stump of a tree, very near the ground, or against the side of a tree, and frequently in a hedge, or solitary bush. Though the thrush feeds on berries and insects in general, it is particularly fond of shelled snails, especially of the helix membranacea, whose shell it breaks by repeated strokes against a stone. It is not uncommon to find a great many fragments of shells together, as if a number had been con-veyed to one particular stone for the purpose. This species breeds twice, and sometimes thrice in the year, and consequently continues long in song. Like the preceding, it is very hurtful to vineyards.

Pseudo. — Mocking bird, or mimic thrush. — Dusky ash above; yellow liquorice beneath; primary quill feathers white on the outer half; bill black; irides yellow; tail four inches long; legs cinereous. Nine inches and a half long. In-habits the moist woods of Virginia, Carolina, Jamaica, &c. In the summer is seen much more to the northward than in winter. This singular species not only possesses musical and solemn notes of its own, but can at pleasure assume the tone of every other animal in the forest, from the humming bird to the eagle, and descending even to the wolf or the raven. One of them, confined in a cage, has been heard to mimic the meowing of a cat, the chattering of a magpie, and the creaking of the hinges of a sign-post in high winds. It is said to take a pleasure in archly deceiving other birds, alluring the smaller kinds, for example, with the call of their mates, and then terrifying them with the scream of an eagle. In the warmer parts of America, it sings incessantly from March to August, both day and night, beginning with its own compositions, and frequently finishing by borrowing from the whole feathered quire, repeating its tunes with such artful sweetness as to excite both pleasure and surprise. The female frequently builds her nest in the bushes or fruit-trees about houses, but is so very shy, that if a person only looks at the nest, she immediately forsakes it. It feeds on grasshoppers, different kinds of berries, &c. and is itself eaten by the Americans, who account it very delicate food.

Pterodactyl. — Mocking thrush. — Back brown; breast and lateral areas tail feathers whitish; eyebrows white. Eight inches and a half long; inhabits South America, and re-sembles the last in its fine song and imitative notes.

Pagoda thrush. — Black; back and rump gray; vent Pterodactyl; white;
ORNITHOLOGY.

Panetes. White; head crested. Size of a finch. Inhabits Malabar and Coromandel, chiefly about the temples and pagodas.

744 "Chili thrush." Glossy black; bill somewhat striated; tail wedged; bill, eyes, legs, and flesh black; tail five inches long. About the size of the missel; is common in Chili, where it sings sweetly; imitates the notes of other birds, and, when tamed, the voice of man. Feeds on worms, seeds, and even on smaller birds, which it kills by perforating the skull with its bill. Congregates with starlings, and makes a nest of twigs and fibres, mixed with mud, and lined with hair. Lays three bluish-white eggs.

745 Roseus. Brown-coloured thrush. Pale rosy; head, wings, and tail black; hind head crested. About eight inches long. Inhabits Europe and Asia, and has been found, though very rarely, in England. As it feeds chiefly on locusts, it is held sacred by the Turks.

746 Centurus. Musician thrush. Reddish-brown, varied with transverse dark streaks; whitish beneath; chin, cheeks, and throat reddish-orange; a black blotch spotted with white on each side of the neck. Four inches long. Inhabits the woods of Cayenne. Is solitary; feeds on ants and other insects, and is celebrated for its sweet and variable note.

747 Turdus. Chiming thrush. Brown above; under parts and rump reddish-tawney; chin white; cap and cheeks white, spotted with black; eyebrows and streaks behind the eyes black. Four inches long. Inhabits the woods of Cayenne and Guiana. Its note resembles the chiming of bells.

748 T. auricola. Marum thrush. Brown above; white beneath; breast spotted with black; tail even; bill black above, white beneath; legs pale plumbeous. Six inches and a half long. Inhabits Cayenne. Every morning and evening, for the space of an hour, cries with a harsh loud voice, like an alarum bell.

749 T. x. King thrush. Reddish-brown above, paler beneath; hind head lead-coloured; front varied with white and brown. Seven inches and a half long. Inhabits South America, near the hillocks raised by the white ants, on which it feeds.

750 Merula. Blackbird. Black; bill and eyelids yellow. Female, and the young male rustly black, and bill dark. There is a variety with the head white, another with the body white and black, and a third entirely white. Inhabits Europe and Asia. A well-known species, admired for its song, which is a shrill kind of whistle of various notes, enlivening the early days of spring. The nest is externally composed of green moss, fibrous roots, &c. having the inside plastered with earth, and then lined with fine dry grass. The female lays four or five blue eggs, thickly covered with pale ferruginous brown spots. The blackbird feeds principally on worms and shellfish, but is also fond of insects and fruit in general. It breaks the shell of the snail with great dexterity on a stone. In confinement it readily eats crumbs of bread, and flesh either raw or prepared for the table. With us it is never observed to migrate or to congregate, but lives solitary in woods and inclosed situations. It is easily tamed, and imitates other sounds, even that of the human voice.

751 Turdus. Ring ouzel. Blackish; bill yellowish; collar white. Rather larger than the blackbird. Inhabits Europe, Asia, and Africa. Is migratory in some countries, but is known to remain and breed in the mountains of Scotland and Wales. When fattened, its flesh is much esteemed. In its habits it is nearly allied to the blackbird.

752 Reed thrush. Rusty brown; white testaceous beneath; quill feathers brown, tipped with reddish. Frequently varies in its markings. Inhabits the reedy marshes of Europe, builds a hanging nest among the reeds, and lays from five to six yellowish white eggs spotted with brown. The male sings while the female is sitting.

753 Songster thrush. Greenish-black, shining with blue or violet; wings and tail black. Inhabits the Philippine isles in numerous flocks; sings very sweetly, and often lays in pigeon houses.

754 Ampelis. Gen. 79. Ampelis, Chatterer. Bill straight, convex, somewhat incurved; each mandible notched; nostrils covered with bristles; tongue sharp, cartilaginous, and bifid; middle toe connected at the base to the outermost.

755 Carrulus. Waxen or Bohemian chatterer. Hind head crested; bill short, thick, convex above, and flat beneath; upper mandible bent down at the tip; nostrils small at the base of the bill, and nearly covered with feathers; tongue jagged at the tip; tail long and wedged.

756 Cape coly. Outermost tail feathers white on the Coperius, outside; body cinereous; whitish beneath. Ten inches and a quarter long. Inhabits the Cape of Good Hope out of which it disperses to all parts of the warmer regions.

757 Panayana coly. Above yellowish ash colour; beneath Pongamia Plate CCCXII. Rufous; breast streaked with black; head crested; bill black; legs pale flesh colour; tail very long, the feathers of which are of different lengths. Native of Panay, one of the Philippine islands.

758 Green coly. Shining green; hind head and eyelids Forster's silky black; wings and tail blackish. Twelve inches long. Inhabits New Holland.

759 Indian coly. Cinereous above; rufous beneath; India. Hind head and chin yellow; lores and naked orbits yellow. Fourteen inches long. Inhabits India.
In summer it frequents woods; and in winter haunts orchards and gardens, where it preys on the young boughs of the trees. It is not gregarious, but is usually observed in pairs, or on broods, and remains with us all the year, making a nest of small dry twigs, lined with fibrous roots, in some thick bush, either in woods or hedges, about the latter end of April or beginning of May, and laying four to five eggs of a bluish-white, speckled and streaked with purple, and rather larger than those of a linnet. The native notes of the bullfinch are few, but remarkably soft, and uttered in so low a tone as to escape a common observer; the call notes are simple, but more audible. In confinement it becomes very docile, and may be taught a great variety of tunes, and even to imitate human speech. But it also acquires harsh strains with equal facility. A friend of the Comte de Buffon saw one of this species that had never heard any person whistle but carters; and it whistled with their strength and coarseness. These birds are also susceptible of strong and durable attachments. Some have been known, after escaping and living a whole year in the woods, to recognise the voice of their mistress, and return to forsake her no more, and others have died of melancholy on being removed from the first object of their attachment.

Cardinal grossbeak.—Crested; red; frontlet black; bill and legs blood red; crest, when erect, pointed. Nearly eight inches long. Inhabits North America.

From the melody of its song, some of the Americans call it nightingale. In spring, and during great part of summer, it sits on the tops of the highest trees, and makes the forests echo with its song. During summer, it lays up its winter provision of maize and buckwheat. Nearly a bushel of the former grain has been found in the retreat of one of these birds, artfully covered with leaves and small branches of trees, and only a small hole left at which the bird enters. In cages it will sing with a very short interval of silence, through the whole year.

Grosbeak, or houfinch.—Chesnut ash; wings with a white line; middle quill feathers rhombic at the tips; tail feathers black at the base of the thinner web; orbits and chin black; tail spotted with white within. The length of this species is six inches; weight about two ounces. The plumage is subject to great variety. It inhabits Europe, and usually appears in Britain in the autumn, continuing till April, and appearing in small flocks of four or five, but not commonly. It is more plentiful in France, and breeds in Burgundy in April. The nest is composed of dried fibres intermixed with liverwort, and lined with finer materials. The eggs are of a bluish green spotted with olive brown, with a few irregular black markings. This bird lives on the kernel of the almond, walnut, and cherry, breaking with the greatest ease their hard stones with its bill.

Pine grossbeak.—Wings with a double white line; tail feathers all black; head, neck, breast, and rump in the young bird, red; in the old yellow; female olive. Nine inches long. Inhabits Europe, Asia, and America, but is limited to the northern regions of these quarters of the globe, and especially to the pine forests. In this island it is only found in the north of Scotland, where it is also supposed to breed. It sings excellently, and during the night, but soon ceases. It builds in trees pretty near the ground a nest of small sticks, and lines it with feathers, laying four eggs. Its food is the seed of the pine.

Bullfinch.—Cinereous; head, wings, and tail black; covert of the tail, and hindmost quill feathers white; crown black; breast cinereous; belly of the male red, of the female chestnut. Scarcely six inches long, and liable to vary in its markings. Inhabits Europe and Siberia.
ORNITHOLOGY.

Passerine. Some thick bush. The eggs are four or five; white, speckled with rusty red at the larger end, and much like those of the hineet, but larger. The principal food of this bird is seed and grain. It is easily tamed if held on one's fingers in the dark and heated gently. Though its native song is trilling, in confinement it will catch the notes of other birds.

Sulphurine. Brimstone grosbeak.—Olive brown; throat and belly pale yellow; eyebrows brown. Nearly six inches long. Inhabits in flocks near the Cape of Good Hope, frequents the banks of rivers, and builds a pendulous nest, with long neck breadth, in trees and shrubs.

Bengaline. Bengal grosbeak.—Gray; crown yellow; temples whitish; belly whitish, spotted with brown. "This bird (says Sir William Jones) is exceedingly common in Hindostan: he is astonishingly sensible, faithful and docile; never voluntarily deserting the place where his young are hatched, but not averse, like most other birds, to the society of mankind, and easily taught to perch on the hand of his master. In a state of nature he generally builds his nest on the highest tree that he can find, especially on the palm, or on the Indian fig tree, and he prefers that which happens to overhang a well or a rivulet; he makes it of grass, which he weaves like cloth, and shapes like a large bottle, suspending it firmly on the branches; but so as to rock with the wind, and placing it with its entrance downward to secure it from birds of prey. Its nest usually consists of two or three chambers; and it is popularly believed that he lights them with fire flies, which he is said to catch alive at night, and confine with moist clay or with cow dung. That such flies are often found in his nest, whose pieces of cow dung are also stuck, is indubitable; but as their light could be of little use to him, it seems probable that he only feeds on them. He may be taught with ease to fetch a piece of paper, or any small thing that his master points out to him. It is an attest fact, that if a ring be dropped into a deep well, and a signal given to him, he will fly down with amazing celerity, catch the ring before it touches the water, and bring it up to his master with apparent exultation; and it is confidently asserted, that if a house or any other place be shown to him once or twice, he will carry a note thither immediately on a proper signal being made. One instance of his docility I can myself mention with confidence, having often been an eye witness of it. The young Hindoo women at Bemars, and in other places, wear very thin plates of gold called tisca, slightly fixed, by way of ornament, between their eyebrows; and when they pass through the streets, it is not uncommon for the youthful libertines who amuse themselves with training these birds, to give them a signal which they understand, and send them to pick the pieces of gold from the foreheads of their mistresses, which they bring in triumph to their lovers."

Philippine. Philippine grosbeak.—Brown; yellowish white beneath; crown and breast pale yellow; chin brown. Inhabits the Philippine islands. A variety found in Abyssinia, has the tail and quill feathers greenish brown, and edged with yellow. Constructs a nest like the bengaline.

Abysinnian. Abysinnian grosbeak.—Yellowish; crown, temples, vol. xiv. part ii.
ORNITHOLOGY.

Passeres. their principal food; though, on examining their nests, I found the wings and legs of different insects. From every appearance, the nest which I dissected had been inhabited for many years; and some parts of it were much more complete than others. This, therefore, I conceive to amount nearly to a proof, that the animals added to it at different times, as they found necessary from the increase of the family, or rather of the nation or community."

785 Grenadier grosbeak.—Gray; bill, front, and belly, black; neck and rump tawney; sometimes the wings are white, and the tail is brown. Size of a sparrow; inhabits Africa, and is found chiefly in marshy and reedy grounds. The nest is formed among the reeds with small twigs, so closely interwoven with cotton, as not to be penetrated by any weather. It is also divided into two compartments, of which the upper is for the male, and the lower for the female and the young.

Among various other species which we have not room to describe, there are two or three of a very small size, which inhabit Surinam.

Emberiza. Gen. 82. Emberiza, Bunting.

786 Characters. Bill conical; mandibles receding from each other from the base downwards, the lower with the sides contracted, the upper with a hard knob within.

Nivolar. Snow bunting, snow bird, or snow flake.—Quill feathers white, the primaries black on the outer edge; tail feathers black, the three lateral ones white; bill and legs brown. Besides the varieties induced by age, sex, and climate, there are others which seem to be more permanent. In winter, the whole body, except the back and middle coverts, often becomes nearly white. Somewhat larger than the chaffinch. In summer, inhabits in vast flocks, the north of Europe, Asia, and America. In winter, migrates to some warmer climate. Breeds in some of the mountains of Scotland, where it is sometimes mistaken for the ortolan. It builds in the fissures of rocks, constructing a nest of grass and feathers lined with the hair and wool of the arctic fox or other quadruped, and lays five eggs. It sings well, sitting on the ground, feeds on grain, and is wakeful during the night. It is taken in great numbers in winter, when it is fat, and its flesh esteemed delicate.

787 Taumey bunting.—Quill feathers dusky, white at the base, the last wholly black; tail feathers black, the middle ones at the edge, and three lateral ones, white on each side, with a dusky spot without. Nearly seven inches long. Inhabituses the last; but is more rare. In some places it is called sea back and Brambling.

Mountain bunting, Lesser mountain Finch or Brambling.

—Five first quill feathers blackish-brown, the rest white, spotted with brown at the tips; tail feathers black, three lateral ones all white on each side; bill yellow, tippet with black; head chestnut; chin white; upper part of the neck and back cinereous; breast and belly with longitudinal flame-coloured spots. Found in Yorkshire, Lincolnshire, and Northamptonshire, but is not common.

788 Common bunting.—Brown; spotted with black beneath, orbits rufous; bill and legs brownish; quill feathers dusky; outer edges pale yellow; tail a little forked, edged with white; legs yellowish. Weight nearly two ounces; length seven inches and a half. Inhabituses Europe in large flocks during the autumn and winter. Seems partial to champaign countries, abounding with grass fields remote from arable land. While the female is employed in incubation, the male sits on the branch of a neighbouring tree, and cheers her with his rude song. The nest is placed on the ground, formed externally of straw, lined with fibrous roots or dry grass, and sometimes finished with long hairs. The eggs are from four to six, of a dirty white, spotted and veined with reddish-brown and ash-colour. These birds are sometimes brought to market, and sold for larks, to which they are little or nothing inferior, but are easily distinguished by the form of the bill, and the tooth like knob in the roof of the mouth, by the most common observer.

Ortolan.—Quill feathers brown, the first three whitish yellow at the edges; tail feathers brown, the two lateral ones black on the outer side; bill, naked eyelids and legs yellowish; head and neck olive-ash; chin yellowish, surrounded with a cinereous line; feathers of the back and scapulars brownish-bay, black in the middle; body reddish beneath. The female is distinguished by the head and neck being cinereous, and each feather with a narrow blackish line. Somewhat less than the yellow hammer; length six inches and a quarter. Inhabits several parts of Europe, but is not found in Britain. Ortolans are common in France, Italy, some parts of Germany, Sweden, &c. migrating in spring and autumn, when they are caught in great quantities, and fattened for the table. For this purpose, they are confined in a dark room, and fed plentifully with oats and millet. They are then killed for sale, and reckoned the most delicate of food. The ortolan will sometimes sing very prettily, its note being not unlike that of the yellow hammer, but finer and sweeter. In some parts, it makes its nest on a low hedge, in others on the ground, and constructs it carelessly, like that of the lark. The female lays four or five grayish eggs, and in general has two broods in the year. —There are five or six varieties.

Yellow hammer, or yellow bunting.—Tail feathers Citrinula, blackish, the two outer ones on the inner edge, with a pointed white spot; bill black; crown, cheeks and body beneath yellow; eyebrows brownish; nape greenish; feathers of the neck and back blackish brown the middle, rufous at the sides, and edged with gray; rump pale tawney; wings chestnut, olive or black, mostly edged with gray; lateral ones olive without; the tip edged with white; legs yellowish-brown. The weight of this species is about seven drams: length six inches. Inhabituses Europe, and is one of the most common indigenous birds of this country. Its song is as little attractive as that of the common bunting, possessing only a repetition of the same note, five or six times successively, and terminating in one more lengthened and shrill. It congregates in winter, approaching houses, and roosting up scattered grains. It does not nest under till late in the spring. The nest is generally placed near the ground, in some low bush or hedge, and is composed of straw and various dried stalks, lined with fine dry grass, and finished with long hair. The eggs differ somewhat in colour and size, some being nearly white, and others having a purplish hue, but all more or less marked with hair-like streaks. The number is usually three, four, or five.

Foolish bunting, or foolish sparrow.—Reddish; head with a few blackish lines; eyebrows white. Size of the yellow.
ORNITHOLOGY.

Reed bunting, or reed sparrow. — Head black; body gray and black; outmost tail feathers with a white wedged spot; bill brown; throat and breast black; belly white, streaked with black at the sides; wing coverts and quill feathers brownish red, black down the middle; tail feathers pointed, the eight middle ones black, two middle ones rufous on each edge, the rest on the outer only; legs brownish. Weight near five drams and a half; length six inches. Inhabitants the marshy and reedy districts of Europe and Southern Siberia. A brown variety occurs at the Cape of Good Hope, and a white one about Astracan. "It is somewhat extraordinary," observes the intelligent ornithologist quoted above, "that the manners and habits of so common a bird should remain so long in obscurity; even modern authors tell us it is a song bird, that it sings after sunset; and describe its nest to be suspended over the water fastened between three or four reeds. There can be no doubt, however, that the nest, as well as the song, of the sedge warbler, have been taken and confounded for those of this bird; for as they both frequent the same places in the breeding season, that elegant little warbler is pouring forth its varied notes concealed in the thickest part of a bush; while this is conspicuously perched above, whose tune is not deserving the name of song, consisting only of two notes, the first repeated three or four times, the last single and more sharp. This inharmonious tune it continues to deliver with small intervals from the same spray, for a great while together when the female is sitting. The nest is most commonly placed on the ground near water; sometimes it builds in a bush some distance from the ground; at other times in high grass, reeds, sedge, or the like, and even in furze at a considerable distance from any water; in all these situations we have met with it, but never fastened or suspended as authors have related. The nest is composed of stalks of grass, or other dry vegetable substances, sometimes partly moss, and lined with fire grass; frequently finished with long hair. The eggs, which are four or five in number, weigh about 36 grains, and are of a dirty bluish-white or purplish-brown, with numerous dark-coloured spots and veins, much resembling those of the chaffinch.

Whitlow bunting. — Black; breast red; four middle tail feathers long and pointed, two very long; bill black. The two middle tail feathers are four inches in length, very broad, and ending in a long thread; the two next are 13 inches or more in length, very broad in the middle, narrower at the end, and rather pointed; from the middle of the shaft of this last arises another long thread; the rest of the tail feathers are only two inches and a quarter long; the two middle long ones are placed somewhat vertically, appear undulated across, and are more glossy than the others; the legs are flesh-coloured. The female is wholly of a deep brown, approaching to black, but does not acquire its full plumage till the third year. This species inhabits Africa, particularly Angola. It molts in November, and also late in spring.

Shaft-tailed bunting. — Four middle tail feathers black, Regia; from nine to ten inches long, equal and feathered only at the tip; bill and legs red; body above, and vent, black; body beneath, and throat, temples, and orbits, rufous; neck above spotted with black. Native of Africa. Less than the linnet.

Green-headed bunting. — Brown; head and neck olives; Chloris.
584

ORNITHOLOGY.

Turaco. — Back and wing-coverts varied with brown and black; tail forked. Only two instances are recorded of this species having been found in England.

Character. Bill conical, pointed, notched, almost triangular at the base, and a little inclining at the tip.

Tanagra. — Red-breasted tanager. — Black; front, throat, and breast, scarlet; bill black; lower mandible silvery, and convex on the hind part; front sometimes black; legs brown. Female purplish-brown; reddish beneath; wings and tail brown. Six inches and a half long. Inhabits South America, frequenting inhabited places, building a pendulous cylindrical nest, and feeding on fruits.

Episcopus. — Bishop tanager. — Cinereous; wings and tail blue without. Six inches and a half long. Inhabits Cayenne, especially about the skirts of the forests, and feeds on the lesser kinds of fruits. During night it roosts on the palm leaves.

Jacinth. — Jacaranda. — Black violet; wings whitish beneath; tail divericated and forked; bill and legs cinereous. Inhabits Brazil and Guiana. Is fond of newly cultivated land; haunts small trees, particularly coffee trees. The male frequently hops upwards from a branch, alighting again, first on one foot, and then on the other, accompanying each leap by a note, and spreading out the tail at the same time. The nest is hemispherical, about two inches in diameter, and composed of dried herbs of a gray colour. The eggs are two in number, of a greenish-white, marked with small numerous red spots, deepest and most in number at the large end.

Siberica. — Siberian tanager. — Black; tips of the interscapular and rump feathers fringed with white; bill short, pale, t ipt with brown; bill notched at the tip; legs black. Native of Siberia; size of a thrush.

The other species, which are numerous, and not very distinctly ascertained by authors, seem to differ from one another more in their markings than their habits.

Gen. 84. Fringilla. Finch.

Character. This is a numerous and active tribe of birds, very generally dispersed over the world, and feeding principally on insects and grain.

Lapponea. — Lapland finch. — Head black; body gray and black; eyebrows white; outmost tail feathers with a white wedged spot. Six inches and a half long. Inhabits Europe, Asia, and America. Runs along the ground like a lark, and sings on the wing.

Chaffinch; provincially, beech finch, horse finch, pink, and twink. — Limbs black; quill feathers white on both sides, the three first without spots: two of the tail feathers obliquely white; bill white, but in spring and summer bluish, t ipt with black; crown, nape, and sides of the neck hoary; temples and throat reddish; belly and vent reddish-white; wing-coverts with a white blotch, the greater with a white band besides; quill feathers yellowish at the edge, and white at the base; tail a little forked; legs brown. The female wants the red on the breast and other parts. Rather less than the sparrow. Inhabits Europe and Africa. Continues with us the whole year; but the females migrate from Sweden to Holland in the autumn, leaving their mates behind, and return in the spring. This bird makes a most elegant nest of green moss, curiously studded with lichen, interwoven with wool, and lined with feathers and hair. It builds against the side of a tree, particularly in ivy, or in some forked branch of a bush; but particularly in apple trees overgrown with moss and lichen, and like many other birds, adapts the materials of its nest to the surrounding colour. The eggs are four or five, larger than those of the goldfinch, of a dirty white, tinged with purple, marked with streaks and spots of dark purple. Its notes are few, and scarcely deserve the name of song. Both sexes have a monotonous call-note, which seems to express the word twink. This species is subject to several varieties.

Mountain finch, brambling, or bromele. — Base of the tail wings fine yellow beneath; bill yellowish, t ipt with black; head, neck, and back black; in the female brown; the feathers edged with reddish brown; rump, lower part of the breast and belly white; throat and upper part of the breast reddish-tawney; in the female reddish gray; lesser wing-coverts reddish; middle ones reddish white; greater black, t ipt with white; those next the body reddish at the tip; quill feathers black, edged with yellowish; tail a little forked; legs gray. Rather larger than the preceding; length about six inches. Inhabits Europe and Asia, breeding in the northern regions. Is frequently seen in large flocks in the winter, on the coasts of Kent and Sussex, when the weather is severe, when it is sometimes so exhausted as to suffer itself to be taken up. They are also found in the interior parts of the kingdom at that season, flying in company with chaffinches and yellow hammers. In hard winters, they are also frequently seen in the neighbourhood of Edinburgh. They are partial to the pine forests in the Highlands, and live on beech mast and the seeds of other trees. They build in trees a nest formed of lumps of nest, and of wood and feathers within, the female laying four or five yellow spotted eggs. Their flesh is tasty, though sometimes bitter.

Goldfinch, or thistlefinch. — Quill feathers black; and Carduelis, except the outmost marked with fine yellow in the middle; two outmost tail feathers in the middle, and the rest at the tips white; bill white, t ipt with black; frontlet scarlet, in the female brown; cheeks, hind head, and belly white; top of the head black; wing-coverts black, in the female brown; back, rump, and breast, chestnut-brown. This beautiful species, which is subject to great variety, is rather less than the chaffinch, and inhabits Europe, Asia, and Africa. It is gregarious in winter, lives to a great age, subsists chiefly on the seeds of the thistle, hemp, and capitulated plants; is dainty and easily tamed, and sings delightfully, even in confinement. It sometimes builds in hedges, but most commonly in trees, especially those that are overgrown. The nest is neatly constructed of bent moss, moss, and lichen, woven together with wool, and sometimes lined with wool, or hair covered with thistle down, or the pappus of the willow. The eggs are four or five, of a bluish white, with a few small spots, chiefly at the larger end. The goldfinch readily breeds with the canary and other congeners.

Lepidoptera. — Greenish-brown; band above and below the eyes and chin orange; breast black. Only half the size of the canary bird. Inhabits the woods of Cuba, and sings with a weak, but very sweet note.

Ethiopian finch. — Deep black; irides russet. Inhabits the habits of...
ornithology.

Canary bird, or canary finch.—Bill and body brown colour; quill and tail feathers greenish. Is now well known over Europe, into which it was brought from the Canary islands, about the beginning of the 16th century. It is somewhat longer than the siskin, and about five inches and a half in length. With us they are kept in a state of captivity, and partake of all the differences and varieties incident to that condition. Buffon enumerates 20 varieties, and many might probably be added to his list. "The breeding and rearing of these charming birds," says Mr Bewick, "form an amusement of the most pleasing kind, and afford a variety of scenes highly interesting and gratifying to innocent minds. In the places fitted up and accommodated to the use of the little captives, we are delighted to see the workings of nature exemplified in the choice of their mates, building their nests, hatching and rearing their young, and in the impassioned ardour exhibited by the male, whether he is engaged in assisting his faithful mate in collecting materials for her nest, in arranging them for her accommodation, in providing food for her offspring, or in chanting his lively and amorous songs during every part of the important business. The canary will breed freely with the siskin and goldfinch, particularly the former; it likewise proves prolific with the linnet, but not so readily, and admits also the chaffinch, yellow hunting, and even the sparrow, though with still more difficulty. In all these instances, excepting the first, the pairing succeeds best when the female canary is introduced to the male of the opposite species. According to Buffon, the siskin is the only bird of which the male and female propagate equally with those of the male or female canaries. "Great numbers of these birds are reared in the Tyrol. Four Tyrolese usually brought over to England about 1600 of them annually; and though they carried them on their backs 1000 miles, and paid 25l. for such a number, they were enabled to sell them at five shillings a-piece. It is not generally known, that the song of the canary bird is usually composed of the notes of the tit-hark or of the nightingale. Mr Barrington saw two of the species which were imported from the Canary islands, neither of which had any song; and he was afterwards informed, that a ship brought over a great many of them with the same defect. Most of those from the Tyrol have been educated under parents whose progenitors were instructed by a nightingale. Our English canary birds, however, have more of the tit-hark's than of the nightingale's notes. The canary bird lives chiefly on the seeds of

Siskin, or aberdeine.—Quill feathers yellow in the middle; the first four without spots; tail feathers yellow at the base, and tip with black; crown black; body yellowish; greenish above, breast greenish; wings green; throat brown, of the female white; head and back, in the female, greenish-ash, spotted with brown. Four inches and three-fourths long. Inhabits Europe, and is liable to several varieties. Though migratory in most places, it does not seem to observe any regular periods, as it is sometimes seen in large, and at other times in very small numbers. Buffon remarks, that the great flights happen only once in the course of three or four years. It conceals its nest with so much art, that it is extremely difficult to discover it. Kramer informs us, that in the forests bordering on the Danube, thousands of young siskins are frequently found, which have not dropped their first feathers, and yet it is rare to meet with a nest. It is not known to breed in this island; nor is it known whence they come over to us. In some parts it is called the barley bird, from its appearing when that grain is sown. Its song, though not so loud as that of the canary, is pleasing and various. It is docile and familiar in captivity, and will imitate the notes of other birds, even to the chirping of a sparrow. Like the goldfinch, it may easily be taught to draw up its little bucket with water and food. It drinks frequently, and seems fond of throwing water over its feathers. The male breeds freely with the hen canary, and is assiduous in his attention to her, carrying materials for the nest, and arranging them, and during the time of incubation, regularly supplying her with food.

Bearded finch.—Pale yellow; wings green, spotted with black and red; chin bearded. Size of the canary bird. Inhabits the mountains of Chili, except in winter, when it descends into the plains. It is easily tamed, sings charmingly, and imitates the notes of other birds.

Greater redpole, or red-headed linnet.—Chesnut brown; Canaria. reddish-white beneath; wings with a longitudinal white band; tail feathers edged with white on each side; bill black; head and neck cinereous; sides yellow; middle of the belly white; tail forked, dusky, both sides edged with white. Head of the female ash-colour, spotted black; crown and breast without the red; breast dirty yellow with black lines. Subject to considerable variety in the markings. Five inches and a half long. Inhabit Europe and America. These birds fly in flocks during winter, at which time the males have little or none of the red markings, which in the return of spring they put forth. In many parts they haunt the sea shore, and in the breeding season, often resort to furry commons. The nest is composed of moss and bents interwoven with wool, and lined with wool and hair. The eggs are four or five, of a bluish-white, with purplish specks and short lines. The redpole sings nearly the whole year, is very familiar, and is easily tamed, as to be cheerful in five minutes after it is taken.

Common or brown linnet.—Chesnut brown; whitish Linaria. beneath; wings with a longitudinal white band; tail feathers edged with white on each side. Though this is usually described as a distinct species, it seems to be only a variety of the preceding.

Lesser redpole or lesser red-headed linnet.—Brown, Linaria; varié with grey; reddish-white beneath; wings with a double white band; crown and breast red; bill and legs brown; back black, the feathers edged with chesnut; sides with narrow dusky lines; quill feathers dusky, edged with dirty white; legs dusky. Female with a saffron spot on the front. Weight about two drams and a half; length
ORNITHOLOGY.

Passerini. — length five inches. Inhabits Europe, Asia, and America. It is gregarious in winter, when many are taken by the bird-catchers near London, &c. under the name of stone redpole. It breeds in Scotland and the north of England; building in the trunk of the alder a nest of dry sticks and wool, lined with hair and feathers, or willow down. Lays four eggs of a light bluish-green, thickly sprinkled with reddish spots, especially at the larger end.

819. Montanum. 
Mountain linnet, or towite.—Black, varied with reddish; whitish beneath; feathers of the lower part of the neck black in the middle; and with a white band; rump red; feathers of the throat and breast black, edged with white; middle quill feathers edged; secondary tipt with white. Rather larger than the greater redpole; length about six inches and a half. Inhabits Europe. Is gregarious, and has much the habits of the other linnets, with which it associates.

820. Coecus. 
Scarlet finch.—Bright orange; wings and even tail black; quill feathers orange at the outer edge, the primaries tipt with black; bill brownish; legs black. Four inches and a half long. Inhabits the Sandwich islands.

821. Domesticus. 
House sparrow.—Quill and tail feathers brown; body gray and black; wings with a single white band; bill black; crown gray; a black spot under each eye; a broad bay mark surrounding the hind part of the head; cheeks white; chin and under side of the neck black, the latter edged with white; lesser wing-coverts bright bay; the last row black, tipt with white. The lower mandible of the female white, and a white line beyond each eye. The most remarkable varieties are, 1. white, 2. yellow, clouded with chestnut above, and 3. blackish. Weighs nearly seven drams; length about six inches. Inhabits Europe, Asia, and Africa. This well known species inhabits the dwellings of the rich and the poor, and is rarely seen far from the habitation of man. It lives on seeds and fruits, and often cunningly avoids the snare that are laid for it. In autumn it is often gregarious, but more frequently so in winter. It does not sing, except when tamed, and then the male will imitate the song of a linnet, or other bird within hearing. It makes a nest conformable to the place which it chooses for incubation, whether in a hole of a wall, in thatch, under the tiles of a house, or in the nest of a martin, or other bird; but when it builds in a tree, the nest is of a large size, and covered at the top, composed of hay and straw, lined warmly with feathers and fragments of thread or worsted, bits of cloth, or any refuse material of that sort found about houses. The female lays six eggs of a whitish colour, spotted with dusky and cinerea, and usually breeds thrice in the year. Mr. Smellie relates a pleasant anecdote of the affection of these birds towards their young. "When I was a boy," says he, "I carried off a nest of young sparrows, about a mile from my place of residence. After the nest was completely removed, and while I was marching home with them in triumph, I perceived, with some degree of astonishment, both parents following me at some distance, and observing my motions in perfect silence. A thought then struck me, that they might follow me home, and feed their young according to their usual manner. When just entering the door, I held up the nest, and made the young utter the cry which is expressive of the desire of food. I immediately put the nest and the young in the corner of a wire cage, and placed it on the outside of a window. I chose a situation in the room where I could perceive all that should happen, without being myself seen. The young animals soon cried for food. In a short time both parents, having their bills filled with small caterpillars, came to the cage; and after chatting a little, as we would do with a friend through the lattice of a prison, gave a small worm to each. This parental intercourse continued regularly for some time till the young were completely fledged, and had acquired a considerable degree of strength. A fine day took one of the strongest of them, and placed him on the outside of the cage, in order to observe the conduct of the parent after one of their offspring was emancipated. In a few minutes both parents arrived, loaded as usual with food. They no sooner perceived that one of their children had escaped from prison, than they fluttered about, and made a thousand noisy demonstrations of joy both with their wings and their voices. These tumultuous expressions of unexpected happiness at last gave place to a more calm and soothing conversation. By their voices and their movements it was evident that they earnestly entreated him to follow them, and to fly from his present dangerous state. He seemed to be impatient to obey their mandates; but, by his gestures, and the feeble sounds he uttered, he plainly expressed that he was afraid to try an exertion he had never before attempted. They, however, incessantly repeated their solicitations; by flying alternately from the cage to a neighbouring chimney top, they endeavored to show him how easily the journey was to be accomplished. He at last committed himself to the air, and alighted in safety. Upon his arrival, another scene of clamorous and active joy was exhibited. Next day I repeated the same experiment, by exposing another of the young on the top of the cage. I observed the same conduct with the remainder of the brood, which consisted of four. I need hardly add, that not one either of the parents or children ever afterwards revisited the executed cage." — Few birds are more persecuted by the farmers, and, perhaps, more unjustly so, than sparrows; as it has been proved, that they are more useful than noxious. Mr. Bradley, in his Treatise on Husbandry and Gardening, shows, that a pair of sparrows, during the time that they have their young to feed, destroy, on an average, every week 3360 caterpillars. He discovered that the two parents carried to the nest 40 caterpillars in an hour. He supposed the sparrows to enter the nest only during 12 hours each day, which would cause a daily consumption of 480 caterpillars. This sum gives 3360 caterpillars exterminated weekly from a garden. But the utility of these birds is not limited to this circumstance alone; for they likewise feed their young with butterflies and other winged insects, each of which, if not destroyed in this manner, would be the parent of hundreds of caterpillars.

Tree or mountain sparrow, Hamburgh grassbank of Muscicapidae. 
Latham, &c.—Quill and tail feathers brown; body gray and black; wings with a double white band; bill, chin, and spot on the ear black; head and nape bay; body above reddish-brown, spotted with black; whitish beneath; wing coverts black, edged with rufous; tail feathers blackish, edged with rufous; legs yellowish. Female without the black spots. Five inches and a half long, and rather smaller than the preceding. Inhabits Europe and North America, and is said to be very plentiful.
ORNITHOLOGY.

Gen. 85. PHYTOTOMA.

Characters. Bill conical, straight, serrated; nostrils oval; tongue short, and obtuse; feet four-toed.

Rara phytotoma, or four-toed plant-cutter.—Bill thick, half an inch long, and toothed on each side like a saw; irides brown; body ash above; paler beneath; quill and tail feathers spotted with black; tail rounded; hind toe shorter than the fore ones. Inhabits Chili, where it is not uncommon. Has a rough voice, and utters at intervals, the syllable ra, ra, very distinctly. Feeds on vegetables, digging and cutting about their roots with its bill as with a saw, and thus making great havoc in gardens. Builds in lofty trees, in retired situations.

Gen. 86. MUSCICAPA. Fly-catcher.

Characters. Bill nearly triangular, notched on each side, bent in at the tip, and beset with bristles at the root; toes in most cases divided to their origin.

The birds of this genus live on insects, particularly flies. Of 92 species, two only inhabit Britain.

Paradisi. Crested; head black; body white; tail wedged; two middle feathers very long; head, neck, and chin greenish-black; back, rump, throat, and body white beneath; wing covert and quill feathers black, edged with white; two middle tail feathers 5 inches long; legs lead-coloured. Eight inches and a quarter long. Of this species there are several varieties. Inhabits Asia and Africa.

Tyrannus. Forked-tail fly-catcher.—Tail very long and forked; body black; white beneath. Fourteen inches long. Inhabits Canada and Surinam.

Malaconyx. Soft-tailed fly-catcher.—Brown; ferruginous beneath; throat of the male blue; tail long, wedged, with loose webbed feathers. Inhabits New Holland, being found about Sidney and Botany Bay, in marshy places, abounding with long grass and rushes, which afford it a hiding place, and where, like the bearded titmouse, it is supposed to make its nest. When disturbed, its flight is very short; but it runs on the ground with great swiftness. This singular bird, which is but three inches long, is well represented in the fourth volume of the Linnean Transactions.

Pygmanus. Plate CCCLI.

Dwarf fly-catcher.—Straw-coloured beneath; head and neck rufous, spotted with black; feathers of the back and wing covert cinereous; edged with greenish; quill feathers black, edged with gray; tail black and short. Hardly three inches long. Inhabits Cayenne.

Eubrachytes. Purple-throated fly-catcher.—Black; chin and throat with a large purple red spot. Twelve inches long. Inhabits woods in South America, is gregarious, feeds on fruits and insects, and often associates with the toco-an.

Africapilla. Pied fly-catcher.—Black above; under parts, spot on the front, and shield on the wings, white; lateral tail feathers white without; bill and legs black; tail covert spotted with white. Female brown; white beneath, and wants the frontal spot. About the size of a linnet, and nearly five inches long. There are three or four varieties, and the young birds at first resemble the female. It is local, and by no means plentiful in this island, affecting wild and uncultivated tracts of furze. According to Dr Latham, it builds in some hole of a tree, not very near the ground, making a nest of a few fibres, mixed with moss, and laying six eggs.

Chatiing fly-catcher.—Green; yellow beneath. Virile belly and vent white; eyebrows and spot under the eyes white; tail brown. Seven inches and three quarters long. Haunts unfrequented places in Carolina; is very shy, and flies with its legs extended. With a black spot; belly and vent bluish; quill and tail feathers dusky-blue. Five inches long. Inhabits the Philippine islands.

Fan-tailed fly-catcher.—Olive above, ferruginous Flaviceps beneath; eyebrows, chin, throat, sides of the neck, and lateral tail feathers white; middle tail feathers, head, and collar black. Six inches and a half long. Inhabits New Zealand. Flies with its tail expanded like a fan; and is easily tamed.

Black fly-catcher.—Totally black; bill, head, and Niger legs dusky black. Inhabits Society islands.

Active fly-catcher.—Olive-brown; whitish beneath; Agilis quill and tail feathers black, and edged with olive-brown. Four inches and a half long. Inhabits Cayenne. Is continually hunting after insects, which it picks out from under the bark of trees.

Spotted fly-catcher.—Brownish whitish beneath; neck Grisola longitudinally spotted; vent pale-fuscous; bill black, whitish at the base; inside of the mouth yellow; head large, brownish, and spotted with black; back mouse-coloured; wings and tail black; the former edged with white; chin spotted with red; legs black. About the size of the tit-lark; length five inches and a half. Inhabits Europe. This bird visits us in spring, and departs in September. It frequents orchards and groves, and will make its nest on the limb of some fruit-tree nailed against the wall, or in a hole, sometimes in outbuildings, on the end of a beam or rafter, and at other times against the body of a large tree, on the stump of a decayed branch. The nest is formed of bents, moss, and such materials, interwoven with spiders webs, and lined with feathers. The female lays four or five eggs, not much unlike those of the redbreast, but rather less, and the rust-coloured spots more distinct, and not so much confined to the larger end. Its food seems to be entirely winged insects, though it is said to be particularly fond of cherries, probably from the circumstance of its frequenting the cherry-tree for the sake of flies that are attracted by the fruit. As soon as the young birds leave the nest, they are led by the old ones to some neighbouring wood or grove where insects abound, and where they may be seen darting in every direction in pursuit of flies, and frequently returning to the same station. The note of this species is a simple weak chirp, not frequently used till after the young are fledged, so that the bird, though not uncommon, is not readily discovered.

Desert fly-catcher.—Body ferruginous and sooty; Deserts wings and tail blackish; bill yellowish. Inhabits the deserts of Arabia.
ORNITHOLOGY.

Gen. 27. Motacilla.

Bill subulated, straight; the mandibles nearly equal; nostrils ovibrate; tongue lacerated at the end.

Characters. Most of this genus feed on insects; a few are gregarious; and on the approach of winter, migrate to warmer climates.

**Nightingale.**—Rufous-ash, white-ash beneath; tail feathers rufous-brown; bracelets cinereous; bill brown; head and back pale mouse-colour, with olive spots; tail red-mouse colour; legs and quill feathers brown-ash, the latter chestnut on the outer edge. About the size of the sky-lark, but of a more slender and elegant form. Weighs six grams; and measures between six and seven inches in length. There is a variety with the body somewhat larger, and another that is entirely white. Inhabits Europe, Asia, and Africa. Appears in England sometimes in April, but most commonly not till the beginning of May. The females do not arrive till a week or ten days after the males; so that on the first arrival of these birds none but males are caught, a circumstance which has given rise to the supposition, that the proportion of males exceeds that of females. The Nightingale is said to be found as far north as Yorkshire, and certainly not farther west than the eastern borders of Devonshire; it is plentiful both in Somersetshire and Dorsetshire. This bird resides wholly in woods and thickets, and is seldom seen. About the latter end of May it prepares a nest of dry leaves, generally of the oak, and lined with dry grass, usually placed on the ground, among the same materials of which it is composed, so that it is not readily discovered. The eggs are four or five, of an uniform brown colour, and rather larger than those of the Hedge-Sparrow. As soon as the young are hatched, the song of the Nightingale ceases; and it is a mistaken notion that this, or any of the later breeding birds, have a second brood in the same season, except when some accident has befallen the first. The young are not easily reared in confinement. At first they are fed with meal-worms, and afterwards with boiled sheep's heart. The winter residence of this bird is said to be in Asia. The sweetness and variety of its notes have been universally admired, and the more so, perhaps, because they are uttered in the silence of night. In a wild state, it does not sing above ten weeks in the year, while those confined in a cage continue their song for nine or ten months. The honourable Daines Barrington once kept a very fine Nightingale for three years, during which time he paid particular attention to its song. Its tone was infinitely more mellower than that of any other bird, though at the same time, by a proper exertion, it could be very brilliant. When it sang its song round, in its whole compass, he observed sixteen different beginnings and closings; at the same time that the intermediate notes were commonly varied, and in their succession, with so much judgment as to produce the most pleasing variety. Sometimes it would continue its song twenty seconds without a pause; whenever respiration, however, became necessary, it was taken as skillfully as by an opera singer. Nightingales will also adopt the notes of other birds, may be instructed to sing by turns, with a chorus, and even to articulate words. The London bird-catchers take them by net-traps, baited with meal-worms from the bakers shops. It is with great difficulty that the old birds are induced to sing after being taken; for a considerable time they refuse to eat; but by great attention to their treatment, and avoiding every thing that might agitate them, they at length resume their song, and continue it during the greater part of the year.

**Hanging warbler.**—Greenish-brown above, tawney beneath; occipital line, and one beneath, black. Size of a robin-redbreast. Inhabits Jamaica, and builds a hanging nest.

**Hedge-sparrow, or hedge-warbler.**—Gray-brown above; wing-coverts rufous with white; breast bluish-ash; bill blackish; cheeks striped with white; feathers of the back and wing-coverts edged with chestnut; wings and tail dusky; rump greenish-brown; chin and breast cinereous; belly white; vent yellowish; legs flesh-coloured. Length five inches and three quarters; weight nearly six grams. Inhabits Europe, and is one of the few of the warbler tribe that remains with us the whole year. It has a pleasing plaintive song, which it begins with the new year, if the weather is mild, breeds early, making, in March, a nest composed of green moss and wool, and lined with hair, which is placed in some low evergreen shrub, thick bush, or cut hedge, and sometimes in saggot piles. The female lays four or five blue eggs. In default of insects and worms, the hedge-sparrow will pick up crumbs of bread, and seems to prefer situations near the habitation of man. The cuckoo frequently makes choice of this bird's nest for the purpose of depositing its egg.

**Lesser petty-chops.**—Greenish-brown above, yellowish beneath; belly whitish; limbs brown; eye-brown whitish; upper mandible black, lower bluish, inside of the mouth red; a yellowish line above and beneath the eyes; quill and tail feathers mouse-coloured, and edged with greenish; the shafts black; lower wing-coverts yellow; belly silvery. Weight about two grams; length rather more than four inches and a half; size inferior to that of the yellow wren, which it much resembles in plumage, and with which, and the wood-wren, it has been often confounded. It is the first of the warblers that visits us in the spring, being generally heard on or before the first of April, repeating its song, if so it may be called; for it consists only of two notes, which seem to express the words chip, chop, four or five times successively. It is a busy, restless bird, always active among the trees and bushes, in search of insects. The nest is oval, with a small hole near the top, composed externally of dry leaves and coarse dry grass, and lined with feathers. For the most part, it is placed on, or near the ground, frequently on a ditch-bank, or in a tuft of grass or low bush. The eggs are five or six, white, speckled with purplish-red at the larger end only, with here and there a single speck on the sides. This species is found in almost every part of the country where wood or hedges can shelter it. Its note is heard long after the yellow wren is silent, and it comes with us, not unfrequently, till the latter end of October.

**Wood-sparrow.**—Olive green above; throat and cheeks yellow; belly and vent fine silvery; tail feathers brown, and, except the first, green on the outer webs, and white on the inner; bill horn-colour; irides hazel; breast pale-yellow; a yellow line through the eye; tail somewhat forked, and brown; under part of the shoulder bright yellow; legs horn-colour. Weight about two grams.
ORNITHOLOGY.

Passerina draws and forty guineas; length five inches and a quarter. The female is rather larger. This is a migratory species, appearing about the end of April, and departing in September. The females arrive ten days or so after the males. From its great similarity to the yellow wren, it has been little noticed as a distinct species, but is far from uncommon in some parts of England. It seems partial to oak and beech woods, where it may be found by its singular note, expressive of the word 'tree', drawn out to some length, and repeated five or six times in succession, terminating with the same notes, delivered in a hurried manner, and accompanied by a shaking of the wings. The nest, which is oval with a small hole near the top, is constructed of dry grass, a few dead leaves, and a little moss, and is invariably lined with finer grass and a few long hairs. It is placed on the ground, and contains six white eggs, sprinkled all over with purplish spots.

Petty-chaps, or greater petty-chaps. —Gray-brown above, white beneath; eyewhites white; quill feathers brown, brown-edged with gray; the outermost on the outer web, and near the tip on the inner web; bill blackish; lateral tail feathers edged with brown; legs brown. Length six inches; weight about five drams. Habits Europe; and occurs during summer in Lancashire, and in some of the southern counties of England. It chiefly frequents thick hedges, where it makes a nest composed of goose-grass, other fibrous plants, flimsily put together, with sometimes an addition of a little green moss externally. It usually contains six eggs, about the size of the hedge-sparrow's, of a dirty white, slightly yellowish, all over with light brown, especially at the larger end, where spots of ash-colour also appear. The song of this species is little inferior to that of the nightingale. Some of the notes are sweetly and softly drawn, others quick, lively, loud, and piercing, reaching the distant ear with pleasing harmony, not unlike the blackbird's whistle, but in a more hurried cadence. It frequently sings after sunset.

Sedge warbler.—Cinereous above, white beneath; eyebrows white; bill black; head brown, with dusky streaks; back of the neck and back reddish-brown; back spotted with black; tail coverts tawny; wing-coverts dusky, edged with pale brown; tail brown and wedged; legs dusky. Weight about three drams; length five inches and a half. Habits soggy situations in Europe. It comes to us about the middle of April, and leaves us again in September. It has a variety of notes, which it utters in a hurried manner, and which partake of those of the sky-lark and swallow, as well as of the chatter of the house-sparrow. It is frequent by the sides of rivers and watery places, where sedge and reeds grow, among which it makes a nest, composed of a little moss intermixed with dry stalks, and lined with dried grass, and occasionally a few hairs, sometimes fastened between two or three reeds, sometimes placed on a tuft of rushes, and fastened round the bottom of them, and at other times, in a low bush, or on the trunk of a willow. The eggs are five or six, of a light-brown colour, mottled with darker shades of the same. Various authors have erroneously ascribed the song of this warbler to the reed-bunting, which has no notes that deserve the name of song, a mistake which has originated from both species breeding in the same places, and the reed-bunting being conspicuous on the upper branches of a tree, while the little warbler, supposed Pascrell in the thickest part, is heard aloft. It has been re-marked, that if it be silent, a stone thrown into the bush, will make it begin singing instantly, and that it will also sing during a moonlight night.

White-throat. — Cinerous above, white beneath; first wing white; outermost tail feathers longitudinally half-black, the second black with white; bill black, with the base brownish-black; back reddish. Female, with the breast and belly snowy. There is a variety that is reddish-black above, and reddish-white beneath, with the throat white; the outermost tail feathers on the upper part of the inner side, and white of the outer side white. Weight about four drams; length five inches and three quarters. Habits Europe, and is very common in our inclosed countries. It arrives about the middle of April, and enlivens our hedges with its song, when it erects the feathers on the crown of the head. The nest is made of goose-grass, lined with fibres, and sometimes a few long hairs, but is of so flimsy a texture that it can afford little warmth to the eggs or young. It is generally placed in some low bush, among nettles or other luxuriant plants. The eggs are four or five, of a greenish-white, and speckled all over with light brown or ash-colour. The white-throat feeds on insects and berries, and frequents our gardens in the summer, for the sake of cherries and currants.

Lesser white-throat. — Brownish-black, dirty-white beneath; middle two tail feathers shorter and subulated; bill dusky, the base beneath yellowish; axillar dusky; crown darker than the body; legs brown. Scarcely five inches long. Though not so common as the preceding, it occurs in many of the hedges of Gloucestershire and Wiltshire; builds in low shrubs, and has a shrill whistling note.

Epicercus warbler.—Brownish, white beneath; face blotched with cinereous. About five inches long. Habits Europe. Its flesh is reckoned delicious.

Dartford warbler. — Chestnut above, ferruginous beneath; middle of the belly, edge of the quill feathers, in spurious wings, and outside of the outmost tail feathers white; eyebrows red; bill black, the base beneath white; axillar scarlet; tail black, and as long as the body; legs yellow. Habits Provence, and rarely England. A pair were shot on a common near Dartford in 1798, and others have since been observed about Felsham, Walsingham, &c. As yet the nest and eggs are unknown. It is rather larger than the common warbler, and five and a half inches in length. It is a shy bird, coqueting itself among the thickest bushes, on the least alarm, and creeping from bush to bush. The shorterness of the wings, and length of tail give it a singular manner of flying, which is in short jumps, with the tail drawn up. Its note is a crisp but shrill piping noise, several times repeated.

Penicil warbler. — Gray, yellow beneath; belly and Penicil. eyebrows white; lores spotted with yellow; wing-coverts with alternate white and black bands. Nearly five inches long. Habits St Domingo, and some of the West India islands, where it feeds chiefly on insects and fruits; and has a very delicate song, which is continued throughout the year." The scalability displayed by this bird (says Mr. Bingley), in building and placing its nest, is truly remarkable. She does not fix it at the forking of the branches, as is usual with most other

4 A birds.
ORNITHOLOGY.

birds, but suspends it to binders hanging from the netting, which she forms from tree to tree, especially those which fall from branches that hang over the rivers and deep ravines. The nest consists of dry blades of grass, the ribs of leaves, and exceedingly small roots interwoven with the greatest art; it is fastened on, or rather it is worked into, the pendant strings. It is in fact a small bed rolled into a ball, so thick and compact as to exclude the rain; and it rocks in the wind without receiving any harm. But the elements are not the only enemies against which this bird has to struggle; with wonderful sagacity it provides for the protection of its nest from other accidents. The opening is not made on the top nor side of the nest, but at the bottom. Nor is the entrance direct. After the bird has made its way into the vestibule, it must pass over a kind of partition, and through another aperture before it descends into the abode of its family. This lodging is round and soft, being lined with a species of lichen, which grows on the trees, or with the silky down of plants.

White or water wagtail; provincially, dishwasher, or swimmer woman. Breast black; two lateral tail feathers obliquely half white; bill, hind head, nape, throat, and legs black; front, orbits, sides of the neck, and belly white; body cinereous above; greater quill feathers blackish; secondary, and wing-coverts dusky, and edged with gray; middle tail feathers black, and edged with gray. Female with the crown brown. Weight nearly six drams; length seven inches and a half. This species inhabits almost everywhere; is a very active bird, and continually in motion, running after flies. In this country, as the weather becomes severe, it is apt to haunt marshes that are subject to the flow of the tide. Early in spring they return to their usual summer situation; and from the number which are sometimes seen together at this time attending sheepfolds and newly ploughed fields, we may presume that they aregregarious in their flights. In the breeding season they seem to prefer pleasure grounds that are constantly mowed, on which they run unencumbered, and where the insects have not sufficient cover to evade their sight. The nest is found in various places, sometimes on the ground, in a heap of stones, the hole of a wall, or on the top of a pollard tree. It is composed of moss, dried grass, and fibres, put together with wool, and lined with feathers or hair. The eggs are four or five, white, and spotted all over with light brown and ash-colour; weighing about forty grains, and much resembling that of the cuckoo, which bird frequently makes choice of the wagtail's nest, in which to deposit her egg. It sings very prettily early in spring, and frequently gives the alarm on the appearance of a hawk, which it pursues in company with the swallows. The young birds have no black on the throat till the returning spring, and the old ones lose it in winter. In this state they have been erroneously described as a variety.

Yellow wagtail. Breast and belly yellow; two lateral tail feathers obliquely half white; bill and legs black; hind claw very long; body olive above; band through, and one beneath the eyes, black; throat with a few black spots; middle and greater wing-coverts black, edged with yellowish; tail black. Female with whitish eyebrows. Length six inches and a half. Habits Europe and Asia. Visits this country in April, and departs in September. It frequents arable land, especially in the more champaign parts, and sometimes partial to bean fields; and breeds in all such situations, being more neglectful of water than the white or gray wagtail. The nest is always placed on the ground, composed of dried stalks and fibres, and lined with hair. The eggs are four or five; not very unlike those of the sedge warbler. Its note is more shrill than that of the white, and less so than that of the gray wagtail.

Wheatar. Back hoary; front, line above the eyes, brow, and base of the tail white; a black band through the eyes; crown, neck, and back reddish-gray; eyebrows, rump, upper tail coverts, and upper half of the tail white; lower half, legs, and quill feathers black, the latter edged with reddish-brown; body yellowish-white beneath. The female wants the line over the eyes. There are, however, several varieties. Weights about six drams and a half; length near six inches and a half. Habits Europe, Asia, and Africa. This bird visits England annually in the middle of March, and leaves it again in September. In some parts they are found in great plenty, and are much esteemed. About Eastbourne in Sussex, they are taken in snare made of horsehair, placed beneath a long turf. Being naturally very timid, the motion even of a cloud, or the appearance of a hawk, will immediately drive them into the traps. These last are first set, every year on St James's day, the 2nd of July; soon after which they are caught in astonishing numbers, considering that they are not gregarious, and that more than two or three are scarcely ever seen flying together. The number annually ensnared in the district of Eastbourne alone, is said to amount to nearly two thousand dozen. The birds caught are chiefly young ones; and they are invariably found in the greatest number when an easterly wind prevails. They are very fat in autumn, and esteemed a great delicacy, little inferior to the ortolan. They live chiefly on insects and earth worms, frequent open stony places, warrens, downs, &c. and breed in stone walls, old rabbit holes, or under stones, making a large nest of dry grass, rabbit's down, feathers, and horse-hair. The female lays five or six eggs, of a uniform pale-blue colour. The wheatar sings prettily, and not unfrequently on wing, hovering over the female.

Whinchat. Blackish; eyebrows white; wings with two white spots; chin and breast yellowish; bill and legs black; chin white; tail white; the lower third part blackish; two middle feathers all blackish. Weights about four drams and a half; length full five inches. Habits Europe, and appears in this island about the middle of April, frequenting the same places with the stonechat, and corresponding with it in most of its habits.

Stonechat, or moortailing. Gray, pale rufous beneath; throat with a white band; lores black; bill and legs blackish; head and neck nearly black; body above blackish, variegated with pale rufous; breast and belly reddish yellow; vent and rump white; tail feathers black, the two outermost, on the outer edge and tip, pale ferruginous; quill feathers black, edged with ferruginous; those next the body at the base, and wing-coverts, with a white spot. Female variegated with blackish and reddish. Weight about five drams; length five inches and a quarter. Habits hedges and dry moors in Europe and Siberia. Feeds on insects and worms, and frequently
ORNITHOLOGY.

Blackcap.—Brick-colour above, cinereous beneath; cap dusky-black; bill brown; crown black, in the female chestnut; body greenish-ashe above, grey beneath, gradually growing white; temple grey; quill and tail feathers brownish-ash, edged with greenish-ashe, the middle ones very short; legs lead colour. Of this species there are at least three or four varieties. Length full six inches. Inhabits Europe. It is a migrative bird, visiting us early in the spring and retiring in September. It frequents woods and thick hedges, and seems very partial to orchards and gardens, where it delights us with its charming melodious song, which is very little inferior to that of the nightingale, except in variety of notes. It makes a nest in some low bush or shrub, composed of dried stalks, generally of goose-grass, put together with a little wool, and sometimes a little green moss on the outside, and lined with fibrous roots, on which are frequently placed a few long hairs. The eggs are four or five, of a pale reddish-brown, mottled with a deeper colour, and sometimes sprinkled with a few ash-coloured spots. On the first arrival of this bird it feeds greedily on ivy berries, but forsakes that food as soon as the verbal sun has roused the insect tribe.

Spinicauda.  

Thorn-tailed warbler.—Chesnut, white beneath; crown spotted with yellow; face and eyebrows yellow; wing covert rufous, varied with brown; the greater and quill feathers brown; tail wedged, the feathers daggred. Four inches and a half long. Inhabits Terra del Fuego.

Least warbler.—Pale brown, whitish beneath; bill and very short tail yellowish. Three inches long. Inhabits New Holland.

Redstart.—Throat black; belly and tail rufous; head and back hoary; front white; bill, cheeks, and legs, black; belly white; rump, breast, and lateral tail feathers rufous; the middle ones brown; wings brown. Female with the crown and back grey-ashe, and chin white. Five inches and a quarter long. Inhabits Europe. It is seen in the country only in spring and summer. It builds in holes of walls, or even of houses, or in hallow trees; and lays four or five eggs. It sings prettily, and imitates the notes of other birds. It is less than the redbreast, and moves its tail horizontally.

Blue-throated warbler.—Breast ferruginous, with a blue band; tail feathers brown, ferruginous towards the tip. Size of the redbreast. Inhabits Europe and Siberia. Sings sweetly, and does not migrate.

Sueuris.  

Cyanes.  

Arundinacea.  

Reed aven.—Olive-brown above, whitish beneath; lore and orbits whitish-brown; band in the middle of the wings tawney-yellow beneath; tail brown, slightly wedged; under part of the toes greenish-yellow. Upper mandible horn-colour, lower flesh-colour; mouth orange; irides brown; chin white; legs pale-olive. Length scarcely five inches and a half; weight nearly three drams. Has often been confounded with the sedge warbler, to which it is nearly allied in form, size, and habits; but it may at once be distinguished by the greater breadth of the base of the bill, by the want of a light stroke over the eye, and having the upper parts of one plain colour. The nest and eggs are also different. The former is composed of long grass, and the seed-branches of reeds, and lined with the finer parts of the latter. It is very deep, and is generally fastened by long grass to several reeds, which are drawn together for that purpose. The eggs are four or five, rather larger than those of the sedge-warbler, of a greenish-white, blotched all over with dusky brown. This species inhabits near Uxbridge, in the fens of Lincolnshire, and in many parts of the south of England and Wales; arriving about the end of April, or beginning of May, and departing again in September.
ORNITHOLOGY.

Passer. black and cinereous; bill dark green; head and body deep reddish brown above; quill feathers alternately barred with black and red; throat yellowish-white; belly and sides crossed with narrow, dusky, and pale reddish-brown lines; tail with dusky bars; legs brownish. Length nearly four inches and a quarter; weight about two drams and three quarters. Inhabits Europe and Asia. Its nest is curiously constructed, and not begun at the bottom, as is the case in most instances, but first traced, as it were, in oval frame-work, and equally fastened in all its parts to a tree, or other support, and afterwards inclosed on the sides and top, a small hole only being left near the latter, for entrance. If the nest is placed under a bank, the top is first begun, and well secured in some small cavity by which the fabric is suspended. The materials are generally adapted to the place; if built against the side of a hayrick, for example, the nest is composed of hay, if against the side of a tree covered with lichen, it is made of that species of moss, &c. The lining is invariably feathers. The eggs are seven or eight, and sometimes more, white, and sparingly marked with small reddish spots. The song of the wren is much admired, being, though short, a very pleasing warble, and louder than could be expected from the size of the bird. It is heard between the months of March and July, and it has been heard to sing, with apparent unconcern, even during a fall of snow. It also sings very late in the evening, though not like the nightingale, after dark. The wren feeds on insects, which it finds in sufficient abundance to support life, even in the severest winters.

Golden-crowned wren.—Greenshade of under edge and white in the middle; crown orange; bill black; crest orange (of the female yellow), each side edged with black; body yellowish-green above, reddish white beneath; wingcoverts brown, with two transverse white bars; legs yellow. Inhabitats every quarter of the globe. This is the smallest British bird; its weight seldom exceeding eighty grains, and its length three inches and three quarters. It migrates from the Shetland Islands in winter, but continues in the Orkneys the whole year. Its song is like that of the common wren, but its voice is weaker. It builds a nest nearly of a round form, with a hole in the side; and lays from six to eight eggs. It erects or depresses the crest at pleasure. Though not uncommon, it often escapes observation, from the smallness of its size. It has also been remarked, that the female, from some cause which has not yet been discovered, is frequently destroyed during the time of incubation; and the nest, with the eggs, left to decay. Mr Montagu communicates the following interesting details relative to a young family of this beautiful species. "When first I discovered the nest, I thought it a favourable opportunity to become acquainted with some of the manners of this minute species, and to endeavour to discover whether the male ever sung by way of instructing the young ones. Accordingly I took the nest when the young were about six days old, placed it in a small basket, and by degrees enticed the old ones to my study window; and after they became familiar with that situation, the basket was placed within the window; then at the opposite side of the room. It is remarkable, that although the female seemed regardless of danger from her attention to her young, yet the male never once ventured within the room; and yet would constantly feed them while they remained at the outside of the window; on the contrary, the female would feed them at the table at which I sat, and even when I held the nest in my hand, provided I remained motionless. But on moving my head one day, while she was on the edge of the nest, which I held in my hand, she made a precipitate retreat, mistook the open part of the window, knocked herself against the glass, and laid breathless on the floor for some time. However, recovering a little, she made her escape, and in about an hour after I was agreeably surprised by her return, and would afterwards frequently feed the young while I held the nest in my hand. The male bird constantly attended the female in her flight to and fro, but never ventured beyond the window-frame; nor did he latterly ever appear with food in his bill. He never uttered any note but when the female was out of sight, and then only a small chirp. At first there were ten young in the nest, but probably for want of the male's assistance in providing food two died. The visits of the female were generally repeated in the space of a minute and a half or two minutes, or upon an average, thirty-six times in an hour; and this continued full sixteen hours in a day, and which, if equally divided between the males, each would receive 72 feeds in the day; the whole amounting to 576. From examination of the food, which by accident now and then dropped into the nest, I judged from those weighed that each feed was a quarter of a grain upon a medium; so that each young one was supplied with 18 grain weights in a day; and as the young birds weighed about 77 grains at the time they began to perch, they consumed nearly their weight of food in four days at that time. I could always perceive by the animation of the young brood when the old one was coming; probably some low note indicated her near approach, and in an instant every mouth was open to receive the insect morsel. But there appeared no regularity in the supply given by the parent bird; sometimes the same was fed two or three times successively; and I generally observed that the strongest got most, being able to reach farthest, the old one delivering it to the mouth nearest to her, and after each feed she waited a while to see if some needed another." Yellow wren.—Dusky green above, yellowish-white beneath; wings tail brown, and edged with green; eyebrows yellow. Four inches and a half long. Inhabits Europe and America. Frequent wood and enclosed situations, especially where willows abound. Visits us early in April, and soon begins its usual song, which is short, with little variety. Makes an oval nest, with a small opening near the top, composed of moss and dried grass, and lined with feathers, either in the hollow of a ditch, or in a low bush, close to the ground. The eggs are six or seven, white, and spotted with light rust colour. Has often been confused with the lesser prettypatches, and the wood wren.

Tailor warbler, or tailor bird.—Entirely yellow, and slender in very small, scarcely exceeding three inches in length. Inhabits India. Its nest is composed of two leaves, one generally dead, which it fixes, at the end of some branch, to the side of a living one, by sewing both together with little filaments (its bill serving as a needle), in the manner of a purse or purse, and open at the top. Sometimes, instead of a dead and a living leaf, two livi...
ORNITHOLOGY.

571. 

Gray wagtail. — Cicerine above, yellow beneath; first tail feathers entirely, second on the inner side, white; bill and legs brown; chin and throat black; wing-coverts brown, and edged with saffron; quill feathers brown, the secondaries white at the base; middle tail feathers black, and edged with greenish. Weighs about five grains; and measures seven inches and three quarters in length. This elegant species inhabits Europe; visits us about the latter end of September, and departs in April. It is much in motion, constantly flits the tall, seldom perches, frequents waters, makes its nest on the ground, and sometimes on the banks of rivulets, and lays from six to eight eggs, of a dirty white, marked with yellow spots.

Gen. 88. Pitra, Menakin.

Bill shorter than the head, hard, nearly triangular at the base, and slightly incurved at the tip; nostrils naked; feet gressorial; tail short.

576. 

Crested or rock manakin. — Crest erect, edged with purple; body saffron; tail coverts truncated. Size of a small pigeon; from 10 to 12 inches long; is shy, but may be tamed, if taken young; feeds on small wild fruits, and builds in the clefts of the most remote rocks, laying two white eggs. Inhabits the rocky parts of South America.

577. 

Black-capped manakin. — Black above, white beneath; spot on the neck above, and on the wings, white; bill black; legs yellow. Inhabits the woods of Guiana. Is restless and gregarious.

578. 

Little manakin. — Gray; head black, speckled with white. Size of a small wren. Inhabits India.

579. 

Tuneful manakin. — Black above, orange beneath; front and rump yellow; crown and nape blue; chin and throat black. Four inches long. Inhabits St Domingo. Is very shy, and easily eludes the vigilance of such as attempt to take it. Its note is musical, and forms a complete octave, one note succeeding another.

Gen. 89. Parus, Thimrouse.

Bill very entire, narrow, somewhat compressed, strong, hard pointed, and covered at the base with bristlestongue truncated, and bristly at the end; toes divided at the origin, the hind ones large and strong.

This is a numerous and prolific tribe, some of the species laying from 18 to 30 eggs at a time. Most of them feed on seeds, fruits, and insects, and some on flesh. They are particularly fond of the berries of other birds, which they get at by cleaving the sides of such as they find dead. They are restless, bold, and will fly to birds less than themselves, and will attack such as are three times their own size. Their note is generally unmusical.

Crested titmouse. — Head crested, under black; belly white. Nearly five inches long. Inhabits Europe, chiefly in fir woods. Is solitary, and not easily tamed.

Great titmouse, or cow-tit. — Head black; temples white; nape yellow; bill, chin, and tail black; back and wings olive; rump blue gray; belly greenish yellow, divided in the middle by a band of black, extending to the vent; quill feathers dusky, edged with blue, partly with white; exterior sides of the outmost tail feathers white, of the others bluish; inner sides dusky; legs head-coloured. This species weighs about 10 drams; length five inches and three quarters. It inhabits Europe, Asia, and Africa; and is common in many parts of Britain, frequenting gardens and orchards, where it does much mischief by picking off the tender buds of trees. The nest is made of moss, lined with hair, and placed in the hole of a wall, or of a tree. The female sometimes lays eight or ten eggs, but more commonly six, which are white, spotted with rust-colour, and so exactly like those of the nuthatch, as not to be distinguished from them. The common note of the great titmouse is a sort of chatter; but in the spring, it assumes a greater variety, a shrill whistle, and a very angular noise, something like the whistling of a cow; but these cease with incubation. A variety was once killed near Faversham in Kent, that had the bill crossed, as in loxia curvirostra. Its characters were olive brown; dirty yellowish beneath; head black; temples cinereous, and bill forked.

Creeping titmouse. — Bluish; temples, breast, and back America-yellowish; flank purplish. Four inches and three quarters long. Inhabits Carolina and Canada. Is constantly running up and down trees in search of insects.

Blue titmouse, or tontit. — Quill feathers blueish, the Cauda; primaries white on the outer edge; front white; crown blue; bill blackish; line from the bill to the eyes, and one surrounding the temples black; back yellowish-green; wing coverts blue; quill feathers black, with dusky edges; tail blue, the middle feathers longer; body whitish-yellow beneath; legs and claws black. Length about four inches and a half; weight three grains. Inhabits Europe. This species would probably be more admired for its beauty, if it were less common. In winter it frequents houses for the sake of bread, and will devour flesh greedily, whether fresh or putrid. It is also a constant attendant where horse-flesh is kept for hounds, and in the farm-yard, being partial to oats, which it plucks out, and returns to a neighbouring bush, and stomachs it with the bill, to break the husk. In summer, it feeds chiefly on insects, in search of which it plucks off a number of young buds from the trees. The nest is always made in some hole, either of a tree or wall, composed of moss, and lined with feathers and hair. The eggs are white, and speckled with rust-colour at the larger end. The female is so tenacious of her nest, that she will often suffer herself to be taken rather than quit it, and will frequently return again after being taken out. It utters every intruder in a singular manner, hissing like a snake, erecting all its feathers, and uttering a sort like the spitting of a cat, biting at the same time, severely, if handled. It has no song, but enters a shrill note quickly repeated.
ORNITHOLOGY

PASSERS. a broad black stripe beneath the eyes, from the bill to the neck; belly and vent reddish white; wing-venters gray, tipt with white; quill and tail feathers brownish ash, edged with gray; legs and claws lead coloured.

Weight about two drams and a quarter; length four inches and a quarter. Has frequently been confounded with the palustris; but it is not so plentiful a species; keeps more to woods; seems to live entirely on insects, and has also a different note.

Marsh titmouse. Head black; back cinereous; temples white. The markings are, however, very subject to vary; the length is about four inches and a half; and the weight two drams and a half. Inhabits Europe. With the blue species it partakes of flesh, and fur. Immens-ricks. It seems to be partial to low wet ground, where old willow trees abound, in the holes of which it frequently nests.

Long-tailed titmouse. Crown white; tail longer than the body; weighs only two drams, and measures five inches and a quarter in length. This very elegant and singular species is confined chiefly to the woods and thickets of Europe and Siberia, where it makes a curious oval nest of lichens, firmly woven together with wool; and having only a small hole on the side, placed in the fork of some bush or branch of a tree. The female lays from nine to seventeen eggs, which are white, and sparingly marked with small rust-coloured spots towards the larger end.

Cape titmouse. Gray ash; quill feathers black, edged with white; tail black above; bill and legs black. Inhabits the Cape of Good Hope. Constructs a luxurious nest of the down of a species of asclepias; near the upper end projects a small tube, about an inch in length, with an orifice about three-fourths of an inch in diameter. Immediately under the tube is a small hole in the side, that has no communication with the interior of the nest. In this hole the male sits at night; and thus both male and female are screened from the weather.

Bearded titmouse. Rufous; crown hoary; tail longer than the body; head bearded; vent black; bill pale orange; irides yellow; legs black; tail wedged; whiskers composed of long black feathers; three outer tail feathers black at the base, and whitish at the tips; middle of the breast flesh colored; sides and thighs pale orange; six inches and a quarter long. Inhabits marshy situations in Europe. Though it breeds with us, and continues the whole year, its history is little known; and authors differ not only with respect to the shape and composition of the nest, but even with respect to the place of nidification.

Penduline titmouse, or remia. Head ferruginous; occular band black; quill and tail feathers brown, and edged on each side with ferruginous; four inches and a half long. Inhabits Europe and Siberia, frequenting watery places for the sake of aquatic insects, on which it feeds. The most curious fact in the history of these birds is the exquisite art displayed in the construction of their nest. They employ the light down found on the buds of the willow, the poplar, and the aspen, on thistles, dandelion, &c. With their bill they entwine this filamentous substance, and form a thick close web, almost like cloth. This they fortify externally with fibres and small roots, which penetrate into the texture, and, in some measure, compose the basis of the nest. They line the inside with the same down, but not with ven, that their young may lie soft; they shut it above to confine the warmth, and they suspend it with hemp, nettles, &c. from the cleft of a small plant branch over some stream, that it may rock more gently, assisted by the spring of the branch. In this situation the brood are well supplied with insects, which constitute their chief food, and are at the same time protected from their enemies. The nest sometimes resembles a bag, and sometimes a short purse. The aperture is made in the side, and is almost always turned towards the water. It is nearly round, and only an inch and a half in diameter, or even less, and is often, though not always, surrounded by a brim. These nests are found in the fens of Bologna, Tuscany, Lithuania, Poland, and Germany. The peasants regard them with superstitious veneration, one of them being usually suspended near the door of each cottage, as a charm against lightning.

Languedoc titmouse. Rufous gray; crown hoary; Nervous wings and tail blackish, edged with rufous; primary six quill feathers edged with white; four inches long. Inhabits France. Builds a strong pendulous nest on the forked branch of a tree.

Amorous titmouse. Blackish blue; longitudinal spot on the middle of the wings, half yellow and rufous; five inches and a half long. Inhabits Northern Asia, and is remarkable for the mutual affection of the sexes.

GEN. 90. Hirundo, Swallow.

Bill small, weak, curved, subulated, depressed at the base; gape larger than the head; tongue short, broad, cleft; wings long; tail mostly forked.

The birds of this genus are readily distinguished, not only by their structure, but by their twittering voice, and their manner of life. They fly with great rapidity, seldom walk, and perform all their functions either on the wing or sitting. By means of their wide mouth they easily catch insects (their principal food) in the air, or on the surface of the water. Naturalists have been much divided in their opinions respecting the migration of the swallow tribe. The Hon. Daines Barrington and others have supposed that they do not leave this country, but that they lie concealed and torpid, during winter, under water, in crevices of rocks, holes in sand banks, &c. In confirmation of this opinion they quote instances which appear to be sufficiently well authenticated. But a migration of the greater part of the birds is not to be contradicted, by what seems to be rather the effect of chance than design. Those that have been hatched late, and have not acquired sufficient strength to accompany their companions in their journey, may alone have supplied the above-mentioned instances. We are all to remain, we should undoubtedly be furnished with more numerous and more generally known examples than have hitherto been recorded. The ingenious Mr John Hunter, on dissecting several swallows, observed in them nothing different from other birds in the organs of respiration, and hence inferred, perhaps too hastily, that none of them can remain, for any length of time, under water. That the migration of swallows does, however, really take place, appears to have been fully proved by a variety of well-attested facts, most of which have been observed by navigators, who were eye-witnesses of the flights of these birds, and whose ships have sometimes
ORNITHOLOGY.

A. Three toes before, and one behind.

Chimney or common swallow.—Front and chin chestnut; tail feathers, except the two middle ones, with a white spot; bill black; body blackish blue above, whitish beneath; tail very much forked; legs short and blackish; weight between five and six drams; length six inches and a half. Inhabits all the quarters of the world; visits us early in April, if the weather be mild, and retires about the end of September or beginning of October. It is supposed to winter in Senegal, and other warm countries. It has got the name of Chimney swallow, from the circumstance of breeding in chimneys. It also nests on the beams or rafters of out-houses, and sometimes on rocks. The nest is made of mud, plastered together, and lined with feathers, and is open at top. The eggs are four or five, white, and speckled with rusty red. Its velocity of wing and quickness of sight are truly astonishing, and enable it to pursue its prey with precision and effect. When a fly is taken, a smart snap from the bill is to be heard, not unlike the noise of the shutting of a watch case; but the motion of the mandibles is too quick for the eye. Wonderful is the address with which this bird ascends and descends through the passages of a chimney. When hovering over the roof of the funnel, the vibrations of its wings acting on the confined air, occasion the rumbling like distant thunder. It is not improbable that the female submits to the inconvenience of having her nest low down in the shaft, in order to secure her offspring from the birds of prey, particularly from owls, which are frequently found to fall down chimneys, probably in their attempts to get at the nestlings. The progressive method by which the young are introduced to their proper habits, deserves to be noted. They first, though not without difficulty, emerge from the shaft, and, for a day or two, are fed on the chimney top; thence they are conducted to the dead leafless bough of some neighbouring tree, where, sitting in a ḍavā, they are attended by the parents with great assiduity. In a day or two after this they are strong enough to fly, but continue still unable to take their own food; they therefore play about near the place where the females are watching for flies; and, when a mouthful is collected, on a certain signal, the dam and the nestling advance, rising towards each other, and meeting at an angle, the young all the while, uttering a short quick note of gratitude and complacency. As soon as the mother has divested herself from the first brood, she immediately commences her operations for a second, which is produced about the middle or latter end of August.

Escolent swallow.—Blackish, whitish beneath; all the tail feathers with a white spot; bill black; tail tip with white; legs brown. Two inches and a quarter in length; in size rather less than the wren. Inhabits China and the islands of the Indian ocean. Many of our readers must have heard of the curious edible nests of this species. The following is the account given of them by Sir George Staunton. “In the Cass, a small island near Sumatra, were found two caverns, running horizontally into the side of the rock; and in these were a number of those birds nests so much prized by the Chinese epicures. They seem to be composed of fine filaments, cemented together by a transparent viscid matter, not unlike what is left by the foam of the sea upon stones alternately covered by the tide, or those gelatinous animal substances found floating on every coast. The nests adhere to each other, and to the sides of the caverns; mostly in rows, without any break or interruption. The birds that build these nests are small gray swallows, with bellies of a dirty white. They were flying about in considerable numbers; but were so small, and their flight was so quick, that they escaped the shot fired at them. The same sorts of nests are said to be also found in deep caverns at the foot of the highest mountains in the middle of Java, at a distance from the sea from which source it is thought that the birds derive no materials, either for their food, or the construction of their nests; as it does not appear probable they should fly in search of either, over the intermediate mountains, which are very high, or against the boisterous winds prevailing thereabout. They feed on insects, which they find hovering over stagnant pools between the mountains, and for the catching of which their wide-opening beaks are particularly adapted. They prepare their nests from the best remnants of their food. Their greatest enemy is the kite, who often intercepts them in their passage to and from the caverns, which are generally surrounded with rocks of gray limestone, or white marbel. The nests are placed in horizontal rows, at different depths, from 30 to 300 feet. The colour and value of the nests depend on the quantity and quality of the insects caught, and perhaps also on the situation where they are built. Their value is chiefly ascertained by the uniform fineness and delicacy of their texture; those that are white and transparent being most esteemed, and fetching often in China their weight in silver. These nests are a considerable object of traffic among the Javanese, many of whom are employed in it from their infancy. The birds, after having spent nearly two months in preparing their nests, lay each two eggs, which are hatched in about 15 days. When the young birds become fledged, it is thought the proper time to seize upon their nests, which is done regularly three times a-year, and is effected by means of ladders of bamboo and reeds, by which the people descend into the caverns; but when these are very deep, rope-ladders are preferred. This operation is attended with much danger, and several perish in the attempt. The inhabitants of the mountains, generally employed in this business, begin always by sacrificing a buffalo; which custom is observed by the Javanese, on the eve of every extraordinary enterprise. They also pronounce some prayers, andoint themselves with sweet-scented oil, and smoke the entrance of the cavern with gum-benjamin. Near some of the caverns a tutelar goddess is worshipped, whose priest burns incense, and lays his protecting hands on every person preparing to descend. A flambeau is carefully prepared at the same time, with a gum which exudes from a tree growing in the vicinity, and which is not easily extinguished by fixed air or subterraneous vapours.”—The nest of this species generally weighs about half an ounce; and is in shape something like a half lemon. The consistency of the several layers of component matter approaches to that of isinglass, or of fine gum-dragon. Such of these nests as are perfectly free from dirt, are dissolved in broth to thicken it, and are said to give it an exquisite flavour; or they are soaked in ...
ORNITHOLOGY.

898. 

Martin, martlet, martinet, or house martin.—Bluish-black above, white beneath; tail feathers without spots; bill black; mouth yellow; rump white; legs covered with a short white down. There is a variety that has the quill and tail feathers tipped with white. About five inches and a half, and rather inferior in size to the chimney swallow. Inhabits Europe, Asia, and North America. Visits Britain in spring, rather later than the common swallow, making its first appearance in low, warm situations, and if the weather is fine, beginning to build early in May. It builds a close nest made of straw and clay, and lined with feathers, with a hole at the top for admission, in windows, under the eaves of houses, the projecting ornaments of steeples and churches, &c. and sometimes against rocks or cliffs, contiguous to the sea. The eggs are four or five, and pure white. The manners and habits of this well-known species nearly resemble those of the common swallow.

899. 

Sand martin, bank martin, or shore bird.—Cinereous; chin and belly grey; bill blackish; throat encircled with a moss-colored ring; legs black, and downy behind. Four inches and three quarters long. Inhabits Europe and America, in which last country it is called ground swallow. In this country it is not so plentiful as the preceding, with which it associates, and which in its manners it much resembles, except that it nests in the banks of rivers or sand pits, and makes a nest of straw and dried fibres, lined with feathers.

900. 

Purple swallow.—Entirely violet; tail forked; bill black; legs blackish. Female brown. Seven inches and three quarters long. Inhabits Carolina and Virginia, during summer. Is much valued by the inhabitants for its use in alarming poultry on the approach of birds of prey, which it does not only by shrieking, but attacking them with the greatest fury.

901. 

Canada swallow.—Bluish black; beneath and mouth whitish-ash; belly white, clouded with brown; quill and tail feathers blackish, edged with brown; legs and claws dusky. Eight or nine inches long. Native of Hudson's bay.

902. 

Amherst-aria. 

903. 

Erythrocephale. 

904. 

Nigra. 

905. 

Apus.

906. 

White-collared swift.—Bluish-violet; head black; shoulders collar liliat; ocular band and thighs white. Five inches and one quarter long. Inhabits Cayenne. Builds a long conical nest, with a division in the middle.

Gen. 92. CAPRIMULGUS, Goatsucker.

Bill slightly curved, very small, subulate and depressed at the base; mouth extremely wide, and furnished with characters at the sides with a series of bristles; ears very large; tongue pointed and entire; tail unforked, with 10 feathers; legs short, middle claw with a broad serrated edge.

The birds of this family seldom appear in the day time, except they are disturbed, or in dark cloudy weather, but wander about in the evening, in search of insects. They lay two eggs on the naked ground. The lateral toes are connected to the middle one by a small membrane.

European or nocturnal goatsucker; provincially night European or dorm-hawk, chura or goatsowl, wheelbird, nightfarr, &c.—Black, varied with cinereous, brown, ferruginous and white; beneath reddish-white, with brown bands; irides hazel; legs short, scaly, and feathered below the knees. The male is distinguished from the female by a large oval white spot near the end of the three first quill feathers, and another on the outmost tail feathers. Inhabits Europe, Asia, and America. With us this bird is only a summer visitant, appearing about the middle of May, and departing again the latter end of September, or beginning of October. It makes no nest, but lays two eggs on the bare ground, among fern, heath, or long grass, sometimes in woods or forest, but at all times contiguous to woods, in which it chiefly conceals itself by day. The eggs are larger than those of a blackbird, oblong oval, whitish, and elegantly marbled with light brown and ash-colour. It generally sits on the ground, but if molested, frequently perches on the limb of a tree, most commonly lengthwise, and not across, as is common with most birds. In the dusk of the evening, it begins its flight in pursuit of the larger insects, particularly scrobiculatus molosotota, and sollicitus, which rise from their earthy abode about that time. It is also fond of the large-bodied moths, and indeed allows few winged
ORNITHOLOGY.

Great goatsucker.—Blackish, with small brown spots and streaks; area of the eyes yellowish; legs white; middle claw not serrated. Nearly two feet long. Inhabits Cayenne. The gape of its mouth can readily admit a man's fist.

Crested goatsucker.—Waved with brown, black, and whitish; whitish beneath; neck and breast with dusky bands; crest on the front erect, and setaceous. Nine inches and a half long and a quarter. Inhabits New Holland. No account has hitherto been procured of its manners, except that it appears about our settlement at Port Jackson in March.

Leone goatsucker.—Variegated gray; wings spotted with rufous and black; a very long naked-shouldered feather on each shoulder. "This singular species," says Dr Latham, "is about the size of the European one, and not far different from it in the general markings: the length from the bill to the end of the tail is eight inches and a quarter; but the remarkable circumstance belonging to it, is the having a single feather springing out of the middle part of the coverts of each wing, full 29 inches in length: this continues as a plain quill shaft for 14 inches and three quarters, having a few solitary hairs on the inside only; from thence it expands into a broad web for the remaining five inches and a quarter of its length. This part is notched, not unlike the darker part of the rest of the plumage, and crossed with five dusky bars; the web or blade has almost the whole of its breadth on the inner side, being there more than one inch broad, but very narrow on the outer part of the shaft; the legs are small. Inhabits Sierra Leona in Africa; several of them have been brought into England." &c.—The same bird is described by Dr Shaw in his Naturalists Miscellany.

We have purposely reserved for an Appendix, the following description of Menura superba, a bird of New South Wales, by Major-General Thomas Davies, F. R. and L. S.

**Menura.**

Char. gen. Rostrum validissimum, convexo-conicum. 

Nubes ovata in mediro rostri.

**Rostreis elongata, penissis de-composea;** intermedia duae longiores angustiae, exteriore ad apicem patulae, revolutae.

Pedes validi ambulatorii.

**Menura Superba.**

The total length of this singular bird, from the point of the bill to the end of the broad tail feathers, is 43 inches; 25 of which are in the tail alone. The bill rather exceeds an inch in length, is strong, formed much like that of a penguin, and black, with the nostrils, which are long open slits, rather large, placed near the middle of its length; the head, which is somewhat crested at the hind part, neck, shoulders, back, upper tail coverts, and upper surface of the tail-feathers, of a dark brownish-black; throat rufous, reaching some way down the middle of the neck; breast, belly, and vent gray.

The feathers of the latter are long, very soft, and of a silky texture; thighs nearly of the same colour, rather long, and feathered down to the knee; scapulars of a brownish tinge; upper tail coverts and prime quill feathers, which are somewhat curved at the ends, brown black; edges of the quills gray; the legs long and very strong, covered with large scales, especially in front; the feet, which are likewise large, and the nails, are black; the last somewhat crooked, convex above and flat beneath; the hind nail near three quarters of an inch long.

The tail consists in the whole of 16 feathers; all of which, except the two upper or middle ones, and the two exterior on each side, have long slender shafts furnished on each side with delicate long filaments, four inches or more in length, placed pretty close towards the rump, but more distant from each other as they approach the extremity, and resemble much those of the greater Paradise bird. The two middle or upper ones are longer than the rest, slender, narrow at the base, growing wider as they approach the ends, which are pointed; webbed on the inner edge all the way, and furnished with some distant hair like threads near the end on the outer side, of a pale gray colour beneath, and brown black above, as is the rest of the tail. The two exterior feathers on each side are of an extraordinary construction, rather more than an inch wide at the base, and growing wider as they proceed to the ends, where they are full two inches broad and curve outwardly; the curved part is black with a narrow white border; the quills of these feathers are double for two-thirds down from the rump. The general colour of the under sides of these two feathers is of a pearly hue, elegantly marked on the inner web with bright rufous coloured crescent-shaped spots, which from the extraordinary construction of the parts, appear wonderfully transparent, although at first sight seemingly the darkest; they are also elongated into slender filaments of an inch or more, especially towards the extremities.

The figure of the male, which accompanies this description, was taken from a specimen sent from New South Wales as a present to Lady Mary Howe. I have also seen two other specimens in the possession of the right hon. Sir Joseph Banks, which I believe have since been deposited in the British Museum.

Since I had the honour of communicating to the Linnean Society the foregoing description of the Menura, I have been favoured with both male and female of that extraordinary bird from my friend Governor King, by the Buffalo store ship; and I am thereby enabled to lay before the society a description of the different sexes. I find, indeed, that, with a little deviation, the same characters and colours will serve for both of them. The female, however, is somewhat smaller, being in length, from the crown of the head to the end of the tail, only 31 inches. The general plumage of the whole bird is of a dull blackish colour, a little rufous under the chin and throat, and of a brownish cast on the scapulæ, as in the male. The plumage of the whole body, from the breast to the vent, and from the shoulders to the rump, is composed of long, slender, thread-like, silky feathers, resembling fringe, of a dull greyish-black; lighter on the breast, belly, and vent. The bill and legs, which are strong and furnished with large scales, as in the cock, are black. From the head to the rump 14 inches; the tail 18 inches, also of a dull brown black colour.
ORNITHOLOGY.

Appendix. The colour above and gray beneath; the two upper tail feathers are sharp-pointed at the ends; the rest are rounded and darker in colour, and shorter by degrees, as they approach the rump, so as to appear cuneated; the two outer feathers are shorter than the rest, but in form like those of the male, brown black above, of a pearly gray beneath; and the crescents, which are of a deeper russet colour, are not so visible nor so large, but more transparent, if possible, than those of the cock. They are about an inch and a half broad, and not black or longer at the ends as in the other sex.

EXPLANATION OF THE PLATES.

Plate CCCXCIII. Accipitres.

Fig. 1. Vultur Percnopterus, Aquiline Vulture.
2. Falco Melanetus, Black Eagle.
4. Virginia, Virginian Owl.

Plate CCCXCV. Piciz.

Fig. 1. Certhia Arundinella, Braceletted Creeper.
2. Corvus Caudatus, Long-tailed Roller.
4. Crocatus Melaenoleucus, Coromandel Crested Cuckoo.

Plate CCCXCV. Piciz.

Fig. 1. Meroops Erithacus, Red-winged Bee-eater.
2. Buceros Panagenses, Panay Hornbill.
3. Todus Cristatus, Crested Tody.
4. Momotus Brasilianus, Brazilian Motmot.
5. Alcedo Cristata, Crested Kingfisher.

Plate CCCXCVI. Anseres.

Fig. 1. Anas Molissima, Eider Duck.
5. Diomedeas Exulans, Wandering Albatross, or Man of War Bird.

Plate CCCXCVII. Anseres.

Fig. 1. Alca Cirrhata, Tufted Auk.
2. Tetractylus, Dusty Auk.
3. Procellaria Pelagica, Stormy Petrel.
5. Storna Minuta, Lesser Tern.

Plate CCCXCVIII. Grallarz.

Fig. 1. Phoenicopterus Ruber, Red Flamingo.
2. Tantalus Abus, White Ibis.
3. Ardea Egreta, Great Egret.
4. Scopus Umbretta, Tufted Umbrella.

Plate CCCXIX. Grallarz.

Fig. 1. Recurvirostra Americana, American Avocet.
2. Charadrius Pileatus, Hooded Plover.
3. Haematopus Ostralegus, Sea-pa, or Pied Oystercatcher.
4. Fulica Atra, Common Coot.

Plate CCC. Gallinace.

Fig. 1. Otis Agra, White-eared Bustard.
2. Struthio Camelus, Black Ostrich.
4. Carus Alector, Female Crested Curassow, Var. from Peru, Lath. Synop. 693.

Plate CCC. Passeres.

Fig. 1. Columba Margrinalis, Marginalated Turtledove.
2. Loxia Monedula, Molucca Grosbeak.
3. Alauda Malabarica, Malabar Lark.
5. Parus Cristatus, Crested Titmouse.

Plate CCC. Passeres.

Fig. 1. Emberiza Regia, Shaft-tailed Bunting.
2. Calis Panagenses, Panayan Coly.
3. Hirundo Subis, Canada Swallow.
5. Tanagra Siberica, Siberian Tanager.

ORNITHOMANCY, a species of divination performed by means of birds; being the same with augury. See DIVINATION AND AUGURY.

ORNITHOPUS, a genus of plants belonging to the diadelphus class; and in the natural method ranking under the 32nd order, Papilionaceae. See BOTANY INDEX.

ORNITHORYNCHUS PARADOXUS, one of the most extraordinary animals of the mammalia class yet known, particularly for the singular conformation of its head, which is the perfect resemblance of the beak of a duck ingrained on the head of a quadruped. See MAMMALIA INDEX.

ORNIS PRAXINUS, is that species of the ash tree, in the Linnaean system, which, according to Dr. Cirillo of Naples, produces the manna. See MATERIA MEDICA INDEX.

OROBANCHE, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 40th order, Persicaceae. See BOTANY INDEX.

OROBIO, Don Balthasar, a celebrated Jew of Spain. He was carefully educated in Judaism by his parents, who were Jews, though they outwardly professed themselves Roman Catholics; abstaining from the practice of their religion in everything, except the observation of the fast of expiation, in the month Tis or September. Orobius studied the scholastic philosophy usual in Spain, and became so skilled in it, that he was made professor of metaphysics in the university of Salamanca. Afterwards, however, applying himself to the study of physic, he practised that art at Seville with success, till, accused of Judaism, he was thrown into the inquisition, and suffered the most dreadful cruelties, in order to force a confession. He himself tells us, that he was put into a dark dungeon, so strait that he could scarce turn himself in it; and suffered so many hardships, that his brain began to be disturbed. He talked to himself often in this way: "Am I indeed that Don Balthasar Orobius, who walked freely about in Seville, who was entirely at ease, and had the blessings of a wife and children?" Sometimes, supposing that his past life was but a dream, and that the dungeon where he then lay was his true birth-place, and which to all appearance would also prove the place of his death. At other times, as he had a very metaphysical head, he first formed arguments of that kind, and then resolved them; performing thus the three different parts of opponent, respondent, and moderator, at the same time. In this whimsical way he amused himself from time to time, and constantly denied that he was a Jew. After having appeared twice or thrice before the inquisitors, he was used as follows: At the bottom of a subterraneous vault, lighted by two or three small torches, he appeared before two persons, one of whom was judge of the inquisition, and the other secretary; who, asking him whether he would confess the truth? protested, that in case of a criminal's denial, the holy office would not be deemed the cause of his death if he should expire under the torments, but that it must be imputed entirely to his own obstinacy. Then the executioner stript his clothes, tied his feet and hands with a strong cord, and set him upon a little stool, while he passed the cord through some iron buckles which were fixed in the wall; then drawing away the stool, he remained hanging by the cord, which the executioner still drew harder and harder, to make him confess, till a surgeon assured the court of examinants, that he could not possibly bear more without expiring. These cords put him to exquisite tortures, by cutting into the flesh, and making the blood burst from under his nails. As there was certainly danger that the cords would tear off his flesh, to prevent the worst, care was taken to gird him with some bands about the breast, which however were drawn so very tight, that he would have run the risk of not being able to breathe, if he had not held his breath in while the executioner put the bands round him; by which device his lungs had room enough to perform their functions. In the severest extremity of his sufferings, he was told that this was but the beginning of his torments, and that he would better confess before they proceeded to extremities. Orobius added further, that the executioner, being on a small ladder, in order to frighten him, frequently let it fall against the shin-bones of his legs; so that the staves being sharp, created exquisite pain. At last, after three years confinement, finding themselves baffled by his perseverance in denying his religion, they ordered his wounds to be cured, and discharged him. As soon as he had got liberty,
liberty, he resolved to quit the Spanish dominions; and, going to France, was made professor of physic at Toulouse. The theses which he made as candidate for this place were upon patreception; and he maintained them with so much metaphysical subtlety, as embarrassed all his competitors. He continued, in the third book of his Ethics, which is now lost, doubt if such a person as Orpheus ever existed. But as the work of Ciceron, in which this passage occurs, is in dialogue, it is not easy to discover what was his own opinion upon the subject, the words cited being put into the mouth of Caecilius Cotta. And Ciceron, in other parts of his writings, mentions Orpheus as a person of whose existence he had no doubts. There are several ancient authors, among whom is Suidas, who enumerate five persons of the name of Orpheus, and relate some particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to one the actions of many. But, however that may have been, we shall not attempt to collect all the fables that poets and mythologists have invented concerning him; they are too well known to need insertion here. We shall, therefore, in speaking of him, make use only of such materials as the best ancient historians, and the most respectable writers among the moderns, have furnished towards his history.

Dr. Cutworth, in his Intellectus Systematis, after exa

mining and confuting the objections that have been made to the being of an Orpheus, and with his usual learning and abilities clearly establishing his existence, proceeds, in a very ample manner, to speak of the opinions and writings of our bard, whom he regards not only as the first musician and poet of antiquity, but as a great mythologist, from whom the Greeks derived the Thracian religious rites and mysteries.

"It is the opinion (says he) of some eminent philo-
egers of latter times, that there never was any such person as Orpheus, except the fairyland; and that his whole history was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there is nothing alleged for this opinion from antiquity, except the one passage of Ciceron concerning Aristotle; who seems to have meant no more than this, that there was no such poet as Orpheus anterior to Homer, or that the verses vulgarly called Orphical, were not written by Orpheus. However, if it should be granted that Aristotle had denied the existence of such a man, there seems to be no reason why his single testimony should preponderate against the universal consent of all antiquity; which agrees that Orpheus was the son of Oege, by birth a Thracian, the father or chief founder of the mythological and allegorical theology amongst the Greeks, and of all their most sacred religious rites and mysteries; who is commonly supposed to have lived before the Trojan war, that is, in the time of the Israelitish judges, or at least to have been senior both to Hesiod and Homer; and to have died a violent death, most affirming that he was torn in pieces by women, because their husbands deserted them in order to follow him. For which reason, in the vision of Hera Pamphilus, in Plato, Orpheus's soul passing into another body, is said to have chosen that of a swan, a reputed musical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the historic truth of Orpheus was not only acknowledged by Plato, but also by Isocrates, who lived before Aristole.
Orpheus, in his oration in praise of Bacchus; and confirmed by the grave historian Diodorus Siculus, who says, that Orpheus diligently applied himself to literature, and when he had learned the mythes, or the mythological part of theology, he travelled into Egypt, where he soon became the greatest proficient among the Greeks in the mysteries of religion, theology, and poetry. Neither was his history of Orpheus contradicted by Origen, when so justly provoked by Celsus, who had preferred him to our Saviour; and, according to Suidas, Orpheus the Thracian was the first inventor of the religious mysteries of the Greeks, and that religion was thence called Orphica, Thracica, as if a Thracian invention. On account of the great antiquity of Orpheus, there have been numberless fables intermingled with his history; yet there appears no reason that we should disbelieve the existence of such a man.

Cudworth is also of opinion, that the poems ascribed to Orpheus were either written by him, or that they were very ancient, and contained his doctrines. He farther argues, that though Orpheus was a polytheist, and asserted a multiplicity of gods, he nevertheless acknowledged one supreme undeity, as the original of all things; and that the Pythagoreans and Platonists not only had Orpheus in great esteem, being commonly called by them Theologer, but were also thought in great measure to have owed their theology and philosophy to him, deriving it from his principles and traditions.

The bishop of Gloucester speaks no more doubtfully of the existence of Orpheus than of Homer and Heiod, with whom he ranks him, as only as a poet, but also as a theologian, and founder of religion.

The family of Orpheus is traced by Sir Isaac Newton for several generations: "Sefas passing over the Hellespont, conquers Thrace; kills Lycurgus king of that country; and gives his kingdom and one of his singing women to Oeagrus, the son of Tharopus, and father of Orpheus; hence Orpheus is said to have had the muse Calliope for his mother. He is allowed by most ancient authors to have excelled in poetry and music, particularly the latter; and that to such a degree, that he is represented as taming the most ferocious animals, changing the course of the winds by his melody, and as causing the trees of the forest to dance in concert with his lyre. This account, though we must suppose it fabulous, yet proves his excellence to have been great before he could have given rise to such fictions. He is said to have early cultivated the lyre, in preference to every other instrument; so that all those who came after him were contented to be his imitators; whereas, according to Plutarch, he adopted no model; for before his time no other music was known, except a few airs for the flute. Music was so closely connected in ancient times with the most sublime sciences, that Orpheus united it not only with philosophy, but with theology and legislation. He abstained from eating animal food; and held eggs in abhorrence as alimen, being persuaded that the egg subsisted before the chicken, and was the principle of all existence; both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as those of Pythagoras many ages after.

With respect to his abstaining from the flesh of oxen, Gesner supposes it may have proceeded from the vegetables shown to that animal so useful in tillage, in the Eleusinian mysteries instituted in honour of Ceres, the goddess of agriculture. He might have added, that, as those mysteries were instituted in imitation of those established in Egypt in honour of Osiris and Isis, this abstinence from animal food was of the like origin, and a particular compliment to Apis. But Abbe Fragnier, in an ingenious dissertation upon the Orphic Life, gives still more importance to the prohibition; for as Orpheus was the legislator and humanizer of the wild and savage Thracians, who were cannibals, a total abstinence from eating human flesh could only be established by obliging his countrymen to abstain from every thing that bad life.

With respect to theology, Diodorus Siculus tells us, that his father Oeagrus gave him his first instructions in religion, imparting to him the mysteries of Bacchus, as they were then practised in Thrace. He became afterwards a disciple of the Idæi Dactyli in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed so much to his skill in theological matters, as his journey into Egypt; where being initiated into the mysteries of Isis and Osiris, of Ceres and Bacchus, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worship, far superior to any one of his age and country. And being much connected with the descendants of Cadmus, the founder of Thebes in Bocotia, he resolved, in order to honour their origin, to transport into Greece the whole fable of Osiris, and apply it to the family of Cadmus. The credulous people easily received this tale, and were much startled by the institution of the ceremonies in honour of Osiris. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he became a citizen, admirably adapted this fable, and rendered it respectable, not only by his beautiful verses and manner of singing them, but by the reputation he had acquired of being profoundly skilled in all religious concerns. Diodorus Siculus also says that he was a most attentive student in all kinds of literature, whether sacred or profane.

At his return into Greece, according to Pausanias, he was held in the highest veneration by the people, as they imagined he had discovered the secret of expiating crimes, purifying criminals, curing diseases, and appeasing the angry gods. He formed and promulgated an idea of a bell, from the funeral ceremonies of the Egyptians, which was received throughout all Greece. He instituted the mysteries and worship of Hecate among the Eginetians, and of Ceres at Sparta.

Justin Martyr says, that he introduced among the Greeks near 360 gods; Hesiod and Homer pursued his labours, and followed the same clue, agreeing in the like doctrines, having all drank at the same Egyptian fountain.

Profane authors: look upon Orpheus as the inventor of that species of magic called evocation of the shades, or raising ghosts; and indeed the hymns which are attributed to him are mostly pieces of incantation, and real conjuration. By all accounts he was an admirable musician; he is said to have received a lyre from Apollo, or according to some from Mercury, upon which he played with such a masterly hand, that even the most rapid rivers ceased to flow, the savage beasts of the forest
Orpheus: he rest forgot their wildness, and the mountains came to 
listen to his song. All nature seemed charmed and 
animated, and the nymphs were his constant companions. 
Eurydice was the only one who made a deep impres-
sion on the melodious musician, and their nuptials were 
celebrated. Their happiness, however, was but short; 
for Aristaeus became enamoured of her; and as she fled 
from her pursuer, a serpent that was lurking in the grass 
bitten her foot, and she died of the poisoned wound. Her 
loss was severely felt by Orpheus, and he resolved to 
recover her or perish in the attempt. With his lyre in 
his hand, he entered the infernal regions, and gained an 
easy admission to the palace of Pluto. The king of hell 
was charmed with the melody of his strains; and ac-
cording to the beautiful expressions of the poets, the 
wheel of Acheron stopped; the stone of Sisyphus stood 
still; Tantalus forgot his perpetual thirst, and even the 
furies relented. Pluto and Proserpine were moved with 
his sorrow, and consented to restore him Eurydice, pro-
vided he forbore looking behind him till he had 
ascended to the extremest borders of hell. The conditions 
were gladly accepted, and Orpheus was already in sight of 
the upper regions of the air, when he forgot his 
promise, and turned back to look at his long lost Eu-
rydice.

All dangers past, at length the lovely bride 
In safety goes, with her melodious guide; 
Longing the common light again to share, 
And draw the vital breath of upper air: 
He first, and close behind him followed she; 
For such was Proserpine's severe decree. 
When strong desires th' impatient youth invade; 
By little caution, and much love betrayed: 
A fault which easy pardon might receive, 
Were lovers judges, or could hell forgive. 
For near the confines of ethereal light, 
And longing for the glimmering of a sight, 
Th' unwary lover cast a look behind, 
Forgetful of the law, nor master of his mind. 
Straight all his hopes exhale'd in empty smoke; 
And his long toils were forfeit for a look.

Dryden's Virgil.

He saw her, but she instantly vanished from his eyes: 
He attempted to follow her, but he was refused ad-
mission; and the only comfort he could find was to soothe 
his grief at the sound of his musical instrument in gro-
toes or on the mountains. He totally separated himself 
from the society of mankind; and the Thracian women, 
whom he had offended by his coldness to their amorous 
passion, or, according to others, by his unnatural grati-
fications and impure indulgencies, attacked him while 
they celebrated the orgies of Bacchus; and after they 
had torn his body to pieces, they threw his head into the 
Hebrus, which still articulated the words Eurydice! 
Eurydice! as it was carried down the streams into the 
Egean sea. Others think, that, as he attempted to 
conjure his wife from the dead, which they understand 
by the story of his going down to hell, he thought he 
saw her; and when afterwards, on looking back he mis-
understood her, he died of grief. There is certainly some 
reason for supposing this to be the case: for there were 
persons and temples publicly appointed for the purpose; 
and Pausanias really speaks of that temple which was in 
Thesprotia, and where Orpheus went to call up the ghost 
of Eurydice. Poets often mention this subject; and in 
stances of it occur in history both sacred and profane.

The witch of Endor is well known to those who read 
the historical part of the Bible. But to particularise 
instances, whether sacred or profane, would be endless. 
Some maintain that he was killed by a thunderbolt. 
He was buried at Pieria in Macedonia, according to 
Apollodorus. The inhabitants of Dion boasted that 
his tomb was in their city, and the people of Mount 
Libethrus in Thrace claimed the same honour; and 
further observed that the nightingales which built their 
 nests near his tomb, sang with greater melody than all 
other birds. Orpheus, as some report, after death re-
ceived divine honours; the muses gave an honourable 
burial to his remains, and his lyre became one of the 
constellations in the heavens.

Tzetzes explains the fable of his drawing his wife 
Eurydice from hell, by his great skill in medicine, 
with which he prolonged her life, or, in other words, 
watched her from the grave. Aelian, and other 
 physicians, have been said to have raised from the 
dead those whom they had recovered from dangerous 
diseases.

The bishop of Gloucester, in his learned, ample, 
and admirable account of the Eleusinian mysteries, says, 
"While these mysteries were confined to Egypt their 
native country, and while the Grecian lawgivers went 
thither to be initiated, as a kind of designation to their 
office, the ceremony would be naturally described in 
terms highly allegorical. This way of speaking was 
used by Orpheus, Bacchus, and others: and continued 
even after the mysteries were introduced into Greece, 
as appears by the fables of Hercules, Castor, Pollux, 
and Theseus's descent into hell; but the allegory was 
so circumstanced, as to discover the truth concealed 
under it. So Orpheus is said to get to hell by the power 
of his harp:

Thraceia fretus cithara, fidibusque canoris. 
Virg. Æn. vi. ver. 119.

That is, in quality of lawgiver; the harp being the 
known symbol of his laws, by which he humanized a 
rude and barbarous people.—Had an old poem, 
under the name of Orpheus, intitled A descent into Hell, 
been now extant, it would perhaps have shown us, that no 
more was meant than Orpheus's initiation." See My-
steries.

Many ancient writers, in speaking of his death, re-
late, that the Thracian women, as hinted at above, 
engaged at being abandoned by their husbands, who were 
disciples of Orpheus, concealed themselves in the woods, 
in order to satiate their vengeance; and notwithstanding 
they postponed the perpetration of their design some 
time through fear, at length, by drinking to a degree of 
toxication, they so far fortified their courage as to put 
him to death. And Plutarch assures us, that the 
Thracians stigmatized their women, even in his time, for 
the barbarity of this action.

Our venerable bard is defended by the author of the 
Divine Legation, from some insinuations to his dis-
advantage in Diogenes Laertius. "It is true (says 
he), if uncertain report was to be believed, the 
mysteries were corrupted very early; for Orpheus himself is said 
to have abused them. But this was an art the detached 
mystics of later times employed to varnish their 
con-
Jamblichus tells us, that the poems under the name of Orpheus were written in the Doric dialect, but have since been trans dialected, or modernised. It was the common opinion in antiquity that they were genuine; but even those who doubted of it, gave them to the earliest Pythagoreans, and some of them to Pythasgoras himself, who has frequently been called the follower of Orpheus, and has been supposed to have adopted many of his opinions.

Of the poems that are still subsisting under the name of Orpheus, which were collected and published at Nuremberg 1702, by And. Christ. Eschenbach, and which have been reprinted at Leipzig 1764, under the title of ΟΡΦΕΩΣ ΑΠΙΑΝΤΑ, several have been attributed to Onomacritus, an Athenian, who flourished under the Pisistratidæ, about 500 years before Christ. Their titles are, 1. The Argonautics, an epic poem. 2. Eighty-six hymns; which are so full of incantations and magical evocation, that Daniel Heinsius has called them veram Satanae liturgiam, "the true liturgy of the devil." Pausanias, who made no doubt that the hymns subsisting in his time were composed by Orpheus, tells us, that though less elegant, they had been preferred for religious purposes to those of Homer. 3. De lapidibus, a poem on precious stones. 4. Fragments, collected by Henry Stevens. Orpheus has been called the inventor, or at least the propagator, of many arts and doctrines among the Greeks. 1. The combination of letters, or the art of writing. 2. Music, the lyre, or cithara, of seven strings, adding three to that of Mercury. 3. Hexameter verse. 4. Mysteries and theology. 5. Medicine. 6. Magic and divination. 7. Astrology. Servius upon the sixth Æneid, p. 450, says, Orpheus first instituted the harmony of the spheres. 8. He is said likewise to have been the first who imagined a plurality of worlds, or that the moon and planets were inhabited.

Orpheus, in Ichthyology, the name of a fish caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its teeth are large and prominent, and its teeth serrated; it has only one fin on the back and the anterior rays of that are prickly, the others soft to the touch; its anus is small, and is said to have no passage for the semen.

This was the fish called Orpheus by the ancients, but the modern Greeks call another fish by that name. It is a species of the spurus, of a flat figure, but very thick, has a small mouth, and is covered with small but very rough scales, which adhere very firmly to the flesh; the tail is not forked; it has fleshy lips, and very small teeth; its back and sides are black; its belly white; it has a large black spot at the root of the tail; its head is reddish, and its fins are very elegantly diversified with various colours; it has only one back-fin, and that has the anterior ray prickly, the hinder ones not at all so. It grows sometimes to 20 pounds weight, and is much esteemed among the modern Greeks.

Orpiment (auripigmentum), in Natural History, a mineral which is composed of sulphur and arsenic, found native in the earth, and constituting one of the ores of arsenic, but sometimes artificially prepared. It is of two kinds, red and yellow. See Arsenic, Mineralogy Index, and Arsenic under Ores, Reduction of.

Ore. See Sedum, Botany Index.
ORRERY, a curious machine for representing the motions or phases of the heavenly bodies. See Astronomy, p. 171.

The reason of its being called an Orrery was this: Mr Rowley, a mathematical instrument maker, having got one from Mr George Graham, the original inventor, to be sent abroad with some of his own instruments, he copied it, and made the first for the Earl of Orrery. Sir Richard Steele, who knew nothing of Mr Graham's machines, thinking to do justice to the first encourager, as well as to the inventor of such a curious instrument, called it an Orrery, and gave Mr Rowley the praise due to Mr Graham.

Orrery, Earls of. See Boyle.

Orricé. See Iris, Botany Index.

Ortegal, Cape, the most northern promontory of Spain, where there is also a castle of the same name. W. Long. 8° 20'. N. Lat. 44° 0'.

Ortelius, Abraham, a celebrated geographer born at Antwerp, in 1527, was well skilled in the languages and the mathematics, and acquired such reputation by his skill in geography, that he was named the Ptolemy of his time. Justus Lipsius, and many of the great men of the 16th century, were Ortelius's friends. He resided at Oxford in the reign of Edward VI. and came a second time into England in 1577. His Theatrum Orbis was the completest work of the kind that had ever been published, and gained him a reputation equal to his immense labour in compiling it. He also wrote several other excellent geographical works; the principal of which are his Theaurus, and his Survey of Geographical.

The world is likewise obliged to him for the Britannia, which he persuaded Camden to undertake. He died at Antwerp in 1598.

Orthez, a city in France, in the department of the lower Pyrenees, and before the Revolution, a bishop's see. Its population in 1800 was 6728. The cathedral is a wretched edifice, very ancient, built in a barbarous style, and almost in ruins. The remains of the castle of Orthez are very noble, and its situation is fine, on a hill which commands the town and a great extent of country. The people call it Le Château de la Reine Jeanne, because that queen resided in it during many years, in preference to the castle of Pau. The princess Blanche, daughter to John king of Aragon and Navarre, was shut up, and died here, in 1464. Her brother being dead, she became heiress to the crown of Navarre; but her father having delivered her into the hands of her younger sister Leonora, countess of Foix, she confined the unhappy Blanche in the castle of Orthez, and, after an imprisonment of two years, caused her to be poisoned.

Orthodox, in church history, an appellation given to those who are sound in all the articles of the Christian faith.

Orthographic Projection of the Sphere, that wherein the eye is supposed to be at an infinite distance; so called, because the perpendiculars, from any point of the sphere, will all fall in the common intersection of the sphere with the plane of the projection. See Geography and Projection.

Orthography, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words, with all the proper and necessary letters, making one of the four greatest divisions or branches of grammar. See Grammar.

Orthography, in Geometry, the art of drawing or delineating the fore-right plane of any object, and of expressing the heights or elevations of each part. It is called Orthography, for its determining things by perpendicular lines falling on the geometrical plane.

Orthography, in Architecture, the elevation of a building.

Orthography, in Perspective, is the fore-right side of any plane, i.e. the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

Orthopnoea, a species or degree of asthma, where there is such a difficulty of respiration that the patient is obliged to sit or stand upright in order to be able to breathe. See Medicine Index.

Orrtive, in Astronomy, the same with eastern. The ortive or eastern amplitude, is an arch of the horizon intercepted between the place where a star rises, and the east point of the horizon, or point where the horizon and equator intersect.

Ortnau or Orthenau, a district or canton in Germany, in Subia, lying along the Rhine opposite Strasbourg. It included eight or ten small towns, of which Offenbourg, Gengenbach, and Zell, were the most considerable: these towns formed a small federation, and held immediately of the empire. At the distribution of the indemnities, after the peace of Lunéville, this territory, with the Bregawa, was assigned to the duke of Modena; but the greater part of it was afterwards annexed to the grand duchy of Baden.

Ortolan. See Emberiza, Ornithology Index.

Ortygia, the birthplace of Diana, was a beautiful grove of trees of various kinds, chiefly cypresses, near Ephesus; on the coast, a little up from the sea. This place was filled with shrines and images. The priests of the goddess were eunuchs, and exceedingly respected by the people. A general assembly was held there yearly, and splendid entertainments were provided, and mystic sacrifices solemnized. The Cenchrus, probably a crooked river, ran through it; and above it was the mountain Solimissus, on which, it was said, the Curetes stood, and rattled on their shields, to divert the attention of Juno. The improved face of a country is parlous like human beauty. Not only the birthplace of Diana and its sanctuary are forgotten, but the grove and buildings which adorned it appear no more; and perhaps, says Dr Cumberland, the land has encroached on the sea, and the valley, in which Arvissia is, was once Ortygia. See Ephesus, and Diana, &c.

Orvieto, a town of Italy, in the patrimony of St. Peter, with a bishop's see, and a magnificent palace. It is the capital of the province of Orvietano, in the ecclesiastical state, in E. Long. 12°. 5'. Lat. 42°. 50'. It is a large strong town, situated at the confluence of the Paglia and the Chiano, on a steep hill, surrounded on every side with rocks and precipices. To this situation it is owing that it has no springs; but there is a very surprising well cut into the rock, to supply it with fresh water. The mules, which bring up the water on their backs, go down by a staircase of 150 steps, and 60 windows, and come up by another, without meeting. The architect
ORYZIVORA, called the rice-bird of Catesby, a species of emberiza, which see, ORNITHOLOGY Index.

OSCHOPHORIA, a festival celebrated by the Athenians, which receives its name from the Greek τὸς ὀσχῷα, "from carrying boughs hung up with grapes," called ọσχῳα. The original institution is thus mentioned by Plat. in These. Theseus, on returning from Crete, forgot to hang out the white sail, by which his father was to be apprized of his success. This neglect proved fatal to Ægæus, for he threw himself into the sea, and perished. Theseus no sooner reached the land, than he sent a herald to inform his father of his safe return, and in the mean time he began to make the sacrifices which he had vowed to make when he first set sail from Crete. The herald, on his entrance into the city, found the people in great agitation. Some lamented the king's death, while others, elated at the sudden news of the victory of Theseus, crowned the herald with garlands in token of their joy. The herald carried back the garlands on his staff to the sea shore; and, after waiting till Theseus had finished his sacrifice, he related the melancholy account of the king's death. Upon this the people ran in crowds to the city, showing their grief by cries and lamentations. From this circumstance, therefore, at the feast of Oschophoria, not the herald but his staff is crowned with garlands, and all the people that are present always exclaim ὁλάου, οὖ, οὖ, the first of which expresses haste, and the others a consternation or depression of spirits. The historian further mentions, that Theseus, when he went to Crete, did not take with him the usual number of virgins, but that in the place of two of them, he took two youths of his acquaintance, whom he caused to pass for women, by disguising their bodies, and by accustomed them to the ointments and perfumes of women, as well as by a long and successful imitation of their voice. The imposition succeeded; their sex was not discovered in Crete; and when Theseus had triumphed over the Minotaur, he he with these two young men led a procession, with branches in their hands in the same habit, which is still used at the celebration of the festival. The branches which were carried were in honour of Bacchus or Ariadne, or because they returned in autumn, when the grapes were ripe. Besides this procession, there was also a race, in which young men only whose parents were both alive were permitted to engage. It was customary for them to run from the temple of Bacchus to that of Minerva, which was on the sea shore. The place where they stopped was called οσχῳάερα, because the boughs which they carried in their hands were deposited there. The reward of the conqueror was a cup called ώτερωπλάκα, "five-fold," because it contained a mixture of five different things, wine, honey, cheese, meal, and oil.

OSCILLA, small images of wax or clay made in the shape of men or women, and consecrated to Saturn, to render him propitious. The word is sometimes used to signify a kind of masks scooped from the bark of trees, and worn by the performers of comedy in the rudest ages of Rome. In this sense we find it in Virg., Georg. ii. 386. It also signifies little heads or images of Bacchus.
Bacchus, which the country men of old hung upon trees, that the face might turn every way, out of a notion that the countenance of this god gave felicity to themselves, and fertility to their vineyards. An allusion to this opinion and custom is also found in Virgil, Georg. ii. 388.

OSENÉY ISLAND, in England, is formed by the river Isis, in the meadows near Oxford, where a magnificent abbey was erected, at the instigation of a concubine of King Henry I. to atone for her sins; and the said king built a palace there, wherein King Richard I. was born, which Edward II. converted into a monastery.

OSIRIS, in Mythology, one of the gods of ancient Egypt, and very generally believed to have been the sun, or at least the mind actuating that luminary.

The Egyptians derived all things from two principles, an active and a passive. Their active principle, according to the learned Jabłonski*, was an infinite and eternal spirit; and their passive principle was might. This spirit they considered sometimes as a male, sometimes as a female, divinity, and occasionally they attributed to it both sexes; but it does not appear to have been the object of their worship. It shall be shown elsewhere (see Polytêism), that the earliest objects of pagan adoration were the sun, moon, and planets: and that the philosophers and priests of ancient Egypt worshipped the sun by the name of Osiris, may be proved by numberless testimonies from the most authentic records of antiquity. Diogenes Laertius affirms, that they held the sun and moon for divinities, and that they called the latter Isis; and Macrobius says expressly, "Nec in occulto est, neque alius esse Osiris quam solem, nec Isis alius esse quam terram." The same writer informs us, that in the hieroglyphic writings of ancient Egypt, "Osiris was represented by a sceptre and an eye," to denote that this god was the sun looking down from heaven on all things upon earth.

It must not, however, be concealed, that some of the ancients, and a few of the most learned moderns, have contended, that by Osiris the Egyptians understood the Nile or spirit of the Nile, whilst others have confounded him with the Grecian Bacchus. Scaliger and Selden have adopted the former of these opinions, and Servius on Virgil has given his countenance to the latter. But that they are all mistaken, has been evinced by Jablonški in such a manner as to enforce the fullest conviction: "When the Egyptians, in their sacred books, sometimes gave the name of Osiris to the Nile and its wonderful increase during the heat of summer, they mean nothing more (says he) but to attribute to their god Osiris the gift which fertilizes their country." This they would the more readily do that they believed the Nile to have its source in heaven. Hence Eusebius tells us, Osiris qui est Nana, in quo omnium conformatu mundi, Osiris is the Nile, because they think it is sent down from heaven. In one sense Osiris might be Bacchus, because the original Bacchus was himself the sun (see Mysteres, No. 12); but that the Egyptian god could not be worshiped as the inventor of wine is indeed undeniable, if, as Osiris, Jabłonski labours to prove, the primitive religion of that country inculcated upon its votaries, that wine was the gift, not of a benevolent god, but of an evil genius, the enemy of the human race. In support of this opinion our learned author quotes a passage from Plutarch, from which it appears, that, before the era of Psalmotichus, the Egyptians neither drank wine themselves, nor offered it in libations to the gods, because they believed that the first vine sprung from the earth was impregnated by the blood of those giants who perished in the war with the gods. It is indeed true, that the Greeks, who borrowed their religion as well as the first principles of science from Egypt, attributed to their Bacchus many of the actions of Osiris; but it is likewise true, that they gave him other attributes, which the Egyptian god could not possess, consistently with the known superstitions of that country. Salmassius, however, attempts to prove, from the import of the name, that the Osiris of Egypt must have been the Bacchus of Greece. Σαρ or Σησ, he says, signifies a son in the Egyptian language; and hence he concludes that the god was by that people called Osiris, for the same reason that by the Greeks he was called Κορες, and by the Romans Liber. But this seems all to be a mistake. Siris makes a part of many Egyptian proper names, as Bu-siris, Terme-siris, Taio-siris, &c. and is in all probability derived from the Hebrew word Sar, Sar, or Sir, which signifies a prince, potentate, or granule. As the name of the god was in Egypt not Osiris, but Isis or Ysiris, it was probably made up of Sir or Siris, and the Hebrew prefix I or ish, denoting strength; so that the whole word will signify the strong or mighty prince. If so, we cannot doubt, as Diodorus Siculus, Eusebius, Sextus Empiricus, &c. all affirm, that the Egyptians worshipped the sun by the name of Osiris, but that by this name they meant the power or governing mind of the sun, as the Greeks and Romans seem to have done by their Phœbus and Apollo.

But though the original Osiris was undoubtedly the sun, or the intelligence actuating the sun, yet there is reason to believe that there was a secondary Osiris, who at a very early period reigned in Egypt, and was deified after his death for the benefits he had rendered to his country (see Polytêism). This is indeed so generally admitted, as to have occasioned great controversies among the learned respecting the time when he flourished, and whether he was the civilizer of rude barbarians or the victorious sovereign of a polished nation. The illustrious Newton it is well known, has adopted the latter opinion; and with much plausibility endeavored to prove, that Osiris was the same with Sesastis or Sesac: but it must be confessed, that his conclusion is contrary to all the most authentic records of antiquity; and that it would be easy, by the same mode of arguing, to give a show of identity to two persons universally known to have flourished in very distant ages (A). The annals of Egypt, as may be seen in the writings of Herodotus, Diodorus Siculus, Strabo, Plutarch, and others, who copied

(A) This has been in fact done by Warburton; who employs Newton's mode of reasoning with equal plausibility, and perhaps superior force, to prove the identity of King Arthur and William the Conqueror. See Divine Legation of Moses, vol. iii. book iv. sect. v.
OSNABURG, or Osnabruck. It was formerly an imperial city, and one of the Hanse towns. It has its name from a bridge over the river Hase, or Ose, which divides it into the Old and New Town, and stands 75 miles west of Hanover, and 30 north-east of Munster, being surrounded with walls and ditches, but commanded by a mountain within cannon-shot. It stands in a fine plain, and is adorned with several good buildings, and on the mountain there is an abbey. The magistracy of this city, which is chosen yearly on the 2d of January, is Lutheran; and the churches belong, some to the Lutherans, and some to the Papists. Both parties have the full and free exercise of their religion, whether the bishop be Protestant or Papist. The bishop's palace, called Petersburg, was built by Bishop Ernest Augustus, brother to King George I. It is well fortified and separated from the town by a bridge. It is a hexagon, with a court in the middle, and at each corner a turret. In the town-house are still preserved the pictures of the plenipotentiaries that assisted at the conferences there for the famous treaty of Westphalia. In the treasury of the cathedral are still to be seen some ornaments given by Charlemagne, as also his crown, which is of silver gilt, and his comb and baton, six feet in length, both of ivory; together with other curiosities. Charlemagne is said to have erected here a school for Latin and Greek, which the Jesuits in 1625 converted into an academy. They have the best bread and beer that is to be met with in all Westphalia, and have a pretty good trade in bacon and linen; as also by brewing a palatable thick sort of beer called buse. This city is noted for a treaty betwixt the emperor and the king of Sweden in 1648, wherein the affairs of the Protestants were regulated, which was a branch of the treaty of Westphalia. In 1613 the greatest part of it was destroyed by fire. In 1630 Bishop Francis William erected an academy here, consisting of thirteen seminaries, which were also confirmed by the emperor Ferdinand II., and Pope Urban VII.; but the capture of the place by the Swedes in 1733 put an end to it. In 1634 the crown of Sweden created Count Gustavus Wasenburg lord of the bishopric of Osnaburg; but at the peace of Osnaburg he renounced all his right obtained over this place during the war, in consideration of receiving 80,000 rix dollars. The town toll was by the town, in the year 1431, given to the bishop, with a reserve of exemption from toll to the burghers, in order to get rid of the Jews, who were that year banished. The cathedral is in the hands of the Roman Catholics, with the church and monastery of the Dominicans in the old city, and the collegiate church of St John in the new. The Protestants are masters of the great parochial church of St Mary in the old city; and both religions have a voice in the election of the magistrates. The bishop's palace is fortified like a castle; here it was that George I. was born on the 28th of May 1660, his father Ernest Augustus being then bishop and prince of the place; and here also he died in the night of the 10th of June 1727, and, as some say, in the very room in which he was born. The inhabitants have considerable manufactures.
manufactures of linen and a good breed of cattle; and of their hogs, for which they are remarkable, is made the best Westphalia bacon. Not far from this city are to be seen the ruins of an old church and castle called Beclen, which some say was built by King Wittekind upon his conversion; and about two miles from it lies the monastery of Rolle, on the bank of a lake so deep, that report says it could never yet be fathomed. This was the first town in Westphalia which received the Lutheran doctrine.

Chicamanna Island, one of the islands in the South sea, discovered by Captain Wallis in 1767. It is a high, round island, not above a league in circuit; in some parts covered with trees, in others a naked rock. S. Lat. 22° 48'. W. Long. 14° 34'.

OSORIUS, JEROME, a Portuguese ecclesiastic, was born of a noble family at Lisbon, in 1500. He was educated at the university of Salamanca, and afterwards studied at Paris and Bologna. On his return to Portugal he gradually rose to the bishopric of Sylves, to which he was appointed by Catharine of Austria, regent of the kingdom in the minority of Sebastian. At the request of Cardinal Henry of Portugal, he wrote his history of King Emanuel, and the Expedition of Gama; which his great contemporary Camoens made at the same time the subject of his immortal Lusiad; a poem which has at length appeared with due lustro in our language, being translated with great spirit and elegance by Mr Mickle. It is remarkable that the history of Osorius, and the epic poem of Camoens, were published in the same year, 1572: but the fate of these two great authors was very different; the poet was suffered to perish in poverty, under the reign of that Henry who patronised the historian; yet allowing for the difference of their professions, they possessed a similarity of mind. There appear many traces of that high heroic spirit even in the priest Osorius, which animated the soldier Camoens; particularly in the pleasure with which he seems to describe the martial manners of his countrymen under the reign of Emanuel. "In that age (says the historian in the close of his manly work), poverty and sadness were banished from Portugal. Complaints were never heard; but every place, from the court to the cottage, resounded with mirth and music. Ilicit love was unknown; nor would the ladies listen to the most honourable addresses of such youths as had not signalized themselves in war. No young man about court, however noble by birth, was permitted to wear the dress of manhood till he had passed over into Africa, and thence brought back with him some animal esteemed for its rarity; and such was the hardy education of the nobility in that age, that many of them travelled everywhere in quest of adventures." This is a striking picture of the manners of chivalry, to which Portugal owed much of its glory in that splendid period. There is one particular in the character of Osorius, which, considering his age and country, deserves the highest encomium; and that is his tolerating spirit. In the first book of his history, he speaks of Emanuel's cruel persecution of the Jews in the following generous and exalted language: "This (says he) was authorized neither by law nor by religion. Can men be compelled to believe what they reject with abhorrence? Do you take upon you to restrain the liberty of the will, or to fetter the understanding? Such an attempt must be unsuccessful; and is not acceptable to Christ, who expects from man devotion of the heart, and not that formal worship which is the offspring of pains and penalties. He wishes them to study his religion, and accept it from conviction, not from terror: for who does not see that forced belief is mere hypocrisy?" Osorius is said to have used many arguments to dissuade Sebastian from his unfortunate expedition into Africa, and to have felt so deeply the miseries which befell the Portuguese after that fatal event, that his grief was supposed to accelerate his death. He expired in 1582, happy, says De Thou (who celebrates him as a model of Christian virtue), that he died just before the Spanish army entered Portugal, and thus escaped being a witness to the desolation of his country.—His various works were published at Rome in 1592, by his nephew Osorius, in four volumes folio, with a life of their author. Among these are two remarkable productions; the first, An Admonition to our Queen Elizabeth, exhorting her to return into the Church of Rome; the second, An Essay on Glory, written with such classical purity, as to give birth to a report, that it was not the composition of Osorius, but the last work of Cicero on that subject.

OSPREY. See FALCO, ORNITHOLOGY INDEX.

OSSA, a lofty mountain of Thessaly, near the Peneus, which runs between this mountain and Olympus; famous in the fabulous story of the giants (Homer, Virgil, Horace, Seneca, Ovid). The bending and unbending of its pines, on the bottom of a strong north wind, formed a clashing sound like thunder (Lasca). It was once the residence of the Centaurs, and was formerly joined to Mount Olympus; but Hercules, as some report, separated them, and made between them the celebrated valley of Tempe. The separation of the two mountains was more probably effected by an earthquake which happened about 188 years before the Christian era. Its greatest celebrity arises from its being one of those mountains which the giants in their wars against the gods heaped up one on the other to scale the heavens with more facility. A town of Macedonia.

OSSAT, ARNAULD DE, a learned French ecclesiastic, was born in the diocese of Auch in 1536, of mean parentage, and was taken notice of by a gentleman in the diocese, who made him study with his ward the Lord of Castienan de Magnoac. He studied the law at Dijon under Cujace, and applied himself to the bar at Paris. He was secretary at Rome to M. de Foix, archbishop of Toulouse; to Cardinal Este; and afterwards to Cardinal de Joyeuse, by the French king's express command. After rising to the highest dignities both in church and state, in 1590 he was created a cardinal by Pope Clement VIII. He died in 1604. An eminent French writer gives him the following character: "He was a man of prodigious penetration; applied himself so closely to affairs, and especially was so judicious in forming his resolutions, and it is almost impossible to find out one false step in the many negotiations in which he was concerned. His works, and especially his letters, have been much esteemed in the learned world.

OSSIAN, the son of Fingal, a celebrated Celtic poet, who flourished about the end of the second and beginning
OSS [575]

beginning of the third century. Several incidents in his poems point out this as his era: particularly the engagement of Fingal with Caracul, or Caracalla, the son of the emperor Severus, styled by Ossian, The Son of the King of the World. M. Tillemont fixes the elevation of Caracalla to a share in the government to the year 158, and the association of his brother Ceta to 208. About which time Gibbon fixes the Caledonian war, and speaks thus upon the subject: “This Caledonian war, neither marked by decisive events, nor attended with any important consequences, would ill deserve our attention; but it is supposed, not without a considerable degree of probability, that the invasion of Severus is connected with the most shining period of the British history or fable. Fingal, whose name, with that of his heroes and bards, has been revived in our language by a recent publication, is said to have commanded the Caledonians in that memorable junction, to have eluded the power of Severus, and to have obtained a signal victory on the banks of the Caurn, in which the son of the King of the World, Caracul, fled from his arms along the fields of his pride." Something of a doubtful mist still hangs over these Highland traditions; nor can it be entirely dispelled by the most ingenious researches of modern criticism (A); but if we could with safety indulge the pleasing supposition that Fingal lived, and that Ossian sang, the striking contrast of the situation and manners of the contending nations might amuse a philosophic mind. The parallel would be little to the advantage of the more civilized people, if we compared the unrelenting revenge of Severus with the generous clemency of Fingal; the timid and brutal cruelty of Caracalla, with the bravery, the tenderness, the elegant genius of Ossian; the mercenary chiefs who, from motives of fear or interest, served under the imperial standard, with the free-born warriors who started to arms at the voice of the king of Morven: if, in a word, we contemplated the untutored Caledonians glowing with the warm virtues of nature, and the degenerate Romans as Muses polluted with the mean vices of wealth and slavery."

The date of this action, if the poems be true, is rather confusing; for the next expedition, which is produced to fix the time in which Ossian flourished, was conducted by Oscar (against the usurper Carausius, the Caros of Ossian), who did not assume the purple till so late as the year 287. This account indeed corresponds pretty well with the account given by Irish histories, which place the death of Fingal in the year 283, and that of Oscar (who died many years before his father Ossian) in the year 296. These hints are not thrown out because we think they militate against the authenticity of the poems; for distant though these dates be, it is yet possible to reconcile them. Old age was and is very common in those regions; and Ossian himself, we are told, was an instance of great longevity. Indeed at such a distance of time, it cannot be expected that we should give either a very particular or a very exact account of Ossian and his heroes. Were there no doubts remaining of the truth of the facts, it is still natural to suppose that they must have suffered obscurity through the rust of time, and above all through the neglect of the poems, which till lately were unknown.

The first expedition on which Ossian's father sent him was, to raise a stone on the banks of Crona, to perpetuate the memory of a victory which the king of Morven had obtained at that place. The Highlanders talk of this as being emblematical of that immortality which heroes were to receive from his future compositions. In this expedition he was accompanied by Toscar, father of the beautiful Malvina, the amiable companion of his grief, after the death of her beloved Oscar, his son. It appears from his poems, that in one of his early expeditions to Ireland, he had fallen in love with and married Evirallin, daughter to Branno, petty king of Lego. "I went in suit of the maid of Lego's sable surge; twelve of my people were there, the sons of streamy Morven. We came to Branno, friend of strangers; Branno of the sounding mail.—From whence (he said) are the arms of steel? Not easy to win is the maid that has denied the blue-eyed sons of Erin. But blest be thou, O son of Fingal! happy is the maid that waits thee. Though twelve daughters were mine, thine were the choice, thou son of fame.—Then he opened the hall of the maid; the dark-haired Evirallin." This Evirallin, Fingal was the mother of his son Oscar, whose exploits he B. iv. celebrates in many of his poems, and whose death he laments in the first book of Temora. Evirallin died some time before Oscar (Fingal. B. iv.), who seems to have been her only child; and Ossian did not marry afterwards; so that his posterity ended in the death of Oscar, who seems to have died as he was about to be married to Malvina, the daughter of Toscar. Several of her lamentations for her lover are recorded by Ossian, which paint her grief in the strongest and most beautiful colours. "It is the voice of my love! few are his visits to my dreams.—But thou dwellest in the soul of Malvina, son of mighty Ossian. My sighs arise with the beams of the east; my tears descend with the drops of night. I was a lovely tree in thy presence, Oscar, with all my branches round me: thy death came like a blast from the desert, and laid my green head low; the spring returned with its showers, but no green leaf of mine arose." Poem of Comra.

The principal residence of Ossian was in the vale of Cona, now Glenclo, in Argyshire. See Fingal.

His poems relate many of his expeditions to Ire-
The poems of Ossian, though always held in the highest esteem by those who knew them, were allowed to remain in the obscurity of their original Gaelic, till Mr Macpherson, above 40 years ago, translated a collection of them into English, which immediately attracted the attention of every person who had a true taste for poetry. Dr Blair, in particular, introduced these poems into the world with those critical remarks which do no less honour to himself than to the poet.

According to that eminent critic, the two great characteristics of Ossian's poetry are tenderness and sublimity. Ossian is, perhaps, the only poet who never relaxes, or lets himself down into the light and amusing strain. He moves perpetually in the high region of the grand and pathetic. The events which he records are all serious and grave; the scenery wild and romantic. We find not in him an imagination that sports itself, and dresses out gay tribes to please the fancy. His poetry, more perhaps than that of any other, deserves to be styled the poetry of the heart. It is a heart penetrated with noble sentiments, with sublime and tender passions; a heart that glows and kindles the fancy; a heart that is full, and pours itself forth. Of all the great poets, Homer is the one whose manner and whose times come the nearest to Ossian's. Homer's ideas were more enlarged, and his characters more diversified, Ossian's ideas fewer, but of the kind fittest for poetry; the bravery and generosity of heroes, the tenderness of lovers, and the attachment of friends. Homer is diffuse; Ossian abrupt and concise. His images are a blaze of lightning, which flash and vanish. Homer has more of impetuosity and fire; Ossian of a solemn and awful grandeur. In the pathetic, Homer has a great power; but Ossian exerts that power much oftener, and has the character of tenderness more deeply imprinted on his works. No poet knew better how to seize and melt the heart. With regard to dignity of sentiment, we must be surprised to find that the pre-eminent must clearly be given to the Celtic bard. This appears nowhere more remarkable than in the sentiments which he expresses towards his enemies. "Uthal fell beneath my sword, and the sons of Berrathon fled. It was then I saw him in his beauty, and the tear hung in my eye. Thou art fallen, young tree, I said, with all thy beauty round thee. Thou art fallen on thy plains, and the field is bare. The winds come from the desert, and there is no sound in thy leaves! Lovely art thou in death, son of car-borne Lathamore." His superior position, that all the little feuds and differences of modern life should be forgotten in a future state, and that those who had once been foes would "stretch their arms to the same shell in Loida," gives us the highest idea of the man as well as of the poet. "Daughter of beauty, thou art low! A strange shore receives thy corse. But the ghosts of Morven will open their halls when they see thee coming. Heroes around the feast of dim shells, in the midst of clouds shall admire thee; and virgins shall touch the harp of mist." — The Celtic fail and the feuds of other years by the mighty dead are forgotten. The warriors now meet in peace, and ride together on the tempest's wing. No clang of the shield, no noise of the spear, is heard in their peaceful dwellings. Side by side they sit, who once mixed in battle their steel. There, Lochlin and Morven meet at the mutual feast, and listen together to the song of their bard."

But the sublimity of moral sentiments, if they want of depth interest the heart takes in tender and pathetic scenes. With scenes of this kind Ossian abounds;
Hence we may expect to find poems among the antiquities of all nations. It is probable, too, that an extensive search would discover a certain degree of resemblance among all the most ancient poetical productions, from whatever country they have proceeded. In a similar state of manners, similar objects and passions operating upon the imaginations of men, will stamp their productions with the same general character. Some diversity will, no doubt, be occasioned by climate and genius. But mankind never hear such resemblances as they do in the beginnings of society. What we call the oriental vein of poetry, because the earliest poetical productions have come to us from the east, is probably no more oriental than occidental; it is characteristic of an age rather than a country; and belongs, in some measure, to all nations at a certain period. Of this the works of Osian seem to furnish a remarkable proof.

He appears clearly to have lived in a period which enjoyed all the benefit I have just now mentioned of traditional poetry. The exploits of Trathal, Trenmor, and the other ancestors of Fingal, are spoken of as familiarly known. Ancient bards are frequently alluded to. In one remarkable passage, Osian describes himself as living in a sort of classical age, enlightened by the memorials of former times, conveyed in the songs of bards, and points at a period of ignorance which lay beyond the reach of tradition. Osian himself appears to have been endowed by nature with exquisite sensibility; prone to that tender melancholy which is so adventitious on great genius; and susceptible equally of strong and soft emotions. He was not only a professed bard, but a warrior also, and the son of the most renowned hero and prince of his age. This formed a conjunction of circumstances, uncommonly favourable towards exalting the imagination of a poet.

The manners of Osian's age were favourable to a poetical genius. Covetousness and effeminacy were unknown. The cares of men were few. The great object pursued by heroic spirits, was, to receive their fame, that is, to become worthy of being celebrated in the songs of bards; and to have their names on the four gray stones. To die uncomplimented by a bard was deemed so great a misfortune as even to disturb their ghosts in another state. In such times as these, in a country where poetry had been so long cultivated, and so highly honoured, is it any wonder that, among the race and succession of bards, one Homer should arise: a man who, endowed with a natural, happy genius, favoured by peculiar advantages of birth and condition, and meeting, in the course of his life, with a variety of incidents proper to fire his imagination, and to touch his heart, should attain a degree of eminence in poetry, worthy to draw the admiration of more refined ages?

Besides, his compositions, when viewed in themselves, have, we are told, all the internal marks of antiquity so strongly impressed upon them, that no reader of taste and judgment can deny their claim to it. They exhibit so lively a picture of customs which have disappeared for ages, as could be drawn only from nature and real life. The features are so distinct, that few portraits of the life continually passing before us are found to be drawn with so much likeness. The manners uniformly relate to a very early stage of society; and no hint, no allusion to the arts, customs, or manners, of a more ad-
OSS

Ossian. 

vanced period, appears throughout the poems. To that
distinction of ranks, which is always found in adult so-
cieties, the poet appears to have been a perfect stranger.
The first heroes prepare their own repasts, and industri-
ously descend to the most menial services. Their
quarrels arise from causes generally slight, but in such a
period extremely natural. A rivalry in love, an emis-
ion at a feast, or an affront at a tournament, are often
the foundation of a quarrel among single heroes. And
the wars in which whole tribes are engaged, are carried
on with a view, not to enlarge their territory, but to
revenge perhaps the killing of a few deer on their moun-
tains, or the taking forcibly away one of their women.
Their occupation was war and hunting; and their chief
ambition was to have their name in the songs of the
bards.

The notions of a future state, exhibited in these
poems, are likewise strongly marked with the character
of antiquity. A creed so uncommon, that the imagina-
tion of a modern could not be supposed to grasp so
strong an idea of it from mere fancy, is uniformly sup-
ported throughout. This creed is extremely simple,
but admirably suited to the times.

The language, too, and the structure, of these poems,
bear the most striking characters of antiquity. The lan-
guage is bold, animated, and metaphorical, such as it is
found to be in all infant states; where the words, as
well as the ideas and objects, must be few; and where
the language, like the imagination, is strong and undis-
ciplined. No abstract, and few general, terms appear
in the poems of Ossian. If objects are but introduced
in a simile, they are always particularized. It is "the
young pine of Inishana." It is "the bow of the shower
Lenn." This character, so conspicuous in the poems of
Ossian, is a striking feature in the language of all
careful states; whose objects and ideas are few and par-
ticular, and whose ordinary conversation is of course
highly figurative and poetical. A picture, therefore,
marked with such striking features, could not be drawn
without an original.

The whole texture of the composition is also, like the
language, bold, nervous, and concise; yet always plain
and artless; without any thing of that modern refine-
ment, or elaborate decoration, which attend the ad-
vancement of literature. No foreign ornament are
hunted after. The wild and grand nature which lay
within the poet’s view, is the only source from which
he draws his ornaments. Beyond this circle, his ima-
agination, though quick and rapid, seldom made any ex-
cursion. We perceive his language always to be that
of a person who saw and felt what he describes; who
lived a part in the expeditions which he celebrates, and
who fought in the battles which he sings. Such is
the nature of the internal proof adduced in the present
case, which unquestionably has weight, and that not con-
sideirable; but unsupported by external proof, or contrary
to facts, however forcible it may be in itself, when con-
sidered in this connection, and found wanting, it will
neither silence the querulous sceptic, nor, in all proba-
ibility, will it ever convince those who have truth for their
object, and who wish to investigate, and, if possible, dis-
cover it on surer grounds. Internal proof is of the
gratest service in a variety of excellent causes; but it
comes in rather as a succedaneum than as direct evi-
dence; and without something more to the purpose, it
may excite admiration, but will seldom enforce belief.

Of the customs and manners of ancient times we know
but little, and of that little we have often but a confus-
ioned notion. There is therefore room for genius and abil-
y to exert itself in descriptive; and in proportion to
the darkness in which the subject is involved, the de-
ception will generally be the more complete, and the se-
cret windings of error less easy to be developed.

Destitute of external proof, authenticity may appear
to be probable, but cannot be certain; and in such cir-
stances, on many occasions, and especially with re-
spect to ancient writings, we may, without any offence
to truth or to sound reasoning, give them up as spurious.
In the present instance, therefore, it is just and proper
to add to what has been already said, the more external
and positive proofs of the authenticity of the poems in
question, by the strength or weakness of which the sub-
ject must be finally determined. It is observed, there-
fore, that there have been in the Highlands of Scot-
land, for some ages back, a vast many poems ascribed
to Ossian: That these poems have been held in the
highest veneration, repeated by almost all persons, and
on all occasions. These are facts so well known, that
nobody as yet has been hardy enough to deny them.
There is not an old man in the Highlands, who will
not declare, that he heard such poems repeated by his
father and grandfather as pieces of the most remote an-
tiquity. There is not a district in the Highlands where
there are not many places, waters, lands, coves, and
mountains, which from time immemorial are called af-
after the names of Ossian’s heroes. There is not a lover
of ancient tale or poetry, however illiterate, who is not
well acquainted with almost every single name, charac-
ter, and incident, mentioned in those translations of Oss-
ian’s poems, which he may have never heard of.

—Bards, who are themselves several centuries old, quote
those poems, imitate them, and refer to them. The or-
dinary conversation and comparisons of the Highland-
ers frequently allude to the customs and characters men-
eted in them; and many of their most common proverbs,
established by the most ancient use, are lines borrowed
from the poems of Ossian. —The most ancient of the
clans boast of deriving their pedigree, each from some ang-
als one of Ossian’s heroes; and many of the signs asso-
ciated to them by the ancients, are drawn from the tales as-
cribed to their predecessors in those poems. —Manuscripts are
mentioned, in which some of those have been preserved
for several centuries; and a list of living names, in which
different part of the Highlands, is appealed to, as per-
some who still repeat a part of these poems. —While
Mr Macpherson was engaged in the translation, many
Kensmen respectable persons, gentlemen and clergymen, avowed
respect to the public, that these were Ossian’s poems, with
which they had long been acquainted, and that the
translation was literal. This appears also from the
large specimens of the originals published and compared
by proper judges. The originals lay in the hands of the bookseller, for the inspection of
Dr Blair’s
curious; and they have been afterwards shown frequent-
ly to many of the best judges, and offered for publica-
tion if the editor had been favoured with subscriptions.

The editor of the pamphlet, in which their authenticity
is attested by many respectable names of undoubted vo-
racity, observes, by way of conclusion, that more tes-
timonies might have been produced by a more enlarged
correspondence.
correspondence with the Highland counties. But I apprehend, if any apology is necessary, it is for producing so many names in a question where the consenting silence of a whole country was, to every unprejudiced person, the strongest proof that spurious compositions, in the name of that country, had not been obstructed upon the world. It is likewise argued in support of the authenticity of these poems, that candid secession, on hearing some of them repeated by illiterate persons, who had never seen the translation, caused them to give the meaning of what they repeated, by an extemore translation into English, and by this means had all their doubts of the authenticity of Ossian removed. They urge further, that such passages of Ossian’s works as are still repeated by some old men, are among the most beautiful parts of Ossian’s poems; such as the battle of Loss, the most affecting parts of Carthon, Berrath, the death of Oscar, and Darthous, or the children of Uamoth, &c.; which gives a credibility to his being equal to the other parts of the collection, none of it being superior to these in merit.

To these and the like arguments advanced in support of the authenticity of the poems ascribed to Ossian, many objections have been urged. Those of Johnson and his friend Shaw are universally known. A later writer objects to them in the following manner: No fragments of British poetry in Scotland are to be found. Many specimens of Irish poetry in Scotland have been published; but none older than a century or two. Translations have also appeared; but, in general, of no fidelity. Those of the poems ascribed to Ossian in particular, have deservedly drawn much of the public attention; but they will only mislead any reader who wishes to form an idea of Celtic poetry. He that believes Ossian to have flourished about the year 300, and his writings preserved by oral tradition for 1460 years, large is his faith, and he might move mountains! Gentlemen of the Highlands of Scotland, with whom our author conversed on the subject, assured him, that they looked upon ninetenths of Mr. Macpherson’s work as his own; and upon the other tenth, as so much changed by him, that all might be regarded as his own composition. There are some evidences, he says, which convince him that not one of the poems given to Ossian, and probably not one passage of them is older than the 17th century. The very first author we know who mentions Finn, is Barbour, a Scotch poet, who wrote in 1375. Finn had an Irish hero: and one God, a schoolmaster at Limerick, sent some account of Ireland to Camden, in 1566, in which mention is made of some strange fabules, that the people amuse themselves with, about the “giant Fin Mac Hayle, and Other Mac Ossin,” of which we shall speak more largely presently. In the mean time, to those and such like objections, it has been answered, that poetry has been cultivated with most success in the earliest ages of society; that in Greece, Orpheus, Linus, Hasiod, and Homer, wrote their admirable poems some ages before any thing had been written in prose in the Greek language; that the book of Job, written in a very early period of society, is highly poetical; that among the tribes of Lapland and America, there have been found, in the earliest state, some excellent pieces of poetry. That the Caledonians, in particular, had some peculiar institutions, which tended to improve their poetry: their druids were among the most learned phil-

lophers which perhaps any age or country produced; their bards or poets were the disciples of those druids, and were always in a standing order, to which none but the most promising geniuses were admitted. This standing college of poets was furnished, not only with the fruits of their own long study and observation, but also with as much as merited to be preserved of the compositions of their predecessors in office, since the list of the other’s conversation; which would excite their emulation, and make them aspire to eminence: They were always present, and generally engaged, in every grand operation that was transacted; which could not fail to inspire their muse with the truest poetic fire.

The case of Ossian was particularly favourable. He lived in an age when manners came to a considerable degree of refinement under the care of the bards and druids. Poetry in his day was considerably advanced; and the language, though strong and figurative, had undergone some degree of cultivation, and learned to flow in regular numbers, adapted to the harp, the favourite instrument of the times. As a prince and a warrior, his mind must have been expanded and much enlarged by his excursions to other countries. At home he had Ulfin, Ossin, and Hving, who conversed with all of them poets of eminence, who would have advanced him greatly by their example and conversation. All these advantages, meeting with a native fire and enthusiasm of genius, as in the case of Ossian, may well be supposed to have produced poems that might challenge the veneration of ages.

But it is not to their merit alone that we owe the preservation of these poems so long by oral tradition. Other circumstances occurred; of which, the institution of the Bards deserves particular notice. In a country, the only one perhaps in the world in which there was always, from the earliest period almost to the present age, a standing order of poets, we cannot reasonably be surprised, either at finding excellent poems composed, or, after being composed, carefully preserved from oblivion. A great part of the business of this order was to watch over the poems of Ossian. In every family of distinction there was always one principal bard, and a number of disciples, who vied with each other in having these poems in the greatest perfection. Should the institution of the bards last for ever, the poems of Ossian could never perish.

Nor were they only the bards of great families who took an interest in these poems; the vassel, equally fond of the song with his superior, entertained himself in the same manner. This, with a life free from care, a spirit unbroken by labour, and a space of time unoccupied by any other employment or diversion, contributed to render the Highlanders a nation of singers and poets. From such a people, the superior merit of Ossian’s poems would naturally procure every encouragement, which they always retained as long as the manners of the people remained unchanged.

Many other reasons conspired to preserve the poems of Ossian. The martial and intrepid spirit which they breathed, made it the interest of the chieftains to preserve them: the strain of justice, generosity, and humanity, which ran through them, recommended them to the superintendents of religion, who well knew how much...
It is more agreeable to remark, as another cause for the neglect of ancient poems and traditions, the growth of industry, which fills up all the blanks of time to more advantage, and especially the increase of more useful knowledge.—But above all, the extinction of the order of the bards hastened the catastrophe of Ossian’s poems. By a happy coincidence Macpherson overtook the last that remained of this order, (Mac- vaurich, bard to Clanronald), and got his treasure. This fact (with the red book furnished by Mr Macdonald of Crodart, and some other MSS.) accounts for Mr Macpherson’s having found these poems in greater number and perfection, than they could ever since be met with. The fragments, however, which have since been gathered, give a credibility to every thing that has been said of the original grandeur of the building.

Although this disquisition has already extended to a length which readers not partial to Scottish antiquities will perhaps think too great, we cannot dismiss it without observing, that Fingal and Ossian have been claimed by the Irish as well as by the Caledonians. On this double claim, as well as on the controversy concerning the authenticity of the poems, there is so much candour and good sense in the following remarks of T. F. Hill, published in the 3d volume of the Gentleman’s Magazine, that we cannot deny ourselves the pleasure of making them conclude the article.

Mr Hill travelled through the Highlands of Scotland during the summer months of 1780. He seems to have been very ardent in his inquiries concerning Ossian, and to have conducted those inquiries with great judgment. The consequence was, that he received different accounts in different places, and picked up various songs relating to Fingal and his heroes.

“From this collection, it is evident (says he) that there are many traditional songs preserved in the Highlands relating to Fingal and his heroes, as well as to several other subjects. It is also evident, that these songs contain portions of the very poems published by Mr Macpherson and Mr Smith, under the name of Ossian. We may therefore justly conclude, that these poems are not wholly the forgeries of their editors, but modified at least from original songs. I by no means think it worth my while to notice the various concessions in favour of this conclusion, which the minor antagonists of Ossian have of late been forced to make. I myself have given proofs of it, which need I hope no external confirmation. To these proofs might be added, that I met with many traditional preservers of these songs, in every different part of the Highlands: some of whom, especially in Argylshire, Lochaber, and on the rest of the western coast, were said to possess various poems attributed to Ossian, although I had neither leisure nor opportunity to collect copies from them.—But enough has already been said on this subject, if my testimony deserves regard.

“These principles being established, it remains to be considered how far the poems published by Macpherson and Smith deserve to be considered as the works of Ossian.

“The songs attributed to that bard, which contain passages of the Ossian of Macpherson and Smith, are by no means uniformly consistent with the poems in which
the parallel passages are found, but frequently relate to different events, and even contain different circumstances. From hence it seems most probable, that Mr Macpherson and Mr Smith compiled their publications from those parts of the Highland songs which they most approved, combining them into such forms as according to their ideas were most excellent, and preserving the old names and the leading events. In this process they were supported and encouraged by the variety of songs preserved in the Highlands upon the same subject, and by the various modes in which the same event is related. Mr Macpherson may indeed have MSS. of all the poems he has published; which MSS. may either have been compiled by himself, or by some former collector; or they may possibly contain entire poems really ancient. But Mr Smith has honestly acknowledged, that he himself compiled his Ossian in the manner above described. After the materials were collected (says he), the next labour was to compare the different editions; to strike off several parts that were manifestly spurious; to bring together some episodes that appeared to have a relation to one another, though repeated separately; and restore to their proper places some incidents that seemed to have run from one poem to another:—and hence it was unavoidably necessary to throw in sometimes a few lines or sentences to join some of the episodes together.—I am sensible that the form of these poems is considerably altered from what is found in any one of the editions from which they are compiled. They have assumed somewhat more of the appearance of regularity and art—than that bold and irregular manner in which they are originally delivered.

Mr Smith also speaks of the Ossian of Mr Macpherson in a somewhat similar manner: 'That we have not the whole of the poems of Ossian, or even of the collection translated by Mr Macpherson, we allow: yet still we have many of them, and of almost all a part. The building is not entire, but we have still the grand ruins of it.'

What portion, therefore, of the Ossian of Macpherson and Smith is original, no man can determine except themselves. Smith indeed says, that he has mentioned all his material alterations, transpositions, and additions, in his notes; and that, for the most part, he was guided in them by the Sguelachds, or traditionary tales accompanying the songs; but there are few such notes in his book, and perhaps as few such Sguelachds in the mouths of the Highlanders. In Macpherson and Smith also we see these poems divested of their idiomatic peculiarities and fabulous ornaments; which renders it impossible to discover what manners and opinions are really ancient, and what are of modern invention. Yet it is remarkable, that in spite of all the objections to their authenticity, necessarily produced by such a treatment of them, they still possess an internal evidence of originality which has enabled them hitherto to withstand all the torrent of opposition.

The Ossian of Macpherson and Smith appears therefore to be a mutilated work, even though we should suppose that the songs they originally compiled from were the undoubted works of that celebrated bard. But this is far from being the case; for even allowing that an Ossian ever existed and wrote, yet time must have introduced such material changes in his works if preserved merely by tradition during so long a period, that their own author would hardly know them again. I think it however doubtful, whether such a being as Ossian ever appeared in the world.

All the songs which I met with in the Highlands relative to the Feinse or Fingalians were attributed to Ossian: his name seems merely a common title, which is ascribed to all the poetic annals of his race.

From these considerations, we seem authorized finally to conclude, that the Ossian of Macpherson and Smith is a mutilated compilation from Highland songs, ascribed indeed to that bard, yet very little likely to be his composition. Out of these they selected the best parts, and rejected such as they thought might discredit the character of Highland antiquity; attributing them to later times, and the ignorant bards of the fifteenth century. Perhaps even the works of Homer himself, which had so many different editions, very considerably varying from each other, were compiled by a somewhat similar process from the ancient Greek songs.

Another question remains to be considered: Whether these songs are the compositions of the Highlanders or of Ireland; and, whether Ossian was an Irish or a Caledonian Scot? It is my opinion, that the songs in this collection evidently manifest a connection with Ireland, though their traditional preservation in Scotland has sometimes introduced the name of Scotland in its stead. One of their principal personages is St Patrick, the peculiar apostle of Ireland, which alone seems sufficient to mark their origin (A). If therefore we may reason from a part to the whole, it is just to conclude, that all the other songs preserved in the Highlands relative to the Fingalians are also Irish. They are wholly confined to the western coast of the Highlands, opposite Ireland; and the very traditions of the country themselves acknowledge the Fingalians to be originally Irish. The genealogy of Fingal was there given me as follows: Fion Mac Coi, Mac Trathal, Mac Araht Rlegh Erin, or king of Ireland, thus attributing the origin of his race to the Irish. I am inclined to believe that these notions about Fingal were common to the Scots in the most ancient times, and brought by them from Ireland to Scotland, the hereditary superstition of both races; for, notwithstanding it may appear most probable that Ireland should receive colonies from Scotland than the contrary, we have direct historic evidences that Scotland received them from Ireland; and no bare theoretic probability deserves to be opposed to the positive assertions of history.

With regard to the Erse manuscripts, about which so much has been said, it becomes me to acknowledge, that

(A) The Scots indeed lay claim to the birth of St Patrick, and boast also his burial-place. Camden, ed. Gibson, 1695, pp. 921, 1014. And so also do the Britons, ib. p. 631, 1014; but his life and miracles all agree to attribute it to Ireland. In Gough's edition of Camden, the account of St Patrick is in vol. iii. p. 612, 618. See Patrich, St.
Ossian. I have never seen enough of them to give any decided opinion; those which I have seen induced me to think they principally owe their existence to Ireland.

"I shall not repeat what others have said to prove the Fingalian Irish; though the connection of Fingal with Ireland has been already warmly asserted.

"But an unnoticed though curious passage in Camden affords us the most remarkable, and perhaps the most convincing proof that Fingal is an Irish hero, which demonstrates at least that he was indisputably claimed by the Irish 300 years ago. It is contained in an extract (already mentioned) made by Camden, from an account of the manners of the native Irish, written by one Good, a schoolmaster at Limerick, in r.566. "They think," says he, speaking of Ireland and its inhabitants, "the souls of the deceased are in communion with famous men of those places, of whom they retain many stories and sonnets; as of the giants Fin-Mac-Hywe, Oskir-Mac-Oschin, or Oeschin-Mac-Owim; and they say, through illusion, that they often see them."

"The very material importance of this curious passage, with reference to the present subject, it is unnecessary to urge; for every eye must see it. We also obtain from it new information in respect to the last part of the history of Fingal and his heroes; as it enables us to determine who they were with a precision which must otherwise have been wanting, to complete these remarks on the Highlands' song.

"The singular agreement of this passage with the accounts of Ossian which were taught me in Scotland is worthy particular remark; it confirms them even in the most novel and peculiar instances. The Fingalians were generally represented as giants: but the most remarkable occurrence is in the mythologic character attributed by both to Fingal, Oscar, and Ossian. In proof of this, I have to observe, that Mac Nab described Fingal as the Odin of the Scots, and that a song called Urnigh Ossion evidently speaks of him as such. This curious passage represents him exactly in the same character; a hero with whom the spirits of the deceased are in communion, who is their chief, and the lord of their feasts. The gods of all the northern nations seem to have been of this class; mighty heroes, esteemed once to have been invincible on earth, though perhaps not ever strictly men, nor yet constantly regarded as giants. Such are Odin, Thor, and the other Teutonic gods; such are Fingal, Oscar, and the rest of the Fingalians among the ancient Scots; such are Hercules, Bacchus, and even Jupiter himself, with all his sons and daughters, among the original Greeks, a people who agreed in many particulars with our own ancestors in northern Europe. The notions entertained about ghosts, as an intermediate order of beings between men and divinities, endowed with some share of power to do evil, is also remarkably congruous with this mythology.

"As Fingal was a divine hero, so Ossian seems to have been a divine bard. Some of the gods of the Teutons were bards in like manner; the god Niord and his wife Skada quarrelled in elegant verse of their own composition; and Odin is the relator of his own Edda. Apollo, the poetic deity of Greece, likewise sung the history of his fellow-deities to men on earth, as well as Orpheus his son. The bards and traditional preservers of songs in Scotland and Ireland have ever been fond of ascribing all ancient poems to this Ossian, and especially those relating to his own race; and from this cause the poems ascribed to Ossian are become so voluminous. The ancient Egyptians had a similar custom of ascribing their works to Hermes: a ãvweiqMa nqum ni naH novOn rum nemawam biqennal yMaa rii,MaM, says Jam-blicius, S. I. c. 1, which rendered the Hermes writings equally voluminous. The Egyptians, who possessed the art of writing, deposited their works in the adyta of their temples; as the Arabsians deposited their poems of old in the temple of Mecca; but because the Egyptians affixed to them no author's name, except that of Hermes, to him, as to the Scottish Ossian, almost all the national literature was attributed by religious flattery.

"I sincerely wish, that some gentleman possessed of adequate abilities and acquaintance with the Ero language, would undertake to collect those Osianic songs in their simple original state; as they undoubtedly contain much curious knowledge, accumulated in the various ages through which they have descended to us, and would probably afford much new information on subjects at present very ill understood. I own, however, that I should rather choose to seek for them in Ireland than in Scotland; but neither country should be unexplored.

"After having thus freely, though I hope not uncandidly, delivered my sentiments on the Ossian of Mr. Macpherson, it becomes me to acknowledge myself deeply indebted to it for the pleasure in perusal it has frequently afforded me. I am willing, and indeed happy, thus publicly to declare myself a warm admirer of it as a literary composition. The novelty of its manner, of its ideas, and of the objects it describes, added to the strength and brilliancy of genius which frequently appears in it, have enabled me to read it with more delight, and to return to it more frequently, than almost any other work of modern times. And let it be regarded in that light it may, the praise of elegant selection and composition certainly belongs to its editor. If I had not entertained these opinions of its merit, I should never have taken such pains to investigate its authenticity; nor indeed can I believe, if the general opinion had not concurred with mine, that the world would ever have wasted so much time in disputing about it."

Since what has now been said concerning the authenticity of the poems of Ossian was written, the same subject has been again brought under discussion, and more keenly and ably agitated than at any former period of the controversy. Among those who have entered the lists in this controversy, Mr Laing the historian appears by far the most powerful opponent of the authenticity of those celebrated poems. In a historical and critical dissertation on this subject, Mr. Laing roundly asserts, that part of the poems, as ascribed to Ossian, a bard of the third century, are forgeries, and charges Macpherson, as well as Smith (in our opinion too hastily and rashly), with direct fraud in imposing on the world their own productions as the genuine translations of ancient Gaelic poems. The arguments for the detection of these forgeries are arranged under eight different heads: 1. The Roman History of Britain with which Macpherson has connected the poems by false and incorrect allusions. 2. The traditional poems in the Highlands refer to the middle ages,
OSS
ages, that is, about the 9th and 10th centuries. 3. The
difficulty or impossibility of preserving poems by oral
tradition for a period of 1,000 years. 4. The remarkable
diversity in the manners of the Highlanders at the period
in which Fingal lived, as described by historians, and as
they are represented by Osian; and the contradiction of
great refinement at an early age and extreme barbarism in
a future age, are considered by Mr. Laing as strong and
decisive proofs of forgery. 5. From tracing the origin of
the poems to other works of Macpherson, particularly
to an epic poem entitled the Highlander, published at
Edinburgh in 1758, which, being unsuccessful, appeared
afterwards as fragments of ancient poetry, Mr. Laing
thinks another proof of detection is derived. 6. A sixth
source of detection, in his opinion, may be traced to the
imitation of the classical, scripture, and other writings.
7. Mr. Laing asserts that the specimens of the origin-
al produced by Macpherson were either written or
translated into Erse from the English original, by the
supposed translator himself. 8. From the ambiguous
language which Macpherson seems to have employed at
different times during the progress of the numerous edi-
tions of the poems, Mr. Laing infers a distinct avowal
of fraud. But for the illustration of the arguments
now noticed we must refer the reader to the dissertation
itself.
It was not to be expected that charges so formally ad-
duced, and so keenly supported, would pass altogether
unnoticed by the admirers of the poems of Osian, or
the believers in their authenticity. Accordingly, we
find that Mr. Laing's arguments have been combated by
different writers with various success. Among the works
on this side of the question which have fallen in our way,
the Essay on the Authenticity of the Poems of Osian by
the Rev. Dr. Graham, holds the most respectable place.
But our limits absolutely preclude us even from stating
his arguments. We refer therefore to the work itself
which, the reader will not dislike to find, is written with
some degree of elegance, and, what is not usual in con-
troversy, with a great degree of temper and moderation.
The reader who wishes to pursue this investigation, may
consult also a Treatise on the same subject by Mr.
Macdonald, the Report on Osian by a Committee of the
Highland Society of Scotland; and the Gaelic scholar
has now an opportunity of perusing the Originals, which
have been published by Sir John Sinclair.

OSSIFICATION, in the animal economy, the for-
mation of the bones, but more particularly the conversion
of parts naturally soft to the hardness and consistency of
bones. Bones, Dr. Drake contends, are formed out of
the most comminate or broken parts of the blood; since
we see that the blood of old men, which by a long course
of circulation becomes in a manner unfit for the common
office of nutrition, will however ossify, and convert into
bones, many of the tendons and ligaments, and even the
casts of the vessels themselves, whose substance being
next to the bones the most compact, admits only of the
smallest particles of the blood, which therefore soonest
become ossous, as they are frequently found. Dr. Nis-
bet's opinion of ossification is, that in the blood, or a fluid
secreted from it, there is an ossifying juice, having par-
ticles which are not apparent: that whenever nature de-
signs an ossification between membranes, or within a car-
tilage, she occasions a more than usual afflux of this
fluid; which so much distends the vessels which were
before invisible, as to make them capable of receiving Os-
sification of the red globules of blood, which is always to be seen
near to the place where ossification is begun. In this
blood gritty bony particles may be felt by the point of
a knife, which have been formed by the attraction and
cohesion of the particles of the ossifying juice obstructed,
along with the other grosser fluids, in the beginning of
the vessels prepared to receive effused juices. The
blood being capable of forming fine membranes, the
membranous parts of a bone, which acts as a gluten to
keep these particles and fibres together, if there be any
such, that do not arise from the casts of its vessels, are
produced by a cohesion round the crenatous particles of
a part of the fluid, in which they were generated and
contained. Thus the membranes of cartilages serve as
a bed, between or within which the bony particles are
deposited, or shoot; but without any intermixture of the
particles of the bone and cartilage, or continuation of the
fibres of the one substance to those of the other, as is
evident in cartilages containing bones kept long enough
in water, and then slit; for the bone will, as soon as
the large vessels that enter its substance are divided, slip
as easily, and perhaps easier, from it than an acorn does
out of its cup: and there is a smoothness and polish of
the parts of both cartilage and bone, which show there
is no conjunction of the fibres of the two substances.
While the bones are increasing within cartilages, the
cartilages are extended and spread out; by which, with
the pressure which they suffer, and the great influx of
various fluids, and the nutritious matter being hindered
to flow freely into them, they decrease continually, and
at last may truly be said to be entirely destroyed. Dr.
Beddoes endeavours to prove, that the preternatural
ossifications, which are commonly said to be formed in
different parts of the body, do not deserve that name;
for that these hard substances have scarcely any other
properties of bone except whiteness and hardness.

OSSORY, the west division of Queen's-county in
Ireland.

Ossory, Balc, bishop of. See BALE.

OSSUNA, an ancient and considerable town of An-
dalusia in Spain, with an university, an hospital, and
the title of a duchy. N. Lat. 37° 8' W. Long. 4° 18'.

OSTADE, ADRIAN VAN, an eminent Dutch painter,
born at Loubec in 1610. He was a disciple of Francis
Hals, in whose school Brouwer was cotemporary with
him, where they contracted an intimate friendship.
The subjects of his pencil were always of a low kind, he hav-
ing nearly the same ideas as Teniers; diverting himself
with clowns and drunkards in stables, ale-houses, and
kitchens. His pictures are so transparent and highly
finished, that they have the polish and lustre of enamel:
they have frequently a force superior to Teniers; yet it
were to be wished that he had not designed his figures so
short. He is perhaps one of the Dutch masters who best
understood the chiuro obscuro; and he was often employ-
ed to paint figures for the best landscape painters of his
countrymen. He died in 1685. His works, especially
those of his best time and manner, are very scarce; so
that when they are to be purchased, no price is thought
too much for them. His prints etched by himself, large
and small, consist of 54 pieces.

OSTALRIC, a town of Catalonia, in Spain, hav-
ing a strong castle, and seated on the river Tordena, in
E Long. 2° 45'; N. Lat. 22° 44'.

OSTEND,
OSTEND, a very strong sea-port town of the Netherlands, with a good harbour and a magnificent town house, and containing 10,268 inhabitants in 1800. It is not very large, but it is well fortified. It was much more considerable before the long siege of the Spaniards, which continued from 1601 to 1604, when it was almost entirely reduced to ashes. The Dutch lost 50,000 men, and the Spaniards 80,000. Isabella Eugenia, governor of the Netherlands, made a vow she would not shift her smock before Ostend surrendered; but before the town was taken it had greatly changed its colour. However, the ladies of the court, to keep her in countenance, had theirs dyed, that they might be like that of their mistress. This place was taken by the Dutch in 1706, but restored to the emperor in 1724, when an East India company was established here, but entirely suppressed by treaty in 1731. It was taken by the French in August 1745, after 10 days siege, but restored by the treaty of Aix-la-Chapelle. It was taken again by the French republicans, under Dumourier, but was quickly recovered by the allies. The French repossessed it in 1794. Here the British landed a body of troops in May 1798, who blew up and destroyed the works of the Bruges canal; but the wind shifting before they could re-embark, they were under the necessity of surrendering to the French. In 1814 it separated from France with the Netherlands. It is 10 miles W. of Bruges, eight N. E. of Newport, 22 N. E. of Dunkirk, and 60 N. W. of Brussels. E. Long. 2°. 56 N. Lat. 51°. 14.

OSTECOLLA, or oscheall, in Natural History, a white or ash-coloured sparry substance, in shape like a bone, and by some supposed to have the quality of uniting broken bones, on which account it is ordered in some plasters; a supposition, we fear, which is not warranted by experience. It is found in long, thick, and irregularly cylindric pieces, which are in general hollow, but are sometimes filled up with a marly earth, and sometimes contain within them the remains of a stick, round which the osteocolla had been formed; but though it is plain from thence that many pieces of osteocolla have been formed by incrustations round sticks, yet the greater number are not so, but are irregularly tubular, and appear to be formed of a flat cake, rolled up in a cylindric shape. The crusts of which these are composed do not form regular concentric circles round the internal cavity, as must have been the case had they been formed by incrustation. On the other hand, they plainly show that they were once so many thin strata, composing a flat surface, which has afterwards been rolled up, as one might do a paper three or four times doubled, into two, three, or more spiral lines; in which case, each single edge of the paper would be everywhere a regular point of a continued spiral line drawn from a given point; but they would by no means be so many detached concentric circles. The osteocolla is found of different sizes, from that of a crow-quill to the thickness of a man's arm. It is composed of sand and earth, which may be separated by washing the powdered osteocolla with water, and is found both in digging and in several brooks, in many parts of Germany, and elsewhere. It is called harnosteu in many parts of Germany. It has this name in these places from its always growing in sand, never in clay, or any solid soil, nor even in gravel. Where a piece of it anywhere appears on the surface, they dig down for it, and find the osteocolla branches run ten or twelve feet deep. They usually run straight down, but sometimes they are found spreading into many parts near the surface, as if it were a subterranean tree, whose main stem began at 12 feet depth, and thence grew up in a branched manner till met by the open air. The main trunk is usually as thick as a man's leg, and the branches that grow out from it are thickest near the trunk, and thinner as they separate from it. The thinnest are about the size of a man's finger. The people employed to collect it, when they cannot find any mark of it on the surface, search after the specks of white or little lumps of whitish soft matter, which they find lying in various parts on the top of the sand. These always lead them either to a bed of perfect osteocolla, or to some in the formation. If they miss of it, they still find a substance like rotten wood; which when traced in its course, is found to proceed from a main trunk, at the depth of that of the osteocolla, and to spread itself into branches in the same manner. The diggers call this substance the flower of osteocolla, or harnosteu. The osteocolla found in the earth is at first soft and ductile, but in half an hour's time, if exposed to the air, it becomes as hard as we find it in the shops. The method to take up a perfect piece for a specimen is to open the ground, clear away the sand, and leave it so for an hour or two, and it will harden, and may be taken out whole. It is certain, that the osteocolla is produced at this time; for if a pit be cleared of it, there will more grow there in a year or two, only it will be softer, and will not harden so easily in the air as the other. What the rotten substance resembling the decayed branches of trees is, we cannot determine, unless it really be such; but the opinion of the common people, that it is the root of something, is absurd, because its thickest part always lies at the greatest depth, and the branches all run upwards. The osteocolla is a marly spar, which concretes round this matter; but what it is that determines it to concretize nowhere on the same ground but about these branches, it is difficult to say. The rottenness of this substance, which forms the basis of the osteocolla, renders it very liable to mould and fall away; and hence it is that we usually see the osteocolla hollow. Sometimes it is found solid; but in this case there will be found to have been a vegetative matter serving as its basis, and instead of one branch, it will be found in this case to have concreted about a number of fibres, the remains of which will be found in it on close examination. See Phil. Trans. No 59.

OSTEOLOGY, that part of anatomy which treats of the bones. See ANATOMY, Part I.

OSTERVALD, JOHN FREDERIC, a famous Protestant divine, was born at Neuchâtel in 1663; and made such rapid progress in his studies, that he became master of arts at Samur before he was 16 years of age. He afterwards studied at Orleans and at Paris. At his return to Neuchâtel in 1699, he became pastor of the church there; and contracted a strict friendship with the celebrated John Alphonso Turretin of Geneva, and the illustrious Samuel Werenfeltz of Basel. The union of these three divines, which was called the Triumvirate of the divines of Switzerland, lasted till his death. Mr Ostervald acquired the highest reputation, by his virtues, his zeal in instructing his disciples, and restored eccl.
These people are very poor, and very lazy, and in the summer time live mostly upon fish. They are of a middle size, with broad faces and noses, and yellowish or red hair. All their garments from top to toe are made of fish skins, for they have neither linen nor woollen: and indeed they might almost as well go naked. Their greatest diversion is hunting; and they go together in crowds, with a weapon like a large knife fastened in a stick. In summer they take and dry the fish which serves them in winter; and when that season begins, they go into the woods with their bows and arrows, their dogs and nets, to kill sables, ermines, bears, reindeer, elk, martens, and foxes. Part of the furs of these is paid as a tax to the empress of Russia, and the rest are sold at a stated price to the Russian governors, but sometimes they are allowed to dispose of them to private persons.

They chiefly live upon venison, wild fowl, fish, and roots, for they have neither rice nor bread. They drink for the most part water, and it is said they can very well relish a draught of train oil. They are immediately fond of tobacco, and of swallowing the smoke, which soon intoxicates them. In the winter they build their huts in woods and forests, where they find the greatest plenty of game, and dig deep in the earth to secure themselves from the cold, laying a roof of bark or rushes over their huts, which are soon covered with snow. In summer they build above ground on the banks of the rivers, to enjoy the convenience of fishing, and make no difficulty of forsaking their habitations. They have a sort of princes among them, in one of whose houses some European travellers found four wives. One of these had a red cloth coat on, and was set off with all sorts of glass beads. There was no other furniture than cradles and chests, made of the bark of trees sewed together. Their beds consisted of wood shavings, almost as soft feathers, and their children lie naked upon them in cradles. They can neither read nor write, nor do they cultivate the land; and seem totally ignorant of times past. They have neither temples nor priests; and their boats are only made of the bark of trees sewed together. Their religion is Pagan; and they have some little brazen idols, tolerably well cast, representing men and animals, made of wood and earth, all of which are dressed in silks in the manner of Russian ladies. In general, however, they are ill made, every man being his own carver. They place them on the tops of hills, in groves, and in the pleasantest places their country affords, and sometimes before their huts; yet they have no set time for performing religious worship, but apply to their gods for success in all their undertakings. As they have no regular priests, every old man may devote himself to that service, and the office is frequently performed by the masters and heads of families. Strahlenberg says, that when he was among them he saw one of their temples, which was built of wood in an oblong form, like a great barn, covered at
OST

Ostracism was the practice in ancient Athens by which a citizen could be voted out of the city and the country. The act was performed by a simple vote of the citizens. If a candidate received a majority of votes cast against him, he was exiled for ten years. The purpose of ostracism was to prevent any one person from gaining too much political power. The word "ostracism" is derived from the Greek word "ostracon," which means "a small clay tablet." The ostracism vote was usually held in the Panathenaic festival in Athens.

The practice of ostracism was first instituted by Cleisthenes in the mid-6th century BC. It was used to limit the power of hoplites, a group of wealthy citizens who were able to afford to arm themselves and were influential in Athenian politics. The ostracism vote was often used to exile political opponents or figuratively "ostracise" them from the community.

The ostracism vote was not without controversy. Some citizens feared that it would be used as a tool of tyranny, and in some cases, it was. However, by the time of the Peloponnesian War, the ostracism vote was largely considered a tool of democracy, and it was used to remove unpopular leaders who were perceived to be threatening the stability of the state.

The late 6th century BC saw the rise of a new form of democracy, which was characterized by the establishment of comitia, or assemblies of citizens. In these assemblies, the people could vote on a wide range of issues, including the ostracism vote. The ostracism vote was still used, but it was now subject to greater scrutiny and oversight.

The use of the ostracism vote declined in the 4th century BC, as Athens moved away from democracy and towards a more aristocratic form of government. By the time of the Roman Republic, the ostracism vote had been abolished, and it was largely replaced by other forms of political control.
The scholastic of Aristophanes informs us of a third difference between ostracism and the common banishment. He says, that a particular place of retirement was assigned to those who were banished by ostracism, which was not appointed to the other exiles. We suspect, however, the truth of this observation; for Theistocles was certainly not limited in his banishment. That great man, as we are told by Thucydides, though his chief residence was at Argi, travelled over all the Peloponnesus.

This punishment, far from conveying the idea of infamy, became, at Athens, a proof of merit, by the objects on which it was inflicted; as Aristides the sophist justly observes, in his second declamation against the Gorgias of Plato, where he says, that ostracism was not an effect of the vindictive spirit of the people against those whom it condemned; that the law, whether good or bad, (for he enters not into an examination of the question), was only meant to prune the luxuriant growth of transcendent merit: that it condemned to an exile of ten years, only those illustrious men who were accused of being exalted far above other citizens by their conspicuous virtue; and that none of that public indignation was shown to the exiles by ostracism, which commonly breaks out against criminals.

Such were the mitigations with which this law was introduced among the Athenians: and by them we see that they were sensible of all the inconveniences to which it was subject. They were indeed too enlightened a people, not to foresee the many instances of injustice which it might produce; that if in some respects it would be favourable to liberty, in others it would be its enemy, by condemning citizens without allowing them a previous defence, and by making a capricious and envious people arbiters of the fate of great men; that it might even become pernicious to the state, by depriving it of its best subjects, and by rendering the administration of public affairs an odious employment to men of capital talents and virtue.

However great the inconveniences of ostracism were, it would not have been impossible to avoid them; and we may add, that this law would have been of service to the state, if the people by whom it was instituted had always had discernment enough only to give it force on such occasions as endangered liberty. But its fate was like that of almost all other laws which the wisest legislators have planned for the good of communities. Deprived by their institution to maintain order, to repress injustice, and to protect innocence, men have found ways to pervert their application, and have made them instruments to gratify their private passions. Thus ostracism was established to prevent the dangerous enterprises of the great, and to preserve the vigour of the democracy; but the people of Athens, naturally jealous and envious, exerted that law, to remove men of eminent merit from the state, by whose presence they were reproved and intimidated. The fear of tyranny was commonly but a specious pretext with which they veiled their malignity. The repeated victories which they had gained over the Persians, had rendered them, says Plutarch, proud and insolent. Intoxicated with their prosperity, they arrogated all its glory to themselves; they were jealous of those citizens whose political and military talents were the subjects of public eulogium. They thought the glory acquired by great men diminished their own reputation.

An Athenian no sooner distinguished himself by a splendid action, than he was marked out as a victim by public envy. His reputation was a sufficient reason for his banishment.

OSTRACITES, in Natural History, a name used for the fossil oysters, common in many parts of England. They are of various shapes and kinds; and the name is by some authors made to signify the shell itself, when preserved in its native state and condition; as is the case with those about Woolwich and Blackheath; and by others, the stones cast or formed in those shells, or in cavities from whence they have been washed away. OSTREA, the Oyster, a genus of shell-fish belonging to the order of vermes testaceae. See OSTREA, CONCHOLOGY Index.

OSTRICH. See Struthio, Ornithology Index.

OSTROVIZZA, in Dalmatia (see DALMATIA), supposed by some to be the Arauzona, and by others the Stupi of the ancients, though probably it has no connection with either the one or the other. It was purchased in 1410 by the republic of Venice, for 5000 ducats, and some pieces of land besides. Its fortress, which was seated on a rock, perpendicularly cut all round, and deservedly reckoned impregnable before the use of artillery, was taken by Soliman in 1524, but soon after restored to the dominion of Venice. At present, no traces of its fortification remain, and it is only a bare and isolated mass. It now belongs to Austria.

OSTUNI, a town of Italy, in the kingdom of Naples, and in the Terra di Otranto, with a bishop's see. Its territory is well cultivated, and abounds with olives and almonds. It is seated on a mountain near the gulf of Venice, in E. Long. 17° 49'. N. Lat. 49° 59'.

OSWEGO, a port of North America, seated on the east side of a river of the same name, and on the south side of the lake Ontario, in W. Long. 76° 30'. N. Lat. 43° 15'.

OSWEIZEN, a town of Austrian Poland, in the palatinate of Cracovia, formerly having the title of a duchy. It carries on a great trade in salt, and is seated on the river Vistula. E. Long. 19° 47'. N. Lat. 50° 1'.

OSWESTRY, an old town of Shropshire, in England, 172 miles from London, with a castle, a wall, and a ditch, and was anciently a borough. It is a place celebrated in Saxton history and legendary piety. On this spot, August 5, 648, was fought the battle between the Christian Oswald, king of the Northumbrians, and the pagan Penda, king of the Mercians, in which Oswald was defeated, and lost his life. The barbarian victor cut the body of the slain prince in pieces, and stuck them on stakes dispersed over the field as so many trophies; but, according to others, his head and hands only were thus exposed. A prince so dear to the church as Oswald, and so attached to the professors of the monastic life, received every posthumous honour they could bestow. He was raised to the rank of a saint, and his sanctity confirmed by numberless miracles, which are too numerous and too striking to admit of particular description. Its church, which is of no great antiquity, was formerly a monastery, and was called Blaconminster. It is, however, spacious, and has a handsome plain tower. In 1542 and 1567, it suffered much by fire. It is governed by two bailiffs, burgesses, &c. and once had a great trade in Welch cottons and flannels; but this is
Oswestry, now much decayed. Its population in 1821 was 2672, and in 1811 it was 3479. But besides a good grammar school, it is noted for an excellent charity school for 40 boys, besides girls, which has the best methods for exciting the emulation of the children in their learning; for 20 of the boys are set to strive against 20 others for shoes, and the 20 who perform their task best have shoes first; then 10 of the boys are set against 10 others for the like premium, and so on till they are all shod; so in the girls school a shift is put up for the best spinner, a head-dress for the best sempstress, a pair of stockings for the best knitter, a Bible for the best reader, and a copy-book for the best writer. In the wall with which the town was fortified there were four gates. That called the Block-gate is demolished; the New-gate, Willow-gate, and the Beatrice-gate, still remain. The last is a handsome building, with a guardroom on both sides. There are only two fragments of the castle remaining. It stood on an artificial mount, surrounded by a fosse, extending to the Willow-gate.

OSYMANDES, a famous king of Egypt, was, according to some authors, the first monarch who collected a great number of books for the purpose of forming a library. To this curious collection he gave the title of Pharmacology of the Soul. Of all the monuments of the kings of Thebes, that of Oysymanes is one of the most magnificent. "He appears (says an elegant author) to have been a prince of great elegance and taste in his day. Diodorus Siculus describes many sumptuous edifices erected by him; among these edifices his palace or mausoleum, whichever it was, has been eminently distinguished for the paintings and sculptures with which it was adorned. When we look to the subject of those works, we shall have reason to think that no man in any age could discover a fairer and more enlightened judgment than he did in the employment of the genius around him, which was not tamely devoted to dull or contracted objects, nor lavished on scenes of savage life, nor wholly engrossed in allusions to himself, but sensibly enlarged to a variety of contemplation which might become a great sovereign; and in each of those parts the subject was characteristically great."

In one place was represented, in a multitude of sculptures, his expedition against the Bactrians, a people of Asia, whom he had invaded with 400,000 foot, and 20,000 horse, and whom he conquered. In another part was displayed the variety of fruits and productions, with which Pan, the great source of all things, had enriched the fertile land over which Oysymanes reigned. A third group of figures represented the monarch himself, as the high priest of the country, offering to the gods the gold and silver which he drew every year from the mines of Egypt. In another part of the edifice was exhibited, in an infinite number of figures, an assembly of judges, in the midst of a great audience attentive to their decisions; the president or chief of these judges, surrounded by many books, wore on his breast a picture of Truth with her eyes shut—those emblematic emblems, beyond which no age could go for the impression of that wisdom and impartiality which ought to prevail in administrative justice."

In short, we cannot without astonishment read the account which Diodorus Siculus gives of the almost incredible magnificence of this prince, and of the immense sums which he spent upon those grand works. Amongst a variety of other surprising curiosities, was to be seen a statue in the attitude of sitting, which was the largest in all Egypt, the length of one of the feet being seven cubits. Not only the art of the sculptor, but also the beauty of the stone, which was perfect in its kind, contributed to render this a masterpiece of sculpture. It bore the following inscription: I am OSYMANDES, king of kings; whoever will dispute with me this title, let him surpass me in any of my works.

Indeed (to use the words of the same elegant author quoted above) "the palace or mausoleum of this accomplished prince must give us a striking assurance of the progress which had been made in the arts at that time; whether he lived, as some have thought, the immediate successor of the first Busiris, which was sometime later than the period of Semiramis; or, as others have conceived, subsequent to Sesastris, which would be 400 years later. Diodorus Siculus, who describes that edifice, says nothing of the age in which Oysymanes lived; every opinion, therefore, on that point must be conjecture. We shall only remark, that there is nothing in the works of art in that edifice which should appear too much for the earliest age in which that monarch has been placed, when we look back to what was done of those works in a period full as early by Semiramis in Assyria."

OTACOUSTIC INSTRUMENT, or Auricular Tube, an instrument to facilitate the hearing. See Acoustics.

OTAHITE, a celebrated island of the South sea, situated in W. Long. 149° 13'. Lat. 17° 46'. It was discovered by Captain Wallis in 1767; afterwards M. Bougainville touched there; and it was visited by Captain Cook in 1773 and 1774, who had in 1769 sailed round the island in a boat to observe the transit of Venus.

The island consists of two distinct kingdoms, which are united by a narrow neck of land; the larger being called by the natives Tiarabou, or O-Tahetees Nuie; the smaller one Opoowoomow, or O-Tahetee-ete-Ete. The circumference of both islands is about 40 leagues; the larger kingdom being divided into 43 districts. The country has a delightful romantic appearance. The aspect of the coast, viewed from the sea, presents a most beautiful prospect, being elevated like an amphitheatre. The island is skirted with a reef of rocks, and towards the sea is level, being covered with fruit trees of various kinds, particularly the cocoa-nut. At the distance of about three miles from the shore, the country rises into lofty hills that are covered with wood, and terminate in peaks, from which large rivers are precipitated into the sea. The stones everywhere appear to have been burnt, not one being found which did not give manifest signs of fire; so that there is great reason for supposing that this and the neighbouring islands are either the shattered remains of a continent, or were torn from rocks, which from the creation of the world have been the bed of the sea, and thrown up in heaps to a height which the waters never reach. What is further extraordinary, the water does not gradually grow shallow as we approach the shore, but is of immense depth close by the land; and the islands in this neighbourhood are almost everywhere surrounded by reefs which appear to be rude and broken in the manner that some violent concussion would naturally leave the solid substance of
Otaheite, and Mr. Foster saw a rock with projecting longitudinal angles of black compact basalt. The exterior ranges of hills are sometimes entirely barren, and contain a great quantity of yellowish clay, mixed with iron ochre; but others are covered with mould and wood like the mountains in the internal parts of the country. Pieces of quartz are sometimes met with here; but no indications of precious minerals or metals of any kind have been observed, iron only excepted.

Climate. The air is extremely healthy and pleasant; the heat is not troublesome; and fresh meat will keep very well for two days, and fish one day. The winds do not blow constantly from the east, but generally a little breeze from east to south-south-east. The tide rises very little; and, being governed by the winds, is very uncertain. "The climate," says M. Bougainville, "is so healthy, that notwithstanding the hard labour of the ships companies while on shore, though the men were continually in the water, and exposed to the meridian sun, though they slept upon the bare soil, and in the open air, none of them fell sick; those who were afflicted with the scurvy, and were sent on shore, regained their strength: although they were obliged to assist in the erecting of a fort, and had scarce one uninterrupted night, yet they were so far recovered in the short space of time they continued there, that they were afterwards perfectly cured on board."

Notwithstanding the great height of the inland mountains of Otaheite, none of their rocks have the appearance of barrenness, every one of them being covered with woods. "We hardly believed our eyes," says M. de Bougainville, "when we saw a peak covered with woods up to its highest summit, which rises above the level of the mountains in the interior parts of the southern quarter of this island. Its apparent size seemed to be more than 30 toises in diameter, and grew less in breadth as it rose higher. At a distance it might have been taken for a pyramid of immense height, which the hand of an able sculptor had adorned with garlands and foliage." One of the mates of the Dolphin, with a party of marines and seamen, penetrated into the interior parts of the island; and having ascended, with great difficulty, a mountain which they supposed to be a mile high, they discovered mountains before them so much higher, that with respect to them they seemed to be in a valley towards the sea the view was enchanting, the sides of the hills were beautifully clothed with woods, villages were everywhere interspersed, and the valleys between them afforded a still richer prospect; the houses stood thicker, and the verdure was more luxuriant; and Mr. Foster, with other gentlemen, ascended to the summit of one of the highest mountains in the island, from whence they had a prospect of the island of Huahine, and some others lying at the distance of 40 leagues; from which we may form some judgment of the prodigious height of that mountain. The view, of the fertile plain below them, and of a river making innumerable meanders, was delightful in the highest degree. The vegetation on the upper part of the mountains was luxuriant, and the woods consisted of many unknown sorts of trees and plants.

Soil and Produce. That the soil of this island is a rich fat earth, of a blackish colour. It produces spontaneously, or with the slightest culture imaginable, a great variety of the most excellent fruits; such as bread-fruit, cocoa-nuts, bananas of 13 Otaheite sorts, plantains, potatoes, yams, a fruit known here by the name of sambo, and reckoned most delicious; sugar-canes, which the inhabitants eat raw; ginger; turmeric; a root of the salep kind, called by the inhabitants pea; a plant called ethe, of which the root only is eaten; a fruit that grows in a pod like that of a large kidney bean, by the natives called ahue; a tree called wherry, which produces fruit something like the pine-apple, and which is known in the East Indies by the name of pandanus; a shrub called nana; the morinda, which also produces fruit; a species of fern; a plant called tere; and the Chinese paper-wulberry, of the bark of which they make their cloth; and herb which the inhabitants eat raw, its flavour somewhat resembling that of the West India spinage called colostrum, but its leaf very different; a plant which the natives call ouw or ouwe, from the root of which they express a liquor, which, if drank to excess, intoxicates like wine or distilled spirits. Here are a sort of shady trees covered with a dark green foliage, bearing golden-coloured apples, which, in juiciness and flavour, resemble the annas or pine-apple. One of the most beautiful trees in the world received here the name of Barrantonia; it had a great abundance of flowers larger than lilies, and perfectly white, excepting the tips of their numerous chives, which were of a deep crimson. Such a quantity of these flowers were seen dropped off, that the ground underneath the tree was entirely covered with them. The natives called the tree budon; and said, that the fruit, which is a large nut, when bruised and mixed up with some shell-fish, and thrown into the sea, intoxicates the fish for some time, so that they come to the surface of the water, and suffer themselves to be taken with men's hands. Several other maritime plants in tropical climates are found to have the same quality. Mr. Dalrymple describes the method of catching fish with these plants as follows: the plant is thrust under the coral rocks or hollows where the fish haunt, the effect is most sensible in still water, though it is effectual in the open sea; for the same gentleman says, he has seen fish soon after loose on the surface of the water half dead, and somewhat totally without life; and where the effect is less violent, the fish will be seen under the water to have lost their poise, without coming up to the surface. Fish caught in this manner are not in the least noxious or ill tasted.

In this island they have domestic poultry exactly resembing those of Europe: besides which there are wild doves; also beautiful green turtle doves; large pigeons of a deep blue plumage and excellent taste; a small sort of pheasants, very singular on account of the various mixture of red and blue in their feathers; also another sort of a greenish colour, with a few red spots; the latter are frequently tamed, and are valued on account of their red feathers. Here is a kingfisher of a dark green, with a collar of the same hue round his white throat; a large cuckoo, and a blue heron. Small birds of various kinds dwell in the shady trees; and, contrary to the generally received opinion that birds in warm climates are not remarkable for their song, have a very agreeable note. There were no quadrupeds but dogs, hogs, and rats: and for these last the natives were said to have a scrupulous regard, so much that they would by no means kill them; however,
however, Captain Cook, in 1773, turned about 14 cats on the island, which have probably reduced the number of these vermin. No frogs, toads, scorpions, centipedes, or any kind of serpent, have been found here; the ants, however, are troublesome, but not very numerous. When the Endeavour first arrived here in 1769, the flies were found excessively troublesome; but musquito nets and fly-flaps in some measure removed the inconvenience. Sydney Parkinson, in his journal, says, that notwithstanding these flies are so great a nuisance, the natives, from a religious principle, will not kill them. But there is a strange disagreement in the accounts of different voyagers concerning this matter. For M. Bougainville says, "this island is not infested with those myriads of troublesome insects that are the plague of other tropical countries." And Mr Forster says, "not a gnat or musquito hummed unpleasantly about us, or made us apprehensive of its bite." This inconvenience must therefore be felt at certain seasons of the year, and in certain districts of the country, more sensibly than at other times and places. There is great variety of excellent fish; and according to Aitourou, a native who embarked with M. de Bougainville, there are sea-snares on the shore of Otaheite, whose bite is mortal.

The inhabitants of Otaheite are a stout, well-made, active, and comely people. The stature of the men, in general, is from five feet seven to five feet ten inches; the tallest man seen by Captain Wallis measured six feet three inches and a half; and Captain Cook, in his second voyage, describes O-Too, the King of Otaheite, to be of that height. "In order to paint a Hercules or a Mars," says M. de Bougainville, "one could nowhere find such beautiful models." They are of a pale brown complexion; in general their hair is black, and finely frizzled; they have black eyes, flat noses, large mouths, and fine white teeth; the men wear their beards in many fashions, all of them plucking out a great part, and have prominent bellies. Most of them smell strong of the cocoa-nut oil. The women in general are much smaller, especially those of the lower rank or tawtows, which is attributed to their early and promiscuous intercourse with the men; whilst the better sort who do not gratify their passions in the same unbridled manner, are above the middle stature of Europeans. Their skin is most delicately smooth and soft: they have no colour in their cheeks; their nose is generally somewhat flat, but their eyes are full of expression, and their teeth beautifully even and white. "The women," says M. de Bougainville, "have features not less agreeable than the generality of Europeans, and a symmetry of body and beautiful proportion of limbs which might vie with any of them. The complexion of the men is tawney; but those who go upon the water are much more red than those who live on shore. Some have their hair brown, red, or black; in which they are exceptions to all the natives of Asia, Africa, and America, who have their hair black universally; here, in the children of both sexes, it is generally flaxen. The strongest expression is painted in the countenances of these people; their walk is graceful, and all their motions are performed with great vigour and ease." "I never beheld statelier men," (says Sydney Parkinson). The men of consequence on the island wear the nails of their fingers long, which they consider as a very honourable badge of distinction, since only such people as have no occasion to work can suffer them to grow to that length. This custom they have in common with the Chinese; but the nail of the middle finger on the right hand is always kept short, the meaning for which peculiarity could not be learned. Only one single cripple was met with among them, and he appeared to have been maimed by a fall. The women always cut their hair short round their heads. Both sexes have a custom of staining their bodies; which they call tattooing: both men and women have the hinder part of their thighs and loins marked very thick with black lines in various forms; these marks are made by striking the teeth of an instrument somewhat like a comb just through the skin, and rubbing into the punctures a kind of paste made of soot and oil, which leaves an indelible stain. The boys and girls under twelve years of age are not marked; a few of the men, whose legs were marked in chequers by the same method, appeared to be persons of superior rank and authority. Mr Banks saw the operation of tattooing performed upon the backside of a girl about thirteen years old. The instrument was ten inches long, and every stroke, of which at least a hundred were made in a minute, drew an ichor or serum a little tinged with blood. The girl bore it with most stoical resolution for about a quarter of an hour; but the pain of so many hundred punctures as she had received in that time, then became intolerable. She first complained in murmurs, then wept, and at last burst into loud lamentations, earnestly imploring the operator to desist. He was, however, inexorable; and when she began to struggle, she was held down by two women, who sometimes soothed and sometimes chid her; and now and then, when she was most unruly, gave her a smart blow. Mr Banks staid in a neighbour house an hour, and the operation was not over when he went away; yet it was performed but upon one side, the other having been done some time before; and the arches upon the loins, in which they most pride themselves, and which gave more pain than all the rest, were still to be done. Both men and women are not only decently but gracefully clothed, in a kind of white cloth that is made of the bark of a shrub, and very much resembles coarse China paper. Their dress consists of two pieces of this cloth; one of them, having a hole made in the middle to put the head through, hangs from the shoulders to the mid-leg before and behind; another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner: This cloth is not woven; but is made like paper, of the macerated fibres of the inner bark spread out and beaten together. Their ornaments are feathers, flowers, pieces of shell, and pearls; the pearls are worn chiefly by the women. In wet weather they wear matting of different kinds, as their cloth will not bear wetting. The dress of the better sort of women consists of three or four pieces: one piece, about two yards wide and eleven long, they wrap several times round their waist, so as to hang down like a petticoat as low as the middle of the leg; and this they call porsow. This simple drapery affords the sex an opportunity of displaying an elegant figure to the greatest advantage, according to the talents and taste of the wearer: no general fashions force them to disfigure instead of adorning themselves, but an innate gracefulness is the companion of simplicity.
simplicity. To this cloth they give a very strong perfume.

The chief use which they make of their houses is to sleep in them; for unless it rains, they eat in the open air under the shade of a tree. These houses are no other than sheds, all built in the wood between the sea and the mountains; they are erected on an oblong square; their width is nearly half of their length; they are nothing more than a roof, not quite four feet from the ground, raised on three rows of pillers, one row on each side, and one in the middle. The roof resembles our thatched houses in England, and consists of two flat sides inclining to each other. Their thatch consists of palm-leaves. The floor of their dwelling is covered with hay, over which they spread mats. Some of these erections are furnished with a stool, which is appropriated solely to the use of the master of the family; they consist of no other furniture except a few blocks of wood, which being square, one side is hollowed in a curve; and these they use as pillows, and with their apparel they cover themselves. In these open dwellings the whole family repose themselves at night. The size of the house is proportioned to the number that constitutes the family. The established order in these dormitories is, for the master and his wife to sleep in the middle; round them the married people; in the next circle the unmarried women; and in the next, at the same distance, the unmarried men; and the servants at the extremity of the shed; but in fair weather the latter sleep in the open air. Some few dwellings, however, constructed for greater privacy, are entirely inclosed with walls of reeds, connected together with transverse pieces of wood, so as to appear somewhat like large bird cages closely lined; in these houses there is commonly a hole left for the entrance, which can be closed up with a board.

Their candles are made of the kernels of a kind of oily nut, which they stick one above another on a skewer that is thrust through the middle of them; the upper one being lighted burns to the second, at the same time consuming that part of the skewer that goes through it; the second taking fire burns in the same manner down to the third, and so to the last; they burn a considerable time, and afford a pretty good light. The natives generally retire to rest about an hour after it is dark.

The food of the common people entirely consists of vegetables. These are, the bread-fruit, with bananas, plantains, yams, apples, and a sour fruit, which, though not pleasant by itself, gives an agreeable relish to roasted bread-fruit, with which it is frequently beaten up. The flesh, which is reserved for the tables of the great, is either poultry, hogs, or dogs; the flesh of their fowls is not well-tasted, but that of dogs is esteemed by the natives beyond pork. The smaller fish are generally eaten raw, as we eat oysters: every thing that can be procured from the sea is made an article of their food; for they will eat not only sea-insects, but what the seamen call blubbers, though some of them are so tough that they are obliged to suffer them to become putrid before they can be chewed. A very large shark being caught by the Dolphin’s people was given to the natives; who soon cut it to pieces, and carried it away with great satisfaction.

They kill the animals they intend for food by suffocating them, which is done by stopping the mouth and nose with their hands; they then singe off the hair, by holding the animal over a fire, and scraping him with a shell; with this instrument they cut him up, and take out the entrails; which are washed, and put into coconut-nut shells, together with the blood. Dogs are eaten that are fed wholly upon bread-fruit, coconut-nuts, yams, and other vegetables, and are never suffered to taste any animal food; and those who have tasted the flesh of a dog thus fed, have declared it to be little inferior to English lamb. In order to dress their food, they kindle a fire, by rubbing the end of one piece of dry wood upon the side of another, in the same manner as a carpenter with us whets a chisel. They then dig a pit about half a foot deep, and two or three yards in circumference; they pave the bottom with large pebble stones, which they lay down very smooth and even, and then kindle a fire in it with dry wood, leaves, and the husks of coconut. When the stones are sufficiently heated, they take out the embers, and rake up the ashes on one side; they then cover the stones with a layer of green coconut-nut leaves, and wrap up the animal that is to be, dressed in the leaves of the plantain. If it is a small hog, they wrap it up whole; if a large one, they split it. When it is placed in the pit, they cover it with the hot embers, and lay upon them bread-fruit and yams, which are also wrapped up in the leaves of plantain. Over these they spread the remainder of the embers, mixing among them some of the hot stones, with more coconut-nut tree leaves upon them, and then close up all with earth, so that the heat is kept in; the oven is kept thus closed a longer or shorter time according to the size of the meat that is dressed. The meat, when taken out, is said to be better dressed than any other way. They use shells for knives; and carve very dexterously with them, always cutting from themselves. One of the principal attendants on Oberes, attempting the use of the knife and fork, could not feed himself therewith; but by the mere force of habit, his hand came to his mouth, and the victuals at the end of his fork went away to his ear.

They are quite unacquainted with the method of boiling water, as they have no vessels among them that will bear the fire. Whilst the noble Oberes was one morning at breakfast with Captain Wallis on board the Dolphin, the surgeon filled the tea-pot by turning the cock of a vase that stood upon the table. One of the lady’s attendants observed this practice very attentively, and soon after turning the cock himself, received the water upon his hand; he no sooner felt himself scalded, than he roared and danced about in an extravagant manner. The other Indians, unacquainted of the cause of these emotions, stood gazing at him in amazement, and not without some mixture of terror: but the gentlemen in company, who soon perceived the cause of the outcry, dispelled the apprehensions of their visitants; and some ointment being applied to the scald, good humour and confidence were again restored. The gunner of the ship, who was appointed comptroller of the market which was established on shore with the natives, used to dine on the spot; the astonishment of these people was very great to see him dress his pork and poultry in a pot; at length an old man, who was extremely serviceable in bringing down provisions to be exchanged, was put into possession of an iron pot, and from that time
time he and his friends ate boiled meat every day. Several iron pots were likewise given to Oberea and some of the chiefs: which were in constant use, and drew every body to see them; but although the particulars of two successive voyages of Captain Cook to this island are circumstantially related, we hear no more of this improvement in the culinary art, or of the further assistance which has been rendered to these people in supplying them with pots for boiling; but however desirous the natives might be to eat boiled meat, it was not advisable to have such an article for barter as iron kettles, when a few spike nails, or a common hatchet, would procure one of their largest hogs.

Salt water in the usual sauce to their food; those who live near the sea have it furnished as it is wanted, others at a distance keep it in large bamboo. The kernels of the cocoa-nuts furnish them with another sauce; these, made into a paste something of the consistence of butter, are beat up with salt water, which has a very strong flavour; but though at first it seemed very nauseous, yet when the taste became familiar, it was much relished.

Their general drink is water, or the milk of the coco-nut. They showed in general an aversion to strong liquors; and whenever any one of them happened to drink so freely with any of the ship's company as to be intoxicated, he resolutely refused to taste anything that was likely to produce the same effect again; but they have a plant which they call ava ava, from the root of which they procure a liquor which has an inebriating quality. Their manner of preparing this strong drink is as simple as it is disgusting to an European. Several of the people take some of the root, and chew it till it is soft and pulpy; then spit it out into a platter or other vessel, every one into the same: into this general receptacle water is poured according to the quantity prepared. The juice thus diluted is strained through some fibrous stuff like fine shavings, after which it is fit for drinking, and it is always prepared for present use; it has a repugnant taste; drinks flat, and rather insipid; and though it intoxicates, yet Captain Cook saw but one instance where it had that effect, as the natives generally drink it with great moderation, and but little at a time. Sometimes they chew this root as Europeans do tobacco, and sometimes they will eat it wholly.

They eat alone, or at least only in company with a guest that happens to call in; and the men and women never sit down together to a meal: the shade of a spreading tree serves them for a parlour; broad leaves spread in great abundance serve for a table-cloth; and if a person of rank, he is attended by a number of servants who seat themselves round him: before he begins his meal, he washes his mouth and hands very clean, and repeats this several times whilst he is eating. The quantity of food which these people eat at a meal is prodigious. Captain Cook says, he has seen one man devour two or three fishes as big as a perch; three bread-fruits, each bigger than two fists; 14 or 15 plantains, or bananas, each six or seven inches long and four or five round, and near a quart of the pounded bread-fruit. Men of rank are constantly fed by their women; and one of the chiefs who dined on board the ships in 1769, showed such reluctance to feed himself, that one of the servants was obliged to feed him to prevent his returning without his meal. In one of the excursions which the gentlemen of the ships made into the country in 1773, they arrived at a neat house, where a very fat man, who seemed to be a chief of the district, was lolling on his wooden pillow; before him two servants were preparing his dessert, by beating up with water some bread-fruit and bananas in a large wooden bowl, and mixing with it a quantity of fermented sour paste called moke. While this was doing, a woman, who sat down near him, crammed down his throat by handfuls the remains of a large baked fish, and several bread-fruits, which he swallowed with a voracious appetite; his countenance was the picture of phlegmatic insensibility, and seemed to testify that all his thoughts centered in the gratification of his appetite. He scarce deigned to look at the strangers; and a few monosyllables which he uttered, were extorted from him to remind his feeders of their duty, when by gazing at them they grew less attentive to him.

That these people, who are remarkably fond of society, and particularly that of their women, should exclude its pleasures from the table, where, among all other nations, whether civil or savage, they have been principally enjoyed, is truly inexplicable. How a meal, which everywhere else brings families and friends together, comes to separate them here, was a singularity much inquired about, but never accounted for. "They ate alone (they said), because it was right;" but why it was right to eat alone, they never attempted to explain. Such, however, was the force of custom in this instance, as it is in every other, that they expressed the strongest dislike, and even disgust, at their visitants eating in society, especially with women, and of the same victuals. "At first (says Captain Cook) we thought this strange singularity arose from some superstitious opinion; but they constantly affirmed the contrary. We observed also some caprices in the custom, for which we could as little account as the custom itself. We could never prevail with any of the women to partake of the victuals at our table, when we were dining in company; yet they would go five or six together into the servants apartments, and there eat very heartily of whatever they could find; nor were they in the least disconcerted if we came in while they were doing it. When any of us have been alone with a woman, she has sometimes eaten in our company; but then she has expressed the greatest unwillingness that it should be known, and always extorted the strongest promises of secrecy. Among themselves, even two brothers and two sisters have each their separate baskets of provisions, and the apparatus of their meal. When they first visited us at our tents, each brought his basket with him; and when we sat down to table, they would go out, sit down upon the ground, at two or three yards distance from each other, and turning their faces different ways take their repast without exchanging a single word. The women not only abstain from eating with the men, and of the same victuals, but even have their victuals separately prepared by boys kept for that purpose, who deposit them in a separate shed, and attend them with them as if they were their meals. But though they would not eat with us, or with each other, they have often asked us to eat with them, when we have visited those with whom we were particularly acquainted at their houses; and we have often upon such
such occasions eaten out of the same basket, and drank out of the same cup. The elder women, however, always appeared offended at this liberty; and if we happened to touch their victuals, or even the basket that contained it, they would throw it away."

After meals, and in the heat of the day, the middle-aged people of the better sort generally sleep. They are indeed extremely indolent; and sleeping and eating are almost all they do those that are elder are less drowsy, and the boys and girls are kept awake by the natural activity and sprightliness of their age.

These islanders, who inhabit huts exposed to all the winds, and hardly cover the earth, which serves them for a bed body of leaves, are remarkably healthy and vigorous, and live to an old age without enduring any of its infirmities; their senses are acute, and they retain their beautiful teeth to the last. M. de Bougainville describes an old man, whom they saw on their landing, who had no other character of old age, than that respectable one which is imprinted on a fine figure. His head was adorned with white hair, and a long white beard; all his body was nervous and fleshy; he had neither wrinkles, nor showed any other tokens of decrepitude. This venerable man seemed displeased at the arrival of these strangers; he even retired without making any returns to the courtesies they paid to him; but he gave no signs either of fear, astonishment, or curiosity; very far from taking any part in the raptures which the multitude expressed, his thoughtful and suspicious air seemed to indicate, that he feared the arrival of a new race of men would interrupt the happiness he had so long enjoyed. From whence it may be inferred, that his mind was not a whit more impaired than his body. There were several sorts of leprous complaints on this island, which appear in cutaneous eruptions of the scaly kind; some were seen that had ulcers upon different parts of their bodies; yet they seemed little regarded by those who were afflicted with them, and no application whatever was used to them, not so much as to keep off the flies. But instances of them are rare, as the excellency of their climate, and the simplicity of their vegetable food, prevent almost all dangerous and deadly disorders. They are sometimes afflicted with the cholic, and coughs are not unknown among them; and the chiefs, who fare more sumptuously, as a punishment for their voluptuousness are sometimes attacked with a disorder similar to the gout, in which the legs are swollen and excessively painful. M. de Bougainville's surgeon assured him, that he had seen many with marks of the small-pox.

The usual method employed here to restore the sick to health, is by pronouncing a set form of words; after which he kneels or sits. He plaites the leaves of the cocoanut plaited to the fingers and toes of the sick; so that nature is left to conflict with the disease, without being assisted with any salutary application of art. But though they seem utterly destitute of medical knowledge, they appear to be no incomparably proficients in surgery, which they had an opportunity of proving while the Dolphin lay here. One of the seamen, when on shore run a large splinter into his foot; and the surgeon not being at hand, one of his comrades endeavoured to take it out with a pen-knife; but after putting the poor fellow to a great deal of pain, he was obliged to give it over; an old native, who had been very active and successful in establishing a good understanding between the ship's company and his countrymen, happening to be present, called a man from the other side of the river, who having examined the lacerated foot, fetched a shell from the beach, which he broke to a point with his teeth; with which instrument he laid open the wound, and extracted the splinter. Whilst this operation was performing, the old man went a little way into the wood, and returned with some gum, which he applied to the wound upon a piece of the cloth that was wrapped round him, and in two days time it was perfectly healed. This gum was produced by the apple tree; the surgeon of the ship procured some of it, and used it as a vulnerary balsam with great success. Capt. Cook, in 1769, saw many of the natives with dreadful scars; one man, in particular, whose face was almost entirely destroyed; his nose, including bone, was perfectly flat; and one cheek and one eye were so beaten in, that the hollow would almost receive a man's fist; yet no one ulcer remained.

The venereal disease is said to have been entailed upon these people by the crew of M. de Bougainville's ships, who visited this island a short time after Capt. Wallis had left it. In 1769, more than one-half of the crew in Captain Cook's ship had contracted it, during a month's stay here. The natives distinguished it by a name of the same import with rottenness, but of a more extensive signification. They described, in the most pathetic terms, the sufferings which the first victims to its rage endured; and told him that it caused the hair and the nails to fall off, and the flesh to rot from the bones; that it spread universal terror and consternation among the inhabitants, so that the sick were abandoned by their nearest relations, lest the calamity should spread by contagion, and were left to perish alone in such misery as till then had never been known among them. But there seems to be some reason to hope that they had found out a specific cure for it, as none were seen on whom it had made a great progress; and one who went from the ship infected, returned, after a short time, in perfect health. Both Captain Cook and Mr. Forster, in their relations of their voyage in the Resolution, endeavoured to establish the opinion that this scourg of licentiousness was felt in the South sea islands previous to any of the modern voyages that have been made thither, and that it was an indigenous disease there. But if that conclusion be well founded, how comes it, that at all the places where the Resolution touched in 1773, which had before been visited by the Endeavour in 1769, such as New Zealand, for instance, the crew, more or less, became infected by their commerce with the women, and not at all so at places which they visited, for the first time, in the Resolution?

The principal manufacture among the Otahiteans is their cloth. This is made of the bark of trees, tucas, which are of three kinds, viz. the Chinese mulberry-tree, or aoula; the bread-fruit tree, or eoro; and one that is described by Dr. Hawkesworth as resembling the wild fig tree of the West Indies. Of all these the paper mulberry affords the best cloth; what is made from that being both finer, softer, whiter, and better suited to take a colour; the eoro produces cloth much inferior in contexture; and the last is very coarse, in
Otaheite. colour resembling the darkest brown paper; but this last is the only kind that withstands water: (See the article Bark).—They likewise prepare a red dye; which is made by mixing the yellow juice of a small species of fig, which the natives call matter, with the greenish juice of a sort of fern or bindweed, or of several other plants, which produce a bright crimson: and this the women rub with their hands, if the piece is to be uniformly of a colour; or they make use of a bamboo reed if the piece is to be marked or sprinkled into different patterns. The colour fades very soon, and becomes of a dirty red; but notwithstanding this defect, and its being liable to be spoiled by rain, the cloth thus stained is highly valued, and is worn only by the principal inhabitants of the country. The inhabitants perfume their cloths with certain plants; concerning which, Mr. Forster made all possible inquiry. Taheta, a friendly native, showed him several plants which are sometimes used as substitutes; but the most precious sort, he either could not, or would not, point out: and from the account of Osami it appears that there are no less than 14 different sorts of plants employed for this purpose.

Matting is another Otaheitean manufacture: and in this they are so dextrous, that they produce finer mats than any made in Europe. Rushes, grass, the bark of trees, and the leaves of a plant called wharran, are the materials which they work up for this purpose. Their matting is applied to various uses: the coarser kind is employed for sleeping on in the night, or sitting on through the day; the finer sort is converted into garments in rainy weather, their cloth being soon penetrated by wet, their heads are very dextrous in making basket and wicker-work: their baskets are of a vast number of different patterns, many of them exceedingly neat; and the making them is an art practised by every one, both men and women.

Instead of hemp, they make ropes and lines of the bark of a tree; and thus they are provided with fishing nets: the fibres of the cocoa-nut furnish them with thread, with which they fasten the different parts of their canoes, &c. The bark of a nettle which grows in the mountains, and is called orawa, supplies them with excellent fishing lines, capable of holding any kind of fish; and their hooks are made of mother-of-pearl, to which they fix a tuft of hair, made to resemble the tail of a fish. Instead of making them bearded, the point is turned inwards. They make also a kind of seine of a coarse broad grass, the blades of which are like flags. These they twist and tie together in a loose manner, till the net, which is about as wide as a large sack, is from 60 to 80 fathoms long. This they haul in and out into cool water; and its specific weight keeps it so close to the ground, that scarcely a single fish can escape. They make harpoons of cane, and point them with hard wood; with which they can strike fish more effectually than an European can with one headed with iron.

The tools used by the Otaheiteans for all their purposes are, an adze made of stone; a chisel or gouge made of bone, generally the bone of a man's arm between the wrist and elbow; a rasps of coral, and the skin of a stinger-ray; also coral and sand, as a file or polisher: and with these they fell timber, cleave and polish it, and hew stone. The stone which makes the blade of their adzes is a kind of basalt, of a gray or blackish colour, not very hard, but of considerable toughness; they are formed of different sizes; some that are intended for felling, weigh from six to eight pounds; others that are used for carving, not more than as many ounces: but it is necessary to sharpen these rude tools almost every minute; for which purpose a cocoa-nut shell full of water and a stone are always at hand. With such tools they generally take up several days in felling a tree; but after it is down, and split into planks, they smooth them very dexterously and expeditiously with their adzes, and can take off a thin coat from a whole plank without missing a stroke.

Their weapons are slings, which they use with great dexterity; pikes headed with the skins of sting-rays; and clubs of about six or seven feet long, made of a very hard wood. Thus armed, they are said to fight with great obstinacy; and to give no quarter to man, woman, or child, who happens to fall into their hands during the battle, nor for some time afterwards, till their passion subsides. They have likewise bows and arrows; but the arrows are good for nothing except to bring down a bird, being headed only with stone, and none of them pointed. They have targets of a semicircular form, made of wicker-work, and plaited strings of the cocoa-nut fibres, covered with glossy, bluish-green feathers belonging to a kind of pigeon, and ornamented with many shark's teeth, arranged in three concentric circles.

Their boats or canoes are of three different sorts. Some are made out of a single tree, and hold from 10 to 20 men. These are principally employed in fishing: the others are constructed of planks very dexterously sewed together; they are of different sizes, and will hold from 10 to 40 men: they generally lash two of these together, and set up two masts between them; or if they are single, they have an out-rigger on one side, and only one mast in the middle; and in these vessels they will sail far beyond the sight of land. The third sort seems to be principally designed for pleasure or show. These are very large, but have no sail; and in shape resemble the gondolas of Venice. The middle is covered with a large awning; and some of the people sit upon it, and some under it. The plank of which these vessels are constructed, is made by splitting a tree, with the grain, into as many thin pieces as possible. The boards are brought to the thickness of about an inch, and are afterwards fitted to the boat with the same exactness that might be expected from an expert joiner. To fasten these planks together, holes are bored with a piece of bone, fixed into a stick for that purpose. Through these holes a kind of plaited cordage is passed, so as to hold the planks strongly together. The seams are caulked with dry rushes; and the whole outside of the vessel is painted over with a kind of gummy juice, which supplies the place of pitch.

The Otaheiteans are a very industrious people, and friendly in their dispositions; but like all other native races, not fully civilized, their passions are extremely violent, and they are very fickle. The manner of singing out a man here for a chosen friend is by taking off a part of your clothing and putting it upon him. Their usual manner of expressing their respect to strangers, is their
Otaheite. their superiors, at a first meeting, is by uncovering themselves to the middle. They have a custom of saluting those who sneeze, by saying *evaroia-eatoua,* "May the good eatoua awaken you," or "May not the evil eatoua lull you asleep!"

Their propensity to theft is very great, insomuch, that M. Bougainville says, "even in Europe itself one cannot see more expert flickers than the people of this country; and indeed, in all the voyages made by Captain Cook and others, they had abundant experience of this disposition of the natives, which often produced quarrels, and sometimes even fatal effects. In their behaviour they are extremely lascivious, almost beyond credibility. A woman of distinction who visited Mr Banks, used the following ceremony on her first approach to the stranger. After laying down several young plantain leaves, a man brought a large bundle of cloth; which having opened, he spread it piece by piece on the ground, in the space between Mr Banks and his visitant. There were in all nine pieces: having spread three pieces one upon another, the lady came forward, and, stepping upon them, took up her garments all around her to her waist; she then turned three times round, after which she dropped the veil: when other three pieces were spread, she practised the same ceremony; and so the third time, when the last three pieces were laid out; after which the cloth was again rolled up, and delivered to Mr Banks as a present from the lady, who with her attending friend came up and saluted him. From the unbridled licentiousness of these people, the French gave this island the name of the *New Cythera.* Nay, to such a degree do they carry their licentious excesses, that a number of the principal people, it is related, have formed themselves into a society, in which every woman is common to every man. This society is distinguished by the name of *Array,* the members of which have meetings from which all others are excluded. At these meetings the passions are excited by as far as the mind of sensuality, and the coarsest and most bawdy pleasures are enjoyed by the whole company. If, however, notwithstanding these excesses, any of the female members of this community should prove with child, unless she can procure some man to adopt the child as his own, not all the strong affections of a mother, if such are not entirely eradicated by a course of life subversive of the feelings as well as the modesty of nature, can save the life of the precondemned innocent; but the child as soon as born is smothered, and the mother is left at liberty to renew her former course of execrable prostitution. Should any man be found to cooperate with a woman in saving the life of a child, they are both excluded for ever from the *array,* and are considered as man and wife. The woman from that time is distinguished by the term *tehamou-moua,* "the bearer of children," which in this part of the world only is considered as a term of reproach; and so depraved are those people, that being a member of such a society is boosted of as being a privilege instead of being stigmatized as the foulest crime. The arrayos enjoys several privileges, and are greatly respected throughout the Society islands, as well as at Otaheite; nay, they claim a great share of honour from the circumstance of being childless. Tupia, one of the most intelligent natives, when he heard that the king of England had a numerous offspring, declared that he thought himself much greater, because he belonged to the arrayos. That this society indulge themselves in promiscuous embraces, and that every woman is common to every man, is contradicted by Mr Forster. He says, that these arrayos choose their wives and mistresses from among the prostitutes; and from this circumstance, as well as their extreme voluptuousness, they have seldom any reason to dread the intrusion of children. He had the following circumstances related to him by Omi or Omiah, one of the natives, who was brought to England. He said, that the pre-eminence and advantages which a man enjoyed as arrayo were so valuable as to urge him against his own feelings to destroy his child; that the mother was never willing to consent to the murder; but that her husband and other arrayos persuaded her to yield up the child; and that where entreaties were not sufficient, force was sometimes made use of. But, more than this, he added, that this action was always perpetrated in secret; and that not even the *totoa* or attendants of the house were present; because, if it were seen, the murderers would be put to death.

Both men and women constantly wash their whole bodies three times a day in running water, and are remarkably cleanly in their clothes. They are most expert swimmers, being accustomed to the water from their infancy. Captain Cook relates the following remarkable instance of their expertness. On a part of the shore where a tremendously high surf broke, in so much that no European boat could live in it, and the best European swimmer, he was persuaded, would have been drowned, as the shore was covered with pebbles and large stones, yet here were 10 or 12 Indians swimming for their amusement. Whenever a surf broke near them, they dived under it, and rose again on the other side. The stern of an old canoe added much to their sport. This they took out before them, and sometimes got into it, and turning the bow toward to the breaking wave, were driven in towards the shore with incredible rapidity, sometimes almost to the beach; but generally the wave broke over them before they got half way; in which case they dived, and rose to the other side with the canoe in their hands, and swimming out with it again were again driven back. This amazing expertness drew the Captain's attention for more than half an hour; during which time none of the swimmers attempted to come ashore, but seemed to enjoy the sport in the highest degree. At another time, one of the officers of the quarter-deck intending to drop a bead into a canoe for a little boy of six years of age, it accidentally missed the boat, and fell into the sea; but the child immediately leaped overboard, dived after it, and recovered it. To reward him for this feat, some more beads were dropped to him; which excited a number of men and women to amuse the officers with their amazing feats of agility in the water, and not only fetched up several beads scattered at once, but likewise large nails, which, from their weight, descended quickly to a considerable depth. Some of these people continued a considerable time under water; and the velocity with which they were seen to go down, the water being extremely clear, was very surprising. Here a green branch of a tree is used as an emblem of peace,
in exact conformity to the custom of the ancient nations. We shall add an extract here from Captain Cook's last voyage to the Pacific ocean.

"Nothing could make a stronger impression at first sight, on our arrival here, than the remarkable contrast between the robust make and dark colour of the people of Tongatapoo, and a sort of delicacy and whiteness which distinguish the inhabitants of Otaheite. It was even some time before that difference could preponderate in favour of the Otaheiteans; and then only, perhaps, because as we became accustomed to them, the marks which had recommended the others began to be forgotten. Their women, however, struck us as superior in every respect; and as possessing all those delicate characteristics which distinguish them from the other sex in many countries. The beard, which the men here wear long, and the hair, which is not cut so short as is the fashion at Tongatapoo, made also a great difference; and we cannot help thinking, that on every occasion they showed a greater degree of timidity and fickleness. The muscular appearance, so common amongst the Friendly islanders, and which seems a consequence of their being accustomed to much action, is lost here, where the superior fertility of their country enables the inhabitants to lead a more indolent life; and its place is supplied by a plumpness and smoothness of the skin; which, though perhaps more consonant with our ideas of beauty, is no real advantage, as it seems attended with a kind of languor in all their motions, not observable in the others. This observation is fully verified in their boxings and calcings, which may be called little better than the feeble efforts of children, if compared to the vigour with which these exercises are performed at the Friendly islands.

"Personal endowments being in great esteem amongst them, they have recourse to several methods of improving them, according to their notions of beauty. In particular, it is a practice, especially amongst the arroyo, or unmarried men of some consequence, to undergo a kind of physical operation, to render them fair. This is done by remaining a month or two in the house; during which time they wear a great quantity of clothes, eat nothing but bread-fruit, to which they ascribe a remarkable property in whitening them. They also speak, as if their corpulence and colour, at other times, depended upon their food; as they are obliged, from the change of seasons, to use different sorts at different times.

"The graceful air and firm step with which these people walk are not the least obvious proof of their personal accomplishments. They consider this as a thing so natural, or so necessary to be acquired, that nothing used to excite their laughter sooner, than to see us frequently stumbling upon the roots of trees, or other inequalities of the ground.

"Their countenances very remarkably express the abundant mildness or good nature which they possess, and are entirely free from that savage keenness which marks nations in a barbarous state. One would, indeed, be apt to fancy that they had been bred up under the severest restrictions to acquire an aspect so settled, and such a command of their passions, as well as steadiness in conduct. But they are at the same time frank, cheerful, and good-humoured, though sometimes, in the presence of their chiefs, they put on a degree of gravity, and such a serious air, as becomes stiff and awkward, and has an appearance of reserve.

"Their peaceable disposition is sufficiently evinced from the friendly reception all strangers have met with who have visited them. Instead of offering to attack them openly or clandestinely, as has been the case with most of the inhabitants of these seas, they have never appeared in the smallest degree hostile, but on the contrary, friendly, like the most hospitable people; we counted an intercourse with their visitors by burning, which is the only medium that unites all nations in a sort of friendship. They understand barter (which they call fukkatou) so perfectly, that at first we imagined they might have acquired the knowledge of it by commercial intercourse with the neighbouring islands; but we were afterwards assured, that they had little or no traffic except with Fejee, from which they get the red feathers, and some few other articles which they esteem. Perhaps no nation in the world traffic with more honesty, and less distrust. We could always safely permit them to examine our goods, and to hand them about one to another; and they put the same confidence in us. If either party repented of the bargain, the goods were re-exchanged with mutual consent and good humour. Upon the whole, they seem possessed of many of the most excellent qualities that adorn the human mind, such as industry, ingenuity, perseverance, affability, and perhaps other virtues which our short stay with them might prevent our observing.

"The only defect in preserving their character that we know of is their propensity to thieving, to which we found those of all ages and both sexes addicted, and to an uncommon degree. It should, however, be considered, that this exceptionable part of their conduct seemed to exist merely with respect to us; for in their general intercourse with one another, I had reason to be of opinion, that thefts do not happen more frequently (perhaps less so) than in other countries, the dishonest practices of whose worthless individuals are not supposed to authorize any indiscriminate censure on the whole body of the people. Great allowances should be made for the foibles of these poor natives of the Pacific ocean, whose minds we overpowered with the glare of objects, equally new to them as they were captivating. Stealing, amongst the civilized and enlightened nations of the world, may well be considered as denoting a character deeply stained with moral turpitude, with avarice unrestrained by the known rules of right, and with profligacy producing extreme indigence, and neglecting the means of relieving it. But at the Friendly and other islands which we visited, the thefts so frequently committed by the natives, of what we had brought along with us, may be fairly traced to less culpable motives. They seemed to arise solely from an intense curiosity or desire to possess something which they had not been accustomed to before, and belonging to a sort of people so different from themselves. And, perhaps, if it were possible that a set of beings seemingly as superior in our judgment as we are in theirs should appear amongst us, it might be doubted, whether our natural regard to justice would be able to restrain many from falling into the same error. That I have assigned the true motive for their propensity to this practice, appears from their stealing every thing indiscriminately at first sight,
what can give them pleasure and case. Their amuse-
mements all tend to excite and continue their amorous pas-
sions; and their songs, of which they are immediately
fond, answer the same purpose. But as a constant suc-
cession of sensual enjoyment must cloy, we found that
they frequently varied them to more refined subjects, and
had much pleasure in obtaining their true subjects in war,
and their occupations in peace; their travels to other
islands and adventures there; and the peculiar beauties,
and superior advantages of their own island over the rest,
or of different parts of it over other less favourite dis-
tricts. This marks that they receive great delight from
music; and though they rather expressed a dislike to
our complicated compositions, yet were they always de-
lighted with the more melodious sounds produced singly
on our instruments, as approaching nearer to the sim-
plicity of their own. Neither are they strangers to the
soothing effects produced by particular sorts of motion,
which in some cases seem to allay any perturbation of
mind with as much success as music. Of this I met
with a remarkable instance. For, on walking one day
about Matavai Point, where our tents were erected, I
saw a man paddling in a small canoe so quickly, and
looking about with such eagerness on each side, as to
command all my attention. At first I imagined that
he had stolen something from one of the ships, and was
pursued; but on waiting patiently saw him return, and
amusement. He went out from the shore till he was
near the place where the swell begins to take its rise;
and, watching its first motion very attentively, paddled
before it with great quickness till he found that it over-
took him, and had acquired sufficient force to carry his
canoe before it, without passing underneath. He then
sat motionless, and was carried along at the same swift
rate as the wave, till it landed him upon the beach.
Then he started out, emptied his canoe, and went in
search of another swell. I could not help concluding,
that this man felt the most supreme pleasure, while he
was driven on so fast and so smoothly by the sea; espe-
cially as, though the tents and ships were so near, he
did not seem in the least to envy, or even to take any
notice of the crowds of his countrymen collected to
view them as objects which were rare and curious. Du-
ing my stay, two or three of the natives came up, who
seemed to share his felicity, and always called out when
there was an appearance of a favourable swell, as he
sometimes missed it, by his bark being turned, and
looking about for it. By them I understood that this
exercise, which is called ehoroe, was frequent amongst
them; and they have probably more amusements of this
sort, which afford them at least as much pleasure as
skating, which is the only one of ours with whose ef-
fects I could compare it."

The language of these islanders is soft and melodious; Language,
it abounds with vowels, and the pronunciation of it is &c.
easily acquired: but it was found excessively difficult
to teach the natives to pronounce a single English word;
probably not only from its abounding with consonants,
but from some peculiarity in its structure; for Spanish
and Italian words, if ending in a vowel, they pronoun-
ced with the greatest ease. A sufficient acquaintance
has not been formed with it to determine whether it is
copious or not; but it is certainly very imperfect, being
totally without inflexion either of nouns or verbs. Few
of the nouns have more than one case, and few of the
verbs
Otaheite. verbs more than one tense. It was impossible to teach the islanders to pronounce the names of their guests. They called Captain Cook Toote; Mr Hicks, the first lieutenant, Hete, &c. and in this manner they formed names for almost every man in the ship. In some, however, it was not easy to find any traces of the original; and they were perhaps not mere arbitrary sounds, formed upon the occasion, but signified words in their own language; and it seems that they could perfectly remember these appellations at the distance of four years, by their enquiries after such gentlemen as were absent on the second voyage by name. Mr Monkhouse, a midshipman, they called Matte, which in their language signifies dead; because he commanded a party that killed a man for stealing a musket. The nearest imitation they could reach of King George, was by calling him Ahiraga. We have the following observations on this subject, in vol. ii. of Cook's last voyage to the Pacific ocean: "The language of Otaheite, though doubtless radically the same with that of New Zealand and the Friendly islands, is destitute of that guttural pronunciation, and of some consonants, with which those latter dialects abound. The specimens we have already given are sufficient to mark wherein the variation chiefly consists, and to show, that, like the manners of the inhabitants, it has become soft and soothing. During the former voyage, I had collected a copious vocabulary, which enabled me the better to compare this dialect with that of the other islands; and during this voyage I took every opportunity of improving my acquaintance with it, by conversing with Onai before we arrived, and by the daily intercourse with the natives while we now remained there (A). It abounds with beautiful and figurative expressions, which, were it perfectly known, would, I have no doubt, put, it upon a level with many of the languages that are most in esteem for their warm and bold images. For instance, the Otaheiteans express their notions of death very emphatically, by saying, "that the soul goes into darkness; or rather into night." And, if you seem to entertain any doubt, in asking the question, "if such a person is their mother?" they immediately reply with surprise, "yes, the mother that bore me." They have one expression that corresponds exactly with the physiology of the scriptures, where we read of the "yearning of the bowels."—They use it on all occasions, when the passions give them uneasiness, as they constantly refer pain from grief, anxious desire, and other affections, to the bowels, as its seat; where they likewise suppose all operations of the mind are performed. Their language admits of that inverted arrangement of words which so much distinguishes the Latin and Greek from most of our modern European tongues, whose imperfections require a more orderly construction, to prevent ambiguities. It is so copious, that for the bread-fruit alone, in its different states, they have above 20 names; as many for the taro root; and about 10 for the coconut. Add to this, that, besides the common dialect, they often expostulate in a kind of stanza or recitative, which is answered in the same manner."

A map of Otaheite, engraved for Captain Cook's first voyage, was taken out, and laid before Tuahou the high-admiral, without informing him of what it was; however, he immediately found it out, and was overjoyed to see a representation of his own country. He pointed out all the districts of it, naming every one of them in their order. These people have a remarkable sagacity in foretelling the weather, particularly the quarter from whence the wind will blow. In their long voyages they steer by the sun in the day, and in the night by the stars; all of which they distinguish by separate names, and know in what part of the heaven they will appear in any of the months during which they are visible in their horizon. They also know the times of their annual appearing and disappearing, with more precision than would easily be believed by an European astronomer. Their time they seem to reckon by moons, 13 of which make a year. The day they divide into six parts, and the night into an equal number. They judge of the time of the day by the height of the sun, but they cannot ascertain the time of the night by the stars. In enumeration, the greatest length they can go is 200; that is, when they have counted each of their fingers and toes ten times over. When they take the distance from one place to another, they express it by the time which is required to pass it.

The government of the Otaheiteans seems greatly to resemble the early state of the European nations under the feudal system. Their orders of dignity are earree, which answer to the king; earree, baron; maahouni, vassal; and toutous, vassal. There are two kings in the island, one being the sovereign of each of the peninsulas of which it consists. Each of them is treated with great respect by all ranks, but does not appear to be invested with so much power as is exercised by the earrees in their own districts. When the king, whom they called O-Too, made a visit to Captain Cook, the chief, who happened to be there before him, immediately stripped themselves in great haste. Captain Cook took notice of it; upon which they said earree, earree, signifying, that it was on account of O-Too being present; but this was the only outward token of respect they paid him, for they never rose from their seats, or made any other obeisance.

The earree are lords of one or more of the districts into which each of the peninsulas is divided, and of which there are 43 in the larger one. These parcel out their territories to the maahounis, who superintend the cultivation of the ground. The lowest class, called toutous, seem to be nearly under the same circumstances with the vassals in feudal governments. They do all the laborious work, cultivate the land, catch fish, fetch wood and water, &c. Each of the earrees keeps a kind of court, and has a great number of attendants, chiefly the younger brothers of their own tribe, and among these some hold particular offices, but of which little more is known than some of their names.

In this country a child succeeds to his father's titles and authority as soon as he is born: and thus the king no sooner has a son born, than his sovereignty ceases.

(A) See this vocabulary at the end of the second volume of Captain Cook's second voyage. Many corrections and additions to it were now made by this indefatigable inquirer; but the specimens of the language of Otaheite, already in the hands of the public, seem sufficient for every useful purpose.
Otaheite. A regent is then chosen; and the father generally retains his power under that title, until his child becomes of age. The child of the baron succeeds to the titles and honours of his father, as soon as it is born, as well as the son of the king; so that a baron who was yesterday called earc, and was approached with the ceremony of lowering their garments, so as to uncover the upper part of the body, is to-day, if his wife happens to be delivered of a child, reduced to the rank of a private man, all sorts of respect being transferred to the child, if it is suffered to live, though the father still continues possessor and administrator of his estate. But the acquis- cence which the lower class of people, or toutoos, yield to the command of their chiefs, is very remarkable. They are not suffered to taste any animal food, although they are employed in feeding it for their lords. They endure patiently very severe blows, if, when collected into a large body, they in any manner press upon or annoy the king or a chief in his progress; and all this passive spirit is preserved without any power being lodged in the hands of the king to exact it; for he uses no military force, nor is even attended with body guards.

There are but few actions which are reckoned crimes among the Otaheiteans. Adultery, however, is sometimes punished with death: but in general, the woman escapes with a severe beating, and the gallant passes unnoticed. The regulation of public justice is not confined to the magistrate; for the injured party redresses his own wrong by inflicting whatever punishment he can upon the offender: but in matters of notorious wrong the chiefs sometimes interpose. The nobility have livery for their servants; and in proportion as the master's rank is more or less elevated, these sashes are worn higher or lower, being fastened close under the arms of the servants belonging to the chiefs, and going round the loins of those belonging to the lowest class of nobility. Several parts of the island seem to be private property, which descend to the heir of the possessor on his death, and the descent seems to fall indifferently on man or woman. Captain Cook was of opinion that the number of inhabitants on the whole island amounted to 224,000 including women and children.

The religious language of the Otaheiteans, like that of the Gentoo Brahmins, is different from what is used in common discourse; but, according to the accounts we have of their notions concerning the origin of the world, nothing can be more ridiculous. They imagine that the Supreme Deity, besides a great many female descendants, has one son named Tane; and to him they direct their worship, though they do not believe that the good or bad conduct of mankind here on earth makes them more or less acceptable to this divinity. They believe the existence of the soul after death, and of a greater or lesser degree of happiness to be then enjoyed: but they seem to have no conception of a state of punishment or of suffering hereafter. The share of happiness which they imagine every individual will enjoy in this future state, will be assigned to him according to the rank he holds on earth. We are not, however, told wherein they suppose the happiness of this future state to consist; but it is most probably a pretty exact imitation of a Mohammedan paradise; for these volupturns can hardly be supposed capable of imagining any pleasure independent of the intercourse of the sexes.

The priesthood seems to be hereditary in one family or tribe; and as it is said to be numerous, probably those of that order are restrained from becoming members of the arreoy: but whether or not any peculiar decorum is necessary to be observed, hath not yet appeared. These priests are professedly the men of science; but their knowledge is altogether frivolous and useless; for it consists in being conversant with the names of their different divinities, and such absurd traditions as have been handed down among them from one generation to another. Their religious notions being posited in an unknown tongue, they are respected because they are not understood; and as the cure of the soul is no object of regard, the most important concern to these people, the cure of their bodies, is committed to the priests, and much parade is used in their attempts to recover the sick, though their remedies consist of ridiculous ceremonies and enchantments rather than any thing else.

The marriages of these people are merely secular contracts; but no one has a right to perform the operation of tattooing except the priests; and this being a custom universally adopted by the natives, it may be supposed that performing it is a very lucrative employment. The males in general undergo a kind of circumcision, which is disgraceful not to comply with, and which is likewise the exclusive privilege of the priests to perform. But what most establishes the credit of this order of men is their skill in astronomy and navigation.

Captain Cook, who had some reason to believe that among the religious customs of this people, human sacri- fices were sometimes offered up to their deities, went to a morai, or place of worship, accompanied by Captain Furneaux, having with them a sailor who spoke the language tolerably well, and several of the natives. In the morai was a tupapaw, a kind of bier, with a shed erected over it, on which lay a corpse and some provisions. Captain Cook then asked if the plantain were for the Eatu? If they sacrificed to the Eatu hogs, dogs, fowls, &c.? To all of which an intelligent native answered in the affirmative. He then asked if they sacrificed men to the Eatu? He was answered, taato eno, "bad men they did; first tiparrary, beating them till they were dead." He then asked if good men were put to death in this manner? His answer was no, only taato eno. The Captain then asked if any cares were? The native replied, they had hogs to give the Eatu, and again repeated taato eno. He was then asked if toutows, who had no hogs, dogs, or fowls, but yet were good men, were ever sacrificed to the Eatu? The answer still was no, only bad men. Many other questions were put to him; all his answers to which seemed to confirm the idea that men for certain crimes were condemned to be sacrificed to the gods, provided they did not possess any property which they might give for their redemption. However, in pursuing such inquiries as these, no certain information could be obtained, on account of the slight knowledge which had been acquired of the language of the country: but according to farther accounts which Captain Cook received from Omai, it seems to rest with the high-priest to single out the victims for sacrifice; who, when the people are assembled on any solemn occasion, retires alone into the house of God, and stays there for some time; when he comes out, he informs the assembly that he has seen and conversed with the great god (the high priest alone having that privilege), and that he has asked for a human sacrifice; and tells them he has desired such a person,
Otaheite. person, naming a man present, who has most probably, on some account or other, rendered himself obnoxious to this ghostly father. The words are no sooner gone out of his mouth, than the devoted wretch is put to death; for his guilt cannot be doubted, after the oracle has pronounced his doom.

On this island was seen the figure of a man constructed of basket work, rudely made, but not ill designed: it was something more than seven feet high, and rather too bulky in proportion to its height. This wicker skeleton was completely covered with feathers, which were white where the skin was to appear, and black in the parts which it is their custom to paint or stain, as well as upon the head, which was designed to represent hair. Upon the head also were four protuberances, three in front, and one behind, which the Indians called tate tete, little men. The image was called Monioe: it was a representation of Manu, one of their Eauxus, or gods of the second class, and was said to be the only one of the kind on Otaheite.

These people pray at sunrise and sunset. They have also a number of superstitious practices, in order to conciliate the influence of evil genii. E-Tee, a chief, who seemed to be the king's prime minister in 1774, very seriously asked Mr. Forster whether they had a god (Eauus) in their country, and whether they prayed to him (epere?) When he told them that they acknowledged a divinity who had made everything, and was invisible, and that they were accustomed to address their petitions to him, he seemed to be highly pleased, and repeated his words with comments of his own, to several persons who sat round him; seeming thereby to intimate, that the ideas of his countrymen corresponded with theirs in this respect.

The morai are used both as burying-grounds and places of worship; they are approached with the most wonderful expressions of reverence and humility; and this, it should seem, not because any thing there is esteemed sacred, but because they there-worship an invisible being, for whom they entertain the most reverential respect, although not excited by the hope of reward or the dread of punishment. Though they do not appear to have any visible object of worship, yet, says Captain Cook: this island, and indeed the rest that lie near it, have a particular bird, some a heron, and others a king’s-fisher, to which they pay a particular regard, and concerning which they have some superstitious notions, respecting good or bad fortune, as we have of the swallow and robin redbreast, and will on no account molest or kill them. One of these cemeteries, or places of worship, was known to Captain Cook, on his first voyage, by the name of Toothah's morai, then the regent; but when, on his second voyage, after the death of that chief, he called it by that name, Maratau, a chief that accompanied the party, interrupted him, intimating, that it was no longer Toothah's after his death, but was then known as O-Too's morai, the then reigning prince. A fine moral for princes! daily reminding them of mortality whilst they live, and teaching them, that after death they cannot call even that ground their own which their dead corpse occupies! The chief and his wife, on passing by it, took their upper garments from their shoulders. From hence it would seem, that the royal family have a particular morai, and that it always bears the name of Otaheite the reigning prince.

An Indian who had snatched away a musket from a sentry whilst on duty, was, by the inhumanity of a midshipman who commanded the guard, pursued and shot. The unhappy fate of this poor fellow gave an opportunity for seeing the manner in which these people treat their dead. They placed the corpse in the air till the bones became quite dry: a shed was erected close by the house where the deceased had resided; it was about 15 feet long, and 11 broad; one end was left quite open; the other end, and the two sides, were partly inclosed with a sort of wicker-work. The bier was a frame of wood, like that on which the sea-beds, called cots, are placed, with a matted bottom, and supported by four posts, at the height of about four feet from the ground. The body was covered first with a mat, and then with white cloth; by the side of it lay a wooden mace, one of their weapons of war; and near the head of it, which lay next to the close end of the shed, lay two coco-nut shells; at the other end a bunch of green leaves, with some dried twigs, all tied together, were stuck in the ground, by which lay a stone about as big as a coco-nut. Near these lay one of the young plantain-leaves that are used for umbrellas of peace, and close by it a stone axe. At the open end of the shed also hung, in several strings, a great number of palm-nuts; and without the shed was stuck up in the ground a plantain tree, about six feet high, upon the top of which was placed a coco-nut shell full of fresh water; against the side of one of the posts hung a small bag, containing a few pieces of bread-fruit ready roasted, which had not been put in all at one time, some being fresh and others stale. This minute examination of their manner of treating their dead, seemed to be very unwelcome to the natives. The food so placed by the corpse is designed as an offering to their gods. They cast in, near the body, small pieces of cloth, on which the tears and blood of the mourners have been shed; for in their paroxysms of grief it is an universal custom, to wound themselves with a shark’s tooth. The mourner is always a man; and he is dressed in a very singular habit. When the bones are stripped of their flesh, and become dry, they are buried. This regard to their dead is very remarkable: one of the ship’s company happening to pull a flower from a tree which grew on one of their sepulchral inclosures, an Indian came suddenly behind him and struck him; and a party of sailors, who were sent to get some stones for ballast for the ship, had like to have been embroiled by the natives, by pulling down some part of an inclosure of this kind. This shed under which their dead are laid is called tepapou; the inclosure in which their bones are deposited is called morai; these latter, as has been already related, are also places of worship. As soon as a native of Otaheite is known to be dead, the house is filled with relations, who deplore their loss; some by loudest lamentations, and some by less clamorous, but more genuine expressions of grief. Those who are in the nearest degree of kindred, and are really affected by the event, are silent; the rest are one moment uttering passionate exclamations in a chorus, and the next laughing and talking without the least appearance of concern. In this manner the remainder of the day on which they assemble is spent, and all the succeeding night. On the next
next morning the body is shrouded in their cloth, and conveyed to the sea-side on a bier, which the bearers support upon their shoulders, attended by the priest, who having prayed over the body, repeats his sentences during the procession. When it arrives at the water’s edge, it is set down upon the beach; the priest renew his prayers, and taking up some of the water in his hands, sprinkles it towards the body, but not upon it. It is then carried back 40 or 50 yards, and soon after brought again to the beach, where the prayers and sprinkling are repeated. The bier is then removed backwards and forwards several times; and while these ceremonies have been performing, a house has been built, and a small space of ground railed in. In the centre of this house, or *tapawa*po, as they term it, posts are set up to support the bier, which is at length conveyed thither, and placed upon it; and here the body remains to putrefy, till the flesh is wholly wasted from the bones. These houses of corruption are of a size proportioned to the rank of the person whose body they are to contain. Those allotted to the lower class are just sufficient to cover the bier, and have no railing round them. The largest that was seen was 11 yards long; and such are ornamented according to the abilities and inclination of the surviving kindred, who never fail to lay a profusion of good cloth about the body, and sometimes almost cover the outside of the house. Garlands of the fruit of the palm not, or pandanus, and cocoa-leaves, twisted by the priests in myste-rious knots, with a plant called by them *ethee no morai*, which is particularly consecrated to funeral solemnities, are deposited about the bier, and the water is also left at a little distance. As soon as the body is de-posited in the tapawa, the mourning is renewed. The women assemble and are led to the door by the nearest relation, who strikes a shark’s tooth several times into the crown of her head; the blood copiously follows, and is carefully received upon pieces of linen, which are thrown under the bier. The rest of the women follow this example; and the ceremony is repeated at the interval, of two or three days, as long as the zeal and sorrow of the parties hold out. The tears also which are shed upon these occasions are received upon pieces of cloth, and offered as oblations to the dead. Some of the younger people cut off their hair, and that is thrown under the bier with the other offerings. This custom is founded on a notion, that the soul of the deceased, which they believe to exist in a separate state, is hoovering about the place where the body is deposited; that it observes the actions of the survivors, and is gratified by such testimonies of their affectionate grief. Whilst these ceremonies are carrying the body to the grave, the women are to be wholly inexpressible of their loss; but two or three days after, they also begin to perform a part. The nearest relations take it in turn to assume the dress, and perform the officer.

The chief mourner carry in his hand a long flat stick, the edge of which is set with sharks’ teeth; and in a frenzy, which his grief is supposed to have inspired, he runs at all he sees, and if any of them happen to be overtaken, he strikes them most mercilessly with his indented endgell, which cannot fail to wound them in a dangerous manner. The processions continue at certain intervals for five moons; but are less and less frequent, by a gradual diminution, as the end of that time approaches. When it is expired, what remains of the body is taken down from the bier; and the bones, having been scraped and washed very clean, are buried, according to the rank of the person, either within or without a morai. If the deceased was an earee, or chief, his skull is not buried with the rest of his bones, but is wrapped up in fine cloth, and put in a kind of box made for that purpose, which is also placed in the morai. This coffin is called *ethee no te oremetau*, "the house of a teacher, or master." After this the mourning ceases, except some of the women continue to be deeply afflicted at the loss, and in that case they will suddenly expel their sorrow with the shark’s tooth wherever they happen to be. The ceremonies, however, do not cease with the mourning; for prayers are still said by the priest, and offerings made at the morai. Some of the things, which from time to time are deposited there are emblematical; a young plantain is said to represent the deceased, and a bunch of feathers the Deity who is invoked. The priest places himself over against the symbol of the god, accompanied by some of the relations, who are furnished with a small offering: he repeats his orison in a set form, consisting of separate sentences: at the same time weaving the leaves of the coco-nut into different forms, which he afterwards deposits upon the ground where the bones have been interred: The Deity is then addressed by a shrill screech, which is used only upon that occasion. When the priest retires, the tuft of feathers is removed, and the provisions are left to putrefy, or be devoured by the rats.

This ceremony of mourning, as described above, was performed by Tore, one of the wives of Tubourai Tamai; and, who, when the breeding season came, which she had thus given herself ceased, looked up with a smile on the company round her, and who had before inquired of her, very earnestly, the cause of her behaviour, without receiving any answer, or having been at all noticed by her. She then began to pick up some small pieces of cloth which she had spread to catch the blood; and having got them all together, she went to the shore, and threw them into the sea. She then plunged into the river; and having washed her whole body, returned to the company as cheerful as ever. To add to the singularity of this conduct, the Indians who stood round her all the time that this frantic distress was performing, conversed with great indifference and jocularity.

There is not a more ancient custom handed down to us than that of cutting the body to express grief and distress of mind. In the code of laws delivered by Moses to the Israelites, 1400 years before the Christian era, this practice is expressly forbidden to that people: "Ye shall not cut yourselves, or make any baldness between the eyes for the dead." Deut. xiv. 1. Hence it may be supposed that this rite prevailed in Egypt, from whence the Jews derived most of those propensities which were inhibited by their great legislator. We are told likewise in the book of Kings, of the priests of Baal wounding themselves, after they had long waited in vain for the supernatural intervention of their idol. D’Arvieux informs us, that the modern Arabs retain the same custom, and that the part they chiefly wound is their arms. The difference in the practice as now prevailing in Otaheite, and Arabia seems to be, that in the first none but the women make use of it, and in the latter it is confined to the men, and generally used to express their desperate passion for some favourite mistress.
The mourning which is worn here is a head dress of feathers, the colour of which is consecrated to death, and a veil over the face. This dress is called cryso. The whole nation is said to appear thus on the death of their king. The mourning for fathers, is very long. The women mourn for their husbands, but not the husbands for their wives.

We shall conclude this account of Otaheite with the history of Omah, or, as he is improperly called Omah, who was brought over to England. He was a native of Utuera, or Raitea; and embarked at Huahine with Captain Furneaux, on board the Adventure, in September 1773; and the two ships separating in a storm on the coast of New Zealand a few months afterwards, the voyage of the Adventure was brought to a much earlier conclusion than that of the Resolution, for she arrived at Spithead the 14th of July following. This youth is said to have had some property in his native soil, of which he was dispossessed by the people of Bolabola; but he was not one of the earcees, or gentry of that country, but of the middling class of people. He was eminent neither for figure, shape, nor complexion; his colour being of a deep brown, resembling a tawny colour of the common people; and both Captain Cook and Mr Forster agree in thinking him no proper sample of the inhabitants of those islands, in respect of personal beauty. However, they are both of opinion, that the qualities of his heart and head resembled those of his countrymen in general, and that no one of the natives would have given more general satisfaction by his behaviour whilst he remained in England. He is described as possessing a good understanding, quick parts, and honest principles: not an extraordinary genius like Tupia; yet not at all deficient in intelligence, which appears from his knowledge of the game of chess, in which he made an amazing proficiency. His principal patron, whilst in England, was the earl of Sandwich, Mr Banks, and Doctor Solander. His noble patron introduced him to his majesty at Kew; and, during his stay in England, he was caressed by many of the principal nobility. He naturally imitated that easy and elegant politeness which is prevalent among the great, and which is one of the ornaments of civilized society. Indeed he adopted the manners, the occupations, and amusements of his companions in general, and gave many proofs of a quick perception and a lively fancy. He appears, however, to have been treated, whilst he resided here, rather as a fashionable exhibition, than as a rational being. No attention seems to have been paid to the enriching his mind with useful knowledge, such as might have rendered him a valuable acquisition to his country on his return thither; no means were used to instruct him in agriculture, or any mechanical art or useful manufacture; and, above all, to possess him with a moral sense: to teach him the exalted ideas of virtue, and the sublime principles of revealed religion. After a stay of two years in England, and having been inoculated for the smallpox, he embarked with Captain Cook, on board the Resolution, on his return home, loaded with a profusion of presents. At parting with his friends here, his tears flowed plentifully, and his whole behaviour bespoke him to be sincerely affected at the separation: but though he lived in the midst of amusement during his residence in England, his return to his native country was always in his thoughts; and though he was not impatient to go, he expressed a satisfaction as the time of his return approached.

Such is the account of this people which our limits permit us to give. In the history of mankind it is not without importance: and in the hands of the philosopher, the moralist, or the divine, it may be useful. The subject, because but new, has been much agitated, and is pretty generally known. Such of our readers as make men and manners their peculiar study, will be anxious for further information; we must refer them, however, to those authors who have written particularly and copiously on the subject. Cook and other voyagers of eminence will at least command attention. We may just remark, that there must surely be something extremely fascinating in the persons, manners, or customs of the inhabitants, or in the soil and appearance of the country, that could tempt the greater part of a ship's crew to resist authority, and forcibly to return to Otaheite; yet such we know was the case; and the sufferings of the commander, and those who refused to join in this vile conspiracy, and who were therefore exposed in an open boat, were indeed shocking. An account of it has been published.

OTALGIA, the EAR-ACH. See MEDICINE Index.

OTELANDS, or OATLANDS, in England, in the county of Surrey, near Weybridge, was formerly a royal palace, wherein Henry duke of Gloucester, third son to King Charles I. was born; and had a deer park, which in the civil wars was by the parliament laid open, and the house demolished. In 1673 there was a brick wall remaining, which encompassed ten acres; but there were then small traces of the chief pile, besides the gardener's lodge, wherein was the silk-worm room raised by King James I.'s queen. It is now a most magnificent building, and commands a most extensive and beautiful prospect. In the park there was a paddock, where Queen Elizabeth used to shoot with a crossbow. It is now the property of his royal highness the duke of York, who purchased it for 43,000l. of the duke of Newcastle, 1780.

OTHREE, a village in England, in the county of Kent, which stands at the bottom of a hill. In 1593 there was a battle at this place, between the two Saxons kings, Offa of Mercia, and Alrick of Kent, who was killed by Offa; and another in 1016, wherein the Danish king Canute was routed by King Edmund Ironside. The said Offa, to atone for the blood he had shed in that battle, first gave this place to Christ-church, Canterbury (as the deed says) in posessu porcorum, "for the support of the archbishop's hogs;" and so it remained in the archbishop's liberty, till exchanged with King Henry VIII. for other lands. There was a chantry founded at the Ryebouse in this parish. The church was once a chapel to Shoreham.

OTHNIEL, in sacred history, the son of Kenaz, of the tribe of Judah. We are told (Josh. xv. 17.), that Othniel was brother to Caleb; and (Judges i. 13.) it is expressly said, that he was Caleb's younger brother. There are, however, some difficulties in this: for if Caleb and Othniel had been brothers, the latter could not have married his niece Achsah, the daughter of Caleb. Secondly, the scripture never assigns to Caleb and Othniel the same father; it always names Kenaz as father to Othniel, and Jephunneh as the father of Caleb. Lastly, Caleb must be much older than Othniel, since
be gave Othniel his daughter Achshah in marriage. Thus it seems much better to suppose Kenaz and Jephunneh to be two brothers, and that Othniel and Caleb were cousin-germans, and in this sense to be nearly related, or brothers, according to the language of scripture. Thus Achshah being but second cousin in respect of Othniel, he might marry her without doing any thing contrary to the letter of the law.

Caleb having received his portion in the mountains of Judah, in the midst of a country that was possessed by giants of the race of Anak, after he had taken the city of Hebron, he advances towards Debir, otherwise called Kirjath-sepher, and declares that he would give his daughter Achshah in marriage to him that should take Kirjath-sepher. Othniel took it, and had Achshah to wife.

After the death of Joshua, the Israelites not giving themselves the trouble to exterminate the Canaanites that were then in the land, and not having continued in their fidelity to the Lord, he delivered them over to Chusnan-rishshathaim king of Mesopotamia (Judges iii. 8, &c.) to whom they continued in subjection for eight years. Then they cried to the Lord, who raised them up a deliverer in the person of Othniel the son of Kenaz, who was filled with the spirit of God, and judged Israel. He came into the field and gave battle to Chusnan-rishshathaim, beat him, and delivered Israel, in the year of the world 2599; and the country was at rest for 40 years. After this Othniel died; but the precise year of his death is not known.

OTHO, M. SAVIUS, a Roman emperor, born A.D. 32, of a family descended from the ancient kings of Etruria. He was among the number of Nero’s favorites, and accordingly was raised to the highest offices of the state, and made governor of Pannonia by the interest of Seneca, who wished to remove him from Rome, lest Nero’s love for Poppea should prove his ruin. After Nero’s death, Otho conciliated the favour of Galba the new emperor; but when he did not gain his point, and when Galba refused to adopt him as his successor, he resolved to make himself absolute, without any regard to the age or dignity of his friend. The great doubts which he had contracted encouraged his avarice; and he procured the assassination of Galba, and made himself emperor. He was acknowledged by the senate and the Roman people; but the sudden revolt of Vitellius in Germany rendered his situation very precarious, and it was mutually resolved that their respective right to the empire should be decided by arms. Otho obtained three victories, but in a general engagement near Brixiellum, his forces were defeated, and he stabbed himself when all hopes of success had vanished. This happened about the 37th year of his age, after a reign of about three months. It has been justly observed, that the last moments of Otho’s life were those of a philosopher. He comforted his soldiers who lamented his fortune, and he expressed his concern for their safety when they earnestly solicited to pay them the last friendly offices before he stabbed himself; and he observed, that it was better that one man should die than that all should be involved in ruin on account of his obstinacy. His nephew was much affected, and feared exceedingly the anger and haughtiness of the conqueror; but Otho comforted him, and observed, that Vitellius would be kind and affec-

tionate to the friends and relations of Otho, since Otho was not ashamed to say, that in the time of their greatest enmity the mother of Vitellius had received every friendly treatment from his hands. He also burnt the letters which, by falling into the hands of Vitellius, might provoke his resentment against those who had favoured the cause of an unfortunate general. These noble and humane sentiments in a man who was the associate of Nero’s shameful pleasures, and who had stained his hand in the blood of his master, have appeared to some wonderful, and have passed for the features of policy, and not of a naturally virtuous and benevolent heart. His father was a favourite of Claudius.

OTHO, a tribune of the people, who, in Cicero’s consularship, made a regulation to permit the Roman knights at public spectacles to have the 14 first rows after the seats of the senators. This was opposed with virulence by some, but Cicero ably defended it, &c.

OTHO, Venius, a very celebrated Dutch painter. He was descended of a considerable family in Leyden, and was born in 1556. He was carefully educated by his parents in the belles lettres, and at the same time learned to design of Isaac Nicholas. He was but 15 when the civil wars obliged him to leave his country. He retired to Liege, finished his studies, and there gave the first proof of the excellence of his mind. He was well known to Cardinal Groesbeck, who gave him letters of recommendation where he went to Rome, where he was entertained by Cardinal Madduccio. His genius was so active, that he applied himself to philosophy, poetry, mathematics, and painting, all at once. He became a great proficient in designing under Frederic Zuccaro. He acquired an excellence in all the parts of painting, especially in the knowledge of the claro-obscuro; by which means he came to be accounted one of the most ingenious men of his age. He lived at Rome seven years, during which time he performed several rare pieces; and then passing into Germany, was received into the service of the emperor. After this the duke of Bavaria and the elector of Cologne employed him; but all the advantages he got from the courts of foreign princes could not detain him there. He had a desire to return into the Low Countries, of which Alexander Farnese, prince of Parma was then governor. He drew the prince’s picture, armed cap-a-pie, which confirmed his reputation in the Netherlands. After the death of that prince, Venius returned to Antwerp, where he adorned the principal churches with his paintings. The archduke Albert, who succeeded the prince of Parma in the government of the Low Countries, sent for him to Brussels, and made him master of the mint, a place which occupied much of his time, yet he found some time for the exercise of his profession. He drew the archduke and the infant Isabella’s portraits at large, which were sent to James L of Great Britain: and, to show his knowledge of polite learning likewise, he published several treatises, which he embelliished with cuts of his own designing. Louis III. made him very great offers to tempt him into his service; but he would never leave his own country, satisfying himself with the character and employments he held there. He was the first, after Polydore Caravaggio, who reduced the claro-obscuro to a principle of the art of painting. Rubens perfected what he began, and the whole Flemish school
learned it of him. Venius died at Brussels, 1634, in his 78th year. He had two brothers, Gilbert, who was a graver, and Peter a painter. He had also the honour of breeding up the famous Rubens in his art.

OTHONNA, a genus of plants belonging to the syngenesia class; and in the natural method ranking under the 40th order, Compositae. See Botany Index.

OTHRYADES, one of the 300 Spartans who fought against 300 Argives, when those two nations disputed their respective right to Thryestata. Two Argives, Alcinor and Cronius, and Othryades, survived the battle. The Argives went home to carry the news of their victory; but Othryades, who had been reckoned among the number of the slain on account of his wounds, recovered himself, and carried some of the spoils of which he had stripped the Argives into the camp of his countrymen; and after he had raised a trophy, and had written with his own blood the word urgi on his shield, he killed himself, unable or unwilling to survive the death of his countrymen.

OTIS, a genus of birds belonging to the order of gallinæ. See Ornithology Index.

OTLEY, a town of England, in the west riding of Yorkshire, under a cliff called Chevin, on the south side of the river Wharfe. The adjacent parts are reeked the most delightful in England. Its church has lately been embellished by a number of old monuments. The adjacent country is much improved, and from the Chevin is a most beautiful view of an extensive scope of undescended mansions. This manor was given by Athelstan to the see of York, whose archbishop had a palace here, with several extensive privileges. There is a free grammar school in this place, founded by Mr Cave, 1611, called Prince Henry’s School. In 1811 the inhabitants amounted to 2622. In 1673, it suffered much by an inundation; which carried away several bridges, mills, &c. as well as much corn, &c. W. Long. 1. 50. N. Lat. 53. 54.

OTODINI, ancient Britons, seated, as some suppose, to the north-east of the Brigantes, in the countries now called Northumberland, Merse, and the Lothians. As the Otodini are not mentioned by any of the Roman historians, but only by Ptolemy, it is uncertain whether they formed a distinct independent state, or were united with the Brigantes. They were however, a considerable people, and possessed a long tract of the sea-coast, from the river Tama to the frith of Forth. Their name is derived by Baxter from the old British words Ot ou dineu, which signify “a high and rocky shore;” descriptive enough of their country. They were probably reduced by Agricol at the same time with their more powerful neighbours the Brigantes; but as they lived without the wall of Severus, they were, like the rest of the Meatie, engaged in frequent revolts. In the most perfect state of the Roman government in this island, the country of the Otodini made a part of the Roman province called Valentinia; which comprehended all that large tract between the two walls. As this province was never long together in the peaceable possession of the Romans, they had but few stations in the country of the Otodini, except those on the line of the wall of Severn.

Various authors have derived the name of this people in various ways, and it is very differently spelled; and various opinions still seem to be entertained among the learned respecting their real situation: and it is even doubtful whether their country was in England or in Scotland. The celebrated Drummond of Hawthornden contends for the latter.

OTRANTO, or TERRA D’OTRANTO, a province of Italy in the kingdom of Naples; bounded on the north by the Terra di Bari and by the gulf of Venice, on the east by the same gulf, and on the south and west by a great bay which is between that and the Basilicata. It is a mountainous country, abounding in figs, olives, and wine. It is often visited by locusta, and by Algerine pirates, who carry off all the people they can catch into slavery. But to keep them off, there are a great many forts on the coasts.

OTRANTO, a city of Italy, in the kingdom of Naples, and capital of the province of the same name, with a commodious harbour, an archbishop’s see, and a strong citadel, where the archbishop resides. Mr Swinburne gives this account of it: “It is (says he) small, stands on a hill, and contains only 3000 inhabitants. Its little harbour is not so bad but it might induce more people to settle here, as no port on the coast lies so convenient for traffic with Greece. The Atheus is here but 60 miles wide. I climbed to the top of a tower to get a sight of the Acrocoriassian mountains; but a vapour hanging over the sea, along the horizon, hid them from my view: in a clear morning, their snowy tops are said to be very visible. The cathedral of Otranto is Gothic, and, according to the Puglian fashion, has its subterraneous sanctuary. The columns are of beautiful marble and granite; the pavement, a rude species of mosaic, commonly called Saracenis: As it is to be met with in all churches founded by the Norman kings of Sicily, the artists who laid it were probably Saracens, or at least Greeks, their scholars. These mosaics are composed of pieces of porphyry, serpentine, and cubes of gilt glass,—disposed in stars, circles, or chequers. The compartments of the stalls are bordered with them; and the small twisted columns, which support the pulpits and canopies, are ornamented with a spiral strip of the same work. It is a pity so much durability, compactness, and beauty of materials, should have been lavished on such barbarous designs. Otranto was a Roman colony, as certified by an inscription, almost the only monument of antiquity left there (A). In the 10th century it was made an archbishop’s see. In 1480, Laurence de Medici, to deliver himself from the attacks of the king of Naples, persuaded Mahomet II. to invade the realm; and Otranto was the unfortunate place where the Turks landed. It was invested, stormed, and pillaged. The prelate was slain at the door of his church; 800 principal citizens dragged out of the gates and butchered; their bodies left 12 months unburied, till the duke of Calabria retook the city, and committed them to hollowed earth. About 100 years after, a devout person affirmed, that these bones had appeared to him in a dream;
OTW

OTW

dream; and, upon the strength of his vision, they became, for the vulgar, objects of almost equal veneration with the relics of the primitive martyrs."

OTRICOLI, a small town in Italy, in the ecclesiastical state, and in the duchy of Spoleto, in E. Long. 12° 23'. N. Lat. 42° 26'. situated on a rising ground on the frontiers of the patrimony of St Peter. From this town is seen a fine plain, and some of the windings of the famous river Tiber. The ruins that are scattered here and there at the entrance of the plain, descending from Otricoli, are thought to be the remains of the ancient Otricolum; they consist of some shapeless fragments of columns, cornices, and other pieces of marble. In the middle of the great streets of Otricoli, there is a marble pedestal, upon which you see an inscription, showing they had erected a statue to Julia Lucilla, who had built public baths at Otricoli at her own expense.

OTTEN. See Mustela, Mammalia Index.

Otter of Rome. See Rosell.

OTTERBURN, in England, near Elland, in the county of Northumberland, was the field of battle between the English and Scots in 1388, wherein Henry Percy, called Hotspur, was taken prisoner, and Douglas the Scotch general was killed. On this battle was founded the delightful old ballad of Chevy chase; the village being situated by the river Rheid, on the south side of the Cheviot hills. The entrenchments are still visible; and a number of tumuli scattered over the adjacent ground mark to future ages the slaughter made there.

OFFTERY, St Mary's, a market town in Devonshire, situated 150 miles west of London, and 10 miles east of Exeter. The church is very ancient, and somewhat resembles a cathedral. A very extensive woollen manufactory was lately established here by Sir George Yonge, and Sir John Dunstoe, Barts. It has no corporation. It derived its name, as some suppose, from the river Otter, and that from the otters formerly found in it. This town was given by King Edward the Confessor to the church of St Mary at Rouen in Normandy; but was afterwards bought by Grandison bishop of Exeter; who made of it a quarter college in 16 Edward III. and therein placed secular priests, with other ministers, to whom he gave the whole manor, parish tythes, tithes, spiritual profits, &c. which amounted to 304l. 2s. rod. yearly. The population in 1811 was 2880.

OTWAY, Thomas, an eminent tragic poet, was the son of Mr Humphry Otway, rector of Wolbeding in Sussex; and was born at Trotton in that county on the 3d of March 1651. He was educated at Oxford; and, leaving the university without a degree, he retired to London, where he commenced player, but with indifferent success. However, the enlightening of his conversation gained him the favour of Charles Fitz-Charles, earl of Plymouth, who procured him a warrant's commission in one of the new raised regiments sent into Flanders; but he returned from thence in very necessary circumstances, and applied himself again to writing for the stage. In comedy he has been deemed too licentious; which, however, was no great objection to his pieces in the prodigal days of Charles II. But, in tragedy, few English poets have ever equalled him; and perhaps none ever excelled him in touching the passions, particularly the tender passion. There is generally something familiar and domestic in the style of his tragedies, and there is amazing energy in his expression.—The heart that doth not melt at the distresses of his Orphan must have a hard heart! But though Otway possessed in so eminent a degree the rare talent of writing to the heart, yet he was not very favourably regarded by some of his cotemporary poets, nor was he always successful in his dramatic compositions. After experiencing many reverses of fortune in regard to his circumstances, but generally changing for the worse, he at last died wretchedly in a public house on Tower-hill; 'whither, it is supposed, he had retired, in order to avoid the pressure of his creditors. Some have said, that downright hunger compelling him to fall too eagerly on a piece of bread, of which he had been for some time in want, the first mouthful choked him, and instantly put an end to his days. Dr Johnson gives this account of the matter: "He died in a manner which I am unwilling to mention. Having been compelled by his necessities to contract debts, and hunted, as is supposed, by the terriers of the law, he retired to a public house on Tower-hill, where he died of want; or, as it is related by one of his biographers, by swallowing, after a long fast, a piece of bread which charity had supplied. He went out, as is reported, almost naked, in the rage of hunger, and finding a gentleman in a neighbouring coffee-house, asked him for a shilling. The gentleman gave him a guinea; and Otway going away bought a roll, and was choked with the first mouthful. All this, I hope, is not true; but that indigence, and its concomitants, sorrow and despondency, brought him to the grave, has never been denied."

Johnson speaks of him in nearly these terms: Otway had not much cultivated versification, nor much replenished his mind with general knowledge. His principal power was in moving the passions, to which Dryden in his latter years left an illustrious testimony. He appears, by some of his verses, to have been a zealous royalist; and had what was in those times the common reward of loyalty; he lived and died neglected. His dramatic writings are nine in number; the most admired of which are, The Orphan, and Venice Preserved. He had also made some translations, and wrote several miscellaneous poems. His whole works are printed in two pocket volumes. He wrote four acts of a play which are lost.

OVAL, an oblong curvilinear figure, otherwise called ellipsis. (See Ellipsis.) However, the proper oval, or egg shape, differs considerably from that of the ellipsis, being an irregular figure, narrower at one end than at another: whereas the ellipsis or mathematical oval, is equally broad at each end; though it must be owned, these two are commonly confounded together; even geometerian calling the oval a false ellipsis.

OVARY, in Anatomy, that part of a female animal wherein the ova or eggs are formed or lodged. See Anatomy, No. 111.

OVARIAL, in Botany, a name by which botanists who are fond of assimilating the animal and vegetable kingdoms have distinguished the germen or seed bud, as containing the rudiments of the future ovary.

OVATION, in the Roman antiquity, a lesser triumph, allowed to commanders for victories won without the effusion of blood; or for defeating a mean and insconsiderable enemy. The show generally began at the Alban mountan, whence the general with his retinue.
OVE [ 606 ] OVE

Ovation

Overall.

The term *ovation*, according to Servius, is derived from *ovis*, a “sheep”; because on this occasion the conqueror sacrificed a sheep, as in a triumph he sacrificed a bull. The senate, knights, and principal plebeians, assisted at the procession; which concluded at the Capitol, where more were sacrificed to Jupiter. The first ovation was granted to Publius Posthumus, for his victory over the Sabines in the 235th year of Rome.

OUEDE, a province of Hindostan Proper, subject to a nabob, whose dominions lie on both sides of the Ganges, occupying the flat country between that river and the northern mountains, as well as the principal part of that fertile tract, lying between the Ganges and Jumna, to within 40 miles of the city Delhi. Oude is about 250 miles in length, by 100 miles in breadth. It is flat, well watered, and fertile in wheat, barley, rice, sugar-canes, indigo, and poppies. The inhabitants are tall, strong, and warlike. Since 1765, a British force has been stationed in the nabob’s territories, and paid by him. But from the disorderly state of the nabob’s government and finances, it was thought proper, in 1801, to put a great part of the country under the immediate government of the Company, and to relieve the nabob from all pecuniary claims. The gross revenue of the districts ceded, amounted to 13,523,474 Sicca rupees. Oude is also the name of a large town in this province. Lucknow is the capital.

OUDENARDE, a rich and strong town, in the kingdom of the Netherlands, in the province of Flanders, in E. Long. 3° 30', N. Lat. 50° 54'. Fifteen miles south of Ghent, and eighteen from Tournay. It is a large well fortified town, having a very considerable fort in the middle of it, situated on the river Scheldt, which divides it into two parts. It is almost encompassed by meadows, only there is a hill which commands it on the south side. The buildings are pretty good, the streets wide and handsome, and it contained 4000 inhabitants in 1800. The market-place is adorned with a beautiful town-house, and a fine large fountain. There are several good churches and monasteries well worthy of the notice of travellers. The town has a trade in fine linen and tapestry, and is the capital of a castellany, which contains 33 villages. The French laid siege to it in 1708, which brought on an obstinate engagement, wherein they were defeated by the allies under the command of the duke of Marlborough. It was taken by the French in 1794, and remained under their power till 1814.

OVEN, a kind of domestic furnace, used for baking bread, pies, tarts, &c. of a circular structure, with a very low roof, well lined, both on the top, bottom, and sides, with stone; it has a small entrance in the front, fitted with a door, which being clapped to the mouth of the oven confines the heat, while bread, pies, or puddings, are baking. Over this, pastry cook have another oven built much in the same manner, which is used for such things as require a less degree of heat. Ovens are heated by burning dry wood, faggots, &c. in them, till all the parts are equally hot.

OVERALL, John, a celebrated English bishop, was born in 1559; and, after a proper foundation in grammar learning, was sent to St John’s college, Cambridge, and was elected a scholar of the society: but afterwards removing to Trinity, was chosen fellow of that college. In 1596 he was made regius professor of divinity, when he took the degree of D.D. and about the same time was elected master of Catherin-hall. In 1601 he was raised to the deanery of St Paul’s, London, by the recommendation of his patron Sir Fulke Greville, and Queen Elizabeth; and in the beginning of King James’s reign, he was chosen proctor of the lower house of convocation. In 1612 he was appointed one of the first governors of the Charter-house hospital, then just founded by Thomas Sutton, Esq. In April 1614 he was made bishop of Litchfield and Coventry; and in 1618 he was translated to Norwich, where he died in May 1619, aged, as it is reported, 60 years. He was buried in that cathedral, where he lay unnoticed and forgotten till some time after the restoration of Charles II. when Cosin, bishop of Durham, who had been his secretary, erected a monument in 1669, with a Latin inscription, in which he is said to be, "Vir undequaque docchissimus, et omni incoequo major."

Wood observes, that he had the character of being the best scholastic divine in England; and Cosin, who perhaps may be thought to rival him in that sort of learning, calls himself his scholar, and absolutely says that he derived all his knowledge from him. He is also celebrated by Smith for his distinguished wisdom, erudition, and piety. In the controversy which in his time divided the church of England concerning predestination and grace, he held a middle opinion, inclining perhaps to Arminianism. He seems indeed to have paved the way for the reception of that doctrine in England, where it was generally embraced a few years afterwards, chiefly by the authority and influence of Archbishop Laud. Overall cultivated a particular friendship with Gerard Vossius and Grotius; and was much grieved to see the love of peace, and the projects of this last great man to obtain it, so ill repaid. He laboured heartily himself to settle the differences in Holland, upon what is known by the name of the Quinquagirturth controversy; as appears in part by his letters to the two learned correspondents just mentioned, some of which are printed in the Epistolae praestantium viorum, &c.

The bishop is known in England chiefly by his Convocation Book, of which Bishop Burnet gives the following account: "This book was wrote on the subject of government, the divine institution of which was very positively asserted. It was read in convocation, and passed by that body, in order to the publishing of it; in opposition to the principles laid down in the famous book of Parsons the Jesuit, published under the name of Doleman. But King James did not like a convocation entering into such a theory of politics; so he discouraged the printing of it, especially since, in order to justify the owning of the United Provinces, who had lately thrown off the Spanish yoke, to be a lawful government, it was laid down, that when a change of government was brought to a thorough settlement, it was then to be owned and submitted to as a work of the providence of God. Here it slept, till Archbishop Sancreft, who had got the book into his own hands, and not observing the last-mentioned passage in it, resolved to publish it in the beginning of King William's reign, as an authentic declaration the church of England had made in the point
Sir Thomas the secrets, but many times gave him the packets and letters unopened, before they had been perused by the king himself: which as it prevailed too much upon his early years, so as to make him, in the opinion of some, thought high and ambitious; yet he was so far from violating his trust and confidence, that he remains now one example among others who have suffered in their persons or their fortunes for a freedom of advice, which none but sincere friends will give, and which many are such ill friends to themselves as not to receive."

**OVER-HEAVING**, the act of opening and extending the several parts of a tackle, or other assemblage of ropes, communicating with blocks or dead eyes. It is used to remove those blocks to a sufficient distance from each other, that they may be again placed in a state of action, so as to produce the effect required. **OVER-HEAVING** is also vulgarly expressed of an examination or inspection into the condition of a person or thing.

**OVER-RAKE**, among seamen: When a ship riding at anchor so oversteers herself into a high sea, that she is washed by the waves breaking in upon her, they say the waves over-rake her.

**OVERSOMAN**, in **Scots Law**, a person appointed by arbiters, or by the parties submitters, to determine the matter submitted, in case the arbiters disagree in their opinion.

**OVERT**, the same with **OPEN**: Thus an overt act signifies an act which, in law, must be clearly proved; and such is to be alleged in every indictment for high treason.

**OVERTURE, or OUVERTURE**, opening or preluding: a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, comedy, concert of music, &c. The overture of the theatre or scene, is a piece of music usually ending with a fugue: the overture of a jubilee is a general procession, &c.

**OVERYSSEL**, one of the Seven United Provinces, so named from its situation beyond the river Yssel, bounded on the east by the bishopric of Munster, on the north by Friesland and the territory of Groningen, on the west by the river Yssel, and on the south by the county of Zutphen and the bishopric of Munster. It is divided into three distinct parts; which are the territories of Drense, Twente, and Salland. There are many morasses in this province, and but few inhabitants, in comparison of the rest. Its greatest riches consist in turf; which are dug up here, and sent to the neighbouring provinces, particularly Holland. It extends near 60 miles in length from north to south, and 40 in breadth from east to west. The whole country is low and marshy, but it produces a tolerable quantity of corn. It was formerly a dependence of the bishopric of Utrecht, before Henry of Bavaria, bishop of that see, transferred the sovereignty of it to the emperor Charles V.

**OVIEDA**, a genus of the aquagermaceae order, belonging to the didynasia class of plants; and in the natural method ranking under the 40th order, **Personatae**. See **Botany Index**.

**OVIEDO**, a town of Spain, and capital of Asturias d'Oviedo, with a bishop's see, and an university; and containing about 7500 inhabitants. It is seated at
the confluence of the rivers Ove and Deva, which form the Asta, 50 miles north-west of Leon, and 208 north-west of Madrid. W. Long. 5. 47. N. Lat. 43. 23.

OUGHTRED, WILLIAM, an eminent mathematician, was born at Eton in 1573, and educated in the school there, whence he was elected to King’s-college in Cambidge, of which he afterwards became fellow. He left Cambridge to take holy orders, and left the university about the year 1629, and was presented to the rectory of Aldbury, near Guildford in Surry; and about the year 1628 was appointed by the earl of Arundel to instruct his son in the mathematics. He kept a correspondence by letters with some of the most eminent scholars of his time upon mathematical subjects; and the most celebrated mathematicians of that age owed most of their skill to him, whose house was full of young gentlemen that came from all parts to receive his instruction. It is said that, upon hearing the news of the vote at Westminster for the restoration of King Charles II. he expired in a sudden transport of joy, aged 88. He wrote: 1. Clavis Mathematica; which was afterwards published in England. 2. A description of the double horizontal dial. 3. Opuscula Mathematica; and several other works. He left also behind him a great number of papers upon mathematical subjects, which are now in the museum of William Jones, Esq. F. R. S.

David Lloyd, in his Memoirs, has given the following short character of him: “That he was as facetious in Greek and Latin, as solid in arithmetic, geometry, and the sphere of all measures, music, &c. exact in his style as in his judgment; handling his tube and other instruments at 80 as steadily as others did at 30; owing this, as he said, to temperance and archery; principling his people with plain and solid truths, as he did the world with great and useful arts; advancing new inventions in all things but religion, which, in its old order and decency, he maintained secure in his privacy, prudence, meekness, simplicity, resolution, patience, and contentment.” He had one son; whom he put an apprentice to a watchmaker, and wrote a book of instructions in that art for his use.

OVID, or Publius Ovidius Naso, a celebrated Latin poet of the Augustan age, was a Roman knight, born at Sulmo, in the 43rd year before the Christian era. He studied rhetoric under Aurelius Fuscus, and for some time frequented the bar. His progress in the study of eloquence was great, but the father’s expectations were frustrated; his son was born a poet, and nothing could deter him from pursuing his natural inclination to write poetry, though he was often reminded that Homer lived and died in the greatest poverty. Everything he wrote was expressed in poetical numbers, as he himself says, Et quod tentabam scribere versus erat. A lively genius and a fertile imagination soon gained him admirers; the learned became his friends: Virgil, Propertius, Tibullus, and Horace, honoured him with their correspondence, and Augustus patronized him with the most unbounded liberality. These favours, however, were but momentary; for after having obtained the esteem of Augustus, he incurred his displeasure, and was banished to Tomos, a city on the Poetus Euusus, near the mouth of the Daubier, when he was 5 years of age. The true cause of this sudden exile is unknown. Some attribute it to a shameful amour with Livia the wife of Augustus, while others suppose that it arose from the knowledge which Ovid had of the unpardonable incest of the emperor with his daughter Julia. These reasons are indeed merely conjectural; the cause was of a very private and very secret nature, of which Ovid himself is afraid to speak. It was, however, something improper in the family and court of Augustus, as these lines seem to indicate:

Cur aliquid vidi? Cur nescia termina faci?
Cur imprudent cognita culpa mihi est?
Insinctus Actaeon vidi sine veste Dianam,
Pravus fuit canibus non minus ille nuis.

And in another place,

Perderunt cum me duo criminis, carmen et error,
Alterius facta culpa silenda mihi est.

In his banishment, Ovid betrayed his pusillanimity in a great degree; and however affecting and distressed his situation was, yet the flattery and impatience which he showed in his writings are a disgrace to his pen, and lay him more open to ridicule than to pity. Though he prostituted his pen and his time to adulation, yet the emperor proved deaf to all entreaties, and refused to listen to his most ardent friends at Rome who wished for his return. Ovid, who really wished for a Brutus to deliver Rome of her tyrannical Augustus, still continued his flattery even to meanness; and when the emperor died, he was so mercenary as to consecrate a small temple to the departed tyrant on the shore of the Exuine, where he regularly offered frankincense every morning. Tiberius proved as regardless as his predecessor to the entreaties which were made for the poet, and he died in the seventh or eighth year of his banishment, in the 77th year of his age. He was buried at Tomos. In the year 1508 of the Christian era, the following epitaph was discovered at Stain, in the modern kingdom of Austria.

Hic situs est vates quem Divi Caesaris ira,
Augusti patria cedere jussit homo.
Sepulcral voluit patriae occumebere terris,
Sed frustra: hanc ibi fata dedere locum.

This, however, is an imposition to render celebrated an obscure corner of the world, which never contained the bones of Ovid. The greatest part of his poems are remaining. His Metamorphoses, in 15 books, are extremely curious, on account of the great variety of mythological facts and traditions which they relate, but they can have no claim to epic honours. In composing this the poet was more indebted to the existing traditions, and to the theology of the ancients, than the powers of his own imagination. His Fasti were divided into 12 books, like the constellations in the zodiac, but of these six are lost; and the learned world have reason to lament the loss of a poem which must have thrown so much light upon the religious rites and ceremonies, festivals and sacrifices, of the ancient Romans, as we may judge from the six that have survived the ravages of time and barbarity. His Tristia,
OVID, John Gonzalvez de, born at Madrid about the year 1475, was educated among the pages of Ferdinand king of Arragon and Isabella queen of Castile; and happened to be at Barcelona in 1493, when Christopher Columbus returned from his first voyage to the island Haiti, which he called Hispaniola, and which now goes by the name of St Domingo. He formed an intimate acquaintance with Columbus and his companions, and was at pains to inform himself of every thing relating to the new discoveries. He rendered such essential service to Spain during the war of Naples, that Ferdinand determined to send him to the land of the ti, as intendant and inspector general of the trade of the New World. The ravages which the venereal disease had made during that war, induced him to inquire into what were the most efficacious remedies for this malady, which was supposed to have come from the West Indies. His inquiries were extended to every thing which regards the natural history of these regions; and, on his return to Spain, he published Summario de la Historia general y natural de las Indias Occidentales, which he dedicated to Charles V. He afterwards made some additions to this work, which he published under the title of La Historia general y natural de las Indias Occidentales; Salamanca, 1555, folio. It was translated into Italian, and afterwards into French; Paris, 1566, folio. In this work, Oviedo says that the French pox is endemic in the island of Haiti, and that it has passed from thence into Europe. He greatly extols the use of the wood of guaiacum for the cure of this disease; but whether the disease is now become more obtuse, or the remedy does not possess that efficacy which is ascribed to it, it is at present in little estimation.

OVILIA, or SEPTA, in ancient Rome, a place in the Campus Martius, at first railed in like a sheep- pen, whence its name. Afterwards it was mounted with marble, and beautified with walks and galleries, as also with a tribunal or seat of justice. Within this precinct or inclosure the people were called to give their suffrages for the election of magistrates. The ascent into the ovilia was not by stairs, but by pontes, or narrow boards, laid there for the occasion; on which account, de ponte dejicii signifies "to be deprived of the privilege of voting;" and persons thus dealt with were called depontanii.

OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, the SHEEP, a genus of the mammalia class, and of the order of Pecora. See Mammalia Index.

OUNCE, a weight, the 16th part of a pound avoirdupois, and the 12th part of a pound Troy. The word is derived from the Latin, uncia, "the twelfth part of any whole," called as; particularly in geometrical measures, an inch, or 12th part of a foot. See INCH and FOOT.

OUNCE. See Felis, Mammalia Index.

OVOLI, or Ovum, in Architecture, a round masonry, whose profile or sweep, in the Ionic and Composite capitals, is usually a quadrant of a circle: whence it is also commonly called the quarter-rounded. It is usually cut with representations of eggs and arrow-heads or anchors placed alternately.

OU-poe-tier, a name given by the Chinese to a kind of nests made by certain insects upon the leaves and branches of the tree called per-fen-tiec. These nests are much used in dyeing, and the physicians employ them for curing many distempers. Some of these nests were brought to Europe, and put into the hands of the celebrated Mr Godfrey. After having examined them with the utmost attention, this learned academician thought he perceived some conformity in them to those excrescences which grow on the leaves of the elm, and which the vulgar call elm-bladders; he found these nests so sharp and astrigent to the taste, that he considered them as far superior to every other species of galls used by the dyers. According to him, they are the strongest astringents existing in the vegetable kingdom.

It is certain that there is a great affinity between the ou-poe-tier and the elm-bladders. The form of both is unequal and irregular; they are covered on the outside with a short down, which renders them soft to the touch; within they are full of a whitish-gray dust, in which may be observed the dried remains of small insects, without discovering any aperture through which they might have passed. These nests or bladders harden as they grow old; and their substance, which appears resinous, becomes brittle and transparent; however, the Chinese de
not consider the ou-poey-tse, notwithstanding their resemblance to elm-bladders, as excrescences of the tree yen-fou-tse, upon which they are found. They are persuaded, that insects produce a kind of wax, and construct for themselves on the branches and leaves of this tree (the sap of which is proper for their nourishment) little retreats, were they may wait for the time of their metamorphosis, or at least deposit in safety their eggs, which compose that fine dust with which the ou-poey-tse is filled. Some of the ou-poey-tse are as large as one's fist; but these are rare, and are generally produced by a worm of extraordinary strength, or which has associated with another, as two silk worms are sometimes seen shut up in the same ball. The smallest ou-poey-tse are of the size of a chestnut; the greater part of them are round and oblong; but they seldom resemble one another entirely in their exterior configuration. At first, they are of a dark green colour, which afterwards changes to yellow; and the husk, though pretty firm, becomes then very brittle.

The Chinese peasants collect these ou-poey-tse before the first hoar-frost. They take care to kill the worm inclosed in the husks, and to expose them for some time to the steam of boiling water. Without this precaution, the worm might soon break through its weak prison, which would immediately burst and be useless. The ou-poey-tse are used at Pekin for giving paper a durable and deep-black colour; in the provinces of Kiang-nan and Tche-kiang, where a great deal of beautiful satin is made, they are employed for dying the silk before it is put on the loom. The Chinese literati also blacken their beards with them when they become white.

The medicinal properties of the ou-poey-tse, are very numerous. The Chinese physicians introduce them into the composition of many of their remedies. They recommend them for stopping bleedings of every kind; they consider them as an excellent specific for curing inflammations and ulcers, and for counteracting the effects of poison; and they employ them with success in the dropsy, phthisis, epilepsy, catarrh, sickness, fluxions of the eyes and ears, and in many other disorders.

GREATER OUSE, a river which rises near Fitwell in Oxfordshire, and proceeds to Buckingham, Stony-Stratford, and Newport-Pagnel, in Buckinghamshire; from thence it proceeds to Bedford, and turning north-east it passes on to Huntingdon and Ely, till at length it arrives at Lynn-Regis in Norfolk, and falls into the sea. It is navigable to some distance above Downham, where there is a good harbour for barges; and a considerable trade is carried on by it to Lynn and other towns.

Smaller OUSE, rises in Suffolk, and, separating that county from Norfolk on the south-west, discharges itself into the great Ouse near Downham. There is still another of the same name, which rises in the west north-west side of Yorkshire; and chiefly running to the south-east, at length falls into the Humber.

OUSTER, or DISPOSSESSION, in Law, an injury which carries with it the amotion of possession; for by means of it the wrong does get into the actual possession of the land or hereditament, and obliges him that hath a right to seek a legal remedy, in order to gain possession, together with damages. This ouster may either be of the freehold by abatement, intrusion, disseisin, discontinuance, and defacement; or of chattels real, as an estate by statute-merchant, statute-staple, or elegit, or an estate for years.

OUSTER le Mains, amovere manum, in Law, denotes a livery of lands out of the king's hands; or a judgement given for him that traversed, or sued, a monstrum le dritt. When it appeared, upon the matter being discussed, that the king had no right or title to the land seized, judgment was given in chancery, that the king's hand be amov'd; and ouster le main or amovere manum, was therefore awarded to the escheator, to restore the land, &c. All wardsheips, liveneries, ouster le mains, &c. are now taken away and discharged by statute 12 Car. II.

OUSTIOUG, a town of the Russian empire, and capital of a province of the same name, with an archbishop's see and a castle; seated on the river Suchana, over against the mouth of the Jug, in E. Long. 43. 25. N. Lat. 61. 48.

OUSTIOUG, a province of the Russian empire, bounded on the north by Dwina, on the east by the forest of Zirani, on the south by Wologda, and on the west by Cargapol and Waga. It is divided into two parts by the river Suchana; is full of forests; and the rivers yield plenty of fish, which the inhabitants dry in the sun, and which make their principal nourishment.

OUT-POSTS, in a military sense, a body of men posted beyond the grand-guard, called out-posts, as being the rounds or limits of the camp.

OUTLAW, signifies one that is deprived of the benefit of the law, and therefore held to be out of the king's protection.

Bracton asserts, that an outlaw forfeits all he has; and that, from the time of his outlawry, he wears a wolf's head; and anybody may kill him with impunity, especially if he defend himself or fly... But in Edward III.'s time it was resolved by the judges, that it should not be lawful for any man, but the sheriff alone (having sufficient warrant for it), to put to death a man that was outlawed.

OUTLAWRY, the punishment of a person who being called into law, and lawfully, according to the usual forms, sought, does contemnuously refuse to appear.

The effect of being outlawed at the suit of another, in a civil cause, is the forfitude of all the person's goods and chattels to the king, and the profits of his land, while the outlawry remains in force. If in treason or felony, all the lands and tenements which he has in fee, or for life, and all his goods and chattels, are also forfeited, and besides, the law interprets his absence as a sufficient evidence of guilt; and without requiring further proof, accounts the person guilty of the fact, on which ensues corruption of blood, &c. And then, according to Bracton, he may perish without law, &c. However, to avoid inhumanity, no man is entitled to kill him wantonly or wilfully; but in so doing he is guilty of murder, unless it happens in endeavouring to apprehend him; for anybody may arrest an outlaw, either of his own head, or by writ or warrant of capias ulcgatum, in order to bring him to execution.

If after outlawry in civil cases, the defendant publicly appear, he is to be arrested by a writ of capias ulcgatum, and committed till the outlawry be reversed; which reversal may be had by the defendant's appearing in court (and in the king's-bench, by sending an attorney, according to statute 4 and 5 W. and M. cap. 18.) and
OWEN, THOMAS, a judge of the common-pleas, son of Richard Owen, Esq. of Condover in Shropshire, was educated at Oxford. Having taken a degree in arts, he left the university, and entered himself of Lincoln's inn in London, where in process of time he became an eminent counsellor. In 1583 he was elected Lent-reader to that society. In 1590 he was made serjeant at law, and queen's serjeant soon after. He arrived at length at the dignity of judge of the common-pleas; which office he is said to have executed, during five years, with great abilities and integrity. He died in 1598; and was buried on the south side of the choir in Westminster abbey, where a monument was erected to his memory. He was the reputation of a learned man, and a patron of literature. He was the author of "Reports in the common pleas, wherein are many choice cases, most of them thoroughly argued by the learned serjeants, and after argued and resolved by the grave judges of those times, with many cases wherein the differences of the year-books are reconciled and explained." Lond. 1656, folio.

OWEN, Dr John, an eminent and learned dissenting minister, was born in 1616, at Hadham, in Oxonshire, of which place his father was vicar. He made this surprising proficiency in learning, that at twelve years of age he was admitted into Queen's college, Oxford, and in 1635 was made master of arts: but soon after, disapproving the new regulations made by Archbishop Laud their chancellor, with which he refused to comply, he was obliged, in 1737, to leave the university: when taking orders, he became chaplain to Sir Robert Dormer of Ascot in Oxfordshire, and was at the same time tutor to his eldest son. He was afterwards chaplain to John Lord Lovelace of Hurley in Berkshire. When the civil war broke out, he openly avowed the cause of the parliament; which was so resented by an uncle who had intended to leave him his estate, that he discarded him, and left it to another. Yet though Lord Lovelace joined the king, he treated his chaplain with great civility; but on his taking the field with the royal army, Mr Owen went to London, and soon after joined the non-conformists. In 1642 he published his book, intitled, A Display of Arminianism, which laid the foundation of his future advancement: for the committee for purging the church of scandalous ministers were so pleased with it, that Mr White their chairman sent him a presentation of the living of Fordham in Essex: but when he had been there about a year and a half, the patron hearing that the sequestered incumbent was dead, presented another to the living; upon which the earl of Warwick gave Mr Owen the living of Coggeshal. He had not, however, been long at that town before he left the Presbyterians; and, joining the Independents, formed a church there. He was now sent for several times to preach before the parliament; and among the rest on the 28th of February 1648-9, the day of humiliation for the intended expedition to Ireland. Cromwell, who was present at this last discourse, and had never heard him before, was extremely pleased with it, and desired his company into Ireland, and that he would reside in the college of Dublin. This he did; but returned in about half a year. Soon after Cromwell sent him into Scotland; but he also returned from there after about a year's stay at Edinburgh. He was then promoted to the deanship of Christ-church, Oxford, whither he went in 1651; and Cromwell, being now chancellor of the university, nominated him his vice-chancellor. The next year he was created doctor of divinity by diploma. Dr Owen enjoyed the post of vice-chancellor five years; during which he behaved with the greatest moderation; for, though often solicited, he never molested the meeting of the royalists at the house of Dr Willis the physician, where divine service was performed according to the liturgy of the church of England: and though he was a commissioner for ejecting scandalous ministers, he frequently overruled his brethren in favour of those royalists who were distinguished by their merit. At the death of Cromwell, he was removed from the vice-chancellorship; and at the Restoration was ejected from his deanship of Christ-church. But he had provided himself a comfortable retreat at an estate he had purchased at Hadham. He now employed himself in preaching as often as he had an opportunity, and in writing books; one of which, intitled Fasti Lux, falling into the hands of Lord Clarendon, he was so pleased with it, or (as is said) from policy pretended to be so, that he sent for Dr Owen, and acknowledging the service he had done by it to the Protestant religion, offered to prefer him in the church if he would conform; but he desired to be excused.—His moderation drew him respect from persons of opposite principles; and in the number of his friends were Dr Wilkins bishop of Chester, and Dr Barlow bishop of London. He died at Ealing in 1683. His works are printed in seven volumes folio.

Wood, after censuring him in many respects, says nevertheless, that, "to speak impartially, he was a person well skilled in the tongues, Rabbinical learning, and Jewish rites and customs; that he had a great command of his English pen, and was one of the genteel and fairest writers who have appeared against the church of England."

OWHYHEF, the easternmost, and by far the largest, of the Sandwich islands. Its greatest length from north to south is 28° leagues, its breadth 24°, and its circumference
Owhihe, circumference nearly 300 English miles. It is divided
into six large districts; two of which on the north-east
side are separated by a mountain, that rises in three
peaks, which is perpetually covered with snow, and may
be seen clearly at 40 leagues distance. To the north of
this mountain, the coast consists of high and steep cliffs,
down which fall many beautiful cascades of water. The
whole country is covered with cocoanut and bread-fruit
trees. The peaks of the mountain on the north-east
side appear to be about half a mile in height, and en-
tirely covered with snow. To the south of this moun-
tain, the coast presents a prospect of the most dreary
kind, the whole country appearing to have undergone
a total change by means of some dreadful convulsion.
The ground is everywhere covered with cinders, and
intermixed in many places with black streaks, which
seem to mark the course of a lava that has flowed not
many ages since from the mountain to the shore. The
southern promontory looks like the mere dregs of a vol-
cano. The projecting headland is composed of broken
and craggy rocks, piled irregularly one upon another,
and terminating in sharp points; yet amidst these ruins,
there are many pieces of rich soil, which are carefully
laid out in plantations, and the neighbouring sea affords
a vast variety of excellent fish: so that this quarter is
much better inhabited than those which are more ver-
dant. The fields are inclosed with stone fences, and are
interspersed with groves of cocoanut nut trees. We are
told indeed by some of Cook's people who walked
through a considerable part of it, that they did not ob-
serve a spot of ground that was susceptible of improve-
ment left unplanted; and indeed the country, from
their account, could scarcely be cultivated to greater ad-
vantage for the purposes of the natives. They were sur-
priised at seeing several fields of hay; and upon their in-
quiry, to what particular use it was applied, they were
informed, that it was intended to cover the grounds
where the young taro grew, in order to preserve them
from being scorched by the rays of the sun. They ob-
served among the plantations a few huts scattered about,
which afforded occasional shelter to the labourers; but
they did not see any villages at a greater distance from
the sea than four or five miles. Near one of them,
which was situated about four miles from the bay, they
discovered a cave forty fathoms in length, three in
breadth, and of the same height. It was open at each
end; its sides were fluted as if wrought with a chisel;
and the surface was glazed over, perhaps by the action
of fire. There are supposed to be on this island about
350,000 inhabitants. So long as the name of Captain
Cook shall be remembered, this island will not be for-
gotten; for he here fell a victim to a strange concaten-
tion of events. See Cook.

We have the following account of the inhabitants of
this island in Ellis's Authentic Narrative, &c. "The
men are above the middle size, stout, well made, and
fleshy, but not fat. Corpulence is not altogether so
great a mark of distinction in these as in the Society
isles; and tallness, for which the Otahiteans have great
partiality, is also overlooked. Their colour is in gen-
eral brown olive. The women are in general masculine,
though there are some delicately made, and the voice
of them all is soft and feminine. The hair both of the
head and beard is black; that of the head the men wear
in the form of a helmet, that is, a long frizzled ridge
from the forehead to the neck, the sides being much
shorter. This fashion seems to prevail only amongst
the principal people, that of the inferior sort being of an
equal length in every part. Most of them were very
desirous of parting with their beards, which, they said,
were disagreeable and troublesome, and were fond of
being shaved by our people. Some of the priests were
their beards long, and would not on any account part
with them. The women wear their hair long before,
but very short behind, which is not the most becoming
mode; and, like those of the Friendly isles, they have
a way of rendering it of different colours, red, yellow,
and brown. The features of both sexes are good, and
we saw some of the females who might readily be called
fine women. Their teeth are even, and perfectly white.
In general, they seem to be very healthy, and we ob-
served several who appeared to be of great age. As to
diseases we saw none who laboured under any during
our stay, except the venereal complaint; coughs and
colds indeed were pretty general, and one man died.
From what we could learn of his disorder from the na-
tives, it was a violent griping or colic.

"Both men and women appeared to be of a good
disposition, and behaved to each other with the tenderest
regard: when they did fall out, which sometimes was
the case, occasioned by the upsetting of a canoe, or some
such trifling accident, they only scolded a little, and this
was soon over and forgotten. We never saw them
strike each other upon any occasion. They are all
thieves, from the area to the town, but not quite so
expert at it as our Otakehe friends.

"The custom of tattooing prevails greatly among
these people, but the men have a much larger share of
it than the women; many (particularly some of the na-
tives of Mow'wha) have one half of their body, from head
to foot, marked in this manner, which gives them a most
striking appearance. It is done with great regularity,
and looks remarkably neat: some have only an arm
marked in this manner, others a leg; some again have
both arm and leg, and others only the hand. The wo-
men are for the most part marked upon the tip of their
tongue; but of these we saw but few. Both sexes have
a particular mark according to the district in which they
live; or it is rather the mark of the area, or principal
man, under whose jurisdiction they more immediately
are. We never saw the operation of tattooing per-
formed, nor could we procure a sight of the instruments
used upon this occasion; but it is likely they are much
the same as those of the Friendly and Society isles.

"Both men and women are very cleanly in their
persons; the latter wash their whole bodies in fresh wa-
twice and sometimes three times a day; but the wo-
men of Otahite have the advantage of them in one
point of cleanliness, which is eradicating the hairs from
under the arm-pits. This is a custom we observed no-
where but at the Society isles.

"There are no people in the world who indulge
themselves more in their sensual appetite than these: in
fact, they carry it to a most scandalous and shameful
degree, and in a manner not proper to be mentioned. The
ladies are very lavish of their favours; but are far from
being so mercenary as those of the Friendly or Society
isles, and some of their attachments seemed purely the
effect
Their clothing consists of cloth of different kinds; that worn by the men, which is called zemro, is about half a yard wide, and four yards long; that of the women three quarters of a yard wide, and of the same length as the men's: this they call padóawa; they both wear it round their middle, but the men pass it between their legs. This is the general dress of both sexes; but the better sort sometimes throw a large piece loosely over their shoulders. Besides the marro, they have several other kinds of cloth, which derive their names either from the different uses to which they are applied to, or their different texture and pattern; all, however, as far as we could learn, are made from the Chinese paper mulberry tree. The principal of these is the cappa, which is about 10 or 12 feet long, and nearly as many wide, and is thick and warm; they wrap themselves up in this when they retire to sleep. They have another kind, which is white, and much thinner; this, as has been before observed, they throw loosely over their shoulders: its length sometimes 20 yards long, and wide in proportion. The marro and padóawa are curiously painted of various patterns, but the others are generally white, or dyed red, black, and yellow.

The principal ornaments of the men are the feather caps and cloaks; some of the latter reach down to their heels, and have a most magnificent appearance. They are made for the most part of red and yellow feathers, which are tied upon fine net-work. The caps are composed of the same kind of feathers, which are sometimes intermixed with black; they are secured upon a kind of basket-work, made in the form of a helmet. Both caps and cloaks are made of various patterns and sizes. The cloaks are not all composed of the same kind of feathers, but are sometimes varied with the long tail feathers of the cock, with a border of yellow or red, and sometimes with those of the tropic bird. Both caps and cloaks, however, are only to be seen in the possession of the principal people. They have also a kind of fly-flap, made of a bunch of feathers fixed to the end of a thin piece of smooth and polished wood; they are generally made of the tail feathers of the cock, but the better sort of people have them of the tropic bird's feathers, or those belonging to a black and yellow bird called moko. The handle is very frequently made of one of the bones of the arms or legs of those whom they have killed in battle, curiously inlaid with tortoise-shell: these they deem very valuable, and will not part with them under any great price. This ornament is common to the superiors of both sexes.

The women too have their share in the ornamental way: that which they value most is the orai. This is a kind of ruff or necklace, made of red, green, black, and yellow feathers, curiously put together, and in most elegant patterns, which really do honour to the fancy of the ladies, whose business it is to make them. They never think themselves dressed without one or two of these round their necks, and those who can afford it wear many. Others again are composed of small variegated shells, disposed in a very neat manner; and some consist of several rows of twisted hair, with a piece of carved wood or bone, highly polished, the Owbyhees bottom part forming a curve. The higher the quality of the wearer, the greater is the size of the wood or bone, and the quantity of the twisted hair. The next thing is the po-o-vah or bracelet; the most valuable are made of bear's tusks fastened together side by side with a piece of string, by means of a hole drilled through the middle; the larger the tusks, the greater the value. Sometimes two shells tied round the wrists, with twisted or braided hair, serve the purpose of bracelets; but even in this case they show great nicety, being particularly careful to match them as near as possible. They were prodigiously fond of these we gave them, which were only a few beads, secured by thread upon a strip of scarlet cloth, and made to button round the wrist. So much did they at first value them, that a small hatchet and one of these would purchase a hog, which without it could not have been bought for three large hatchets. The women were perpetually teasing the men to dispose of their various articles for these bracelets; at least one of them was always ready to make a part of the price. W. Long. 1565. G. N. Lat. 19. 25.

OWL. See STRIX, Ornithology Index.

OWLING, so called from its being usually carried on in the night, is the offence of transporting wool or sheep out of this kingdom, to the detriment of its staple manufacture. This was forbidden at common law, and more particularly by statute 1 Edw. III. c. 13. when the importance of our woollen manufacture was first attended to; and there are now many later statutes relating to this offence, the most useful and principal of which are those enacted in the reign of Queen Elizabeth and since. The statute 8 Eliz. c. 3, makes the transportation of live sheep, or embarking them on board any ship, for the first offence forfeiture of goods, and imprisonment for a year, and that at the end of the year the left hand shall be cut off in some public market, and shall be there nailed up in the open market place; and the second offence is felony. The statutes 12 Car. II. c. 32. and 7 and 8 Will. III. c. 26. make the exportation of wool, sheep, or fullers earth, liable to pecuniary penalties, and the forfeiture of the interest of the ship and cargo by the owners, if privy to, and confession of goods, and three years imprisonment to the master and all the mariners. And the statute 4 Geo. II. c. 11. (amended and further enforced by 12 Geo. II. c. 21. and 19 Geo. II. c. 34.), makes it transportation for seven years, if the penalties be not paid.

OXALIS, Woodsorrel, a genus of plants belonging to the decandria class, and in the natural method ranking under the 14th order, Grumineæ. See Botany Index.

OXFORD, the capital of a county of the same name in England, celebrated for its university, and pleasantly situated in a plain, in the middle of a fine fruitful country. The composition of the name is obvious. In the British times it seems to have been a place of study. The wisdom of our ancestors (says Camden) as appears in our history, consecrated even in the British times this city to the muse, translating them from Greek-land (now a small town in Wiltz) thereto, as to a more fruitful nursery. For Alexander Necham writes "It is a fine Report of Civil Law."
of divinity and the liberal arts proves, that the university of Paris deserves the preference to all others. Agreeable also to Merlin’s prophecy, Wisdom has flourished at the Ford of Oxen, and will in its due time pass over also into Ireland.” But in the following Saxon age, when so many cities were destroyed, it underwent the common fate, and for a long time was famous only for the relics of Frideswide, who was ranked among the saints for her holy life, merely because she had solemnly devoted herself to God; and Prince Algar, soliciting her in marriage, was miraculously, as they say, deprived of his eye-sight."

Perhaps the following additional extract from Camden will be more to the purpose in developing the ancient state of learning in this city, than any thing which we could bring forward of our own. "When the storm of the Danish war was over, the most religious Prince Alfred restored their retreats to the long-exiled monks, by founding three colleges, one for grammarians, another for philosophy, and a third for divinity. This will be more fully explained by the following passage in the old annals of the New Monastery at Winchester. "In the year of our Lord 866, the second year of the arrival of St Grimbald in England, the university of Oxford was begun; the first who presided and read divinity lectures in it being St Neoth, an abbot and able divine; and St Grimbald, a most eminent professor of the incomparable sweetness of the sacred pages; Asser the monk, an excellent scholar, professing grammar and rhetoric; John monk of the church of St David giving lectures in logic, music, and arithmetic; and John the monk, colleague of St Grimbald, a man of great parts, and an universal scholar, teaching geometry and astronomy before the most glorious and invincible King Alfred, whose memory will dwell like honey in the mouths of all."

Sooner after, as we find in an excellent MS. of the said Asser, who was at that time professor here, "broke out a sharp and fatal quarrel between Grimbald and those very learned men whom he had brought with him, and the old scholars whom he found there; who, on his coming, unanimously refused to receive the rules, methods, and forms of lecturing, that Grimbald introduced. Three years had passed without any great difference between them; but the secret aversion afterwards broke out with the utmost violence. In order to quell it, the invincible King Alfred, as soon as he heard of it, by the messages and complaints from Grimbald, went in person to Oxford to put an end to the dispute, and he took the greatest pains to hear the causes and complaints on both sides. The foundation of the difference was this: The old scholars maintained, that before Grimbald came to Oxford, learning had flourished there, though the scholars at that time were fewer than in more ancient times, the greater part being driven out by the cruelty and oppression of the Paganas. They also proved and showed, and that by the undoubted testimony of ancient chronicles, that the ordinances and regulations of the place were established by certain religious and learned men, such as Gildas, Melkinnus, Ninnius, Kentigern, and others, who had all lived to a good old age in these studies, having settled matters in peace and harmony; and also that St Germanus came to Oxford, and staid there half a year in his journey over Britain to preach against the Pelagian heresies, and wonderfully approved their plan and institution. The king, with unheard-of censure, gave both parties attentive hearing, and repeated his pious and reasonable advice to maintain mutual union and concord, and left them with the prospect that both parties would follow his advice and renounce his institutions. But the monks, offended at this proceeding, immediately retired to the monastery at Winchester lately founded by King Alfreed. He also caused his tomb to be removed to Winchester, in which he had intended to lay his bones when his course of life was ended, in the vault under the chancel of St Peter’s church at Oxford, which church himself had built from the ground, of stone polished in the most costly manner."

"This happy restoration of learning was followed in a few years by various calamities. The Danes in the reign of Edward plundered and burnt the place; and soon after Harold Harefoot practised the most inhuman barbarities here in revenge for some of his men who were killed in an affray; so that the most melancholy remove of the students ensued, and the university remained almost extinct, a lamentable spectacle, till the time of William the Norman. Some have falsely supposed this prince took the city, misled by a wrong reading in some copies of Osmona for Exonam. At that time, it was the seat of an university, as we learn from these words of Ingulphus, who lived at that time. "I Ingulphus settled first at Westminster, was afterwards sent to study at Oxford, having made greater proficiency than many of my own age in Aristotle, &c. What we call an university, they in that age called a study.” Many are of opinion that it was deserted till about the year 1129, and that this desertion was in consequence of its having been besieged and taken by William the Conqueror. About this year, however, Robert Pulton began to read lectures in divinity, or (as it is expressed in the chronicle of Osney abbey) the Holy Scriptures, which had fallen into neglect in England; and such was the resort of students to it, that in the reign of King John there were not fewer than 3000. Robert d’Oily, a Norman, to whom William the Conqueror had given the greatest part of it, built a castle on the west side, in 1271; and he is also supposed to have surrounded it with walls. In a palace built by Henry I. was born Richard I. commonly called Coeur de Lion. About the tenth of King John, there happened a quarrel between the citizens and students; in consequence of which many of the latter quitted it, but returned again a few years afterwards. Here Henry III. held a parliament to settle the difference between him and his barons; when he confirmed the privileges granted to the university by his predecessors, and added others of his own. In this reign the students are said to have been 30,000, who were all excommunicated by the pope for some rudeness to his legate. In the time of Dun Scotus, we are told that 30,000 scholars attended his lectures. Matthew Paris styles the university of Oxford, 'the second school of the church after Paris,' and the very foundation of the church.' The pope had before this honoured it with the title of University, which they had conferred by their degrees on no other but that of Paris, this of Oxford, and those of Bologna and Salamanca. It was decreed in the council of Verona,
OXFORD [ 615 ] OXFORD

The schools for the study of the Hebrew, Arabic, and Chaldee languages, should be erected in the universities of Paris, Oxford, Bologna, and Salamanca (as the most considerable), that the knowledge of these languages might prevail by their being thus taught; and that Catholic persons be chosen, sufficiently versed therein, two in each language. For those in Oxford, the bishops, monasteries, chapters, convents, colleges, exempt and not exempted, and the rectories of churches throughout England, Scotland, Ireland, and Wales, were to provide a competent maintenance.” In Edw. III.'s time, the scholars were split into two factions, called the northern and southern men; a division which was attended with many disorders and much violence, but in a short time concord and harmony again prevailed.

As colleges began about this time to be founded and endowed, we shall here present our readers with a list of them, together with the time when, and the persons by whom, they were founded:

Worcester was called Gloucester-hall till lately, that it was endowed by Sir Thomas Coke and made collegiate. Hartford was Hart-hall till 1740, that it was erected into a college by Dr Richard Newton.

All these are richly endowed, and have fine gardens, libraries, chapels, &c. The halls in which the students maintain themselves, except a few that have exhibitions, are these: St Edmund's, belonging to Queen's college; Magdalen, to Magdalen college; St Alban's, to Merton; St Mary's, to Oriel; New Inn, to New college. Several persons have been great benefactors to particular colleges, as Dr Ratcliffe to University college; Colonel Codrington and Dr Clarke, to All Souls; Queen Caroline, to Queen's; the bequest of Dr Clarke and Mrs Eaton, to Worcester; Dr Wake, archbishop of Canterbury, to Christ-church. The most considerable of these colleges are Magdalen's and Christ-church, which are as noble foundations as any in the world. The church of the latter is the cathedral, and has a dean, eight canons, eight chaplains, eight singing men, eight choristers, a teacher of music, and an organist. Each of the colleges has its visitor appointed by its statutes, except Christ-church, which is subject to the visitation of the Sovereign alone. The other remarkable buildings belonging to the university are, first, the public schools; secondly, the Bodleian or public library; thirdly, Ratcliffe's library, a most elegant structure, for building and furnishing which, Dr Ratcliffe left 40,000l.; fourthly, the theatre, built by Sheldon, archbishop of Canterbury; fifthly, the museum, in which is an elaborate and a repository for natural and artificial rarities and antiquities; sixthly, the Clarendon printing-house, so called, because it was built partly with the money arising to the university by the sale of Lord Clarendon's history.

To the south of Magdalen college lies the physic garden, instituted by the earl of Danby, and much improved by Dr Sherrard. It contains five acres, in which is a complete series of such plants as grow naturally, disposed in their respective classes; together with two neat and convenient green-houses, stocked with a valuable collection of exotics, and a hot-house, where various plants brought from the warmer climates are raised. The whole body of the university, including professors, fellows, and students of all sorts, exceeds 3000. Each college has its particular statutes and rules for government. There are four terms in the year for public exercises, &c. and particular days and hours for public lectures by the several professors. The university is governed by a chancellor, high-steward, vice-chancellor, two proctors, a public orator, (see public orator); a keeper of the archives, a regidor, three esquire beadle, and three yeomen beadle. As to the city, it has had the same privileges granted to it as London, particularly an exemption from toll all over England. It was made an episcopal see in 1541, when Robert King, the last abbot of Osney, was made bishop. It is governed by a mayor, two aldermen, twenty-five councillors, two bailiffs, a town-clerk, two chamberlains, all that have borne the office of bailiff and chamberlain, and 24 common-council men; but these are subject to the chancellor or vice-chancellor of the university in all affairs of moment; and the mayor, the principal citizens, and sheriff of the county, take an oath to maintain the privileges of the university. The city, including the colleges, is a place of considerable magnitude, having 13 parish-churches, besides the cathedral, well built, clean, and regular. The number of inhabitants in 1811 was 12,931. At the entrance of the town from the Woodstock and Banbury roads, a neat hospital was erected by the trustees of Dr Ratcliffe's benefaction, out of the surplus money remaining after defraying the expense of his library. The male line of the family of Vere, to whom the city had given the title of earl for 300 years, failing in Aubrey de Vere, who was twelfth earl, Queen Anne conferred the title upon Robert Harley, a descendant of the Vere's, whose family it still continues. The chief trade of the city is in malt, conveyed in barges to London. It is impossible, in the narrow bounds necessarily prescribed to this article, to give so particular an account of this celebrated place as its importance demands; but we shall refer our readers to the article UNIVERSITY, when this seminary, amongst others, shall be more particularly described.

OXFORDSHIRE, which made part of the territory
OXY

Oxfordshire, a county of England, bounded on the west by Gloucestshire; on the south, where it is broadest, the river Isis divides it from Berkshire; on the east, it is bounded by Buckinghamshire; and on the north, where it terminates in a narrow point, it has on the one side Northamptonshire, and on the other Warwickshire. It extends 50 miles from north to south, and 35 from east to west, making about 1,500 square miles, within which are contained one city, 15 market towns, 280 parishes, 14 hundreds, and 53,000 acres. The number of inhabitants in 1811 was 119,191. The air is sweet and pleasant, and the soil rich and fertile. The lower parts consist of meadows and corn-fields, and the higher were covered with woods till the civil wars; in which they were so entirely destroyed, that wood is now extremely scarce and dear, except in what is called the Chilterns, and so is coal. The county is extremely well watered for besides the Isis, Tam, Cherwell, Evenlode, and Windrush, there is a great number of lesser rivers and brooks. One of the four great Roman woods passes quite through this county, entering at the parish of Chinner, and going out at that of Goring. There is another lesser one, that extends between Colnbrook and Wallinsford, called Gremesdale. The county sends nine members to parliament, viz. two for the shire, two for the city, two for the university, two for New Woodstock, and one for Banbury. See Oxfordshire, Supplement.

OXGANG, or OXGATE, is generally taken, in our old law-books, for 15 acres, or as much ground as a single ox can plough in a year.

OXUS, or JHUN, a large river of Asia, much taken notice of in ancient histories, but does not rise in the north of India, as most writers affirm; for, according to the best and latest maps made by those who have been upon the spot, it ran a course of about 260 miles from the Caspian sea to the lake Aral, whose dimensions have lately been discovered, and is but very lately known to the Europeans; but, as it passes through a desert country abounding with sands, the inhabitants so diverted its course, that the old channel can hardly be discovered.

OXCRATE, an old term, in Pharmacy, denoting a mixture of vinegar and water, proper to assuage, cool, and refresh. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

OXDE, or OXIDE, in Chemistry, is the term used to denote a very numerous class of bodies formed by the union of certain bases with a smaller proportion of oxygen than what is necessary for their conversion into acids. The most remarkable of these bodies are what were formerly called metallic calces, and have for their base some metallic substance. It is in this state that metals are often contained in the ores, from which they are extracted, and converted into the metallic form, by the process called reduction. Metals are converted into oxides by combustion, and by solution in acids; and many of them assume this form from the action of the atmosphere alone, but more readily when this is assisted by moisture. See the history of the metals under Chemistry.

OXIDATION, or OXIDATION, is a term employed to express the process by which bodies are converted into oxides. See Metals under Chemistry.

OXGEN, a term adopted in the new chemical nomenclature, to express the acidifying principle from Oxygen, "acid," and genus, "to generate." It is not found naturally in a separate state, but always combined with some other substance. In its aereiform or elasmatic state, it is called oxygenous gas, and is the same as the dephtlogistificated air of Priestley and Cavendish, the empirical air of Scheele, the vital and pure air of other chemists. See Oxygen, Chemistry Index.

OXYGALCU, a species of drink prepared of the sweetest honey-combs macerated and boiled. The combs, from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept; and, when diluted with cold water, is to be drank in the summer time, in order to remove thirst.

OXYMEL, in Pharmacy, a composition of vinegar and honey.

OXER, in law-books, seems to have been anciently used for what is now called assises. See Assise.

OYES, a corruption of the French OYZE, Her ye; a term or formula frequently used by the clerks in our courts on making proclamations, or to enjoin silence.

OYSTER, a shell fish. See Ostrea, Conchology Index.

Oyster-Catcher. See Haematopus, Ornithology Index.

OYSTER, Fossil. The largest bed that is known of fossil oysters is that near Riding in Berkshire. Their shape is entire, and they consist of the same substance with recent oyster-shells; and yet since the oldest histories that mention the place give an account of them, we must suppose they have lain there for a long time. They extend over no less than six acres of ground; and just above them is a large stratum of a greenish loam, which some writers call a green earth, and others a green sand. It is composed of a crumbly marle, and Phoca, a large portion of sand. Under them is a thick stratum of chalk. They all lie in a level bed; and the lower strata above the shells are natural, and appear never to have been dug through till the time of finding the shells.

OZENA, a foul and malignant ulcer of the nose, distinguished by its scero, and often accompanied with a caries of the bones of the nose.

OZANAM, JAMES, an eminent French mathematician, born at Bolignieu in Bresse, in 1640, of a wealthy family. His father gave him a good education, and designed him for the church; but some mathematical books falling into his hands, inspired him with a love for that science; and though he had no master to instruct him, he made such progress in it, that, at 15 years of age, he wrote a piece in mathematics, which he thought proper to insert in the works he afterwards published. He at length taught that science at Lyons; and his mathematical lessons brought him in a considerable revenue, till the year 1701; at which period, a war breaking out on the succession to the crown of Spain, he lost almost all his scholars, and was reduced to a very melancholy situation; and his never dying the same year, he was so affected, that he never perfectly recovered it. In 1702 he was admitted into the Royal Academy of Sciences; and died of an apoplexy in 1717. — He was of a mild and se
OZI [617] OZO

OZI, in sacred history, the son of Micha, of the tribe of Simeon, one of the governors of Bethulia when it was besieged by Holofernes. He vigorously supported the siege against this general, and received Achior into his house, when he had been driven from the Assyrian camp. Finding however at length that the city was reduced to great necessity for water, and that the people mutinied against him, he promised to surrender the place in five days, if in that time God did not send him relief. Judith (vi., vii., viii., ix., and x.) being informed of this resolution, sent to speak with Ozius, and the other leading men of the city; made a prudent remonstrance upon their seeming to prescribe a time to the Lord, in which he must succour them; encouraged them to patience; and without discovering her design, told them that she would go out in the night. Ozius being at the gate of the city when Judith departed, opened it to her, and waited in the city for the success of her undertaking, praying with her people to God that he would be pleased to deliver them. See the article JUDITH.

OZOLÆ, or OZOLI, a people who inhabited the eastern parts of Etolia which were called Oslowa. This tract of territory lay at the north of the bay of Corinth, and extended about 12 miles. They received their name from the bad stench (γαργήσας) of their bodies and clothes, which were the raw hides of wild beasts. Some derive it from the stench of the stagnated water in the neighbouring lakes and marshes. According to a fabulous tradition, they received their name from a very different circumstance: During the reign of a son of Deucalion, a bitch brought into the world a stick instead of whelps. The stick was planted into the ground by the king, and it grew up to a large vine, and produced grapes, from which the inhabitants of the country were called Ozoler, not from ἀργυρός, “to smell bad,” but from γραφέω, “a branch or sprout.” The name Oisolae, on account of its indelicate signification, was highly disagreeable to the inhabitants; they therefore exchanged it soon for that of Etolians.

P.

The 15th letter and 11th consonant of the alphabet; the sound of which is formed by expressing the breath somewhat more suddenly than in forming the sound of s; in other respects these two sounds are pretty much alike, and are often confounded one with another. When p stands before t or s, its sound is lost; as in the words psalms, psychology, ptolmaic, ptisan, &c. When placed before h, they both together have the sound f; as in philosophy, physic, &c.

P and B are so like each other, that Quintilian declares, that in the word optimus, his reason required him to put a b, but that his ears could hear nothing but a p, optimus: hence in ancient inscriptions, and old glossaries, it appears that these two letters have often been confounded. Several nations still pronounce one for the other, the Welsh and Germans particularly.

Vol. XV. Part II.

who say, ponum vinum, for bonum vinum. Plutarch observes, it was usual for those of Delphi to say "παλάμος" for dinis, "παμακα" for amec; and among the Latins, as often as an s followed, the b was changed into a p, as scribo, scripsi.

As an abbreviation, P stands for Publius, Pondo, &c., pa. dig. for Paternia Dignitatis; F. C. for Fatas Conscripti; P. F. for Public Filus; P. P. for Propositum, or Propositione publice; P. R. for Populus Romanus; P. S. for Praetorius senetia; P. S. P. for Praetex provincia.

P. M. among Astronomers, is frequently used for post meridiem, or "afternoon," and sometimes for post mane, "after the morning," i.e. after midnight. P was also used among the ancients as a numeral letter, signifying the same with the G, viz. a hundred; according to the verse of Uguio.

43 P
Though Baronius thinks it rather stood for seven.

When a dash was added a-top of 7, it stood for four hundred thousand.

St Jerome observes on Daniel, that the Hebrews had no P; but that the ph served them instead thereof; adding that there is but one word in the whole Bible read with a Ph, viz. opodium. The Greek ψ signified 50. On the French coins, P denotes those that were struck at Dijon.

In the Italian music, P stands for piano, or "softly;" and P. P. P. for pianissimo, or "very softly."

Among physicians, P stands for pulvis, or the eighth part of an hundred; P, æ. partes aequales, or equal parts of the ingredients; P. P. signifies pulvis patrum, or Jesus' bark in powder; and ppt. preparatus or prepared.

PABULUM, among natural philosophers, the same with Fuel.

PACA, see Mus, Mammalia Index.

PACE, a measure taken from the space between the two feet of a man in walking; usually reckoned two feet and a half, and in some men a yard or three feet. The geometrical pace is five feet; and 60,000 such paces make one degree on the equator.

PACT, in the manage, is of three kinds, viz. walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

Horses which go shuffling, or with mixed paces between the walk and amble, are for the most part of no value; which commonly proceeds from their fiery temper, but sometimes from a weakness in their reins or legs.

PACHAMAC, a valley of Peru, in South America, ten miles south of Lima; celebrated for its pleasantness and fertility, but more on account of a magnificent temple built by the Incas of Peru, to the honour of their gods. When the Spaniards conquered Peru, they found some ancient riches therein.

PACHSU, a small island in the Mediterranean sea; near the coast of Epirus, and in European Turkey. It lies south of Corfu, and is subject to Venice.

PACIFIC OCEAN, that vast ocean which separates Asia from America. It is called Pacific, from the moderate weather the first mariners who sailed in it met with between the tropics; and it was called South sea, because the Spaniards crossed the isthmus of Darien from north to south when they first discovered it; though it is properly the Western ocean with regard to America.

Geographers call the South sea Mare Pacificum, "the Pacific ocean," as being less infected with storms than the Atlantic; but Montezaffi affirms it does not deserve that appellation, and that he has seen as violent storms therein as in any other sea; but Magellan happening to have a very favourable wind, and not meeting with any thing to ruffle him when he first traversed this vast ocean in 1520, gave it the name which it has retained ever since. Many, however, adds, that the wind is so regular there, that the vessels would frequently go from Acapulco to the Philippine islands without shifting a sail.

PACK, in commerce, denotes a quantity of goods made up in loads or bales for carriage. A pack of wool is 17 stone and 2 pounds, or a horse's load.

PACKAGE, is a small duty of one penny in the pound, paid for all goods not particularly rated.

PACKET, or Packet Boat, a vessel appointed by the government to carry the mail of letter, packets, and expresses from one kingdom to another by sea in the most expeditious manner. Thus, the packet-boats, under the direction of the postmaster-general of Great Britain, carry the mails from Dover to Calais, from Falmouth to Lisbon, from Harwich to Helvoetians, and from Parkgate to Dublin. See Post.

PACOS, or Pago, in Zoology, a species of camel, commonly, though improperly, reckoned a species of sheep; and known among many by the name of the Indian sheep, or Peruvian sheep. See Camelus, Mammalia Index.

This creature has been accounted a sheep, because its hair is so long as to resemble wool, and it is prodigiously thick, its head and neck alone having more wool on them than the whole body of our largest sheep. Its body is clothed in the same proportion with a woolly hair equally fine.

PACTOLUS, in Ancient Geography, a river of Lydia, called Chrysorhoas, from its rolling down golden sand, according to Herodotus, Phuthar, Phus, and Strabo; rising in Mount Timolus (Strabo). From this river Cresus is thought to have had all his riches. In Strabo's time it ceased to roll down any. It ran through Sardis; after which it fell into the Hermus, and both together into the Ægean sea at Phocæa in Ionia. A river celebrated by Virgil, Ovid, Lucan, Lycophron, Horace, Appollonius.

PACUVIUS, Marcus, of Brindesium in Calabria, a tragic poet in high reputation about the year of Rome 600. He was nephew of Ennius; published several theatrical pieces, though we have only some fragments of his poetry remaining; and died at Tarentum at above 90 years of age.

PADAN-ARAM (Bible), literally the plains of Aram, or Syria; translated by the Seventy simply Mesopotamia, or Mesopotamia of Syria; by the Vulgate, Syria; the Syrians on this and on the other side of the Euphrates, not differing remarkably from each other in language and manners, as Josephus allows.

PADDOC, or Paddoc-Course, a piece of ground encompassed with pales or a wall, and taken out of a park, for exhibiting races with greyhounds, for plates, wagers, or the like.

A paddoc is generally a mile long, and a quarter of a mile broad: at the one end is a little house where the dogs are to be entered, and whence they are slipped; near which are pens to inclose two or three deer for the sport. Along the course are several posts, viz. the low post, which is 150 yards from the dog-house and pens; the quarter of a mile post, half-mile post, and pinching post; besides the ditch, which is a place made to receive the deer, and preserve them from further pursuit. And near this place are seats for the judges chosen to decide the wager.

The keepers, in order to slip the dogs fairly, put a falling collar upon each, slipped round a ring; and the deer being turned loose, and put forward by a teamer,
PADDORE, a duchy of Germany in the circle of Westphalia, has the county of Lippe on the north and west; Hesse-Cassel and Waldeck on the south; and Munster, with the duchy of Westphalia on the west. Its greatest length from east to west is about 40 miles, and its breadth where widest 30. Some parts of it yield good pasture, and breed abundance of cattle; but it is not very fruitful in corn. There is a heath called the Senne or Senda, of great extent, but very barren and desolate. There are, however, good iron mines in the country, with salt and medicinal springs, plenty of deer and other game; and it is watered with several rivers abounding with fish, as the Weser, the Dimer, the River, the Nette, the great Emscher, the lippe, the Alme, and the Pader. It contains 54 parishes, in which are 25 market towns and 16 monasteries. The Roman Catholic is the predominant religion of the country, yet there are also many Protestants in it. The bishopric was erected by Charlemagne, towards the close of the eighth century, and the cathedral was consecrated by Pope Leo in person, anno 796. The bishop was sovereign of the country, a prince of the empire, and suffragan of the archbishop of Mentz. His revenue was about 30,000 pounds a-year, and he was able to raise 3000 men. In the matricula his assessment is 18 horse and 34 foot, or 352 florins monthly in lieu of them. Towards the charges of the sovereign courts of the empire, he paid for each term 162 rix-dollars and 29 kruitzers. The chapter consisted of 24 capitular canons, who must prove their noble extraction by four descents. At the settling of the new taxes in 1601 this bishopric was secularised and given to Prussia. It was afterwards annexed to the kingdom of Westphalia, but was restored to Prussia in 1814. It is reckoned to contain 76,000 inhabitants. It was in this bishopric that Quintillus Varus, with the Roman army under his command, was routed by the Germans under Arminius.

PADDEBORN, the capital of the above bishopric. It stands 40 miles north-west of Cassel, 50 south-east of Munster, and 60 south-west of Hanover; being a large, populous, well-built, and well fortified city. Its name is compounded of Pader, a rivulet, which rises just under the high altar of the cathedral, and Born, i.e. a spring. It was one of the Hanse-towns; and, till 1604, an imperial city. The cathedral is a grand fabric, inferior to few in the empire. There is a gold crucifix in it of 60 pounds weight, presented by Otho II. The university, of which the Jesuits have the direction, was founded in 1592, and the walls were built in the beginning of the 17th century. In 1530 an attempt was made to introduce Lutheranism; but 16 of the principal citizens who had embraced it were executed, and the rest obliged to abjure it. Duke Christian of Brunswick carried off from hence, in 1629, the silver images of the twelve apostles, and the silver coffin of St. Lutharius; and had them coined into money, with this inscription, God's Friend, the Priest's Enemy. The trade of this town, though formerly great, is now inconsiderable; and the inhabitants subsist mostly by agriculture and breeding of cattle. Though the bishop had a palace in the city, he resided at Neuaus, seven miles off, where he had a magnificent castle. Charlemagne and other emperors sometimes resided here, and held diets of the empire. Paderborn contains about 12,000 inhabitants.

PADOGE, a punishment used in Russia. The body of the criminal is stripped to the waist, and then laid upon the ground; one slave holds the head of the person to be punished between his knees, and another the lower part of the body; then rods are applied to the back till some person gives notice to desist, by crying out, enough. This punishment is considered in Russia merely as a correction of the police, exercised on the soldier by military discipline, by the nobility on their servants, and by persons in authority over all such as are under their command. After the accession of Elizabeth to the throne of Russia, the punishments were reduced to two kinds, viz. the padogi and Knout.

PADUA, an ancient, large, and celebrated city of Italy, with a university and a bishop's see. It is also capital of the Paduano; but is much less considerable than it was formerly: for it now contains no more than 30,000 inhabitants, whereas it formerly had 100,000, and many of the houses are gone to ruin. The cathedral church, and the college of the university, are in that part called the Old Town; and there are piazzas under all the houses, where persons may walk without being exposed to the weather. The garden of the university is curious, on account of the number of plants. Here a student may take his degrees, let him be of what sect of Christianity he will; nay, though he should be a Jew or a Turk. The patron of this city is St. Anthony, who lies in the cathedral; they have such a veneration for him, that the beggars do not ask charity in the name of God, but for the love of St. Anthony. The Jews live in a distinct part of the city; and the neighbouring mountains produce excellent wine and oil, with delicious fruit. It was taken by the Venetians in 1706, and now belongs to Austria. It is seated on the rivers Brenta and Bacchiglione, in a fine plain, and is about seven miles in circumference. E. Long. 11° 55'. N. Lat. 45° 24'.

PADUAN, among medalists, a modern medal struck in imitation of the antique, or a new medal struck with all the marks and characters of antiquity. This name is properly applicable to those medals only that were struck in the seventh century by an Italian painter born at Padua; who succeeded so well in the imposture, that the best judges are at a loss to distinguish his medals from the genuine ones. Though it is frequently used in general for all medals of this kind.

PADUANO, a small province of Italy, in the Austron-Venetian territories, bounded on the east by the Dogado, on the south by the Folesino di Rovigo, on the west by the Vergonese, and on the north by the Vicentino. Its soil is well watered, and is one of the most fertile in Italy. The province is about 40 miles in length, and 35 in breadth. Padua is the capital town. PADUS,
PADUS, now the Po, anciently called Eridanus, especially by the Greeks; a river famous for the fable of Phaoen (Ovid). It rises in Mount Vesulus, in the Alpes Cothie, from three springs, dividing the Cisalpine Gaul into the Transpadana and Cispadana, (Strabo;) and swelled by other rivers falling into it on each side from the Alps and Apennines, it discharges itself with a course from west to east, at seven months, into the Adriatic (Mela). The lake through which it discharges itself into the sea, is called by the natives the Seven Seas.

PADUS, a species of cherry. See Prunus, Botany Index.

PÆAN, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph. See Apollo.

PÆAN, in the ancient poetry, a foot consisting of four syllables; of which there are four kinds, the Pæan primus, secundus, &c.

The Pæan primus consists of one long syllable and three short ones, or a trochees and pyrrhicus, as tæmporibus; the Pæan secundus consists of a short syllable, a long, and two short, or an iambus and a pyrrhicus, as potentia; the Pæan tertius consists of two short syllables, a long and a short one, or a pyrrhicus and a trochees, as animatus; the Pæan quartus consists of three short syllables and a long one, or a pyrrhicus and iambus, as celeritas.

PÆDEROTA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 30th order, Contortae. See Botany Index.

PÆDO BAPTISM; infant baptism, or that conferred on children: from nux, infant, and bathmeus, baptism. This has been the subject of great controversy in the church. See Anabaptists, Baptists, &c.

PÆONIA, Piony, a genus of plants belonging to the polyandria class, and in the natural method ranking under the 26th order, Multilinseae. See Botany Index.

PÆSTUM, called Posidonia by the Greeks, a town of Lucania, on the Sinus Pestinum; an ancient colony prior to the first Punic war, according to Livy; but later, according to Velcium. Pæstana roseae were in great esteem, and produced twice a-year (Virgil, Ovid.)

PAGAN, BLAISE FRANCOIS COMTE DE, an eminent French mathematician, was born at Avignon in Provence, March 3, 1604; and took to the profession of a soldier at fourteen, having been bred to it with the greatest care. In 1620 he was engaged at the siege of Caen, in the battle of Pont de Cte, and the reduction of the Navarins, and the rest of Bearn, where he signalized himself, and acquired a reputation far surpassing his years. He was present, in 1621, at the siege of St John d'Angeli, as also that of Ciarac and Maontauben, where he lost his left eye by a musket-shot. At this siege he had another loss, which equally afflicted him, viz. that of the constable of Luynes, who died there of a scarlet fever. The constable was a near relation, and had been his patron at court. He did not, however, sink under the misfortune, but on the contrary took fresh spirits from the necessity he was now in of trusting solely to himself. Accordingly there happened after this time neither siege, battle, nor any other occasion, in which he did not signalize himself by some effort of courage and conduct. At the passage of the Alps, and the barricade of Suza, he put himself at the head of the forlorn hope, consisting of the bravest youths among the guards; and undertook to arrive the first at the attack, by a private way which was extremely dangerous; when, having gained the top of a very steep mountain, he cried out to his followers, "See the way to glory!" He slipt along this mountain; and his companions following him, they came first to the attack, as they wished to do. They immediately began a furious assault; and, the army coming to assist, they forced the barricade. He had afterwards the pleasure of standing on the left hand of the king, when his majesty related this heroic action to the duke of Savoy with the deserved commendations, in the presence of a very full court. When the king laid siege to Nancy in 1633, our hero had the honour to attend his sovereign, in drawing the lines and forts of circumanvallation. In 1642 his majesty sent him to the service in Portugal, in the post of field marshal. In this same year he unfortunately lost his eye sight by a distemper. But though he was thus disabled from serving his country with his conduct and courage, he reassumed, with greater vigour than ever, the study of the mathematics and fortification; and in 1645, gave the public a treatise on this latter subject. It was allowed by all who understood the science, that nothing had then appeared that was preferable to it; and, indeed, whatever improvements have been made since, they have perhaps been derived chiefly from this treatise, as conclusions from their principles. In 1651 he published his Geometrical Theorems, which show a perfect knowledge of all the parts of the mathematics. In 1655 he printed A Paraphrase, in French, of the Account, in Spanish, of the River of the Amazons, by Father de Remes, a Jesuit; and we are assured, that though blind, he drew the chart of that river and the parts adjacent which is seen in this work. In 1657 he published The Theory of Orbs, cleared from that multiplicity of eccentric circles and epicycles, which the astronomers had invented to explain their motions. This work distinguished him among astronomers as much as that of fortifications did among engineers; and be printed, in 1658, his Astronomical Tables, which are very succinct and plain. Few great men are without some foible: pagan's was that of a prejudice in favour of judicial astrology; and though he is more reserved than most others, yet we cannot put what he did on that subject among the productions which do honour to his understanding. He was beloved and respected by all persons illustrious for rank as well as science; and his house was the rendezvous of all the polite and worthy both in city and court. He died at Paris, Nov. 18, 1665; and was never married. The king ordered his first physician to attend him in his illness, and gave several marks of the extraordinary esteem which he had for his merit.

He had an universal genius; and, having turned himself entirely to the art of war, and particularly to the branch of fortification, he made extraordinary progress in it. He understood mathematics not only better than is usual for a gentleman whose view is to push his fortune in the army, but even to a degree of perfection superior to that of the ordinary masters who teach that science. He had so particular a genius for this kind of learning, that he obtained it more readily by meditation than
than by reading authors upon it; and accordingly spent less time in such books than he did in those of history and geography. He had also made morality and politics his particular study; so that he may be said to have drawn his own character in his Homme Héroïque, and to have been one of the completest gentlemen of his time. Louis XIII. was heard to say several times, that the count de Pagan was one of the most worthy, best turned, most adroit, and most valiant men, in his kingdom. That branch of his family, which removed from Naples to France in 1524, became extinct in his person.

Pagan, a heathen, gentle, or idolater; one who adores false gods. See Mythology.

Paganalia, certain festivals observed by the ancient Romans in the month of January. They were instituted by Servius Tullius, who appointed a certain number of villages (pagi), in each of which an altar was to be raised for annual sacrifices to their tutelar gods; at which all the inhabitants were to assist, and give presents in money, according to their sex and age, by which means the number of country-people was known. The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

Paganellus, a species of fish. See Gobius.

Ichthyology. Index.

Paganism, the religious worship and discipline of pagans: or, the adoration of idols and false gods. See Mythology, and Polytheism.

Pageant, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shows, processions, &c.

Pagi, Antony, a very famous Cordelier, and one of the ablest critics of his time, was born at Rogne in Provence in 1624. He took the habit in the convent at Arles in 1641, and was at length four times provincial of his order; but his religious duties did not prevent his vigorous application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is, A Critique upon the Annals of Baronius; where, following the learned cardinal year by year, he has rectified an infinite number of mistakes both in chronology and in the representation of facts. He published the first volume in 1689, dedicated to the clergy of France, who allowed him a pension: the whole was printed after his death, in 4 vols folio, at Geneva, in 1705, by the care of his nephew Francis Pagi, of the same order. He wrote some other things before his death, which happened in 1699; and had the character of an able historian as well as of a learned and candid critic. His nephew Francis, above mentioned, wrote a Chronological Abridgement of the History of the Popes, in Latin, 3 vols 4to. Francis had also a nephew, Anthony Pagi, who added three more volumes to the History of the Popes; of which two more were intended, if not executed.

Pagninus, Sanctus, an Italian dominican, eminent for his skill in oriental languages and biblical learning, was born at Lucca in 1466, and became afterwards an ecclesiastic of the order of St Dominic. He was Pagninus, deeply and accurately skilled in Latin, Greek, Hebrew, Chaldee, and Arabic; but he was particularly excellent in the Hebrew. He applied himself to examine the vulgar translation of the Scriptures; and believing it to be either not of Jerome, or greatly corrupted, he undertook to make a new one from the present Hebrew text; in which he meant to imitate St Jerome, who set about making a new translation at a time when the church would admit no other but the Septuagint. This design of Pagninus, so early after the restoration of letters, seemed a bold one; yet such was the reputation of the man, that it was approved by Pope Leo X., who promised to furnish him with all necessary expenses for carrying on the work: and, besides, we find at the beginning of his translation, which was printed at Lyons in 1527, two letters of the succeeding popes, Hadrian VI. and Clement VII. which licensed the printing of it. Pagninus, in his Letters to Pope Clement, for the printing of this translation, openly declares, that the Vulgar edition, as it is at present, is not St Jerome's; yet adds, that he has retained in his translation as much of it as he could. It appears by a letter of Pius Mirandula to Pagninus, that he had spent 25 years upon this translation. It is the first modern translation of the Bible from the Hebrew text; and the Jews who read it affirmed, that it agreed exactly with the Hebrew, and was in some respects superior to the ancient translations. The great fault of Pagninus was, that he adhered with too great servility to the original text; and this servility of attachment made his translation, says Father Simon, "obscure, barbarous, and full of solecisms. He imagined, that to make a faithful translation of the Scriptures, it was necessary to follow exactly the letter according to the strictness of grammar. This, however, is quite contrary to his pretended exactness, because two languages seldom agree in their ways of speaking; and therefore, instead of expressing the original in its proper purity, he defaces and robs it of all its ornaments." Father Simon nevertheless allows the great abilities and learning of Pagninus; and all the later commentators and translators of the Scriptures have agreed in giving him his just praise. Hueter, though he thinks Father Simon's criticism of him just and well grounded, yet proposes his manner as a model for all translators of the sacred books: Scripturae interpretatione rationem utile nobis exemplar proponuit Sanctus Pagninus. He also translated the New Testament from the Greek, as he had done the Old from the Hebrew, laying the Vulgar all the while before him; and dedicated it to Pope Clement VII. He was author of a Hebra Lexicon, and a Hebrew Grammar: which Buxtorf, who calls him vir linguarem Orientalium peritusissimus, made great use of in compiling his. He died in 1536, aged 70. Luther spoke of him and his translations in terms of the highest applause.

Pago, an island in the gulf of Venice, separated from the continent of Morlachia by a narrow channel. The ancient geographers have left us no description of it: though (as Fortis observes) its form (a), extent, and rich produce, unquestionably deserved it." And this

(a) Its figure is indeed remarkably irregular, its breadth being in no proportion to its length; for one of the extremities, called Punta di Loni, is above ten miles long, and less than one broad. Almost all the circumference is
is full of gravel and small stones: and hence the wine is of good quality. The air is not unhealthful, notwithstanding the vicinity of the salt pits; but the frequent high winds carry off the noxious exhalations. The most considerable product of the island is the salt. The greatest part of the people of Pago live by working in the salt pits, and have a comfortable subsistence regularly paid by the government: it is therefore a very important circumstance for the inhabitants of the city to have a dry summer; and hence the ignorant vulgar look up on rain as a mischief brought upon the country by the force of witchcraft. In consequence of this idea, they elect a friar to exorcise the meteors, and keep the rain off the island. If, notwithstanding the poor friar's endeavours, the summer happens to be rainy, he loses his reputation and his bread; but if two or three dry seasons follow successively, he meets with great reverence and advantage. Part of the salt works belongs to the government, and the rest to private proprietors; they are meliorated every year; and for that end the public lends money to those proprietors who want it, and who without that assistance could not make the requisite improvements.

"Many vestiges of ancient habitations still remain on the island of Pago, as well as of walled places, which either have been destroyed by the incursions of enemies or by time. Historians say that the island was often abandoned by its inhabitants; and indeed it is rather to be wondered at, how men ever could resolve to settle in so wretched a country. The small number of inhabitants, after so many years of peace and tranquility under the Venetian governement, evidently proves how little the island is really habitable. The town of Pago was built by the Venetians about 300 years ago; and contains upwards of 2000 inhabitants, and all the rest of the island scarcely 1000. The difficulty of access to the city of Pago, and the ill accommodation that strangers meet with, make it very little frequented. Hence the inhabitants are as wild and unpolished as if they lay at the greatest distance from the sea and the commerce of polite people. The gentry, who pretend to show their manners different from those of the vulgar, are truly grotesque figures, both in their dress, behaviour, and insolent pretensions. The ignorance of their clergy is incredible; a priest of the greatest consequence there, and who was thought a man of learning, did not know how Pago was called in Latin. There are two convents of friars in Pago and one of nuns; and several churches, all in very bad order, and ill served. At Terra Vecchia also there is a convent of Franciscan monks; a race of men who, under various names and disguises, insist every place where credulous ignorance can be persuaded to maintain the idle and superstitious. One superstitions custom,
custom, amongst a variety of others, exists among their women, and particularly among those who have been married but a short time: if their husband happens to die, they tear their hair out in go-d earnest, and scatter it on the coffin; and this ceremony is so much consecrated by custom, that no woman, even though she had notoriously hated her husband, would fail in performing it.

**Pagod** or **pagoda**, a name given by the East Indians to the temples where they worship their gods. We shall not in this place enter into a full detail of the several pagodas of different nations, and their peculiar circumstances. These matters seem to come in more properly under the religion, or, as others will call it, the superstition, of the people to whom they belong. We shall therefore content ourselves in the present article with an account of a paper in the Asiatic Researches, concerning the sculptures, &c. at Malaviparum, a few miles north of Sadrus, and known to seamen by the name of the seven pagodas.

The monuments which Mr. Chambers (who communicated the paper) describes, appears, he says, to be the ruins of some great city decayed many centuries ago. "They are situated close to the sea, between Covelong and Sadrus, somewhat remote from the high road that leads to the different European settlements. And when visited in 1776, there was still a native village adjoining to them which retained the ancient name, and in which a number of barams resided that seemed perfectly well acquainted with the subjects of most of the sculptures to be seen there. The rock, or rather hill of stone, on which great part of these works are executed, is one of the principal marks for mariners as they approach the coast, and to them the place is known by the name of the seven pagodas, possibly because the summits of the rock have presented them with that idea as they passed: but it must be confessed that no aspect which the hill assumes as viewed on the shore, seems at all to authorize this notion; and there are circumstances, which will be mentioned in the sequel, that would lead one to suspect that this name has arisen from some such number of pagodas that formerly stood here, and in time have been buried in the waves."

The rock here mentioned, as it rises abruptly out of a level plain of great extent, naturally engrosses the attention of the eye. It consists chiefly of a single stone; and in its shape (which is singular and romantic), in a distant view, it has the appearance of an antique and lofty edifice. Works of imagery and sculpture crowd thicker upon the eye on a nearer approach, and at first sight at least favours the idea of a petrified town, which, through the credulity of travellers*, has been supposed to exist in various parts of the world. "Proceeding on by the foot of the hill on the side facing the sea, there is a pagoda rising out of the ground, of one solid stone, about 16 or 18 feet high, which seems to have been cut upon the spot out of a detached rock that has been found of a proper size for that purpose. The top is arched, and the style of architecture according to which it is formed, different from any now used in these parts." Beyond this a numerous group of human figures in bas-relief, considerably larger than life, attract attention. They represent considerable persons, and their exploits, many of which are now very indistinct through the injuries of time, assisted by the corroding nature of the sea air; others, while protected from that element, are as fresh as when recently finished.

The hill, which is at first of easy ascent, "is in other parts rendered more so, by very excellent steps cut out in several places, where the communication would be difficult or impracticable without them. A winding stair of this sort leads to a kind of temple cut out of the solid rock, with some figures of idols in high relief upon its walls, very well finished and perfectly fresh, as it faces the west, and is therefore sheltered from the sea air." This temple our author conjectures to have been a place of worship appertaining to a palace; some remains of which still exist, and to which there is a passage from the temple by another flight of steps. This conjecture (for it is brought forward as merely such) is in some measure favoured by several ruins still remaining, and by the tradition of the braminis who inhabit the place. This finishes the objects "on that part of the upper surface of the hill, the ascent to which is on the north; but on descending from thence, you are led round the hill to the opposite side, in which there are steps cut to the bottom to a place near the summit, where is an excavation that seems to have been intended for a place of worship, and contains various sculptures of Hindoo deities. The most remarkable of these is a gigantic figure of Fishikin (A), asleep on a kind of bed, with a huge snake wound about in many coils by way of pillow for his head; and these figures, according to the manner of this place, are all of one piece hewn from the body of the rock." These works, however, although they are unquestionably stupendous, are, in our author's opinion, surpassed by others about a mile and a half to the southward of the hill. "They consist of two pagodas of about 30 feet long by 20 feet wide, and about as many in height, cut out of the solid rock, and each consisting originally of one single stone. Near these also stand an elephant full as big as life, and a lion much larger than the natural size, but very well executed, each hewn also out of one stone. None of the pieces that have fallen off in cutting these extraordinary sculptures are now to be found near or any where in the neighbourhood of them, so that there is no means of ascertaining the degree of labours to have that has been spent upon them, nor the size of the rock or rocks from which they have been hewn; a circumstance which renders their appearance the more striking and singular. And though their situation is very near the sea beach, they have not suffered at all by the corrosive air of that element, which has provided them with a defence against itself, by throwing up before them a high bank that completely shelters them. There is also a great symmetry in their form, though that of the pagodas is different from the style of architecture according to which idol temples are now built in that country. The latter resembles the Egyptian; for the towers are always pyramidal, and the gates and roofs flat and without arches; but these sculptures approach nearer to the Go-

---

thtic taste, being surmounted by arched roofs or domes that are not semicircular, but composed of two segments of circles meeting in a point at top." Our author observes, that the lion in this group, as well as one on a stone couch in what he took to be a royal palace, are perfectly just representations of the true lion, and the natives there give them the name which is always understood to mean a lion in the Hindoo language, to wit, sing; but the figure which they have made to represent that animal in their idol temples for centuries past, though it bears the same appellation, is a distorted monster, totally unlike the original; insomuch that it has from hence been supposed, that the lion was not anciently known in this country, and that sing was a name given to a monster that existed only in Hindoo romance. But it is plain that that animal was well known to the authors of these works, who, in manners as well as arts, seem to have differed much from the modern Hindoos.

"There are two circumstances attending these monuments which cannot but excite great curiosity, and on which future inquiries may possibly throw some light. One is, that on one of the pagodas last mentioned, there is an inscription of a single line, in a character at present unknown to the Hindoos. It resembles neither the Devanagari, nor any of the various characters connected with, or derived from it, which have come to the writer's knowledge from any part of Hindostan. Nor did it, at the time he viewed it, appear to correspond with any character, Asiatic or European, that is commonly known. He had not then, however, seen the alphabet of the Balic, the learned language of the Siamese, a sight of which has since raised in his mind a suspicion that there is a near affinity between them, if the character be not identically the same. But as these conjectures, after such a lapse of time, are somewhat vague, and the subject of them is perhaps yet within the reach of our researches, it is to be hoped that some method may be fallen upon of procuring an exact copy of this inscription.

"The other circumstance is, that though the outward form of the pagodas is complete, the ultimate design of them has manifestly not been accomplished, but seems to have been defeated by some extraordinary convulsion of nature. For the western side of the most northerly one is excavated to the depth of four or five feet, and a row of pillars left on the outside to support the roof; but here the work has been stopped, and an uniform rent of about four inches breadth has been made throughout the solid rock, and appears to extend to its foundations, which are probably at a prodigious depth below the surface of the ground. That this rent has happened since the work began, or while it was carrying on, cannot be doubted; for the marks of the masons tools are perfectly visible on the excavated part on both sides of the rent, in such a manner as to show plainly that they have been divided by it. Nor is it reasonable to suppose, that such a work would ever have been designed or begun upon a rock that had previously been rent in two. Nothing less than an earthquake, and that a violent one, could apparently have produced such a fissure in the solid rock: and that this has been the case in point of fact, may be gathered from other circumstances, which it is necessary to mention in an account of this curious place. The great rock above described is at some small distance from the sea, perhaps 50 or 100 yards, and in that space the Hindoo village before mentioned stood in 1776. But close to the sea are the remains of a pagoda built of brick, and dedicated to Sib, the greatest part of which has evidently been swallowed up by that element; for the door of the innermost apartment, in which the idol is placed, and before which there are always two or three spacious courts surrounded with walls, is now washed by the waves, and the pillar used to discover the meridian at the time of founding the pagoda is seen standing at some distance in the sea. In the neighbourhood of this building there are some detached rocks, washed also by the waves, on which there appear sculptures, though now much worn and defaced. And the natives of the place declared to the writer of this account, that the more aged people among them remembered to have seen the tops of several pagodas far out in the sea, which being covered with copper, (probably gilt) were particularly visible at sunrise, as their shining surface used then to reflect the sun's rays, but that now that effect was no longer produced, as the copper had since become incrusted with the mould and verdigrise.

"From these circumstances our author conjectures, and we think reasonably, that the magnificent city of which these appear to be part of the ruins, has been destroyed partly by an earthquake, by which the rock was rent, and partly by a sudden inundation of the sea, occasioned by this commotion of the earth. The braminis give an account of this matter peculiar to themselves, filled with extravagance, fable, and folly; from which, however, with the assistance of ancient monuments, coins, and inscriptions, some probable conjectures at least, if not important discoveries, may, it is hoped, be made on these subjects, which are far from being uninteresting to us either as men, philosophers, or Christians. Our author thinks, therefore, that the inscription on the pagoda mentioned above is an object which merits considerable attention; and he defends, by very reputable authorities, the conjecture which places it among the languages of Siam; but which it is unnecessary for us either to abridge or to transcribe. In the course of this inquiry, our author remarks a very near resemblance between Sommonarodom, the idol of the Siamese, and the great idol Budho, held sacred by the Chingelays; and this resemblance extends also to their priests. But from the detail of circumstances which our author brings forward, and to which we refer, he thinks this a system of religion different from that of the Vedas, and some of them totally inconsistent with the principles and practice of the braminis; none of whom, as far as we can collect from Mr. Knox's, 6th of exist among the Chingelays, whose religion is totally different from that of the present Hindoos. The only part in which there seems to be any agreement is in the worship of the Deitahs, which has probably crept in among them from their Tamulian neighbours, but that is carried on in a manner very different from the braminical system, and appears to be held by the nation at large in very great contempt, if not abhorrence. Knox's account of it is this: "Their temples (i.e. those of the Deitahs) are called korets," which is the Tamulie word for pagoda. He then goes on to say, "a man piously disposed builds a small house at his own charge,
PAGOD, or PAGODA, is also the name of a gold and silver coin, current in several parts of the East Indies.

PAIN, an uneasy sensation, arising from a sudden and violent solution of continuity, or other accident in the nerves, membranes, vessels, muscles, &c. of the body.

Pain, according to some, consists in a motion of the organs of sense; and, according to others, it is an emotion of the soul occasioned by those organs.

As the brain is the seat of sensation, so it is of pain. Boerhaave, and most other authors on this subject, assign a stretching of the nerves as the only immediate cause of pain: but as the nerves do not appear to consist of fibres, this cause of pain does not seem to be well-founded; nor indeed will it be easy to treat this subject clearly, but in proportion as the means of sensation are understood.

Many kinds of pain are met with in authors: such as,

A grattitative pain; in which there is a sense of weight on the part affected, which is always some fleshy part, as the liver, &c. A pulsative pain; which, Galen says, always succeeds some remarkable inflammation in the containing parts, and is observed in abscesses while suppressing. A tense pain, which is also called a distending pain; it is excited by the distension of some nervous, muscular, or membranous part, either from some humour, or from flatulence. An acute pain is, when great pain is attended with quick and lively sensations: A dull pain is, when a kind of numbness is as much complained of as the pain is.

The mediate and more remote causes of pain are generally obvious; and when this is the case, the cure will consist for the most part in removing them: for though in many instances the chief complaint is very distant from the seat of those causes, yet their removal is the proper method of relief. See Medicine, passion.

Perhaps all pains may be included, with irritation, in those that have spasm or inflammation for their source. When pain is owing to inflammation, the pulse is quicker than in a natural state; it is also generally full, hard, and tense; the pain is equal, throbbing, and unremitting. If a spasm be the cause, the pulse is rarely affected; at intervals the pain abates, and then returns with some degree of aggravation; gentle motion sometimes abates, or even cures, in some instances; but in inflammatory cases no such effects are ever experienced. See Dr. Lobb's Treatise on Painful Distemps.

The pain so frequently attendant on women in childbed, called after-pains (from their happening only after being delivered of a child), are often occasioned by attempts to bring away coagulated blood, which is a needless endeavour. When no improper treatment in delivering the secondimes can be suspected, the irri-
tability of the uterus alone is to be considered as the cause. Care should be taken not to confound these after-pains with, or mistake the pains attending several fevers for the colic. After-pains come by fits, and soon go off; but return at different intervals, which are longer each day, and after two or three days are usually at an end, though sometimes they continue seven or eight: notwithstanding these pains, the lochia flow properly, and generally more abundantly after the cessation of each fit; this does not happen in colicky complaints, nor is the belly so free from tumefaction when the puerperal fever is attendant.

As these pains are of the spasmodic kind, anodynes

and
PAINING.

PAINTING is the art of representing to the eye, by means of figures and colours, every object in nature that is discernible by the sight: and of sometimes expressing, according to the principles of physiognomy, and by the attitudes of the body, the various emotions of the mind. A smooth surface, by means of lines and colours, represents objects in a state of projection; and may represent them in the most pleasant dress, and in a manner most capable of enchanting the senses. Still farther, the objects which delight us by their animation and lively colours, speak to the soul, by giving us the image of what we hold most dear, or by indicating an action which inspires us with a taste for innocent pleasures, with courage, and with elevated sentiments. Such is the definition, and such are the effects of painting.

By an admirable effort of human genius, painting offers to the eye everything which is most valuable in the universe. Its empire extends over every age and country. It presents to us the heroic deeds of ancient times as well as the facts in which we are more conversant, and distant objects as well as those which we daily see. In this respect it may be considered as a supplement to nature, which gives us only a view of present objects.

The art of painting is extremely difficult in the execution; and its merit can only be appreciated by those who profess the art.

The painter who invents, composes, and colours conceptions which are only agreeable, and which speak merely to the eye of the spectator, may be reckoned to possess the first merit in the style of embellishment and decoration.

The painter who is distinguished for noble and profound conceptions; who, by means of a perfect delineation, and colours more capable of fixing the attention than dazzling the eye, conveys to the spectators the sentiments with which he himself was inspired; who animates them with his genius, and makes a lasting impression on their minds; this artist is a poet, and worthy to share even in the glories of Homer.

It is in forming this great idea of his art that the painter becomes himself great.

But if he seek only to please or astonish by the illusion of colours, he must rest contented with the secondary merit of flattering the eye with the variety and opposition of tints, or of making an industrious assemblage of a great multiplicity of objects. It is in painting as it is in poetry. The man who clothes trivial or common ideas in verse, exercises the profession of twisting syllables into a certain measure. The poet who clothes in good verse, ideas and sentiments that are merely agreeable, professes an agreeable art. But he who by the magic of verse, of ideas, of imagery, or of colours, adds sublimity to the sublime objects of nature, is a great poet and a great painter. He deserves the crown which the nations have decreed to Homer, Virgil, Milton, Raphael, and the statuary who modelled the ancient Apollo. It is reasonable to place in the same class those who have expressed the same ideas, whether it be in verse or in colours, on brass or on marble. The painter and statuary, who excel in their professions, deserve all the respect due to genius: they are of the number of those men whom nature, sparing of her best gifts, grants but occasionally to the inhabitants of the earth. If they are sublime, they elevate the human race; if they are agreeable only, they excite those sweet sensations necessary to our happiness.

In laying before our readers a succinct account of this noble art, we shall, first, give the history of painting, including its rise, progress, and decline, in ancient and modern times; an account of the schools, and of the different merits of painters; and a comparison between the ancient and modern painting. Secondly, we shall lay down the principles of the art, and the order in which the artist conducts his studies. Thirdly, we shall enumerate the different classes of painting, with observations on each. And, Fourthly, we shall treat of economical or house painting.

HISTORY.

SECT. I. Rise, Progress, and Decline of Painting in Ancient and Modern Times.

It is to be imagined that men must naturally, and very early, have conceived an idea of the first principles of the art of painting; the shadow of each plant and animal, and of every object in nature, must have afforded them the means of conceiving, and pointed out the possibility of imitating, the figures of all bodies. Thus the savage nations, an emblem of what men were in the infancy of society, possess the first rudiments of this art, even before those which are useful and almost necessary to existence; their naked bodies are covered with punctures of various forms, into which they infuse indelible colours. The next demand for this art, is to preserve the memory of warlike exploits. It is more natural to form some representation of an action, than to give an account of it by means of arbitrary characters. Hence the picture-writing of the Mexicans, and the more complex hieroglyphics of Egypt.

Painting consisted of simple outlines long before the expression of relievo, or the application of colour. It
PAINTING.

The monuments of Egyptian painting with which we are best acquainted (says Winklemann) are the chests and coffins of mummies. These works have resisted the injuries of time, and are still submitted to the examination of the curious. The white, made of white lead, is spread over the ground of the piece: the outlines of the figure are traced with black strokes, and the colours are four in number; namely, blue, red, yellow, and green, laid on without any mixture or shading. The red and blue prevail most; and those colours seem to have been prepared in the coarsest manner. The light is formed by leaving those parts of the ground, where it is necessary, covered with the white lead, as it is formed by the white paper in some of our drawings. This description is sufficient to convince us that the whole art of painting in Egypt consisted in colouring: but every person knows, that without tints and the mixture of colours painting can never arrive at great perfection.

In Upper Egypt there seems to have existed a kind of colossian painting, which has never been examined, except by travellers who were not great critics in the art. Winklemann had some reason to express a desire that those remains of antiquity, with regard to the manner of working, the style, and the character, had been accurately explored. Walls of 24 feet in height, and pillars of 32 feet in circumference, are wholly covered with those colossian figures. According to Norden they are coloured in the same manner with the mummies: the colours are applied to a ground prepared in manner of fresco; and they have retained their freshness for many thousand years. Winklemann adds, that all the efforts of human skill and industry could make as little impression on them as the injuries of time. His enthusiasm for antiquity has perhaps led him into this extravagant exaggeration.

It appears that the great employment of the Egyptian painters was on earthen vessels, on drinking cups, in ornamenting barges, and in covering with figures the coffins of mummies. They painted also on cloth; but painting, as an industrious occupation, supposes a workman not an artist: the decoration of temples, houses, painting, and that of the figures relative to religion, are to be considered only in this point of view. The workmen in Russia who paint our Saviour holding the globe in one hand, and blessing the people with the other, are not members of the imperial academy of fine arts.

Pliny informs us that the Egyptian artists painted also the precious metals; that is to say, they varnished or enamelled them. It is doubtful what this art was, but most probably it consisted in covering gold or silver with a single colour.

The Egyptians are supposed to have continued this coarse style till the reign of the Ptolemies. The Persians were so far from excelling in the arts, in Persia, that the paintings of Egypt were highly esteemed among them after they had conquered that country.

The carpets of Persia were of great value in Greece, even in the time of Alexander the Great, and these were adorned with various figures; but this is no proof that they were well executed, any more than a demand for several of the Chinese productions is of present a proof of the taste of that people in the arts. It was the fabrication of the silk, and not the truth of the representation, which made the Greeks admire the carpets of the Persians.
PAINTING.

The Persians, as well as the Arabians, had some knowledge of mosaic work. This is only valuable when it copies, in a manner that cannot be destroyed, the works of a great master; but if the Persians had no good pictures to copy into mosaic, it was of no consequence to be able to arrange, in a solid manner, pieces of fire one beside another.

There is only one Persian painter whose name has descended to posterity; and he is preserved, not because he was a painter, but because he acquainted the ancient doctrine of the two principles to the Christian religion. Besides, it is doubted whether Manes was a Persian or a Greek, and it is still less known whether he was a painter. He is praised in Asia for drawing straight lines without a ruler.

The modern Persians have made no kind of progress in the arts. The emperor Schah Abbas, wishing from caprice to be instructed in drawing, was obliged to have recourse to a Dutch painter who happened to be in his dominions.

The modern Persians paint on cloth, and the artists in India are their rivals in this branch of industry; but their paintings are purely capricious. They represent plants and flowers which have no existence in nature; and their only merit consists in the brightness and the strength of their colours.

Besides this, an art in India, as it was in the most remote antiquity, is confined to monstrous figures connected with their religion, animals not to be found in the world, and idols with a multitude of arms and heads, which have neither exactness in their forms nor proportions. See POLYTHEISM.

The paintings of Thibet discover great patience in the artist, and are remarkable for the fineness of their strokes. Their painters might dispute with Apelles and Protogenes for extreme tenuity of pencil; but it is in this alone, without any regard to the art, in which their merits consist.

Some of the idols in Thibet are executed in a certain style of relievo; but those productions are not only imperfect, they are also so destitute of beauty as to forbid every hope of excellence in the art. The same thing may be observed with regard to many of the eastern nations; they seem to have that want of style which would for ever condemn them to mediocrity, even if they should happen to arrive at it.

The Chinese seem not to have the smallest conception of perspective. Their landscapes have no plan, no variety in the appearance of the clouds, and no diminishing of the objects in proportion to their distance.

The great object of their painting seems to consist in making their figures as unlike nature as possible; it is a serious caricature of the human figure.

To make the art flourish, it is necessary that the artist be esteemed and rewarded. In China, there is no artist so poorly paid as the painter.

The ignorant admire the brightness and purity of their colours; but simple colours appear always bright and pure. The difficulty of the art consists in melting them into one another in such a manner that the mixture shall not be perceived. It must at the same time be confessed, that their natural colours are more brilliant than ours; but if there be any merit in this, it is to be ascribed to their climate, not to their abilities.

A Jesuit missionary, who in his youth had been a grinder of colours, was raised to the greatest eminence as a painter in the Imperial court of China, and Raphael himself was never so much respected. The Chinese battles sent from that country to Paris to be engraved, are the work of the Jesuits; and except they were done by the Chinese themselves, it is impossible to conceive that they could be worse executed.

The Chinese, like other eastern nations, have a few simple strokes which they repeat in all their variety of figures. In the figures on the earthenware, they discover no knowledge of forms, no expression of the most conspicuous muscles, and no idea of proportion. And in all the paintings of China, anatomy seems to bear no relation to the art. Some heads done by a Chinese painter have a sort of resemblance to nature, but they are in a low and vicious taste: The fullness of the drapery conceals the parts in such a manner that they do not seem to exist under it. Sculpture in China is in a state of no great perfection, but at the same time it is better executed than their paintings.

The ancient inhabitants of Etruria, now called Tuscan, were the first who connected the arts with the study of nature. In some of their monuments which still remain, there is to be observed a first style, which shows the art in its infancy; and a second, which, like the works of the Florentine artists, shows more of greatness and exaggeration in the character than precision or beauty.

Pliny says that painting was carried to great perfection in Italy before the foundation of Rome; perhaps he means in comparison with the infancy of the art in Greece at that period; but it appears that even in his time the painters of Etruria were held in great estimation.

The only Etrurian paintings which remain, have been found in the tombs of the Tarquins. They consist of long painted frizes, and pilasters adorned with huge figures, which occupied the whole space from the base to the cornice. These paintings are executed on a ground of thick mortar, and many of them are in a state of high preservation.

Winklemann is of opinion, that the Greek colonies estabished at Naples and Nola, had at a very early period cultivated the imitative arts, and taught them to the Campanians established in the middle of the country. This learned antiquarian considers as works purely Campanian, certain medals of Capua and Teanum, cities of Campania into which the Greek colonies never penetrated. The head of a young Hercules, and the head of Jupiter, according to Winklemann, are executed in the finest manner. It is still a question, however, in the learned world, whether these medals owe their existence to Carthage or to Campania.

But there has been discovered (adds Winklemann) a great number of Campanian vases covered with painting. The design of the greatest part of these vases (says he) is such, that the figures might occupy a distinguished
History.

Painting.

We have already seen, that before the foundation of Rome, the arts were cultivated in Etruria. They were early introduced into Latium; but whether that country employed its own artists or those of Etruria, remains altogether uncertain. One need not be sure, among the Romans, that at a period when the arts were in their infancy in Greece, they were raising statues to their kings in Rome: but at that period all their artists were Etrurians or Latins; and when they conquered Italy, they made all the nations of it as barbarous as they were themselves.

In the year 259 from the building of the city of Rome, and 494 years before the Christian era, Appius Claudius consecrated a number of shields in the temple of Bellona, which contained in baso relieve the portraits of his family. This example was followed; and in process of time it was common among the Romans to place those images in private houses. The execution in baso relieve is a proof that they had an idea of painting, at least with one colour. As long as the Romans employed artists of other nations, they had little desire to cultivate the arts; but towards the year of Rome 450, and 303 years before Christ, one of the Fabii thought it no discredit to a noble family to employ himself in painting. He painted the temple of Safety; and his works remained till that temple was destroyed by fire, in the reign of Claudius. It is worthy of remark, that the same man was the first painter and the first historian in his country.

The example of Fabius, surnamed Pictor from his profession, did not excite his fellow citizens to imitation. A century and a half elapsed before the tragic poet Pacuvius, nephew of Ennius, painted the temple of Hercules in the forum boarium. The glory which he had acquired by his dramatic works shed some lustre on the art, which he had consecrated to exercise; but did not confer on it that respect which could recommend it to general practice. The paintings of Fabius were the works, or rather the recreations of his youth; those of Pacuvius, the amusements of his old age: but painting is a difficult art, which requires the whole attention, and which can never be prosecuted with success, except those who love it are solely devoted to the performance.

It appears that there were no eminent painters at Rome till the time of the emperors; but as the national spirit was changed, the profession of the fine arts acquired more respectability. The Romans, during the time of the republic, were animated with the spirit of liberty and the desire for conquest. When these two passions were weakened, the love of the arts obtained among them. As a proof of this it is sufficient to say, that Nero himself gloried in being an artist. A colossal picture of 120 feet was painted at Rome by command of this emperor, which was afterward destroyed by lightning. The name of the painter is not recorded, and there are various opinions concerning the merit of the performance; but the thing chiefly worthy of observation is, that this is the only painting on cloth mentioned by ancient authors.

The paintings of the ancient artists were either moveable, or on the ceilings or compartments of buildings, modes of According to Pliny, the most eminent were those who painted the painted moveable pictures. The latter were either on the ancient for wood, larch, boxwood, or canvas, as in the colossus picture.
PAINTING.

picture mentioned above, and sometimes on marble. When they employed wood, they laid on in the first instance a white ground. Among the antiquities of Herculaneum are four paintings on white marble.

Their immovable paintings on walls were either in fresco or on the dry stucco in distemper. Indeed all the ancient paintings may be reduced to, first, fresco painting; secondly, water colour, or distemper painting on a dry ground; and, thirdly, encaustic painting.

The ancient fresco paintings appear to have been always on a white stucco ground, the colours laid very deep, and the drawing much more bold and free than any similar performance of modern art. The outlines of the ancient paintings on fresco were probably done at once, as appears from the depth of the incision and the boldness and freedom of the design, equal to the care and spirit of a pencilled outline.

In general the ancients painted on a dry ground even in their buildings, as appears from the Herculaneum antiquities, most of which are executed in this manner. At Rome and Naples, the first (deepest) coat is of true pizzolana, of the same nature with the tarsas now used in mortar required to keep out wet, about one finger thick; the next of ground marble or alabaster, and sometimes of pure lime or stucco, in thickness about one third of the former. Upon this appear to have laid a coat of black, and then another of red paint; on which last the subject itself was executed. Such seems to have been their method of painting on walls; but in their movable pictures, and in the performance of their first artists, and where effect of shade and light were necessary, they doubtless used white.

The colours employed they seem to have mixed up with size, of which they preferred the made by boiling the ears and genitals of bulls. This appears to have made the colour so durable and adhesive, that the ancient paintings lately found bear washing with a soft cloth and water; and sometimes even diluted aquafortis is employed to clean their paintings on fresco. Pliny says that gum dissolved in vinegar and then dried, is not again soluble.

What the encaustic painting of the ancients was, has been much disputed. From the works of Vitruvius and Pliny, it appears evidently that it was of three kinds.

First, Where a picture painted in the common way, was covered with a varnish of wax melted, diluted with a little oil, and laid on warm with a brush.

Secondly, Where the colours themselves were mixed up with melted wax, and the mixture used while warm. And,

Thirdly, Where a painting was executed on ivory by means of the cestrum or viriculum.

Some experiments on this last method by Mr Colebrook may be found in the Phil. Trans. vol. li. and more particular directions in Muntz's Treatise on Encaustic Painting.

It appears from ancient writings of the best authority, that in the earliest and purest times of this art, the painters used few colours, perhaps not more than four. "The paintings of the ancients (says Dionysius Halicarnasseus) were simple and unvaried in their colouring, but correct in their drawing, and distinguished by their elegance. Those which succeeded, less correct in their drawing, were more finished, more varied in their light and shades, trusting their effect to the multitude of their colours." But no certain conclusion can be drawn, that the more early among the great painters of the ancients, such as Apollodorus, Zeuxis, Timanthes, &c. had only four different colours, merely because they did not use them. On the contrary, it may be conjectured with some degree of probability, from their chasteness in design, and from the complaints Pliny makes of the gaudy taste of the Roman painters, that the Greeks in general were designedly chaste in their colouring, and not merely from necessity, at least about the time of Zeuxis and Apelles; for the former could not have painted grapes so naturally as he is said to have done with four colours only; and the rebuke given by the latter to one of his scholars who had painted a Helen very gaudily, is a confirmation of these observations. "Young man (says Apelles), not being able to make her beautiful, you have made her rich."

Of white colouring substances, the ancients had white lead variously prepared, a white from calcined egg shells, and preparations from cretaceous and argillaceous earths. The moderns, in addition, have magistry of bismuth, little used; and sought to have the calces of tin and zinc.

Of blacks, the ancients had preparations similar to lamp, ivory, blue, and Francfort black; also to Indian ink, and common writing ink; and they used, what we do not, the precipitate of the black dyers vats.

The ancients possessed a species of vermillion or fine cinnabar, a coarser cinnabar, red lead, various earths burnt and unburnt, apparently similar to our red ochre, Venetian red, Indian red, Spanish brown, burnt terra de Sienna, and scarlet ochre; they had also a substance alike in colour and in name to our dragon's blood.

The yellow pigments of the ancients were generally the same with our orpiments, king's yellow, Naples yellow, &c. They did not possess turpeth-mineral, mineral yellow, or gamboge; nor do they appear to have known of gall-stone as a pigment.

Of blue paints they had preparations from the lapis cyanus and lapis armenius. Indigo they had, and perhaps bice and small; for they made blue glass, but whether from some ore of coal or of wolf-rain must be uncertain; they had not Prussian blue, verditer, or linsia, which we have. We do not use the blue precipitate of the dyers vats, or mountain blue, which they certainly employed.

Of green colours they had verdigrise, terre verte, and malachite or mountain green. The latter is not in use among us. Sap-green, green verditer, and Scheele's green, appear to have been unknown to them; like us, they procured as many tints, as they pleased from blue and yellow vegetables.

We have no original purple in use; that from gold by means of tin, though very good when well prepared, is too dear perhaps, and unnecessary. Their purple was a tinged earth. Their orange or sandarac (red orpiment) we also possess. Hence there does not appear to have been any great want of pigments, or any very material difference between the colours they used and such as we generally employ. Perhaps the full effect of colouring may be obtained without the use of exceeding brilliant pigments, depending chiefly on the proportion and opposition of tints.
PAINTING.

The ancients could not know any thing about the spirit varnishes, distillation being a modern invention; but they were undoubtedly acquainted with the use of the better oil varnishes, that is, with the use and effect of resinosous gums dissolved in boiling inspissated oils.

One of the best preserved mummies in the British Museum has an astonishing brightness of colours on the outside of the coffin. Thousands of years have not impaired them; they are as fresh as if they had been laid on yesterday.

The chalk ground, and the excellency of the colours, some of which imply a good deal of chemical and metallic knowledge, do not sufficiently account for their splendour and freshness: it must be owing to other circumstances; either to the mixture of shining colours, or to a hard glossy skin, which visibly covers them all over.

From an accurate examination of one of those mummies belonging to the university of Cambridge, it appeared, that the varnish which covered the colours could not be dissolved, or in the least affected by common water; and that it equally resisted the dissolving power of the stronger spirits: hence it is reasonable to conclude that the colours and varnishes were not covered with size, white of eggs, simple gums, or any preparation of wax, but with a fine transparant oil varnish. It was discovered at the same time, that the colours themselves were not prepared or mixed with oil; for where the external glossy skin was damaged, broken, or rubbed off, even common water would wash the colours away, and affect the chalk ground under them.

Pliny has described the general and particular effects of the varnish of Apelles, under the name of atramentum, so indistinctly, that nobody can distinguish the thing or the mixture he is speaking of. He has mentioned the shining glossy skin of the varnish which excites the brightness of the colours, and preserves them against dust; he observed, that this skin was laid on so thin, that it could not be discerned at any distance: nor was he less accurate in reporting the particular effects of that mixture which Apelles made use of; it harmonized and lowered the tone of the brightest florid colours in an imperceptible manner; he appeared as if it had been thrown through isinglass. The chemists and connoisseurs are fully of opinion, that no liquid substance or mixture of any kind is fit to produce these effects besides the oil varnishes: and if there are not, Apelles and the Greeks were certainly acquainted with those varnishes a fact which might be strongly urged in behalf of their knowledge of oil colours.

The black outlines of the figures on the most ancient Greek paintings yet extant, that is, on Etruscan vases, are so sharp, so thick, and drawn in so easy and masterly a manner, that one cannot help looking upon them as having been drawn in oil colours. Had they been in distemper or water colours on the red clay ground on which they are applied, they would have been imbibed and soaked into it. Our china and enamel painters prepare and apply their colours with spirit or other liquid oils; and the Greek masters seem to have done the same, unless they should appear to have burnt their vases before they painted them, or to have used a mixture of dissolved wax or gum for giving a body to their colours, which might have answered the same ends as oils. And this is the more probable, as there is some reason to believe that these vases went through two different fires, that of baking them, and that of smelting or burning in their colours.

The Greek and Roman paintings that have been preserved or discovered at Rome and Herculaneum do not countenance the supposition of oil colours; at least, Turnbull and the academists at Naples, who have described the royal collection at Portici, Cochin, and many other authors who have seen and described them, do not hint any thing of that nature. On the other hand, Vitruvius, who has left us so many valuable notices of the ancient arts, acquaints us, that there was a kind of painting which absolutely required a mixture of oil: And Pliny, to the same purpose, expressly says, "Sun and moon shine are inimical and obnoxious to red lead. The remedy is to apply the red wax when hot and melted with some oil on the well dried walls, which is to be done with brushes."

From these observations, the evidence which the ancients have given us in behalf of themselves, and of their knowledge of oil painting, may be summed up in few words.

Their having been acquainted with the white chalk ground, which many modern masters have used for oil painting on boards, proves no more than that the ancients might have done the same.

The oil varnishes used by the Egyptians and by Apelles might have brought them to the discovery of oil painting; but as it appears both from mummies and from the works of Pliny, that their colours were not prepared and mixed with that varnish, and as it is plain rather that this varnish was externally laid over the finished pictures; no other conclusion can be drawn, except that they were within sight of the discovery, and that it is a matter of wonder that they should not have laid hold of it.

The outlines of the old Greek or Etruscan vases are merely fallacious appearances.

The old Greek and Roman paintings on walls and stones are either painted in distemper and fresco, or they have not been sufficiently examined.

The oil used in the counter wax and wall paintings proved at most that experience had been tried with oils: but we have no direct proofs of oil painting having been understood or used by the Egyptians, Greeks, or Romans, and that, however great their skill or ingenuity, they might very well have been within sight and reach of the discovery, and nevertheless have missed it.

The art of painting was revived in Europe about the end of the 13th or beginning of the 14th century. The great and human mind, however, plunged in profound ignorance, and modern painting was destitute of every principle of sound philosophy which might enable it to determine on the objects of the arts; and of consequence the painters contented themselves with works adapted to the general taste, without beauty and without proportion. In Italy, where the first attempts were made, they were employed in representing the mysteries of the passion, and subjects of a similar nature, on the walls of chapels and churches. Their labours were directed to a vast number of figures, rather than to the beauty and perfection of each; and the art in more modern times has always preserved somewhat of this absurd fault which it contracted at that early period. The artist, in our times is not, like those in Greece, at liberty to...
devote his talents only to men of knowledge and discernment; he is constrained to please those who are rich, and very frequently those who are ignorant. Instead of proposing to himself the perfection of the art as the great object of his pursuit, he must rest his success and character on the facility of his operation and the abundance of his works.

Painting did not long continue in the imperfect condition in which it was left by those who first cultivated it among the moderns. It was natural that their successors should endeavour to surpass them, by joining some degree of theory to the barbarous practice they had adopted. The first thing which they discovered, or rather which they revived after the manner of the ancients, was perspective. This made the artists capable of expressing what is called foreshortening, and of giving more effect and more truth to their works.

Domoinique Ghirlandaio, a Florentine, was the first who enriched the style of his composition by grouping his figures, and who gave depth to his pictures, by distinguishing, by exact gradations, the spaces which his figures occupied; but his successors have far surpassed him in boldness of composition.

Leonardo da Vinci, Michael Angelo, Giorgian, Titian, Bartholomew de St Marc, and Raphael, flourished about the end of the 14th century. Leonardo da Vinci was the inventor of a great many details in the art: Michael Angelo, by studying the ancients, and by his knowledge of anatomy, arrived at great elegance in drawing the outlines of his figures: Giorgian enriched the art in general, and gave greater brilliancy to his colours than his predecessors: Titian, by a careful imitation of nature, made great proficience in the truth and perfection of his tones: Bartholomew de St Marc studied particularly the part of drapery, and discovered the claro obscuro, the best manner of giving drapery to his figures, and of making the naked to be felt even where they were covered. Raphael, endowed with a superior genius, began with studying carefully all his predecessors and all his contemporaries. He united in himself all the excellencies which they possessed; and formed a style more perfect and more universal than any painter who went before or who has succeeded him. But while he excelled in every part of the art, he was chiefly superior in those of invention and composition. It is probable that the Greeks themselves would have been fill'd with admiration if they had beheld his chief pieces in the Vatican, where to the greatest abundance of paintings is joined so much perfection, and purity, and ease.

After painting had arrived at the greatest perfection among the Greeks by the exertions of Zeuxis and Parrhasius, Apelles found nothing to add to the art except grace; in the same manner among the moderns, after Raphael had appeared, grace was the only thing wanting to the art, and Corregio became the Apelles of Europe. Painting was by him carried to the highest degree among the moderns; the taste of the best critics and the eye of the vulgar were equally gratified.

After these great masters a considerable interval elapsed till the time of the Caracci. Those artists born at Bologna, by studying the works of their predecessors with great care, and particularly those of Corregio, became the first and the most celebrated of their imitators. Hannibal possessed a very correct design, and united somewhat of the ancient style to that of Lewis his brother; but he neglected to inquire into the intricate principles and philosophy of the art. The pupils of the Caracci formed a school after their manner; but Guido, a painter of an easy and happy talent, formed a style altogether graceful, and rich, and easy. Guersehen formed after Caravaggio, or invented himself, a particular style of the claro-obscuro, composed of strong shades and vivid oppositions.

Peter de Cortona succeeded those great imitators of their predecessors and of nature; who finding it difficult to succeed in that kind of painting, and having besides great natural abilities, applied himself chiefly to composition or arrangement, and to what the artists call taste. He distinguished invention from composition; appeared not to have attended to the former, but chiefly to those parts which are most prominent in the picture, and to the contrasting of groups. It was then that the practice was introduced of loading pictures with a great number of figures, without examining whether or not they agreed to the subject of the history. The ancient Greeks employed a very small number of figures in their works, in order to make the perfection of those which they admitted more evident. The disciples or imitators of Cortona on the other hand, have sought to conceal their imperfections by multiplying their figures. This school of Cortona is divided into many branches, and has changed the character of the art. The multiplication of figures, without a judicious and proper choice, carried back the art of painting to that point where the first restorers of it among the moderns had left it; while at the same time the disciples of Cortona were enabled to give to this first condition of the art a greater degree of perfection than the first artists.

About the middle of the 17th century flourished at Rome Carlo Maratti, who, aiming at the greatest perfection, carefully studied the works of the first painters, and particularly those of the school of the Caracci. Although he had already studied nature, he discovered by the works of these artists that it is not always proper to imitate her with a scrupulous exactness. This principle, which he extended to every part of the art, gave to his school a certain style of carefulness, which however is considerably degenerated.

France has also produced great masters, particularly in the part of composition; in which Poussin, after Raphael, is the best imitator of the style of the ancient Greeks. Charles le Brun and many others distinguished themselves for great fertility of genius: and as long as the French school departed not from the principles of the Italian school, it produced masters of great merit in the different branches of the art.

Mengs, from whom this account is taken, is not deceived when he declares the art of painting to have degenerated in France after Le Brun; but he seems to be mistaken in giving the imitation of the works of Robens found at Paris as the cause of this decay. It appears from this opinion, that the recent French school was not well known to him. The French, indeed, if we may believe their own authors, were never much occupied in the imitation of Robens; and they have for a long time despised him. But the perfection of the dramatic art in France, the dress of their actors, the magnificence and manners of the court, have contributed very much to the decay of painting.
were honoured, and they deserved to be honoured. Their distinguished reputation has conferred a value on the general paintings of their countrymen. The desire of possessing taste, or of being thought to possess it, had led the rich and the ignorant of all nations to give a preference to the Italian market. Necessity, in this case, would multiply the painters; and their abilities must bear a pretty exact proportion to the discrimination of those who give the price.

The decline of painting has also arisen from the despotism which for some time reigned in the academic societies. In fact, these have often been ruled by men who would force every exertion of genius into their peculiar tract of operation. If they required such or such merit of execution, the first principles of the art were neglected for that peculiar excellency. In this manner the schools were absolute in behalf of design as long as statutory was held in chief estimation. The artist, whose abilities and inclination led him to colouring, was obliged to abandon a pursuit which could be of no service to him, and devote himself to that for which he was not qualified by nature. On the other hand, if the instructions of the schools be confined to colouring, a mind disposed to the choice and exactness of forms will find no encouragement, and be for ever lost to the art. In this manner the ignorance of those who wish to be connoisseurs, and the narrow views of those who pretend to direct the general taste, have equally contributed to the decline of the arts.

SECT. II. Of the Schools.

A School, in the fine arts, denominates a class of artists who have learned their art from a certain master, or by receiving his instructions, or by studying his works; and who of consequence discover more or less of his manner, from the desire of imitation, or from the habit of adopting his principles.

All the painters which Europe has produced since the renovation of the arts are classed under the following schools: the school of Florence, the school of Rome, the school of Venice, the Lombard school, the French school, the German school, the Flemish school, the Dutch school, and the English school.

This school is remarkable for greatness; for attitudes of seeming in motion; for a certain dark severity; for an expression of strength, by which grace perhaps is excluded; and for a character of design approaching to the gigantic. The productions of this school may be considered as overcharged; but it cannot be denied that they possess an ideal majesty, which elevates human nature above mortality. The Tuscan artists, satisfied with commanding the admiration, seem to have considered the art of pleasing as beneath their notice.

This school has an indisputable title to the veneration of all the lovers of the arts, as the first in Italy which cultivated them.

Painting, which had languished from the destruction of the Roman empire, was revived by Cimabue, born of a noble family in Florence in the year 1240. This painter translated the poor remains of the art from a Greek artist or two into his own country. His works, as may easily be imagined, were in a very ordinary style, but they received the applause and admiration of his fellow-citizens; and if Cimabue had not found admirers, Florence in all probability
PAINTING.

If any man had a right to look down upon the lower accomplishments as beneath his attention, it was certainly Michael Angelo; nor can it be thought strange, that such a mind should have slighted, or been withheld from paying due attention to, all those graces and embellishments of art which have diffused such lustre over the works of other painters.

Ancient Rome, rich with the works brought from Greece, or finished in its own bosom by Grecian artists, handed down in its ruins the remains of that glory to which it had been elevated. It was by the study of these remains that the modern artists were formed; they derived from them the knowledge of design, the beauty of exquisite forms, greatness of style, and justness of expression, carried to that length only which did not affect the beauty of the figure. From them also they derived the principles of the art of drapery; and they followed these principles even while they made the drapery of modern paintings more large and flowing than what was practised by the ancient sculptors. The Roman school was altogether devoted to the principal parts of the art, to those which require genius and vast conceptions; and was no farther occupied with colours than what was necessary to establish a difference between painting and sculpture, or rather between painting varied with colours and in clari-obscura.

Raphael Sanzio, born at Urbino in 1483, and scholar to Pietro Perugeno, was the undoubted founder of this school. His first manner was that of Perugeno his master; but he travelled twice to Florence to study the great artists who flourished in that city.

It was fortunate for Raphael, says Menga, that he was born, in what he terms the infancy of the art, and that he formed himself by copying nature before he had access to see the works of any great master. He began by studying, with great exactness, the simple truth in his figures. He was then ignorant that any choice was necessary; but he saw the works of Leonardo da Vinci, of Massacio, and of Michael Angelo, which gave him genius a new direction. After this he perceived that there was something more in the art of painting than a simple imitation of truth. But the works of those masters were not sufficiently perfect to point out the best service to make; and he continued in uncertainty till he saw at Rome the works of the ancients. Then he perceived that he had found the true models which he wanted; and in imitating them he had only to follow the natural impulse of his genius.

Habituated by his first manner to imitate nature with precision, it was not difficult to carry the same exactness into the imitation of the ancients; and it was a great advantage to him that he flourished in an age wherein the artists were not arrived at facility of execution at the expense of rigorous exactness. He never lost sight of nature; but he was instructed by the ancients in what manner she should be studied. He perceived, that the Greeks had not entered into minute details, that they had selected what was great or beautiful, and that one of the chief causes of the beauty of their works was the regularity of their proportions; he began, therefore, by carefully studying this part of the art. He saw also that the joinings of the bones, and the free play of their articulations, are the causes of all graceful movements; he therefore
His design is excellent, but neither so perfect nor so finished as that of the Greeks. He excelled in representing the character of philosophers, apostles, and other figures of that kind; but he did not equal the Greeks in ideal figures, which ought to carry the impression of divinity. His taste for design was more Roman than Greek, because he formed it chiefly on the basso-relievo which he found at Rome. On this account he had the habit of marking strongly the bones and the articulations, and labouring the fleshy parts less; but as these basso-relievo are very exact with regard to the reciprocal proportions of every member, he excelled in this part, while at the same time he did not give to his figures all the elegance of the Greek artists, nor the flexibility of articulation which is admired in the Laocoon, in the Apollo of Belvédère, and in the Gladiator.

The manners and spirit of his age, and the subjects which he most commonly treated, prevented him from reaching the ideal of the ancients. Having seldom occasion to represent figures altogether ideal, he devoted himself to purity of expression. He knew that the expression of the passions of the soul is absolutely necessary in an art which represents the actions of men, since from those affections the actions may be said truly to originate. To make figures act, and yet neglect the interior springs of action, is nothing more than a representation of automatism. The attitudes and action are evident; but they appear not to act of themselves, because they are void of those principles from which alone men are supposed to act. An artist who neglects expression gives no just representation of character, even though he should take nature for his model.

Raphael's first care, when he wanted to compose a piece, was to weigh the expression; that is to say, to establish, according to the nature of the subject, the passions which were to animate the characters. All the figures, all the accessories, all the parts of the composition, were moulded to the general expression.

As he had not found examples in the ancient statues of the claro-obscuro, he was comparatively weak in this part; and if there was anything remarkable in his distribution of light and shade, he owed it to the works of the Florentine painters. It cannot be said, however, even with regard to the claro-obscuro, that he imitated nature without taste. He delighted in what are called masses of light; and disposed the great lights in the most conspicuous places of his figures, whether naked or in drapery. If this method did not produce effects highly illustrous, it gives his works that distinctness which makes his figures conspicuous at a distance; and this must be allowed to be an essential part of the art of painting. He did not proceed beyond this; and content with that kind of claro-obscuro which comprehends imitation, he never attempted that which is ideal.

The composition and the ensemble of his figures were the chief excellencies of Raphael. His philosophical mind could not be affected with objects which had not expression. He had too high an idea of painting to consider it as a mute art; he made it speak to the heart and soul; and he could only do this in subjects which required expression. If Raphael did not reach the Greek excellence, if he did not possess the art of embellishing nature in the same high degree, he saw at least, and imitated her in whatever was expressive and beautiful. "The Greeks sailed with majesty (says Mengs) between earth and heaven: Raphael walked with propriety on the earth."

"Composition is in general (says the same author) of two kinds: Raphael's is the expressive kind; the other is the theatrical or picturesque, which consists of an agreeable disposition of the figures. Lanfranc was the inventor of this last, and after him Pietro de Cor- tona. I give the preference to Raphael, because reason presides over all his works, or at least the greatest part of them. He never allowed himself in common ideas, and was never allowed to give any thing in his secondary figures which might turn the attention from the principal object of the piece."

A history of the schools is nothing more than a history of the painters who founded them. In those two which we have already given, Michael Angelo and Raphael come readily forward to claim our attention; and therefore we cannot do better than conclude the account by the masterly contrast of these eminent painters given by Sir Joshua Reynolds. "If we put those great artists (says he) in a light of comparison with each other, Raphael had more taste and fancy, Michael Angelo more genius and imagination. The one excelled in beauty, the other in energy. Michael Angelo has more of the poetical in operation; his ideas are vast and sublime; his people are a superior order of beings; there is nothing about them, nothing in the air of their actions or their attitudes, or the style and cast of their limbs or features, that puts one in mind of their belonging to our species. Raphael's imagination is not so elevated; his figures are so much disjointed from our own diminutive race of beings, though his ideas are grand, noble, and of great conformity to their subjects. Michael Angelo's works have a strong, peculiar, and marked character; they seem to proceed from his own mind entirely; and that mind so rich and abundant, that be never needed, or seemed to disdain, to look abroad for foreign help. Raphael's materials are generally borrowed, though the noble structure is his own. The excellency of this extraordinary man lay in the propriety, beauty, and majesty of his characters; his judicious contrivance of composition, correctness of drawing, purity of taste, and the skilful accommodation of other men's conceptions to his own purpose."

This school is the child of nature. The Venetian painters not having under their eyes like the Roman school the remains of antiquity, were destitute of the means of forming a just idea of the beauty of forms and of expression. They copied without choice the forms of nature; but they were chiefly delighted with the beauties which presented themselves in the mixture and the variety of natural colours. Their attention not being detached from this part by any thing of greater importance, colouring was their chief object, and they succeeded in it. They did not rest contented with characterizing the objects by comparison, in making the colour proper for one of more value by the
PAINTING.

Schools. colour more proper for another; but they endeavoured
still farther, by the agreement and opposition of the
coloured objects, and by the contrast of light and
shade, to produce a vigorous effect, to demand and fix
the attention. Dominic, who was said to have per-
ished at Florence by the jealousy of André Castagna,
and who was the second Italian artist who painted in
oil, had educated, before he quitted Venice, his native
country, Jacques Bellin, who was remarkable for no-
thing but the picturesque education which he gave to
Geniel and John his two sons.

Gentil, who was the eldest, painted chiefly in water
colours. John contributed much to the progress of his
art in painting constantly in oil, and after nature. Al-
though he always retained great stiffness in his manner,
he had less than his father or brother. Great neatness
of colouring, and an approach to harmony, are evi-
dent in his works. His taste in design is Gothic, the
air of his heads is sufficiently noble, his attitudes are
without judgment, and his figures without expression.
He had for scholars Giorgion and Titian, who de-
served to be considered as the founders of the Venetian
school.

Giorgion distinguished himself by a design of a bet-
ter taste than that of his master; but he chiefly sur-
passed him in colouring. He died in his 32d year;
and excited the emulation of Titian, who soon greatly
excelled him.

Tiziano Vecelli, known by the name of the Titian,
was instructed to copy nature in the most servile
manner in the school of John Bellin; but when he had
seen the works of Giorgion, he began to study the ideal
in colouring.

The truth of history is not to be expected in his his-
torical paintings, or in those of the artists of the same
school. He seems to have paid little attention to the
consistence of scene, to the costume, to expression
adapted to the subject, or finally, to the accommoda-
tion of parts which characterise the works of those who
have studied the ancients. He was in short a great
painter and nothing more.

But although he deserves not to be placed among the
most distinguished artists in point of judgment, yet he
is by no means destitute of great and noble conceptions.
There is often to be found among his male figures a
considerable degree of grandeur; but if he has some-
times, like Michael Angelo, overcharged his design, it
was more discovered in the swelling of the soft and
fleshy parts than in vigour and muscular strength.

Almost devoted to simple imitation, he had a
scarcely greater choice in the claro-obscur than in de-
sign. He cannot be justly reproached at the same
time for weakness in this particular; because in en-
deavouring to imitate the colours of nature, he was ob-
igated to observe the degrees of light. And in propor-
tion as he succeeded in the imitation of natural colours
he must be less defective in the claro-obscur; but it is
not in the knowledge of this part of the art that we are
to seek for the beauties of his works. These are to be
found in the happy dispositions of colours both proper
and local, and he carries this to the highest point of
perfection.

The artists in the Florentine and Roman schools
painted most commonly in water colours or in fresco;
and in the exercise of their profession, instead of na-
ture, they finished their works from their first sketches.
Titian painted in oil, and finished from the objects in
nature; and this practice, joined to his exquisite ta-
lents, gave the greatest truth to his colours. His be-
ing a portrait painter was also of advantage to him as
a colourist. In this department he was accustomed to
the colours of nature in carnations and draperies. He
was a landscape-painter, and here also he took the
colours from nature.

"As Titian perceived (says Mengs) that the ob-
jects which are beautiful in nature have often a bad ef-
fect in painting, he found it necessary to make a choice
in the objects of imitation; and he observed, that
these were objects of which the local colours were ex-
tremely beautiful, which nevertheless were in a great
measure destroyed by the reflection of light, by the
porosity of the body, and by different luminous tints,
&c. He perceived also, that in every object there
was an infinite number of half tints, which conducted
to the knowledge of harmony. In short, he observed
in the objects of nature, a particular agreement of
transparency, of opacity, of rudeness, and of polish,
and that all objects differed in the degrees of their tints
and their shades. It was in this diversity he sought
the perfection of his art; and in the execution he mo-
derated the effect of natural colours. For example, in
a carnation which had many demi-tints, he confined
himself to one; and he employed even less than a dem-
tint, where there were few in the nature of the object.
By this means he obtained a colouring exquisitely fine;
and in this part he was a great master, and deserves to
be carefully studied."

Titian has in general little expression in his pictures,
and he sometimes introduces figures which augment the
coldness of the piece; for if it be true that the heads,
even in historical painting, ought to be studied after
nature, it is true also that an individual nature ought
to be presented, but one general and ideal. It is
necessary that they should be men, while they resemble
not men we are accustomed to see. The painter fails
in the effect which he ought to produce, if, when he
represents Achilles, Hector, and Caesar, his personages
are familiar to our observation.

The colours of his paintings are so mingled toge-
ather, as to give no idea of the colours on his pallet;
which distinguishes him from Rubens, who placed his
colours one at the side of another. It is impossible to
say, on the narrowest inspection, with what colours
he produced his tints. This practice, which enabled
him to imitate so exactly the colours of nature, gives
a marked distinction to his manner of painting. In
the examination of his works, the critics lose an or-
 customary source of pleasure, which arises from marking
the freedom of hand; but they may console them-
sehelves with the natural and exquisite touches of this
artist.

He is of historical painters one of those who have
succeeded in landscape. His situations are well chosen;
his trees are varied in their forms, and their foliage
well conceived. He had a custom of representing some
remarkable appearance in his landscapes to render
them more striking.

The distinguishing characteristics of this school are, Londa
grace, school.
History.

PAINTING.

Scho

Scho

Scho

Scho
gace, an agreeable taste for design, without great cor
gerence, a mellowness of pencil, and a beautiful mix
ture of colour.

Antonio Allegri, called Correggio, was the father and
greatest ornament of this school. He began like the
painters of his time to imitate nature alone; but, as
he was chiefly delighted with the graceful, he was care
ful to purify his design from all short turnings and un
necessary angles. He perceived that large forms con
tributed to grace; and therefore he not only rejected all
small figures, but enlarged as much as possible the out
lines, avoided acute angles and straight lines, and by
these means give an easy grandeur to his design. He
made his figures elegant and large; he varied the out
lines by frequent undulations; but he was not always
pure and correct.

Correggio painted in oil, a kind of painting suscep	ible of the greatest delicacy and sweetness; as his
character led him to cultivate the agreeable, he
gave a pleasing captivating tone to all his pictures.
He sought transparent colours to represent shades con
formable to nature, and adopted a manner of glazing
which actually rendered his shadows more obscure.
Obscurity in painting cannot be fully obtained without
transparent colours; for these absorb the rays of light,
and of consequence give less reflection. He laid his col
ours very thick on the brightest parts of his pictures,
to make them capable of receiving, by a proper touch,
the greatest degree of light. He perceived, that the re
fections of light correspond with the colour of the body
from which they are reflected; and on these principles
he founded his theory of colours with respect to light
and shade and reflection. But it is chiefly in the col
our of his shades that he deserves to be imitated; for
his lights are too clear, and somewhat heavy; and his
fleshy parts are not sufficiently transparent.

Harmony and grace are connected together; and
on this account Correggio excelled also in harmony.
As the delicacy of his taste suffered him not to em
ploy strong oppositions, he naturally became a great
master in this part, which chiefly consists of easy gra
dations from one extreme to another. He was har
monious in his design, by making the lines which for	med the angles of the contour arched and undula
ted. But in the lights and shades, he placed always
between the two extremes a space which served to
unite them, and to form a passage from the one to
the other. The delicacy of his organs made him per
ceive, better than any other artist, what relief was
necessary to the eye after a violent exertion; and he
was therefore careful to follow a bold and prevailing
colour with a dominant, and to conduct the eye of the
spectator, by an invisible gradation, to its ordinary
state of tension. In the same manner (says Mengs)
does agreeable and melting music pull one so gently out
of sleep, that the awaking resembles enchantment more
than the disturbing of repose. A delicate taste in co
lours, a perfect knowledge of the clairobscur, the art
of uniting light to light, and shade to shade, togeth
er with that of detaching the objects from the
ground, inimitable, grave, and perfect harmony, were
the qualities which distinguished Correggio from all
the painters, and placed him near the head of his pro
fession.

The Caracci, Lewis, Augustin, and Hannibal, form
ed what is called the second Lombard school, which is
frequently distinguished by the name of the school of
Bologna.

Lewis was the master of the other two; he had
studied the works of Titian and Paul Veronese at Ven
cie, those of Andre del Sarto at Florence, those of
Correggio at Parma, and those of Jules Roman, at
Mantua; but he chiefly endeavoured to imitate the man
ner of Correggio. Hannibal fluctuated between Cor	reggio and Titian. Augustin, their rival in painting,
and his mind cultivated by learning, and devoted part
of his time to poetry and music, to dancing and to oth
er manly exercises. These three painters often employed
their talents on the same piece; and it was admirable
that their united labours seemed to be animated with
the same spirit.

They established an academy at Bologna, which their
zeal for the advancement of their art made them call
L’Academia degli Desiderosi; but it was afterward call
ed the Academy of the Caracci, because the reputation
which these artists acquired, permitted not a more il
lustrous name to be given to an establishment of which
they were the founders. In this school they taught the
art of constructing models, perspective, and anatomy;
lessons were given on the beautiful proportions of na
ture, on the best manner of using colours, and on the
principles of light and shade. They held frequent con
ferences, in which not only artists, but men of general
knowledge, were permitted to elucidate points relative
to the art of painting; but they were separated upon
Hannibal’s going to Rome to adorn the gallery of the
cardinal Farnese.

The works of the Caracci are often, from the resen
blance of their manner, confounded together; espe
cially those which were finished previous to the residence
of Hannibal at Rome. Meanwhile each of them has a de
cided character distinct from the other two. Lewis had
less fire, but more of gracefulness and grandeur; Au	ustin had more spirit in his conception, and more plea
santness in his execution: Hannibal is characterized by
boldness, by a design more profound, by an expression
more lucky, and by an execution more solid.

Sir Joshua Reynolds, who saw the works of Lewis at
Bologna, holds him out in his discourses as the best mo
del for what is called style in painting; which is the fa	culty of disposing colours in such a manner as to ex%
press our sentiments and ideas. “Lodovico Caracci,” says
he, “(I mean in his best works) appears to me to ap	roach the nearest to perfection. His unaffected breadth
of light and shadow, the simplicity of colouring, which
holding its proper rank, does not draw aside the least
part of the attention from the subject, and the solemn
effect of that twilight which seems diffused over his pic
tures, appears to me to correspond with grave and digni
fied subjects better than the more artificial brillian
cy of sunshine which enlightened the pictures of Ti	tian.”

Hannibal is esteemed by the best judges as a model
for beauty and design. Those who blame him for be	coming less a colourist at Rome than he was at Bologna,
ought to recollect that it is his performances at Rome
which have chiefly secured his reputation. Severe cri
tics have maintained that his design is too little varied
in his figures; that he excels only in male beauty; that
in imitating ancient statues, he excites some resemblance,
but without arriving at the sublimity of ideas and of style which characterize the ancients; or, in other words, that he hath successfully imitated the exterior of their manner, but that he was incapable of reaching the interior and profound reasonings which determined those admirable artists.

The success of Hannibal, and the reputation which he acquired, have been pernicious to the art. His successors, dulled by these considerations, have made him the object of their imitation, without according to the sources from which he derived his knowledge, and which he never could equal. The result has been, that, instead of becoming equal to Hannibal, they have often copied his imperfections.

This school has been so different under different masters, that it is difficult to characterize it. Some of its artists have been formed on the Florentine and Lombard manner, others on the Roman, others on the Venetian, and a few of them have distinguished themselves by a manner which may be called their own. In speaking in general terms of this school, it appears to have no peculiar character; and it can only be distinguished by its aptitude to imitate easily any impression; and it may be added, speaking still in general terms, that it unites, in a moderate degree, the different parts of the art, without excelling in any one of them.

It is equally difficult to determine the progress of painting in France. Miniature painting, and painting on glass, were early cultivated in that country; and in these two kinds, the Italians had often recourse to the French artists. When Francis I. encouraged Rosso a Florentine, and Primaticcio a Bolognian, the painters in France were not remarkable for any superior talent; but they were capable of working under these foreign artists.

Cousin, a painter on glass, and portrait painter, was the first who established any kind of reputation in France. He was correct, but possessed very little elegance of design.

Painting, for some time encouraged by Francis I., fell into a state of languor, from which it was not recovered till the reign of Louis XIII. Jacques Blanchard, formed at the Venetian school, and called the French Titian, flourished about this period. But as he died young, and without educating any pupils to perpetuate his manner, he must be regarded as a single good artist, and not as a founder of the French school.

In the same manner Poussin, one of the greatest French painters, and who is called the Raphael of France, educated no pupils, nor formed any school. His style and character of painting are described by Sir Joshua Reynolds as simple, careful, pure, and correct. No works of any modern (adds the same author) have so much of the air of antique painting as those of Poussin. His best performances have a remarkable dryness of manner, which, though by no means to be recommended for imitation, yet seems perfectly correspondent to that ancient simplicity which distinguishes his style.

In the latter part of his life he changed from this manner to one much softer and richer; where there is a greater union between the figures and the ground.

His favourite subjects were ancient fables; and no painter was ever better qualified to paint such objects, not only from his being eminently skilled in the knowledge of the ceremonies, customs, and habits of the ancients, but from his being so well acquainted with the different characters which those who invented them gave their allegorical figures.

If Poussin, in the representation of the ancients, represents Apollo driving his chariot out of the sea by way of representing the sun rising, if he personifies lakes and rivers, it is no way offensive in him, but seems perfectly of a piece with the general air of the picture. On the contrary, if the figures which people his pictures had a modern air or countenance, if they appeared like our countrymen, if the draperies were like cloth or silk of our manufacture, if the landscape had the appearance of a modern view, how ridiculous would Apollo appear? instead of the sun, an old man; or a nymph with an urn, instead of a river or a lake.

Poussin, however, more admired than imitated, had no manner of influence in forming the French school. Simon Vouet, his enemy and persecutor, had this honour, because his pupils, in the happy age of the arts in France, conferred on it the highest splendour. Vouet was a man of distinguished abilities; but the school which he erected would have had no continuance if his scholars had pursued his manner of painting. He had a kind of grandeur and facility; in his design he was false with regard to colours, and without any idea of expression. It was said of him, that he only needed to take the pencil in his hand to finish with one stroke the subject which he had conceived; and on this account one is tempted to be pleased, because he is astonished. He had the merit of destroying the insipid manner which reigned in France, and of pointing the way to a better taste.

If Vouet laid the foundation of the French school, Le Brun finished the edifice. When Le Brun was placed under the tuition of Vouet, he astonished his master and the rest of his pupils with the rapidity of his progress. At the age of 26 he finished his piece called the horses of Diomed, which gained a place in the palace royal (a), beside those of the most eminent painters. He was afterwards recommended to Poussin; but the young artist was more disposed by his natural inclinations to that modern part of the art which is called the great machine, than to the profound and studied manner of the Greek artists. Poussin at the same time was of great service to him in recommending to him the study of the monuments, the customs, the dress of the ancients; their architecture, their rites, their spectacles, their exercises, their combat, and their triumphs.

Le Brun had a noble conception and a fruitful imagination. He was on no occasion inferior to the vast compositions which he undertook, and he chiefly excelled in rigorous costume and exact likenesses.

Few painters have united so great a number of essential

(a) Where it may now be is uncertain. Perhaps it perished during the revolutionary frenzy of the French, which at first threatened the utter destruction of every thing connected with science or the liberal arts.
most artful and the noblest manner. His design was in general more slender than that of Raphael; but, like his, it was formed on the model of the ancients. Like Raphael he represented with art and precision the affections of the soul; like him, he varied the air of the head, according to the condition, the age, and the character of his personages; and, like him, he made the different parts of every figure contribute to the general effect. His intention in composing was to express his subject, not to make shining contrasts or beautiful groups of figures, not to astonish and bewitch the spectator by the deceitful pomp of a theatrical scene, or the splendour of the great machine. His tones are delicate, his tints harmonious, and his colours, though not so attractive as those of the schools of Venice and Flanders, are yet engaging. They steal peaceably on the soul, and fix it without distraction on the parts of the art, superior to that of colouring.

His preaching of St Paul, and the picture which he painted at St Gervais, which the critics compare with the best productions of the Roman school, and the 22 pictures which he painted for the Carthusian monastery at Paris, and which were formerly in possession of the king, are esteemed his best pieces. His contemporaries affirm, that he considered as sketches merely those excellent performances which are the glory of the French school.

If Le Sueur had lived longer, or if, like Le Brun, he had been employed under a court, fond of the arts, and of learning, to execute the great works of the age, the French school would have adopted a different and a better manner. The noble beauty of his heads, the simple majesty of his draperies, the lightness of his design, the propriety of his expression and attitudes, and the simplicity of his general disposition, would have formed the character of his school. The deceitful pomp of theatrical decoration would have been more lately introduced, or perhaps would never have appeared, and Paris might have been the counterpart to Rome. But as Le Brun, by an accidental concurrence of favourable circumstances, was the fashionable painter, to be employed or rewarded it was necessary to imitate his manner; and as his imitators possessed not his genius, his faults became not only current but more deformed.

The French school not long ago changed its principles; and if, when peace shall be restored to this unhappy nation, they continue to follow the road which, while the artists flourished among them, they marked out for themselves, they have the chance of becoming the most rigid observers of the laws imposed on the Greek artists. The count de Caylus, pupil of Bouchardon, who by his rank and fortune had the means of encouraging the imitators of the ancients, and of the masters of the 15th century, first formed the design of restoring a pure taste to the art of painting. He was seconded by the talents of M. Vien, an artist who had only occasion to have his lessons and his example laid before him.—In this manner commenced a revolution, so much the more wonderful, as it was scarcely ever known that any nation substituted a system of simple and rigid excellence in place of a false and glittering taste. The history of all nations, on the contrary, discovers a gradual progress from a rude beginning to perfection, and afterwards to irremediable decay. The French had the prospect of stopping short in this ordinary course. They began
began in a manner which promised success; and the best consequences may be expected, from being in possession of those precious treasures of sculpture and painting of which they plundered the countries subdued by their arms.

In Germany there can hardly be said to be a school, as it is a continuation of single artists, who derived their manner from different sources of originality and imitation. There were some German painters of eminence, when the art, emerging from its barbarous state, first began to be cultivated with success in Europe. As they were totally unacquainted with the ancients, and had scarcely access to the works of their contemporaries in Italy, they copied nature alone, with the exception of somewhat of that stiffness which forms the Gothic manner. It is this manner, if we speak of the early German painters, which characterizes their school. But this is by no means the case with their successors, part of whom were educated in Flanders and part in Italy: For if Meugs or Dietrich were comprehended in this school, there would be nothing peculiar to its manner discovered in their works. And it is therefore necessary to confine our observations to the more ancient German painters, in whom the Gothic style is conspicuous.

Albert Durer was the first German who corrected the bad taste of his countrymen. He excelled in engraving as well as painting. His genius was fertile, his compositions varied, his thoughts ingenious, and his colours brilliant. His works, though numerous, were finished with great exactness; but as he owed everything to his genius, and as works of inferior merit were by the false taste of the times preferred to his, it was impossible for him altogether to avoid the faults of his predecessors. He is blamed for stiffness and aridity in his outlines, for little taste or grandeur in his expression, for ignorance of the costume of aerial perspective and of gradation of colours; but he had carefully studied linear perspective, architecture, and perspective.

John Holbein or Holbein, nearly contemporary with Albert Durer, painted in oil and water colours. He excelled chiefly in history and in portrait painting. His colours are fresh and brilliant, and his works are highly finished; but in his historical subjects, his draperies are not in so good a taste as those of Albert Durer.

The Flemish school is recommended to the lovers of the art by the discovery, or at least the first practice, of oil painting. Van Mander gives us the account of this wonderful discovery in the following words: "John Van Eyck was so excellent a chemist, that he discovered a method of varnishing his distemper colours with a varnish, which was made of some oils, and was very pleasing on account of the gloss and lustre it gave them. Many artists in Italy had vainly attempted to find out that secret; they never hit on the true method. It happened once that John, in his usual manner, having highly finished one of his pictures on boards, and having varnished it with his new invented varnish, exposed it to dry in the sun; but whether the boards were not well joined, or whether the heat of the sun was too violent, the boards split asunder and opened in the junctures. John saw with concern that his work was spoiled, and resolved to contrive something against future accidents of the same kind. Being disgusted at distemper painting and varnishing, he thought of a varnish that might dry without sunshine; and having tried many oils and substances, he found that linseed and nut oil dried better than any other. He boiled them with some other drugs, and produced the best varnish in the world. Ever bent on improvements, he found, after much inquiry, that colours mixed with these oils worked and dried extremely well, and when dried would be water-proof. He observed likewise, that these oils would animate and give them a gloss and lustre without any further varnishing."

The truth, however, of this account is now very much questioned; and it is even proved by the manuscripts of Theophilus Presbyter, and also by some old paintings in England, that this method of painting was discovered long before the time of John Van Eyck. At the same time we admit, that John and his brother Hubert may have been the first who brought oil painting into general practice, not only by showing the excellence of which it was susceptible, but also by making several improvements on the art. And this is the more probable, from the great reputation which their pictures acquired over all Europe, by the softness and delicacy of their colours. The attention of the Italian painters was chiefly excited, insomuch that Antoine de Messima performed a journey into Flanders for the express purpose of acquiring the confidence of John Van Eyck, and of discovering the secret.

John de Bruges was the founder of painting as a profession in Flanders; Peter Paul Rubens was the founder of the art. This extraordinary person produced an immense number of works. He excelled equally in historical, portrait, and landscape painting; in fruits, flowers, and in animals. He both invented and executed with the greatest facility; and to show the extent of his powers, he frequently made a great number of sketches on the same subject altogether different, without allowing any time to elapse between them. The works of Rubens were destitute of that soft inspiration, productive of sweet and pleasant effects, so conspicuous in the works of Raphael; but he possessed that sponginess of genius and strength of mind which is ever ready to burst forth in wonderful and astonishing effects. His figures appear to be the exact counterpart of his conceptions, and their creation nothing more than a simple act of the will.

His talent for design is unjustly censured, for on every occasion his design is noble and easy. He had great knowledge of anatomy, but he was hurried away by the impetuosity of his imagination and the ardour for execution; he preferred splendour to the beauty of forms, and sacrificed correctness of design too often to the magic of colours. In short, his qualities suppose a mind full of fire and vigour, rather than accuracy or profound thought. His drapery may be considered rather as one than properly adapted to his figures; for, in the language of the art, to clothe and to give drapery are not synonymous terms. A portrait painter may excel in clothing his personages, while he is totally incapable of giving good drapery to a historical painting. His chief merit consists in colouring; though in this branch of the art he has not equalled Titian. He is the first among painters eminent for pomp and mystery; the first among those who speak to the eye, and the power of the art is often carried by him almost to enchantment.

It is evident from the works of Rubens, that his method of painting was to lay the colours in their place, one at the side of another, and mix them afterwards by
History.

PAINTING.

A slight touch of the pencil. Titian mingled his tints as they are in nature, in such a manner as to make it impossible to discover where they began or terminated; the effect is evident, the labour is concealed. Thus Rubens is more dazzling, and Titian more harmonious. In this part, the first excites the attention, the second fixes it. The carnations of Titian resemble the blush of nature; those of Rubens are brilliant and polished like satin, and sometimes his tints are so strong and separated as to appear like spots.

"Rubens (says Sir Joshua Reynolds) is a remarkable instance of the same mind being seen in all the various parts of the art. The whole is so much of a piece, that one can scarce be brought to believe that if any one of them had been more correct and perfect, his works would not be so complete as they appear. If we should allow a greater purity and correctness of drawing, his want of simplicity in composition, colouring, and drapery, would appear more gross."

In his composition his art is too apparent. His figures have expression, and act with energy, but without simplicity or dignity. His colouring, in which he is eminently skilful, is not without being too much of what we call tinted. Throughout the whole of his works there is a proportional want of that nicety of distinction and elegance of mind, which is required in the higher walks of painting; and to this want it may be in some degree ascribed, that those qualities which make the excellency of this subordinate style appear in him with their greatest lustre.—Indeed the facility with which he invented, the richness of his composition, the luxuriant harmony and brilliancy of his colouring, so dazzle the eye, that, whilst his works continue before us, we cannot help thinking that all his deficiencies are fully supplied.

The Flemish school, of which Rubens is the greatest master, is remarkable for great brilliancy of colours and the magic of the claro-obscur. To these may be joined a profound design, which is yet not founded on the most beautiful forms; a composition possessed of grandeur, a certain air of nobleness in the figures, strong and natural expressions; in short, a kind of national beauty, which is neither copied from the ancients nor from the Roman nor Lombard schools, but which deserves to please, and is capable of pleasing.

To speak in general terms, and without regarding a great number of exceptions, the Dutch school carries none of the above qualities to great perfection, except that of colouring. Far from excelling in the beauty of heads and forms, they seem chiefly to delight in the exact imitation of the lowest and most ignoble. Their subjects are derived from the tavern, the smith's shop, and from the vulgar amusements of the rudest peasants. The expressions are sufficiently marked; but it is the expression of passions which debase instead of ennobling human nature. One would think that they practised the art of degrading the bodies and souls of men.

It must be acknowledged, at the same time, that the Dutch painters have succeeded in several branches of the art. If they have chosen low objects of imitation, they have represented them with great exactness; and truth must always please. If they have not succeeded in the most difficult parts of the claro-obscur, they at least excel in the most striking, such as in light confined in a narrow space, night illuminated by the moon or by torches, and the light of a smith's forge. The Dutch understand the gradations of colours; and by their knowledge of contrast they have arrived at the art of painting light itself. They have no rivals in landscape painting, considered as the faithful representation or picture of a particular scene; but they are far from equaling Titian, Poussin, Claude Lorrain, &c. who have carried to the greatest perfection the ideal landscape, and whose pictures, instead of being the topographical representation of certain places, are the combined result of every thing beautiful in their imagination or in nature. The Dutch, however, distinguish themselves by their perspective, by their clouds, sea scenes, animals, fruits, flowers, and insects; and they excel in miniature painting. In short, every thing which requires a faithful imitation, colour, and a nice pencil, is well executed by the Dutch painters.

Holland has also produced history painters, as Octavius Van Bein, and Vander Hilst the rival of Vandyke, and perhaps his superior: but it is not in the works of those artists that we find the character of the Dutch school.

The origin of their style is to be derived from the works of Lucas of Leyden, though, from the time he flourished, viz. about the end of the 16th century, he may be considered as the patriarch of the Dutch school. Lucas painted in oil, in water colours, and on glass; and the kinds of his painting were history, landscape, and portrait. His picture of the Last Judgment is preserved in the Hotel-de-Ville of Leyden; it possesses vast merit in point of composition, and a great variety of figures.

If miniature painting be considered as a characteristic of the Dutch school, Cornelius Polembourg may be regarded as the father of it. He possessed the colour, delicacy of touch, and disposition of the claro-obscur, which chiefly distinguishes this school; and if anything is to be added, it is want of correctness in his design.

But if the choice of low figures is its chief characteristic, this is to be found in the greatest perfection in the works of the celebrated Rembrandt Vanry; and it is the more offensive in this artist, as his compositions frequently required an opposite choice of figures. As his father was a miller near Leyden, his education must altogether have depended on the exertion of great talents and the study of nature. He studied the grotesque figure of a Dutch peasant or the servant of an inn with as much application as the greatest masters of Italy would have studied the Apollo of Belvidere or the Venus de Medicis. This was not the manner of elevating himself to the noble conceptions of Raphael; but it was acquiring the imitation of truth in vulgar painting.

"Rembrandt (says M. Descamps) may be compared to the great artists for colour and delicacy of touch and claro-obscur. It appears that he would have discovered the art, though he had been the first person that ever attempted it. He formed to himself rules and a method of colouring, together with the mixture of colours and the effect of the different tones. He delighted in the great oppositions of light and shade; and he seems to have been chiefly attentive to this branch of the art. His workshop was occasionally made dark, and he received the light by a hole, which fell as he chose to direct it on..."
PAINTING.

Schools.

on the place which he desired to be enlightened. On particular occasions he passed behind his model a piece of cloth of the same colour with the ground he wanted; and this piece of cloth receiving the same ray which enlightened the head, marked the difference in a sensible manner, and allowed the painter the power of augmenting it according to his principles.

Joshua's manner of painting is a kind of magic. No artist knew better the effects of different colours mingled together, nor could better distinguish those which did not agree from those which did. He placed every tone in its place with so much exactness and harmony, that he needed not to mix them, and so destroy what may be called the flower and freshness of the colours. He made the first draught of his pictures with great precision, and with a mixture of colours altogether particular: he proceeded on his first sketch with a vigorous application, and sometimes loaded his lights with so great a quantity of colour, that he seemed to model rather than to paint. One of his heads is said to have a nose nearly as much projected as the natural nose which he copied."

Such is the power of genius, that Rembrandt, with all his faults, and they are enormous, is placed among the greatest artists by M. Descamps, who saw his works, and was himself an artist. It is necessary to observe, that if Rembrandt was ignorant of the essential parts of his art, or neglected them, he was yet acquainted with expression, which alone was capable of giving animation to his works. His expressions are not noble, but they are just, lively, and excited with great judgment.

John de Laer, a miniature painter, and who made choice of his subjects from common life, deserves a distinguished place in the Dutch school. He painted hunting-scenes, the attacks of robbers, public festivals, landscapes, and sea-views; and he ornamented his pictures with old ruins, and enriched them with figures of men and animals. He had a correct design, and employed vigorous and lively colouring.

Van Ostade, although born at Lubeck, Gerard Dow, Metsu, Miris, Vowerman, Berghem, and the celebrated painter of flowers Van Huysum, belong to the Dutch school.

The greater part of the schools of which we have treated have no longer any existence. Italy alone had four schools, and there only remain at present a very few Italian artists known to foreigners. The school of Rubens is in vain sought for in Flanders. If the Dutch school still exists, it is not known beyond the precincts of Holland. Mengs a German artist has made himself famous in our days; but it was in Italy that he chiefly improved his talents and exercised his art. M. Dietrich, another German, has made himself known to strangers; but two solitary artists do not form a school.

The English school.

A new school is formed in our times and in our own country, called the English school. It is connected with the academy in London, instituted in 1766 by letters patent from the king, and formed only in 1769. Sir Joshua Reynolds is the undoubted founder of it. His works give him a distinguished rank among the artists of the present age, and exhibit a genius in their author which has seldom been surpassed: but the effects which he has contrived to give to them by the formation of a new school, and by the good principles which his discourses to academicians, and his example as a painter, have disseminated, will secure his reputation as long as England shall esteem the advantages and the worth of great abilities. The English taste appears to be formed on the great masters of the Italian and the Flemish schools. Sir Joshua was greatly beholden to Michael Angelo, and particularly recommends him to the attention of the academicians. "I feel (says Sir Joshua), a self-congratulation in knowing myself capable of such sensations as he intended to excite. I reflect, not without vanity, that these discourses bear testimony of my admiration of that truly divine man; and I should desire that the last words which I should pronounce in this academy, and from this place, might be the same of—Michael Angelo."

But though he thus enthusiastically admired this very great man, yet he allows, what cannot indeed be denied, that he was capricious in his inventions: "And this (says he) may make some circumstance necessary in studying his works; for though they appear to become him, an imitation of them is always dangerous, and will prove sometimes ridiculous. In that dread circle none durst tread but he." To me, I confess his caprice does not lower the estimation of his genius, even though it is sometimes, I acknowledge, carried to the extreme; and however those eccentric excursions are considered, we must at the same time recollect, that those faults, if they are faults, are such as never could occur to a mean and vulgar mind; that they flowed from the same source which produced his greatest beauties; and were therefore such as none but himself was capable of committing; they were the powerful impulses of a mind unused to subjection of any kind, and too high to be controlled by cold criticism."

The effect of Sir Joshua's discourses is visible in the pictures of this school. The Death of General Wolfe, the Departure of Regulus for Carthage, the Arrival of Agrippina, and some other subjects, are decided proofs that the English school is acquainted with greatness of style, boldness of expression, and the art of managing a great number of figures. It will be fortunate for the painters of this school, if, more rigid with regard to their forms, than ambitious of poignant and astonishing effects, they support the character which they have already acquired. But although England had not enjoyed this brilliant success in painting, she would have immortalized herself by the excellency of her engravings.

It is easy to perceive in all those schools the cause of the character which distinguishes them. In the Roman school, it is the excellent education of its first masters, together with the precious remains of antiquity found in the ruins of ancient Rome. In the Venetian school, the magnificence derived from the commerce of the east, the frequency of feasts and masquerades, and the necessity of painting to the rich and luxurious, who were accustomed to behold those magnificent objects, were the causes of its gaudy taste. In the Dutch school, the peculiarity of its grovelling manner may be accounted for from the habits of the artists. Accustomed to visit taverns and workshops, and having most commonly exposed to their view low
PAINTING.

Sect. III. Comparison between the Ancient and Modern Painting.

No person of judgment or taste hesitates to give the superiority to the ancient sculpture; but the Moderns comfort themselves with refusing the same superiority to the Greek artists in the art of painting. The small number of their productions which remain, and the probable conjectures which may be formed concerning those which have perished, go to length to prove that the Greek painters conducted themselves on other principles than those which have received the sanction of custom and the force of laws in our schools. But this censure might be applied with equal justice to Homer as an epic poet, and to Sophocles and Euripides as writers of tragedy.

The principal difference between the ancient and modern manner of painting consists in the complication of figures, and the pompous decoration of scenery which prevails in the modern, when compared with the unity and simplicity of the ancient painters. This simplicity, however, does not seem to arise from the want of capacity, but from a choice, as Polygnotus, one of their most ancient painters, represents in one of his pieces the siege of Troy, and in another the descent of Ulysses into hell; but they soon decided in favour of simplicity, and their pieces generally contain one or two figures, and very rarely more than three or four.

Poetry in this particular is conducted on very different principles. A poet may with great propriety multiply his characters, and enter into details of a variety of actions, because the whole of his characters and actions do not occupy the mind of his readers at the same time. The whole of his arts consists in making one naturally succeed another; but every part of the poem which contains a separate transaction would make a picture capable of fixing the attention. In painting, the eye takes in the whole; and it is by no means satisfied if 20 or 30 figures are presented to it, which it cannot possibly comprehend. It is in vain to group the figures, or to call the attention to the principal object by a greater degree of light; the spectator is anxious to examine every object which is presented to him; and if they are not to be examined, for what reason are they painted? An excellent piece, at the same time, consisting of a great number of figures, will give pleasure; but it is accompanied with that fatigue which one experiences when he runs over a gallery furnished with a great variety of excellent pictures.

Those observations on the attention of the spectator led the Greeks to make similar ones on the attention of the artists. They perhaps thought that the painter who had to execute a great variety of figures in the same work, could not study each of them with equal accuracy and care; and of consequence that he might produce something astonishing in the extent, and yet disgusting in the detail.

This difference, however, between ancient and modern painting, cannot give any decided principle to determine on their comparative merit. We are accustomed to behold assemblages in nature! and it is a fact, that even in affecting scenes a great number of figures may not only be brought together, but that they may heighten the distress. It is supposing a picture to have little effect, to imagine that we can coolly, and with the same kind of attention, examine the principal and the accessory figures. If it is highly finished, our whole soul must be absorbed in that object which the artist intended to be most conspicuous; and if we give any attention to the surrounding figures, we shall consider them as spectators of the same scene, and derive from them an addition of sympathy and of feeling. The whole question in this particular point of view amounts to this, that the moderns have chosen a more difficult part; and if they have executed it with success, their merit is greater. And this observation will hold good, unless it can be proved that it is utterly impossible to make an assemblage of figures lead to one general and common effect.

The proper manner of deciding the comparative merit of the ancients and moderns, is to consider, as far as we have sufficient data to go upon, to what degree the ancients excelled in the particular departments of this art. There are two sources from which we can derive information; namely, from the morsels of antiquity which yet remain, and from what the ancient writers have said on the subject of painting, both of which are extremely defective. It is allowed, however, by every skilful person who has viewed the remains of ancient paintings, that none of them appear to be the performances of superior artists, notwithstanding much merit in the design and accuracy in the drawing, which indeed seems to have been habitual to almost every ancient artist. The best among these paintings (according to Sir Joshua Reynolds), "the supposed marriage in the Aldobrandine palace," is evidently far short of that degree of excellence undoubtedly implied in the descriptions of ancient authors, and which from them we are fairly led to expect.

Still more defective, if possible, is this last species of evidence: for we have no direct treatise remaining on the subject by any of the ancients, although many were composed by their art. The passages from which we are
PAINTING.

are to decide or, either the cursory remarks of writers not expressly treating on the subject of painting, or the descriptions of those who at best can rank but as amateurs of a fashionable art. From these indeed we may pretty safely assert the degree of excellence which the passages imply; but we should reason very inconclusively, were we to deny them any higher or any other merit than appears to be strictly contained in these scattered observations. Let any one for a moment place the modern painter in his mind in the same situation as the ancients, and he will quickly decide on the truth of these remarks.

Nevertheless, it is necessary on this subject to derive some conclusions from the information which is occasionally given in ancient authors. That the ancients paid a particular attention to design, would be evident from the manner in which they speak of this department of the graphic art, even though the moderns were not in possession of such remaining proofs of their excellence herein (though by artists of an inferior class), as to place this point beyond the reach of doubt.

Indeed, when it is considered that, with respect to freedom and correctness of outline, painting and sculpture are very nearly connected; that Phidias and Apelles were nearly contemporaries; that many of the ancient painters, such as Zeuxis, Protogenes, Apelles, &c. were accustomed to modelling for the purpose of sculpture or of casting; that the extreme elegance of design in the ancient statues is so notorious as to be the acknowledged model even for modern artists; and that these ornaments of sculpture were well known and universally admired among the ancients—we shall have little hesitation in admitting their equality with the moderns so far as design is concerned. But should any doubt remain on this point, the drawings from the antiquities of Herculaneum will be striking proofs that truth, elegance, and spirit, in a degree rarely to be met with among the moderns, were habitual even to the common run of artists in the declining age of ancient painting.

The ancients excelled moreover not merely in the common and obvious parts of design; but they appear to have had no inconsiderable degree of skill in the art of foreshortening. The performance of Pausanias is a proof of this: Fecit autem grandis tabulas sicu spectatam in Pompeii porticus basm immolatam. Eam enim picturam primus invenit, quam postea imitati sunt multi, equavit nem. Ante omnia, cum longitudinem bovis ostenderi vellet, adversum cum pinxit, non transversum, et obscuras intelligitur amplitudo. Dein cum omnes qui volent eminentia videndi, candidantiam fiant, coloremque condant, hic totum lovent atri coloris ficit; umbraque corpus ex ipso reddit; magis prorsus arte in aequo extrant ostendens et in conferto solidi omnia.

Nor will it be difficult to show, that the ancient painters were not inferior to the moderns in expression. The state of sculpture alone among the ancients would almost furnish a decisive proof that the sister art of painting could not be deficient. Among the ancient statues which yet remain, expression is carried to a wonderful height; not merely the features of the face, but almost every muscle of the body, combining to enforce the idea intended to be conveyed.

Mr Webb very properly observes, that "the ancients thought characters and manners so essential to painting, that they expressly term painting an art descriptive of manners." Aristotle in his Poetics says of Polygnotos, that he was a painter of the manners; and objects to Zeuxis, his weakness in this part. We have in Philostratus the following description of a picture: "We may instantly (says he) distinguish Ulysses by his severity and vigilance; Menelaus by his mildness; and Agamemnon by a kind of divine majesty. In the son of Tydeus is expressed an air of freedom; Ajax is known by his sullen fierceness; and Antilochus by his alertness. To give to these such sentiments and actions as are consequent from their peculiar characters, is the ethic of painting." Another instance of excellence in expression among the ancient paintings was the Medea of Timomachus. She was painted about to kill her infant. Ausonius speaks with admiration of the mingled expression of anger and maternal fondness in her face; and manner.

Immanem exhaust rerum in diversa laborum
Fingeret affectum matris ut ambiguum,
Ira sub est lacrymis, miserrato non carere ira,
Alter utrum videt ut sit in altere utro.

It may not be amiss, however, at this period of our inquiry, to make some observations on the testimonies of ancient authors respecting this subject.

It is certainly true, that when the works of an ancient artist are praised for any real or supposed merit, the commendations will be relative to the degree of perfection to which the art had arisen at the time, and to the opportunities of information, the taste, and judgment of the person who bestows them. Excellence will always be ascribed to him who leaves his contemporaries far behind; and those performances will often be considered as supremely beautiful which exceed in beauty all that have gone before. In like manner, a person of natural sensibility, but who has been accustomed all his life to performances of an inferior stamp, will be in raptures at any which much exceed the best he has heretofore been taught to admire; and whatever opportunities of information he may have, his evidence will not be of much weight, if he do not possess a sufficient degree of taste and judgment to use them properly.

In ascertaining therefore the degree of credit due to the praises bestowed on any performance in a branch of the fine arts, we must take into consideration the general state of the art at the time, and the competence of the person who bestows the praise.

No slight degree of probability, however, may be attained on both those points, by attending to a circumstance not generally noticed, viz. that in an advanced state of the art, and when the observer is acquainted with his subject, the praise will seldom be given in loose, general, and comprehensive expressions; but the terms in which it is conveyed will be characteristic and determinate, and often technical; they will frequently show the state of the art, by marking the subdivisions and the skill of the observer by judicious discrimination. When, added to these, the latter can resort for comparison to any existent standard of perfection, his praise may fairly be adopted in its full extent, and regarded as evidence upon the point in question.

To apply these observations to painting, it is clear, with.
History.

PAINTING.

Comparison between the Ancient and Modern.

with respect to the most difficult, the most fundamental, and the highest in rank among the departments of the art, viz. design and expression, that the ancients were fully equally to the moderns; and their expressions of praise must be allowed to imply an equal degree of absolute skill, with similar expressions, if applied to the great masters of modern art. It is also clear that painting was extremely cultivated among the ancients, and that their good painters were more esteemed than artists of equal merit in modern times; that what we should term gentlemen artists were frequent with them (apud Romanos quoque honos muturur hac arti contigit); and that the expressions of the ancient connoisseurs evince much theoretical and technical knowledge of the art, and display a distribution of its parts almost as minute, complete, and scientific, as the present state of it can boast.

With regard to colouring, the praises of the ancient authors chiefly relate to the style of it as executed upon single figures or particular tints. It may therefore be doubted whether the ancients were possessed of the art of distributing their colours through the whole of a picture, so as to produce an harmony and general tone of colouring similar to that which we admire in the Lombard and Flemish schools. The present remains of ancient paintings do not appear to warrant any such conclusion; but being undoubtedly the works of inferior hands, their authority is very small when alleged against the general or particular merit of the ancient artists. The following extracts will be sufficient to evince, that the ancients did attend to this technical branch of colouring.

Indeed the modern technical expressions appear borrowed, from the following passage of Pliny, which may be regarded as decisive on the subject. Tandem sese ipse distincti, et iuvavit lumen atque umbrae, differentiae colorum alterna vice seae excitate. Dein adjectis est splendor, alius hic quae, lumen; quem qua inter hoc et umbrae esset appetiavertum tonon. Commisuratas vero colorum et transitum, harmogen. The lumen atque umbrae of this passage might have been regarded as merely descriptive of the light and shade necessary to relieve single figures, if it were not for the subsequent definition of tone. The harmogen of Pliny means the handling or skilful blending and softening colours into one another, rather than what we now call harmony.

Lucian, in his fine description of that spirited painting by Zeuxis of the male and female centaurs, after relating the treatment of the subject itself, proceeds to notice the technical execution of the picture; and he praises particularly the truth and delicacy of the drawing, the perfect blending of the colours, the skilful shading, the scientific preservation of size and magnitude, and the equality and harmony of the proportions throughout the whole piece.

Painters, says Plutarch, increase the effect of the light and splendid parts of a picture by the neighbourhood of dark tints and shades. And Maximus Tyrius observes, that bright and vivid colours are always pleasant to the eye; but this pleasure is always lessened if you omit to accompany them with somewhat dark and gloomy. These passages seem to imply a knowledge of the use of cold and dark tints even where a brilliancy of tone is required. The best among the ancient painters, however, seem to have preferred a chaste and sober style of colouring to the gaudiness and flutter of the later artists.

Upon the whole, therefore, with respect to colouring as employed upon single figures, as the ancients were fully as competent to judge of excellence herein as the moderns; as the expressions of the ancient connoisseurs are very warm in praise of the colouring of many of their painters; as they appear also to have attended very much to the art of colouring; and moreover, as probable evidence can be adduced that they attended to miniature painting—a considerable degree of merit may be allowed them in the use of the colours they possessed.

Chiaroscuro, or the art of placing and proportioning light and shade: in such a manner as to produce a pleasing effect, independently of any other circumstance connected with the picture, has been commonly deemed a characteristic difference between the knowledge of ancient and modern painters. On this subject the works of the ancients now remaining give little or no information; hence Sir Joshua Reynolds observes, that this, which makes so considerable a part of the modern art, was to them totally unknown. If the great painters had possessed this excellence, some portion of it would have infallibly been diffused, and have been discovered, in the works of the inferior ranks of artists which have come down to us, and which may be considered as on the same rank with the paintings that ornament our public gardens. But the accounts of the places where these paintings have been found, make it evident that they were thus ornamented at a very considerable expense. The generality of them consist of single figures; some of them of two or three figures, generally relieved by an uniform ground; and, except in a few instances, evidently designed as mere reliefs to a compartment, and answering, as near as may be, to the stuccoed ornaments in our modern rooms; nor do any of them seem the works of artists equal in their day to those at present employed on the painted ceilings of private houses.

The Abbé du Bos maintains, on the other hand, that what Pliny and other ancient writers say concerning the chiaro-obscurro and the delightful distribution of light and shade, is altogether decisive; and that their writings are full of so many probable circumstances, that it cannot be denied that the ancients at least equalled the most celebrated of the moderns in this part of the art.

On the examination of the greater part of the passages from antiquity, it is evident that they may relate to the light and shade of single figures, without involving what is now called the science of the chiaro-obscurro. The passage of Pliny, however, already quoted, and several others, go very near to prove that this branch of painting was understood among the ancients. The dark, the light, and mezzotint, are evidently and accurately described in that passage.

Equally strong is that expression in Quintilian: Zeuxis luminum umbraeque rationem inventisse tradidit. This cannot well be otherwise translated than by the science of light and shade.

That some technical knowledge of the effect producible by masses of light and shade was possessed by the ancients, appears indubitable from the passages added:
to what extent it was carried cannot now be ascertained. In all probability they were much inferior in this respect to the moderns; otherwise, although much science of this kind could hardly be expected from the trifling performances that remain, much more would have occurred on the subject, it would have been more largely dwelt on, and more precisely expressed among the observations of ancient authors on the best painting of the ancient masters.

Neither is there sufficient evidence that the ancients were eminent in that important branch of the composition of a picture, which consists in distributing the figures and objects in groups, or masses. There are few examples of this difficult branch of the art among the remaining antiquities; and indeed from the paucity of the figures introduced in the generality of these ancient paintings, there is little room to expect them. But what makes it still more doubtful whether the ancients attained any degree of eminence in grouping is, that among the many paintings of these great masters enumerated by Pliny, Lucian, or Philostratus, there is none of them praised for this species of excellence. This, however, it must be confessed, may as well arise from want of knowledge in the writer, as from want of skill in the artist; for in a picture found in Hercules, which represents in all probability the education of Achilles, the figure of an old man holding a child on his knees, together with that of a woman behind him, form a very agreeable group. A work of the same collection, painted in one colour on marble, consists of five figures grouped very much after the modern idea, if it were not that three of the heads are at the same height. It is extremely probable, that this morsel had been the copy of a picture finished in the purest times of the art. But although it were proved that the ancients did not attempt grouping their figures, it is still uncertain whether this might not arise from their peculiar and perhaps excellent taste in the arts. Wishing to enjoy in the fullest manner their painted figures as they enjoyed the aspect of a statue, they took care that every figure should be detached from another in the same picture, which permitted them to give their objects more relief, and to render them more distinct to the eye of a distant spectator.

We are therefore not to conclude, that they were entirely ignorant of grouping, on the one hand; or that they declined the execution of it from want of skill, on the other. Indeed it actually appears to have been technically attended to by them, whatever might be their comparative excellence in it; for Apelles is expressly asserted by Pliny to have been inferior to Melanthius in composition (de dispositione): and one of their paintings mentioned by the same author, is said to have contained one hundred figures; but this unwieldy number must have been offensive, if they were not grouped with some skill.

From the connection between the sister arts of poetry, painting, and sculpture, and the admirable performance of the ancients in the other two departments of the fine arts, it is reasonable to conclude that the ancient painters were not deficient in invention. Many instances, were it necessary, might be collected in support of their well-founded claim to this branch of the art; but it will be sufficient to observe, that as invention is rather a natural endowment than an acquired talent, and as the ancients universally seem to be at least equal to the moderns in the gifts of genius and good sense, we cannot but admit, on their part, an equality with ourselves so far as invention is concerned.

Very nearly connected with the subject of invention is that of the costume; by which is meant an attention to probability with respect to times, places, objects, persons, and circumstances in the transaction represented.

The ancient paintings now remaining, so far from exhibiting any proofs of attention to this important branch of the art, are full of gross violations of probability, and representations of impossible connection. But very little stress is to be laid on these instances; first, because they are evidently the performances of artists of no reputation; secondly, because none of them to which this objection can be made are regular representations of any person or transaction; and thirdly, because, as they were (for the most part) manifestly intended as ornaments to apartments, the taste of the owner, and not of the artist, would of course be chiefly consulted. Nothing, however, can be more clear than that the ancients required an attention to probability in the works of their artists; and from the manner in which their writers express themselves on the subject (not so much recommending the practice of it as taking it for granted), we may reasonably conclude, that their best painters were seldom guilty of any gross violation of the costume. Sint facta similima veris was an apophthegm generally known, and when known must have been universally admitted.

The principles of the costume are well expressed and illustrated by Horace in the first lines of his Art of Poetry; and Vitruvius, lib. vii. chap. 5., says, that no pictures can be approved of which have not a resemblance to truth and nature. Whether the ancient painters put in practice a greater share of good sense with respect to the costume than the moderns, cannot now be accurately determined; the advantage seems to be in favour of the former; for, as we shall have occasion more particularly to observe afterwards, the most celebrated of modern painters from Raphael to Sir Joshua Reynolds have been guilty of such flagrant breaches of probability, as would appear astonishing to those who are not in the habit of expecting them.

It has been doubted whether the ancients were acquainted with the science of perspective: and if the remains of ancient painting were alone to decide this question, it must be determined against them: for the works of the ancient painters now in possession of the moderns afford no proof of attention to the rules of perspective equal to the performance of a modern sign-painter. The picture of the sacrifice among the Herculanean antiquities, and the fourth of the prints which Bellori has published and described, taken from the paintings in the sepulchre of the Nasoni, are barely tolerable; but the other landscapes (almost the only remaining antique paintings which admit of perspective) are grossly defective in this particular; so much so indeed, that considering the late period when landscape-painting was introduced among the ancients, together with this manifest imperfection in point of perspective of such as are yet extant, we cannot help suspecting the inferiority of the ancients in this respect. In perspective, as in the charac-
**History.**

PAINTING.

Comparsion between the Ancient and Modern.

secure, had good practice been common, some traces would have been discovered in the works of their lowest artists.

And yet some general knowledge of the principles, and some degree of attention to the practice, of perspective, cannot well be denied to the ancients. They were good mathematicians, they were excellent architects, and some of them are celebrated for their skill in scene-painting. Geminus the Rhodian, contemporary with Cicero, was the author of an express treatise on perspective; and Euclid, Heliodorus, Larisseus, Agatharchus, wrote also on the same subject. It is well known, besides, that the ancients practised the art of painting in perspective on walls in the same way that it is now done by the moderns; Pliny (Nat. Hist. lib. xxxv. c. 4.) says, that one of the walls of the theatre of Claudius Pulcher, representing a roof covered with tiles, was finished in so masterly a manner, that the roots, birds of no small sagacity, taking it for a real roof, attempted to light upon it. We are likewise told, that a dog was deceived to such a degree, by certain steps in a perspective of Dantos, that expecting to find a free passage, he made up to them in full speed, and dashed out his brains. But what is still more, Vitruvius tells us in express terms by whom and at what time this art was invented. It was first practised by Agatharchus, a contemporary of Aeschylus, in the theatre of Athens; and afterwards reduced to certain principles, and treated as a science, by Anaxagoras and Democritus; thus faring like other arts which existed in practice before they appeared in theory.

Portrait painting seems to have been a principal employment of the first artist whom the ancients have to boast of, since Alexander is said to have permitted no painter but Apelles, and no sculptor but Phidias, to take his likeness. Pliny particularizes several instances of Apelles as a portrait painter.

In the drawing and colouring of single figures, to which the ancients paid particular attention, they must be allowed to be equal, if not superior, to the moderns. That spirit and animation, ease and dignity, were common to the performances of ancient artists, the ancient statues and paintings still remaining most evidently evince; and as they possessed, therefore, all the requisites to excel in portrait painting, a branch of the art at all times much in request among them, there is good reason to infer, in favour of the ancients, at least an equality with the moderns in this respect.

Of the whole, all the principal parts of the art, as purity of design, and beauty and expression in the forms were not only to be found in the ancient statues, but were actually the foundation of excellence in modern painting; and hence we may conclude that their painters formed on the same models, and very often the same men who excelled in sculpture, were not inferior in those branches of the art. But with regard to the inferior parts, the allurement of colouring, the ingenuity of the clara-obscuro, the splendour of composition, the art of grouping figures, and the nice handling of the pencil, the moderns are superior to those ancient painters who have most deserved the notice of their contemporaries. It is still to be observed, however, that the progress of the arts among the ancients, from the principal parts to the more splendid, was somewhat similar to that among the moderns; and as the painters of the first rank were more immediately the objects of criticism and delight to authors of genius, it is impossible at this distance of time to state any accurate comparison between the ancients and moderns in all which may be termed the decay of the art. This is particularly the case with regard to colours, there being in ancient as well as in modern times two epochs; the one comprehending Polygnotus and his immediate successors, and the other the painters both of the moderns, Rome after the art began to decay. The colouring of Polygnotus was hard, and his manner had something of wildeness; but his design was in the highest style of perfection. In the succeeding ages the colouring was more varied, more brilliant, more harmonious, and the handling more agreeable; but the design was less elegant and exact. And the true connoisseurs continued to prefer the works of the ancient school, in the same manner that the best writers in our times prefer the works of the Roman and Venetian masters to the more brilliant pictures of their successors. From this statement of facts it is abundantly evident, that from the ancient authors we can form some comparison between the best ancient and modern painters in those things which are most excellent in the art; while in the inferior parts, from the silence of authors, and the loss of paintings, we have no grounds upon which a comparison can be accurately made. See ARTS FINE, SUPPLEMENT.

**PART I. Principles of the ART, and the Order of the Artist's STUDIES.**

WE have joined these together, because they are like cause and effect; and comprehend both on what parts in the execution of the art the painter is to employ his chief attention, and also the manner in which he is to employ it. We shall not therefore be confined to the dry and abstract, and as it were unembodied principles, but connect them with the useful and agreeable branches of the art, in that order in which it appears to us they should be studied.

**SECT. I. Of Anatomy.**

To ask if the study of anatomy is requisite to a painter, is the same thing as to ask if, in order to learn any science, a man must first make himself acquainted with the principles of it. It would be an useless waste of time to cite, in confirmation of this truth, the authorities of the ancient masters, and the most celebrated schools. A man, who is acquainted with the form and construction of the several bones which support and govern the human frame, and does not know in what manner the muscles moving these bones are fixed to them, can make nothing of what appears of them through the integuments with which they are covered; and which appearance is, however, the noblest object of the pencil. It is impossible for a painter to copy faithfully what he sees, unless he thoroughly understand it. Let him employ so much time and study in the attempt,
PAINTING.

Anatomy. It cannot but be attended with many and great mistakes: just as it must happen to a man, who undertakes to copy something in a language which he does not understand; or to translate it into his own, what he has written in another, upon a subject with which he is not acquainted.

It seldom happens, that nothing more is required of a painter than to copy exactly an object which he has before him. In still and very languid attitudes, in which every member is to appear motionless and dead, a living model may, no doubt, yield for a long time a faithful image, and prove an useful pattern to him. But in regard to gestures any way sudden, motions any way violent, or those momentary attitudes which it is more frequently the painter’s business to express, the case is quite different. In these a living model can hold an instant or two; it soon grows languid, and settles into a fixed attitude, which is produced by an instantaneous concourse of the animal spirits. If, therefore, a painter possess not so thoroughly all the principles of anatomy, as to be at all times able to have immediate recourse to them; if he know not the various manners in which the several parts of the body play, according to the various positions; living models, far from proving an useful pattern to him, will rather tend to lead him astray, and make him lose sight of truth and nature, by exhibiting the very reverse of what is required, or at least exhibiting it in a very faint and imperfect manner. In living models, we often behold those parts slow, which should be quick; those cold and torpid, which should have the greatest share of life and spirit in them.

Nor is it, as some may be apt to imagine, merely to represent athletic and vigorous bodies, in which the parts are most bold and determined, that anatomy is requisite: it should be under-told to represent persons of the most delicate frame and condition, even women and children, whose members are smoothest and roundest, though the parts made known by it are not to be strongly expressed in such object; just as logic is equally requisite under the polished insinuations of the orator, and the rough arguments of the philosopher.

But where it is not so much time in proving, that a painter should be acquainted with anatomy; or in showing, how far his acquaintance with it should extend.

For instance, it is unnecessary for him to enter into the different systems of the nerves, blood-vessels, bowels, and the like; parts which are removed from the sight, and which therefore may be left to the surgeon and the physician, as being a guide in the operations of the former and in the prescriptions of the latter. It is enough for the painter, to be acquainted with the skeleton; in other words, with the figure and connection of the bones, which are, in a manner, the pillars and props of a human body; the origin, progress, and shape of the muscles which cover these bones; as also the different degrees in which nature has clothed the muscles with fat, for this substance fies thicker upon them in some places than in others. Above all, he should know in what manner the muscles effect the various motions and gestures of the body. A muscle is composed of two tendons and slender parts, one called the head, the other, the tail; or to off-termine into the bones; and of an intermediate part, called the body. The action of a muscle consists in an extraordinary swelling of this intermedium part, while the head remains at rest, so as to bring the tail nearer the head, and consequently the part to which the tail of the muscle is fixed, nearer to that part into which the head is inserted.

There are many motions to effect which several of the muscles (for this reason called co-operating muscles) must swell and operate together, while those calculated to effect a contrary motion (and therefore called antagonist muscles) appear soft and flaccid. Thus, for example, the biceps and the brachialis internus labour when the arm is to be bent, and become more prominent than usual; while the ghamellus, the brachicus externus, and the anconus, whose office is to extend the arm, continue, as it were, flat and idle. The same happens respectively in all the other motions of the body. When the antagonist muscles of any part operate at one and the same time, such part becomes rigid and motionless. This action of the muscle is called tonic.

Michael Angelo intended to give the public a complete treatise on this subject, and it is no small misfortune, that he never accomplished so useful a design. This great man, having observed, as we are told in his life by Condé, that Albert Durer was deficient in the subject, as treating only of the various measures and forms of bodies, without saying a word of their attitudes and gestures, though things of much greater importance, resolved to compose a theory, founded upon his long practice, for the service of future painters and statuaries. And, certainly, no one could be better qualified to give anatomical precepts for that purpose, than he who, in competition with Da Vinci, designed that famous cartoon of naked bodies, which was studied by Raphael himself, and afterwards obtained the approbation of the Vatican, the greatest school of the art we are now treating of.

The want of Michael Angelo’s precepts may, in some measure, be supplied by other books written on the same subject by Moro, Cesio, and Tornabuoni; and lately by Bouchardon, one of the most famous statuaries in France. But nothing can be of equal service to a young painter, with the lessons of some able dissector; under whom, in a few months, he may make himself master of every branch of anatomy which he need be acquainted with. A course of osteology is of so great length; and of the infinite number of muscles discovered by curious myologists, there are not above 80 or 90, with which nature sensibly operates all those motions which he can ever have occasion to imitate or express. These, indeed, he should closely study, these he should carefully store up in his memory, so as never to be at the least loss for their proper figure, situation, office, and motion.

But there is another thing, besides the dissection of dead bodies, by which a young painter may profit greatly; and that is anatomical casts. Of these we have numbers by several authors; nay, some which pass under the name of Buonarroti himself. But there is one in which, above all the rest, the parts are most distinctly and lively expressed. This is the performance of Hercules Lelli, who has perhaps gone greater lengths in this kind of study than any other master. We have, besides, by the same hand, some casts of particular parts of the human body, so curiously coloured for the use of young painters, as to represent these parts exactly as they appear on removing the integuments; and thus,
PAINTING.

Part I.

by the difference in their colour as well as configuration, render the tendinous and the fleshy parts, the belly and the extremities of every muscle, surprisingly distinct; at the same time that, by the various direction of the fibres, the motion and play of these muscles become very obvious; a work of the greatest use, and never enough to be commended! Perhaps, indeed, it would be an improvement, to give the muscles various tints; those muscles especially which the pupil might be apt to mistake for others. For example, though the masticoid, the deltoid, the sartorius, the fascia lata, the gastrocnemius, are, of themselves, sufficiently distinguishable, it is not so with regard to the muscles of the arm and of the back, the right muscles of the belly, and some others, which, either on account of the many parts into which they branch, or of their being interwoven one with another, do not so clearly and fairly present themselves to the eye. But let the cause of confusion to young beginners be what it will, it may be effectually removed, by giving, as already hinted, different colours to the different muscles, and illuminating anatomical figures; in the same manner that maps are coloured, in order to enable us readily to distinguish the several provinces of every kingdom, and the several dominions of every prince.

The better to understand the general effect, and remember the number, situation, and play of the muscles, it will be proper to compare, now and then, the anatomical casts, and even the dead body itself, with the living body covered with its fat and skin; and above all things with the Greek statues still in being. It was the peculiar happiness of the Greeks, to be able to characterize and express the several parts of the human body much better than we can pretend to do; and this, on account of their particular application to the study of naked figures, especially the fine living ones which they had continually before their eyes. It is well known, that the muscles most used are likewise the most protuberant and conspicuous; such as, in those who dance much, the muscles of the legs; and in boatmen, the muscles of the back and arms. But the bodies of the Greek youth, by means of their constant exertion of them in all the gymnastic sports, were so thoroughly exercised, as to supply the statuary with much more perfect models than ours can pretend to be.

The many exercises, which a young painter should go through while engaged in the study of anatomy, in order to make himself more thoroughly master of that science. For example: The thighs of any figure, a Laocoön for instance, being given, he should add to them legs suitable to that state in which the muscles of the thighs are represented, that is the muscles which serve to bend and extend the legs, and to erectuate in them such a precise position and no other. To the simple contour of an anatomy or a statue, he should add the parts included in it, and give it a system of muscles conformable to the quality of that particular contour; for every contour denotes some one certain attitude, motion, exertion, and no other. Exercises of this kind would soon establish him in the most fundamental principles of painting, especially if he had an opportunity of comparing his drawings with the statue of a cast from which the parts given him to work upon were taken, and thereby discovering and correcting his mistakes. This method is very like that used by those who teach the Latin tongue; when, having given their scholars a passage of Livy or Cæsar already translated into their mother-tongue, to translate back into Latin, they make them compare their work with the original text.

Sect. II. Of Perspective.

The study of perspective should go hand in hand with that of anatomy, as not less fundamental and necessary. In fact, the contour of an object drawn upon paper or canvas, represents nothing more than such an intersection of the visual rays sent from the extremities of it to the eye, as would arise on a glass put in the place of the paper or canvas. Now, the situation of an object at the other side of a glass being given, the delimitation of it on the glass itself depends entirely on the situation of the eye on this side of the glass; that is to say, on the rules of perspective: a science which, contrary to the opinion of most people, extends much farther than the painting of scenes, floors, and what generally goes under the name of quadrature. Perspective, according to that great master da Vinci, is to be considered as the reins and rudder of painting. It teaches us what proportion the parts fly from, and lessen upon the eye; how figures are to be massaheld upon a plain surface, and foreshortened. It contains, in short, the whole rationale of design.

Such are the terms which the masters best grounded in their profession have employed to define and commend perspective: so far were they from calling it a fallacious art, and an insidious guide; as some amongst the moderns have not blushed to do, insisting that it is to be followed no longer than it keeps the high road, or leads by easy and pleasant paths. But these writers plainly show, that they are equally ignorant of the nature of perspective, which, founded as it is on geometrical principles, can never lead its votaries astray; and of the nature of their art, which, without the assistance of perspective, cannot, in rigour, expect to make any progress, not so much as to delineate a simple contour.

When a painter has formed a scene in his mind, and supposed, as it is customary, that the capital figures of this scene lie close, or almost close, to the back of his canvas, he is, in the next place, to fix upon some point on this side of the canvas, from which he would choose his piece should be seen. But in choosing this point, which is called the point of sight, regard should be had to its situation to the right or left of the middle of the canvas: but, above all things, to its distance and its height with respect to the lower edge of the canvas; which edge is called the base line, and is parallel with the horizontal line that passes through the eye. For by assuming the point of sight, and consequently the horizontal line, too low, the planes upon which the figures stand will appear a great deal too shallow; as, by assuming it too high, they will appear too steep, so as to render the piece far less light and airy than it ought to be. In like manner, if the point of sight is taken at too great a distance from the canvas, the figures will not admit of degradation enough to be seen with sufficient distinctness; and if taken too near it, the degra-
PAINTING.

When a picture is to be placed on high, the point of sight should be assumed low, and vice versa; in order that the horizontal line of the picture may be, as near as possible, in the same horizontal plane with that of the spectator; for this disposition has an amazing effect.

When a picture is to be placed very high, as, amongst many others, that of the Purification, by Paolo Veronese, engraved by le Fèvre, it will be proper to assume the point of sight so low, that it may lie quite under the picture, no part of whose ground is, in that case, to be visible; for, were the point of sight to be taken above the picture, the horizontal ground of it would appear sloping to the eye, and both figures and buildings as ready to tumble head foremost. It is true, indeed, that there is seldom any necessity for such extraordinary exactness; and that, unless in some particular cases, the point of sight had better be rather high than low: the reason of which is, that, as we are more accustomed to behold people on the same plane with ourselves, than either higher or lower than the figures of a piece must strike us most when standing on a plane nearly level with that upon which we ourselves stand. To this it may be added, that by placing the eye low, and greatly shortening the plane, the heels of the back figures will seem to bear against the heads of the foremost, so as to render the distance between them far less perceptible than otherwise it would be.

The point of sight being fixed upon according to the situation in which the picture is to be placed, the point of distance is next to be determined. In doing this, a painter should carefully attend to three things: first, that the spectator may be able to take in, at one glance, the whole and every part of the composition; secondly, that he may see it distinctly; and, thirdly, that the degradation of the figures, and other objects of the picture be sufficiently sensible. It would take up too much time to lay down certain and precise rules for doing all this, considering the great variety in the sizes and shapes of pictures; for which reason we must leave a great deal to the discretion of the painter.

But there is a point still remaining, which will not admit of the least latitude. This is, the delineation of the picture, when once the point of sight has been fixed upon. The figures of a picture are to be considered as so many columns erected on different spots of the same plane; and the painter must not think of designing any thing, till he has laid down, in perspective, all those columns, which are to enter his composition, with the most scrupulous exactness. By proceeding, in this manner, he may not only be sure of not committing any mistake in the diminution of his figures according to their different distances, but may flatter himself with the thoughts of treading in the steps of the greatest masters. It is to the punctual observance of these laws, that we are to attribute the grand effect of some paintings by Carpazio and Mantegna, so careless in other respects; whereas a single fault against them is often sufficient entirely to spoil the works of a Guido, in spite of the sublimity and beauty of his superior style.

Now, as the demonstration of the rules of perspective depends on the doctrine of proportions, on the properties of similar triangles, and on the intersection of planes, it will be proper to put an abridgment of Euclid into the hands of the young painter, that he may understand these rules fundamentally, and not stand confined to a blind practice of them: but, then, there is nothing in this author relative to the art of painting, which may not be easily acquired in a few months. For, as it would be of no use to a painter to launch out into the anatomical depths of a doing or an Albinius, it would be equally superfluous to perplex himself with the intricacies of the higher geometry with a Taylor, who has handled perspective with that rich profundity, which we cannot help thinking does a great deal more honour to a mathematician, than it can possibly bring advantage to a simple artist.

But though a much longer time were requisite to become a perfect master of perspective, a painter, surely, ought not to grudge it; as no time can be too long to acquire that knowledge, without which he cannot possibly expect to succeed. Nay, we may boldly affirm, that the shortest road in every art is that which leads through theory to practice. From theory arises that great facility, by means of which a man advances the quicker, in proportion as he is more fully not taking a long step, whilst those, who are not grounded in the science, labour on in perpetual doubt; obliged, as a certain author expresses it, to feel out their way with a pencil, just as the blind, with their sticks, feel for the streets and turnings, with which they are not acquainted.

As practice, therefore, ought in every thing to be built upon principle, the study of optics, as far as it is requisite to determine the degree in which objects are to be illuminated or shaded, should proceed hand in hand with that of perspective: And thus, in order that the shades, cast by figures upon the planes on which they stand, may fall properly, and be neither too strong nor too light; in a word, that those most beautiful effects of the chiaro-securo may run no risk of ever receiving the lie from truth, which sooner or later discovers itself to every eye.

SECT. III. Of Symmetry.

The study of symmetry, it is obvious, should immediately follow that of anatomy; for it would avail us little to be acquainted with the different parts of the human body, and their several offices, were we at the same time ignorant of the order and proportion of those parts in regard to the whole in general, and to each other in particular. The Greek statues distinguished themselves above all others, as much by the just symmetry of their members, as by their skill in anatomy; but Polycletes surpassed them all by a statue, called the Rule, from which, as from a most accurate pattern, all the other artists might take measures for every part of the human body. These measures, to say nothing of the books which treat professedly of them, may now be derived from the Apollo of Belvedere, the Laocoon, the Venus of Medicis, the Faunus, and particularly the Antinous; which last was the rule of the learned Posinus.

It is the general opinion of painters, that the ancients were not so happy in representing the bodies of children, as they are allowed to have been in representing those of women and men; especially those of their gods; in which they excelled to such a degree, that with these gods were often worshipped the artists who had carved them. Yet the
PAINTING.

The Venus of Gnido by Praxiteles was not more famous than her Cupid, on whose account alone people flocked to Theespiae. To children, say they, the ancients knew how not to impart that softness and effeminacy which Flaminiaus has since contrived to give them, by representing their cheeks, hands, and feet, swelled, their heads large, and with scarce any belly. But such critics seem to forget, that these first sketches of nature very seldom come in the painter's way, and that this puny and delicate state has not in its form even the least glimmering of perfection. The ancients never undertook to represent children less than four or five years old; at which age the superfluous humour of the body being in some measure digested, their members begin to assume such a contour and proportion as may serve to point out what they are afterwards likely to be. This observation is confirmed by the children which we meet with in ancient baso-relievos and paintings: for they are all doing one thing or another; like those most beautiful little Cupids in a picture at Venice, who are playing with the arms of Mars, and lifting up the ponderous sword of that deity; or that little urchin in the Danse of Caracci, who empties a quiver of its arrows in order to fill it with the golden shower. Now, what can be a greater blunder in point of costume, than to attribute actions, which require some degree of strength and judgment, to infancy, to that raw and tender age so totally unable to govern and support itself?

Let a young painter consider the Greek statues ever so often, of whatever character or age they may be represented, it is impossible he should ever consider them without discovering new beauties in them. It is therefore impossible he could copy them too often, according to that judicious motto placed by Maratti on his print called The school. This truth was acknowledged by Rubens himself; for though, like one bred, as he was, in the foggy climate of the Low Countries, he generally painted from life; in some of his works he copied the ancients; nay, he wrote a treatise on the excellency of the ancient statues, and on the duty of a painter to study and imitate them. As to the satirical print, or rather pasquinade, of the great Titian, in which he has represented a parcel of young monkeys peeping the group of Laocoön and his sons; he intended nothing more by it than to laugh at the dulness and vanity of those artists, who cannot so much as draw a figure without having a statue before them as a model.

In fact, reason requires, that an artist should be so much master of his art, as seldom to stand in need of a pattern. To what other purpose is he to sweat and toil from his infancy, and spend so many days and nights in studying and copying the best models; especially the finest faces of antiquity, which we are still possessed of; such as the two Niobes, mother and daughter; the Ariadne, the Alexander, the young Nero, the Silenus, the Nile: and likewise the finest figures; for instance, the Apollo, the Gladiator, the Venus, and others; all which (as was said of Pietro Festa), be should have, as it were, perfectly by heart! With a stock of excellencies like these, treasured up in his memory, he may one day hope to produce something of his own without a model; form a right judgment of those natural beauties which fall in his way; and, when occasion offers, avail himself properly of them.

It is very injudicious to send boys to an academy to draw after naked figures, before they have imbibed a proper relish for beautiful proportions, and have been well-grounded in the true principles of symmetry. They should first learn, by studying the precious remains of antiquity, to improve upon life; and discern where a natural figure is faulty through stiffness in the members, or clumsiness in the trunk, or in any other respect; so as to be able to correct the faulty part, and reduce it to its proper bounds. Painting, in this branch, is, like medicine, the art of taking away and adding.

It must not, however, be dissembled, that the methods hitherto laid down are attended with some danger: for by too slavish an attention to statues, the young painter may contract a hard and dry manner; and, by studying anatomies too servilely, a habit of representing living bodies as stripped of their skin: for after all, there is nothing but what is natural, that, besides a certain peculiar grace and liveliness, possesses that simplicity, ease, and softness, which is not to be expected in the works of art, or even in those of nature when deprived of life. Poussin himself has now and then given into one of these extremes, and Michael Angelo very often into the other: but from this we can only infer, that even the greatest men are not infallible. It is, in short, to be considered as one instance, among a thousand, of the ill use those are wont to make of the best things, who do not know how to temper and qualify them properly with their contraries.

But no such danger can arise to a young painter from confining himself for a long time to mere design, so as not to attempt colouring till he has made himself master of that branch. If, according to a great master, colours in painting are in regard to the eye what numbers in poetry are in regard to the ear, so many charms to allure and captivate that sense; may we not affirm, that design is in the same art what propriety of language is in writing, and a just utterance of sounds in music? Whatever some people may think, a picture designed according to the rules of perspective and the principles of anatomy, will ever be held in higher esteem than a picture ill designed, let it be ever so well coloured. Hannibal Carracci set so great a value upon the art of contour, that, according to some expressions of his which have reached us, he considered almost every thing else as nothing in comparison with it. And this his judgment may be justified, by considering, that nature, though she forms men of various colours and complexions, never operates in the motions contrary to the mechanical principles of anatomy, nor, in exhibiting these motions to the eye, against the geometrical laws of perspective: a plain proof, that, in point of design, no mistake is to be deemed trifling. Hence we are enabled to feel all the weight of those words in which Michael Angelo, after he considered a picture drawn by a prince of the Venetian school, addressed Vasari: “What a pity it is,” said he, “that this man did not set out by studying design!” As the energy of nature shines most in the smallest subjects, so the energy of art shines most in imitating them.

SECT. IV. Of Imitation.

When you consider art as the imitation of nature (says Mengs), it is not to be understood that nature, which is the object, is more perfect than art which imitates.
Imitation. Imitation, in all its forms, is subject to many accidents. Art, working on passive and obedient materials, renders perfect the objects of its creation, chooses every thing in nature the most excellent, and collects the different parts and the different beauties of many individuals into one whole. It is seldom that we find in the same man greatness of soul and the due proportions of body, vigour, suppleness, firmness, and agility, joined together. Art constantly represents what is rarely or never to be met with in human nature; regularity in the outlines, grandeur in the forms, grace in the attitudes, beauty in the members, force in the breast, agility in the limbs, address in the arms, frankness in the forehead, spirit in the eyes, and affability over the whole countenance. Let an artist give force and expression to all the parts of his subject, let him vary this force and expression as different circumstances make it necessary, and he will soon perceive that art may surpass nature. But although this be granted, the artist is not to imagine that art is actually arrived at this supreme degree of perfection, and can proceed no farther. The moderns seem never to have perceived the track pointed out by the ancient Greeks: for, since the revival of painting, the true and the agreeable, instead of the beautified, have been the objects of cultivation. Still, however, imitation is the first part of the art of painting, though not the most excellent or beautiful. It is a necessary step in the progress which leads forward to greater perfection.

A painter ought attentively to consider, compare together, and weigh in the balance of reason and truth, all the different styles of the great masters; but he ought likewise carefully to guard against too great a fondness for any one of them in particular that he may think proper to adopt; otherwise, to use the expression of a first-rate master, instead of the child, he would become the grandchild of nature.

Besides, his imitation must be of generals, and not of particulars. Whatever a young painter's natural disposition may be, whether to pant boldly and freely like Tintoret and Rubens, or to labour his works, like Titian or da Vinci, let him follow it. This kind of imitation is very commendable. It is thus that Dante, at the same time that he carefully avoided adopting the particular expressions of Virgil, endeavoured to seize his bold and free manner, and at last caught from him that elegance of style which has done him so much honour.

As to the rest, nothing should hinder an artist from making use now and then of any antique, or even modern figure, which he may find his account in employing. Sanzio, in St. Paul at Lystra, sculpted not to avail himself of an ancient sacrifice in basso-relievo; nor did Buonarroti himself disdain to use, in his paintings of the Sixtine chapel, a figure taken from the famous cornelian which tradition tells us he wore on his finger, and which was lately in the possession of the most Christian king. Men like these avail themselves of the productions of others in such a manner as to make us apply to them, what La Bruyère said of Desproux, that one would imagine the thoughts of other men had been of his own creation.
Part I.  

PAINTING.

Colouring, avoid mentioning here an error which students are apt to fall into.

"He that is forming himself must look with great caution and wariness on those peculiarities or prominent parts which at first force themselves on view, and are the marks, or what is commonly called the manner, by which that individual artist is distinguished.

"Peculiar marks I hold to be generally, if not always, defects, however difficult it may be wholly to escape them.

"Peculiarities in the works of art are like those in the human figure; it is by them that we are cognizable and distinguished one from another; but they are always so many blemishes, which, however, both in the one case and in the other, cease to appear deformities to those who have them continually before their eyes. In the works of art, even the most enlightened mind, when warmed by beauties of the highest kind, will by degrees find a repugnance within him to acknowledge any defects; nay, his enthusiasm will carry him so far as to transform them into beauties and objects of imitation.

"It must be acknowledged, that a peculiarity of style, either from its novelty, or by seeming to proceed from a peculiar turn of mind, often escapes blame; on the contrary, it is sometimes striking and pleasing; but it is vain labour to endeavour to imitate it, because novelty and peculiarity being its only merit, when it ceases to be new, it ceases to have value.

"A manner, therefore, being a defect, and every painter, however excellent, having a manner, it seems to follow that all kinds of faults as well as beauties may be learned under the sanction of the greatest authority."

SECT. V. Of Colouring.

Colouring, though a subject greatly inferior to many others which the painter must study, is yet of sufficient importance to employ a considerable share of his attention; and to excel in it, he must be well acquainted with that part of optics which has the nature of light and colours for its object. Light, however simple and uncompounded it may appear, is nevertheless made up, as it were, of several distinct substances; and the number, and even dose of these ingredients, has been happily discovered by the moderns. Every undivided ray, let it be ever so fine, is a little bundle of red, orange, yellow, green, azure, indigo, and violet rays, which, while combined, are not to be distinguished one from another, and form that kind of light called white; so that white is not a colour per se, as the learned Da Vinci† (so far, it seems, the precursor of Newton) expressly affirms, but an assemblage of colours. Now these colours, which compose light, although immutable in themselves, and endowed with various qualities, are continually, however, separating from each other in their reflection from and passage through other substances, and thus become manifest to the eye. Grass, for example, reflects only green rays, or rather reflects green rays in greater number than it does those of any other colour; one kind of wine transmits red rays, and another yellowish rays: and from this kind of separation arises that variety of colours with which nature has diversified her various productions. Man, too, has contrived to separate the rays of light by making a portion of the sun's beams pass through a glass prism; for after passing through it, they appear divided into seven pure and primitive colours, placed in succession one by the other, like so many colours on a painter's pallet.

Now, though Titian, Corregio, and Vandyke, have been excellent colourists, without knowing any thing of these physical subtilties, that is no reason why others should neglect them. For it cannot but be of great service to a painter to be well acquainted with the nature of what he is to imitate, and of those colours with which he is to give life and perfection to his designs; not to speak of the pleasure there is in being able to account truly and solidly for the various effects and appearances of light. From a due tempering, for example, and degrading, of the tints in a picture; from making colours partake of each other, according to the reflection of light from one object to another; there arises, in some measure, that sublime harmony which may be considered as the true music of the eye. And this harmony has its foundation in the genuine principles of optics. Now this could not happen in the system of those philosophers, who held, that colours did not originally exist in light, but were, on the contrary, nothing else than so many modifications which it underwent on being reflected from other substances, or in passing through them; thus subject to alterations without end, and every moment liable to perish. Were that the case, bodies could no more receive any hues one from another, nor this body partake of the colour of that, than scarlet, for example, because it has the power of changing into red all the rays of the sun or sky which immediately fall upon it, has the power of changing into red all the other rays reflected to it from a blue or any other colour in its neighbourhood. Whereas, allowing that colours are in their own nature immutable one into another, and that every body reflects, more or less, every sort of coloured rays, though those rays in the greatest number which are of the colour it exhibits, there must necessarily arise, in colours placed near one another, certain particular hues or temperaments of colour: nay, this influence of one colour upon another may be so far traced, that three or four bodies of different colours, and likewise the intenseness of the light falling upon each, being assigned, we may easily determine in what situations and how much they would tinge each other. We may thus, too, by the same principle of optics, account for several other things practised by painters; insomuch that a person, who has carefully observed natural effects with an eye directed by solid learning, shall be able to form general rules, where another can only distinguish particular cases.

But after all, the pictures of the best colourists are, it is universally allowed, the books in which a young painter must chiefly look for the rules of colouring; that is, of that branch of painting which contributes so much to express the beauty of objects, and is requisite to represent them as what they really are. Giorgio and Titian seem to have discovered circumstances in nature which others have entirely overlooked; and the last in particular has been happy enough to express them with a pencil as delicate as his eye was quick and piercing. In his works we behold that sweetness of colouring which is produced by union, that beauty which is consistent with truth; and all the insensible transmutations,
PAINTING.

Part 1

Colouring, transmutations, all the soft transitions, in a word, all the pleasing modulations, of tints and colours. When a young painter has, by close application, acquired from Titian, whom he can never sufficiently dwell upon, that art which, of all painters, he has best contrived to hide, he would do well to turn to Bassano and Paolo, on account of the beauty, boldness, and elegance of their touch. That richness, softness, and freshness of colouring for which the Lombard school is so justly cried up, may likewise be of great service to him. Nor will he reap less benefit by studying the principles and practice of the Flemish school; which, chiefly by means of her varnishes, has contrived to give a most enchanting lustre and transparency to her colours.

But whatever pictures a young painter may choose to study the art of colouring upon, he must take great care that they be well preserved. There are very few pieces which have not suffered more or less by the length, not to say the injuries, of time; and perhaps that precious patina, which years alone can impart to paintings, is in some measure akin to that other kind which ages alone impart to medals; inasmuch as, by giving testimony to their antiquity, it renders them proportionately beautiful in the superstitious eyes of the learned. It must indeed be allowed, that if, on the one hand, this patina betrays, as it really does, an extraordinary degree of harmony upon the colours of a picture, and destroys, or at least greatly lessens, their original rawness, it, on the other hand, equally impairs the freshness and life of them. A piece seen many years after it has been painted, appears much as it would do, immediately after painting, behind a dull glass. It is an idle opinion, that Paolo Veronese, attentive above all things, to the beauty of his colours, and what is called strepito, left entirely to time the care of harmonizing them perfectly, and (as we may say) mellowing them. But most of the old masters took that task upon themselves; and never exposed their works to the eyes of the public, until they had ripened and finished them with their own hands. And who can say whether the Christ of Moneta, or the Nativity of Bassano, have been more improved or injured (if it may so speak) by the touchings and retouchings of time, in the course of more than two centuries? It is indeed impossible to be determined. But the studious pupil may make himself ample amends for any injuries which his originals may have received from the hands of time, by turning to truth, and to Nature which never grows old, but constantly retains its primitive flower of youth, and was itself the model of the models before him. As soon, therefore, as a young painter has laid a proper foundation for good colouring, by studying the best masters, he should turn all his thoughts to truth and nature. And it would perhaps be well while to have, in the academies of painting, models for colouring as well as designing; that as from the one the pupils learn to give their due proportion to the several members and muscles, they may learn from the other to make their caricatures rich and warm, and faithfully copy the different local hues which appear quite distinct in the different parts of a fine body. To illustrate still farther the use of such a model, let us suppose it placed in different lights: now in that of the sun, now in that of the sky, and now again in that of a lamp or candle; one time placed in the shade, and another in a reflected light. Hence the pupil may learn all the different effects of the complexion in different circumstances, whether the livid, the lucid, or transparent; and, above all, that variety of tints and half tints, occasioned in the colour of the skin by the epidermis having the bones immediately under it in some places, and in others a greater or less number of blood-vessels or quantity of fat. An artist who had long studied such a model would run no risk of degrading the beauties of nature by any particularity of style, or of giving into that pre-posterous fulness and floridness of colour which is at present so much the taste. He would not feed his figures with roses, as an ancient painter of Greece shrewdly expressed it, but with good beef; a rich and the difference which the learned eye of a modern writer could perceive between the colouring of Barocci and that of Titian. To practise in that manner, is, according to a great master, no better than inuring one's self to the commission of blunders. What statues are in design, nature is in colouring; the fountain-head of that perfection to which every artist, ambitious to excel, should constantly aspire: and accordingly the Flemish painters, in consequence of their aiming solely to copy nature, are in colouring as excellent as they are wont to be awkward in designing. The best model for the tone of colours and the degradation of shades is furnished by means of the camera obscura. See Diorum, Sect. vi. and ix.

SECT. VI. Of Drapery.

Drapery is one of the most important branches of the whole art, and accordingly demands the greatest attention and study. It seldom happens that a painter has nothing but naked figures to represent; nay, his subjects generally consist of figures clothed from head to foot. Now the flowing of the folds in every garment depends chiefly upon the relief of the parts that lie under it. A certain author, we forget his name, observes, that as the inequalities of a surface are discoverable by the inequalities in the water that runs over it, so the posture and shape of the members must be discernible by the folds of the garment that covers them. Those idle windings and gatherings, with which some painters have affected to cover their figures, make the clothes made up of them look as if the body had fled from under them, and left nothing in its place but a heap of empty bubbles, fit emblems of the brain that conceived them. As from the trunk of a tree there issue here and there boughs of various forms, so from one mistress fold there always flow many lesser ones: and as it is on the quality of the tree that the elegance, compactness, or openness of its branches chiefly depends; it is, in like manner, by the quality of the stuff of which a garment is made, that the number, order, and size of its folds must be determined. To sum up all in two words, the drapery ought to be natural and easy, so as to show what stuff it is, and what parts it covers. It ought, as a certain author expresses it, to cover the body, as it were, with a skin, to show it. It was formerly the custom with some of our masters to draw all their figures naked, and then drape them from the same principle that they first drew the skeletons of their figures, and afterwards covered them with muscles.
Drapery. And it was by proceeding in this manner that they attained to such a degree of truth in expressing the folds of their drapery, and the joints and direction of the principal members that lay under it, so as to exhibit in a most striking manner the attitude of the person to whom they belonged. That the ancient sculptors covered their statues with equal truth and grace, appears from many of them that are still in being; particularly a Flora lately dug up in Rome, whose drapery is executed with so much judgment, and in so grand and rich a style, that it may vie with the finest of their naked statues, even with the Venus of Medicis. The statues of the ancients had so much beauty when naked, that they retained a great deal when clothed. But here it must be considered, that it was usual with them to suppose their originals clothed with wet garments, and of an extreme fineness and delicacy, that, by lying close to the parts, and in a manner clinging to them, they might the better show what these parts were. For this reason a painter is not to confine himself to the study of the ancient statues, lest he should contract a dry style, and even fall into the same faults with some great masters who, accustomed to drapery with such light stuffs as sit close to the body, have afterwards made the coarsest lie in the same manner, so as plainly to exhibit the muscles underneath them. It is therefore proper to study nature herself, and those modern masters who have come nearest to her in this branch; such as Paolo Veronese, Andrea del Sarto, Rubens, and above all, Guido Reni. The flow of their drapery is soft and gentle; and the gatherings and plaits are so contrived, as not only not to hide the body, but to add grace and dignity to it. Their gold, silk, and woolen stuffs, are so distinguishable one from another, by the quality of their several lustres, and the peculiar light and shade belonging to each, but above all by the form and flow of their folds, that the age and sex of their figures are hardly more discernible by their faces. Albert Durer is another great master in this branch, insomuch that Guido himself was not ashamed to study him. There are still extant several drawings made with the pen by this great man, in which he has copied whole figures from Albert, and scrupulously retained the flow of his drapery as far as his own peculiar style, less harsh and sharp, but more easy and graceful, would allow. It may be said that he made the same use of Albert that our modern writers ought to make of the best authors of the 17th century.

To drape a figure well, it is necessary that the folds be large and few in number; because large folds produce great masses of light and shadow, while small ones multiply the objects of view and distract the attention. But if the character of the drapery or kind of stuff require small folds, they should at least be distributed in groups, in such a manner that a great number of small folds shall be subordinate to an equal mass formed by a principal fold.

It is also proper to observe, that the colour of the drapery contributes to the harmony of the whole, and produces effects which the claro oscuro cannot do alone. At the same time, the principles of the claro oscuro must be regulated by the light, which regulates the art of drapery. If the folds of the stuff which cover the members exposed to the light are too strongly shaded, they will appear to enter into the members, and cut them.

Drapery contributes to the life, to the character, to the expression of the figures, provided all the movements of the folds announce the lively or more tranquil movement of those figures. The colour, and the kind of stuff, concur also to promote the general expression; brilliant or fine drapery cannot be properly introduced in a mournful subject, nor the opposite in a gay one.

The drapery must also agree with the age and character of the figures: And if nature in any instance is found to contradict those principles, it is because they relate to the ideal of the art; and it is this ideal which carries it to the greatest perfection.

Great attention is also necessary to the situation in which the figures are placed, and the actions about which they are employed. If they are in the act of ascending, a column of air weighs down the drapery; if, on the contrary, they are descending, the drapery is supported and spread out. The folds placed on every member, and the general play of the drapery, should indicate whether the figure is in action or about to be so; whether action be beginning or ending; and whether it be slow, or quick, or violent. All this is agreeable to nature; but it also partakes of the ideal, since nature never can be copied in such fluctuating situations. The practice of the Roman schools, first to draw after nature, and then to paint after the drawing, cannot be adopted by colourists; because nature, according to the kind of the stuffs, produces tones and lights which give more perfection and truth to the work. Meanwhile Raphael, who followed this practice, enjoys the first reputation for giving play to his drapery, and disposing the folds in the best order. In this part he has even attained the height of ideal beauty. He is the greatest painter of drapery, as the Venetians are the greatest in painting stuffs.

Raphael, says Mengs, imitated at first his master Perugin's manner of drapery; and he brought this manner to perfection, by studying the works of masaccio and of Bartholomew: but he departed entirely from the taste of the school in which he was educated when he had seen the works of the ancients. It was the basso-relievo of antiquity which pointed out to him the true swelling of drapery, and he was not backward to introduce it. He discovered, by attending to the principles of the ancients, that the naked is the principal part; that drapery is to be regarded altogether as an accessory, and that it is intended to cover not to conceal; that it is employed from necessity, not caprice; that of consequence the clothes should not be so narrow as to constrain the members, nor so ample as to embarrass them; but that the artist should adapt them to the size and attitude of the figures intended to wear them.

He understood that the great folds should be placed at the large places of the body; and where the nature of the drapery required small folds, that it was necessary to give them a projection, which indicates a subordination to the principal parts.

He made his ample draperies without useless folds, and with bendings at the articulations. It was the form of the naked figure which pointed out to him the form
PAINTING.

Landscape of his folds, and on the great muscles he formed great masses. When any part required to be foreshortened, he covered it with the same number of folds as if it had been straight; but then he crowded them in proportion to the foreshortening. He frequently discovered the border of his drapery, to show that his figures were not dressed in a simple black. The form of the principal parts, and the specific weight of the air, were always the causes of his folds. It was easy to discover in his works, by the folds of his drapery, the attitude of the figure previous to the one in which it was placed; and whether, for example, the arm was extended or otherwise, immediately before the action. This was an expression which he had carefully studied on all occasions, because he found it in nature.

When the drapery was to cover the leg or arm but half, or in an imperfect manner, he made it cut obliquely the member which was partly to be covered. His folds were of a triangular form. The reason of this form is in nature: for all drapery has a tendency to enlarge itself and be extended; and as at the same time its own weight obliges it to fall back on itself, it is naturally formed into triangles.

He knew perfectly that the movements of the body and of its members are the causes of the actual situation of drapery, and of the formation of its folds. All his practice is nothing else but the unfolding and demonstrating of this theory; and drapery executed in any other manner must be in a false and vicious taste.

Sect. VII. Of Landscape and Architecture.

When our young painter has made a sufficient progress in those principal branches of his art, the designing, perspective, colouring, and drapery of human figures, he should turn his thoughts to landscape and architecture; for, by studying them, he will render himself universal, and qualified to undertake any subject; so as not to resemble certain literati, who, though great masters in some artifices, are mere children in everything else.

The most eminent landscape painters are Poussin, Lorenese, and Titian. Poussin was remarkable for his great diligence. His pieces are quite exotic and uncommon; being set off with buildings in a beautiful but singular style; and with learned episodes, such as poets reciting their verses to the woods, and youths exercising themselves in the several gymnastic games of antiquity; by which it plainly appears, that he was more indebted for his subjects to the descriptions of Pausanias than to nature and truth.

Lorenese applied himself chiefly to express the various phenomena of light, especially those perceivable in the heavens. And thanks to the happy climate of Rome, where he studied and exercised his talents, he has left us the brightest skies, and the richest and most gloriously cloud-tipt horizons, that can be well conceived. Nay, the sun himself, which, like the Almighty, can be represented merely by his effects, has scarcely escaped his daring and ambitious pencil.

Titian, the great confidant of nature, is the Homer of landscape. His works have so much truth, so much variety, and such a bloom in them, that it is impossible to behold them, without wishing, as if they were real, to make an excursion into them. And perhaps the most perfect landscape that ever issued from mortal hands, is the background of his martyrdom of St. Peter; where, by the difference between the bodies and the leaves of his trees and the disposition of their branches, one immediately discovers the difference between the trees themselves; where the different soils are so well expressed, and so exquisitely clothed with their proper plants, that a botanist has much ado to keep his hands from them. See Part II. sect. ii.

Paolo Veronese is in architecture what Titian is in landscape. To excel in landscape, we must, above all things, study nature. To excel in architecture, we must chiefly regard the finest works of art; such as the fronts of ancient edifices, and the fabrics of those moderns who have best studied and best copied antiquity. Next to Brunelleschi and Alberti, who were the first revivers of architecture, came Bramante, Giulio Romano, Sannino, Sannichelli, and lastly Palladio, whose works the young painter should study and imitate closely to the extent of his mind. Nor is Vignola to be forgotten; for some think he was a more scrupulous copier of antiquity, and more exact, than Palladio himself, insomuch that most people consider him as the first architect among the moderns. For our part, to speak of him, not as fame, but as truth seems to require, we cannot help thinking, that rather than break through the generality of the rules contrived by him to facilitate practice, he has in some instances deviated from the most beautiful proportions of the antique, and is rather barren in the distribution and disposition of certain members. Moreover, the extraordinary height of his pedestals and cornices hinders the columns from showing in the orders designed and employed by him, as it does in those of Palladio. Amongst that great variety of proportions to be met with in ancient ruins, Palladio has been extremely happy in choosing the best. His profiles are well contrasted, yet easy. All the parts of his buildings hang well together. Grandeur, elegance, and beauty, walk hand in hand in them. In short, the very blemishes of Palladio, who was not slave to conveniency, and sometimes perhaps was too precise in his decorations, are picturesque. And we may reasonably believe, that it was by following so great a master, whose works he had seen before his eyes, that Paolo Veronese formed that fine and masterly taste which enabled him to embellish his compositions with such beautiful structures.

The study of architecture cannot fail, in another respect, of being very useful to the young painter, inasmuch as it will bring him acquainted with the form of the temples, thermes, basilicas, theatres, and other buildings of the Greeks and Romans. Besides, from the baso-relievo with which it was customary to adorn these buildings, he may gather with equal delight and profit, the nature of their sacrifices, arms, military ensigns, and dress. The study of landscape, too, will render familiar to him the form of the various plants peculiar to each soil and climate, and such other things as serve to characterize the different regions of the earth. Thus by degrees he will learn what we call contours, one of the chief requisites in a painter; since by means of it he may express with great precision the time and place in which his scenes are laid.
There are many of the heads in which the passions are 
represented in an outrageous manner. He appears to
give instructions in expression, as Diogenes gave ex-
amples of morality: I act like musicians, said that 
 cynic, who give a high tone, in order to indicate a true 
one. But the fervour of youth has naturally more in-
clination to seize the extreme than the middle; and 
hence it is difficult for the young artist, in copying after 
Le Brun, to seize the true tone. Youth in general 
may be supposed to have that regard for the calm 
and moderate in the arts, which they have for the precepts 
of wisdom and virtue."

Other French writers have given instructions re-
specting the expression of the passions, equally excep-
tionable with those of Le Brun. All of them whom 
we have consulted make so many divisions and subdivi-
sions of passions, that a philosopher cannot follow 
them in metaphysical theory, nor a painter exhibit their 
effects upon canvas. Nature therefore must be his 
guide, particularly in treating those very minute and 
almost imperceptible differences, by which, however, 
things very different from each other are often ex-
pressed. This is particularly the case with regard to 
the passions of laughing and crying; as in these, how-
ever contrary, the muscles of the face operate nearly 
in the same manner. As the famous Pietro de Cor-
tona was one day finishing the face of a crying child in 
a representation of the Iron Age, with which he 
was adorning the floor called the Hot-bath in the royal 
palace of Pitti, Ferdinand II, who happened to be 
looking over him for his amusement, could not forbear 
expressing his approbation, by crying out, “Oh how 
well that child cries!” To whom the artist,—“Has 
your majesty a mind to see how easy it is to make chil-
dren laugh? Behold, I’ll prove it in an instant:” And 
taking up his pencil, by giving the contour of the 
mouth a concave turn downwards instead of the con-
vex upwards which it before had, and with little or no 
alteration in any other part of the face, he made the 
child, who a little before seemed ready to burst its heart 
with crying, appear in equal danger of bursting its sides 
with inmoderate laughter; and then, by restoring the 
altered features to their former position, he soon set the 
child a-crying again.”

The different expressions of laughter and weeping are 
thus described by Le Brun. “The movements of the eye-

brrows are expressed by the eye-brows elevated to-
rwards the middle of the eye, and lowered towards the 
sides of the nose: the eyes, almost shut, appear some-
times moistened with tears: the mouth, a little open, 
leaks, allows the teeth to be seen: the extremities of the 
mouth drawn back, make a dimple in the cheeks, 
which appear to be swollen: the nostrils are open: and the face becomes red. The changes which weep-
ing occasions are equally visible. The eye-brow is 
lowered on the middle of the forehead; the eyes are 
almost shut, moistened, and lowered towards the sides 
of the cheeks: the nostrils are swollen, and the veins of 
the forehead very apparent: the mouth shut, by the 
lowness of its sides, occasional wrinkles in the cheeks; 
the under lip is turned down, and presses at the same 
time the upper lip: the whole countenance is wrinkled 
and becomes red; especially the eye-brows, the eyes, 
the nose, and the cheeks.”

According to Leonardo da Vinci, the best masters

Vol. XV. Part II.
that a painter can have recourse to in this branch are
those dumb men who have found out the method of
expressing their sentiments by the motion of their hands,
eyes, eye-brows, and in short every other part of the
body. If this advice be at all proper, such gestures
must be imitated with great sobriety and moderation,
lest they should appear too strong and exaggerated;
and the piece should show nothing but pantomimes,
when speaking figures alone are to be exhibited; and so be-
come theatrical and second-hand, or, at best, look like
the copy of a theatrical and second-hand nature.

The artist will reap greater benefit from studying
such fine ancient heads as those of Mithridates, Senec-
a, Alexander, Dying, Cleopatra, Néobe, &c. and above
all, from attentively observing such movements of na-
ture as we daily meet with in the world. But let him
chiefly consult his looking-glass, and study after his
own face; what, in certain expressions, are the muscles,
the lineaments, the tints, and the accidental circum-
stances which characterise the situation of the soul.
It rarely happens that a model, which is affected with
no sentiment, presents that to us which we ourselves
feel, and which we are capable of expressing when we
are our own model. Puget executed the legs of his
Milo after his own; and many ingenious artists have
had recourse to a similar expedient. In short, to be
affected ourselves is the true secret of affecting the
spectator.

We must not neglect, at the same time, to secure
the fleeting characters which nature presents to us on
a thousand occasions. We must distrust our memory,
and all the resources which are not easily employed
when we happen to stand in need of them. It is neces-
sary to watch the circumstances from which we can de-
rive any useful hint; to seize them when they present
themselves; and to be careful never to lose, by an ir-
reparable negligence, the fruit of a happy incident.

Let us also endeavour to possess the feeling of what
we are to express: whether it be by forming the
image of a thing absent as if it were present, or by
being affected with the lively idea of a situation which
we have either experienced, or with which we have
seen another person remarkably affected. We must
never forget, that all the terrible or agreeable, the
violent or slight movements, are to be treated in a na-
tural manner, and bear a relation to the age, condi-
tion, sex, and dignity of the person. Those grada-
tions, which art varies according to the nature of the
situation, and the character of men, compose the prin-
cipal ingredients of discernment, knowledge, and taste.
They have been the objects of attention and inquiry
in the most eminent painters of every age; and they
were of the last importance in assisting them to arrive
at that degree of excellence to which they have carried
expression.

We are told strange things of the ancient painters
of Greece in regard to expression; especially of Ari-
sides; who, in a picture of his, representing a woman
wounded to death at a siege, with a child crawling to
her breast, makes her appear afraid, lest the child,
when she was dead, should, for want of milk, suck her
blood. A Medea murdering her children, by Timom-
achus, was likewise much cried up, as the ingenious
artist contrived to express, at once, in her countenance,
both the fury that hurried her on to the commission of
so great a crime, and the tenderness of a mother that
seemed to withhold from it. Rubens attempted to
express such a double effect in the face of Mary of Me-
dicis, still in pain from her past labour, and at the same
time full of joy at the birth of a Dauphin. And in the
countenance of Sancta Polonia, painted by Tiepolo
for St Anthony's church at Padua, one may clearly
read a mixture of pain from the wound given her by the
executioner, and of pleasure from the prospect of para-
dise opened to her by it.

Few, to say the truth, are the examples of strong
expressions afforded by the Venetian, Flemish, or Lor-
bard schools. Deprived of that great happiness, the
happiness of being able to contemplate, at leisure, the
works of the ancients, the purest sources of perfection
in point of design, expression, and character; and los-
ing nothing but nature constantly before their eyes;
they made strength of colouring, blooming compo-
tions, and the grand effects of the chiaro-obscur,
their principal study: they aimed more at charming the
senses than at captivating the understanding. The Ve-
etians, in particular, seem to have placed their whole
glory in setting off their pieces with all that rich va-
riety of personages and dress, which their capital is
continually receiving by means of its extensive com-
come, and which attracts so much the eyes of all those
who visit it. It is much to be doubted, if, in all the
pictures of Paolo Veronese, there is to be found a box
and judicious expression, or one of those attitudes
which, as Petrarch expresses it, speak without words;
unless, perhaps, it be that remarkable one in his Mair-
riage Feast of Cana of Galile. At one end of the table,
and directly opposite to the bridegroom, whose eyes are
fixed upon her, there appears a companion, in red, hold-
ing up to him the skirts of her garment; as much as to
say, we may suppose, that the wine miraculously produc-
ed was exactly of the colour with the stuff on her back.
And in fact it is red wine we see in the cups and
pitchers. But all this while the faces and attitudes
of most of the company betray not the least sign of wonder
at so extraordinary a miracle. They all, in a manner,
appear intent upon nothing but eating, drinking, and
making merry. Such, in general, is the style of the
Venetian school. The Florentine, over which Michael
Angelo presided, above all things curious of design, was
most minutely and scrupulously exact in point of anat-
omy. On this she set her heart, and took singular
pleasure in displaying it. Not only elegance of form,
and nobleness of invention, but likewise strength of ex-
pression, triumph in the Roman school, nussed as it were
amongst the works of the Greeks, and in the bosom of a
city which had once been the seminary of learning
and politeness. Here it was that Domenichino and
Poussin, both great masters of expression, refined them-
sew, as appears more particularly by the St Jerome
of the one, and the Death of Germanicus, and the
Slaught of the Innocents, by the other. Here it was
that Raphael arose, the sovereign master of them all.
One would imagine that pictures, which are generally
considered as the books of the ignorant, and of the igno-
rant only, he had undertaken to make the instructors
even of the learned. One would imagine, that he in-
tended in some measure, to justify Quintilian * , who affirms,
that painting has more power over us than all the
arts of rhetoric. There is not, indeed, a single pic-
ure
Part I.

Expression of the Passions

Painting.

The nature of Raphael's, from the study of which those who are curious in point of expression may not reap great benefit; particularly his Martyrdom of St. Felicita, his Transfigurations, his Joseph explaining to Pharaoh his dream, a piece so highly rated by Poussin. His School of Athens in the Vatican, is, to all intents and purposes, a school of expression. Among the many miracles of art with which this piece abounds, we shall single out that of the four boys attending on a mathematician, who, stooping to the ground with his compasses in his hand, is given them the demonstration of a theorem. One of the boys, recollecting within himself, keeps back, with all the appearance of profound attention to the reason of the master; another, by the briskness of his attitude, discovers a greater quickness of apprehension; while the third, who has already seized the conclusion, is endeavouring to beat it into the fourth, who, standing motionless, with open arms, a staring countenance, and an unpeachable air of stupidity in his looks, will never perhaps be able to make any thing of the matter. And it is probable from this very group that Albani, who studied Raphael so closely, drew the following precept of his: "That it behaves a painter to express more circumstances than one by every attitude; and so to employ his figures, that, by barely seeing what they are actually about, one may be able to guess, both what they have been already doing, and are next going to do." This is indeed a difficult precept; but it is only by a due observance of it that the eye and the mind can be made to hang in suspense on a painted piece of canvas. It is expression that a painter, ambitious to soar in his profession, must, above all things, labour to perfect himself in. It is the last goal of his art, as Socrates proves to Parmenides, it is in expression that dumb poetry consists, and what the prince of our poets calls a visible language.

Sect. IX. Of Invention.

As the operations of a general should all ultimately tend to battle and conquest, so should all the thoughts of a painter to perfect invention. Now, the studies which we have been hitherto recommending, will prove so many wings by which he may raise himself, as it were, from the ground, and soar on high, when desirous of trying his strength this way, and producing something from his own hand. Invention is the finding out probable things, not only such as are adapted to the subject on hand, but such, besides, as by their sublimity and beauty are most capable of exciting suitible sentiments in the spectator, and of making him, when they happen to be well executed, fancy that it is the subject itself in its greatest perfection, and not a mere representation of it, that he has before him. We do not say true things, but probable things; because probability or verisimilitude is, in fact, the truth of those arts which have the fancy for their subject. It is, indeed, the business and duty of both naturalists and historians to draw objects as they find them, and represent them with all those imperfections and blemishes, to which, as individuals, they are subject. But an ideal painter, and such alone is a true painter, resembles the poet: instead of copying, he imitates: that is, he works with his fancy, and represents objects endowed with all that perfection which belongs to the species, and may be conceived in the archetype.

"Tis nature all, but nature methodised;" says an eminent poet, speaking of poetry: And the same may be said of painting; it is nature methodised, and made perfect. Inasmuch that the circumstances of the action, exalted and sublimed to the highest degree of beauty and boldness they are susceptible of, may, though possible, have never happened exactly such as the painter fancies and thinks proper to represent them. Thus, the piety of Æneas, and the anger of Achilles, are things so perfect in their kind, as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more instructive, and more entertaining, than history.

Here it is proper to observe, what great advantages the ancient had over the modern painters. The history of the times they lived in, fraught with great and glorious events, was to them a rich mine of the most noble subjects, which, besides, often derived no small sublimity and pathos from the mythology upon which their religion was founded. So far were their gods from being immaterial, and placed at an infinite distance from their worshippers; so far was their religion from recommending humility, penance, and self-denial, that, on the contrary, it appeared calculated merely to flatter the senses, inflame the passions, and poison the fancy. By making the gods partake of our nature, and subjecting them to the same passions, it gave man hopes of being able to mix with those who, though greatly above him, resembled him, notwithstanding, in so many respects. Besides, those deities of theirs were in a manner visible, and to be met at every step. The sea was crowded with Tritons and Nereids, the rivers with Naiads, and the mountains with Dryads. The woods swarmed with Fauns and Nymphs, who, in those obscure retreats, sought an asylum for their stolen embraces. The most potent empires, the most noble families, the most celebrated heroes, all derived their pedigree from the greater divinities. Nay, gods interested themselves in all the concerns of mankind. Apollo, the god of long arrows, stood by the side of Hector in the fields of Troy, and inspired him with new strength and courage to batter down the walls and burn the ships of the Greeks. These, on the other hand, were led on to the fight and animated by Minerva, preceded by Terror, and followed by Death. Jove nods, his divine locks shake on his immortal head; Olympus trembles. With that countenance, which allays the tempest, and restores serenity to the heavens, he gathers kisses from the mouth of Venus, the delight of gods and of men. Among the ancients, every thing sported with the fancy; and in those works which depend entirely on the imagination, some of our greatest masters have thought they could not do better than borrow from the Paragons, if we may be allowed to say it, their pictures of Tartarus, in order to render their own drawings of hell more striking.

After all, there have not been wanting able inventors in painting among the moderns. Michael Angelo, notwithstanding the depth and boldness of his own fancy, is not ashamed in some of his compositions, to Dante's; as Phidias and Apelles may be said formerly to have.

Homerized.
Painting.

Part I.

Invention

Homerojised. Raphael, too, tutored by the Greeks, has
found means, like Virgil, to extract the quintessence of
truth; has seasoned his works with grace and nobleness;
and exalted nature, in a manner, above herself, by
giving her an aspect more beautiful, more animating,
and more sublime, than she is in reality accustomed to
wear. In point of invention, Domenichino and Hannibal
Caracci, come very near Raphael, especially in the
pieces painted by them in Rome; nor does Poussin fall
very short of him in some of his pictures, particularly
in his Esther before Ahasuerus, and his Death of Germani
us, the richest jewel belonging to the Barberini family.
Of all the painters, who have achieved any extraordinar
degree of reputation, no one studied less to set off
his pieces by bold and beautiful circumstances, or was
more a stranger to what is called poetical perfection,
than Jacopo Bassano. Among the numberless instances
we could produce of his carelessness in this way, let it suf
fice to mention a Preaching of St Paul painted by him
in a place, near that of his birth, called Marostego.
Instead of representing the apostle tall a divine enth
usiasm, as Raphael has done, and thundering against
the superstitions of the heathen in an assembly of Athen
ians; instead of exhibiting one of his auditors struck
to the quick, another persuaded, a third inflamed; he
makes him bold forth, in a village of the Venetian state,
to a parcel of poor peasants and their wives, who take
not the least notice of him; the women especially, who
seem to mind nothing but the country labours in which
he had found them employed.

With a just sense of painting and poetry resemble
each other so much in many other respects, bes
ides that of combining in every action all the beauty
and elegance it will admit, that they well deserve the
name of sister arts. They differ, however, in one point,
and that of no small importance. It is this.
The poet, in the representation of his story, relates what has already happened, prepares that which is still to come,
and so proceeds, step by step, through all the circumstances
of the action; and, to produce the greater effect
on his hearers, avails itself of the succession of time
and place. The painter, on the contrary, deprived
of such helps, must be content to depend upon one single
moment. But what a moment! A moment, in which
he may conjure up, at once, to the eyes of the specta
tor, a thousand objects; a moment, teeming with the
most beautiful circumstances that can attend the action;
a moment, equivalent to the successive labours of the
poet. This the works of the greatest masters, which
are everywhere to be seen, sufficiently evince: among
others, the St Paul at Lystra, by Raphael, whom it is
impossible not to praise as often as this picture is men
tioned. In order to give the spectator a thorough in
sight into the subject of this piece, the painter has placed
in the front of it the cripple already restored to his
limbs by the apostle, fired with gratitude towards his be
nefactor, and exciting his countrymen to yield him all
kinds of honour. Round the cripple are some figures
lifting up the skirts of his coat, in order to look at the
legs reduced to their proper shape, and acknowledging
by gestures full of astonishment the reality of the mira
cle; an invention, says a certain author, a professed ad
mirer of antiquity, which might have been proposed as
an example in the happiest age of Greece.

We have another shining instance of the power of
painting to introduce a greater variety of objects on the
scene at the same time, and of the advantage it has in
this respect over poetry, in a drawing by the celebrated
La Fage. This drawing represents the descent of Eneias
into hell. The field is the dark caverns of Pluto's
kingdom, through the middle of which creeps slowly
the muddy and melancholy Acheron. Nearly in the
centre of the piece appears Aeneas with the golden
bough in his hand, and with an air of astonishment at
what he sees. The Sibyl, who accompanies him, is
answering the music which he is hearing. The
sonage there is the ferryman of the pitchy lake, by
which even the gods themselves are afraid to swear.
Those who, crowding in to the banks of the river,
numberless as the leaves shaken off the trees by autum
nal blasts, express, with outstretched hands, an impa
ience to be ferried to the opposite shore, are the un
happy manes, who, for want of burial, are unqualified
for that happiness. Charon, accordingly, is crying
out to them, and with his lifted-up oar driving them
from his boat, which has already taken in a number
of those who had been honoured with the accustomed
funeral rites. Behind Aeneas and the Sibyl we discover
a confused group of wretched souls, lamenting bitterly
their misfortune in being denied a passage; two of
them wrapped up in their clothes; and, in a fit of de
spair, sunk upon a rock. Upon the first lines of the
piece stands a third group of uninhumed shades. Le
capes, Eronuba, and, in the middest of them, the good
old Palinurus, formerly master and pilot of the hero's
vessel, who with his hands honestly de
sires to be taken along with him into the boat, that
after death, at least, he may find some repose, and his
dead body no longer remain the sport of winds and
waves. Thus, what we see scattered up and down in
many verses by Virgil, is here, as it were, gathered into
a focus, and concentrated by the ingenious pencil of
the painter, so as to form a subject well worthy of being
exposed, in more shapes than one, to the eyes of the public.

When a painter takes a subject in hand, be it his
rical, be it fabulous, he should carefully peruse the
books which treat of it, imprints well on his mind all
the circumstances that attend it, the persons concern
ed in it, and the passions with which they must have
been severally animated; not omitting the particulars
of time and place. His next business is to create it,
as it were, anew, observing the rules already laid down
for that purpose: From what is true, choosing that
which is most striking; and clothing his subject with
such accessory circumstances and actions, as may render
it more conspicuous, pathetic, and noble, and best dis
play the powers of the inventive faculty. But, in
doing this, great discretion is requisite; for, let his ima
gination grow ever so warm, his hand is never to ex
cute any thing that is not fully approved by his judg
ment. Nothing low or vulgar should appear in a lofty
and noble argument; a fault, of which some of the
greatest masters, even Lampi and Poussin, have
been now and then guilty.

The action must be one, the place one, the time
one. We need not say any thing of those painters,
who, like the writers of the Chinese and Spanish
theatre, cram a variety of actions together, and so give
us at once the whole life of a man. Such blunders, it is
presumed, are too gross to be feared at present. The
politeans
Part I.

Painting.

Invention. The best modern performances in picturesque allegory are certainly those of Poussin, who availed himself, with great discretion and judgment, of the vast treasures with which, by a close study of the ancients, he had enriched his memory. On the other hand, Le Brun, his countryman, has been very unhappy this way. Ambitious to have every thing his own, instead of allegories, he has filled the gallery of Versailles with enigmas and riddles, of which none but himself was qualified to be the Oedipus. Allegory must be ingenious, it is true; but then it must be equally perspicuous; for which reason, a painter should avoid all vague and indeterminate allusions, and likewise those to history and heathen mythology, which are too abstruse to be understood by the generality of spectators. The best way, perhaps, to symbolize moral and abstract things, is to represent particular events: as Caracci did, by advice of Monsignor Belvedere's Life of Agucchi, in the Farnese palace. For example, what Caracci can better express a hero's love towards his country, than the virtuous Decius consecrating himself boldly to the infernal gods, in order to secure victory to his countrymen over their enemies? What finer emblems can we desire of emulation, and an inextinguishable thirst for glory, than Julius Caesar weeping before the statue of Alexander in the temple of Hercules at Cæsarea; or the inconstancy of fortune, than Marius sitting on the ruins of Carthage, and receiving, instead of the acclamations of an army joyfully saluting him imperator, orders from a licitor of Sextilius to quit Africa; of indiscretion, than Candaules, who, by showing the naked beauties of his wife to his friend Gyges, kindled a passion that soon made him repent his folly? Such representations as these require no comment; they carry their explanations along with them. Besides, supposing, and it is the worst we can suppose, that the painter's aim in them should happen not to be understood, his piece would still give delight. It is thus that the fables of Ariosto prove so entertaining, even to those who understand nothing of the moral couched under them; and likewise the Æneas, though all do not comprehend the allusions and double intent of the poet.

Sect. X. Of Disposition.

So much for invention. Disposition, which may be considered as a branch of invention, consists in the proper stationing of what the inventive faculty has imagined, so as to express the subject in the most lively manner. The chief merit of disposition may be said to consist in that disorder, which, wearing the appearance of mere chance, is in fact the most studied effect of art. A painter, therefore, is equally to avoid the dryness of those ancients who always planted their figures like so many couples in a procession, and the affectation of those moderns who jumble them together as if they were met merely to fight and squabble. In this branch Raphael was happy enough to choose the just medium, and attain perfection. The disposition of his figures is always exactly such as the subject requires. In the Battle of Constantine, they are confusedly clustered with as much art, as they are regularly marshalled in Christ's commitment of the keys to St Peter, and constituting him prince of the apostles.

Let the inferior figures of a piece be placed as they will, the principal figure should strike the eye most, and stand...
of his, representing the Virgin at the foot of the cross. Disposition.

on Mount Calvary; the principal light darting upon

her through a break of the clouds, while the rest of the

figures about her stand more or less in the shade. Tin-
toret, too, acquired great reputation, as well by that
briskness with which he enlivened his figures, as by his
masterly manner of shading them; and Polidoro de Ca-

ravagge, though he scarcely painted anything but bas-

so-relievos, was particularly famous for introducing

with great skill the effects of the chiaro-scuro, a thing

first attempted by Mantegna in his Triumph of Julius Cæsar.

It is by this means that his compositions appear so strik-

ingly divided into different groups, and, among their

other perfections, afford so much delight, through the

beautiful disposition that reigned in each.

In like manner, a painter, by the help of perspective,

especially that called aerial, the opposition of local co-

ours, and other contrivances which he may expect to

hit upon by studying nature, and those who have best

studied her before him, will be able not only to part

his groups, but make them appear at different distances,

so as to leave sufficient passages between them.

But the greatest caution is to be used in the pursuit

of the methods here laid down; especially in the ma-

nagement of the chiaro-scuro, that the effects attributed

to light and shade, and to their various concomitants,

may not run counter to truth and experience. This is

a capital point. For this purpose, a painter would do

well to make, in little figures, as Tintoret and Poussin

used to do, a model of the subject that he intends to repre-

sent, and then illuminate it by lamp or candle light.

By this means he may come to know with certainty, if the

chiaro-scuro, which he has formed in his mind, does not

match with the results of his model. By varying the

height and direction of his light, he may easily discover

such accidental effects as are most likely to recommend

his performance, and so establish a proper system for the

illuminating it. Nor will be afterwards find it a difficult

matter to modify the quality of his shades, by softening

or strengthening them, according to the situation of his

scene, and the quality of the light falling upon it.

If it should happen to be a candle or lamp-light scene, he

would then have nothing to do but consider his model

well, and faithfully copy it.

In the next place, to turn a group elegantly, the best

pattern is that of a bunch of grapes adopted by Titian.

As, of the many grains that compose a bunch of grapes,

some are struck directly by the light, and those opposite
to them are in the shade, whilst the intermediate ones

partake of both light and shade in a greater or less de-

gree; so, according to Titian, the figures of a group

should be so disposed, that, by the union of the chiaro-

scuro, several things may appear as it were but one

thing. And in fact it is only from his having pursued

this method, that we may account for the very grand ef-

cfect of his pieces this way, in which it is impossible to

study him too much.

The mannerists, who do not follow nature in the track

of the masters just mentioned, are apt to commit many

faults. The reason of their figures casting their shades

in this or that manner seldom appears in the picture, or

at least does not appear sufficiently probable. They are

besides, wont to trespass all bounds in splashing their

pieces with light, that is, in enlivening those parts which

we usually term the darks of a picture. This method,
no doubt, has sometimes a very fine effect; but it is, however, to be used with no small discretion, as otherwise the whole loses that union, that pause, that majestic silence, as Caracci used to call it, which affords so much pleasure. The eye is not less hurt by many lights scattered here and there over a picture, than the ear is by the confused noise of different persons speaking all together in an assembly.

Guido Reni, who has imparted to his paintings that gayety and splendor in which he lived, seems enamoured with a bright and open light; whereas Michael Angelo de Caravaggio, who was of a sullen and savage disposition, appears fondest of a gloomy and clouded sky: so that neither of them were qualified to handle indiscriminately all objects. The chiaro-scuro may likewise prove of great service to a painter in giving his composition a grand effect; but, nevertheless, the light he chooses must be adapted to the situation of the scene where the action is laid: nor would be be less faulty, who in a grotto or cavern, where the light entered by a chink, should make his shades soft and tender, than he who should represent them strong and bold in an open sky-light.

But this is by no means the only fault which mannerists are apt to be guilty of in historical pieces, and particularly in the disposition of their figures. To say nothing of their favourite group of a woman lying on the ground with one child at her breast, and another playing about her, and the like, which they generally place on the first lines of their pieces; nor of those half-figures in the back ground peeping out from the hollows contrived for them: they make a common practice of mixing naked with clothed figures; old men with young; placing one figure with its face towards you, and another with its back; they contrast violent motions with languid attitudes, and seem to aim at opposition in every thing; whereas oppositions never please, but when they arise naturally from the subject, like antinomies in a discourse.

As to foreshortened figures, too much affectation in using or avoiding them is equally blamable. The attitudes had better be composed than otherwise. It very seldom happens that there is any occasion for making them so impetuous as to be in danger of losing their equilibrium; a thing too much practised by some painters.

In regard to drapery, equal care should be taken to avoid that poverty, which makes some masters look as if, through mere penury, they grudged clothes to their figures; and that profusion which Albani imputed to Guido, saying, that he was rather a tailor than a painter. The ornaments of dress should be used with great sobriety; and it will not be amiss to remember what was once said to an ancient painter: "I pity you greatly: unable to make Helen handsome, you have taken care to make her fine."

Let the whole, in a word, and all the different parts of the composition, possess probability, grace, costume, and the particular character of what is to be represented. Let nothing look like uniformity of manner; which does not appear less in the composition than it does in colouring, drapery, and design; and is, as it were, that kind of accent, by which painters may be as readily distinguished as foreigners are, by pronouncing in the same manner all the different languages they happen to be acquainted with.

Sect. XI. Of Illusion.

Among painters, and the writers on painting, there is one maxim universally admitted and continually inculcated; it is, that nature ought to be imitated, and objects are said to be represented naturally, when they have such relief that they may seem real. If we inquire to what degree painting may carry this illusion, we shall find that it deceives the eye, and obliges the spectator to employ the touch in mouldings and in basso-relievos where they are a little projected; but that it is weakened, and the effect partly destroyed where the projection is one or two feet. It is possible also to make it in the highest degree complete in pictures of flowers, fruits, and other representations of still life, provided they be seen in a certain point of view, and at a considerable distance; but there is no example of a picture containing a number of figures, and placed in a proper light, being mistaken for real life. We are told, indeed, of a bust of an abbé painted by Charles Coypel, which, placed in a certain direction behind a table, and in a certain light, deceived several persons so completely as to induce them to salute it: but, without admitting any thing very extraordinary in the projection or illusion of this painting, it is evident, from the circumstances attending the relation, that the deception arose from surprise and inattention, which might happen to a production of an inferior artist. And hence we may conclude that it is vain to pretend to perfect the illusion, especially in pictures consisting of a number of figures, and with considerable distances supposed between them.

Among the obstacles which are opposed to the perfection of this branch of the art, we shall chiefly attend to those which naturally proceed from our habits of thinking and judging on all occasions. These, together with the experience we daily have of light on all kinds of surfaces, and of all colours, are sufficient to demonstrate the want of reality in the mere representation of any scenes.

It has been elsewhere shown, that distance, figure, and magnitude, are not naturally objects of perception by the sense of sight; that we judge of these things by the eye only, in consequence of associations early formed between the perceptions of touch and the corresponding impressions on the retina and optic nerve by the rays of light; and that a painter makes his picture resemble the original, merely by laying his colours on a plane surface in such a manner, as that they reflect the same rays of light with the convex or concave original, when the spectator stands at the proper distance (see Metaphysics, No. 49, 50, 51, 52, and 95.). But if this be admitted, illusion in painting can never be made perfect, on account of the inevitable falsity of the shades which mark the most distant parts of the picture. The painter can only imitate those shades by obscure colours, laid on a plane surface, and susceptible of reflecting the light with a degree of force relative to the real distance. Now our eyes give us the tree plane of this surface, opposed to the idea of deepening which the painter wishes to produce, a contrariety which prevents the deception. On this account, the faults found in the works of the greatest
PAINTING.

Part I.

The greatest masters, with regard to the effects produced by the whole, most frequently relate to their manner of shading, which is sufficient to prove, that the want of illusion in painting depends chiefly on the imprecation of the shades.

This defect, though it cannot be wholly avoided, may yet be rendered less perceptible. There has yet, indeed, been no painter able to imitate shadow, nor is it probable that any one will ever perfectly accomplish his task.

Shadow in nature is not a body, but the privation of light, which destroys colours in a greater or less degree, in proportion as it is more or less complete. Now the painter can only imitate this privation and real darkness, by colours which must from their very nature be capable of reflecting light. The colours may be more or less obscure, but they preserve always something which gives a mixture of reflection. To carry the imitation of shadow to the highest degree of perfection, it would be necessary to apply a colour capable of darkening all others, more or less as there should be occasion, and which might have no visible trace of its existence, that is, no one part of it which reflected one coloured ray more strongly than another. Perhaps this kind of negative colour might be found in practice to be of service to the art; but it would not render the surface totally invisible, for it would be necessary, farther, that it should have the property of not reflecting a single ray of light when exposed to it; which is altogether impossible, as there is no colour or body in nature without reflection in such a situation.

We shall be further convinced of the impossibility of painting shadow, if we attend to the pictures of the greatest masters, with regard to the imitation of truth. Every part, when taken by itself, connected with light, or with demitints, presents a perfect imitation. Even the different degrees of light or the objects are sufficiently exact; but notwithstanding this assemblage of circumstances corresponding with truth, and of which the result should be perfect illusion, yet in considering the whole, we are never so completely deceived, as to take a picture for a reality; from which we may conclude, that the want of illusion proceeds almost entirely from the imprecation of shading.

Illusion then, in the strictest sense, cannot exist in painting; but there is another kind of illusion, perhaps improperly so called, which is one of the principal parts of the art, and worthy of the greatest attention: It is, that the picture shall resemble truth to such a degree, by the justness of its forms, by the combination of colours, and by all its general effects, that the image shall give all the pleasure to be expected from the imitation of truth. This is not illusion in the proper sense of the word, since it exists as well in pictures on a small scale as in those of equal dimensions with the original; but it is that truth of imitation of which painting is susceptible, even in pictures containing any numbers of figures at any reasonable distance from each other.

But it remains to be considered whether this imitation of truth, taken by itself, be the highest attainable perfection in painting. It is generally granted, that the greatest beauty is that which not only pleases at first view, but on the nearest and most critical examination. But if illusion, such as we have described it, were the sole merit of the art, it would follow, that the person who was least acquainted with its beauties would experience the same pleasure as he who had studied them most. Farther, in examining the works of the greatest masters, it is easy to perceive, that it is not their illusion which has excited the attention and admiration of the critic. Even the works of the divine Raphael do not deceive the eye in any point of view more completely than those of an ordinary painter. Raphael, pure in his character and design, is, without doubt, very deficient in this part of the art. Meanwhile the grandeur of his ideas in composition, and the choice of his forms; the beauty of his heads, wherein one does not admire simply the imitation of any known truth; his ingenious and noble manner in drapery, which yet does not resemble any known stuff, or the garb of any nation; in short, all his beauties are superior to the simple imitation of truth, and contradict the sentiment of the greatest pleasure arising from illusion.

If we pass to those who have pursued colouring with the greatest success, we shall find them, doubtless, approach nearer to illusion than those who have neglected it; and it is also a fact, that their works have been more universally admired.

At the same time it is not the illusion occasioned by colours which has altogether excited this admiration. The exquisite demitints and the freshness of Correggio and Titian, which excel the ordinary beauties of nature, and even imitate her most perfect productions, may perhaps not be considered as destroying illusion; but it is no less a fact, that weaker and less precious colouring would carry it to greater perfection. Besides, this large, easy, and exquisite manner of painting, this harmony, of which they have given us the best examples, are owing to qualities in them much more excellent than what would be sufficient to produce the simple imitation of truth. Guide, Cortona, and some others, appear to approach nearer to illusion. But even those masters prove by their works, that the most estimable beauties in painting do not all tend to this branch of the art; for notwithstanding the high character which they have gained, they are much inferior to Raphael, Correggio, and Titian, although the first failed in colouring and in the knowledge of the clairo-obscuro, the second in point of correctness, and the third in the choice of noble subjects.

From this we may conclude, that the nearest resemblance to truth is not the sole object in painting; that it requires a superior degree of elevation by the art of adding beauty and perfection to the most exact resemblance; and that it is this art which distinguishes and characterizes extraordinary men.

If we run over the great branches of painting, we shall find a number of essential beauties different from those which are capable of carrying illusion to the greatest possible height. In composition, we principally admire the extent of genius, the choice of picturesque and graceful attitudes, the ingenious combination of groups, whether in uniting the light and shade in order to obtain the greatest effect, or in disposing a whole in such a manner as to make no part superfluous; and finally, that kind of practical talent by which the mind takes possession of nature, and forces it to produce all the beauties of which the art is susceptible. In this enumeration of particulars it is easy to perceive that the beauties of composition are very distant from those of illusion.
To obtain illusion in design, there is no occasion for correctness nor taste beyond what is perceived in nature by the most ignorant spectator. And with regard to colouring, that is not always most admired which is most natural. What departs widely from truth, indeed, is not of consequence beautiful, but many qualities are required besides the simple imitation of truth. Truths, sense, and transparency in certain tones, are deemed absolutely requisite; and the most esteemed colourists have carried their beauties in all these respects beyond what they have seen in nature. If some tones in the fleshly parts have approached towards vermillion, to a light-blue, or a silver-gray, they have made them more apparent; not only to point them out to the spectator, but to show their knowledge in the discovery and their art in painting them. This would have been going beyond the limits of perfection, if these had consisted in simple illusion.

The opposition of colour, of light, and of shade, would have been in this case also superfluous; for nature is always true, without any pointed attempt to make her more engaging. The supposition of certain lights, which truth would require, and which art extinguishes, in order to augment the harmony of effect, would be also worthy of ceniture, whatever pleasure would result from it.

Finally, one of the greatest beauties of the art, namely, the peculiar manner of a great master, has no relation to illusion. This is not even founded in nature, but depends on the genius or singularity of the artist. It is this manner which distinguishes the original of a great master from the most exact copy; and which characterizes the talents of the artist so well, that the smallest part of the picture, and even the least interesting, is sufficient to discover the painter. The distinction between the beautiful and illusive in painting has been made by Sir Joshua Reynolds, in express terms, recommend a perfection superior to the imitation of nature. "The principle now laid down (says he), that the perfection of the art does not consist in mere imitation, is far from being new or singular. It is, indeed, supported by the general opinion of the enlightened part of mankind. The poets, orators, and rhetoricians of antiquity, are continually enforcing this position, that all the arts receive their perfection from an ideal beauty, superior to what is to be found in individual nature. They are ever referring to the practice of the painters and sculptors of their times, particularly Phidias the favourite artist of antiquity, to illustrate their assertions. As if they could not sufficiently express their admiration of his genius by what they knew, they have recourse to poetical enthusiasm. They call it inspiration; a gift from heaven. The artist is supposed to have ascended the celestial region to furnish his mind with this perfect idea of beauty. He (says Proclus) who takes for his model such forms as nature produces, and confines himself to an exact imitation of them, will never attain to what is perfectly beautiful. For the works of nature are full of disproportion, and fall short of the true standard of beauty. So that Phidias, when he formed his Jupiter, did not copy any object ever presented to his sight, but contemplated only that image which he had conceived in his mind from Homer's description."
PAINTING.

Part I.

When Raphael in his cartoons introduces monks and Swift guards; when he puts into a boat more figures than is evident the boat could actually contain; when in the chafillment of Heliodorus, who attempted to despoil the temple of Jerusalem, Pope Julius II, is depicted as being present; when, in the donation of Constantine in the Vatican, a naked boy is placed conspicuous in the fore ground astride upon a dog, in the immediate presence of the pope and the emperor; when Venetian senators are introduced while Pope Alexander excommunicates Barbarossa; when Ariostole, Plato, Dante, and Petrarch, are brought together in the school of Athens, to omit the lefer improprieties of shoefuls apofhles, &c.—every person must acknowledge that such omissions as these against truths so obvious, if they do not arise from a defect of understanding, are instances of inexcusable carelessness.

In like manner when the same great master paints the dreams of Joseph and his fellow prisoners in circles over their heads; when similar contrivances to express future events are used by Albani, Pameggiano, and Fufelli—is it not evident that no possibility can make the fiction true; and that real and feigned existences are unnaturally introduced in one narration?

When Polydore chooses to represent the death of Cato, and exposes to the spectator the hero of the piece with his bowels gutting out; when Paul Veronefs, at a banquet painted with his usual magnificence, places before us a dog gnawing a bone, and a boy making water; however such disgusting circumstances may be forgiven in the chef d'oeuvre of a Michael Angelo, had he represented these instead of the horrible figures of his Day of Judgment, the performance of an inferior artist cannot alone for them.

So also, when one of the first rate among the modern painters, we mean Paul Veronefs, introduces Beneficent monks at the marriage of Cana; when, in a picture of the crucifixion, he puts the Roman soldiers in the jerkins of the 16th century, and adorns their heads with turbans; when Guido, in a painting of Jesus appearing to his mother after his resurrection, places St Charles Borromeo in a kind of desk in the back-ground as witness to the interview; when Tintoret, at the miraculous fall of manna, arms the Israelites with fuls; and Corregio appoints St Jerome as the instructor of the child Jesus—common sense revolts at the impropriety; and we are compelled to exclaim, Lyceum offendet mihi sic, incredulius odi!

The mythological taste of the learned Poufbin is well known; but Rubens seems to claim the merit of costume, having presented to the world a still greater number of supreme absurdities in this learned style: nor is it easy to conceive a more heterogeneous mixture of circumstances, real and imaginary, sacred and profane, than the Luxembourg gallery, and the other works of that great master, perpetually exhibit.

When fo high an authority as Sir Joshua Reynolds contends for the rejection of common senfe in favour of a somewhat he terms a higher senfe; when he laments, p. 16, indirectly, that art is not in such high estimation with us, as to induce the generals, lawyers, and kings of modern times, to suffer themselves to be represented naked, as in the days of ancient Greece; when he defends even the ridiculous aberrations from possibility, which the extravagant pencil of Rubens has so plentifully produced—it is not surprising that the artists of the present day should be led to reject the company of common sensé; or that Sir Joshua's performances should furnish examples of his own precepts.

Mrs Siddons is represented by Sir Joshua in the character (as it is said) of the tragic muse: She is placed in an old-fashioned arm chair; this arm chair is supported by clouds, suspended in the air; on each side of her head is a figure not unapt to suggest the idea of the attendant imp of an enchantress: of these figures, one is supposed to represent Comedy, and the other Tragedy; Mrs Siddon's herself is decently attired in the fashionable habiliments of 20 or 30 years ago.

If this be a picture of the tragic muse, she ought not to appear in a modern dress, nor ought the to be seated in an old arm chair. If this be a portraiture of Mrs Siddon's, she has no business in the clouds, nor has she any thing to do with aerial attendants. If this be Mrs Siddon's in the character of the tragic muse, the first set of objections apply; for she is placed in a situation where Mrs Siddon could never be.

In the death of Dido, Sir Joshua Reynolds introduces her sister, lamenting over the corpse of the unfortunate queen. This is possible; but he has also introduced Atropos cutting Dido's hair with a pair of scissors, a being equally real and apparent in the painting with Dido or her sister. This (continues our author) appears to me a gross offence against mythological probability; nor is it the only offence against the costume with which that picture is chargeable.

There is one other breach of the costume, however common among painters, more gross and offensive than any of the instances hitherto alleged; we mean the peptic and unnecessary display of the naked figure. We shall not flay to inquire whether more skill can be shown in painting the human body clothed or unclad. If the personages introduced in any picture are more naked in the representation than can be justified by the probability of the times, persons, places, or circumstances, it is a breach of the costume proportionate to the deviation. This fault, however, is so common as hardly to be noticed; so slight indeed, when compared with that general taste for voluptuous imagery and obscene representation, which has so long disgraced the art of painting in every flag of its progress, that science and morality are culpable to the slightest offence.

This depravity of imagination, this prostitution of the pencil to the base purposes of lascivious inclination, was a subject of much complaint among the ancients.
Part I.

Nor is there less reason to complain in modern times, that this delightful art, which might be employed in exciting the noblest sentiments, and become subfervent to the best interests of society, should so often be exercised upon subjects solely calculated to please the eye of the voluptuary and debauche. It is hardly possible to pass through any admired collection without meeting with some of these; of which, however excellent the performance may be, the common feelings of decency and morality (if we are neither professed artists nor connoisseurs) prevent us from viewing them without a mixture of disgust."

*Abbe de Marly.*

It is impossible to express how much a picture suffers by such licences of fancy, and sinks as a bastard of the art in the esteem of good judges. Some people, indeed, are of opinion, that to sculp to an absurdity an observance of the costume is apt to hurt pictures, by depriving them of some air of truth, arising, they think, from those features and habits to which we are accustomed; and which are therefore apt to make a greater impression, than can be expected from things drawn from the remote sources of antiquity; adding withal, that a certain degree of licence has ever been allowed those artists who in their works must make fancy their chief guide. See, say they, the Greeks; that is, the masters of Raphael and Poussin themselves. Do they ever trouble their heads about such niceties? The Rhodian statues, for example, have not sculp to represent Laocoon naked; that is, the priest of Apollo in the very act of sacrificing to the gods, and that in presence of a whole people, of the virgins and matrons of Ilium. Now, continue they, if it was allowable in the ancient statues to neglect probability and decency to such a degree, to have a better opportunity of displaying their skill in the anatomy of the human body; why may it not be allowable in modern painters, the better to attain the end of their art, which is deception, to depart now and then a little from the ancient maxims, and the too rigorous laws of the costume? But these reasons, we beg leave to observe, are more absurd than they are ingenious. What are we to draw conclusions from an example, which, far from deciding the dispute, gives occasion to another? The learned are of opinion, that those Rhodian masters would have done much better had they looked out for a subject in which, without offending so much against truth, and even probability, they might have had an equal opportunity of displaying their knowledge of the naked. And certainly no authority or example whatsoever should tempt us to do any thing contrary to what both decency and the reason of things require, unless we intend, like Carpioni, to represent

*Sogni d'infermi, è stile di romanzi.*

The dreams of sick men, and the tales of fools.

No: a painter, the better to attain the end of his art, which is deception, ought carefully to avoid mixing the antique with the modern, the domestic with the foreign; things, in short, repugnant to each other, and therefore incapable of gaining credit. A spectator will never be brought to consider himself as actually present at the scene, the representation of which he has before him, unless the circumstances which enter it perfectly agree among themselves, and the field of action, if we may use the expression, in no shape belies the action itself. For instance, the circumstances, or, if you please, the accessories, in a Finding of Moses, are not, surely, to represent the borders of a canal planted with rows of poppies, and covered with country-boules in the European taste; but the banks of a great river shaded with clusters of palm trees, with a Sphinx or an Anubis in the adjacent fields, and here and there in the background a towering pyramid. And indeed the painter, before he takes either canvas or paper in hand, should paint the wings of fancy, transport himself to Egypt, to Thebes, or to Rome; and summoning to his imagination the physiognomy, the dress, the plants, the buildings, suitable to his subject, with the particular spot where he has chosen to lay his scene, so manage his pencil, as, by the magic of it, to make the enraptured spectators fancy themselves there along with him.

Sect. XIII. Of Proper Books for a Painter.

From what has been already said, it may be easily gathered, that a painter should be neither illiterate nor unprovided with books. Many are apt to imagine, that the Iconologia of Ripa, or some such collection, is alone sufficient for this purpose, and that all the apparatus he stands in need of, may be reduced to a few calls of the remains of antiquity, or rather to what Rembrandt used to call his antiques, being nothing more than coats of mail, turbans, shreds of stuff, and all manner of old household trumpery and wearing apparel. Such things, no doubt, are necessary to a painter, and perhaps enough for one who wants only to paint half-lengths, or is willing to confine himself to a few low subjects. But they are by no means sufficient for him who would soar higher; for a painter who would attempt the Universe, and represent it in all its parts, such as it would appear, had not matter proved reddy to the intentions of the sovereign artist. Such a painter alone is a true, an universal, a perfect painter.——No mortal, indeed, must ever expect to rise to that sublimity; yet all should aspire to it, on the pain of otherwise ever continuing at a very mortifying distance from it, as the orator, who wishes to make a figure in his profession, should propose to himself no less a pattern than that perfect orator described by Tully; nor the courtier, than that perfect courtier delineated by Castiglione. It cannot, therefore, appear surprising, if we insist on the propriety of reckoning a good collection of books as part of such a painter's implements. The Bible, the Greek and Roman historians, the works of Homer, that prince of poet, and of Virgil, are the most classical. To these let him add the Metamorphoses of Ovid, some of our best poets, the voyage of Pausanias, Vinci, Vafari, and others, upon painting.

It will also be of considerable advantage to him to have a well chosen collection of drawings by the best masters (d), in order to trace the progress and history

(d) We have formerly (see History of Anatomy), mentioned a great anatomical work carrying on by Andrew
of his art, and make himself acquainted with the various
styles of painting which have been, and now are, in the
greatest vogue. The prince of the Roman school was
not averse to hang up in his study the drawings of Al-
bert Dürer; and spared no pains or expense to acquire
all the drawings he could meet with that were taken
from engravings made by him; things which the art of engraving
has since rendered so common as to be in every one's
hands. This art of multiplying drawings by means of
the graver, is of the same date, and boasts the same ad-
vantages, with the art of painting, by means of which
the works of the mind are multiplied, as it were, at one
stroke, and diffused over the whole world.

The sight of fine subjects treated by able masters, and
the different forms which the same subjects assume in dif-
f erent hands, cannot fail both of enlightening and in-
flaming the mind of the young painter. The fame may
be said to be the perusal of good poets and historians, with
the particulars and proofs of what they advance; not to
mention those ideas and flights of invention, with which
the former are wont to clothe, beautify, and exalt every
thing they take in hand. Bouchardon, after reading
Homer, conceived, to use his own words, that men were
three times taller than before, and that the world was
enlarged in every respect. It is very probable, that the
beautiful thought of covering Agamemnon’s face with the
skirt of his mantle at the sacrifice of Iphigenia, was
suggested to Timantes by the tragedy of Euripides.
And the sublime conceit of Raphael, who, in a Creation
of his, represents God in the immensities of the space, with one
hand reaching to the sun and the other to the moon,
may be considered as the child of the following words of
the Psalmist: The heavens declare the glory of God, and
the firmament shineth with his handy work.

This thought of Raphael has been, indeed, confounded
by Mr Webb. “A God (says this gentleman), extending
one hand to the sun, and another to the moon, de-
f roys the idea of immensity which should accompany
the work of creation, by reducing it to a world of a few
inches.” But the opinion of Count Algarotti is very
different. “For my part, (says that elegant critic, I
cannot discover in this painting a world of a few inches,
but a world on a much greater scale; a world of mil-
ions and millions of miles; and yet this so immense a
world, by means of that act of the Godhead, in which
with one hand he reaches to the sun, and with the other
to the moon, shuns, in my imagination, to a mere
nothing, in respect to the immensity of God himself;
which is all that the powers of painting can pretend to.

This invention is, though in a contrary sense, of the
same kind with that of Timantes, who, to express the
enormous size of a sleeping Polyphemus, placed round
him some satyrs measuring the monster’s thumb with a
thyrsus. Hence Pliny, who relates the fact, takes oc-
casion to tell us, that his works always imply more than
they express; and that bow greater foever he may be in
execution, he is still greater in invention: 
Atque in omnibus ejus operibus intelligitur plus semper quam pingitur;

et cum artis summis filius, ingenium tamen ultra artem ostendit.”

The perusal of good authors cannot but be very fa-

corable to a painter in another respect; as, among
the greatest number of subjects afforded by history and poetry,
he may expect to meet with many on which his talents
may display themselves to the greatest advantage. A
painter can never be too nice in the choice of his argu-
ments; for on the beauty of them that of his piece will
greatly depend. How much to be pitied, therefore,
were our first masters, in being so often obliged to re-
ceive their subjects from the hands of simple and illite-
rate persons! and what is worse, to spend all the riches
of their art upon barren or unworthy subjects! Such are
the representations of those faints, who, though they
never had the least intercourse with each other, and
perhaps even lived in different ages, are, notwithstanding to
be introduced, tete à tete, as it were, into the fame picture.
The mechanic of the art may, indeed, display itself on
those occasions: but by no means the ideal. The dis-
position may be good and praiseworthy, as in the works
of Cortoni and Lanfranc; but we are not to expect in
them either invention or expression, which require for
their basis the representation of some fact capable of pro-
ducing such effects. Who does not, on the bare men-
tion of this abuse, immediately reflect upon the many fading
ances of it? Such as the famous St Cecilia of Raphael,
surrounded by St Paul, St Mary Magdalen, St John,
and St Augustin; and the picture of Paolo Veronese,
in the vestry of the Nuns of St Zachary at Venice, in
which St Francis of Assisium, St Catharine, and St
Jerome richly habited in his cardinal’s robes, form a
ring round the Virgin seated on a throne with the child
Jesus in her arms; perhaps the most beautiful and pic-
turesque of all the infidel and insignificant pieces with
which Italy abounds. It is very shocking to think, that
young painters should be obliged to study their art from
such wretched compositions.

The subjects in which the pencil triumphs most, and
with which a judicious painter may flock himself by the
perusal of good books, are, no doubt, those which are
most universally known, which afford the largest field
for a display of the passions, and contain the greatest va-

diety of incidents, all concurring, in the same point of
time, to form one principal action. Of this the story of
Coriolanus besieging Rome, as related by Livy, is a
shining example. Nothing can be imagined more beau-
tiful than the scene of action itself, which ought to take
in the prætorium in the camp of the Volscians, the Ti-
ber behind it, and the seven hills, among which the
towering Capitol is, as it were, to lord it over the rest.
It is impossible to conceive a greater variety, than what
must appear in that crowd of soldiers, women, and chil-
dren, all which are to enter the composition; unless
perhaps, it be that of the different passions with which
they are severally agitated; some with delighting that Corio-
lanus may raise the siege, others fearing it, others again su-
fpeeting it. But the principal group forms the picturesque
part

Andrew Bell, Esq. in Edinburgh, of the figures of which, as they are engraved under the inspection of so able
an anatomist as Mr Fyfe, and with the approbation of Dr Monro, we may at least form a favourable opinion;
and if well executed, of which there can be but little doubt, they will unquestionably be of essentail service to
the painter.
part of the piece. Coriolanus, hastily descending from his tribunal, and hurried on by filial affection, to embrace his mother, flaps short through flame, on her crying out to him, Hold me first know, if it is a son, or an enemy, I am going to embrace? Thus a painter may impart novelty to the most hackneyed subject, by taking for his guides those authors who possest the happy talent of adding grace and dignity, by their beautiful and sublime descriptions, even to the most common and trifling transfections.

Sect. XIV Of the Painter's Balance.

The celebrated De Piles, who by his writings has thrown so much light upon painting, in order to assist young painters in forming a right judgment of those masters who hold the first rank in the profession, and to reduce such judgment to the greater precision, thought himself of a picturesque balance, by means of which a painter's merit may be weighed with the greatest exactness. This merit he divides into Composition, Design, Colouring, and Expression; and in each of those branches he has assigned to every painter that share to which he thought him intituled, according as he approached more or less the highest degree of excellence and cunning of perfection; so that, by summing up the numbers which, standing against each master's name, express his share of merit in each of these branches, we have his total merit or value in the art, and may hence gather what rank one painter holds in regard to another. Several objections, it is true, have been started to this method of calculation, by a famous mathematician of our days, who, among other things, inflicts, that it is the product of the above numbers multiplied by each other, and not the sum of them, that gives the merit of the artist. But this is not a place to enter into such niceties, nor indeed would the doing of it be of any service to the art. The only thing worth our notice is, whether the original numbers, standing for the painter's merit in the several branches of his art, are such as he is really intituled to, without suffering ourselves to be baffed by any partiality, as De Piles has been, in favour of the prince of the Flemish school; the consequence of which, strange as it may appear, is, that in his balance Raphael and Rubens exactly turn out of the fame weight.

The idea of the painter's balance is doublets curious, and therefore deferred to be mentioned; but as the merits of the most eminent painters have been already appreciated under the second section of the historical part of our article, to which we refer, it is needless to be more particular here, or to repeat what has been already treated of at sufficient length.

Sect. XV. Practical Observations.

Having thus laid down the principles of the art, and ventured to give the student some directions with regard to his studies, we shall conclude this part of the subject with a few observations relative wholly to practice.

And I. The young painter must be careful not to be led astray by the ambition of composing easily, or attaining what is called a masterly handling of the chalk or the pencil; a pernicious attempt, by which students are excluded from all power of advancing in real excellence. To this attempt, however, young men have not only the frivolous ambition of being thought masterly, inviting them on the one hand, but also their natural flint tempting them on the other. They are terrified at the prospect before them, and of the toil required to obtain exactness; whilst the lives of the most eminent painters furnish us with examples of the most unceasing industry. When they conceived a subject, they first made a variety of sketches; then a finished drawing of the whole; after that a more correct drawing of every separate part, heads, hands, feet, and pieces of drapery; they then painted the picture, and after all retouched it from the life. The pictures thus wrought with such care, now appear like the effects of enchantment, and as if some mighty genius had struck them off at a blow.

But a student is not always advancing because he is employed; he must apply his strength to that part of the art where the real difficulties lie; to that part which distinguishes it as a liberal art, and not by mistaken industry lose his time in that which is merely ornamental. The students, instead of vying with each other who shall have the readiest hand, should be taught to labour who shall have the purest and most correct outline; instead of striving who shall produce the bright, or endeavouring to give the gloss of stuffs so as to make them appear real, let their ambition be directed to contend, who shall diffuse his drapery in the most graceful folds, and give the greatest dignity to the human form.

He who endeavours to copy accurately the figure before him, not only acquires a habit of exactness and precision, but is continually advancing in his knowledge of the human figure; and though he seems to superficial observers to make a flower progress, he will be found at last capable of adding (without running into capricious wildness) that grace and beauty which is necessary to be given to his more finished works, and which cannot be got by the moderns, as it was not acquired by the ancients, but by an attentive and well-directed study of the human form.

2. It is, in the next place, a matter of great importance, that the drawings on which the young artist first exercises his talents be of the most excellent kind. Let the profiles, the hands, and the feet given him to copy, be of the best masters, so as to bring his eye and his hand early acquainted with the most elegant forms and the most beautiful proportions. A painter who has early acquired a fine taste, finds it an easy matter to give dignity to the meaneast features, while even the works of a Praxiteles or a Glycon are seen to suffer in the hands of another. A vessel will ever retain the scent which it has first contracted.

3. It would be proper also to make the pupil copy some fine heads from the Greek and Roman medals; not so much for the reason just laid down, as to make him acquainted, if we may use the expression, with those personages which in time he may have occasion to introduce into his pieces, and, above all, to improve him early in the arts of copying from relief. Hence he will learn the rationale of light and shade, and the nature of that chiaro scuro by which it is, properly speaking, that the various forms of things are distinguished.

There is no danger of studying too much the works of
of the greatest masters, either in painting or sculpture; but how they may be studied to advantage is an inquiry of great importance. Some (says Sir Joshua Reynolds), who have never raised their minds to the consideration of the real dignity of the art, and who rate the works of an artist in proportion as they excel or are defective in the mechanical parts, look on theory as something that may enable them to talk, but not to paint better; and, confining themselves entirely to mechanical practice, very audibly toil in the drudgery of copying, and think they make a rapid progress, while they faithfully exhibit the minutest part of a favourite picture. This appears to me a very tedious, and, I think, a very erroneous method of proceeding. Of every large composition, even of those which are most admired, a great part may be truly said to be common place. This, though it takes up much time in copying, conduces little to improvement. I consider general copying as a delusive kind of industry: the student satisfies himself with the appearance of doing something; he falls into the dangerous habit of imitating without selection, and of labouring without any determinate object: as it requires no effort of the mind, he sleeps over his work; and those powers of invention and composition which ought particularly to be called out, and put in action, lie torpid, and lose their energy for want of exercise.

However, as the practice of copying is not entirely to be excluded, since the mechanical practice of painting is learned in some measure by it, let those choice parts only be selected which have recommended the work to notice. If its excellence confits in its general effect, it will be proper to make slight sketches of the machinery and general management of the picture. Those sketches should be kept always by you, for the regulation of your style. Instead of copying the touches of those great masters, copy only their conceptions. Instead of treading in their footsteps, endeavour only to keep the same road. Labour to invent on their general principles and way of thinking. Possess yourself with their spirit. Consider with yourself how a Michael Angelo or a Raphael would have treated this subject, and work yourself into a belief that your picture is to be seen and criticized by them when completed. Even an attempt of this kind will route your powers.

PART II. Of the Different Classes of Painting.

SECT. I. General Enumeration.

As all the objects in nature are susceptible of imitation by the pencil, the masters of this art have applied themselves to different subjects, each as his talents, his taste, or inclination may have led him.—From whence have arisen the following classes.

I. History painting; which represents the principal events in history sacred and profane, real or fabulous; and to this class belongs allegorical expression. These are the most sublime productions of the art; and in which Raphael, Guido, Rubens, Le Brun, &c. have excelled.

II. Rural history; or the representation of a country life, of villages and hamlets, and their inhabitants. This is an inferior class; and in which Teniers, Breughel, Watteau, &c. have great reputation, by rendering it at once pleasing and graceful.

III. Portrait painting; which is an admirable branch of this art, and has engaged the attention of the greatest masters in all ages, as Apelles, Guido, Vasdyke, Rembrandt, Reguens, Peine, Kneller, La Tour, &c.

IV. Grotesque histories; as the nocturnal meetings of witches, sorceries and incantations; the operations of mountebanks, &c. a sort of painting in which the younger Breughel, Teniers, and others, have exercised their talents with success.

V. Battle
PAINTING.

V. Battle pieces; by which Huchtenberg, Wouvermanns, &c. have rendered themselves famous.

VI. Landscapes; a charming species of painting, that has been treated by masters of the greatest genius in every nation.

VII. Landscapes diversified with waters, as rivers, lakes, cataracts, &c.; which require a peculiar talent, to express the water sometimes smooth and transparent, and at others foaming and rushing furiously along.

VIII. Sea pieces; in which are represented the ocean, harbours, and great rivers; and the vessels, boats, barges, &c. with which they are covered; sometimes in a calm, sometimes with a fresh breeze, and at others in a storm. In this class Backhuysen, Vanderwelde, Blome, and many others, have acquired great reputation.

IX. Night pieces; which represent all sorts of objects, either as illuminated by torches, by the flames of a conflagration, or by the light of the moon. Schalk, Vanderweerck, Vanderpool, &c. have here excelled.

X. Living Animals: A more difficult branch of painting than is commonly imagined; and in which Rosa, Carre, Vanderwelde, and many others, have succeeded marvellously well.

XI. Birds of all kinds; a very laborious species, and which requires extreme patience minutely to express the infinite variety and delicacy of their plumage.

XII. Culinary pieces; which represent all sorts of provisions, and animals without life, &c. A species much inferior to the rest, in which nature never appears to advantage, and which requires only a faint imitation of objects that are but little pleasing. The painting of fishes is naturally referred to this class.

XIII. Fruit pieces; of every kind, imitated from nature.

XIV. Flower pieces; a charming class of painting, where Art in the hands of Huyzum, P. Segers, Merian, &c. becomes the rival of Nature. Plants and insects are usually referred to the painters of flowers, who with them ornament their works.

XV. Pieces of architecture; a kind of painting in which the Italians excel all others. Under this class may be included the representations of ruins, seaports, streets, and public places; such are seen in the works of Canclotti, and other able masters.

XVI. Instruments of music, pieces of furniture, and other inanimate objects; a trifling species, and in which able painters only accidentally employ their talents.

XVII. Imitations of bas-reliefs; a very pleasing kind of painting, and which may be carried by an able hand to a high degree of excellence.

XVIII. Hunting pieces; these also require a peculiar talent, as they unite the painting of men, horses, dogs, and game, to that of landscapes.

It will not be expected that we should here give the rules that the painter is to observe in handling each particular subject. What has been said on historical painting (Part I. *) may throw some light on the rell, and the particular rules must be learned from the study of the art itself. Good masters, academies of reputation, and a rational practice, are the sources from whence the young painter must derive the detail of his art. We shall however infer some rules and observations relative to Landscape and Portrait; these, with History painting (already pretty fully treated), forming the principal branches of the art.

Sect. II. Of Landscape.

LANDSCAPE painting includes every object that the country presents: and it is distinguished into the heroic, and the pastoral or rural; of which indeed all other styles are but mixtures.

The heroic style is a composition of objects, which in De Piles on their kinds draw both from art and nature every thing that is great and extraordinary in either. The situations are perfectly agreeable and surprising. The only buildings are temples, pyramids, ancient places of burial, altars consecrated to the divinities, pleasure houses of regular architecture; and if nature appear not there as we every day casually see her, she is at least represented as we think she ought to be. This style is an agreeable illusion, and a sort of enchantment, when handled by a man of fine genius and a good understanding, as Pouffin was, who has so happily expressed it. But if, in the course of this style, the painter has not talent enough to maintain the sublime, he is often in danger of falling into the childish manner.

The rural style is a representation of countries, rather abandoned to the caprice of nature, than cultivated: we there see nature simple, without ornament, and without artifice; but with all those graces wherewith she adorns herself much more when left to herself than when constrained by art.

In this style, situations bear all sorts of varieties: sometimes they are very extensive and open, to contain the flocks of the shepherds; at others very wild, for the retreat of solitary persons, and a cover for wild beasts.

It rarely happens that a painter has a genius extensive enough to embrace all the parts of painting: there is commonly some one part that pre-engages our choice, and so fills our mind, that we forget the pains that are due to the other parts; and we seldom fail to see, that those whose inclination leads them to the heroic style, think they have done all, when they have introduced into their compositions such noble objects as will raise the imagination, without ever giving themselves the trouble to study the effects of good colouring. Those, on the other hand, who practice the pastoral, apply closely to colouring, in order to represent truth more lively. Both these styles have their favours and partisans. Those who follow the heroic, supply by their imagination what it wants of truth, and they look no farther.

As a counterbalance to heroic landscape, it would be proper to put into the pastoral, besides a great character of truth, some affecting, extraordinary, but probable effect of nature, as was Titian's custom.

There is an infinity of pieces wherein both these styles happily meet; and which of the two has the ascendant, will appear from what we have been just observing of their respective properties. The chief parts of landscapes are, their openings or situations, accidents, skies and clouds, offskips and mountains, verdure or turfing, rocks, grounds, or lands, terraces, fabrics, waters, fore-grounds, plants, figures, and trees; of all which in their places.

*In the sections of invention and disposition.
PAINTING.

Part II.

Of Openings or Situations. The word *fine*, or situation, signifies the "view, prospect, or opening of a country." It is derived from the Italian word *fine*; and our painters have brought it into use, either because they were used to it in Italy, or because, as we think, they found it to be very expressive.

Situations ought to be well put together; and so diffused in their make, that the conjunction of grounds may not seem to be obstructed, though we should see but a part of them.

Situations are various, and represented according to the country the painter is thinking of: as either open or close, mountainous or watery, tilled and inhabited, or wild and lonely; or, in fine, variegated by a prudent mixture of some of these. But if the painter be obliged to imitate nature in a flat and regular country, he must make it agreeable by a good disposition of the *claro-obfuro*, and such pleasing colouring as may make one foil unite with another.

It is certain that extraordinary situations are very pleasing, and cheer the imagination by the novelty and beauty of their make, even when the local colouring is but moderately performed; because, at worst, such pictures are only looked on as unfinished, and wanting to be completed by some skilful hand in colouring; whereas common situations and objects require good colouring and absolute finishing, in order to please. It was only by these properties that Claude Lorrain has made amends for his infidel choice in most of his situations. But in whatever manner that part be executed, one of the best ways to make it valuable, and even to multiply and vary it without altering its form, is properly to imagine some ingenious accident in it.

Of Accidents. An accident in painting is an obstruction of the sun's light by the interposition of clouds, in such manner, that some parts of the earth shall be in light and others in shade, which, according to the motion of the clouds, succeed each other, and produce such wonderful effects and changes of the *claro-obfuro*, as seem to create so many new situations. This is daily observed in nature. And as this newness of situations is grounded only on the shapes of the clouds, and their motions, which are very inconstant and unequal, it follows, that these accidents are arbitrary; and a painter of genius may dispose them to his own advantage when he thinks fit to use them: For he is not absolutely obliged to do it; and there have been some able landscape painters who have never profited it, either through fear or custom, as Claude Lorrain and some others.

Of the Sky and Clouds. The sky, in painters terms, is the ethereal part over our heads; but more particularly the air in which we breathe, and that where clouds and storms are engendered. Its colour is blue, growing clearer as it approaches the earth, because of the interposition of vapours arising between the eye and the horizon; which, being penetrated by the light, communicates it to objects in a greater or lesser degree, as they are more or less remote.

But we must observe, that this light being either yellow or reddish in the evening, at sunset, these same objects partake not only of the light, but of the colour: thus the yellow light mixing with the blue, which is the natural colour of the sky, alters it, and gives it a tint more or less greenish, as the yellowness of the light is landscape more or less deep.

This observation is general and infallible: but there is an infinity of particular ones, which the painter must make upon the natural, with his pencil in his hand, when occasion offers; for there are very fine and singular effects appearing in the sky, which it is difficult to make one conceive by physical reasons. Who can tell, for example, why we see, in the bright part of some clouds, a fine red, when the source of the light which plays upon them is a most lively and distinguishing yellow? Who can account for the different reds seen in different clouds, at the very moment that these reds receive the light but in one place? for these colours and surprising appearances seem to have no relative to the rainbow, a phenomenon for which the philosopher pretends to give solid reasons.

These effects are all seen in the evening when the weather is inclining to change, either before a storm, or after it, when it is not quite gone, but has left some remains of it to draw our attention.

The property of clouds is to be thin and airy, both in shape and colour: their shapes, though infinite, must be studied and chosen after nature, at such times as they appear fine. To make them look thin, we ought to make their grounds unite thinly with them, especially near their extremities, as if they were transparent: And if we would have them thick, their reflections must be so managed, as, without destroying their thinness, they may seem to wind and unite, if necessary, with the clouds that are next to them. Little clouds often discover a smaller manner, and seldom have a good effect, unless when, being near each other, they seem altogether to make but one object.

In short, the character of the sky is to be luminous; and, as it is even the source of light, every thing that is upon the earth must yield to it in brightness: If, however, there is any thing that comes near it in light, it must be waters, and polished bodies which are susceptible of luminous reflections.

But whilst the painter makes the sky luminous, he must not represent it always thinning throughout.

On the contrary, he must contrive his light so, that the greatest part of it may fall only upon one place: and, to make it more apparent, he must take much care as possible to put it in opposition to some terrestrial object, that may render it more lively by its dark colour; as a tree, tower, or some other building that is a little high.

This principal light might also be heightened by a certain disposition of clouds having a superficial light, or a light ingeniously inclosed between clouds, whose sweet obscurity spreads itself by little and little on all hands.

We have a great many examples of this in the Flemish school, which best understood landscape; as Paul Bril, Brugel, Saveri: And the Sadeiers and Merian's prints give a clear idea of it, and wonderfully awaken the genius of those who have the principles of the *claro-obfuro*.

Of Skiffs and Mountains. Offshifs have a near affinity with the sky; it is the sky which determines either the force or faintness of them. They are darkest when the sky is most loaded, and brightest when it is most clear. They sometimes intermix their shapes and lights;
PAINTING.

lights; and there are times, and countries, where the clouds pass between the mountains, whose tops rise and appear above them. Mountains that are high, and covered with snow, are very proper to produce extraordinary effects in the offskip, which are advantageous to the painter, and pleasing to the spectator.

The disposition of offskips is arbitrary; let them only agree with the whole together of the picture, and the nature of the country we would represent. They are usually blue, because the impression of air between them and the eye: but they lose this colour by degrees, as they come nearer the eye, and so take that which is natural to the objects.

In distancing mountains, we must observe to join them insensibly by the roundings off, which the reflections make probable; and must, among other things, avoid a certain edginess in their extremities, which makes them appear in slices, as if cut with scissors, and stuck upon the cloth.

We must further observe, that the air at the feet of mountains, being charged with vapours, is more susceptible of light than at their tops. In this case we suppose the main light to be set reasonably high, and to enlighten the mountains equally, or that the clouds deprive them of the light of the sun. But if we suppose the main light to be very low, and to strike the mountains, then their tops will be strongly enlightened, as well as every thing else in the same degree of light.

Though the forms of things diminish in bigness, and colours lose their strength, in proportion as they recede from the first plan of the picture, to the most remote offskip, as we observe in nature and common practice; yet this does not occur in the use of the accidents. They contribute greatly to the wonderful in landscape, when they are properly introduced, and when the artist has a just idea of their good effects.

Of Verdure, or Turfing. By turfing is meant the greenness with which the herbs colour the ground: This is done several ways; and the diversity proceeds not only from the nature of plants, which, for the most part, have their particular verdures, but also from the change of seasons, and the colour of the earth, when the herbs are but thin sown. By this variety, a painter may choose or unite, in the same tract of land, several sorts of greens intermixed and blended together, which are often of great service to those who know how to use them; because this diversity of greens, as it is often found in nature, gives a character of truth to those parts, where it is properly used. There is a wonderful example of this part of landscape, in the view of Mechlin, by Rubens.

Of Rocks. Though rocks have all sorts of shapes, and participate of all colours, yet there are in their diversity certain characters which cannot be well expressed without having recourse to nature. Some are in banks, and set off with beds of shrubs; others in huge blocks, either projecting or falling back; others consist of large broken parts, contiguous to each other; and others, in short, of an enormous size, all in one stone, either naturally, as free-stone, or else through the injuries of time, which in the course of many ages has worn away their marks of separation. But, whatever their form be, they are usually set out with cliffs, breaks, hollows, bushes, moss, and the stains of time; and these particulars, well managed, create a certain idea of truth.

Rocks are of themselves gloomy, and only proper for solitudes; but when accompanied with trees, they inspire a fresh air; and when they have waters, either proceeding from, or washing them, they give an infinite pleasure, and seem to have a soul which animates them, and makes them sociable.

Of Grounds or Lands. A ground or land, in painters terms, is a certain distinct piece of land, which is neither too woody nor hilly. Grounds contribute, more than any thing, to the gradation and distancing of landscape; because they follow one another, either in shape, or in the claro-obscur, or in their variety of colouring, or by some insensible conjunction of one with another.

Multiplicity of grounds, though it be often contrary to grand manner, does not quite destroy it; for besides the extent of country which it exhibits, it is susceptible of the accidents we have mentioned, and which, with good management, have a fine effect.

There is one nicety to be observed in grounds, which is, that in order to characterize them well, care must be taken, that the trees in them have a different verdure and different colours from those grounds; though this difference, withal, must not be too apparent.

Of Terraces. A terrace, in painting, is a piece of ground, either quite naked or having very little herbage, like great roads and places often frequented. They are of use chiefly in the foregrounds of a picture, where they ought to be very spacious and open, and accompanied, if we think fit, with some accidental verdure, and also with some stones, which, if placed with judgement, give a terrace a greater air of probability.

Of Buildings. Painters mean by building any structure they generally represent, but chiefly such as are of a regular architecture, or least are most conspicuous. Thus building is not so proper a name for the houses of country-people, or the cottages of shepherds, which are introduced into the rustic taste, as for regular and showy edifices, which are always brought into the heroic.

Buildings in general are a great ornament in landscapes, even when they are Gothic, or appear partly inhabited and partly ruinous: they raise the imagination by the use they are thought to be designed for; as appears from ancient towers, which seem to have been the habitations of fairies, and are now retreats for shepherds and owls.

Poussin has very elegantly handled the Roman manner of architecture in his works, as Bourdon has done the Gothic; which, however Gothic, fails not to give a sublime air to his landscapes. Little Bernard has introduced into his sacred history what may be called a Babylonian manner; which, extraordinary as it is, has its grandeur and magnificence. Nor ought such pieces of architecture to be quite rejected: they raise the imagination; and perhaps would succeed in the heroic style, if they were placed among half-distant objects, and if we knew how to use them properly.

Of Waters. Much of the spirit of landscape is owing to the waters which are introduced in it. They appear in divers manners; sometimes impetuous, as when a storm makes them overflow their banks; at other times rebounding, as by the fall of a rock; at other times, through unusual pressure, gushing out and dividing into an infinity of silver streams, whose motion and murmuring agreeably deceive both the eye and ear; at other times calm and purling in a sandy bed; at other times so still and standing, as to become a faithful looking-glass, which doubles
PAINTING.

Part II.

Landscapes.

doubles all the objects that are opposite to it; and in this state they have more life than in the most violent agitation. Consult Bordon's works, or at least his prints, on this subject: he is one of those who have treated of waters with the greatest spirit and best genius.

Waters are not proper for every situation: but to express them well, the artist ought to be perfect master of the exactness of watery reflections; because they only make painted water appear as real: for practice alone, without exactness, destroys the effect, and abates the pleasure of the eye. The rule for these reflections is very easy, and therefore the painter is the less pardonable for neglecting it.

But it must be observed, that though water be as a looking-glass, yet it does not faithfully represent objects but when it is still; for if be in any motion, either in a natural course, or by the driving of the wind, its surface becoming uneven, receives on its surges such lights and shades as, mixing with the appearance of the objects, confound both their shapes and colours.

Of the Foreground of a Picture. As it is the part of the foreground to usher the eye into the piece, great care must be taken that the eye meet with good reception; sometimes by the opening of a fine terrace, whose design and workmanship may be equally curious; sometimes by a variety of well distinguished plants, and those sometimes flowered; and at other times, by figures in a lively taste, or other objects, either admirable for their novelty or introduced as by chance.

In a word, the artist cannot too much study his foreground objects, since they attract the eye, impress the first character of truth, and greatly contribute to make the artifice of a picture successful, and to anticipate our esteem for the whole work.

Of Plants. Plants are not always necessary in foregrounds, because, as we have observed, there are several ways of making those grounds agreeable. But if we resolve to draw plants there, we ought to paint them exactly after the life; or at least, among such as we paint practically, there ought to be some more finished than the rest, and whose kinds may be distinguished by the difference of design and colouring, to the end that, by a probable supposition, they may give the others a character of truth. What has been said here of plants may be applied to the branches and barks of trees.

Of Figures. In composing landscape, the artist may have intended to give it a character agreeable to the subject he has chosen, and which his figures ought to represent. He may also, and it commonly happens, have only thought of his figures after finishing his landscape. The truth is, the figures in most landscapes are made rather to accompany than to suit them.

It is true, there are landscapes so disposed and situated, as to require only passing figures; which several good masters, each in his style, have introduced, as Poussin in the heroic, and Fouquier in the rural, with all probability and grace. It is true also, that resting figures have been made to appear inwardly active. And these two different ways of treating figures are not to be blamed, because they act equally, though in a different manner. It is rather inaction that ought to be blamed in figures; for in this condition, which robs them of all connection with the landscape, they appear to be pasted on. But without obstructing the painter's liberty in this respect, undoubtedly the best way to make figures valuable is, to make them so to agree with the character of the landscape, that it may seem to have been made purely for the figures. We would not have them either insipid or indifferent, but to represent some little subject to awaken the spectator's attention, or else to give the picture a name of distinction among the curious.

Great care must be taken to proportion the size of the figures to the bigness of the trees, and other objects of the landscape. If they be too large, the picture will discover a little manner; and if too small, they will have the air of pigmies; which will destroy the worth of them, and make the landscape look enormous. There is, however, a greater inconvenience in making figures too large than too small, because the latter at least gives an air of greatness to all the rest. But as landscape figures are generally small, they must be touched with spirit, and such lively figures as will attract, and yet preserve probability and a general union. The artist must, in fine, remember, that as the figures chiefly give life to a landscape, they must be dispersed as conveniently as possible.

Of Trees. The beauty of trees is perhaps one of the greatest ornaments of landscape; on account of the variety of their kinds, and their freshness, but chiefly their lightness, which makes them seem, as being exposed to the air, to be always in motion.

Though diversity be pleasing in all the objects of landscape, it is chiefly in trees that it shows its greatest beauty. Landscape considers both their kinds and their forms. Their kinds require the painter's particular study and attention, in order to distinguish them from each other; for we must be able at first sight to discover which are oaks, elms, firs, sycamores, poplars, willows, pines, and other such trees, which, by a specific colour, or touching, are distinguishable from all other kinds. This study is too large to be acquired in all its extent; and, indeed, few painters have attained such a competent exactness in it as their art requires. But it is evident, that those who come nearest to perfection in it, will make their works infinitely pleasing, and gain a great name.

Besides the variety which is found in each kind of tree, there is in all trees a general variety. This is observed in the different manners in which their branches are disposed by a sort of nature; which takes delight in making some very vigorous and thick, others more dry and thin; some more green, others more red or yellow. The excellence of practice lies in the mixture of these varieties: but if the artist can distinguish the sorts but indifferently, he ought at least to vary their makes and colours; because repetition in landscape is as tiresome to the eye, as monotony in discourse is to the ear.

The variety of their makes is so great, that the painter would be inexcusable not to put it in practice upon occasion, especially when he finds it necessary to awaken the spectator's attention; for, among trees, we discover the young and the old, the open and close, tapers and squat, bending upwards and downwards, steeping and shooting: in short, the variety is rather to be conceived than expressed. For instance, the character of young trees is, to have long slender branches, few in number, but
but well set out; boughs well divided, and the foliage vigorous and well shaped: whereas, in old trees, the branches are short, stocky, thick, and numerous; the tufts blunt, and the foliage unequal and ill shaped; but a little observation and genius will make us perfectly sensible of these particulars.

In the various makes of trees, there must also be a distribution of branches, that has a just relation to, and probable connection, with the boughs or tufts, so as mutually to assist each other in giving the tree an appearance of thickness and of truth. But whatever their natures or manners of branching be, let it be remembered, that the handling must be lively and thin, in order to preserve the spirit of their characters.

Trees likewise vary in their barks, which are commonly gray; but this gray, which in thick air, and low and marshy places, looks blackish, appears lighter in a clear air: and it often happens, in dry places, that the bark gathers a thin moss, which makes it look quite yellow; so that, to make the bark of a tree apparent, the painter may suppose it to be light upon a dark ground, and dark on a light one.

The observation of the different barks merits a particular attention; for it will appear, that, in hard woods, age shapes them, and thereby gives them a sort of embroidery; and that, in proportion as they grow old, these shapes grow more deep. And other accidents in barks may arise either from moisture, or dryness, or green mosses, or white stains of several trees.

The barks of white woods will also afford much matter for practice, if their diversity be duly studied; and this consideration leads us to say something of the study of landscape.

Of the study of Landscape. The study of landscape may be considered either with respect to beginners, or those who have made some advances in it.

Beginners will find, in practice, that the chief trouble of landscape lies in handling trees; and it is not only in practice, but also in speculation, that trees are the most difficult part of landscape, as they are its greatest ornament. But it is only proposed here, to give beginners an idea of trees in general, and to show them how to express them well. It would be needless to point out to them the common effects of trees and plants, because they are obvious to every one; yet there are some things, which, though not unknown, deserve our reflection. We know, for instance, that all trees require air, and some more, some less, as the chief cause of their vegetation and production; and for this reason, all trees (except the cypress, and some others of the same kind) separate in their growth from one another, and from other strange bodies as much as possible, and their branches and foliage do the same: wherefore, to give them that air and thinness, which is their principal character, the branches, boughs, and foliage, must appear to fly from each other to proceed from opposite parts, and be well divided. And all this without order; as if chance-sided nature in the fanciful diversity. But to say particularly how these trunks, branches, and foliage, ought to be distributed, would be needless, and only a description of the works of great masters: a little reflection on nature will be of more service than all that can be said on this head. By great masters, we mean such as have published prints; for those will give better ideas to young copyists than even the paintings themselves.

Among the many great masters of all schools, De Piles prefers Titian’s wooden prints, where the trees are well shaped; and those which Cornelius Cort and Agostino Caracci have engraved. And he asserts, that beginners can do no better than contract, above all things, an habit of imitating the touches of these great masters; and of considering at the same time the perspective of the branches and foliage, and observing how they appear, either when rising and seen from below, or when sinking and seen from above, or when fronting and viewed from a point, or when they appear in profile; and, in a word, when set in the various views in which nature presents them, without altering their characters.

After having studied and copied with the pen or crayon, first the prints, and then the designs of Titian and Caracci, the student should imitate with the pencil those touches which they have most distinctly specified, if their paintings can be procured; but since they are scarce, others should be got which have a good character for their touching; as those of Fouquier, who is a most excellent model: Paul Bril, Breuigel, and Bourdon, are also very good; their touch is neat, lively, and thin.

After having duly weighed the nature of trees, their spread and order, and the disposition of their branches, the artist must get a lively idea of them, in order to keep up the spirit of them throughout, either by making them apparent and distinct in the fore-grounds, or obscure and confused in proportion to their distance.

After having thus gained some knowledge in good manner, it will next be proper to study after nature, and to choose and rectify it according to the idea which the aforesaid great masters had of it. As to perfection, it can only be expected from long practice and perseverance. On the whole, it is proper for those who have an inclination for landscape, above all things to take the proper methods for beginning it well.

As for those who have made some advances in this part of painting, it is proper they should collect the necessary materials for their further improvement, and study those objects at least which they shall have most frequent occasion to represent.

Painters usually comprise, under the word study, anything whatever which they either design or paint separately after the life; whether figures, heads, feet, hands, draperies, animals, mountains, trees, plants, flowers, fruits, or whatever may confirm them in the just imitation of nature: the drawing of these things is what they call study; whether they be for instruction in design, or only to assure them of the truth, and to perfect their work. In fact, this word study is the more properly used by painters as in the diversity of nature they are daily making new discoveries, and confirming themselves in what they already know.

As the landscape-painters need only study such objects as are to be met with in the country, we would recommend to him some order, that his drawings may be always at hand when he wants them. For instance, he should copy after nature, on separate papers, the different effects of trees in general, and the different effects of each kind in particular, with their trunks, foliage, and colours. He should also take the same method with some sorts of plants, because their variety is a great ornament to terraces on fore-grounds. He ought likewise to study the effects of the sky in the several times of the day.
Painting. Part II.

Landscapes.

and seasons of the year, in the various dispositions of clouds, both in serene, thundering, and stormy weather; the offskip, the several sorts of rocks, waters, and other principal objects.

These drawings, which may be made at different times, should be collected together; and all that relate to one matter be put into a book, to which the artist may have recourse at any time for what he wants.

Now, if the fine effects of nature, whether in shape or colour, whether for an entire picture or a part of one, be the artist's study; and if the difficulty lies in choosing these effects well, he must for this purpose be born with good sense, good taste, and a fine genius; and this genius must be cultivated by the observations which ought to be made on the works of the best masters, how they choose nature, and how, while they corrected her, according to their art, they preserved her character.

With these advantages, derived from nature, and perfected by art, the painter cannot fail to make a good choice; and, by distinguishing between the good and the bad, must needs find great instruction even from the most common things.

To improve themselves in this kind of studies, painters have taken several methods.

There are some artists who have designed after nature, and in the open fields; and have there quite finished those parts which they had chosen, but without adding any colour to them.

Others have drawn, in oil colours, in a middle tint, on strong paper; and found this method convenient, because, the colours sinking, they could put colour on colour, though different from each other. For this purpose they took with them a flat box, which commodiously held their pallet, pencils, oil, and colours. This method, which indeed requires several implements, is doubtless the best for drawing nature more particularly, and with greater exactness, especially if, after the work be dry and varnished, the artist return to the place where he drew, and retouch the principal things after nature.

Others have only drawn the outlines of objects, and slightly washed them in colours near the life, for the ease of their memory. Others have attentively observed such parts as they had a mind to retain, and contained themselves with committing them to their memory, which upon occasion, gave them a faithful account of them. Others have made drawings in pastel and wash together. Others, with more curiosity and patience, have gone several times to the places which were to their taste: the first time they only made choice of the parts, and drew them correctly; and the other times were spent in observing the variety of colouring, and its alterations through change of light.

Now these several methods are very good, and each may be practised as best suits the student and his temper: but they require the necessities of painting, as colours, pencils, pastels, and leisure. Nature, however, at certain times, presents extraordinary but transient beauties, and such as can be of no service to the artist who has not as much time as is necessary to imitate what he admires. The best way, perhaps, to make advantage of such momentary occasions, is this:

The painter being provided with a quire of paper, and a black-lead pencil, let him quickly, but slightly, design what he sees extraordinary; and to remember the colouring, let him mark the principal parts with characters, which he may explain at the bottom of the paper, as far as is necessary for himself to understand them: A cloud, for instance, may be marked A, another cloud B, a light C, a mountain D, a terrace E, and so on. And having repeated these letters at the bottom of the paper, let him write against each that it is of such or such a colour; or, for greater brevity, only blue, red, violet, gray, &c. or any other shorter abbreviartion. After this, he must go to painting as seen as possible; otherwise most of what he has observed will, in a little time, slip out of his memory. This method is the more useful, as it not only prevents us losing an infinity of sudden and transitory beauties, but also helps, by means of the aforesaid marks and characters, to perfect the other methods we have mentioned.

If it be asked, Which is the properest time for these studies? the answer is, That nature should be studied at all times, because she is to be represented at all seasons; but autumn yields the most plentiful harvest for her fine effects: the mildness of that season, the beauty of the sky, the richness of the earth, and the variety of objects, are powerful inducements with the painter to make the proper inquiries for improving his genius and perfecting his art.

But as we cannot see or observe every thing, it is very commendable to make use of other men's studies, and to look upon them as if they were our own. Raphael sent some young men into Greece to design such things as he thought would be of service to him, and accordingly made use of them to as good purpose as if he himself had designed them on the spot: for this, Raphael is so far from deserving censure, that he ought, on the contrary, to be commended; as an example, that painters ought to leave no way untried for improving in their professions. The landscape painter may, accordingly, make use of the works of all those who have excelled in any kind, in order to acquire a good manner; like the bees which gather their variety of honey from different flowers.

General Remarks on Landscapes. As the general rules of painting are the basis of all the several kinds of it, we must refer the landscape painter to them, or rather suppose him to be well acquainted with them. We shall here only make some general remarks on this kind of painting.

I. Landscape supposes the knowledge and practice of the principal rules in perspective, in order to maintain probability.

II. The higher the leaves of trees are to the earth, the larger they are, and the greener; as being aptest to receive, in abundance, the sap which nourishes them; and the upper branches begin first to take the redness or yellowness which colours them in autumn. But it is otherwise in plants; for their stocks renew all the year round, and their leaves succeed one another at a considerable distance of time, insomuch that nature, employed in producing new leaves to adorn the stock as it rises, does by degrees desert the under leaves; which, having first performed their office, are the first that die: but this effect is more visible in some trees than in others.

III. The under parts of all leaves are of a brighter green than the upper, and almost always insensible to the silverish;
Part II.

Painting.

Landscapes.

silverish; and those which are wind-shaken are known from others by that colour: but if we view them from beneath, when penetrated by the sun's rays, they discover such a fine and lively green as is far beyond all comparison.

IV. There are five principal things which give spirit to landscape, viz. figures, animals, waters, wind-shaken trees, and thinness of pencilling; to which add smoke, when there is occasion to introduce it.

V. When one colour predominates throughout a landscape, as one green in spring, or one red in autumn, the piece will look either as of one colour, or else as unfinished. We have seen many of Bourbon's landscapes, which, by handling the corn one way throughout, have lost much of their beauty, though the situations and waters were very pleasant. The ingenious painter must endeavour to correct, and, as they say, redeem, the harsh unsightly colouring of winter and spring by means of figures, waters, and buildings; for summer and autumn subjects are of themselves capable of great variety.

VI. Titian and Carrache are the best models for inspiring good taste, and leading the painter into a good track, with regard to forms and colours. He must use all his efforts, to gain a just idea of the principles which those great men have left us in their works; and to have his imagination filled with them; if he would advance by degrees towards that perfection which the artist should have always in view.

VII. The landscapes of these two masters teach us a great many things, of which discourse can give us no exact idea, nor any general principle. Which way, for example, can the measures of trees in general be determined, as we determine those of the human body? The tree has no settled proportions; most of its beauty lies in the contrast of its branches, an unequal distribution of boughs, and, in short, a kind of whimsical variety which nature delights in, and of which the painter becomes a judge when he has thoroughly relished the works of the two masters aforesaid. But we must say, in Titian's praise, that the path he struck out is the surest; because he has exactly imitated nature in its variety with an exquisite taste, and fine colouring: whereas Carrache, though an able artist, has not, more than others, been free from manner in his landscapes.

VIII. One of the greatest perfections of landscape, in the variety it represents, is a faithful imitation of each particular character: as its greatest fault is a licentious practice, which brings us to do things by rote.

IX. Among those things which are painted practically, we ought to intermix some done after nature, to induce the spectator to believe that all are so.

X. As there are styles of thought, so there are also styles of execution. We have handled the two relating to the cottage, viz. the heroic and pastoral; and find that there are two also with regard to execution, viz. the firm style, and the polished; these two concern the pencil, and the more or less ingenious way of conducting it. The firm style gives life to work, and excuse for bad choice; and the polished finishes and brightness every thing; it leaves no employment for the spectator's imagination, which pleases itself in discovering and finishing things which it ascribes to the artist, though in fact they proceed only from itself. The polished and pencilling style degenerates into the soft and dull, if not supported by a good opening or situation; but when these two characters meet, the picture is fine.

Sect. III. Of Portraiture.

If painting be an imitation of nature, it is doubly so in a portrait; which not only represents a man in general, but such a one as may be distinguished from all others. And as the greatest perfection of a portrait is extreme likeness, so the greatest of its faults is to resemble a person for whom it was not made; since there are not in the world two persons quite like one another. But before we proceed to the particulars which let us into the knowledge of this imitation, it is necessary, for shortening this part of our subject, to attend to some general propositions.

I. Imitation is the essence of painting: and good choice is to this essence what the virtues are to a man; they raise the value of it. For this reason, it is extremely the painter's interest to choose none but good heads, or favourable moments for drawing them, and such positions as may supply the want of a fine natural.

II. There are views of the natural more or less advantageous; all depends upon turning it well, and taking it in the favourable moment.

III. There is not a single person in the world who has not a peculiar character both in body and face.

IV. Simple and genuine nature is more proper for imitation; and is a better choice than nature much formed, and embellished too artificially.

V. To adorn nature too much is doing it a violence; and the action which attends it can never be free when its ornaments are not easy. In short, in proportion as we adorn nature, we make it degenerate from itself, and bring it down to art.

VI. Some means are more advantageous than others to come at the same end.

VII. We must not only imitate what we do see in nature, but also what we may possibly see that is advantageous in art.

VIII. Things are valuable by comparison; and it is only by this we are enabled to make a right judgment of them.

IX. Painters easily accustom themselves to their own tints, and the manner of their masters: and after this habit is rooted in them, they view nature not as she really is, but as they are used to paint her.

X. It is very difficult to make a picture, the figures of which are as big as the life, to have its effects near as at a distance. A learned picture pleases the ignorant only when it is at some distance; but judges will admire its artifice near, and its effect at a distance.

XI. Knowledge makes work pleasant and easy. The traveller who knows his road, comes to his journey's end with more speed and certainty than he who inquires and gropes it out.

XII. It is proper, before we begin a work, to meditate upon it, and to make a nice coloured sketch of it, for our own satisfaction, and a help to the memory.

We cannot too much reflect on these propositions; and
PAINTING. Part II.

Portraits, it is necessary to be well acquainted with them, that they may present themselves to our mind, of their own accord, without our being at the trouble to recall them to our memory when we are at work.

There are four things necessary to make a portrait perfect; air, colouring, attitude, and dress.

Of Air. The air respects the lines of the face, the head attire, and the size.

The lines of the face depend upon exactness of draught, and agreement of the parts; which altogether must represent the physiognomy of the person painted in such a manner, that the picture of his body may seem to be also that of his mind.

It is not exactness of design in portraits that gives spirit and true air, so much as the agreement of the parts at the very moment when the disposition and temperament of the sitter are to be hit off. We see several portraits which, though correctly designed, have a cold, languishing, and stupid air; whilst others, less correct in design, strike us, however, at first sight with the sitter's character.

Few painters have been careful enough to put the parts well together: Sometimes the mouth is smiling, and the eyes are sad; at other times, the eyes are cheerful, and the cheeks lank: by which means their work has a false air, and looks unnatural. We ought therefore to remember, that, when the sitter puts on a smiling air, the eyes close, the corners of the mouth draw up towards the nostrils, the cheeks swell, and the eyebrows widen: but in a melancholy air, these parts have a contrary effect.

The eyebrows, being raised, give a grave and noble air; but if arched, an air of astonishment.

Of all the parts of the face, that which contributes most to likeness is the nose; it is therefore of great moment to set and draw it well.

Though the hair of the head seems to be part of the dress which is capable of various forms without altering the air of the face; yet the head attire which one has been most accustomed to creates such a likeness, that one can know a familiar acquaintance on his putting on a periwig somewhat different from that which he used to wear. It is necessary therefore, as far as possible, to take the air of the head ornament, and make it accompany and set off that of the face, if there be no reason to the contrary.

As to the stature, it contributes so much to likeness, that we very often know people without seeing their face: It is therefore extremely proper to draw the size after the sitter himself, and in such an attitude as we think fit; which was Vandyke's method. Here let us remark, that, in sitting, the person appears to be of a less free make, through the beaving of his shoulders: Wherefore, to adjust his size, it is proper to make him stand for a small time, swaying in the posture we would give him, and then make our observation. But here occurs a difficulty, which we shall endeavour to examine:

"Whether it is proper, in portraiture, to correct the defects of nature?"

Likeness being the essence of portraiture, it would seem that we ought to imitate defects as well as beauties, since by this means the imitation will be more complete: It would be even hard to prove to the contrary to one who would undertake the defence of this position. But ladies and gentlemen do not much approve of those painters who entertain such sentiments, and put colouring to their practice. It is certain that some complaisance in this respect is due to them; and there is little doubt but their pictures may be made to resemble, without displeasing them; for the effectual likeness is a just agreement of the parts that are painted with those of nature; so that we may be at no loss to know the air of the face, and the temper of the person, whose picture is before us. All deformities, therefore, when the air and temper may be discovered without them, ought to be either corrected or omitted in women's and young men's portraits. A nose somewhat awry may be helped, or a shrivelled neck or high shoulders adapted to a good air, without going from one extreme to another. But this must be done with great discretion: for, by endeavouring to correct nature too much, we ineffectually fall into a method of giving a general air to all our portraits; just as, by confining ourselves too much to the defects and littleness of nature, we are in danger of falling into the low and tasteless manner.

But in the faces of heroes and men of rank, distinguished either by dignities, virtues, or great qualities, we cannot be too exact, whether the parts be beautiful or not: for portraits of such persons are to be standing monuments to posterity; in which case, every thing in a picture is precious that is faithful. But after whatever manner the painter acquires himself in this point, let him never forget good air nor grace; and that there are, in the natural, advantageous moments for hitting them off.

Of Colouring. Colouring, in portraiture, is an effusion of nature, discovering the true tempers of persons; and the temper being essential to likeness, it ought to be handled as exactly as the design. This part is the more valuable, as it is rare and difficult to hit. A great many painters have come to a likeness by strokes and outlines; but certainly they are few who have shown in colours the tempers of persons.

Two points are necessary in painting: exactness of tints, and the art of setting them off. The former is acquired by practice, in examining and comparing the colours we see in life with those by which we would imitate it; and the art of those tints consists in knowing what one colour will produce when set by another, and in making good what either distance or time may abate of the glow and freshness of the colours.

A painter who does nothing more than what he sees, will never arrive at a perfect imitation; for though his work may seem, on the easel, to be good to him, it may not appear so to others, and perhaps even to himself, at a distance. A tint which, near, appears disjoined, and of one colour, may look of another at a distance, and be confounded in the mass it belongs to. If you would have your work, therefore, to produce a good effect in the place where it is to hang, both the colours and lights must be a little loaded; but learnedly, and with discretion. In this point consult Titian, Rubens, Vandyke, and Rembrandt's method; for indeed their art is wonderful.

The tints usually require three times of observation. The first is at the person's first sitting down, when he has more spirit and colour than ordinary; and this is to be noted in the first hour of his sitting. The second is when, being composed, his look is as usual; which is to be observed in the second hour. And the third is when,
Attitude when through tiresomeness by sitting in one posture, his colour altern to what weariness usually creates. On which account, it is best to keep to the sitter's usual tint, a little improved. He may also rise, and take some turns about the room, to gain fresh spirits, and shake off or prevent tiresomeness.

In draperies, all sorts of colours do not suit all sorts of persons. In men's portraits, we need only observe great truth and great force: but in women's there must also be charm; whatever beauty they have must appear in a fine light, and their blemishes must by some means or other be softened. For this reason, a white, lively, and bright tint, ought never to be set off by a fine yellow, which would make it look like plaster; but rather by colours inclining to green, blue, or gray, or such others as, by the opposition, they make the tint appear more fleshly than usual in fair women. Vandyke often made ailedmot coloured curtain for his ground; but that colour is soft and brown. Brown women, on the other hand, who have yellow enough in their tints to support the character of fleshliness, may very well have yellowsdraperies, in order to bring down the yellow of their tints, and make them look the fresher; and near very high coloured and lively carnations, linen does wonder.

In grounds, two things are observable; the tone and the colour. The colour is to be considered in the same manner as those of draperies, with respect to the head. The tone must be always different from the mass it supports, and of which it is the ground, that the objects coming upon it may not seem transparent, but solid and raised. The colour of the hair of the head usually determines the tone of the ground; and when the former is a bright chestnut, we are often embarrassed, unless helped by means of a curtain, or some accident of the claro-obscuro supposed to be behind, or unless the ground is a sky.

We must further observe, that where a ground is neither curtain nor landscape, or such like, but is plain and like a wall, it ought to be very much party-coloured, with almost imperceptible patches or stains; for, besides its being so in nature, the picture will look the more grand.

Of Attitude, or Posture.—Attitudes ought to suit the ages, qualities of persons and their tempers. In old men and women, they should be grave, majestic, and sometimes bold: and generally, in women, they ought to have a noble simplicity and modest cheerfulness; for modesty ought to be the character of women; a charm infinitely beyond coquetry! and indeed coquettes themselves are not to be painted such.

Attitudes are of two kinds: one in motion, the other at rest. Those at rest may suit every person; but those in motion are proper for young people only, and are hard to be expressed; because a great part of the hair and drapery must be moved by the air; motion, in painting, being never better expressed than by such agitations. The attitudes at rest must not appear so much at rest as to seem to represent an inactive person, and one who sits for no other purpose but to be a copy. And though the figure that is represented be at rest, yet the painter, if he thinks fit, may give it a flying drapery, provided the scene or ground be not a chamber or close place.

It is above all things necessary that the figures which are not employed should appear to satisfy the spectator's curiosity; and for this purpose show themselves in such an action as suits their tempers and conditions, as if they would inform him what they really were: as most people pretend to sincerity, honesty, and greatness of mind, we must avoid in attitudes, all manner of affectation; every thing there must appear easy and natural, and discover more or less spirit, nobleness, and majesty, in proportion to the person's character and dignity. In a word, the attitudes are the language of portraits; and the skilful painter ought to give great attention to them.

But the best attitudes are such as induce the spectator to think that the sitter took a favourable opportunity of being seen to advantage, and without affectation. There is only one thing to be observed with regard to women's portraits, in whatever attitude they are placed; which is, that they sway in such a manner as to give the face but little shade; and that we carefully examine whether the lady appear most beautiful in a smiling or in a serious air, and conduct ourselves accordingly. Let us now proceed to the next article.

Practice in Portraiture.—According to De Piles, portraiture requires three different sittings and operations; viz. dead colouring, second colouring, and retouching or finishing. Before the painter dead colour, he must attentively consider what aspect will best suit the sitter, by putting him in different positions, if we have not any settled design before us: and when we have determined this, it is of the last consequence to put the parts well together, by comparing always one part with another; for not only the portrait acquires a greater likeness when well designed, but it is troublesome to make alterations at the second sitting, when the artist must only think of painting, that is, of disposing and uniting his colours.

Experience tells us, that the dead colouring ought to be clean, because of the slope and transparency of the colours, especially in the shades: and when the parts are well put together, and become clammy, they must be judiciously sweetened and melted into each other; yet without taking away the air of the picture, that the painter may have the pleasure of finishing it, in proportion as he draws. But if fiery geniuses do not like this method of scumbling, let them only mark the parts slightly, and so far as is necessary for giving an air.

In dead colouring, it is proper to put in rather too little than too much hair about the forehead; that, in finishing, we may be at liberty to place it where we please, and to paint it with all possible softness and delicacy. If, on the contrary, you sketch upon the forehead a lock which may appear to be of a good taste, and becoming the work, you may be puzzled in finishing it, and not find the life exactly in the same position as you would paint it. But this observation is not meant for men of skill and consummate experience, who have nature in their heads, and make her submit to their ideas.

The business of the second sitting is, to put the colours well in their places, and to paint them in a manner that is suitable to the sitter and to the effect we propose. But before they are made clammy, we ought to examine afresh whether the parts are rightly placed, and
PAINTING.

Practice of and here and there to give some touches towards likeness, that, when we are assured of it, the work may go on with greater satisfaction. If the painter understands what he is about, and the portrait be justly designed, he ought as much as possible to work quick; the sitter will be better pleased, and the work will by this means have the more spirit and life. But this readiness is only the effect of long study and experience; for we may well be allowed a considerable time to find out a road that is easy, and such as we must often travel in.

Before we retouch or finish, it is proper to terminate the hair, that, on finishing the carnations, we may be able to judge of the effect of the whole head.

If, at the second sitting, we cannot do all we intended, which often happens, the third makes up the loss, and gives both spirit, physiognomy, and character.

If we would paint a portrait at once, we must load the colouring; but neither sweeten, nor drive, nor very much oil it; and if we dip the pencil in varnish as the work advances, this will readily enable us to put colour on colour, and to mix them without driving.

The use and sight of good pictures give greater light into things than words can express: What hits our artist's understanding and temper may be disagreeable to another's; and almost all painters have taken different ways, though their principles were often the same.

We are told that a friend of Vandyke's having observed to him how little time he bestowed on his portraits, Vandyke answered, "That at first he worked hard, and took great pains, to acquire a reputation, and also to get a swift hand, against the time he should work for his kitchen." Vandyke's custom is said to have been this: He appointed both the day and hour for the person's sitting, and worked not above an hour on any portrait, either in rubbing in or finishing; so that as soon as his clock informed him that the hour was out, he rose up, and made a bow to the sitter, to signify, that he had done enough for that day, and then appointed another hour some other day; whereupon his servant came to clean his pencils, and brought a fresh pallet, whilst he was receiving another sitter, whose day and hour he had before appointed. By this method he worked on several pictures the same day, with extraordinary expedition.

After having lightly dead-coloured the face, he put the sitter into some attitude which he had before contrived; and on a gray paper, with white and black crayons, he designed, in a quarter of an hour, his shape and drapery, which he disposed in a grand manner, and an exquisite taste. After this, he gave the drawing to the skilful people he had about him, to paint after the sitter's own clothes, which, at Vandyke's request, were sent to him for that purpose. When his disciples had done what they could to these draperies, he lightly went over them again; and so, in a little time, by his great knowledge, displayed the art and truth which we at this day admire in them. As for hands, he had in his house people of both sexes, whom he paid, and who served as models.

This conduct of Vandyke, however, is mentioned rather to gratify the reader's curiosity than to ex-judge his imitation; he may choose as much of it as he pleases, and as suits his own genius, and leave the rest.

We must observe by the way, that there is nothing so rare as fine hands, either in the design or colouring. It is therefore convenient to cultivate, if we can, a friendship with some woman who will take pleasure in serving for a copy: The way to win them is, to praise their beauty exceedingly. But if an opportunity serves of copying hands after Vandyke, it must not be let slip; for he drew them with a surprising delicacy, and admirable colouring.

It is of great service to copy after the manners which come nearest to nature; as are those of Titian and Vandyke. We must, at such times, believe them to be nature itself; and, at some distance, consider them as such, and say to ourselves—What colour and tint shall I use for such a part? And then, coming near the picture, we ought to examine whether we are right or not; and to make a fixed rule of what we have discovered, and did not practise before without uncertainty.

It is recommended, before we begin colouring, to catch the very first moments, which are commonly the most agreeable and most advantageous, and to keep them in our memory for use when we are finishing: for the sitter, growing tired with being long in the same place, loses those spirits, which, at his first sitting down, gave beauty to the parts, and conveyed to the tint more lively blood, and a fresher colour. In short we must join to truth a probable and advantageous possibility, which, far from abating likeness, serves rather to set it off. For this end, we ought to begin with observing the ground of a tint, as well what it is in lights as in shades; for the shades are only beautiful as they are proportioned to the light. We must observe, if the tint be very lively, whether it partake of yellowness, and where that yellowness is placed; because usually, towards the end of the sitting, fatigue diffuses a general yellowness, which makes us forget what parts were of this colour, and what were not, unless we had taken due notice of it before. For this reason, at the second sitting, the colours must be everywhere readily clapped in, and such as appear at the first sitting down; for these are always the finest.

The surest way to judge of colours is by comparison; and to know a tint, nothing is better than to compare it with linen placed next it, or else placed next to the natural object, if there be occasion. We say this only to those who have little practised nature.

The portrait being now supposed to be as much finished as you are able, nothing remains, but, at some reasonable distance, to view both the picture and sitter together, in order to determine with certainty, whether there is any thing still wanting to perfect the work.

SECT. IV. Of Theatrical Decorations; the Designs for Furniture, Embroidery, Carriages, &c.

Or Theatrical Decorations.—This is a particular art, which unites several of the general parts of painting with the knowledge of architecture, perspective, &c. They
PAINTING.

of China and Europe, on Delft ware, &c. are so many sorts of enamel.

8. Painting in wax, or encaustic painting: This is a new, or rather an old invention renewed, in which there are in France performances highly pleasing. It is done with wax mixed with varnish and colours.

9. Painting on glass; of which there are various kinds.

See all the articles here enumerated, explained in the order of the alphabet. On one of them, however, some additional observations may here be subjoined.

§ 1. Of Painting in Fresco.

Of all kinds of painting, fresco is the most ancient, the most durable, the most speedily executed, and the most proper to adorn great buildings. It appears, that the fragments of ancient painting handed down to us by the Romans are all in fresco. Norden, quoted by Winkelman, speaks of the ruins of Egyptian palaces and temples, in which are colossal paintings on walls 80 feet high. The description which those authors have given of these paintings, of the prepared ground, and of the manner in which the colours have been employed, &c. shows plainly that they have been executed in fresco.

The stability of fresco is demonstrated by the existence of those fragments of the highest antiquity. There are other kinds of paintings which could equally have resisted the injuries of the weather, the excessive aridity of certain climates, the moisture of subterraneous situations, and the encroachments of barbarians.

There are different opinions concerning the climate most proper to preserve this kind of painting. “It is observed (says Felibien), that the colours in fresco fade sooner in Italy and Languedoc than at Paris; perhaps from less heat in the last-mentioned place, or better lime.” M. Falconet contradicts this assertion in his notes on Pliny, vol. i. p. 223. of his miscellaneous works, published at Paris 1787. Painting in fresco, according to this author, is longer preserved in dry and warm, than in northern and moist climates. However opposite the sentiments of these two authors may appear to be, it is possible to reconcile them, when we consider, that the exposure to a burning sun is capable of operating a great change of the colours on the one hand, and that the frost in a cold climate inevitably destroys the paintings of fresco on the other. Frost is capable of bursting stones, of corroding the petrified veins of earth in the heart of coloured marble, and, in short, nothing can resist its destructive operation.

These observations on fresco paintings lead us to conclude, that the choice of place, when they are without doors, is of the greatest importance. In countries where there is little or no frost, an exposure to the north is the most favourable; and in cold climates a western exposure should be made choice of, because the first rays of the rising sun have a very pernicious effect after frost. We are not, however, wholly to adopt the sentiment of M. Falconet with regard to the pernicious effects of moisture on fresco paintings: for, 1. The ancient paintings recovered from moist places, in which they were buried for many ages, have, under enormous heaps of earth, preserved all their colours. Those from the ruins of Herculaneum have been ob.
served, on the contrary, to lose their colours in a short
time after they have been dried by the exterior air.
2. The mortar which composes the ground of this
painting is not destroyed in our rainy climates. It is
necessary frequently to use powder in removing pieces
of this mortar, which are now found to obstruct some
buildings in Paris.

After the choice of place, the choice of materials is
the next thing of importance in executing fresco. To
make it durable, the ground is the object of chief atten-
tion; and to make it perfect, the mortar used by the
ancients, now unknown, would be necessary.

It is easy to perceive, that a minute detail of forms,
an extensive mixture and gradation of tints, and the
merit of a delicate and gentle touch, can make no part
of the excellencies of this kind of painting. It can-
not bear a close examination like a picture in oil. There
is always something dry and rough which displeases.
An artist who would flatter himself with success in a
fresco placed near the eye would be grossly deceived:
a common spectator would find it coarse and badly fi-
nished.

Fresco is chiefly employed in palaces, temples, and
public edifices. In these vast places no kind of paint-
ing can be preferred to it; large, vivid in its strokes,
and constantly fresh, it enriches the architecture, ani-
mates it, and gives relief to the eye from the repetition
of the same forms, and the monotony of colour in a
place where coloured marbles and bronzes are not em-
ployed. Still more a fine fresco gives the greatest
effect to a lofty building, since this building serves
as a frame and support to this enchanting art, which
fixes the attention of every person of sensibility and
taste.

We shall afterwards have occasion to show the man-
ner of executing fresco, as well as the nature and ap-
plication of the colours employed in it; it is necessary
to demonstrate here, that it has a freshness, splendour,
and vigour not to be found in oil or water colours.

A known principle in all kinds of painting is, that
the colouring is more perfect in proportion as it ap-
proaches to the lights and shades in nature. As co-
lours applied to any subject can never reach this degree
of perfection, the illusion which painters produce con-
sists in the comparison and opposition of the tones of
colours among themselves.

If the white of the finest and purest oil appears hea-
vy and gray, compared with great lights in natural
whites, it follows, that, in order to copy them with fide-
licity, the tones which follow the first white must be de-
graded in an exact proportion. Thus it is necessary
that the shades of a picture be considerably deeper than
those of the model; especially if, from the greatest
lights to the browns, one hath proportionally followed
the distance which is found between the colours on the
pallet, and the tones of the object copied.

Now if the white of fresco be infinitely more bright
than that of oil, the same effect will be obtained in a
brown tone. On the other side, if it constantly hap-
pens that the brown tones of fresco are much more vi-
gorous than those of water colours, and equal even to
the browns of oil itself, it is certain that it possesses
a splendour and vigour more extensive than any other
kind of painting. Thus in the hands of an artist who
is well acquainted with the colours fit for fresco, it is
more susceptible of the general effect, and more capable
than any other kind, of giving projection and the sem-
blance of life to the figures.

If we were to inquire why painting in fresco is now
scarcely or never practised, we should perhaps ascribe
it to the great talents required to execute it. "Many
of our painters (says Vasari in his Treatise on Pain-
ting) excel in oil or water colours, and yet fail in fresco;
because of all kinds this requires the greatest strength
of genius, boldness in the strokes, and resolution." If
in an age abounding in great masters, it was difficult
to excel in this kind, it must be much more so in ours;
but we should not require the characters of sublimity
and style to which men were accustomed in the time of
Vasari.

We should execute in fresco as we do in oils; for
Italy herself, along with Michael Angelo and Zui-
charo, had Cortonni, Giardano and Francischini as
middling fresco painters. And in France, Lefosse,
Bon-Boulogne, and Perur, performed several works in
fresco which might be imitated by the painters of our
times. But let us proceed to the real causes for aban-
donning this art. These proceed from the want of know-
ledge and taste in the persons who employ the artists,
and from the manners of the age. As a pleasant or licen-
tsious conceit, unfinished colouring, and bold effects
of shade, are the chief objects of consideration, a very
smooth painting enlivened by gentle touches completely
gratifies the person who pays the price; and therefore
the philosophical principles of the art, which require
study, are not cultivated.

We shall now attend to the mechanical process of
this useful and beautiful kind of painting. Before
painting, it is necessary to apply two layers. If the
wall on which you are to paint is of brick, the layer
is easily applied; but if it is of free stone closely unit-
ed, it is necessary to make excavations in the stone,
and to drive into them nails or pegs of wood in order
to hold the first layer.

The first layer is made of good lime and a cement
of pounded brick, or, which is still better, river sand;
this latter forms a layer more uneven, and better fitted
to retain the second smooth and polished layer applied
to its surface.

There should be experiments to discover a layer
still more compact, and more independent of the vari-
atations of the air; such for example, as covers the
aqueducts and ancient reservoirs constructed by the Romans
in the neighbourhood of Naples.

Before applying the second layer, or what you are
to paint, it is necessary that the first be perfectly dry,
for there issues from the lime, when it is moist, a smell
both disagreeable and pernicious to the artist.

When the first layer is perfectly dry, it is wet with
water in proportion to its dryness, that the second layer
may the more easily incorporate with it.

The second layer is composed of lime, slaked in the
air, and exposed for a year, and of river sand, of an
equal grain, and moderately fine.

It requires an active and intelligent mason to apply
this layer, as the surface must be altogether equal. The
operation is performed with a trowel; and the operator
requires to have a small piece of wood to take away
the large grains of sand, which, remaining, might render
the surface uneven.
Part II.

Painting.

To give a fine polish to this layer, one ought to take a sheet of paper, apply it to the wall, and pass and repass the trowel over the paper. By this means the little inequalities which hurt the exactness of the stroke, and which produce false appearances at a distance, are entirely smoothed.

The artist must not lay more than the painter can finish in a day, as this kind of painting must be executed on a fresh ground.

The layer being thus prepared, the painter begins his operation; but as painting in fresco must be executed rapidly, and as there is no time to retouch any of the strokes, the painter, as we have observed under the article Fresco, takes care to provide himself with large cartoons, on which he has drawn, with exactness, and in their full size, the figures which he is to paint, which leaves him nothing to do but to copy them on the wall.

The cartoons are composed of several sheets of large paper pasted one on another, neither too thick nor too slender.

The painter traces the tracks of the figures on the plaster, by passing a steel point over the tracks in the cartoons, or in prickling them.

Having in this manner attained an exact and speedy drawing, it now remains to execute the painting.

It is essential, when one wishes to finish any small work of this kind, in the first place to be informed of the proper colours, and of those which cannot be used.

In general, the colours which are extracted from earth, and those which have passed through the fire, are the only ones which can be employed in this kind of painting.

The colours are white, made of lime, the white of egg shells, ultramarine; the black of charcoal, yellow ochre, burnt vitriol, red earth, green of Verona, Venetian black, and burnt ochre.

There are others which require to be used with great precaution, such as enamel blue, cinnabar, and white marble dust.

When enamel blue is used, it requires to be applied instantaneously, and when the lime is very moist, otherwise it does not incorporate with the plaster; and if one retouch with this colour, it must be done an hour or more after the first application, to increase its lustre.

With regard to the white marble dust, it is subject to turn black if it be not mixed up with a convenient quantity of white lime.

Cinnabar, which has a splendour almost superior to all other colours, loses it almost entirely when mixed with lime. At the same time, it may be employed in places not exposed to the air, with a little degree of care in the preparation. Reduce a quantity of the purest cinnabar to powder, put it into an earthen vessel, and pour lime water on it, for two or three times. By this process the cinnabar receives some impression of lime water, which makes it capable of being employed in fresco painting.

One of the best colours, and the one most used in fresco for the gradation of tints, and for giving the requisite tone, is white of lime. This white is prepared by mixing lime slaked long before with good water.

The lime deposits a sediment at the bottom of the vessel; when the water is poured off, this sediment is the white of lime.

Another kind of white might be used, the effects of which would be known by experience, namely, the white of egg shells. To prepare this white, one must take a great quantity of shells of eggs, which must be pounded and boiled in water along with a quantity of quicklime; after this they are put into a strainer, and washed repeatedly with fountain water.

The shells are again pounded until the water employed for that purpose become pure and limpid; and when they are in this manner reduced to powder, this powder is grinded in water, and formed into small pieces, and dried in the sun.

All the different kinds of ochres make excellent colours for fresco, and take different shades, being previously burned in iron chests.

With regard to the Naples yellow, it is dangerous to use it where the painting is much exposed to the air. The blacks of charcoal, of peach stones, and of vine twigs, are good: but that extracted from bones is of no value.

Roman vitriol gathered at the furnaces, and which is called burnt vitriol, grinded afterwards in spirit of vine, resists the air extremely well when employed in lime. There is also a red extracted from this preparation somewhat like that produced from lac.

This colour is very proper for preparing the layers, to be coloured with cinnabar; and the draperies painted with these two colours will vie in splendour with those painted with fine lac in oil.

The ultramarine is the most faithful colour; and it not only never changes, but it communicates this precious quality to those colours with which it is mixed.

The manner of employing those colours, is to grind them in water, and to begin by arranging them into the principal tints you are to employ: these are afterwards put into pots; and it is necessary to use a great many pallets raised at the edges, to form the intermediate shades, and to have under your eye all the shades you require.

As all the tints, except burnt ochre, violet, red, and blacks of all kinds, are apt to become clear, the painter must have beside him some pieces of brick or new tile very dry. A dash of the colours is applied to one of these with the pencil before using them; and as the tile instantaneously imbibes the water, one perceives what the shade will be after the fresco is dry.

§ 2. Elydoric Painting, invented by M. Vincent of Montpeut.

This new kind of painting is little known, and capable of great improvement.

Its principal advantages are, that the artist is able to give the greatest finishing possible to small figures in oil; to add to the mellowness of oil painting, the greatest beauty of water colours in miniature, and to do it in such a manner that it appears like a large picture seen through a glass which diminishes objects.

This kind of painting takes its name from two Greek words expressive of oil and water; because those two liquids are employed in the execution. The following is the manner of proceeding: A piece of very fine linen,
linen, or of white taffety, is sized with starch, in the most equal manner possible, on pieces of glass about two inches square, the angles of which are blunted in order that the cloth may cover them neatly and without wrinkles.

When these pieces of cloth are sufficiently dry, a layer composed of white lead finely ground, and oil of poppies or of poppies, the whitest that can be found, is applied to them with a knife. When this layer is dry enough to admit of scraping, more may be applied if necessary.

As it is of the greatest importance for the preservation of this kind of painting, that the different layers be purged of oil, in order that they may imbibe the colours applied to them, it is necessary that their surface be very smooth, very dry, and very hard.

The artist is next provided with a circle of copper nearly two inches in diameter, one-fourth of an inch in height, extremely thin, and painted on the inside with black. This circle is employed to contain the water on the surface of the picture.

The preference is given to water distilled from rain or snow; because ordinary water, from the salts which it contains, is pernicious to this kind of painting.

It is necessary also to observe, that the colours must be grinded between two oriental agates, most carefully preserved from dust, and mixed with oil of poppies, or any other lubricating oil which has been extracted without fire, and pure as water.

All the colours being grinded, they are placed in a small heap on a piece of glass, which is covered with distilled water in a tin box.

When the materials are thus prepared, the subject is slightly traced on one of the pieces of cloth above mentioned with a lead pencil.

The tints are formed on the pallets from the heaps of colours under the water, and the pallet placed as usual on the left arm with the thumb through the aperture.

The picture is held between the thumb and forefinger, supported by the middle, and the necessary pencils between the third and little fingers. The hand is supported on the back of a chair, that there may be full liberty of bringing the work near, or keeping it at a distance from the eye.

The pencils are cleaned with the essence of rectified turpentine.

After having made the rough draught with the colours still fresh, the circle of copper, which ought to surround the picture, is fitted exactly to the surface:

The distilled water is poured within this circle to the height of one eighth part of an inch; and the body is leaned forward till the light fall perpendicularly on the object.

The third finger of the right hand must rest on the internal right angle of the picture.

The artist, with a fine and firm pencil, runs over the first draught, to give colours to the weak places, and to soften those which appear too strong.

As soon as the oil swims on the top, the water is poured off, and the picture is carefully covered with a watch glass, and dried in a box with a gentle heat.

When it is sufficiently dry, to be scraped almost to a level with the knife: the above operation is renewed till the artist is satisfied with his work.

It is in this last work that the artist feels all the advantage of this new method for finishing.

The water poured on the picture discovers all the faults of the pencil, gives facility in searching into the bottom of the shades, and the power of correcting the work and of rendering it perfect.

When the work is finished, it is put under a crystal, where there is no admission of external air, and dried with a gentle heat:

PART III. OF ECONOMICAL PAINTING.

Sec. I.

The object of this Part is to give an account of some mechanical proceedings in certain kinds of painting, calculated to preserve and embellish the walls of houses and furniture. This branch of the art extends to every part of architecture. The whole building becomes the workshop of the artist; the stairs, the balustrades, the sashes, the doors, and the railing of all kinds, occupying his first care, and then the ceiling and wainscoting.

The artist gives to all his subjects a chosen and uniform tint; but he has it in his power to vary the colours on different parts of the building in such a manner as to produce the most pleasing objects.

Among the utensils of the painter, it is needless, but for rendering the article complete, to mention brushes and pencils of all sizes as absolutely necessary.

The brushes are made of boars bristles, or of hair with a mixture of bristles; they ought to be straight, very smooth, and of a round form. Half an hour before they are used, it is proper to soak them in water, in order to swell the wood of the handle, and prevent the hairs from falling off; after this they may be applied to all purposes, either in water colours or in oil; but it may be observed that for the former they require less softening.

The pencils are made of badgers' hair, or any fine hairs enclosed in the pipes of quills of all sizes.

The vessel wherein the pencils are cleaned is made of copper or of tin, smooth below, rounded at the end, and divided into two parts by a thin plate in the middle. The oil, or the substance with which the pencil is cleaned, is contained in one of the divisions.

The pallet is made of the wood of the pear or apple tree, of an oval or square shape, very slender, but somewhat thicker at the centre than at the extremities.

A hole is made in one of its sides sufficiently large to admit the thumb of the workman.

When the pallet is new, it is covered with oil of walnuts; and as often as it dries, the operation is repeated, till it be fully impregnated; it is afterwards polished, and finally rubbed with a piece of linen dipped in oil of common nuts.

The painter's knife is a thin flexible plate, equally alcalde.
Part III.

Painting.

Application of Colours.

1. Prepare only the quantity necessary for the work you undertake, because they do not keep long; and those which are newly mixed are more vivid and beautiful.

2. Hold the brush straight before you, and allow only the surface to be applied to the subject: if you hold it inclined in any other direction, you will ruin the hazard of painting unequally.

3. It is necessary to lay on the colours boldly, and with great strokes; taking care at the same time to spread them equally over the surface, and not filling up the moulding and carved work. If this accident should happen, you must have a little brush to clean out the colours.

4. Stir them frequently in the vessel, that they may preserve always the same tint, and that no sediment may remain at the bottom.

5. Take care not to overcharge the brush with the colour.

6. Never apply a second layer till the first or preceding one be perfectly dry; which it is easily known to be when, in beating the hand gently over it, it does not adhere.

7. In order to render this drying more speedy and uniform, make always the layers as thin as possible.

8. Before painting, it is necessary to prime the subject; that is, to give it a layer of size, or of white colouring oil, to fill up the pores, and render the surface smooth: by this means fewer layers of colour or of varnish are afterwards necessary.

9. Every subject to be painted or gilded ought to have first a white ground; this preserves the colours fresh and vivid, and repairs the damage which they occasionally receive from the air.

§ 1. Of Painting in Water Colours.

To paint in water colours, is to do it in those which are ground in water and diluted in size. There are three kinds of this painting; namely common, the varnished, and that which is called king's white; but before entering on these, it is necessary to make some preliminary observations.

1. Take care that there be no grease on the subject; and if there be, scrape it off, or clean it with a lye, or rub the greasy part with garlic and wormwood.

2. Let the diluted colour fall in threads from the end of the brush when you take it out of the vessel; if it adheres to it, it is a proof that it wants size.

3. Let all the layers, especially at the beginning, be laid on very warm, provided that the liquid be not boiling, which would effectually spoil the subject; and if on wood, expose it to crack. The last layer, given immediately before the varnish, is the only one which ought to be applied cold.

4. In very fine work, where it is necessary to have beautiful and solid colours, the subjects are prepared by size and proper whites, which serve as a ground to receive the colour, and render the surface very equal and smooth.

5. Whatever colour is to be laid on, the white ground is the best, as it assimilates most easily with the painting, which borrows always something of the ground.

6. If knots of wood are found in the subject, it is necessary to rub them with garlic, to make the size adhere.

To make the following details sufficiently plain, we shall take the measures to which the quantity of colours are applied at lathe; that is to say, six feet in height by six feet in breadth. We shall afterwards fix the quantity of materials; and of liquids, necessary to cover this surface. This, however, cannot be exactly defined, as some subjects imbibe the colours much more than others. The manner of employing them also makes a difference; as habit enables one to manage them to greater advantage.
PAINTING,

§ 4. Of Badegeon.

Badegeon is a pale yellow colour applied to plaster to make it appear like fine stones. It gives to old houses and churches the exterior of a new building, by assuming the colour of stones newly cut.

1. Take a quantity of lime newly killed.

2. Add to it half the quantity of what the French call sciure de pierre in which you have mixed of the ochre of rue, according to the colour of the stone you intend to imitate.

3. Steep the whole in a pail of water, in which is melted a pound of rock alum. When the sciure de pierre cannot be obtained, it is necessary to use a greater quantity of ochre de rue, or of yellow ochre, or grind the scales of the stone de St Leu; pass it through a sieve and along with the lime it will form a cement, on which the weather will scarcely make any impression.

§ 5. Of Ceilings and the Roofs of Rooms.

When the ceilings or roofs are new, and you wish to whiten them, take white of Bougival, to which add a little of the black of charcoal to prevent the white from growing reddish; infuse them separately in water; mix the whole with half water and half size of glove leather, which being strong would make the layer come off in rolls if it were not reduced with water. Give two layers of this tint while it is lukewarm.

If the roof has been formerly whitened, it is necessary to scrape to the quick all the remaining white; then give it two or three layers of lime to ground and whiten it: Brush it carefully over; and give it two or three layers of the white of Bougival prepared as before.

§ 6. Of Colouring the backs of Chimneys with Lead Ore.

Clean them with a very strong brush, and carefully rub off the dust and rust; pound about a quarter of a pound of lead ore into a fine powder, and put it into a vessel with half a pint of vinegar; then apply it to the back of the chimney with a brush. When it is made black with this liquid, take a dry brush, dip it in the same powder without vinegar, and dry and rub it with this brush till it become shining as glass.

§ 7. Of Varnished Water Colours.

The advantages of this kind of painting are, that the colours do not fade; that they reflect the light; that they give no offensive smell, but permit the places to be inhabited as soon as finished; and that the varnish preserves the wood from insects and moisture.

To make a fine varnish on water colours, seven principal operations are necessary; namely, to size the wood, to prepare the white, to soften and rub the subject, to clean the moulding, to paint, to size, and to varnish.

To size the wood is to give one or two layers of size to the subject which you intend to paint.

Take three heads of garlic and a handful of wormwood leaves; boil them in three pints of water till they are reduced to one; pass the juice through a linen cloth, and mix it with a pint of parchment size; add half a handful of salt and half a pint of vinegar; and boil the whole on the fire.

Size
Part III.

PAINTING.

Application of Colours.

Size the wood with this boiling liquor; allow it to penetrate into the carved and smooth pieces of the wood, but take care at the same time to make it as clean off the work as possible, or at least to leave it at no place thicker than another. This first sizing serves to fill up the pores of the wood, and to prevent the materials afterwards from collecting in a body, which would cause the work to fall off in scales.

In a pint of strong parchment size, to which you have added four pints of warm water, put two handfuls of white Bougival, and allow it to infuse for the space of half an hour.

Stir it well, and give a single layer of it to the subject very warm but not boiling, equally and regularly laid on, and dashed with repeated strokes of the brush into the mouldings and carved work.

To prepare the white, take a quantity of strong parchment size, and sprinkle lightly over it with the hand, Bougival white, till the size be covered with it about half an inch in thickness; allow it to soak for half an hour as near the fire as to keep it milk warm; and then stir it with the brush till the lumps are broken and it be sufficiently mixed.

Give seven, eight, or ten layers of this white, or as many as the nature of the work or the defects in the wood shall render necessary, giving more white to the parts which require to be softened; but in general, the layers must be equal both with regard to the quantity of the white and the strength of the size.

The last layer of the white ought to be clearer than the rest, which is made by adding water. It must be applied more slightly, taking care with small brushes to cover all the different places in the mouldings and carved work. It is necessary also, between the drying of the different layers, to fill up all the defects with white mastich and size.

To soften, is to give to the subject after the whitening a smooth and equal surface, and to rub it over with a pumice stone.

The wood being dry, take little pieces of white wood and of pumice stone, grinded for the purpose into all necessary forms, either for the pannels or the moulding.

Take cold water, heat being destructive of this kind of work; in summer it is common to add a little ice. Soften the wall with a brush, only as much at a time as you can easily work, as the water might dilute the white and spoil the whole: Then smooth and rub it with the pumice stones and with the small pieces of wood. Wash it with a brush as you smooth it, and rub it over with a piece of new linen, which gives a fine lustre to the work.

The mouldings and carved work are cleaned with an iron; and the only thing to be attended to in the operation is not to raise the grain of the wood.

The subject thus prepared is ready to receive the colour you intend to give it. Choose your tint; suppose a siver colour.

Grind white ceruse and Bougival white separately in water, of each an equal quantity, and mix them together. Add a little blue of indigo and a very small quantity of black of charcoal; from the vine tree very fine, grinded also separately, and in water; more or less of the one or other gives the tint you require. Dilute this tint in strong parchment size; pass it through a boiling cloth of silk very fine, and lay the tint on your work, taking care to spread it very of Colours equally; and then give it two layers, and the colour is applied.

Make a weak, beautiful, and clean size; stir it till it cools; strain it through a fine cloth, and give two layers to the work with a soft painting brush, which has been used, but which you have been careful to clean. Take care not to choke up the mouldings nor to lay on the size thicker on one place than another, and spread it over the work very slightly, otherwise you will dilute the colours, and occasion undulations in the painting.

The beauty of the work depends on this last sizing; for if any part is omitted, the varnish will penetrate into the colours and give it a darker shade.

When the sizing is dry, lay on two or three layers of spirit of wine varnish, taking care that the place on operation, in which you lay it be warm, and the work is finished.

§ 8. Of the King's White.

This derives its name from the use of it in the apartments of the French king. It is in all respects conducted like the former, except that there is only a small quantity of indigo, to take the yellow from the white, without any black of charcoal, and without varnish.

This white answers extremely well for apartments which are seldom used; but otherwise it spoils easily, especially in bedchambers. It is the best white where there is any kind of gilding; and in this case it receives a little varnish.

Sect. III. Of Painting in Oil Colours.

To paint in oil is to apply to all sorts of subjects, as walls, wood, cloths, and metals, coloured earths, ground and diluted in oil. The ancients are thought to have been ignorant of this art, and the honour of the discovery is generally ascribed to John Van Eyck a Flemish painter. The secret is nothing more than substituting oil in place of water in grinding and diluting colours.

By means of oil the colours are longer preserved; and not drying so speedily, they give painters longer time to smooth, finish, and retouch their works; the colours being more marked, and mixing better together, give more distinguishable tints, and more vivid and agreeable gradations, and the colouring is more sweet and delicate.

The painting in oil consists of two kinds, namely, of that in simple oil and of that in polished oil varnish.

§ 1. Observations on Painting in Oil.

1. When bright colours, as white or gray, are ground and diluted in oil, it is necessary to make use of the oil of walnuts; but if the colours be dark, such as chestnut, or olive, or brown, you must make use of pure linseed oil.

2. When the colours are ground and diluted in oil, they must be laid on cold, except on a new or moist plaster, which requires them to be boiling.

3. Every colour diluted in pure oil, or in oil mixed with essence, ought to fall in threads from the end of the brush.

4. Take care to stir from time to time your colour before
PAINTING.

Painting in oil, before taking it up on the brush, that it may preserve as equal a thickness as possible, and consequently the same tone.

Notwithstanding the precaution of stirring, it is found to be thicker towards the bottom, it will be necessary to pour in from time to time a little oil.

5. In general, every subject which is painted in oil ought first to receive one or two layers of white ceruse, grinded and diluted in oil.

6. When the painting is exposed to the air, as in doors, windows, and other works, which cannot be varnished, it is necessary to make these layers with pure oil of walnuts, mixed up with about one ounce of essence to a pound of colours; more would make the colours brown, and occasion them to fall off in dust; but this quantity prevents the sun from blistering the work.

7. In subjects on the inside of the house, or when the painting is varnished, the first layer ought to be grinded and diluted in oil, and the last diluted with pure essence.

8. If copper or iron, or other hard substances, are to be painted, it is necessary to mix a little essence with the first layers, to make the oil penetrate into them.

9. Where there are many knots in the subject, as is particularly the case with fir wood, and when the colour does not easily take impression on these parts, it is necessary, when you paint with simple oil, to lay on a little oil mixed with litharge on the knots. If you paint with polished oil varnish, it is necessary to apply a hard tint, which we shall have occasion to speak of afterwards. A single layer well applied is generally sufficient to give a body to the wood, and make the other layers apply easily.

10. There are colours, such as the French call *stilts-de-grain*, black of charcoal, and especially bone and ivory blacks, which are difficult to dry when grinded in oil. To remedy this inconvenience, the following siccatives are mixed with the colours, to make them dry, viz. litharge both of the silver and gold colour, vitriol or copperas, and what is called siccative oil.

1. Do not mix the siccatives with the colours till they are to be employed, otherwise it will thicken them.

2. Mix it only in very small quantities in tin, where there is white lead or ceruse, because those colours are siccative of themselves, especially when they are diluted in essence.

3. In painting which is to be varnished, give the siccative only to the first layer, and allow the other layers, in which there is essence, to dry of themselves.

4. In dark colours in oil, give to every pound of colours in diluting them half an ounce of litharge; to bright colours, a drachm of white copperas grinded in walnut oil.

5. When in place of litharge or copperas the siccative oil is employed, it requires a quartem of this oil to every pound of colour.

The siccative oil is prepared of one half ounce of litharge, as much of calcined ceruse, as much of *terre d'ombre*, a colour with which the French paint shadows, and as much of tale boiled for two hours on a slow and equal fire, with one pound of linseed oil, and stirred the whole time. It must be carefully skimmed and clarified, and the older it grows it is better.

§ 3. Observations on the Quantities of Substances and Liquids.

1. Ochres and earths require more liquids both in grinding and diluting than ceruse.

2. Different quantities of liquids are required in the grinding only on account of greater or less dryness; but in diluting, the quantity is always the same.

3. For the first layer after the priming, which has no relation to the colours laid on afterwards, to square fathom give fourteen ounces of ceruse, about two ounces of liquid to grind, and four ounces to dilute it. If there is a second layer of the same materials, the quantities will require to be less.

4. It will require three pounds of colour for three layers of a square fathom. The first may consume eighteen ounces, the second sixteen, and the third fourteen.

5. To compose these three pounds of colour, take two or two and a half pounds of grinded colours, and dilute them in a pint or three half pints of oil, mixed with essence or pure oil. But if the first layer of ceruse is not used, there will be a necessity for a greater quantity of colours.

N. B. In the following kinds and applications of oil painting, we are to hold those proportions in our eye.

§ 4. Painting in Simple Oil.

On doors and windows give a layer of ceruse grinded of bone, linseed, and vitriol in oil of walnuts diluted in the same oil, together with a little siccative; then give another layer of the same preparation; to which, if you want a greyish colour, ten parts add a little black of charcoal and Prussian blue, grinded also in oil of walnuts. If to these you incline to add a third layer, grind and dilute it in pure walnut oil; observing that the two last layers be less clear, or have less oil in them, than the first; the colour in this case is more beautiful and less apt to blister with the sun.

Walls that are to be painted must be very dry; and of walls, this being supposed, give two or three layers of boiling linseed oil to harden the plaster; then lay on two layers of ceruse or ochre, grinded and diluted in linseed oil; and when these are dry, paint the wall.

To paint tiles of a slate colour, grind separately ceruse and German black in linseed oil; mix them together in the proportion which the colour requires, and dilute them in linseed oil; then give the first layer very clean to prime the tiles; and make the three next layers thicker, to give solidity to the work.

To paint arbours and all kinds of garden work, give a layer of white ceruse grinded in oil of walnuts, and diluted in the same oil, with the addition of a little litharge, then give two layers of green, composed of one pound of verdigris and two pounds of white lead, grinded and diluted in oil of walnuts. N. B. This green is of great service in the country for doors, window shutters, arbours, garden seats, rails, either of wood or an iron; and in short for all works exposed to the injuries of the weather.

To white statues, vases, and all ornaments of stone, give an even coat within or without doors; first clean the subject and then well,
Part III.

PAINTING.

Oil Colours.

Painting in Oil Colours.

36. Painting on the inside of the house.

37. Chairs, benches, stone, and plaster.

38. Steel colour for locks.

40. Wainscoting of apartments.

41. Painting in water colours, if they find it more agreeable, may finish it in oil colours as above.

When the pores of the wood are well stopped by the prepared white, a layer of white ceruse, ground in oil of walnuts, and diluted in the same oil, mixed with essence, may be applied. This will be sufficient, the wood being previously primed; and afterwards lay on your intended colour and varnish.

§ 5. Painting in Oil with the Polished Varnish.

This is the best kind of oil painting, owing more to the care it requires than to the proceedings, for they are nearly the same with those of simple oil painting; the difference consisting only in the preparation and manner of finishing.

To paint wainscottings of apartments with the polished Wainscot-ed varnish, it is necessary, in the first place, that the tings-pannels be new. Then,

1. Make the surface of the subject which you mean to paint very smooth and level, which is done by a layer, which serves to receive the hard tint or polished ground and the colours.

This layer ought to be of white, whatever colour you are afterwards to apply. It consists of white ceruse, ground very fine in linseed oil, with a little litharge, and diluted in the same oil mixed with essence.

2. Make the polished ground by seven or eight layers of the hard tint. In painting equipages, a dozen is necessary.

The hard tint is made, by grinding pure white ceruse, which has been much calcined, very finely in thick oil, and diluting it with essence. You must take care that the layers of the hard tint be not only equal as to the application, but to the quantity of the white ceruse and the oil, and to the degree of calculation. Then,

3. Soften this ground with pumice stone.

4. Polish it moderately with a piece of serge soaked in a pail of water, in which you have put some powder of pumice stone finely ground and passed through a fine sieve. There is no occasion to spare washing, as this part of the operation will not spoil with water.

5. Choose the tint with which you intend to decorate your apartment; grind it in oil, and dilute it in essence; pass it through a piece of very fine silk, give two or three layers carefully and thinly spread over the surface, as on this part of the operation depends a great measure the beauty of the colour. All sorts of colours may be employed in this manner in oil of essence.

6. Give two or three layers of a spirit of wine varnish, if it is to wainscoting; if to the body of a coach, a varnish of oil is employed. If the varnish is to be polished, it is necessary to give seven or eight layers at least, laid on equally and with great precision, not to be thicker in one place than another, which occasions spots.

7. It is again polished with pumice stone reduced to powder, and water and a piece of serge. If the wainscoting has been painted before, it is necessary to rub off the colour till you come to the hard tint, which is done with pumice stone and water, or with a piece of linen dipped in essence.

There is a white painting in oil, called white varnish, which corresponds to the king's white in water, called white varnish, which corresponds to the king's white in water, called...
PAINTING.

Painting in colours, and is equal to the freshness and gloss of Oil Colours, marble if it is applied to wood. To paint in this manner,

1. Give a layer of white ceruse ground in oil of
   walnuts, with a little calcined copperas, and diluted in
   essence. But if it is applied to stone, it is neces-
   sary to employ oil of walnuts and calcined copperas
   alone.

2. Grind white ceruse very fine in essence, and dilute
   it in fine white oil varnish with copal.

3. Give seven or eight layers of it to the subject.—
   The varnish mixed with the white ceruse dries so prompt-
   ly, that three layers of it may be given in a day.

4. Soften and polish all the layers as above.

5. Give two or three layers of white lead ground in
   oil of walnuts, and diluted in pure essence.

6. Give seven or eight layers of white spirit of wine
   varnish, and then polish them.

To paint in varnish, is to employ colours ground and
   diluted in varnish, either in spirits of wine or oil, on all
   sorts of subjects. Vainscotting, furniture, and equi-
   pages, are painted in this manner, though we shall con-
   fine ourselves to the first.

1. Give two layers of white of Bougival, diluted in
   a strong size boiling pot.

2. Give a layer of what the French call de blanc
   apprêts.

3. Fill up the defects of the wood with mastich in
   water; and when the layers are dry, smooth them with
   the pumice stone.

4. When the wood is smooth, suppose the paint a
   gray colour, take one pound of white ceruse, one draw
   of Prussian blue, or of black of charcoal or ivory black;
   put the white into a piece of leather, so tied that the
   colours cannot escape; shake them till they are suffi-
   ciently mixed.

5. Put two ounces of colours into a quartern of
   varnish; mix them carefully; give one layer above the
   white.

6. This layer being dry, put one ounce of colours
   into the same quantity of varnish as above, and give a
   second layer.

7. To the third layer give half an ounce of colour to
   the same quantity of varnish.

8. As each of these layers dry, be careful to rub
   them with a piece of new coarse cloth, in such a man-
   ner, however, as not to injure the colour. N. B. The
   three layers may be given in one day.

9. If you want to give a perfect lustre, add a fourth
   layer prepared as the third.

All other colours, as blue, &c. may be applied in the
   same manner. This method is the only one by which
   ornament can be employed in all its beauty, but not with-
   out some of its inconveniences.

Another manner of performing this kind of work,
   is to apply the colours and the varnish without previously
   using the size and the white ground. This is ex-
   tremely expeditious, but it is easy to perceive it will
   want the polish and brilliancy of the other.

SECT. IV.

We cannot perhaps more properly conclude this ar-

icle, than with an account of M. de Morveau's at-

tempts to render more perfect the proportion of colours, Oil Colours,

and especially of white, employed in painting. These

we shall extract from a memoir of his read in the acade-

my of Dijon.

"White (says the ingenious academian) is the most

important of all colours in painting. It affords to the

painter the materials of light, which be distributes in

such a manner as to bring his objects together, to give

them relief, and that magic which is the glory of his art.

For these reasons I shall confine my attention at present

to this colour.

"The first white which was discovered, and indeed

the only one yet known, is extracted from the calx of

lead. The danger of the process, and the dreadful dis-
temper with which those employed in it are often seized,

have not yet led to the discovery of any other white. 

Less anxious, indeed, about the danger of the artist than

the perfection of the art, they have varied the prepara-

tion, to render the colour less liable to change. Hence

the different kinds of white, viz. white of Cremes in Au-

straia, white lead in shells, and white ceruse. But every

person conversant in colours, knows that the foundation of

all these is the calx of lead, more or less pure, or more or

less loaded with gas. That they all participate of this

metallic substance, will indeed appear evident from the

following experiment, which determines and demonstrates

the alterability of colours by the phlogistic vapour.

"I poured into a large glass bottle a quantity of li-

ver of sulphur on a basis of alkali, fixed or volatile, it

makes no difference if I added three drops of distilled

vinegar, and I covered the mouth of the bottle with a

piece of pasteboard cut to its size, on which I disposed

different samples of cremes, of white lead, and of ceruse,

either in oil or in water; I placed another ring of paste-

board, over the first, and tied above all a piece of bladder

round the neck of the bottle with a strong pack-thread.

It is evident, that in this operation I took advantage of

the means which chemistry offers to produce a great

quantity of phlogistic vapour, to accomplish instantane-

ously the effect of many years; and, in a word, to apply

to the colours the very same vapours to which the picture

is necessarily exposed, only more accumulated and more

concentrated. I say the same vapour, for it is now fully

established, that the smoke of candles, animal exhalations

of all kinds, alkaline odours, the electric effluvium, and

even light, furnish continually a quantity more or less

of matter, not only analogous, but identically the same

with the vapour of vitriolic acid mixed with sulphur.

"If it happens that the samples of colours are sensibly

altered by the phlogistic vapour, then we may conclude

with certainty, that the materials of which the colours

are composed, bear a great affinity to that vapour; and

since it is not possible to preserve them entirely from it

in any situation, that they will be more or less affected

with it, according to the time and a variety of circum-

stances.

"After some minutes continuance in this vapour, I

examined the samples of colours submitted to its influ-

ence, and found them wholly altered. The ceruse and

the white lead both in water and oil were changed into

black; and the white of cremes into a brownish black;

and hence those colours are bad, and ought to be aban-

doned. They may indeed be defended in some measure

by varnish: but this only retards for a time the contact of
PAINTING.

is only necessary to mix equal parts of this earth, or even the mixture will be susceptible of being ground in oil or in gum without being extinguished; it will easily unite with any coloured substance, and be productive of no bad consequences to the pure earths.

Nature and art present to us a considerable number of earthy compositions sufficiently white for the purposes of painting; such as the jasper white, the fieldspar white, the schirl white, &c. But all these substances, in all the trials which I made, had the fault which I have already mentioned; and originating from the same cause, they wanted a fixed colouring body, which would not change when it is pulverized, nor be extinguished when it is diluted.

The ultramarine blue, which is extracted from the blue jasper, and known by the name of laipi lazuli, seems at first view to warrant the possibility of appropriating to painting all the opaque half vitrified compositions of the nature of jasper.

Prepossessed with this idea, I conceived the hope of producing a true white laipi; but I soon perceived that the experiment confirmed the principle which I had laid down from my observations on pure earths; since it is not the substance peculiar to the jasper which constitutes the ultramarine blue, but the metallic substance which accidentally colours this particular kind of jasper.

In the same manner, art in this imitation of nature should have for its object to give a permanent base to a colour already formed, to fix it without altering, and to augment perhaps its splendour and its intensity, without attempting to produce a colour.

In excepting from earthy and metallic salts all those of which the acid is not completely saturated, which would easily attract the humidity of the air, or which would be easily dissolved, you have but a very small number to make experiments on.

The natural and artificial selinite gives with oil a paste without colour, and tasting somewhat like honey; its white is better preserved with a gum, but even in this case it resembles a half transparent pap.

The natural or regenerated heavy spar is the most likely salt to produce white. As it is of all others the most difficult to dissolve, it appears after pulverization to be a very fine white, but is scarcely touched with oil when it becomes gray and half transparent: the mucilaginous alters it also, although less discernibly; and it does not even resume its white colour after it becomes dry on the canvas.

The same is the case with calcareous borax, formed by the solution of borax in lime water; its white is completely extinguished when oil, less so with gum, and it is hardened so instantaneously with the latter, that it is impossible ever to dilute it again.

Calcareous tartar, obtained by casting quicklime into a boiling solution of cream of tartar, is affected with oil in the same manner as selinite, but with mucilaginous water it gives a pretty good white, only possessed of little reflection, and appearing like plaster; it applied very well to the canvas, and resisted the phlogistic vapour.

According to M. Weber, in his work entitled Fabriken und Künste, published 1781, the white, called in Germany kremser wies, is nothing but the vitriol...
PAINTING.

Painting is of lead, prepared by dissolving lead in nitrous acid, and precipitating it in vitriolic acid; and forming it afterwards into solid tablets by means of gum water. It is certain that this resembles in no shape the white called in France the white of creme; at least, I never found that it could be dissolved in vinegar; but I tried the white prepared in M. Weber's manner, and the result was the same as above, that is to say, it turned completely black.

The vitriols of lead and of bismuth alter more speedily than the calces of those metals. And thus, with the exception of calceareous tartar, which may be of some use in watercolours, the best earthy salts on which I have made experiments, may all, or the most of them, give a base of some colours, but cannot constitute by themselves a colour useful in painting.

Of the fifteen known metallic substances, there are nine which yield white calces; namely, silver, mercury, lead, tin, antimony, bismuth, zinc, arsenic, and manganese.

Of these nine substances, we may almost pass over silver and mercury; because, though they yield a very fine white, precipitated by means of crystallized vegetable albumen, it is easily altered when exposed to the air; that from silver changing into black, and that from mercury into yellow.

It is well known that lead gives a very good white, and one which unites easily with oil or size; but that it is extremely liable to change, has been my principal object to prove, and the experiments which I have made place it beyond contradiction.

I shall only add, that if there is a preparation able to correct this fault, it should be the precipitation of the earth of this metal in its acetic dissolution by Prussian alkali; but the white which results from this preparation becomes sensibly brownish when it is exposed a few minutes only to the phlogistic vapour.

It would be therefore unreasonable to persevere in the use of this substance, or to wish to render it fixed, since the changes which it undergoes do not alter its nature, and the indestructible order of its affinities.

The calx of tin is easily applied to any purpose, and experiences no change to the concentrated phlogistic vapour. These considerations induced me to endeavour to obtain this calx perfectly white; and here follows the result of my operations: The tin calced gives a pretty white calx; but whatever attention I paid to take off the red surface which the violence of the fire occasioned, a shade of grey always appears when it is diluted. Tin calced by nitre in fusion, gives a tarnished and gross calx, which multiplied washings could not deprive of a yellowish tint.

Having precipitated, by means of crystallized vegetable alkali, a solution of English tin, which had been made in the muriatic acid, after the manner of M. Baeyn to extract the arsenie, I had a calx of the greatest whiteness, so light that it buoyed up to the surface of the liquid; and so thin that the greater part of it passed through the filter; but it experienced at the same time a kind of adherence with the salts, which makes the part of it retained by the filter incapable of being pulverized, gummy, half-transparent, and even a little changed into yellow. In this condition it is extinguished when diluted; it is necessary, therefore, to maintain it in boiling water, and afterwards to calcine slightly the sediment after it has had sufficient time to settle.

I have tried the calcination by means of moisture in employing the tin of the purest essence, and rectified nitrous acid, according to the method of Meyer. It formed a very white sparkling calx, which remained in the filter in the consistency of jelly. Meanwhile, I observed that it was always a little yellow by the mixture of a portion of that earth which took, in the operation, the colour of turbid mineral.

A very fine white calx is extracted from antimony, calxined by nitre in fusion; but the earth of this semi-metal must be placed in the number of those which combine too easily with the phlogistic vapour. The diaphoretic antimony, grinded in oil, took in ten minutes in my phlogistic apparatus a colour somewhat like sulphur.

The property of bismuth to give a very fine white calx, known by the name of smagnityery, or white aur, is generally known; it is easily prepared, since it is only necessary to dissolve the bismuth in nitrous acid, and to precipitate the solution by pure water: it dilutes perfectly with oil and mixtures. But this colour ought to be rejected, as the most liable to the phlogistic vapour. It became completely black in ten minutes in my apparatus; and this fact is also proved from what happens to women who use this colour, when they are exposed to the vapours of sulphur, of garlic, or of any putrid substances.

Zinc furnishes by all the processes of calculation and precipitation a pretty white calx, when it is pure and separated from iron; otherwise the solutions of the vitriol of zinc will become yellow when exposed to the air. I have precipitated those solutions by lime water, by caustic, and effervescent alkalies; I have calxined this semi-metal alone and with nitre; and in all those operations I have obtained an earthy substance of different degrees of whiteness, which, after it was dried and prepared, mixed readily with oil mixtures without losing its colour; and which experienced no sensible change when exposed to the phlogistic vapour.

These valuable properties, the chief object of my researches, engaged me to multiply my experiments to determine at once the most economical process, and the most advantageous and infallible preparation.—Those attempts have convinced me, that the calxination of this semi-metal alone in a crucible, placed horizontally as the corners of a reverberating furnace, gives the purest, the whitest, and the least reducible calx; and that to make an excellent colour, it is sufficient to separate the parts not burned with water, and grind it with a little of the earth of zinc or chalk to give it a body. Zinc calxined in Prussian alkali, even in distilled vinegar, retains always a shade of yellow, does not unite as well in oil, and takes a demi-transparent consistence like cheese.

White arsenic extinguishes much less than one would believe from its saline nature; it preserves its colour best in gum water; and it is remarkable, that instead of turning black in the phlogistic vapour, it takes a very distinct shade of yellow. This property is sufficiently singular and constant to furnish a new method of analysing arsenic, as a new to know it. And this alteration of colour makes it so easy
PAINTING.

Painting, in its painting, although its deleterious qualities did not forbid the practice.

"The semi-metal known by the name of manganese, gives also white calcio. I had at first great hopes from this colour, as, contrary to all those extracted from the other metals, it became white by the phlogistic vapour. There remained, therefore, but one difficulty to overcome, viz., to separate from the manganese the portion of iron which it usually contained, and which infallibly makes the earth a little yellow. To accomplish this in the cheapest manner, I submitted the black ore of the manganese to a long calcination to render its iron insoluble; I afterwards applied vinegar to it, after the example of M. de la Peyrone; and in precipitating the dissolution by effervescent alkali, I easily obtained a pure white precipitate. But I soon perceived that the facility with which a colouring body loses its phlogiston, is no less an inconvenience than that of attracting it, and productive of the same alterations.

"The white of manganese became very soon yellow when exposed to the air; and this is not to be ascribed to the iron contained in it, since neither the galls nor Prussian alkali had discovered any of it in the dissolution. This substance, therefore, can be of no use in producing a white colour for painting."

The experiment by which M. de Morveau tried the colours not alterable by the phlogistic vapour, was performed before the academy, the prince of Condé being president. "I placed (says he) in my apparatus pieces of cloth, on which I laid the white of calcareous tartar in water, different preparations of white from tin and zinc, in oil and water; and I allowed them to continue exposed to the phlogistic vapour during a sitting of the academy: if they were not altered, their superiority over the whites in use would be sufficiently established. The sitting continued for near an hour; and the bottle having been opened, all the colours continued to have the same shade which they had before. I can, therefore, recommend to painters those three whites, and particularly that of zinc, the preparation of which is exposed to least variation, the shade more lively and uniform, and moreover it is fit for all purposes, and perhaps procured at less expense.

"I will assert farther, that it may be procured in sufficient quantities to supply the place of cinnabar in every branch of the art, even in interior house painting;—I would recommend it, less with the view of adding new splendour to this kind of ornamentation, than for the safety of those who are employed in it, and perhaps for the safety of those who inhabit houses ornamented in this manner.

"But, without being too sanguine, although the processes in the fabrication be simplified in proportion to the demand, as is usually the case, yet there is reason to apprehend that the low price of cinnabar will always give it the preference in house-painting. With regard to those who apply colours to sober purposes, they will not hesitate to employ the white of zinc. I am assured that four franks is paid for the pound of the white of creos; and I believe the white in question, prepared in the manner in which I have pointed out, might be sold for six.

"M. Courters, connected with the laboratory of the academy, has already declared that it is used for house-painting; less, however, in regard to its unalterability, than to its solubility; and this can be the more readily believed, as the flower of zinc enters into many compo-sitions of the apothecary. The same M. Courters has arrived at the art of giving more body to this white, which the painters seemed to desire, and also of making it bear a comparison with white lead either in water or oil. The only fault found with it, is its drying slowly when used in oil; but some experiments which I have made, incline me to believe that this fault may be easily remedied, or at least greatly corrected, by giving it more body. At any rate, it may be rendered incisive at pleasure, by adding a little varnish white of zinc or copperas slightly calcined.

"Painters already know the properties of this salt, but perhaps they do not know that it mixes with the white of zinc better than with any other colour; the reason is, they have chemically the same base. It is prepared by purging the white coppers of that small portion of iron which would render it yellow; and this is easily done in digesting its solution, even when cold, as the filagree of zinc.

"The mixture of this salt thus prepared is made on the pallet, without producing any alteration, and a small quantity will produce a great effect."

APPENDIX.

We shall here add an account of some processes which have been recommended, an account of their cheapness, for preparing different materials for economical painting. The first is a method of house painting with milk, by Cadet de Vaux. The following are the directions for preparing this paint.

"Take of skimmed milk a pint, which makes two
pints of Paris, or nearly two quarts English; fresh slaked lime, six ounces; (about six and a half ounces avoidupois; oil of caraways, or larded, or nut, four ounces; Spanish white (whiting) three pounds; put the lime into a stone-ware vessel, and pour upon it a sufficient quantity of milk to make a mixture resembling thin cream; then add the oil a little at a time, stirring it with a small spatula; the remainder of the milk is then to be added, and lastly, the Spanish white. Skimmed milk in summer is often defatted, but this is a circumstance of no consequence to our object, because the contact with the lime soon restores its fluidity. But it must on no account be sour, because in that case it would form with the lime a kind of calcareous acetate, capable of attracting moisture."

"The lime is slaked by dipping it in water, out of which it is to be immediately taken, and left to fall in pieces in the air."

"The choice of either of these oils is indifferent; nevertheless for white paint the oil of caraways is to be preferred, because colourless. The commonest oils may be used for painting with the ochres."

"The oil when mixed in with the milk and lime disappears, and is totally dissolved by the lime, with which it forms a calcareous soap."

"The Spanish white is to be crumbled, or gently spread over the surface of the fluid, which it gradually imbibes, and at last sinks; in this period it must be well stirred in. This paint may be coloured like distemper (or size colour) with burnt umber, charcoal, yellow ochre, &c."

"And ."
"And it is used in the same manner:

"The quantity here prescribed is sufficient for the first coat of six toises, or 27 square yards English.

"The price of this amount amounts to nine sols, which reduces the price of the square toise to one sol, six deniers, prime cost."

And to give this paint a greater degree of solidity, that it may be employed as a substitute for oil paint, the artist adds the proportions of the paint for oil, and to make the paint more solid, the pitch is to be melted with a gentle heat in the oil, and then added to the smooth mixture of the milk and lime. In cold weather this mixture is to be warmed, that it may not occasion too speedy cooling of the pitch, to facilitate its union with the milk of lime. This paint, it is said, has some analogy with that known by the name of encaustic.

A method has been proposed by Mr. Van Buren, for making cheap and durable paints with fish oil. The paints thus prepared, beside their cheapness, are not subject to blister or peel off by exposure to the weather. They may be manufactured of any colour, and laid on by ordinary labourers. The price of some of them is so low as to be as cheap as paint, and the highest does not exceed threee times per pound, in a state fit for use. The artist adds, that white lead ground with prepared fish oil, and thinned with linecd oil, surpasses any white hitherto employed for resisting all weathers, and retaining its white weather.

"To refine one Ton of Cod, Whale, or Seal Oil, for painting, with the cost attending it.

One ton of fish oil, or 232 gallons, L.36 o 0
32 gallons of vinegar, at 2s. per gallon, - 3 4 o
12 l. of litharge, at 5d. per lb, - 3 5 o
12 lbs. of white copperas, at 6d. ditto, - 6 0 o
12 lbs. of linecd oil, at 4s. 6d. per gallon, 2 14 0
2 gallons of spirits of turpentine, at 8s. ditto, 0 16 0

L.43 5 0

252 gallons of fish oil,
12 ditto linecd oil,
2 ditto spirits of turpentine,
32 ditto vinegar.

298 gallons, worth 4s. 6d. per gallon.
Which produces L.67 1 0
Deduct the expense 43 5 0

L.23 16 0 prof.

"To prepare the Vinegar for the Oil.

"Into a cauld which will contain about forty gallons, put 32 gallons of good common vinegar; add to this 8 pounds of litharge, and 12 pounds of white copperas in powder; bung up the vessel, and shake and roll it well twice a day for a week; when it will be fit to put it into a ton of whale, cod, or seal oil; (but the Southen Painting Oil is to be preferred, on account of its good colour, and little or no smell); shake and mix altogether, when it may settle until the next day; then pour off the clear, which will be about seven eighths of the whole. To this clear part add twelve gallons of linecd oil, and two gallons of spirit of turpentine; shake them well together, and after the whole has settled two or three days, it will be fit to grind white lead, and all fine colours in; and, when ground, cannot be distinguished from those ground in linecd oil, unless by the superiority of its colour.

"If the oil is wanted only for coarse purposes, the linecd oil and oil of turpentine may be added at the same time that the prepared vinegar is put in, and after being well shaken up, is fit for immediate use without being suffered to settle.

"The vinegar is to dissolve the litharge; and the copperas accelerates the dissolution, and strengthens the drying quality.

"The residue, or bottom, when settled, by the addition of half its quantity of fresh lime-water, forms an excellent oil for mixing with all the coarse paints for preserving outside work.

"Note. All colours ground in the above oil, and used for inside work, must be thinned with linecd oil and oil of turpentine.

"The oil mixed with lime-water, I call incorporated oil.

"The method of preparing, and the expense of the various Impenetrable Paints.

"First.—Subdued Green.

Fresh lime water, 6 gallons, L.0 3
Road dirt finely sifted, 112 pounds, 0 1 0
Whiting, 112 ditto, 0 2 4
Blue-black, 30 ditto, 0 2 6
Wet blue, 20 ditto, 0 1 0
Residue of the oil, 3 gallons, 0 6 0
Yellow ochre in powder, 24 pounds, 0 2 0

L.1 4 1

"This composition will weigh 368 pounds, which is scarcely one penny per pound. To render the above paint fit for use, to every eight pounds add one quart of the incorporated oil, and one quart of linecd oil, and it will be found a paint with every requisite quality, both of beauty, durability, and cheapness, and in this state of preparation does not exceed twicee halfpenny per pound; whereas the coal tar of the same colour is sixpence.

To this we shall only add the following receipt for a constant white for inside painting. This paint, the author observes, is not entirely free from smell in the operation, but becomes dry in four hours, at the end of which time the smell is entirely dissipated.

"White Paint.

"To one gallon of spirits of turpentine, add two pounds of frankincense; let it simmer over a clear fire until dissolved; strain it and bottle it for use. To one
Painting is gallon of my bleached linseed oil, add one quart of the Oil Colours, above, shake them well together and bottle it also. Let any quantity of white lead be ground with spirits of turpentine very fine; then add a sufficient portion of the last mixture to it, until you find it fit for laying on. If Painting in working it grows thick, it must be thinned with spirits of turpentine.—It is a flat or dead white."

PAIR; two of a sort, a couple.

PAIRING, the uniting or joining in couples.

The instinct of pairing is bestowed on every species of animals to which it is necessary for rearing their young; and on no other species. All wild birds pair; but with a remarkable difference between such as place their nests on trees and such as place them on the ground. The young of the former, being hatched blind, and without feathers, require the nursing care of both parents till they be able to fly. The male feeds his mate on the nest, and cheers her with a song. As soon as the young are hatched, singing yields to a more necessary occupation, that of providing food for a numerous issue; a task that requires both parents.

Eagles and other birds of prey build on trees, or on other inaccessible spots. They not only pair, but continue in pairs all the year round; and the same pair procreates year after year. This at least is the case of eagles: the male and female hunt together, unless during incubation, at which time the female is fed by the male. A greater number than a single pair are never seen in company.

Gregarious birds pair, in order probably to prevent discord in a society confined to a narrow space. This is the case particularly of pigeons and rooks. The male and female sit on the eggs alternately, and divide the care of feeding their young.

Partridges, plovers, pheasants, sea fowl, grouse, and other birds that place their nests on the ground, have the instinct of pairing; but differ from such as build on trees in the following particular, that after the female is impregnated, she completes her task without needing any help from the male. Retiring from him, she chooses a safe spot for her nest, where she can find plenty of worms and grass seed at hand; and her young, as soon as hatched, take foot, and seek food for themselves. The only remaining duty incumbent on the dam is, to lead them to proper places for food, and to call them together when danger impends. Some males, provoked at the desertion of their mates, break the eggs if they stumble on them. Eider ducks pair like other birds that place their nests on the ground; and the female finishes her nest with down plucked from her own breast. If the nest be destroyed for the down, which is remarkably warm and elastic, she makes another nest as before. If she is robbed a second time, she makes a third nest; but the male furnishes the down. A lady of spirit observed, that the eider duck may give lesson to many a married woman, who is more disposed to pluck her husband than herself. The black game never pair: in spring, the cock on an eminence crow, and claps his wings; and all the females within hearing instantly resort to him.

Pairing birds, excepting those of prey, flock together in February, in order to choose their mates.

PAIRING is unknown to quadrupeds that feed on grass. To such it would be useless; as the female gives suck to her young while she herself is feeding. If M. Buffon deserves credit, the roe deer are an exception. They pair, though they feed on grass, and have but one litter in a year.

Beasts of prey, such as lions, tigers, wolves, and foxes, do not. The female is left to shift for herself and her young; which is a laborious task, and often so unsuccessful as to shorten the life of many of them. Pairing is essential to birds of prey, because incubation leaves the female no sufficient time to hunt for food. Pairing is not necessary to beasts of prey, because their young can bear a long fast. Add another reason, that they would multiply so fast by pairing, as to prove troublesome neighbours to the human race.

Among animals that pair not, males fight desperately about a female. Such a battle among horned cattle is finely described by Lucretius. Nor is it unusual for seven or eight lions to wage bloody war for a single female.

The same reason that makes pairing necessary for gregarious birds, obtains with respect to gregarious quadrupeds; those especially who store up food for winter, and during that season live in common. Discord among such would be attended with worse consequences than even among lions and bulls, who are not confined to one place. The beavers, with respect to pairing, resemble birds that place their nests on the ground. As soon as the young are produced, the males abandon their stock of food to their mates, and live at large; but return frequently to visit them while they are suckling their young.

Hedge-bog pair, as well as several of the monkey kind. We are not well acquainted with the natural history of these animals; but it would appear that the young require the nursing care of both parents.

Seals have a singular economy. Polygamy seems to be a law of nature among them, as a male associates with several females. The sea turtle has no occasion to pair, as the female concludes her task by laying her eggs in the sand. The young are hatched by the sun, and immediately crawl to the sea.

PAISLEY, a town of Renfrewshire, in Scotland, situated about six miles and a half west of Glasgow, on the river White Cart, over which there are two stone bridges of two arches each, and one which consists of three arches. The town is very ancient; but was of much less consequence formerly than it is at present. "No Statistical account of Paisley. The following has been suggested by a good Gaelic scholar: 'A ridge of rocks that rung across the river, and forms a beautiful cascade, would, prior to the building
building of the town, be undoubtedly the most striking
object that this place would present. The beam or face
of a rock is in Gaelic *Pais-liacht*. A church is front of
the rock would be the church in *Pais-liacht*. A church
did stand here previous to 1160: it is named in the
foundation charters *Ecclesia de Paisielit*, Latinized, in
the records of the monastery, *Paulatunum*, so easily derivate
from *Pais-liacht*, in all probability the original of the
modern Paisley. It was erected into a burgh of barony
by James IV, in the year 1488, at that time probably
deriving all its importance from the rich monastery
which had been established there for several ages; for
George Shaw, who was then abbot of the monastery,
obtained this privilege from the king. Even in Mr
Crawford's time, who wrote the history of the shire of Ren-
frew near the beginning of the 18th century, it seems
to have been but an inconvenient place; for he describes
it as consisting only of one principal street, about half a
mile in length, with several lanes belonging to it;
whereas now the town, with its suburbs, occupies such
an extent of ground, that strangers are apt to consider
it as, next to Edinburgh and Glasgow, the largest and
most populous town in Scotland. Its buildings of late
years have been greatly improved; its streets are well
paved; and the different parts of the town and suburbs,
where the river intervenes, are connected with one an-
other by three bridges at convenient distances.

In the affairs of the community are managed by three
bailies, of which the eldest is common in the commis-
sion of the peace, a treasurer, a town clerk, and 17
counsellors, who are annually elected upon the first
Monday after Michaelmas. It enjoys all the powers
necessary for government and police, without any of the
burdens to which royal boroughs are subject. The
freedom of the place is conferred on very moderate terms.
The revenues of the town are not great, but they have been
managed to the best advantage. The rapid increase
of the place has not been attended with a proportional in-
crease of revenue; therefore several necessary improve-
ments, and intended public buildings, are not yet car-
ried into execution. It gives the title of baron to the
earls of Abercorn; the first of whom was a younger son
of the Duc de Chatelherault. The black book of Paisley,
frequently mentioned in Scottish history, was a chronicle
of the public affairs and remarkable events, kept by the
monks who resided in the monastery. It agreed in every
material fact with the Scott Chronicle of Fordun; and
is by many thought to be the same performance.

The old part of the town runs from east to west upon
the south slope of a ridge of hills, from which there is
a fine prospect of the city of Glasgow and the adjacent
country; but to the southward, the view terminates in
a ridge of green hills, about two miles distant. Includ-
ing the late buildings and suburbs, it is fully a mile
long, and nearly as much in breadth. On the east side
of the river Cart, stand the abbey and new town. This
new town was some years ago faced off by the earl of
Abercorn, and now consists of a number of handsome
buildings. The streets are laid off in a regular manner,
but (rather unfortunately for the convenience and ele-
gance of some of the houses) not in right angles.
Here the earl of Abercorn has built at his own expense
one of the largest, most commodious, and most elegant
mansions in Scotland. In the vicinity of it was proposed
also to build several convenient and necessary market
places. A little south of the inn stands the ab-

Paisley church, the only one which Paisley formerly requi-
red. This church, when entire, has been a most noble
building, and consisted of several distinct and separate
places of worship; what now remains of this magnifi-
cent Gothic structure is not yet unworthy the notice of
curious observers. Mr. Pennant says, the great
north window is a noble ruin, the small octagon, the
middle pillar wonderfully light, and still entire: only the
chancel now remains, which is divided into a middle
and two side aisles, by very lofty pillars, with Gothic
arches; above these is another range of pillars much
larger, being the segment of a circle, and above a row
of arched niches from end to end, over which the roof
ends in a sharp point. The outside of the building is
decorated with a profusion of ornaments, especially the
great west and north doors, than which scarce anything
lighter or richer can be imagined.

The town of Paisley continued a part of the original
or Abbey parish of Paisley till the year 1738; when
the magistrates and council having purchased the right
of patronage from the then earl of Dundonald, a new
church was built, and the town was erected into a sepa-
rate parish. This is called the Leigh Church, is built
in the form of a Greek cross, very well laid out, and
able of containing a great number of people. In
1756 another church was built, upon a very extended
plan, to accommodate its multiplied inhabitants in
which, though it is one of the largest in Scotland, yet
the most distant of the congregation can hear a tolerably
good speaker with ease and distinctness; and as it stands
upon the highest part of the town, it was afterwards or-
namented with a lofty and well-proportioned spire, visible
at a great distance. This is called the High Church,
and is a very fine building: it is an oblong square of
82 feet by 62 within the walls, built of free stone well
smoothed, having rustic corners and an elegant stone
cornice at the top. In the construction of the roof
(which is a pavilion covered with slate, having a plat-
form covered with lead on the top), there is something
very curious, and it is admired by every person of taste.
In 1781, the number of the inhabitants still rapidly in-
creasing, another church, called the Middle Church, was
built, not quite so large as the former, but very hand-
somely and elegantly finished: and in the following year,
the town was divided and erected into three separate
parishes, exclusive of the Abbey parish, and named ac-
cording to their respective churches.

There are two large dissenting congregations in the
town; those of the Antiburgher persuasion and the
Reform. The first of these has existed there for upwards
of 30 years; the other is of a late date. There is be-
sides a small congregation of Cameronians.

The townhouse is a very handsome building of cut
stone, with a tall spire and a clock. The flesh market
has a genteel front of cut stone, and is one of the nest-
and most commodious of the kind in Britain. Butchers
meat, butter, cheese, fish, wool, and several other
articles, are sold here by what they call the ton
pound, of 22 English ounces and a half.

The poor house is a large building, very well laid
out; and stands opposite to the quay, in a fine free
air. It is supported by a small tax laid upon the inhabitants
quarterly.

Close by the Abbey church is the earl of Abercorn's
buriel.
Paisley, burial place, the greatest curiosity in Paisley. It is a vaulted Gothic chapel, without pulpit, pew, or any other ornament, but has the finest echo perhaps in the world. When the end door (the only one it has) is shut, the noise is equal to a loud and very distant clap of thunder. If you strike a single note of music, you have the sound gradually ascending, with a great number of repetitions, till it dies away as if at an immense distance, and all the while diffusing itself through the circumambient air. If a good voice sings, or a musical instrument is well played upon, the effect is inexpressibly agreeable. The deeper, as well as the most acute tones, are distinctly reverberated, and these in regular intervals of time. When a musical instrument is sounded, it has the effect of a number of instruments of a like size and kind playing in concert. When a number of different instruments in unison sound the same note, a good ear is able to distinguish the variety of sound produced by each. A single instrument sounding a particular note, and then instantly its fifth, or any other concordant note, the two sounds can be heard, as it were, running into and uniting with each other in a manner peculiarly agreeable. But the effect of a variety of instruments playing in concert is particularly charming, and must excite such emotions in the soul as it is impossible to describe. In this chapel is the monument of Mary Bruce (a); she was daughter of Robert Bruce, and wife of Walter, great steward of Scotland, and mother of Robert II. In the same chapel were interred Elizabeth Muir and Euphemia Ross, both consorts to Robert II.

A particular account of the abbey of Paisley would fill many pages. It was founded as a priory for monks of the order of Cluny about the year 1160 by Walter, great steward of Scotland. It was afterwards raised to the rank of an abbacy; and the lands belonging to it were by Robert II. erected into a regality, under the jurisdiction of the abbot. After the Reformation, the abbacy was secularized by the pope in favour of Lord Claud Hamilton, third son of the duke of Chatelherault, in reward of his steady adherence to the cause of Queen Mary; and, in 1588, it was by the king and parliament erected into a temporal lordship, and Lord Claud was created Lord Paisley. The revenues of the abbacy were very considerable. They consisted of the tithes of 28 different parishes, with the property of the lordships of Paisley, of Kilpatrick in Dumbartonshire, and of Monkton in Ayrshire, extending each to a hundred merkland; and the forty pound land of Glen in Lochwinnoch, with the lands of Achnengow, Grange, &c. and a considerable detached property in different parts of the kingdom. All this property, with the patronage of the several churches, fell to Lord Claud Hamilton, last abbot of Paisley. It continued in that family till 1563.

Vol. XV. Part II.

(a) Her story is singular: In the year 1317, when she was big with child, she broke her neck in hunting near this place; the Caesarean operation was instantly performed, and the child taken out alive; but the operator aiming to hurt one eye with his instrument, occasioned the blemish that gave him afterwards the epithet of Blewer-eye; and the monument is also styled that of Queen Blairy. Elizabeth Muir died before the accession of her husband Robert.

(b) This was introduced into this town about 60 or 70 years ago. The method of making what is called glazed white thread, has been discovered and brought to as great perfection as that made by Mr Leland and Son, London. The value of this branch is computed at about 60,000l annually.
PAI

Paisley. The river on which Paisley stands runs from south to north; and falls into the Clyde, after it has joined the confluence of the rivers Grifie and Black Cart at Inchman bridge, about three miles below the town. At spring tides, vessels of 40 tons burden come up to the quay. The communication by water is of great importance to the inhabitants: for in this way they are frequently supplied with fish of different kinds, and can send their goods and manufactures to Port Glasgow and Greenock, and to Glasgow likewise; and now, by means of the great canal, they have also a communication with the frith of Forth.

The air here is moist; a necessary consequence of the prevailing south-west winds, which, coming loaded with vapour from the Atlantic, produce frequent and heavy rains. The effects of this moist atmosphere appear in rheumatisms, quinsseys, pulmonary ailments, and all the tribe of inflammatory disorders. Upon the whole, however, neither the town nor country adjacent can be said to be unhealthy. Contagious, indeed, at times visit this as other places, which run their usual course as epidemics; but none are remembered of any uncommon violence except a pleurey in summer 1771, and which, contrary to the received opinion, was not a pandemic. There are no disorders that can be said to be endemic, unless scrofula is to be excepted, which is still but too common. This has been ascribed to the water used by the inhabitants of Paisley: It more probably proceeded from, and certainly was greatly aggravated by, poor living, and by the damp shops which were necessary for the linen manufacture; for since silk weaving became the general employment, and increase of trade has introduced better living, this disorder is less frequent. From the same causes probably it is in that swelled and sore legs, once extremely common here, are now but rarely met with. Dysentery raging with great violence in 1763, since that time it has been scarcely complained of. Nervous fevers at times appear; but they are neither very general nor uncommonly fatal. It is to be apprehended, that the constant and sedentary posture of the weaver, and the laboursome life of the bleacher, are frequent causes of consumptive complaints. Intermittents, which, from the damp air, and adjoining moss, might be expected to be common, are not so much as known. W. Long. 4. 20. N. Lat. 55. 52.

PAITA, a sea-port of America, in Peru, and in the audience of Quito. The town consists of about 200 houses but one story high; and the walls are made of split cane and mud, and the roofs only a covering of leaves. The only defense of Paitsa is a fort without either ditch or outwork; but it is surrounded by a brick wall of little or no strength, on which are mounted eight pieces of cannon. It was frequently plundered by the buccaneers; and Commodore Anson got possession of its fort in 1741, and took and burnt the town because the governor refused to ransom it. W. Long. 81. 19. 8. Lat. 6. 12.

PAIX, or Port Paix, a town on the north coast of the island of Hispaniola, which has a pretty good harbour. W. Long. 72. 51. N. Lat. 19. 58.

PALACE.
PALACE, PALATIUM, a name generally given to the dwelling houses of kings, princes, and other great personages; and taking different epithets, according to the quality of the inhabitants, as imperial palace, royal palace, pontifical palace, cardinal palace, ducal palace, episcopal palace, &c.

It is customary in China to build palaces in honour of great ancestors. Hu-pi-lay, of the Mogul empire, in the year 1263, built one for his ancestors; and he is the first who borrowed this Chinese custom. Amongst the works of the ancient Egyptians, we have an account, in the Ancient Universal History, of a most magnificent palace in the Upper Egypt, not far from Aswan, the ancient Syene; the ruins whereof are enough to strike a spectator with astonishment. It is as large as a little city, having four avenues of columns, leading to as many porticoes. At each gate, between two pillars of porphyry, stand two gigantic figures of fine black marble, armed with maces. The avenues consist of columns set three and three together, in a triangle, on one pedestal: on the chapter of each triangle is placed a sphinx and a tomb alternately. Every column is 70 feet high, all of one stone. There are in all the four avenues about 5000 or 6000 of those columns, a great many of which are fallen down.

The first hall of this palace is adorned with pieces of history, which seem as fresh as if the painting had not been long finished. In some places they have represented the hunting of antelopes; in others, feasts, and a great many young children playing with all kinds of animals. From thence you go into other apartments, incrustated with marble, the roof being supported with pillars of porphyry and black marble. Notwithstanding the vast quantity of rubbish, our author made shift to get up to the top of this building, from whence he had a prospect of the ruins of the greatest city that ever had been, as he thought, in the world. He supposes it might be the ancient Thebes; but that city stood much lower.

PALÆMON, or MICHELIS. See MICHELIS.

PALÆMON, Q. Rhenusius, a famous grammarian of Rome, in the reign of Tiberius. He was born a slave at Vienza. We are told he was first brought up in the business of a weaver: but attending his master's son to school, he used this opportunity to procure knowledge; and acquired so much skill in the common learning, that he obtained his freedom, and became a teacher or preceptor at Rome. His claim to learning cannot be questioned, since he is recorded as a scholar even by Juvenal:

Quis quem dixit doctus Palæmonis afferit?
Quantum grammaticus meruit labor?

Sat. vii.

He had also an excellent memory, a ready elocution, and could make verses extemporane. On account of these qualities, notwithstanding his debauched course of life, which was such that nobody was more unworthy to have the preceptorship of youth, he held the first rank among those of his profession. But his arrogance surpassed his merit: he had the confidence to assert, that learning was born when he was born, and would die when he died; and that Virgil had inserted his name in his Eclogues by a certain prophetic spirit; for that he, Palæmon, would infallibly become one day sole judge and arbiter of all poetry. He was excessively prodigal for the gratification of his voluptuous humour; insomuch that neither the immense sums he gained by teaching, nor the great profit he made, both by cultivating his lands and in the way of traffic, proved a sufficient fund to support his extravagancies. We have only some fragments of his works.

PALEOLOGUS, MICHAEL, a very able man who was governor of Asia under the emperor Theodorus Lascaris; and who, by various stratagems and cruelties, procured the empire for himself and his posterity. See CONSTANTINOPE, from No. 145: to the end of that article.

PALKAPHOS (Strabo, Virgil, Pliny), a town of Cyprus, where stood a temple of Venus; and an adjoining town called Neo Paphos; where St Paul struck Elymas blind, and converted the proselyte Sergius Paulus.

PALESTRA, in Grecian antiquity, a public building where the youth exercised themselves in wrestling, running, playing at quoits, &c. To prevent the combatants from hurting themselves by falling, the bottoms of the palestra were covered with dust or gravel. Some will have the palestra to be only a part of the gymnasium. Many authors imagine that the palestra was of two kinds; the one for the exercise of the body, the other for the cultivation of the mind; but the derivation of the word seems to confine it to bodily exercise.

We have this account of the palestra in Barthelemai's Anacharsis: "They are nearly of the same form with the gymnasium. We visited the apartments appropriated to all the species of baths; those where the wrestlers leave their clothes, where they rub their bodies with oil to render their limbs supple, and where they roll themselves in the sand in order to give their antagonists a hold.

"Wrestling, leaping, tennis, and all the exercises of the lyceum, were here repeated before us with greater variety, and with more strength and skill on the part of the performers. Among the different groups before us we distinguished men of the most perfect beauty, and worthy of serving as models for artists: some with vigorous and boldly marked outlines, as Hercules is represented; and others of a more slim and elegant shape, as Achilles is described. The former, devoting themselves to wrestling and boxing, had no object but to increase their bodily strength; the latter, educated to less violent exercises, such as running, leaping, &c. confined themselves to acquirement of agility.

"Their regimen is suited to the different exercises for which they are designed. Some of them abstain from women and wine; others lead a very abstemious life; but those who make laborious exertions stand in need of a great quantity of substantial food, such as roasted beef and pork, to restore their strength. If they require only two minae a-day, with bread in proportion, they give a very favourable idea of their temperance. But several are mentioned who have made a terrible consumption of provisions. These men of Thamos, for instance, is said to have eaten a whole ox in a day. The same exploit is attributed to Milo of Crotona, whose usual quantity of food for a day was twenty minae of meat, as many of bread, and three congil of wine. It is said likewise, that Astydamas of Miletus, when at the table of Ario-
barzanes the Persian satrap, devoured alone the supper prepared for nine guests. These stories, no doubt exaggerated, prove at least the idea generally entertained of the voracity of this class of wrestlers. When they are able to gratify it without danger, they acquire extraordinary strength: their stature becomes sometimes gigantic; and their adversaries, struck with terror, either decline entering the lists, or sink under the weight of their enormous bodies.

"They are so oppressed by excess of nutriment as to be obliged to pass part of their lives in a profound sleep, and soon become so extremely corpulent as to be no longer known to be the same persons: this is succeeded by disorders which render them as wreathen as they have always been unserviceable to their country; for it cannot be denied that wrestling, boxing, and all those combats disputed with so much fury and obstinacy in the public solemnities, are no longer anything but ostentatious exhibitions, since tactics have been brought to perfection. Egypt at no time adopted them, as they give only a temporary strength. Lacedaemon has corrected their inconveniences by the wisdom of her institutions. In the other states of Greece, men have discovered, that, by injuring their children to them, they incur the risk of injuring their shape and preventing their growth; and that, in a more advanced age, professional wrestlers never make good soldiers, because they are unable to support hunger, thirst, watching, the smallest wants, or the most trifling deviation from their usual habits." See Pentathlum and Pancratium.

PALÆSTROPHYLAX, was the director of the palaistra, and the exercises performed there.

PALEMBANG, a town and district on the north-east coast of the island of Sumatra, where the Dutch had a factory. The town is situated on a river of the same name, about 60 miles from the sea. The religion is Mahometan. The town and district were taken possession of by the British forces in 1812.

PALAMEDEA, a genus of birds belonging to the order of grallae. See Ornithology Index.

PALAMEDES, a Greek chief, son of Nauplius king of Ithaca, by Cleomedes. He was sent by the Grecian princes who were going to the Trojan war, in order to bring Ulysses to the camp, who, to avoid the expedition, pretended insanity; and the better to carry on the imposition, he often harnessed different animals to a plough, and sowed salt instead of barley. Palamedes soon discovered the cheat. He knew that regret to part with Penelope, whom Ulysses had lately married, was his only reason for pretending insanity; and to demonstrate this, Palamedes took Telemachus, whom Penelope had lately been delivered, and put him before his father's plough. Ulysses turned the plough a different way, not to hurt his child. He was therefore obliged to attend the Greek princes to the war; but a mortal enmity took place between Ulysses and Palamedes. The king of Ithaca determined to take every opportunity to distress him; and when all his expectations were frustrated, he was mean enough to bribe one of his servants, and to make him dig a hole in his master's tent, and there conceal a large sum of money. After this Ulysses forged a letter in Phrygian characters, as from Priam to Palamedes. In the letter the Trojan king seemed to beg Palamedes to deliver into his hands the Grecian army, according to the conditions which had been previ-ously agreed upon when he received the money. This forged letter was carried, by means of Ulysses, before the princes of the Grecian army, Palamedes was summoned, and made the most solemn protestations of innocence, but in vain. The money that was discovered in his tent served to corroborate the accusation; and he was therefore found guilty by the whole army and sentenced to death. Homer is silent about the unfortunate fate of Palamedes; and Pausanias mentions, that it had been reported by some that Ulysses and Diomedes had drowned him in the sea as he was fishing on the coast. Philostratus, who mentions the tragic story as above related, adds, that Achilles and Ajax buried his body with great pomp on the sea-shore; and that they raised upon it a small chapel, where sacrifices were regularly offered by the inhabitants of Troas. Palamedes was a man of learning as well as a soldier; and, according to some, he completed the alphabet of Cadmus by the addition of the four letters η, θ, ρ, φ, during the Trojan war. To him also is attributed the invention of dice and backgammon; and it is said that he was the first who regularly ranged an army in a line of battle, and placed sentinels round the camp, and excited their vigilance and attention by giving them a watch-word.

PALARIO, among the Romans, a kind of exercise performed at a stake by the soldiers. The stake being fixed in the ground, and six feet high above it, the young undisciplined soldiers advanced against it, armed with a burdele and cudgel, instead of a sword and shield, and went through all the rules of attack and defence, as if actually engaged with an adversary. Sometimes they stood at a distance, and attacked with missile weapons; at the same time using all the requisite motions for defending themselves, and warding off what might be thrown against them.

PALATE, in Anatomy, the flesh that composes the roof, or the upper and inner part of the mouth.

The palate has much the same structure with the gums; but it has also a great number of glands, discovered so early as the time of Palpoues; these are principally situated in the hinder part near the uvula, where it is pendulous, in the manner of a curtain, which part is called the velum or clastrum, of the palate. The glands situated particularly in this part, secrete a mucous fluid, serving to lubricate the mouth and throat, and to facilitate deglutition: they have a great number of apertures there for the discharge of this humour into the mouth.

The great uses of this membrane are, to defend the bones of the palate from corrupting; and for preventing, by its clastrum or velum, the things to be swallowed from getting up to the nostrils.

PALATINATE, a province or signiory, possessed by a palatine.

PALATINATE of the Rhine, a province of Germany, divided into two parts by the Rhine, called the Upper and Lower Palatinate. The former lies in the circle of Bavaria, and belongs to the elector thereof; but the latter, in the circle we are now treating, belongs to the elector palatine. The latter part is bounded to the east by the county of Katzenelnbogen, the archbishopric of Mentz, the bishopric of Worms, and part of the territory of the Teutonic order in Frisania; to the west by Alsace, the duchy of Deuxponts, the county of Spantin,
Palatinate. Sponeheim, the duchy of Simmern, and certain districts of the electorate of Mentz; to the south by the duchy of Wurttemberg and the bishopric of Spire; and to the north by a part of the archbishopric of Mentz and the county of Katzenelobogen. It contains 41 towns, besides several boroughs; and is about 100 miles in length, and 70 in breadth. The air is healthful, and the soil fruitful in corn, pastureage, wine, tobacco, and all sorts of pulse and fruits, particularly walnuts, chestnuts, and almonds. This country also breeds abundance of cattle, and is well watered by the Neckar, the Nahe, and the Rhine. In the last of these, near Germersheim and Selz, is found gold; the exclusive right of searching for which is farmed out by the elector. The state of religion bath varied greatly here since the Reformation, Lutheranism and Calvinism having been uppermost by turns, till the electorate devolved to the Popish branches of the family, when Popery, with all its superstition and mummeries, was established anew: so that the Protestant religion is now on a very precarious footing in the Palatinate, though most of the natives are still of that persuasion: but the two sects of Protestants, namely, the Lutherans and Calvinists, have greatly contributed to their own ruin, by their mutual jealousy and animosity, being no less rancorous against one another than against their common adversaries the Papists. The Lutherans reckon themselves 50,000 strong, and are possessed of about 8 churches; but not one half of their preachers and schoolmasters have a competent maintenance. The number of Calvinist clergy here is estimated at 500, and that of the Roman Catholics at 400. Besides schools and Jesuit colleges in this country, there is one university, namely, that of Heidelberg; but there is very little trade in it except in wine. Authors are divided about the origin of the name Palatina, or Palatgraves, as the Germans call them; but it seems most likely to be derived from the palatia, or palaces, which the old Frankish and German kings and Roman emperors were possessed of in different parts of the country, and over which they appointed supreme stewards or judges, who are called Palatines or Palatgraves. The countries where these Palatines kept their courts, were, from them, called Palatinate; which name came last to be appropriated, by way of eminence, to this country, as being the most considerable of them. The ancient electoral line failing in 1685, the electorate devolved to Philip William duke of Neuburg; and upon the death of his second son Charles Philip, to the prince of Sultzbach. This elector has the title of arch-treasurer of the empire, as well as the elector of Brunswick Luneburg, and is the fifth in rank among the secular electors. He is also one of the vicars of the empire alternately with the elector of Bavaria, and enjoys many other prerogatives. In his own dominions, he disposes of all vacant benefices; but allows the ecclesiastical council, composed of two clergymen and two laymen, to present two candidates, of which he chooses one. He is also master of all the tithes in his dominions; but he either grants them to the clergy, or salaries in lieu of them, out of the revenues of the church. His title is Baron of the Rhine; arch-treasurer and elector of the holy Roman empire; duke of Bavaria, Juliers, Cleve, and Berg: prince of Mons; marquis of Bergen-op-Zoom; count of Veldens, Spoonhe, the Mark, and Ravensberg; and lord of Ravenstein. His quota to the army of the empire is 30 horse and 138 foot, or 914 florins monthly. Palatinate.

To the chamber of Wetzlar, he contributes, each term, 404 rixdollars, 82 kruithers. There is an order of knighthood in this country, viz. that of St Hubert; the badge of which is a quadrangular cross pendant to a red ribbon, with a star on the breast. The whole of the elector's revenue, arising from the Palatinate, the duchies of Berg and Juliers, the seigniority of Ravenstein, and the duchies of Neuburg and Sultzbach, hath been estimated at about 300,000l. per annum. The military establishment consists of several regiments of horse and foot, besides the horse and Swiss life guards: in time of peace he is said to maintain about 6000 men.

The part of the Lower Palatinate on the left side of the Rhine was overrun by the French in 1795, and annexed to the republic under the name of the Department of Mont Tonnerre. Of what remained on the right side, the greater part was given at a subsequent period to Baden, to which it remains united. But in 1815 the district on the left bank was separated from France, and with some additions on the west and south, was given to the king of Bavaria. In the modern part of the Universal History, we have the following account of the rise of the Palatinate of the Rhine, under the history of Germany.

"Though Conrad the son of Everhard inherited from his father the duchy of Franconia, with the counties of Hesse and Alsace, he could not succeed him in the dignity of Count Palatine, because Otho had taken it from his father, and conferred it on Herman third son of Arnold duke of Bavaria: but as this honour was unattended with any solid advantage, the emperor began to annex to it the lands and castles situated on the Rhine, whence he acquired the title of Count Palatine of the Rhine: and, in process of time, these counts made great acquisitions by marriages, purchases, mortgages, and imperial donations, so as to form a very considerable province." The powers of counts palatine in the German empire have always been ample; we have this account of it in the same learned work.

When the counts palatine of the Rhine began to execute their office, they neither possessed on that river lands, cities, nor castles; but having by degrees made great acquisitions by marriages, purchases, agreements, imperial donations, or otherwise, they have at length formed a very considerable principality. We are told that under the emperors of the house of Suabia, their authority and power increased greatly, though it was a gradual increase. Under the reign of the emperor Henry IV. the credit of the counts palatine was very considerable at the court; and by the German law, the count palatine of the Rhine enjoys not only during the absence of the emperor, but likewise during a vacancy of the empire, the right of the ban beyond the Rhine, to within a mile of the city of Metz, and as far as the ocean, as well as in Flanders. However, this right of the ban has not been granted to him by the emperors. There is likewise an ancient ordinance, in which the office of count palatine is mentioned; it imports, that the count palatine is always by right the representative or lieutenant of the kingdom. Lastly, how great the power of the counts palatine was, may be understood from this, that in the election of Rodolphus of Hapsburgh, and in that of Henry VII. the other electors promised to acknowledge as emperor him whom he should
PALATINES

Palatinate should name. Although, however, the power of the counts palatine had as it were secured to them the vicarage of the empire, nevertheless the emperors still reserved to themselves the right of establishing vicars. See BAVARIA.

PALATINATES of POLAND. Previous to the revolution in this unfortunate country, it was divided into palatinates; whether those will be now changed cannot at present be ascertained, though it seems likely. A Polish palatinate is thus described in the Universal History.

"A palatine may be regarded as the governor of a province, who levies and leads the troops of his own jurisdiction to join the army of the republic. His civil power is likewise considerable, as he presides at the assemblies of his palatinate, rates the prices of all commodities and merchandize in the province, regulates the weights and measures, and judges and defends the Jews within his jurisdiction. This part of his function is particularly specified, that a set of men the most useful and industrious in Poland may not be oppressed; the king beingaverse obliged, by his oath, to afford them the protection of the laws and his sovereignty. Under him is appointed a substitute or vice-palatine, who takes an oath to his superior, and must be possessed of a land estate to a certain value."

PALATINE, or COUNT PALATINE, a title anciently given to all persons who had any office or employment in the prince's palace: but afterwards conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, that is, a court of justice, in their own houses.

Counties Palatine in England.—Chester, Durham, and Lancaster, are called counties palatine. The two former are such by prescription, or immemorial custom; or, at least as old as the Norman conquest: the latter was created by King Edward III. in favour of Henry Plantagenet, first earl and then duke of Lancaster; whose heiress being unborn, it was left to John of Gaunt, the king's son, the franchise was greatly enlarged and confirmed in parliament, to honour John of Gaunt himself, whom, on the death of his father-in-law, the king had also created duke of Lancaster. Counties palatine are also called \textit{à palatio}; because the owners thereof, the earl of Chester, the bishop of Durham, and the duke of Lancaster, had in those counties \textit{jura regalia}, as fully as the king hath in his palace; \textit{regalem potestatem in omnibus}, as Bracton expresses it. They might pardon treasons, murders, and felonies; they appointed all judges and justices of the peace; all writs and indictments ran in their names, as in other counties in the king's; and all offences were said to be done against their peace, and not, as in other places, \textit{contra pacem domini regis}. And indeed by the ancient law, in all peculiar jurisdictions, offences were said to be done against his peace in whose court they were tried; in a court-leet, \textit{contra pacem domini}; in the court of a corporation, \textit{contra pacem bali-}

diavorum; in the sheriff's court or town, \textit{contra pacem vicariorum}. These palatine privileges (so similar to the regal independent jurisdictions usurped by the great barons on the continent during the weak and infant state of the first feudal kingdoms in Europe) were in all probability originally granted to the counties of Chester and Durham, because they bordered upon enemies countries, Wales and Scotland: in order that the owners, being Palatine, encouraged by so large an authority, might be the more watchful in its defence; and that the inhabitants, having justice administered at home, might be obliged to go out of the county, and leave it open to the enemy's incursions. And upon this account also there were formerly two other counties palatine, Pembroke and Hexam, the latter now united with Northumberland: but these were abolished by parliament, the former in 27 Henry VIII. the latter in 14 Eliz. And in 27 Hen. VIII. likewise, the powers before mentioned of owners of counties palatine were abridged; the reason for their continuance in a manner ceasing; though still all writs are witnessed in their names, and all forfeitures for treason by the common law secure to them.

Of these three, the county of Durham is now the only one remaining in the hands of a subject. For the earldom of Chester, as Camden testifies, was united to the crown by Henry III. and has ever since been given to the king's eldest son. And the county palatine or duchy of Lancaster was the property of Henry of Bohun, who, on a false charge, was banished, and there he was wrested the crown from King Richard II. and assumed the title of Henry IV. But he was too prudent to suffer this to be united to the crown; lest, if he lost one, he should lose the other also. For, as Plowden and Sir Edward Coke observe, "he knew he had the duchy of Lancaster by sure and indefeasible title, but that his title to the crown was not so assured: for that after the decease of Richard II. the right of the crown was in the heir of Lionel duke of Clarence, second son of Edward III.; John of Gaunt, father to this Henry IV. being but the fourth son." And therefore he procured an act of parliament, in the first year of his reign, ordaining that the duchy of Lancaster, and all other his hereditary estates, with all their royalties and franchises, should remain to him and his heirs for ever; and should remain, descend, be administered, and governed, in like manner as if he never had attained the regal dignity: and thus they descend to his sons and grandsons Henry V. and Henry VI.; many new territories and privileges being annexed to the duchy by the former. Henry VI. being attained in 1 Edw. IV. this duchy was declared in parliament to have become forfeited to the crown, and at the same time an act was made to incorporate the duchy of Lancaster, to continue the county palatine (which might otherwise have determined by the attainer), and to make the same parcel of the duchy: and, farther to vest the whole in King Edward IV. and his heirs, kings of England, for ever; but under a separate governing and governance from the other inheritances of the crown. And in 1 Hen. VII. another act was made, to resume such part of the duchy lands as had been dismembered from it in the reign of Edw. IV. and to vest the inheritance of the whole in the king and his heirs for ever, as amply and largely, and in like manner, form, and condition, separate from the crown of England and possession of the same, as the three Henrys and Edward IV. or any of them, had and held the same.

The isle of Ely is not a county palatine, though sometimes erroneously called so, but only a royal franchise: the bishop having, by grant of King Hen. I. \textit{jura regalia} within the isle of Ely; whereby he exercises a jurisdiction over all causes, as well criminal as civil.

Palatin
PALATINE Games, in Roman antiquity, games instituted in honour of Augustus by his wife Livia, after he had been enrolled among the gods. They were celebrated in the palace, from whence the name, and were confirmed by the succeeding emperors.

Some authors say these games were instituted in honour of Julius Caesar, and others again confound them with the Ludi Augustales; but neither of these opinions seems to be well supported. See Augustales.

PALATINUS Mons, or Palatium, the first mountain of Rome occupied by Romulus, and where he fixed his residence and kept his court, as did Tullus Hostilius, Augustus, and all the succeeding emperors; and hence it is that the residence of princes is called palatium. The reason of the name is variously assigned; some say it is derived from the goddess Pales, or from the Palatini, who originally inhabited the place, or from balare or palare, the bleating of sheep, which were frequent there; or perhaps from the word palantes, wandering, because Evander, when he came to settle in Italy, gathered all the inhabitants, and made them all one society. To the east it has Mount Carus, to the north the Aventine, to the west the Capitoline, and to the north the Forum.——Palatium, the surname of Apollo from this place; where Augustus built a temple to that god, adorned with porcuses and a library, valuable for the various collections of Greek and Latin manuscripts which it contained.

PALATIUM, in Ancient Geography, a place in the territory of Reate, distant from it 25 stadia. Dionysius Halicarnassaeus reckons it one of the first towns of the Aborigines; and from it Varro accounts for the name of the Mons Palatium; namely, that a colony from Palatium settled there.

Palatium (Pliny), Palatium (Pausanias), Palatium (Livy); Palatium (Solinus). This last is the true writing; the great grandfather of Evander, from whom it took its name, being called Pallas, not Palas; A town of Arcadia, which concurred to form Megalopolis (Pausanias). From it the Palatium, or Mons Palatium, takes also its name, according to Virgil and Pliny:

Palatium Dioclesiání; the villa of Dioclesian, near Salone, where he died, (Eusebius). Afterwards called Spalatum; which rose to a considerable city from the ruins of Salone; situated in Dalmatia on the Adriatic. Now Spalato, or Spalato.

Palatium Luculi (Flutarch), or Villa Luculli; a place between Misenum and Baiae in Campania, of wonderful structure. Now in ruins, and called Piscina Mirabilis.

Palatino; See Anatomy, Table of the Muscles.

PALE, a little pointed stake or piece of wood used in making enclosures, separations, &c. The pale was an instrument of punishment and execution among the ancient Romans, and still continues so among the Turks. Hence empaling, the passing a sharp pale up the fundament through the body.

Pale, in Heraldry. See Heraldry.

PALENCIA, a town of Spain, in the kingdom of Leon, with a rich archbishop's see. It had an university, but it was removed to Salamanca. It is seated in a fertile soil, on the river Carion, on the frontiers of Castile, in W. Long. 3. 7. N. Lat. 42. 10.

PALERMO, a city of Sicily, in the Val-di-Mazara, with an archbishop's see and a large harbour. This city (says Mr Hill*), which is the capital of Sicily, is a Town of great antiquity; and if a conjecture may be formed through Sicily and Calabria, it was formerly in a very flourishing condition. By whom it was founded is uncertain, nor have we any authentic accounts of its inhabitants till it became a colony of the Phoenicians, after which it passed into the hands of the various nations that became masters of this island. The present city principally consists of two wide, uniform, and well built streets, each about a mile in length, crossing each other at right angles in the centre, where there is a small octagon space, ornamented with four statues. Most of the cities of Sicily have the same surnames: Palermo is denominated the happy. It has gained this epithet, no doubt, on account of the advantages of its situation. It has two harbours: in the one, which is very large, and in which there is a mole 1300 paces in length, ships lie at anchor; in the other their cargoes are laden and unladen. Both the harbours open to the west: there is also a superb quay which extends a mile from west to east, in a rectilinear direction, and is called La Marina. The prospect is, on the one side, lost in the wide expanse of the ocean, and on the other confined by the walls of the city; the walls appear adorned with pilasters, and crowned with a row of balustrades through which the eye discovers a long range of palaces. These objects altogether form a delightful spectacle. Indeed nothing can be more picturesque than the bay of Palermo. It forms a large amphitheatre, with the capital of Sicily in the centre; surrounded for some miles by a most delightful country, and enclosed by romantic rocks and mountains. The town was formerly surrounded by a strong wall; but the fortifications are now entirely neglected, except towards the sea, where there are still a few weak works. The quay is the principal public walk here. Palermo is embellished all around with avenues of trees, and has four principal entrances, facing the four cardinal points, which are at the extremities of the two spacious streets which cross each other. The most frequented of these two streets is called Cassero. It begins where the quay ends, with the north gate called Porta Felice, the happy gate; and terminates on the south, at the new gate, which opens on the road to Montreal. Near the last of these gates, this city, which so well merits the attention of a lover of arts, exhibits a large square of buildings; stand some extensive monasteries, the palace of the archbishop, and the palace of the viceroy. Directly opposite to the palace of the viceroy stands, on a pedestal richly ornamented with a variety of figures, a statue of Philip IV. The statue, the pedestal, and the ornaments are all of marble.

Palermo is quite filled with public monuments, churches, monasteries, palaces, fountains, statues, and columns. These are not all eminently beautiful; for they have not been all erected under the reign of good taste; but every one of them shows that the nation is fond of the arts, and possesses a genius for decoration. Spring waters are very copious in this city. Not a quarter in Palermo but is liberally supplied with fountains,
with common churches, only on a smaller scale. The Palermo
nave is circled with pillars; on the right and the left are
two narrower openings, called lateral or low passa-
ges: the choir and sanctuary are at the end of the nave.
Among all the pillars which enclose the nave, it would
be hard to find two exactly of the same form and work-
manship. Opposite to a channelled column stands an-
other on which the graving tool has made no such im-
pressions; several have neither astragel, nor base, nor
scale: they are formed of various kinds of marble, and
are of different orders and unequal in height. The walls,
the arcades, and the arches, are covered with mo-
saic work, in gold and colours, representing angels, and
male and female saints.

Over the entrance into the choir, and fronting the nave,
there is an Eternal Father of a huge size; the de-
sign of which has, in all probability, been to impress
the beholder with a sufficiently awful idea of the great-
ness of God. Such representations of the deity, how-
ever improper, not to say impious, occur pretty com-
monly in the churches of Sicily. The cathedrals of
both Monreale and Palermo display the Divine Ma-
jesty with equal dignity. Over the walls of the cha-
pel there are many pieces of granite, porphyry, and
serpentine, cut into a round, or a square, or some other
form, and set like panes of glass. The edges are en-
circled with various draughts in gold and colours; de-
corations unquestionably expensive, as they are indeed
very finely executed in their kind. But it is amazing
that such irregularity of design was admitted in a build-
ing of such magnificence and raised at such an enormous
expense. The pavement of the chapel has been origi-
nally laid, and still consists in part of large blocks of tin,
porphyry, and serpentine. Most of these are round;
ornamented with compartments of draughts, and cover-
ed over, as well as the walls, with incrustations of co-
lored mosaic work. The seat designed for the vice-
croy is of the same kind, and highly ornamented. The
candlestick intended to receive the wax lights at the
festival of Easter is of white marble. All the riches of
sculpture are lavished on it with such profusion as ren-
der it a prodigy of labour; but in a fantastic unnatu-
ral way.

In a long gallery in the palace of the viceroy, stand
two figures of rams in bronze, concerning which we
find the following tradition.—Archimedes is said to
have long ago erected in one of the public squares of
Syracuse four columns with a brazen ram upon the top of
each. He is said to have placed them there in such
a posture, as that some one of them always indicated
which of the four principal winds was blowing; and it is
added, that they were fabricated with such art, that the
wind caused them to utter sounds exactly similar to the
bleating of sheep; and whenever any one of the four
bleated, he thereby gave notice that the wind was blow-
ing from that quarter towards which he stood. It is
certain (as travellers inform us) that the two brazen
rams in this gallery are perforated with small holes in
their flanks, close to their thighs, and in other places
over their bodies; and the blowing through these
holes a sound is produced pretty much like the bleating
of sheep. The wind appears to pass through the holes,
and to pass out at the mouth: there might, however,
be other holes in the pedestal on which the ram stood,
or in other parts of the body, which might contribute to
produce
produce the bleating; for travellers agree in saying, that those which they could observe do not appear to be sufficient to produce the effect. The prince of Torre Musa, one of the most enlightened men in Sicily, informed M. Houel, that these two rams were dug up from among the ruins of Syracuse in the fourteenth century: as they were buried under ground, they had probably lain there for many centuries. They were bought by the Marquis Geraci, of the family of Ventimiglia, and lay long in his castle. About the end of the 17th century they were brought to Palermo, and placed in the palace of the viceroy. It is not known what is become of the other two. They are probably buried in some ancient ruins, and may be one day or other discovered in digging for the foundation of some new building. The proportions of these two rams are larger than nature. They are pieces of very fine workmanship: both the heads and the horns are formed with taste, delicacy, and truth; the wool is not so well executed; the forms all together are not absolutely the finest that might be selected from among the whole species.

The cathedral of Palermo is dedicated to St Rosalia. The Sicilians, though so exceedingly devout, have been neglected to repair it; and it is at present in a most miserable state, as the interior parts appear to be falling into ruins. Proposals have been made for rebuilding it, and various plans have been shown.

The present church appears to have been built by the Counts Roger. The external parts are in a Gothic taste, and very heavy: within, it has been at different periods repaired and embellished. The pillars of the nave are adorned with pilasters of the Corinthian order: these are joined by arches through which you pass to the sides of the building. In some places it is overloaded with ornaments, in others but very poorly ornamented: viewed all together, it is so destitute of order or propriety, as to be absolutely ridiculous.

In a chapel on one side of the cathedral are four Gothic tombs of the same period. They have been originally sarcophagi; and having escaped the fate of most of the other works of antiquity, have been spoiled by attempts to repair or improve them, and have been set up here to preserve the remains of some of the kings of Sicily. The only thing about them that can deserve attention is the beauty of the stone; they are of a fine red porphyry.

In the same chapel there is a fine large tabernacle; the whole of which, when viewed without distinction of the parts, resembles the dome and the front gate of the Val-de-grâce at Paris. It is of rich lapis lazuli, of the very finest colour. The whole of it is plated, and the pillars are said to be solid. All its ornaments are of gilt brass; and on the whole it is extremely beautiful.

Around the church are several statues of saints by Giugini, the celebrated sculptor. On the way from the cathedral down the Cassere there is, on the right hand, a small square, at the entrance of which stands a pedes-

trian statue of Charles V. in bronze. Near the place where the two great streets cross stands the senate house, in a small court, before which there is a fine marble fountain; there are besides about this edifice many curi-

ous fragments of antiquity. It would extend this ar-
ticle beyond all proportion if we were to mention all the curiosities which are to be found in Palermo. We shall now endeavour to give our readers an idea of the internal government of the place, which we shall do in the words of Mr Hill.

"The magistrates appointed to preserve the order of society in this city are, first, the supreme judge, to whom belongs the administration of justice in criminal cases; he is the head of the nobility, and immediately follows the viceroy in all the solemn functions. Secondly, The praetor, who regulates the affairs of the city. He is the perpetual deputy of the kingdom; chief in parliament of the order to whom appertains the right of regulating the king's demesne, and possessed of the prerogative of captain-general during the absence of the viceroy. Thirdly, The praetorian court, which consists of three judges, citizens of Palermo, who are chosen annually by the king. They assist the supreme judge in the decision of criminal affairs, and the praetor in the deliberations upon the finances; these two officers, however, have neither vote nor signature, except the praetor, in the business respecting the public bank and first fruits.

Fourthly, The senate of Palermo, composed of the praetor and six practitioners of the law, named by the king, who wear the toga after the manner of the ancient Roman senators, and principally inspect the police which regards the grain and provisions. There are besides seven great officers of state, to each of whom is assigned a peculiar employment. First, Il Maestro Portolano, to whom is committed the care of the public granaries, and who manages the sale of the corn both at home and abroad. The imposition of a tax upon this commodity has nearly proved the ruin of agriculture, especially as the exportation of it is prohibited to all those who are not able to pay an exorbitant price for that privilege. The quantity of corn annually produced in the island does not at present amount to more than a tenth part of what was collected in former years. Secondly, The auditor general, who passes judgment without appeal upon all offenses committed within the precincts of the palace. Thirdly, The high admiral, whose jurisdiction extends over the marine. Fourthly, The chancellor, who overlooks all the notaries of the kingdom, prepares all official patents, reads the propositions when the parliament assembles, and at the time of a coronation orders the oath of fidelity to the people, and also proclaims that of the monarch, who thereby binds himself to maintain and defend the privileges of the city of Palermo. The same ceremony takes place upon the installation of a viceroy. Fifthly, The prothonotary of the queen's chamber, who has the inspection of the demesnes of six cities, viz. Syracuse, Lentini, Carcintini, St Filippo, Micas, and Virdini, which were formerly appropriated to the queens of Sicily. Sixthly, The chief secretary, who presides over the officers appointed to receive the taxes and duties in the places of their respective jurisdictions. And, seventhly, The lieutenant of the royal exchequer, who has the administration of all effects that have been sequestered or confiscated.

"Palermo is the principal residence of the greater part of the Sicilian nobility; and as it is not the custom for any gentleman to walk in the streets, at least 1000 carriages are said to be kept in the town. They are for the most part in the English taste, very elegant, shown
shown to the greatest advantage, with beautiful horses richly caparisoned, and as many footmen in splendid liveries as can be crowded together behind. Every evening all the people of rank drive about in this manner on the grand public terrace by the sea side. There are also very convenient hackney coaches, covered and open, waiting all day in their respective stations.

It is very remarkable, that the dead in Palermo are never buried. Captain Sutherland gives the following account of this circumstance in his Tour to Constantinople. The dead bodies are carried to the Capuchin convent, which is one of the largest in Italy; “where, after the funeral service is performed, they are dried in a stove heated by a composition of time, which makes the skin adhere to the bones. They are then placed erect in niches, and fastened to the wall by the back or neck. A piece of coarse drab is thrown over the shoulders and round the waist; and their hands are tied together, holding a piece of paper with their epitaph, which is simply their names, age, and when they died. We of course (says Captain Sutherland) visited this famous repository; and it is natural to suppose that so many corpses would impress one with reverence and awe. It was nearly dusk when we arrived at the convent. We passed the chapel, where one of the order had just finished saying vespers, by the gloomy glimmering of a dying lamp. We were then conducted through a garden, where the yew, the cypress, and the barren orange, obscured the remaining light; and where melancholy silence is only disturbed by the hoarse murmuring of a feeble waterfall. All these circumstances turned our minds for the dismal scene which we were going to behold; but we had still to descend a flight of steps impervious to the sun; and, at last, conveyed us to the dreary mansion of the dead. But (will you believe me?) notwithstanding the chilling scene through which we had passed, notwithstanding our being in the midst of more than a thousand lifeless bodies, neither our respect for the dead, nor for the holy fathers who conducted us, could prevent our smiling.

The physiognomies of the deceased are so ridiculously mutilated, and their muscles so contracted and distorted in the drying, that no French mimic could equal their grimaces. Most of the corpses have lost the lower part of the nose; their nails are generally a little twisted; their mouths drawn awry in one direction; their noses in another; their eyes sunk and pointed different ways; one ear perhaps turned up, the other drawn down. The frions soon observed the mirth which these unexpected visages occasioned; and one of them, in a kind of memento, pointed out to me a captain of cavalry, who had just been cut off in the pride of his youth: but three months ago, he was the minion of a king—the favourite of a princess—Alas! how changed! Even on earth there is no distinction between him and the meanest beggar. This idea in a moment restored my reflection; and I felt with full force the folly of human vanity. I turned to the holy father, who gave me this lesson. His eyes were fixed on what was once a captain of horse.—I saw in them, ’Read this, titled pomp, and shrink to thy original nothingness. Hie thee to my lady’s chamber; tell her, though she paint an inch thick, to this must she come at last—make her laugh at that.’ The relations of the deceased are bound to send two wax tapers every year for the use of the convent; in default of which, the corpse is taken down and thrown into the charnel house. Were it not for the number of vacancies occasioned by the nonpayment of this stipend, the Capuchins would be unable to find niches for the number of men who must die every year in so populous a city as this. Women are dried as well as the men, but are not exposed. Nobles are siut up in chests.

The number of the inhabitants is above 200,000; and the harbour, though very large, is not so commodious as might be expected; and the vessels that ride therein are not always very safe. There is a magnificent castle built near the sea side, wherein the viceregal residence is not much less than six months in the year; and his presence draws a great number of nobility to this place. This city has suffered greatly by earthquakes, particularly in 1693; and it was greatly damaged by fire in 1770, when a magazine of powder was blown up, containing 400 tons. It stands in a pleasant fruitful country, on the north-east coast of the island, and at the bottom of the gulf of the same name. E. Long. 13. 23. N. Lat. 38. 15.

PALESTINE, in pagan worship, the goddess of the shepherds, to whom they offered milk and honey, in order that she might deliver them and their flocks from wild beasts and infectious diseases. This goddess is represented as an old woman. She was worshipped with great solemnity at Rome; and her festivals, called Palatin, were celebrated on the 21st of April, the very day that Romulus began to lay the foundation of the city of Rome; the ceremonies of which consisted in burning heaps of straw, and leaping over them. No sacrifices were offered, but purifications were made with the smoke of horses blood, and with the ashes of a calf that had been taken from the belly of its mother after it had been sacrificed, and with the ashes of beans. The purification of the flocks was also made with the smoke of sulphur, of the olive, the pine, the laurel, and the rosemary. Offerings of mild cheese, boiled wine, and cakes of millet, were afterwards made to the goddess. Some call the festival Parrilia, quass à puringo, because the sacrifices were offered to the divinity for the fecundity of the flocks.

PALESTINE, in its present state, is a part of Asiatic Turkey, situated between 31° 30' and 33° 20' north latitude, and between 34° 50' and 37° 15' east longitude. It is bounded by Mount Libanus, which divides it from Syria, on the north; by Mount Hermon, which separates it from Arabia Deserta on the east; by the mountains of Seir and the deserts of Arabia Petrae, on the south; and by the Mediterranean sea on the west.

This once fertile and happy spot was first called the land of Canaan, or Chanaan, from Noah’s grandson. In Scripture, however, it is frequently distinguished by other names; such as the Land of Promise, the Land of God, the Land of Israel, &c. It received the name of Palestine from the Philistines, who possessed a great part of it; and it has the name of Judaea, or Judea Palestina, from Judah, the most considerable of the twelve sons of Jacob. The Christians have denominated it the Holy Land; partly on account of the many singular blessings it received from the Divine Providence, and partly on account of its metropolis being made
made the centre of God's worship and his peculiar habitation; but much more for its being the place of our Saviour's birth, the scene of his preaching and manifold miracles: especially the place in which he accomplished the great work of our redemption. As to the name of Judea, it did not begin to receive that till after the return of the Jews from the Babylonian captivity, though it had been styled long before the Kingdom of Judah, in opposition to that of Israel, which revolted from it under Jeroboam, in the reign of Rehoboam the son of Solomon. But after the return, the tribe of Judah, the only one that made any figure, settling at Jerusalem, and in the countries adjacent, quickly gave its name to the whole territory. By profane authors it was called by many different names: such as Syria, Palestine Syria, Cælisyria, Iduma, Idumea, and Phœnicia or Phœnicise; but these are supposed only to have been given out of contempt to the Jewish nation, whom they looked upon as unworthy of any other name than what distinguished the most obscure parts of the neighbouring districts.

That part of the country which was properly called the Land of Promise, was enclosed on the west by the Mediterranean; on the east by the lake Asphaltites, the Jordan, the sea of Tiberias or of Galilee, and the Samachonite lake; to the north it had the mountains of Libanus, or rather of Antilibanus, or the province of Phœnicia; and to the south, that of Edom or Idumea, from which it was likewise parted by another ridge of high mountains. The boundaries of the other part, which belonged to the two tribes and a half beyond the river Jordan, are not so easily defined, as well as those of the conquests made by the more prosperous kings of the Jews. That all can be said with any probability is, that the river Arnon was the first northern boundary on that side; and with respect to those on this side the Jordan, there is a considerable disagreement between the Hebrew and Samaritan versions of the Pentateuch.

The extant of this country is likewise variously settled by geographers; some giving it more than 170 or 180 miles from north to south, and 140 in breadth where broadest, though not much above half that breadth where narrowest. But from the latest and most accurate maps, it appears to extend near 200 miles in length, and about 80 in breadth about the middle, and about 10 or 15, more or less, where it widens or contracts.

The climate is certainly very happy, its situation being neither too far south nor too far north. The longest day is not above 14 hours 15 minutes: But the limits of Palestine appear so small, considering that the country is likewise intersected by high ridges of mountains, woods, deserts, &c. that many learned men have been induced to question what we read of its fertility and populousness in former times. It must be owned, indeed, that when we compare its ancient and flourishing state, when it was cultivated with the most diligence, by persons well skilled in every branch of agriculture, with what it has been since the total extinction of the Jews out of it, and more especially since it fell into the hands of the Turks, the contrast is amazingly great: but when we consider the many evident causes which have contributed to effect this change, and even yet consider the nature of the country itself, we find not the least reason to doubt the truth of what the sacred historians have related. Moses describes the richness of it in the strongest terms, even before the Israelites got possession of it. It even exceeded the land of Egypt, so much celebrated by ancient historians; especially in the vast numbers of cattle which it produced; in the quantity and excellence of its wine, oil, and fruits. With respect to the oil and fruits, it is plain, that the olives and oil of Canaan exceeded in goodness those of Egypt, since the tribes sent them thither from thence; and as for vines, Herodotus tells us, that the Egyptians had none at all, but supplied the want of them by a liquor brewed from barley. The presents which Jacob sent to his son Joseph, of honey, spices, myrrh, almonds, and other fruits of Palestine, show that they must have been much better in the land of Judea than in Egypt. The wines of Gaza, Ascalon, and Sarepta, were famous among the most remote nations; though it is allowed, that the wine which was made at and in the neighbourhood of Bethlehem, in great quantities, was equal at least, if not superior, to any of the rest; and that of Libanus, mentioned by the prophet Hosea, was no less celebrated for its excellent flavour.

Several circumstances contributed to this wonderful fecundity: such as, the excellent temperature of the air, which was never subject to excessive heats or colds; the regularity of its seasons, especially the former and latter rain; and the natural fatness and fertility of its soil, which required neither dunging nor manuring, and could be ploughed with a single yoke of oxen and a small kind of plough; for the soil was, and is still, so shallow, that to have gone deep into it, would rather have endangered than improved the crop. With respect to the excellency of its corn, we are told, that the bread of Jerusalem was preferred above all other; and the tribe of Asher produced the best of both, and in greater quantity than any other tribe; and such plenty was there of it, that, besides what sufficed the inhabitants, who made it their chief sustenance, Solomon, we read, could afford to send 20,000 cors, or measures, of it, and as many more, to Hiram, king of Tyre; besides what they exported into other countries. And we find, even so late as King Herod, surnamed Agrippa, the countries of Tyre and Sidon received most of their sustenance from his tetrarchy.

As to their fruits, the grapes were delicious, finely flavoured, and very large. The palm tree and its dates were in no less request; and the plain of Jericho, among other places, was famed for the great plenty and excellence of that fruit; insomuch, that the metropolis of that territory was emphatically styled the city of palm trees. But what both this plain, and other parts of Palestine, were most celebrated for, was the balsam shrub, whose balm was esteemed so precious a drug among the Greeks, Romans, Egyptians, and other nations, and is still to this day, under the name of balm of Gilead. They bad likewise the greatest variety of other fruit trees in the highest perfection; and which might be, in some sense, styled perpetual, because they were not only covered with a constant verdure, but because the new buds always appeared on the same boughs before the old fruit was ripe; and of those buds, which were in too great quantities to be allowed to come to maturity, they gathered enough to make very delightful pickles and
Palestine. Sweetmeats, especially of their citrons, oranges, and apples of paradise, which last commonly hung by hundreds in a cluster, and as big as hen’s eggs, and of an excellent taste and flavour. Their vines yielded grapes twice, and sometimes three times a year, great quantities of which were dried up, and preserved for use, as well as their figs, plums, and other fruits. They had plenty of honey; the very trees distilled it; and the rocks yielded it in great quantities; but whether that of the latter kind was there deposited by the industrious bees, or produced some other way, is much disputed by travellers and naturalists. They likewise cultivated sugar canes in great abundance; and the cotton, hemp, and flax, were mostly of their own growth and manufacture, except some of a finer sort, that were brought to them from Egypt, and worn by those of the higher rank. Their vicinity to Libanus made the cedars, cypress, and other stately fragrant trees, very common in most parts of the land, but more especially in Jerusalem. Cattle, both large and small, they fed in vast quantities; and the billy countries not only afforded them variety and plenty of pasture, but also of water, which descended thence into the valleys and low lands, and fertilized them to the degree we have seen; besides several other rivers and brooks, some of the most remarkable of which we shall speak of in their proper places. But the most fertile pasture grounds were those on each side of the river Jordan; besides those of Sharon, or Sarona, the plains of Lydda, Jarmnia, and some others then justly famed for their fecundity. As for fish, the river above mentioned, the lake of Tiberias, and the Mediterranean sea, afforded, as they do to this day, great plenty and variety. Vast quantities were brought to Jerusalem, on which the inhabitants mostly subsisted; and hence one of the gates of that metropolis was, according to St Jerome, called the fish gate. The lake Asphalitizes yielded salt in abundance, wherewith to season and preserve their fish, which Galen affirms to have been preferable to any other for wholesomeness, digestion, and extenuation. In short, the Scripture is so pregnant with proofs of the extraordinary richness and fecundity of this once happy land, and the vast number of people that lived in it, almost wholly upon its product, to say nothing of the vast exports of its corn, wine, oil, raisins, and other fruits, &c. that a man must have taken a strange warp to infidelity, that can call it in question, merely on account of the melancholy and quite opposite figure it now makes under its present tyrannical government.

But its fertility has been called in question; and Voltaire and other infidel writers have raised difficulties and objections against the authority of Scripture, from the pretended sterility of the land of Judæa. In answer to which, the abbé Guenée communicated to the Academy of Inscriptions and Belles Lettres at Paris, Two Memoirs concerning the Fertility of Palestine, in order to show that such objections had no solid foundation.

In the first of them, the author proves, that from the captivity of Babylon to the war of Adriam, Judæa was always considered as a rich and fertile country. The positive and multiplied authorities of the writers of that period, Jews, Greeks, and Romans, not only attest in general the fertility of that country, but many of these writers, entering into a particular detail of circumstances, prove it from the nature of the climate, the qualities of the soil, and the excellencies and variety of its productions. These are confirmed by proofs of another kind, but which are of a very convincing nature, even those resulting from a great number of medals struck under the reigns of the kings of Syria and Judæa, and under the Romans, both by Jews and Pagans, and which all bear the symbols of a rich fertility. To these proofs are added a multitude of facts, recorded in the history of the Jews during this period; the efforts of the neighbouring kings to conquer their country; the long and bloody wars that the Jews carried on with vigour, and sometimes with success, against powerful princes and nations; the tribute and taxes they paid to the kings of Egypt and Syria, to the Romans, and to their own princes; the magnificence of their sovereigns, and among others of Herod; the troops he raised and kept on foot; the temples, fortresses, palaces, and cities, which he erected and embellished, not only in his own country, but also in Syria, Asia Minor, and even in Greece; the immense sums he lavished among the Romans, the donations he made to his own people, and the vast treasures which he left behind him: all these circumstances concur in proving the fertility and riches of Palestine during that period.

In the second memoir, the abbé Guenée considers the state of Palestine as it was from the time of the emperor Adrian to the caliphate of Omar, which comprehends a period of four centuries. From sundry facts he shows, that it could not then have been the barren country which it has been represented by some sceptical writers. He particularly mentions the project formed by Adrian of rebuilding and embellishing Jerusalem, of forming it into a Roman colony, and giving it its own name; a project of which he could never have entertained a thought, if Judæa, which he had seen and examined with his own eyes, had appeared to him such a barren and wretched country as it is said to be by some who have neither seen that country nor examined the matter with care and attention. Our author also produces a variety of other facts, to show that Judæa, after all that it had suffered from the desolations of war both in ancient and latter times, still remained at the period in question fertile, rich, and populous. This is the idea which the writers of the time, Pagan and Christian, as well as Jewish, have given of Palestine. Antoninus Martyr, a citizen of Phœnicia, who in the 6th century travelled to Palestine, and composed an account of his voyage, which is still extant, says, that the canton of Nazareth was not inferior to Egypt in corn and fruits; and that though the territory of that city was not very extensive, it abounded in wine, oil, and excellent honey. The country about Jericho appeared to him still more fertile. He saw Mount Tabor, which he represents as surrounded with cities: and he observed, in the neighbourhood of Jerusalem, vineyards, great plantations of fruit trees, and through the whole country a considerable number of hospitium, monasteries, and beautiful edifices. Our learned abbé, in concluding his work, acknowledges, that the opulence and fertility of Judæa might begin to diminish towards the middle of the period treated of in his second memoir: but he does not think
think that any argument can be drawn from hence against its having been at the commencement of this period in a flourishing state; and much less can any proof be brought from hence, that in preceding periods, under the kings, or under the administration of Moses, the country of Palestine was a barren and uncultivated district.

Besides, it ought to be considered, that it was then inhabited by an industrious people, who knew how to improve every inch of their land, and had made even the most desert and barren places to yield some kind of productions, by proper care and manure; so that the very rocks, which now appear quite bare and naked, were made to produce corn, pulse, or pasture; being, by the industry of the old inhabitants, covered with mould, which, through the laziness of the succeeding proprietors, has since washed off with rains and storms. We may add, that the kings themselves were not above encouraging all kinds of agriculture, both by precept and example; and, above all, that they had the divine blessing promised to their honest endeavours and industry: whereas it is now, and hath been since long, inhabited by a poor, lazy, indolent people, growing under an intolerable servitude and all manner of discouragements; by which their aversion to labour and agriculture, farther than what barely serves to supply their present wants, is become in a manner natural and invincible. We may further observe, after the judicious Mr. Maundrell, that there is no forming an idea of its ancient flourishing state, when under the influence of heaven, from what it is now under a visible curse. And, if we had not several concuring testimonies from profane authors, who have extolled the fecundity of Palestine, that single one of Julian the Apostle, a sworn enemy to Jews and Christians, as well as all the sacred writings, would be more than sufficient to prove it; who frequently makes mention, in his epistles, of the perpetuity, as well as excellence and great abundance, of its fruits and products. The visible effects of God's anger, which this country has felt not only under Titus Vespasian (when multitudes of inhabitants were either slain, or perished by the most severe famine, pestilence, and other calamities, and the rest sold for slaves into all lands; and new colonies sent to repopulate it, who found it in such desolate state, as quite discouraged them from restoring it to its pristine fruitfulness); but much more since that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and destructive Christians during the crusades; and in the oppression it now feels under the Turkish yoke, may be more easily owned to be more than sufficient to have wrought the dismal change we are speaking of, and to have reduced the far greater part into a mere desert.

Nevertheless, if we may credit those who have viewed it under this disadvantage, even to tell us, there are still such visible signs of its natural richness and fertility, as plainly show, that the bare want of culture is the main if not the only cause of its present poverty and barrenness. We shall hint, as a further proof of this, what a learned traveller hath lately written of it from his own observations.

"The Holy Land (says Dr. Shaw), were it as well peopled and cultivated as in former times, would still be more fruitful than the very best part of the coast of Syria and Phoenice; for the soil is generally much richer, and, all things considered, yields a preferable crop. Thus the cotton that is gathered in the plains of Ramah, Esdraelon, and Zabulun, is in greater esteem than what is cultivated near Siden and Tripoli. Neither is it possible for pulse, wheat, or any sort of grain to be more excellent than what is sold at Jerusalem. The barrenness, or scarcity rather, which some authors may, either ignorantly or maliciously, complain of, doth not proceed from the incapacity or natural unfruitfulness of the country, but from the want of inhabitants, and the great aversion there is to labour and industry in those few who possess it. There are, besides, such perpetual discords and depredations among the petty princes who share this fine country, that allowing it was better peopled, yet there would be small encouragement to sow, when it was uncertain who should gather in the harvest. Otherwise, the land is a good land, and still capable of affording its neighbours the like supplies of corn and oil which it is known to have done in the time of Solomon."

And Volney, in his Travels in Egypt and Syria, observes, that though the whole of Palestine is almost an entire level plain, without either river or rivulet in summer, and only watered by the winter torrents, the soil is yet good, and may even be termed fertile: for when the winter rains do not fail, every thing springs up in abundance; and the earth, which is black and fat, retains moisture sufficient for the growth of grain and vegetables during the summer. More cress, sesame, watermelons, and beans, are sown here than in any other part of the country. They also raise cotton, barley, and wheat; but though the latter be most esteemed, it is less cultivated, for fear of too much inviting the avarice of the Turkish governors and the rapacity of the Arabs.

Juda, in its largest sense, was divided into maritimo and inland, as well as into mountains and champaign; and again subdivided into Judas on this side, and Judas beyond Jordan. But the most considerable division is that which was made among the twelve tribes, by lot, to prevent all murmuring and discontent among that stubborn people; of these, two and a half were seated beyond Jordan, and the rest on this side. The next rea. &c. markable was made by King Solomon, who divided his kingdom into twelve provinces or districts, each under a peculiar officer; and every one of these was to supply the king with provisions for his household in his turn; that is, each for one month in the year. But the most Kings fatal division of all was that which obtained under his iv. &c. imprudent son Reboham, when ten of the twelve tribes revolted, under the conduct of Jeroboam, who became head of this new monarchy, styled the kingdom of Israel, in opposition to that of Judah, the title which distinguished the maimed kingdom of Reboham from that time downwards. Under the second temple the distinction lasted a considerable time, and the same bloody hatreds continued between them, and two kingdoms; that of Israel taking the name of Assyria from its capital. The inhabitants were a mixture of the old Israelites, and of new colonies sent thither by the kings of Assyria after their conquest of it, till they were subdued by the Maccabees, and their metropolis destroyed. Under the Romans it began to be divided into tetrarchies and toparchies: the larger were those of Judas, Samaria, and Galilee, Upper and Lower; the lesser, those of Garraritis, Sarea, and others of less note; all which lay on this side of the Jordan. The rest, on the
the other side were those of Gilead, Persea, Gania-
nitis, Auranitis, Batanea, and Decapolis. Josephus men-
tions another division made in Gabinius’s time into five
districts, or, as he styles them, 
橄欏 or 
 councillor, a-
greeable to the Roman manner; these were Jerusalem,
Jericho, and Seborsa, on this side Jordan; and Gadara
and Amathus on the other. In the reigns of the 
Christian emperors, it was divided areshinto Palestine Prima,
Palestina Secunda, and Palestine Tertia or Salutaris;
which last included the far greater part, if not the whole
country, as is known to all who are acquainted with
history. On that account we shall wave other divisions
and changes that happened to it under the northern bar-
barians, Saracens, &c. and conclude this article with
the present state and division of it under the Turks.

The whole country of Palestine is now reduced to a
district or province, under the beglerbegate or bashaship
of Sacham or Damascus, who hath the seven following sa-
giars or subgovernors under him, styled, according to the
different places of their residence. 1. The sanguiar of
Damascus, who is under the bashaw of that province; 2. Of
Jerusalem, or, as the Turks call it, 
7. Nabolos. Each of these has a number of 
ziemets, and each ziamet a number of timiaroys under them; for
the better understanding of which terms, we shall refer
our readers to Sir Paul Rycaut’s account of the 
Ottoman empire. At present it will be sufficient to say of these
inferior subdivisions, under the sanguiar of this district, or
sangiace of Jerusalem, that it hath nine of the former
and sixteen of the latter class. Neither must the reader
imagine these sanguiar or sub-governors to be any
thing considerable, or the residence of these officers to be
places of any note or opulence. The former indeed live
by oppressing the people under them, and extort con-
tributions of every thing that comes within their reach,
such as the protection of travellers, merchants, and cars-
vans; but being all under their respective bashats, who
are still more greasing than their underlings, they are
commonly fleeced of some considerable part of their un-
just gains. As for the places of their residence, except
it be here and there one in a considerable city, as at
Damascus and Jerusalem, the rest are either some old
cities or even inconsiderable villages.

There are a variety of curiosities in Palestine both
natural and artificial; but they are so very numerous as
almost to preclude description: we therefore refer
our readers to the Ancient Universal History, vol. ii. where
they are mentioned and particularly described. The
principal mountains, rivers, and other places of note,
have already been, or will be, noticed under their re-
spective names.

PALESTRINA, a town of Italy, in the Campagna
di Roma, with a bishop’s see. It is the capital of
a principality of the same name, and the bishop is one of
the six cardinal bishops. It was anciently famous for
the temple of Fortune, being then called 
Franeste, and
seated on the top of a mountain, the ruins of which may
yet be seen. E. Long. 12. 55 N. Lat. 41. 51.

PALESTRINA is one of the largest and most populous
of the islands called the Lagunes near Venice, and where
the most considerable of the noblemen have houses of plea-
sure. It is 15,000 acres in length and 400 in breadth;
the principal harbour has also the same name.

PALFREY, is one of the better sort of horses used
by noblemen or others for state; and sometimes of old
taken for a horse fit for a woman to ride. Camden
says, that William Faulconberge held the manor of
Cuckeney, in the county of Nottingham, in serjeancy,
by the service of shoeing the king’s palfer when the
king should come to Mansfield.

PALICAUD, or PALGATCHERRY, a fortress of con-
siderable strength in India, which commands the passage
between the two coasts of Malabar and Coromandel, by
which the Trichinopoly and Coimbatore country;
there is also a communication with it through the Nya-
ra country. It was held by the English; and was of great
importance to them, when Coimbatore was in the hands
of Tipoo, because, by our holding this place on the
west, and Dindigul on the east of Coimbatore, that pro-
vince was of little use to him in the time of war, with-
out a very large force to protect it. But the fall of that
sovereign, and the reduction of his territories, have ef-
fected a total change of circumstances. See Memoir
of a Map of the Peninsula of India by Major Renell.

PALICATE, a sea port town of India, on this side
of the Ganges. It is seated on the coast of Coromandel,
in the kingdom of Carnate, 70 miles north of Fort St.
George. Here the Dutch had a factory, and fort called
the Fort of Guelderland. E. Long. 86. 1 N. Lat. 13. 34.

PALLICI, or PALLI, in Fabulous History, two de-
ties, sons of Jupiter by Thalia, whom Αἰσχυλος, ac-
cording to Musonius, calls Ζένα, a tragedy which
is lost. The nymph Ζένα, when pregnant, begged Ju-
piter to remove her from the pursuit of Juno, Upon
whom he concealed her in the bowels of the earth; and
when the time of her delivery arrived, the earth opened
and brought into the world two children, to whom were
given the name of Palli, 
παλλί, παλλί, διό 
μηδενα
, because
they came again into the world from the bowels of the
earth. These deities were worshipped with many cer-
emonies by the Sicilians; and near their temple were two
small lakes, which were supposed to have sprung out of
the earth when they were born. Near those pools it was
usual to take the most solemn oaths when any body wish-
ed to decide controversies and quarrels. If any of
the persons who took the oaths were perjured, they were
immediately punished supernaturally; and those whose
oath, by the deities of the place, was sincere, departed
unhurt. The Palli had also an oracle, which was con-
sulted upon some great emergencies, and which rendered
the truest and most univocal answers. In a stupen-
dious age, the altars of the Palli were stained with the
blood of human sacrifices; but this barbarous custom
did not last long, as the deities were satisfied with the
usual offerings.

PALINDROMUS, a verse or sentence which runs
the same when read either backwards or forwards. Such
is the verse,

Roma tibi subito motibus ibit amor.

Some people of leisure have refined upon the Palindrome,
and composed verses, each word of which is the same
backwards as forwards; for instance, that of Camden:

Odo teneat mulum, modidam mappam tenet Anna.
Anna teneat mappam modidam, mulum teneat Odo.

PALINGENESIA, among divines, the same with
regeneration. Among the older chemists, it denotes the
producing of a body from its principles.

PALINGENUS,
PALINGENIUS, Marcellus, an Italian poet, well known by a poem divided into 12 books, and entitled Zodiaccus Vitae, which he was several years in composing, and dedicated to Hercules II. of Este, duke of Ferrara. Some say he was a physician to that prince: others rank him among the learned Lutherans, to whom the duchess of Ferrara gave a reception in her court, and honoured with her protection. His Zodiac contains good things, and is a philosophical satire against immorality and false prejudices. Of the author’s life, however, but little is known. He died some time between the years 1537 and 1543.

Palinody, a discourse contrary to former avowed principles; hence the phrase of palinodium canere was taken for a recantation.

PALINIUS POMONORIUM (Virgil, Velleius), with a commodious port, was situated at the south extremity of the Sinus Petusanus on the coast of Lucania: so called from Palinurus, Æneas’s steersman, who there perished (Mela, Dionysius Halicarnassaeus.)

PALINURUS, in Fabulous History, Æneas’s pilot, whose fate Virgil very particularly describes. He fell into the sea when asleep; and was three days exposed to the tempests and its agitation, and at last came safe ashore, when the cruel inhabitants of the place murdered him to get his clothes. His body was left unburied on the sea shore: and since, according to the religion of the old Romans, no one could cross the Stygian lake before 100 years were elapsed, if his remains had not been decently buried, we find Æneas, when he went down to hell, speaking to Palinurus, and assuring him, that though his bones were deprived of a funeral, yet the place where his body was exposed should soon be adorned with a monument, and bear his name; and accordingly a promontory was called Palinurus.

PALISADES, in fortification, stakes made of strong split wood, about nine feet long, or seven or eight inches square, three feet deep in the ground; in rows about two and a half or three inches asunder, placed in the covert way, at three feet from, and parallel to, the parapet or side of the glacis, to secure it from surprise. They are also used to fortify the avenues of open forts, gorges, half moons, the bottoms of ditches, and in general all posts liable to surprise. They are usually fixed perpendicularly, though some make an angle inclining towards the ground next the enemy, that the ropes cast over them to tear them up may slip off.

Turning Palisades: an invention of M. Coehorn, in order to preserve the palisades of the covert way from the besiegers shot. They are so ordered, that as many of them as stand in the length of a rod, or about ten feet, turn up and down like traps, so as not to be in sight of the enemy till they just bring on their attack; and yet are always ready to do the proper service of palisades.

PALISSEE, in Heraldry, a bearing like a range of palisades before a fortification, represented on a fesse, rising up a considerable height, and pointed a-top, with the field appearing between them.

PALIUS, in Botany. See Rhambus, Botany Index.

PALL, in Heraldry, a figure like a Greek χ, about the breadth of a pellet; it is by some heralds called a cross pall, on account of its being looked upon as an archiepiscopal bearing.

PALLA, in Roman antiquity, a mantle which women wore over the gown called stola. It was borne on the left shoulder; whence passing to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare. It had a great many folds, and derived its name from τάκλα, to shake or tremble.

Palladio, Andrea, a celebrated Italian architect of the 16th century, was a native of Vicenza in Lombardy, and the disciple of Trissin. He made exact drawings of the principal works of antiquity in Rome, adding commentaries to them, which went through several impressions. But this, though a very useful work, was greatly exceeded by the Treatise of Architecture in four books, which he published in 1570. Inigo Jones wrote some excellent remarks on it; which were included in an edition of Palladio, published by Leonis, in two parts, folio, 1741.

Palladium, in antiquity, a statue of the godess Pallas. It was about three cubits high, and represented the goddess sitting and holding a pike in her right hand, and in her left a distaff and a spindle. It fell down from heaven near the tent of Ilias, as he was building the citadel of Illium. Some, however, suppose, that it fell at Pessinus in Phrygia; or, according to others, Dardanus got it as a present from his mother Electra. There are some who maintain, that the palladium was made with the bones of Pelops by Abaris; but Apollodorus says, that it was no more than a piece of clockwork which moved itself. However various the opinions of ancient authors be about this celebrated statue, it is universally allowed, that on its preservation depended the safety of Troy. This fatality the Greeks, during the Trojan war, were well aware of; and therefore Ulysses and Diomedes were commissioned to steal it. This they effected; and if we can rely upon the authority of some, they were directed how to carry it away by Helenus, a son of Priam, who in this betrayed his country, because his brother Deiphobus, at the death of Paris, had married Helen, of whom he was enamoured. Minerva was enraged at the violence offered to her statue; and, according to Virgil, the palladium itself seemed to have received life and motion; and by the flashes which started from its eyes, and sudden risings from the earth, it seemed to show the resentment of the goddess. The true palladium, as is observed by some, was not carried away from Troy by the Greeks, but only a statue of similar size and shape, which was placed near it, to deceive whatever sacrilegious persons attempted to steal it. The palladium, therefore, as they maintain, was conveyed safe from Troy to Italy, and it was afterwards preserved by the Romans, with the greatest secrecy and veneration in the temple of Vesta; a circumstance which none but the vestal virgins knew. It was esteemed the destiny of Rome; and there were several others made perfectly like it, to secure it from being stolen, as was that of Troy, which the oracle of Apollo declared should never be taken so long as the palladium was found within its walls. A palladium was also placed by Nicetas in the citadel of Athens.

Palladium, one of the newly discovered metals, which is found alloyed with platina. See Chemistry Index, and Ores, Reduction of, under Platina.

Palladius, bishop of Helenopolis in Bithynia, and then of Aspasia. He was a Galatian, and born at Cappadocia.
Pallas was a revered man of Claudius, celebrated for the power and the riches which he obtained. He advised the emperor to marry Agrippina, and to adopt his son Nero for his successor. It was through him and Agrippina that the death of Claudius was hastened, and that Nero was raised to the throne. Nero, however, forgot to whom he was indebted for his coronation. He discarded Pallas, and some time after caused him to be put to death, that he might procure his great riches.

Pallas, a small planet recently discovered, belonging to the solar system. See Planet.

Pallavicini, Ferrante, an Italian writer, descended from a noble family in Placentia, was born about the close of the 16th century. He soon gave proofs of an extraordinary genius, and quickly improved in classical studies. He was afterwards sent to complete his education in the monastery of Augustinian friars at Milan, where he took the habit, lived much esteemed for piety and learning, and raised great expectations of future fame; but being somewhat amorously inclined, he engaged in an intrigue with a young courtier of Venice, whose charms proved irresistible; and in order to enjoy them without restraint, he obtained leave from his general to make the tour of France. Accordingly, he pretended to set out for that country; but it was only a blind to cover his real design. He never left Venice, but lived there privately, enchanted in the arms of his Venus; and having, too, ready a talent at invention, he imposed upon his friends by often sending them in letters forged accounts of his travels through France; also informing them of several things respecting that court, which he learned from the advices of many considerable persons with whom he corresponded.

His finances were in the mean time greatly reduced; and in this exigence he naturally had recourse to his wits for supplies. He wrote for the booksellers; and composed several pieces, more for the sake of lucre than out of kindness for authorship. Among other things, he wrote a collection of letters, mostly satirical, which he called The Courier Robbed of his Mail. The work appeared at first in such a cast, as could not give great offence except to the Spaniards, against whom he had no grudge. The piece was accordingly licensed by the inquisitors; but falling into the hands of the secretaries of the republic of Venice, who at that time was licensor of books, he would not give his imprimatur, though great interest was employed for that purpose, neither would he return the manuscript. This enraged Pallavicini so much, that had not his friends restrained him, he would have pursued the affair to his ruin.

At length he found an opportunity of travelling into Germany with the duke of Analfi, as his chaplain. This journey, as was to be expected, had no good effect either upon his wit or his morals. On the contrary, finding himself, from the manners of the Germans, more at liberty, he indulged his genius and passions with greater ease; and after a residence there of upwards of a year with the duke, he returned to Venice. He was now resolved to have his full measure of revenge against the secretary of the republic for keeping his manuscript; and with him his resentment joined the family of Barberini, Pope Urban VIII. and his nephew, because they also endeavoured, at the instigation of the Jesuits, to get all his manuscripts forbid the press. In this rancorous spirit he cast his Courier into a new model, and enlarged it with many letters and discourses. Thus new modelled, he offered it to a bookseller, who undertook to get it printed; but our author was betrayed by a pretended friend, who acted the part of a spy, and informed the archbishop of Vitelli, then the pope's nuncio at Venice, just as the work was finished at the press: at the same time, this treacherous friend bought the whole impression; and upon the nuncio's complaint, Pallavicini was imprisoned. In this miserable condition he found a friend in one of his mistresses, who, seeing him abandoned by most of his patrons, not only supported him, but conveyed letters to him, by which she gave him such information as enabled him to make a proper defence, and to recover his liberty.

But a war having in the mean time broken out between the Barberini and the duke of Parma; Pallavicini, in order to revenge himself upon the supposed instruments of his imprisonment, wrote a piece entitled "The Tinkling Instrument to call together the Barberini Bees;" and dedicated it in terms of the profoundest contempt to the nuncio Vitelli. The nuncio, finding that little notice was taken of his complaints on the occasion, procured by bribery one Charles Morfo, a Frenchman of infamous character, who pretended to pass for a gentleman, to ensnare Pallavicini; to which end, the traitor used his best endeavours to insinuate himself into his friendship, and at length exorted him to accompany him to France. He declared that his fortune would be made by the extraordinary encouragement which was given to men of letters by Cardinal Richelieu; and the better to favour the project, he produced forged letters from the Cardinal, inviting our author to France, and expressing a desire he had to establish in Paris an academy for the Italian tongue, under the direction of Pallavicini. The news took; and now, fascinated by the prospect of gain, Pallavicini suffered himself to be led like an ox to the slaughter, whitewas over Morfo thought proper. He left Venice much against the advice of his friends, and went first to Bergamo, where he spent a few
his return from Germany, but when he was in the company of some mean women. Upon the whole, it is difficult to determine whether vice or virtue was the most predominant feature in his character. His death gave birth to a dialogue, entitled, \textit{Anima erranti di Ferrante Pallavicini}, or, \textit{The wandering Ghost of Pallavicini.} Besides his life at the head of his works in two volumes, there is another prefixed to the \textit{Divortio celeste,} at Amsterdam, 1696.

\textsc{Pallene}, a small peninsula of Thrace or Macedon, formerly called \textit{Pityros.} It is situated near the bay of Thermus, and contains five cities, the principal of which is called \textit{Pallene.} It was famous, according to some of the ancients, for an engagement between the gods and the giants.

\textsc{Pallet}, among painters, a little oval table, or piece of wood or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil. This middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but, instead thereof, a hole at one end to put the thumb through to hold it.

\textsc{Pallet}, among potters, crucible makers, &c. a wooden instrument, almost the only one they use, for forming, beating, and rounding their works. They have several kinds: the largest are oval, with a handle; others are round, or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off whatever is superfluous on the moulds of their work.

\textsc{Pallet}, in gilding, an instrument made of a squirrel's tail, to take up the gold leaves from the pillow, and to apply and extend them on the matter to be gilt. See \textsc{Gilding}.

\textsc{Pallet}, in \textit{Heraldry}, is nothing but a small pail, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

\textsc{Pallet}, is also a part belonging to the balance of a watch or movement. See the article \textit{Watch}.

\textsc{Palliatæ}, a name which the Romans gave to such plays as laid the plot in Greece, and required the performers to appear in Grecian habits. It is used in distinction to \textit{togæ}, in which the scene was laid at Rome, and in which the dresses were Roman. The word palliast is derived from \textit{pallium}, which was a part of dress peculiar to the Greeks; whereas the toga belonged to the Romans only. See \textit{Togæ, Comedy}, &c.

\textsc{Palliation}, or a \textit{Palliative Cure}, in \textit{Medicine}, is when, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain or some other urgent symptoms, as in ulcerated cancers, or cananeous fistulas, and the like.

\textsc{Pallio Cooperiti}. It was an ancient custom, where children were borne out of lawful wedlock, and their parents were afterwards married, that those children, together with the father and mother, should stand \textit{pallio cooperiti}, under a cloth, while the marriage was solemnized; which was a kind of adoption, and had the effect of a legitimation. Thus Robert Grosbool, the famous bishop of Lincoln, in one of his letters says: \textit{In signum legitimatis, nati ante matrimonium consue}
P A L [ 714 ]

Palermo Old Palermo, or Palma Nova, a very strong town of Italy, in Friuli, in the territory of Venice. It is a very important place, for the defence of the Venetians against the Austrians and Turks; and was built in 1593, for that very purpose. They have cut a canal near this place, which is very advantageous. It is seated on the sea side, 10 miles south-east of Udine, and 55 north-east of Venice. East Long. 13° 15', North Lat. 46° 2. 0.

PALLMA, an island in the Atlantic ocean, and one of the Canaries, 56 miles north-west of Gomera, and about 75 in circumference. It abounds in wine and sugar; and has a handsome town of the same name, which carries on a trade in wine to the West Indies and other parts. Their best vines grow in a soil called the Bremia, where they make 12,000 butts of wine every year, which is well known by the name of palm wine. There is plenty of cattle, and all sorts of fruits. In 1625 a volcano broke out in this island, with a most violent earthquake; the flame was seen for six weeks together, and a great quantity of ashes were thrown as far as Tenerife. It was conquered by the Spaniards in 1460.

PALMAE, Palma. Under this name Linnaeus has arranged several genera, which, although capable of a place in separate classes of his system, he chooses rather, on account of their singular structure, to place apart, in an appendix to the work.—See Botany Index.

The same plants constitute one of the seven families or tribes into which all vegetables are distributed by Linnaeus in his Philosophia Botanica. They are defined to be plants with simple stems, which at their summit bear leaves resembling those of the fern, being a composition of a leaf and a branch; and whose flowers and fruit are produced on that particular receptacle or seat called a spadix, protruded from a common calyx in form of a sheath or scabious, termed by Linnaeus spatha.

Palmæ is likewise the name of the first order in Linnaeus's Fragments of a Natural Method.

PALMARIS MUSCLE, in Anatomy. See there, Table of the Muscles.

Palmated, something resembling the shape of the hand: thus we say, palmated leaves, roots, stones, &c.

PALMERSTON'S ISLAND, situated in the South Seas, which Captain Cook visited in his second and last voyages. It consists of a group of small islets, nine or ten in number, connected by a reef of coral rocks, and lying in a circular direction. It admits of no anchorage, nor are there any inhabitants on it, though it abounds with cocoanut trees, succulent grass, and the wild mango tree. This island is not more than a mile in circumference, and is not elevated above three feet above the level of the sea. It consists entirely of coral sand, with a small mixture of blackish mould, which appears to be produced from rotten vegetation. At one part of the reef (say our navigators), which bounds the lake within, almost even with the surface, there was a large bed of coral, which afforded a most enchanting prospect. Its base, which was fixed to the shore, extended so far that it could not be seen, so that it appeared to be suspended in the water. Even this delightful scene was greatly improved by the multitude of fishes that gently glided along, seemingly with the most perfect security. Their colours were the most beautiful that can be imagined, blue, yellow, black, red, &c. far excelling any thing that can be produced by art. The
richness of this submarine grotto was greatly increased by their various forms; and the whole could not possibly be surveyed without a pleasing transport, accompanied at the same time with regret, that a work so astonishingly elegant should be concealed in a place so seldom explored by the human eye." E. Long. 196. 35. S. Lat. 18. 8.

PALMIPEDES, among ornithologists, the same with web-footed birds. See Ornithology.

PALMISTRY, a kind of divination, or rather a deceitful art practised by gypsies, who pretend to foretell events by looking upon the lines and marks of the hand.

PALMUS, a long measure used both by the Greeks and Romans. The Grecian palmus was of two sorts; the greater, which contained nine finger breadths, and the less which contained four. The Roman palmus was also of two sorts; the greater, which contained twelve finger breadths, or eight inches and a half English; and the less, which contained four finger breadths, or near three inches English. The great palmus was taken from the length of the hand or span; the less from the breadth of it. The Greek palmus was called dory.

See Measure.

PALMYRA, or Tadmor, a noble city of ancient Syria, now in ruins, the origin of whose name is uncertain. Neither is it well known by whom this city was built; for though, from the identity of the names, it is thought by many to have been the Tadmor in the wilderness built by Solomon, this point, however, is much controverted by many learned men. For the world has been long and justly astonished to find in the desert of Syria, at a distance from the sea, with a very precarious and scanty supply of water only, and without a particular connexion with any great monarchy, ruins of a city more extensive and splendid than Rome itself, the depositary of all the arts which Greece in its most flourishing periods could afford. The problem is an intricate one; yet when we divest it of many of its difficulties, we shall bring this stupendous prodigy to no very uncommon magnitude. The coast of Syria was in very early ages rich and populous; and either from the convenience of procuring water, or from the vicinity of India and Egypt, the population, instead of increasing on the mountains, extended to Judea, and from thence through its plains only to the internal parts. The ruins of this numerous people, and of their habitations, remain; but as their edifices were not commonly splendid, or, as the causes of their destruction were powerful, they have not attracted much attention. Yet the ruins of more than 30 towns are discoverable to the southeast of the Dead Sea, and from thence towards Tadmor or Palmyra; we know the cause of the destruction of these towns, and we know that it did not reach Palmyra. This splendid city was not, therefore, insulated in a mass of sand; it was probably a link of a continued chain of population, or perhaps its termination. The situations of towns in the sandy desert must necessarily be determined by local advantages. Tadmor is situated where two hills converge, and beyond the point where they approach. These hills afforded water, that necessary aid to animal life; and the aqueducts, through which it was brought from them, were discovered and described by Mr. Wood. Though the other towns now in ruins afford some remains of luxury and opulence, yet in these respects they are much inferior to Palmyra; and this deserves to be explained. Palmyra was undoubtedly very ancient. "The two springs of fresh water it possesses (says Volney) were above all, a powerful inducement in a desert everywhere else so parched and barren. These, doubtless, were the two principal motives which drew the attention of Solomon, and induced that commercial prince to carry his arms so remote from the limits of Judea." He built strong walls there (says the historian Josephus), to secure himself in the possession, and named it Tadmor, which signifies the Place of Palm trees." Hence it has been inferred that Solomon was its first founder; but we should, from this passage, be rather led to conclude that it was already a place of known importance. The palm trees he found there are not the trees of uninhabited countries. Prior to the days of Moses, the journeys of Abraham and Jacob from Mesopotamia into Syria, sufficiently prove a communication between these countries, which must soon have made Palmyra famous. The cinnamon and pearls mentioned in the time of the Hebrew legislator, demonstrate a trade with India and the Persian gulf, which must have been carried on by the Euphrates and Palmyra. At this distance of time, when the greater part of the monuments of these early ages have perished, we are liable to form very false opinions concerning the state of these countries in those remote times, and are the more easily deceived, as we admit as historical facts antecedent events of an entirely different character. If we observe, however, that men in all ages are united by the same interests and the same desires, we cannot help concluding, that a commercial intercourse must early have taken place between one nation and another, and that this intercourse must have been nearly the same with that of more modern times. Without, therefore, going higher than the reign of Solomon, the invasion of Tadmor by that prince is sufficient alone to throw a great light on the history of this city. The king of Jerusalem would never have carried his attention to so distant and detached a spot, without some powerful motive of interest; and this interest could be no other than that of an extensive commerce, of which this place was already the emporium. This commerce extended itself to India; and the Persian gulf was the principal point of union."

From the nature of the commodities, from the requisite assistance of the Tyrians, and other forcible arguments, M. Volney shows that the Persian gulf was the centre of the most ancient commerce of the eastern world; and that it was with a view of obtaining a shorter route, by means of the Euphrates, that Solomon turned his attention to Tadmor, distant but three days journey from it. Our author goes on, "We may even reasonably conjecture, when we reflect on the revolutions of the following ages, that this commerce became a principal cause of those various wars in Lower Asia, for which the barren chronicles of those early times assign no motives. If, after the reign of Solomon, the Assyrians of Nineveh turned their ambitious views towards Chaldea, and the lower part of the Euphrates, it was with the intention to approach that great source of opulence the Persian gulf. If Babylon, from being the vassal of Nineveh, in a short time became her rival, and the seat of a new empire, it was because her situation rendered her the emporium of this lucrative trade; in short, if the kings of this great city waged perpetual
wars with Jerusalem and Tyre, their object was not only to despoil these cities of their riches, but to prevent their invading their trade by the way of the Red sea. An historian who has informed us that Nabuchodonosor, before he laid siege to Jerusalem, took possession of Tadmor, clearly indicates that the latter city acted in concert with the two neighbouring capitals. Their gradual decline became, under the Persian empire, and the successors of Alexander, the efficient cause of the sudden greatness of Palmyra in the time of the Parthians and Romans; she then enjoyed a long peace for many centuries, which allowed her inhabitants to erect those monuments of opulence whose ruins we still admire. If the former observations showed the connection of this remote spot with a more populous country, these remarks explain the cause of the renovation, and of the magnificence of this city. Our author’s remarks are at least probable, and are, in our opinion, very convincing.

Cairo, in another, probably a subordinate route, never attained the splendour of Palmyra; but the genius of the Egyptians, perhaps the laws of Egypt, prevented it.

There is, however, no authentic history of Palmyra till after the captivity of the Roman emperor Valerian by the Persians. It is first mentioned by the Roman historians, as a place which Mark Antony attempted to plunder, upon pretence that it had not observed a just neutrality between the Romans and Parthians. Pliny takes notice of it as being situated in a rich soil, among pleasant streams, and totally separated from the rest of the world by a vast sandy desert, which had preserved its independence between Parthia and Rome. There is still a considerable spot of good soil next the town and on the hills; and even in the wilderness, there were palms and fig trees, some of which remained till the latter end of the 17th century, though not one is now to be found.

After the captivity of Valerian, it was become an opulent city, to which its situation in the vicinity of the Roman and Parthian empire greatly contributed; as the caravans, in going to or returning from the east, frequented the place, and thus rendered it a considerable seat of merchandise. It enjoyed an independence till the time of Trajan; who, having made himself master of almost all the Parthian empire, reduced Palmyra likewise, and it was afterwards accounted part of the Roman dominions. But when the defeat and captivity of Valerian had so much weakened the empire, that the Persians seemed to be in a fair way of becoming masters of all the eastern provinces, the Palmyrenians began to entertain thoughts of recovering their liberty.

Odenathus, prince of Palmyra, sent a very respectful letter to Sapor on his return, accompanied with considerable presents; but by that haughty conqueror his letter and embassy were treated with the most provoking contempt. The presents were thrown into the Euphrates: and to his letter Sapor replied, That his insolence in presuming to write to his lord was inexcusable; but if he could atone for it in any way, it would be by presenting himself before the throne, bound hand and foot, in token of a consciousness of his crime, and the punishment he deserved. With this injurious treatment Odenathus was so provoked, that he swore either to bring down the pride of the haughty conqueror, or die in the attempt. Accordingly, having assembled what forces he could, he fell upon the Persians, destroyed a number of them, took a great part of their baggage, and some of the king’s concubines. The war of Odenathus with the Persians, however, we know very little: only that though the latter were often vanquished, and the independency of Palmyra established for the present; yet Valerian was never released from his captivity, though Odenathus earnestly wished to have the honour of rescuing him from his enemies.

Odenathus enjoyed his sovereignty but a very short time; being murdered by his nephew, who was soon after put to death by Zenobia the wife of Odenathus. This lady is said to have been possessed of very extraordinary endowments both of body and mind, being, according to Mr. Gibbon, almost the only Asiatic woman who is recorded to have overcome the obstacles arising from the confined situation of the fair sex in that part of the world. Immediately on taking vengeance for the murder of her husband, she assumed the government, and soon strengthened herself so much, that she resolved to submit neither to the Roman nor Persian power. The neighbouring states of Arabia, Armenia, and Persia, dreaded her enmity, and solicited her alliance. To the dominions of Odenathus, which extended from the Euphrates to the frontiers of Bithynia, his widow added the inheritance of her ancestors, the populous and fertile kingdom of Egypt. The emperor Claudius acknowledged her merit, and was content that, while he pursued the Gothic war, she should assert the dignity of the empire in the east. The conduct, however, of Zenobia, was attended with some ambiguity; nor is it unlikely that she had conceived the design of erecting an independent and hostile monarchy. She blended with the popular manners of Roman princes the stately pomp of the courts of Asia, and exacted from her subjects the same adoration that was paid to the successors of Cyrus. She bestowed on her three sons a Latin education, and often showed them to the troops adorned with the imperial purple. For herself she reserved the diners, with the splendid but doubtful title of Queen of the east.

When Aurelian passed over into Asia, against an adversary whose sex alone could render her an object of contempt, his presence restored obedience to the province of Bithynia, already shaken by the arms and intrigues of Zenobia. Advancing at the head of his legions, he accepted the submission of Ancrea: and was admitted into Tyana, after an obstinate siege, by the help of a perfidious citizen. The generous, though fierce temper of Aurelian, abandoned the traitor to the rage of the soldiers: a superstitious reverence induced him to treat with lenity the countrymen of Apollonius the philosopher. Antioch was deserted on his approach; till the emperor, by his salutary edicts, recalled the fugitives, and granted a general pardon to all who, from necessity rather than choice, had been engaged in the service of the Palmyreneian queen. The unexpected mildness of such a conduct reconciled the minds of the Syrians, and as far as the gates of Emesa, the wishes of the people succeeded the terror of his arms.

Zenobia would have ill deserved her reputation, had she indolently permitted the emperor of the West to approach within 100 miles of her capital. The fate of the East was decided in two great battles; so similar in almost every circumstance, that we can scarcely distinguish
Sapor, which happened about this time, distracted the councils of Persia; and the inconsiderable succours that attempted to relieve Palmyra were easily intercepted either by the arms or the liberality of the emperor. From every part of Syria a regular succession of convoys safely arrived in the camp, which was increased by the return of Probus with his victorious troops from the conquest of Egypt. It was then that Zenobia resolved to fly. She mounted the fleetest of her dromedaries; and had already reached the banks of the Euphrates, about 500 miles from Palmyra, when she was overtaken by the pursuit of Aurelian's light horse, seized and brought back a captive to the feet of the emperor. Her capital soon after surrendered, and was treated with unexpected lenity. The arms, horses, and camels, with an immense treasure of gold, silver, silk, and precious stones, were all delivered to the conqueror; who, leaving only a garrison of 600 archers, returned to Emesa, and employed some time in the distribution of rewards and punishments at the end of so memorable a war, which restored to the obedience of Rome those provinces that had renounced their allegiance since the captivity of Valerian.

When the Syrian queen was brought into the presence of Aurelian, he sternly asked her, How she had presumed to rise in arms against the emperors of Rome? The answer of Zenobia was a prudent mixture of respect and firmness: "Because I disdained to consider Roman emperors an Aureolus or a Gallienus. You alone I acknowledge as my conqueror and my sovereign." But as female fortitude is commonly artificial, so it is seldom steady or consistent. The courage of Zenobia deserted her in the hour of trial; she trembled at the angry clamours of the soldiers, who called aloud for her immediate execution; forgot the generous despair of Cleopatra, which she had proposed as her model; and ignominiously purchased life by the sacrifice of her fame and her friends. It was to their counsels, which governed the weakness of her sex, that she imputed the guilt of her obstinate resistance; it was on their heads that she directed the vengeance of the cruel Aurelian. The fame of Longinus, who was included among the numerous and perhaps innocent victims of her fear, will survive that of the queen who betrayed, or the tyrant who condemned him. Genius and learning were incapable of moving a fierce unlettered soldier, but they had served to elevate and harmonise the soul of Longinus. Without uttering a complaint, he calmly followed the executioner, pitying his unhappy mistress, and bestowing comfort on his afflicted friends.

Returning from the conquest of the East, Aurelian had already crossed the straits which divided Europe from Asia, when he was provoked by the intelligence that the Palmyrenians had massacred the governor and garrison which he had left among them, and again erected the standard of revolt. Without a moment's deliberation, he once more turned his face towards Syria. Antioch was alarmed by his rapid approach, and the helpless city of Palmyra felt the irresistible weight of his resentment. We have a letter of Aurelian himself, in which he acknowledges that old men, women, children, and peasants, had been involved in that dreadful execution, which should have been confined to armed rebellion: and although his principal concern seems directed to the re-establishment of a temple...
to meet; between them there was a vale, through which an aqueduct formerly conveyed water to Palmyra. On each side of this vale they remarked several sculptures of the ancient Palmyreans, which they had scarce passed, when the hills opening on a sudden, they discovered such piles of ruins as they had never seen. They were all of white marble; and beyond them, towards the Euphrates, was a wide level, stretching farther than the eye could reach, totally desolate, without variety, and without bounds. After having gazed some time upon this prospect, which rather exceeded than fell short of their expectations, they were conducted to one of the huts of the Arabs, of which there are about 30 in the court of the great temple. The inhabitants of both sexes were well shaped, and the women, though very swarthly, had good features. They were veiled, but did not so scrupulously conceal their faces as the eastern women generally do. They paint the ends of their fingers red, their lips blue, and their eyebrows and eyelashes black. They had large rings of gold or brass in their ears and nostrils, and appeared to be healthy and robust. The walls of the city are flanked by square towers, into which some ancient funeral monuments have been converted; but the walls are in most places level with the ground, and sometimes not to be traced. It is, however, probable, by their general direction, that they included the great temple, and are three miles in circumference.

The Arabs showed a tract which was near ten miles in circumference; the soil of which was raised a little above the level of the desert: this, they said, was the extent of the old city; and that by digging in any part of it ruins were discovered.

These ruins consist of temples, palaces, and porticoes of Grecian architecture; and lie scattered over an extent of several miles. They were accidentally discovered by some English travellers from Aleppo somewhat more than a century ago. By far the most remarkable of them is the Temple of the Sun, of which the ruins are spread over a square of 220 yards. It was encompassed with a stately wall, built of large square stones, and adorned with pilasters within and without, to the number of 62 on a side. Within the court are the remains of two rows of very noble marble pillars 37 feet high, with their capitals of most exquisite workmanship. Of these only 58 remain entire; but there must have been many more, for they appear to have gone round the whole court, and to have supported a double piazza. The walks on that side of the piazza which is opposite to the front of the castle seem to have been the most spacious and beautiful. At each end of this line are two niches for statues, with their pedestals, borders, supporters, and canopies, carved with the utmost propriety and elegance. The space within this inclosure, which is now filled with the dirty huts of the inhabitants, seems to have been an open court, in the middle of which stood the temple, encompassed with another row of pillars of a different order, and much taller, being 50 feet high; but of these 16 only remain. The whole space contained within these pillars is 59 yards in length, and near 28 in breadth. The temple is no more than 33 yards in length, and 13 or 14 in breadth. It points north and south; and exactly into the middle of the building, on the west side, is a most magnificent entrance, on the re-
The remains of the Great Temple of the Sun in PALMYRA from the West.
Palmyra. The remains of which are some vines and clusters of grapes, carved in the most bold and masterly imitation of nature that can be conceived. Just over the door are discerned a pair of wings, which extend its whole breadth; the body to which they belonged is totally destroyed; and it cannot now certainly be known whether it was that of an eagle or a cherub, several representations of both being visible on other fragments of the building. It is observed of the windows of this building, which were not large, that they were narrower at the top than below. The north end of the building is adorned with the most curious fret-work and bas-relief; and in the middle there is a dome or cupola about ten feet diameter, which appears to have been either hewn out of the rock, or moulded to some composition which by time is grown equally hard. North of this place is an obelisk, consisting of seven large stones, besides its capital and the wreathed work about it. It is about 50 feet high; and, just above the pedestal, is 12 feet in circumference. There was probably a statue upon it, which the Turks, in their zeal against idolatry, destroyed. At about the distance of a quarter of a mile from this pillar, to the east and west, are two others, besides the fragment of a third; so that perhaps they were originally a continued row.

About 100 paces from the middle obelisk, straight forward, is a magnificent entry to a piazza, which is 40 feet broad, and more than a half a mile in length, inclosed with two rows of marble pillars 26 feet high, and eight or nine feet in compass. Of these there still remain 129; and, by a moderate computation, there could not originally have been less than 560. The upper end of the piazza was shut in by a row of pillars, standing somewhat closer than those on each side. A little to the left are the ruins of a stately building, which appears to have been a banquetting-house. It is built of better marble, and is finished with yet greater elegance, than the piazza. The pillars which supported it were of one entire stone, which is so strong, that one of them which is fallen down has received no injury. It measures 22 feet in length, and in compass 8 feet 9 inches. In the west side of the piazza are several apertures for gates into the court of the palace. Each of these was adorned with four porphyry pillars, not standing in a line with those of the wall, but placed by couples in the front of the gate facing the palace, two on each side. Two of these only remain entire, but one standing in its place. They are 30 feet long and 9 in circumference. On the east side of the piazza stands a great number of marble pillars, some perfect, but the greater part mutilated. In one place 11 are ranged together in a square: the space which they inclose is paved with broad flat stones, but there are no remains of a roof. At a little distance are the remains of a small temple, which is also without a roof, and the walls are much defaced. Before the entry, which looks to the south, is a piazza supported by six pillars, two on each side of the door, and one at each end. The pedestals of those in front have been filled with inscriptions both in the Greek and Palmyrene languages, which are become totally illegible. Among these ruins are many sepulchres: they are ranged on each side of a hollow way, toward the north part of the city, and extend more than a mile. They are all square towers, four or five stories high. But though they are alike in form, yet they differ greatly in magnitude and splendour. The outside is of common stone, but the doors and partitions of each story are marble. There is a walk across the whole building, just in the middle; and the space on each hand is subdivided into six partitions by thick walls. The space between the partitions is wide enough to receive the largest corpse; and in these niches there are six or seven piled upon one another.

Many inscriptions have been found at Palmyra, which have occupied much of the attention of the learned; and if any thing certain could be derived from them, there is no doubt but they would tend very considerably to the elucidation of ancient history. See Barthelemy's Reflections on the Palmyrene Alphabet, published at Paris in 1754; and An Explanation of the Inscriptions at Palmyra hitherto published, by John Swinton of Christ-church, Oxford. See also Phil. Trans. N° 217, and 218; the first volume of the Ancient Universal History; and, above all, consult the Ruins of Palmyra, or Tadmor in the Desert, published by Mr R. Wood, who, with M. Bouvier and Mr. Dawkins, travelled thither in 1751. The result of their observations was published in 1753, in the form of an atlas. The ruins of this once mighty and celebrated city are represented in 57 copperplates, 16 by 12 inches, printed on imperial paper. They are admirably executed; the drawing is correct and masterly; and the engraving highly finished: nor can they fail to give satisfaction to those who are connoisseurs in the art, or to those who delight in the labours of antiquity.

Palmyra was visited by Mr Bruce before his journey into Abyssinia; but, on account of the many publications concerning these celebrated ruins, he has declined saying much concerning them. He informs us, that before he came in sight of the ruins, he ascended a hill of white gritty stone, in a very narrow winding road, such as is called a pass; but on getting up to the top, his eyes were struck with the most stupendous sight which he believes, ever mortal saw. The whole plain below, which is very extensive, was so covered with magnificent buildings, that they seemed to touch one another. All of them are finely proportioned, agreeably shaped, and composed of white stones, which at that distance appeared like marble. In taking a draught of these ruins, Mr Bruce divided the whole into six angular views, for which the situation of the place is very convenient. The columns are all uncovered to the very bases, the ground on which they are built being hard and solid. The views he took were upon large paper; some of the columns being represented a foot long, and some of the figures in the foreground of the Temple of the Sun (a magnificent building which stood at one end of the town) being near four inches. Before he left Palmyra he observed its latitude with a reflecting quadrant of Hadley; but as the instrument was out of order, he could not determine it exactly. In his opinion, however, 33° 58' is not far distant from truth. From such observations as he could make on the longitude, he concluded it to be 33° 9' east from Greenwich. Mr R. Wood makes the latitude 34° north.

From Palmyra Mr Bruce proceeded to Baalbec, distant about 130 miles, where he found ruins still more magnificent. The interior part of the great temple...
at this place, according to our author, surpasses anything he had seen at Palmyra, or anywhere else. "All these views of Palmyra and Baalbec (says he) are now in the king’s collection. They are the most magnificent offering, in their line, that ever was made by one subject to his sovereign." In the neighbourhood of Palmyra are some salt-marshes; and to the adjacent country a trade is carried on in kelp from Tripoli in Syria. There are two Arab tribes, almost equally powerful; one of them, called Annocy, remarkable for the finest horses in the world.

Respecting the latitude and longitude there are still various opinions: that which appears to be nearest the truth is E. Long. 38. 50. N. Lat. 33. 20. It stands about 50 leagues south-east of Aleppo, as much from Damascus, and 20 leagues west of the Euphrates.

PALPABLE, something perceivable by the senses, particularly that of feeling.

PALPATION OF The Heart. See Medicine Index.

PALSY. See Medicine Index.

PALUDAMENTUM, in Roman antiquity, a habit that differed but little from the chlamys, except that this last belonged chiefly to the lower class of people. It was worn by the officers and principal men among the Romans in time of war, who are therefore called Paludati; which distinguished them from the common soldiers, who, because they wore the sagum, were called the Sagati. The paludamentum came down only to the navel, was open on the sides, had short sleeves resembling angels wings, and was generally white or red. It is sometimes used to signify the common soldier’s coat.

PALUS MEGITIS, the ancient name of a gulf between Europe and Asia, to the north of the Black Sea, now called the sea of Zabach or Assop.

PALSY, or PALE, in Heraldry, is when the shield is divided into four or more equal parts, by perpendicular lines falling from the top to the bottom.

PALT Bende, is when the escutcheon is divided by perpendicular lines, which is paly; and also by diagonal, which is called bendy.

PAMBOKUK, the Turkish name of the ruined city of Hierapolis. See Hierapolis.

PAMLICO SOUND, an inland sea on the east coast of the United States, about 80 miles long, and 20 or 30 broad. It is formed by a range of low sandy islands scarcely a mile broad, which stretch along the shores of North Carolina at a greater or less distance from the continent. Through these islands there are three inlets, the deepest of which has only ten feet water. They render the coast of North Carolina inaccessible to an enemy.

PAMPAN LUNA, the capital of the kingdom of Navarre in Spain, with a very strong citadel and rich bishoripric. It is handsome and populous, and carries on a great trade, seated in a very fertile plain, in E. Long. 2. 25. N. Lat. 42. 42.

PAMPAN LUNA, a town of New Granada in South America, famous for its gold mines and numerous flocks of sheep. W. Long. 68. 30. N. Lat. 6. 50.

PAMPHELIS, a celebrated painter of Macedonia, in the age of Philip. He was founder of the school for painting at Scyros; and he made a law which was observed not only in Scyros but all over Greece, that none but children of noble and dignified persons should be permitted to learn painting. Apelles was one of his pupils.

PAMPYRIA, the ancient name of a country in Asia, now called Carmania and Cog-ley, between Lycia and Cilicia, to the south coast, to the north of the Mediterranean sea.

PAN, the god of shepherds, hunters, and all country exercises. Such he is described by the Greek and Roman poets; but he bore a higher character among the earliest Greeks, as well as among the Egyptians; from whom his worship was borrowed by that people. In Egypt he was known by the name of Mendes, which, according to Jablonski, signifies fecundity. Hence his symbol was a living he-goat, the most sala-Egyptian of all animals: "Hicurn Mendesium colunt in Aegypti, eo quod virtuti profuisse ac generosissimi consecratus est,—Nam animal hoc coitus valde caputam est." His principal temple was a magnificent building in a city of Lower Egypt, called after his name. It is well known (see Polytheism) that from dedicating certain animals to certain gods, the Egyptians proceeded to consider the animals themselves as actuated by the divinities to whom they were sacred. Hence the origin of brute worship. In the temple of Mendes was kept a he-goat, to whom sacrifices of a very monstrous kind were offered. Herodotus, speaking of the prefecture of Mendes, says, "Εὐδοξὶν ἡ τώρα ταύτα διάθεσιν ἔχει," the same words as he used for Persepolis. Our readers, learned and unlearned, will forgive us for not translating this passage, which contains, however, nothing that is not confirmed by the testimony of other writers; particularly of Plutarch, and Pindar as he is quoted by Strabo. The most wonderful circumstance of this monstrous sacrifice is, that it was made publicly in the presence of a great concourse of men! But to what divinity was it made? To a mere goat, or to some superior principle animating the goat? Doubtless to the latter; for it is said that the fair worshippers were of the first rank, and of unsought fame; and that if they had borne a different character, the deity would not have accepted of their devotions.

The deity whom the Egyptians adored by the name of Mendes, was no other than the Soul of the Universe; for he was their most ancient god: and we are told by Plutarch, "That they took the first God Dei lique, and the Universe for one and the same thing." Hence of the name Per among the Greeks: not that either the Greeks or their masters in theology worshipped, as their first god, mere brute matter, but that spirit which they conceived to be coeternal with matter, and to animate all things, making them one. Thus Orpheus, who imported the Egyptian doctrine into Greece, declares that all things are one: and after him Parmenides, and other philosophers, taught that one being, that "one is the universe," and that "the universe is immovable." That the ancient Grecian Pan, or the Egyptian Mendes, was not the corporeal world, as senseless and inanimate, but the whole system of things unaltered and eternal, appears further from the following testimony of Macrobius. "Hunc deum Arcades co-ulant, appelantes τὸν τῆς ἔλεος κυρίον, non sylvarum dominum, sed universae substantiae dominantem;—The Arcadians worship this god, calling him the
PAN

lord of Hyll; i. e. not the lord of the woods, but the lord of all material substance." In the same manner Pharamus * describes the Pan of the other Greeks, not as the mere corporeal world, but as the intellectual principle actuating it and presiding over it: and he adds, that "Pan was feigned to be lascivious, because of the multitude of sanguine reasonings in the world, and the continual increase of the generation of the species."

The Egyptians, as we learn from Jubaenski, had nearly the same notion with the Greeks of the spirit which they worshipped as the Soul of the Universe; only they gave it to both sexes. As the maker, governor, and bountiful father of universal nature, they considered it as a male, whose symbol was the he-goat of Mendes; and as a female it was adored by the name of Iris, to whom the she-goat was consecrated, though not held in such veneration as the male. From this view of the Egyptian creed, the sacrifice which we have mentioned appears no longer unaccountable. It was made to a god, believed to be the universal source of fecundity, and to whom, from the well-known character of the animal whom he was supposed to actuate, they had reason to believe that it would be most acceptable.

The Greeks never worshipped their Pan by the emblem of a living goat; but they painted him with the lower parts of a goat, for a reason which shall be afterwards mentioned. How he came to degenerate among that people, from one of the Dioscurovan gods, or rather from the first principle of all things, to the rank of a demon or demi-god, we cannot pretend to say: but that such was his fate, is certain; for under this last character mention is made both of his birth and his death.

Whose son he was, is not agreed among them. Homer makes him the son of Mercury, and says he was called Pan from was, oinie, because he charmed all the gods with his flute; others say that he was the son of Demogorgon, and first invented the organ, of seven unequal reeds, joined together in a particular manner: Having on a time fought with Cupid, that god in spite made him fall in love with the coy nymph Syrinx, who, flying from him to the banks of Ladon, a river of Arcadia, at the instant prayers of the Nymph was turned into a reed, as her name in Greek signifies, which the god grasping instead of her, made a pipe of it; and for his music was adored by the Arcadians. The most common opinion was, that he was the son of Mercury and Penelope. But Not Ganes, out of Duris Suidus, makes his birth scandalous, by saying he was called was, because begot by all Penelope's spouses. He was painted half-man half-goat, having large goats horns, a chaplet of pine on his red face, a pleasant laughter, with the feet and tail of a goat; a motley skin covering his body, with a crooked stick in one hand, and his pipe in the other. See him nicely described by Stil. Ital. 13. 326 et seq. a sight enough to fright women and children, etc., armed men too; for when Breamus the Gaul was about to pillage the temple of Apollo at Delphos, he by sight struck such a terror into his army, that he quitted his sacrilegious design: hence Parnes teretes. Yet, as homely as he was, he pleased the goddess Luna, turning himself easily into a white ram, Virg. Georg. iii. 392. et deinde; and the nymph Dryope also, almost putting off his divinity, and turning Vol. XV. Part H.

shepherd for her sake. Neither was he displeasing to other nymphs, who are generally made dancing round about him to bear the charms of his pipe. The usual offerings made him were milk and honey, in shepherds wooden bowls: also they sacrificed to him a dog, the wolf's enemy; whence his usual epithet is Amaus; and whence also his priests were called Luperi. This festival was celebrated on February 15th by the Romans, brought into Italy by Evander the Arcadian, and revived afterwards by Romulus, in memory of his preserver. He was also called by the Romans Iapyn, ab ipseundo, Vid. Liv. i. 5. Macrob. Sat. i. 21. and Surv. in Virg. Aen. vi. 775. The ancients, by giving so many adjuncts and attributes to this idol, as we have observed above, seem to have designed him for the symbol of the universe; his upper parts being human, because the upper part of the world is fair, beautiful, smiling, like his face; his horns symbolize the rays of the sun and of the moon; his red face, the splendour of the sky; the spotted skin wherewith he is clothed, the stars which bespangle the firmament; the roughness of his lower parts, beasts and vegetables; his goat's feet, the solidity of the earth; his pipe, compact of seven reeds, the seven planets, which they say they make the harmony of the spheres; his crook, bending round at the top, the years circling in one another. Surv. Interpr.

Having said so much of Pan, both as a self-existent god and as a generated demon, we shall conclude the article with some observations on Piutarch's account of the prodigy which happened at his death; for in the Pagan creed, demons were not all believed immortal.

In the reign of Tiberius (says cur author*), certain persons on a voyage from Asia to Italy, and sailing towards the evening by the Echinides, were there becalmed, and heard a loud voice from the shore calling on one Thamus an Egyptian pilot whom they had on board. Thamus, as may be supposed, listened with attention; and the voice, after repeating his name thrice, commanded him when he came to the Pelodes, to declare that the Great Pan was dead. The man, with the advice of his companions, resolved, that if they should have a quick gale off the Pelopes, he would pass by in silence; but that if they should be becalmed, he would perform what the voice had commanded. Adhering to this resolution, they soon arrived off the destitute islands, and were immediately becalmed, there being neither breath of wind nor agitation of water. Upon this Thamus looking from the hinder part of the ship towards the land, pronounced with a loud voice: Pan moritur. Thamus morte. The Great Pan is dead! and was instantly answered from the shore by numberless howlings and lamentations."

This story, which has so much of the air of imposture, has not only been admitted as truth by men of the first eminence for learning and acuteness, but has been applied to our Saviour, whose death (says Cudworth) the demons mourned not from love, but from a presage that it would put an end to the tyranny and domination which they had so long exercised over the souls and bodies of men. In support of this opinion, he quotes several passages of Scripture, such as, "Now is the prince of this world judged," and, " Having spoiled principalities and powers (by his death upon the cross), he triumphed over them in it." He affirms likewise, that "Pan being taken for that re-
The authority of Cudworth is great; but a groundless opinion has seldom been propounded by weaker reasoning. The same may be seen on this occasion. Plutarch indeed says, and seems to believe, that this prodigy fell out during the reign of Tiberius; but as he mentions not the year of that reign, there is no evidence that it was at the crucifixion of our Saviour. The demons who inhabited the Echinides knew what had been transacted at Jerusalem far distant from their islands; they knew the name of the pilot of a strange ship; they knew that the mariners of that ship had resolved to disobey their command, unless becalmed off the Pelodes; they had power over both the winds and waves at the Pelodes, and exerted that power to enforce obedience to their command; and yet these all-knowing and powerful beings were under the necessity of calling in the aid of a man to deliver a message to their companions, inhabiting a place to which the very same story assures us that their own power and knowledge reached. Should it be said that the demons were compelled by divine power thus publicly to make known to man Christ’s triumph over the kingdom of darkness, we beg leave to ask why they were not likewise compelled to give him another name, since it is certain, that at the era of Tiberius, and long before, illiterate Pagans, such as common seamen must be supposed to have been, knew no other Pan than the fabled son of Penelope and Mercury?—Indeed the other Pan, taken for that reason or understanding by which all things were made, could not possibly be the being here meant; for, erroneous as the Pagan system was, there is nothing in it so completely absurd as the death of the soul of the universe, the maker of all things: nor do we believe that any Pagan ever existed, who dreamed that such a death was possible.

What then, it will be asked, are we to understand by this story? Plutarch was eminent for knowledge and integrity, and he relates it without expressing a doubt of its truth. He does so; but many a man of worth has been crouded; and though that was not his character, this prodigy may be accounted for by natural means. Germanicus was believed to have been poisoned, at least with the knowledge, if not by the command, of Tiberius; and there was nothing which the Romans so deeply deplored as the untimely death of that accomplished prince*. They fancied that his body was animated, not by a human soul, but by a superior demon: and they decreed to him statues, religious ceremonies, and even sacrifices. His widow was highly honoured, as having been nearly related to a divinity, and his children were adored as demi-gods. These facts being admitted, nothing appears to us more probable than the opinion of the learned Mo- sheim†, who thinks that some shrewd statesman, in order to excite the popular fury against Tiberius to the highest pitch, invented this story, and bribed foreign mariners to spread it among the people, who would naturally believe, that by the great Pan was meant their favourite Germanicus. This hypothesis is at least countenanced by what Plutarch tells us of the anxiety of the emperor to discover what personage could be meant by the Pan whose death was announced to the seamen: he consulted the learned men of Rome, who, in order to restore peace to the city, declared that they understood it of none other than the son of Penelope and Mercury.

PANACEA, among physicians, denotes an universal medicine, or a remedy for all diseases; a thing impossible to be obtained.

PANADA, a diet consisting of bread boiled in water to the consistence of pulp, and sweetened with a little sugar.

PANAMA, the capital city of the province of Darien in South America, where the treasure of gold and silver, and the other rich merchandises of Peru, are lodged in magazines till they are sent to Europe. W. Long. 82. 15. N. Lat. 8. 57.

When Guzman first touched at this place in 1514, it consisted entirely of fishermen’s huts. Orius d’Avila settled a colony here in a few years after, and in 1521 it was constituted a city by the emperor Charles V. with the proper privileges. In 1670 it was sacked and burnt by John Morgan, an English adventurer, who had the preceding year taken Porto Bello. This misfortune induced the inhabitants to remove the city to its present situation, distant about a league from the place where it stood before. For the greater security, the new city was enclosed by a stone wall, and the houses were built of stone and brick. Since that time several bastions have been added, and now there is always a complete garrison maintained, and the walls are mounted with large cannon. But all these precautions could not save this city from another misfortune; it was entirely consumed by fire in the year 1737. After this accident it was again rebuilt, in the manner as it now stands, with neat elegant houses, but not magnificent. The inhabitants are rather independent in their fortunes than rich; there are few of them opulent, and scarce any in a state of poverty. As to the harbour, it is convenient, and well secured against storms by a number of surrounding islands, and is capable of containing the largest fleets. Here the royal audience is seated, at which the governor of Panama resides; for which reason this city is commonly deemed the capital of the province.

This place, a little while after it was founded, became the capital of the kingdom of Terra Firma. Some hopes were at first entertained from the three provinces of Panama, Darien, and Veragua, which composed it; but this prosperity vanished instantaneously. The savages of Darien recovered their independence; and the mines of the two other provinces were found to be neither sufficiently abundant, nor of an alloy good enough to make it worth while to work them. Five or six small boroughs, in which are seen some Europeans quite naked, and a very small number of Indians who have come to reside there, form the whole of this state, which the Spaniards are not ashamed of honouring with the great name of kingdom. It is in general barren and unwholesome, and contributes nothing to trade but pearls.

The pearl fishery is carried on in the islands of the gulf. The greatest part of the inhabitants employ such of their negroes in it as are good swimmers. These slaves plunge and replunge into the sea, in search
of pearls, till this exercise has exhausted their strength or their spirits.

Every negro is obliged to deliver a certain number of oysters. Those in which there are no pearls, or in which the pearl is not entirely formed, are reckoned.

What he is able to find beyond the stipulated obligation, is considered as his indisputable property; he may sell it to whom he pleases; but commonly he cedes it to his master at a moderate price.

Sea monsters, which abound more about the islands where pearls are found than on the neighbouring coasts, render this fishing dangerous. Some of these devour the divers in an instant. The manta fish, which derives its name from its figure, surrounds them, rolls them under its body, and suffocates them. In order to defend themselves against such enemies, every diver is armed with a poniard: the moment he perceives any of those voracious fish, he attacks them with precaution, wounds them, and drives them away. Notwithstanding this, there are always some fishermen destroyed and a great number crippled.

The pearls of Panama are commonly of a very fine water. Some of them are even remarkable for their size and figure: these were formerly sold in Europe. Since art has imitated them, and the passion for diamonds has entirely superseded or prodigiously diminished the use of them, they have found a new mart more advantageous than the first. They are carried to Peru, where they are in great estimation.

This branch of trade has, however, infinitely less contributed to give reputation to Panama, than the advantage which it has long enjoyed of being the mart of all the productions of the country of the Incas that are destined for the old world. These riches, which are brought hither by a small fleet, were carried, some on mules, others by the river Chagre, to Porto Bello, that is situated on the northern coast of the isthmus which separates the two seas. See Darien.

PANARI, one of the Lipari islands, lying in the Tuscan sea. It is only five miles in circumference, and the soil is barren. E. Long. 15° 0. N. Lat. 39° 0.

PANARO, a river of Italy, which rises in the Apennines, crosses the valley of Frignano, and running on the confines of the Modenese and Bolognese, waters Fena', and falls into the Po at Bondeno, ten miles above Ferrara.

PANATHENAEAE, παναθηναϊα, in Grecian antiquity, an ancient Athenian festival, in honour of Minerva the protectress of Athens, and called Athenaea. Harpocrates and Suidas refer the institution of this festival to Erechthonius IV. king of Athens, who lived before Theseus. Theodoret alone says the feast was established by Orpheus. Be this as it will, till Theseus it was never a particular feast of the city of Athens, and was called simply Athenaea: but that prince, uniting all the people of Attica into one republic, they afterwards all assisted at the feast; whence the name Panathenaea, i.e. the feast of all Attica. In effect all Attica was present; and each person sent a bullock for the sacrifices, and for the entertainment of the vast multitude of people assembled.

There were two festivals under this denomination, the greater and the lesser. The greater panathenaea were exhibited every five years; the less every three, or, according to some writers, annually. Though the celebration of neither, at first, employed more than one day; yet in after times they were protracted for the space of many days, and solemnized with greater preparations and magnificence than at their first institution.

The ceremonies were the same in the great and the little panathenaea; excepting for a banner, wherein the actions of the goddess were represented in embroidery, performed by maidens, with the names of those who had distinguished themselves in the service of the republic; which was only borne at the greater.

Prizes were established there for three different kinds of combat: the first consisted of foot and horse races; the second, of athletic exercises; and the third, of poetical and musical contests. These last are said to have been instituted by Pericles. Singers of the first class, accompanied by performers on the flute and cithara, exercised their talents here upon subjects prescribed by the directors of these exhibitions.

The following is the order observed in this festival, Ancharchis, according to M. Barthelèmi, who quotes numerous authorities on the occasion: "The inhabitants of the different towns of Attica thronged to the capital, leading with them a great number of victims destined for sacrifices to the goddess. In the first morning were the horse-races, in which the sons of the first citizens of Athens contended for the honour of the victory. In the stadium were other young men struggling for the prize at wrestling, and different exercises of the body; and in the oedem were several musicians engaged in lighter and less perilous contests. Some executed pieces on the flute or cithara; others sang, and accompanied their voices with one of these instruments. The subject proposed to them was the eulogy of Harmodius, Aristogiton, and Thrasybulus, who had rescued the republic from the yoke of the tyrants by which it was oppressed: for, among the Athenians, public institutions are so many monuments for the citizens who have served the state, and lessons for those who are called upon to render it service. A crown of olive, and a vessel filled with oil, were the prizes bestowed upon the victors. Crowns were afterwards conferred on individuals, who appeared to the people to have merited that mark of honour by their zeal in the service of their country."

"At the Ceramicus passed a procession, formed without the walls, and which began at that place to file off. It was composed of different classes of citizens crowned with chaplets of flowers, and remarkable for their personal beauty. Among the number were old men of a majestic and venerable appearance, bearing branches of olive; middle-aged men, who, armed with lances and with bucklers, seemed only to inspire war; youths from 18 to 20, who sang hymns in honour of the goddess; beautiful boys, clad in a simple tunic, adorned only with their native graces; and, lastly, girls, who were of the first families in Athens, and whose features, shape, and deportment, attracted every eye. With their hands they held baskets on their heads, which, under a rich veil, contained sacred utensils, cakes, and every thing necessary for the sacrifices. Female attendants, who followed them, with one hand held over them an umbrella, and carried in the other a folding chair. This is a species of servitude imposed on the daughters of all foreigners settled at Athens: a servitude they share in common with their fathers and mothers, who likewise carried on their shoulders vessels filled with water and honey,"
honey, for the purpose of libations. They were followed by eight musicians; four of whom played on the flute and four on the lyre. After them came bridesmaids singing the poems of Homer; and dancers armed at all points, who, attacking each other at intervals, represented, to the sound of the flute, the battle of Minerva with the Titans. Next came a ship that appeared to glide over the ground by the power of the wind, and the efforts of a great number of rowers, but which really was put in motion by concealed machinery. The vessel had a sail of light stuff, on which young girls had represented in embroidery the victory of Minerva over the Titans. On it also they had depicted by order of the government, some heroes whose illustrious deeds had merited to be celebrated with those of the gods. This procession marched on with solemn steps, under the direction of several magistrates; and traversed the most frequented quarter of the city amid a crowd of spectators, most of whom were placed on scaffolds erected for the occasion. When it had reached the temple of the Pythian Apollo, the sail of the ship was taken down and carried to the citadel, where it was deposited in the temple of Minerva.

"In the evening, at the academy, was the torch race. The course is only six or seven stadia in length. It extends from the altar of Prometheus, which is at the gate of this garden, to the walls of the city. Several young men are stationed in this interval at equal distances. When the shouts of the multitude have given the signal, the first lights his flambeau at the altar, and, running with it, hands it to the second, who transmits it in the same manner to the third, and so successively. He who suffers it to be extinguished can no more enter the lists; and they who slacken their pace are exposed to the railings, and even blows, of the populace. To gain the prize, it is necessary to have passed through the different stations with success. This trial of skill was frequently repeated, and is diversified according to the nature of the competitors."

"The candidates who had been crowned at the different exercises invited their friends to supper. Sumptuous repasts were given in the prytaneum and other public places, which lasted till the following day. The people among whom the immolated victims were distributed spread tables on every side, and gave a loose to their lively and tumultuous mirth."

PANAX, GINSENG; a genus of plants belonging to the polypodium class. See BOTANY and MATERIA MEDICA Index.

PANAY, an island of Asia, and one of the Philippines, lying between those of Paracas and Negro. It is 252 miles in circumference, and is the most populous and fertile of them all. It is watered by a great number of rivers and brooks, and produces a great quantity of rice. Its shape is triangular. The names of its principal capes are Potol, Naso, and Bulacabi. The coast from Bulacabi to Potol lies east and west; from Potol to Naso, north and south; from Bulacabi to Ioilo, another cape, less than the greater one, is also north and south; from Ioilo to Cape Naso, east and west. The middle of the island is in the latitude of ten degrees. On the north side, almost in the middle between the two capes of Potol and Bulacabi, the famous river Panay falls into the sea; and the mouth of the harbour is covered by a small island called Lataya, in which port the Spaniards had a safe retreat before they discovered and conquered Manilla and Cavite. The fertility of Panay is caused by the many rivers that water it, for there is no travelling a league without meeting a river; but more particularly by the Panay, which gives its name to the island, and runs a course of 40 leagues. The island, for the better administering of justice, is divided into jurisdictions: the first, called Panay, contains all that lies between Cape Potol and Balacabi; the rest of the island is subject to the alcalde of Otton, who resides at Hilo, a point of land running out into the sea, on the south side, between the two rivers of Tig Bawan and Jaro, and, with the island Imaras, forms a strait above half a league over, or rather an open harbour. On this point the governor Don Gonzalo Romullo caused a fort to be built in the year 1681. The island contains about 16,300 tributary Indians, partly belonging to the king and partly to particular vecindades or lords; but they all pay in rice, the island producing 100,000 bushels, Spanish measure, and but little other grain. The inhabitants are stout, lusty, and industrious farmers, and expert hunters, the country being full of wild boars and deer. The women make clothes of several colours. There are in the island 14 parishes, belonging to the fathers of the order of St Augustine, three benefices of secular priests, and formerly one college of the society of Jesus, wherein they administer the sacraments to the garrison of Hilo. Besides the tributary Indians, there are here those blacks the Spaniards called Negroillos, who were the first inhabitants of the island, and afterwards driven into the thick woods by the Bisayas who conquered it. Their hair is not so stiff curled, nor are they so stout and strong as the Guinean blacks. They live in the most uncouth parts of the mountains with their wives and children, all naked like beasts. They are so swift that they often overtake wild boars and deer. They stay about the dead beasts as long as it lasts; for they have no other subsistence but what they acquire with their bow and arrows. They fly from the Spaniards, not so much through hatred as from fear. Among the islands about Panay lies Imaras, opposite to Hilo, and about a quarter of a league distant. It is long and low, ten leagues in compass and three in length, the soil fertile, abounding in sarapilla, and exceeding good water. On the mountains there are wild boars, deer, and good timber. It has also in it the port of St Anne, three leagues from Hilo.

PANCARPUS, in Roman antiquity, a kind of dew which the Roman emperors frequently exhibited to the people. The word is formed from the Greek pan, all, and sarpous, fruit. Whence the name was also given by the Athenians to a sacrifice wherein all kinds of fruits were offered. In this spectacle, the circus being all set over with large trees, represented a forest, into which the beasts being let from the dens under ground, the people, at a sign given by the emperor, pursued, shot, and killed all they could lay hold of, which they afterwards carried away, to regale upon at home. The beasts usually given on these occasions were bears, deer, oxen, and sheep.

Cassabon, Cujas, Piton, &c. make the pancarpus and sylva the same thing; Salmussius will have them different. The sylva, according to him, was such a diversion as that above described: but the pancarpus a combat, wherein robust people, hired for that purpose, fought.
PANCRAS, a town of England, in the county of Middlesex, on the north-west side of London, and in the highway to Kentish town. It church is one of the prebends of St Paul's, of which cathedral some call it the mother, it being thought to be as old as that church in the reign of Queen Elizabeth, when it is represented as weather-beaten and standing alone, without any company, though it had formerly many buildings about it. A veterinary college was established here in 1791, for the improvement of farriery, and the treatment of cattle in general.

PANCRIATUM, (composed of pan, all, and ancratome, I overcome), among the ancients, a kind of intermixed exercise, consisting of the lucta or wrestling, and the boxing or pugilate: but it differs in this, that as the athlete are not to seize the body, their hands are not armed with gauntlets, and give less dangerous blows.

The pancratiun was the third gymnastic exercise, and was not introduced till long after the others. The people who engaged in these exercises were called pancratiates; which name was also given to such as did not confine themselves to one exercise, but succeeded in several different ones.

Bartholomew, in his Travels of Anastarhis, gives us a short account of one of those at which he supposes him to have been present, in these words: "The action was soon terminated: a Sicilian named Sostratus, a champion celebrated for the number of prizes he had won, and the strength and skill which had procured them, had arrived the preceding day. The greater part of the combattants yielded up all pretensions to the crown as soon as he appeared, and the others on the first trial; for in those preliminary essays in which the athlete try their strength by taking each other's hands, he squeezed and twisted the fingers of his adversaries with so much violence as instantly to decide the victory in his favour."

PANCREAS. See Anatomy Index.

PANDA, in Mythology, a goddess who was invoked and honoured as the protectress of travellers and navigators. The goddess of peace was also called Pandar, because she opened the gates of cities which were shut in time of war. According to Varro, Panda is a surname of Ceres, derived from pae danda, because she gave bread to mankind.

PANDATARIA (Suetonius, Pliny, Strabo); PANDATERIA (Mela, Tacitus): An island in the Tuscan sea: a place of banishment for the more illustrious exiles. Hither Julia, the daughter of Augustus, was banished for her incontinence. To this island Tiberius banished Agrippina his daughter-in-law (Suetonius). It was the place of confinement of Octavia the daughter of Clodius, married to Nero; a sight that affected every eye (Tacitus). Now Santa Maria, situated between Pontia and Istibia (Holstenius).

PANDECT, in jurisprudence, the digest or collection, made by Justinian's order, of 534 decisions or judgments of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by the epistle prefixed to them.—The word is Greek, Ἰστορία, compound of πᾶν, "all," and ἱστορία, copia, "I take," Pandoeis i.e. a compilation, or a book containing all things. Though others, as Bartoli, will have it formed from πᾶν, and ἱστορία; as if these books contained the whole doctrine of the civil law.

The Pandects consist of 50 books, and made the first part of the body of the civil law.

They were denoted by two Π; but the copyists taking these Π for η, the custom arose of quoting them by η.

In the year 1137, the Pandects of Justinian, which had been brought by an Amaurian merchant from the east, fell into the hands of the Pisans. Angelus Politianus believes this copy to be that which had been compiled by order of the emperor. However that be, it is certain that all other copies are taken from it, as being the most ancient. The Pisans having obtained their request from the emperor, carried the volumes to Pisa, and for near three centuries they were known by the name of the Pandecte Pisae. But, about the year 1416, Pisa being taken by the Florentines, they were transported from thence to Florence, where they are now preserved in the library of the Medici, and known by the name of the Pandecte Florentiae. Some authors allege that Lutherans ordained by an edict that the Pandects should be publicly read and explained at Bologna, and pleaded in the tribunals; but Corringius and Linusbriguus fully refute their opinion.

Papais extends the denomination of Pandects to the Old and New Testament.

There are also Pandecte Medicene, "Pandects of Medicine," a kind of dictionary of things relating to medicine, compiled by Mat. Sylviacius of Mantua, who lived about the year 1297. Lemchusius has published Pandects of Turkey; and Bishop Beveridge Pandecta Cornutum.

PANDICATION, a stretching; or that violent and extensive motion of the solids that usually accompanies the act of yarning.

PANDORA, in fabulous history, a woman formed by Prometheus, to whom each of the gods gave some perfection. Venus bestowed upon her beauty; Pallas wisdom; Juno, riches; Apollo, music; and Mercury eloquence: but Jupiter being displeased at Prometheus for having stolen fire from heaven to animate the mass he had formed, gave Pandora a box, which she was ordered not to open; and then sent her to the earth with this box, in which were enclosed age, diseases, pestilence, war, famine, envy, discord, and all the evils and vices that could affright mankind. This fatal box was opened by Epimetheus, Prometheus's brother, when instantly all the diseases and mischiefs with which it was filled spread over the earth, and Hope only remained at the bottom. He said she was the first woman.

PANOUIRS, are Hungarian infantry: they wear a loose garment fixed tight to their bodies by a girdle, with great sleeves, and large breeches hanging down to their ankles. They use fire-arms and are excellent marksmen: they have also a kind of sabre near four feet long, which they use with great dexterity.

PANDOSIA (Livy, Justin, Strabo), an inland town of the Bruttii, and a place of strength on the river Acheron, where Alexander of Epirus, deceived by the oracle of Dodona, met his fate and perished. Now Mendicino (Holstenius) Another of Epirus (Strabo); situated
Pandosia is situated on the river Acheron (Livy); which Alexander of Epirus was advised to avoid as fatal, but which he met with in Italy. This last is said to have been the residence of the Oenotrian kings (Strabo).

PANDURA, or PANDRON, a musical instrument, used among the ancients, resembling the lute. The word is said to be formed from the Greek πανδοχ, i.e. "all gifts, all sorts of gifts." Isidore derives the name from its inventor Pandorus; others from Pan, to whom they attribute its invention, as well as that of the flute. It has the same number of strings with the lute; but they are of brass, and of consequence give a more agreeable sound than those of the lute. Its frets are of copper, like those of the ciste; its back is flat, like that of the guitar; and the rims of its table, as well as its ribs, are cut in semicircles. Du Cange observes, that Varro, Isidore, and others of the ancients, mention it as having only three strings; whence it is sometimes also spoken of under the denomination τριχώριον.

PANEAS (Pliny, Josephus): the apparent spring from which the Jordan rises, on the extremity of the west side of the Trachonitis (Pliny).

PANEAS (Coins, Pliny, Josephus), the name of a district adjoining to the spring Panes, with a cognominal town, either enlarged and adorned, or originally built, by Philip son of Herod, and called Cesarea by Josephus, and in St Matthew, Cesarea of Philip; with a temple erected to Augustus his benefactor, who conferred the Trachonitis upon him (Coins). It was afterwards called Nero nian, in honour of Nero (Josephus).

PANEYRIC, an oration in praise of some extraordinary thing, person, or virtue.

The name is Greek, πανευρικος; formed of παν, "all," and ευρικος, "I assemble!" because anciently held in public and solemn assemblies of the Greeks, either at their games, their feasts, fairs, or religious meetings.

To make their panegyrics the more solemn, the Greeks used to begin with the praises of the deity in whose honour the games, &c. were celebrated; then they descended to the praise of the people, or country where they were celebrated; then to the princes or magistrates who presided at them; and at length to the champions, especially the conquerors, who had gained the prizes in them.

PANEYRICUM, in church history, an ecclesiastical book, used by the Greek church, containing the panegyrical orations of various authors, on the solemnities of Jesus Christ and the saints. It is found in MS. in most churches, but is not the same in all; each church having its particular saints; and the compilers of this kind of books usually suited their collections to the taste of their own devotion. They are disposed according to the order of the months, and frequently consist of 12 volumes, answering to the 12 months of the year.

Among the principal authors of this work are Athanasius, Cyril, Basil, Chrysostom, &c.

PANEL. (Panella, Panclum), according to Sir Edward Coke, denotes "a little part;" but the learned Spelman says, that it signifies schedula vel pagina, "a schedule or roll;" as a panel of parchment, or a counterpane of an indenture: but it is used more particularly for a schedule or roll, containing the names of such jurors as the sheriff returns to pass upon any trial. And the impaneling a jury is the entering their names in a panel or little schedule of parchment.

PANEL, in Scots Law, signifies the prisoner at the bar, or person who takes his trial before the court of justiciary for some crime.

PANGOLIN, a species of the manis peculiar to Hindostan. See MANIS, MAMMALLA INDEX.

PANIC, denotes an ill-grounded terror or fright. Polyaeus says, it originates from Pan, one of the captains of Bacchus, who with a few men put a numerous enemy to rout, by a noise which his soldiers raised in a rocky valley, favoured with a great number of echoes. This stratagem making their number appear far greater than it was, the enemy quitted a very commodious encampment, and fled. Hence all ill-grounded fears have been called panic, or panic fears; and it was this that gave occasion to the fable of the nymph Echo's being beloved by the god Pan. Others derive the origin of it hence: that in the wars of the Titans against the gods, Pan was the first who struck terror into the hearts of the giants. Theron on Aratus says, he did it by the means of a sea shell, which served him for a trumpet, whereof he was the inventor.

PANICLE, in Botany, denotes a soft woolly beard, on which the seeds of some plants hang pendulous; as in millet, reeds, and hay.

PANICUM, a genus of plants belonging to the triandria class. See BOTANY INDEX.

PANINI, PAOLO; a painter of perspective and architecture. He was born at Placentia in 1691, with a most happy genius to painting, which he cultivated by studying at Rome, where he designed every vestige of ancient magnificence, the ruins of superb Roman edifices, cenotaphs, columns, baths, arches, and obelisks, as also some of the most entire buildings, the ornaments of modern Rome.

He studied the works of Ghisolfi with peculiar pleasure; he formed his taste, style, and manner, by the compositions of that esteemed artist; and his strongest ambition was to imitate him; so that he soon became eminent in that style beyond all his contemporaries. His composition is rich; the truth of his perspective is critically exact; and his paintings are universally esteemed for the grandeur of the architecture, for the clearness of his colouring, for the beautiful figures which he generally introduced, and also for the elegant taste with which he disposed them. He always designed them correctly, and set them off with suitable attitudes and expression.

However, this description of his merit must be supposed to allude to his early and prime performances; for in his latter time, his pictures were distinguishable by a free and broad touch, but they are feeble in their colouring and effect. At all times, indeed, he was too apt to design his figures rather too large for the architecture, which diminished the grandeur of the most magnificent parts of his composition, and was quite contrary to the practice of Ghisolfi; whose works must perpetually afford a pleasing deception to the eye, by the perspective proportions observed between the figures, buildings, and distances.

At Rivoli, a pleasure house belonging to the king of Sardinia, there are several of Panini's paintings, which are views of that fine retreat and its environs. They are beautifully coloured, well handled, and with a touch
full of spirit; though in some parts the yellow seems a little too predominant, and the lights are not always distributed in such a manner as to produce the most striking effect.

PANIONIA, in antiquity, a festival celebrated in honour of Neptune by a concourse of people from all the cities of Lonia. It is remarkable in this festival, that if the bull offered in sacrifice happened to bellow, it was accounted an omen of divine favour; because that sound was thought to be acceptable to Neptune.

PANNARIA, one of the Lipari islands. See LIPARA and LIPARI.—The ancients called it Therminia, from the hot waters which they found in it. It may be about eight or nine miles in circumference. It bears wheat, and grapes, from which the inhabitants make wine. Pannaria, like the other adjacent islands, appears to be a volcano; its original having been destroyed by continued eruptions. It is now no longer of a conical figure. It contains about 100 inhabitants, reckoning every soul, men, women, and children. It is, like Stromboli, governed by a curate, who depends on the priest of the parish of St. Joseph in Lipari; and when any couple in the island determine to marry, they must cross the sea to Lipari to receive the nuptial benediction in the parish of St. Joseph, or pay a sum for a license to empower the curate of Pannaria to perform the ceremony. All the other adjoining islands are subject to the same regulations.

The inhabitants of Pannaria live by fishing, and by taking small quantities of game on this and the little contiguous islands. They have an excellent breed of pigeons known by the name of galla, which are seen in tempestuous weather flying near the surface of the sea. They are here called corracio. The body of the bird and the tips of its wings are white; but the head, the tail, and the rest of the wings, are gray: they are of the size of Indian hens; their wings are prodigiously large: they have their nests on the steep inaccessible cliffs of the several islands. When the islanders bring these birds up tame, they feed them with fish, which, though of such size that you would think it impossible for their stomachs to receive them, they eagerly stretch their necks and swallow rapaciously. These birds are thus brought up to be as tame as pullets or pigeons; and such an attachment do they often acquire to the places in which they are reared, that some of them have been known to return to these islands after being conveyed to Mellazzo and Messina.

On the summit of a hill in this island, which projects over the sea, the inhabitants pretend to show a castle and an inscription. But that castle is only an elevated peak of the rock, which Nature seems to have prepared as a retreat for birds. It consists of puzolana; and has been actually formed by the action of winds and rains, for a long course of time, into a fantastic figure, which may appear, when carelessly viewed from a distance by an undistinguishing eye, the remains of some ancient structure. The good people of the island, not being able to judge of it otherwise than from appearance, are persuaded, that it can be nothing but a castle, which must have been reared for the defence of the island against the Turks and the corsairs of Barbary. These they consider as the most dreadful scourge with which mankind can possibly be afflicted, and fear them much more than the eruptions of the volcano. When they feel their island shaken, they embark with all their wealth, which a single sloop easily contains; and on board they are safe from both the shaking of the earth and the eruptions of the lava, but not from an hostile fleet.

In this island there appear various remains of ancient buildings, but very ruinous and very scanty. In ploughing the fields, many remains of sepulchres, in different modes of construction, are found; some of rough stones, tiles, or bricks; others consisting of each of a single stone. Vases of various sorts and sizes are also said to have been found in the same fields, utensils of different kinds, money, chains, and medals of lead. But none of these relics of antiquity have been preserved: the good people who found them were ignorant of their value, and therefore neglected them as trifts. In places along the shore of the island, where the sea appears to have encroached, there are some hewn stones to be seen: they seem to be remains of walls, which must have been very strong and of elegant architecture. In other places further distant from the shore, there likewise appear fragments of walls sunk in the ground, and apparently overwhelmed with mud, which the winds and rains have brought down from the mountain above. These remains show, that Pannaria, either under the Greeks, or in that period when all the elements were taxed for the gratification of Roman luxury, must have been adorned with superb buildings, as well as the adjacent islands of Lipari, Stromboli, and Basiluzzo.

PANNELS of a saddle, are two cushions or bolsters, filled with cows, deer, or horses hair, and placed under the saddle, on each side, to prevent the bows and bands from galling the horse.

PANNICULUS CARNOSUS, in Comparative Anatomy, a robust fleshy tunic, situated in beasts between the skin and the fat; by means of which they can move their skin in whole or in part. It is altogether wanting in mankind.

PANNONIA (Pliny, Strabo, Dio), an extensive country of Europe, having the Danube on the north, Dalmatia on the south, Noricum on the west, and Moesia on the east. It is divided into Superior and Inferior (Ptolemy, Dio). The common boundary between both were the river Arabo and Mount Cetus, having the Superior to the west, and the Inferior on the east side. This division is thought to be no older than the times of the Antonines. Pannonicus the epithet (Martial).

PANOMPHAÆUS, in antiquity, a designation given to Jupiter, because he was said to be the original author of all sorts of divination, having the books of fate, and out of them revealing either more or less, as he pleased, to inferior demons.

PANOPOLIS. See Achimium.

PANORMUS (Polybius, Pausanias), a town of Achaea, in Peloponnesus, near the promontory Rhium.—Another (Ptolemy, Pliny), a town on the north side of Crete.—A third (Ptolemy), in Macedonia, on the Ægean sea, near Mount Athos. —A fourth, of Samos (Livy).—A fifth, of Sicily; an ancient city, built by the Phoenicians (Thucydides); a principal town of the Carthaginians (Polybius); situated between Lilybaeus and Pelorus (Mela); a Roman colony. Now Palermo, capital of the island, on the north side. E. Long. 13.

N.
PAN | [ 728 ]

PANORAMA. — N. Lat. 38° 30'. A sixth Panorama of the Thracian Chersonesus, placed by Pliny on the west side of the peninsula, and mentioned by no other writer.

POROMUS (Ptolemy), a port of Attica; its name denoting it to be capacious. — Another, of Epirus (Strabo, Ptolemy); a large harbour in the heart of the Montes Ceraunii, below the citadel Chimaera. — A third of Ionia (Strabo); near Ephesus, with the temple of the Ephesian Diana.

PANORPA, the Scorpio fly, a genus of insects belonging to the order of neuroptera. See Entomology.

PANTALARIA, an island in the Mediterranean sea, between Sicily and the main land of Africa, about 17 miles in circumference. It is near the coast of Tunis, and abounds in cotton, fruits, and wine; but the inhabitants are obliged to bring all their corn to Sicily, as it belongs to the king of the two Sicilies. E. Long. 12° 25'. N. Lat. 36° 55'.

PANTHENUS, a Stoic philosopher, born in Sicily (though some have erroneously supposed him to be a Hebrew) about the beginning of the reign of Commodus. He presided over the celebrated school of Alexandria, where from the time of St Mark, the founder of that church, they had always — divine that was eminent for his learning and piety, to explain the Holy Scriptures, and to instruct them in human learning. This employment he was obliged to leave; for when the Indians required of Demetrius bishop of Alexandria to send them one to instruct them in Christianity, he sent Pantenus, who undertook the mission with joy, and behaved himself very properly in it. We are told, that the Indians had been inculcated with Christianity by St Bartholomew the apostle; and that Pantenus met with the Hebrew original of St Matthew's gospel, which the apostle had left there. St Jerome says that Pantenus brought it with him; and that it was, in his time, preserved in the library of Alexandria. But we suspect St Jerome to be mistaken in this respect. When Pantenus returned to Alexandria, he reassumed the government of the school of that city, which it is probable, he had, during his absence, committed to the care of St Clement, a presbyter of Alexandria. He explained the Scriptures publicly, under the reign of Severus Antoninus Caracalla; and was, in St Jerome's opinion, more serviceable to the church by his discourses than by his writings. He published some commentaries upon the Bible, which are lost. "That the prophets often express themselves in indifferent terms, and that they make use of the present time instead of the past and future," is a rule of Pantenus, which has been followed by all succeeding interpreters. Theodorus has related this rule; but he speaks of it as if Pantenus had rather said than written it.

We may have some notion of Pantenus's manner of explaining the Scriptures by the like performances of St Clement of Alexandria, Origen, and others who were brought up in that school.

PANTALOON, a sort of garment consisting of breeches and stockings of one piece; said to have been first introduced by the Venetians.

PANTALOON, on the theatre, is a buffoon or masked person, who performs high and grotesque dances, and shows violent and extravagant postures and airs. The word is likewise used for the habit or dress these buffoons usually wear; which is made precisely to the form of their body, and all of a piece from head to foot.

And hence those who wear a habit of this kind, for convenience, under their other clothes, are called pantalons of Venice.

PANTHEISM, a philosophical species of idolatry leading to atheism, in which the universe was considered as the supreme God. Who was the inventor of this system, is perhaps, not known; but it was of early origin, and differently modified by different philosophers. Some held the universe to be one immense animal, of which the incorporeal soul was properly their God, and the heavens and earth the body of that God; whilst others held but one substance, partly active and partly passive; and therefore looked upon the visible universe as the only Numen. The earliest Grecian Pantheist of whom we read was Orpheus, who called the world the body of God, and its several parts his members, making the whole universe one divine animal. According to Cudworth, Orpheus and his followers believed in the immaterial soul of the world; there being a strong resemblance with Aristotle, who certainly held that God and matter are coeternal; and that there is some such union between them as subsists between the souls and bodies of men. See Metaphysics, No. 264.

In the ancient Orphic theology, we are taught, that "this universe, and all things belonging to it, were made within God; that all things are contained together in the womb of God; that God is the head and middle of all things; that he is the basis of the earth and heaven; that he is the depth of the sea, the air we breathe, the force of the unchangeable fire; that he is the sun, moon, and stars; that there is one divine body; for,

πάντα γὰς εἰς μονὰς τὰ διὰ συμφήμην κοινά,

"all these things lie in the great body of God." — But further, to prove that the most ancient Greek philosophers resolved all things into God, and made God all, we shall cite a most remarkable passage from Plutarch's Defect of Oracles. "Whereas there are two causes of all generations, the divine and the human, the most ancient theologers and poets attended only to the more excellent of these two; resolving all things into God, and pronouncing this of them universally;"
PAN [ 729 ]

PANtheon, regard at all to the other natural and necessary causes of things: but on the contrary, their juniors, who were called naturalists, deviating from this most excellent and divine principle, placed all in bodies, their passions, collisions, mutations, and mixtures.

That by the most ancient theologers here mentioned, Plutarch meant Orpheus and his immediate followers, is plain from the phrase where he proves their antiquity. By their juniors, whom he calls naturalists, he could mean no other than the first Grecian philosophers, Anaximander, Anaximenes, and Hippo, who were followed by the atheistical atomists, Leucippus, Democritus, Protagoras, and Epicurus. But with respect to the universe being God, and all things divine and human being modifications of mere matter, the stoics undoubtedly agreed with Anaximander and his followers; for the school of Zeno held but one substance. See Metaphysics, No. 265. This impossum doctrine, that all things are God, and that there is but one substance, was revived in modern times by Spinoza, an apostate Jew. As we shall give a life of him and a view of his principles, we must refer the reader for a fuller account of Pantheon to Spinoza. See also Pan.

Pantheon, a beautiful edifice at Rome, anciently a temple, dedicated to all the gods; but now converted into a church, and dedicated to the Virgin and all the martyrs.

This edifice is generally thought to have been built by Agrippa son-in-law to Augustus, because it has the following inscription upon the frieze of the portico.

M. Agrippa L. F. Cos. Tertium fecit.

Several antiquarians and artists, however, have supposed that the Pantheon existed in the times of the commonwealth; and that it was only embellished by Agrippa, who added the portico. Be this as it will, however, the pantheon, when perfected by Agrippa, was an exceedingly magnificent building: the form of whose body is round or cylindrical, and its roof or dome is spherical: it is 144 feet diameter within; and the height of it, from the pavement to the grand aperture on its top, through which it receives the light, is just as much. It is of the Corinthian order. The inner circumference is divided into seven grand niches, wrought in the thickness of the wall; six of which are flat at the top; but the seventh, opposite to the entrance, is arched. Before each niche are two columns of antique yellow marble fluted, and of one entire block, making in all 14, the finest in Rome. The whole wall of the temple, as high as the grand cornice inclusive, is cases with divers sorts of precious marble in compartments. The frieze is entirely of porphyry. Above the grand cornice arises an attic, in which were wrought, at equal distances, 14 oblong square niches: between each niche were four marble pilasters, and between the pilasters marble tables of various kinds. This attic had a complete entablature; but the cornice projected less than that of the grand order below. Immediately from the cornice springs the spherical roof, divided by bands which cross each other like the meridians and parallels of an artificial terrestrial globe. The spaces between the bands decrease in size as they approach the top of the roof; to which, however, they do not reach, there being a considerable plain space between them and the great opening. That so bold a roof might be as light as possible, the architect formed the substance of the spaces Pantheon, between the bands of nothing but lime and pumice-stones. The walls below were decorated with lead and brass, and works of carved silver over them; and the roof was covered on the outside with plates of gilded bronze. There was an ascent from the springing of the roof to the very summit by a flight of seven stairs. And if certain authors may be credited, these stairs were ornamented with pedestrian statues ranged as an amphitheatres. This notion was founded on a passage of Pliny, who says, "That Diogenes the sculptor decorated the pantheon of Agrippa with elegant statues, yet that it was difficult to judge of their merit, upon account of their elevated situation." The portico is composed of 16 columns of granite, four feet in diameter, eight of which stand in front, with an equal intercolumniation all along, contrary to the rule of Vitruvius, who is for having the space answering to the door of a temple, wider than the rest. On these columns is a pediment, whose tympanum, or flat, was ornamented with bas-reliefs in brass; the cross beams which formed the ceiling of the portico were covered with the same metal, and so were the doors. The ascent up to the portico was by eight or nine steps.

Such was the pantheon, the richness of which induced Pliny to rank it among the wonders of the world.

The eruption of Vesuvius, in the reign of Tiberius, damaged the Pantheon very considerably: it was repaired by Domitian; which occasioned some writers to mention that prince as the founder of the building. The emperor Adrian also did something to it. But it appears that the pantheon is more indebted to Septimius Severus, than to any one since its erection. The most, perhaps, that any of his predecessors had done, was the adding some ornament to it: Septimius bestowed essential reparations upon it. The following inscription appears upon the architrave:

IMP. CAES. SEPTIMIVS. SEVERVS.
PIVS. PERTINAX.
ARABIVS. PARTHIVS. PONTIF.
MAX. TRIB. POT.
XI. COS. III. P. P. ET. IMP. CAES.
MARCVS.
AVRELIVS. ANTONIVS. PIUS.
FELIX. AVG. TRIB.
POT. V. COS. PRINC. PANTHEVM.
VETVSSTATE.
OBRVPTVM. CVM. OMNI. CVLTVS.
RESTITVNT.

It is really a matter of astonishment, that a structure, which, granting it to have been built by Agrippa, was not more than 200 years old, should have fallen into decay through age. This single consideration seems sufficient to confirm the opinion of those who believe it to have stood in the times of the commonwealth.

The temple subsisted in all its grandeur till the incursion of Alaric in the time of Honorius. Zosimus relates, that the Romans having engaged to furnish this barbarian prince with 3000 pounds weight of gold and 3000 pounds weight of silver, upon condition that he should depart from their walls; and it proved impossible to raise those sums either out of the public treasury or private purses, they were obliged to strip the temples
It does not appear that from this time to Urban VIII. any pope did any thing remarkable to the Pantheon.

Raphael Urban, who had no equal as a painter, and who as an architect had no superior, left a considerable sum by his will for the repair of the Pantheon, where his tomb is placed. Perino de la Vaga, Jacomo Udino, Filippino Lippi, and the celebrated Archangelo Corelli, did the same. All the ornaments within, that have any claim to be called good, are of the later times; the paintings merit esteem; and the statues, though not masterpieces, do honour to sculpture, which alone is a proof that they are posterior to the 15th century.

But, with all the respect due to a pontiff, who was otherwise a protector, and even a practiser of the arts, it were much to be wished that Urban VIII. had not known that the Pantheon existed. The inscriptions cut at the side of the door inform us, that he repaired it; yet, at the same time that he built up with one hand, he pulled down with the other. He caused two bellfries of a wretched taste to be erected on the ancient front work, and he divested the portico of all the remains of its ancient grandeur, viz. the brazen covering of the clymenium, which amounted to such a prodigious quantity, that not only the vast baldacchino or canopy of the confessional in St Peter’s was cast out of it, but likewise a great number of cannon for the castle of St. Angelo. This pope, who was of the family of Barberini, presented also as much of this metal to his nephew, as was sufficient for the decoration of his new palace; on which occasion this remarkable pasquinade was stuck up:

Quod non fecerant Barbari fecerunt Barberini.

If ever gingo added force to wit, it was certainly in this instance.

It is surprising, that whilst these operations were carrying on in the portico, he never once thought of repairing the damages which time had wrought in it. Of the 16 pillars which supported this magnificent pile, there were no more than 13 left; the three next the temple of Minerva had disappeared; with these the entablature and an angle of the front had tumbled down. There were not wanting in Rome fragments enough of antique columns that might have been put together, and set up, to have prevented the downfall of a pile which deserved to stand as long as the world endured.

Alexander VII. did what Urban VIII. had neglected to do. At the same time that Bernini was constructing the colonnade of St Peter, this pontiff ordered search to be made for pillars to match those of the portico of the Pantheon; and some were found not far from the French church of St. Lewis of the very same model. They were granite of the isle of Iva, or Elba, and those of the portico were Egyptian granite; the colour, however, was the same, so that the effect was equal. The pope’s zeal did not stop here; he caused all the old houses before the portico to be pulled down, and the soil and rubbish to be cleared away which covered the steps, and even the bases of some of the pillars. He began covering the roof with marble, and raised a lantern over the aperture, to keep out rain; but death took him off before his project was completed. Clement
PAN

PANTHEON. See FELIS, MAMMALIA INDEX.

PANTING, consists in a rapid succession of inspirations and expirations, which happens when we run or perform any violent motion.

PANTOMIME, παντομιμη, among the ancients, a person who could imitate all kind of actions and characters by signs and gestures without speaking.

The pantomimes made a part in the theatrical entertainments of the ancients; their chief employment was to express, in gestures and action, whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied. They were very ancient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato's time. In Rome, it was so late as the time of Augustus before they made their appearance. As to their dress, it was various, being always suited as near as possible to that of the person they were to imitate. The crocota was much used among the Roman pantomimes, in which and other female dresses they personated women.

We have this account of them in Gibbon's history:

"The pantomimes (A), who maintained their reputation from the age of Augustus to the sixth century, expressed, without the use of words, the various fables of the gods and heroes of antiquity; and the perfection of their art, which sometimes disarmed the gravity of the philosopher, always excited the applause and wonder of the people. The vast and magnificent theatres of Rome were filled by 3000 female dancers, and by 3000 singers, with the masters of the respective choircresses. Such was the popular favour which they enjoyed, that in a time of scarcity, when all strangers were banished from the city, the merit of contributing to the public pleasures exempted them from a law which was strictly executed against the professors of the liberal arts (B)."

Pantomimes are still very common in England: they differ indeed in some respects from those of antiquity; but they retain the name, and like these they consist in the representation of things merely by gestures.

PANOCA, a town and province of North America, in New Spain, lying to the north of Mexico, with a bishop's see. There are veins of gold, and salt works, which are the principal revenue of the inhabitants.—It is seated near the mouth of a river of the same name, at a small distance from the gulf of Mexico. W. Long. 100° 5'. N. Lat. 24° 0'.

PAO-TENG-FOU, in China, where the viceroy resides, is the most considerable city in the province next to Pekin. It has 20 others under its jurisdiction, three of the second and 17 of the third class. The country around it is pleasant, and inferior in fertility to no part of China. It is necessary to pass this city in going from Pekin to the province of Chan-si.

PAOLO, MARCO. See PAULO.

PAPA, a small but strong town of Lower Hungary, in the county of Vespriin. It was taken from the Turks in 1683, after raising the siege of Vienna, and is subject to the house of Austria. It is seated on a mountain, near the river Marebacz, in E. Long. 18° 10'. N. Lat. 47° 20'.

PAP-Castle, in England, in Bridekirk parish, Cumberland, stood two miles from Cockermouth, on the other side of the Derwent, whose Roman antiquity is proved by several monuments; and a large green stone vessel found here, with little images upon it, is supposed to have

(A) "See the dialogue of Lucian, entitled, De Saltatione, tom. ii. p. 265—317. edit. Reitz. The pantomimes obtained the honourable name of pantomimes; and it was required that they should be conversant with almost every art and science. Burttie (in the Memorie de l'Academie des Inscriptions, tom. i. p. 127, &c.) has given a short history of the art of pantomimes.

(B) "Ammiannus, l. xiv. c. 6. He complains, with decent indignation, that the streets of Rome were filled with crowds of females, who might have given children to the state, but whose only occupation was to curl and dress their hair; and jactari volubilique gyris, dum exprimunt innumeram simulacram, qua finxere fabule theatralis."
The name of Pap-castle seems to be contracted from Pipard its owner: it is said to have been demolished, and the materials employed to build Cockermouth castle.

Mr Routh, in a letter to Mr Gale, thus describes the ruins discovered at Pap-castle, Jan. 16, 1747:

"I made particular inquiry of the man in whose grounds they were discovered, and some of the neighbours present at the discovery. The close in which they lay is a little to the south of the fort, on the declivity of the hill to the river, and bounded on the west by a narrow lane, probably the via militaris continued; and immediately shown to strangers as the most remarkable here for finding Roman coins. They are the largest ruins ever known to be discovered in these parts: for they met with three walls besides the pavement; the first lay east and west, and was covered with earth near a foot high; parallel to it, at seven yards, they found a second; and between these two, about two yards deep (the height of the walls, which were six yards broad, and strongly cemented), they came to a pavement curiously laid with large flags, three quarters of a yardsquare, and two or three inches thick, as I measured them: but imagining there must be money under it, they covered it up till night, and then tore it all up. It was composed of flags of different thicknesses: under the thinner was a coarse strong cement, which caused them to be broken in taking up; but the thicker are pretty entire. Part of the wall stood on the floor, and the edge was secured by a fine red cement two inches thick, supposed to be intended to keep the floor dry. They imagined themselves at the corner of the building, the third wall standing on either sides with the first, and the second parallel to the other side, on which was an old hedge. On the floor they found a stone trough, or rather base of a pillar, about a foot high, and the hollowed part square, and two inches deep. They likewise found a small earthen patens, which I procured, of Pap-castle, the fine red clay, beautifully smooth, with letters impressed on the bottom; but so decayed as not to be intelligible.—Some years ago, the man's father who found these ruins dug up a conduit. The owner had no coins, nor knew of any. One of his neighbours showed me a large brass one decayed."

Mr Routh, in another letter to Mr Gale, April 13, 1743, describes a fibula, a coin of Trajan, ... IANO AVG ... P. M. Rev. the emperor seated on a pile of arms, a trophy before him, S. P. Q. R. OPTI ... S. C. and two oaken pieces of the adjoining timber of a house which appeared to have been burnt, in the garden of Jerome Tully, Esq. of Carlisle. The earth as far as they dug was artificial, and antiquities are only found at a considerable depth.

Dr Stukeley says, the Roman castrum lies on the top of the hill above the village, and he traced its whole circumference, a bit of the Roman wall by the river side going to Wigton, and there the ditch is plainly visible, though half filled up with the rubbish of the wall. A subterraneous vault, floored with large slabs of freestone, was found in the pasture of the south-east angle. The name of Boroughs includes both places where it stood; and they find stones and slates with iron pins in them, coins, &c. on the whole spot below it, towards the water-side. It was a beautiful and well chosen plan, on the south-west side of a hill, a noble river running under, and pretty good country about it. Coins of Claudius, Adrian, and a silver Geta, Pont, rev. princeps inventitis. He supposes its ancient name Derwent, derived from the Derwent.

PAPAVER, the Poppet; a genus of plants belonging to the polyandria class, and in the natural method ranking under the 27th order, Rhoeales. See BOTANY and MATERIA MEDICA Index.

PAPAV, or PAPA-TREE. See CARICA, BOTANY Index.

PAPER.

Paper is a word evidently derived from the Greek περγίνες, pergines, the name of that celebrated Egyptian plant which was so much used by the ancients in all kinds of writing. It would be unnecessary particularly to describe the different expedients which men in every age and country have employed for giving stability to their ideas, and for handing them down to their children. When the art of writing was once discovered, stones, bricks, leaves of trees, the exterior and interior bark, plats of lead, wood, wax, and ivory, were employed. In the progress of society, men have invented the Egyptian paper, paper of cotton, paper manufactured from the bark of trees, and in our times from old rags.

The inhabitants of Ceylon, before the Dutch made themselves masters of the island, wrote on the leaves of the talipot. The manuscript of the brahmans, sent to Oxford from Fort St. George, is written on the leaves of a palm of Malabar. Herman speaks of another palm in the mountains of that country, which produces leaves of several feet in breadth. Ray, in his History of Plants, vol. ii. book xxxii. mentions some trees both in India and America, the leaves of which are proper for writing. From the interior substance of these leaves they draw a whitish membrane, large, and somewhat like the pellicle of an egg; but the paper made by art, even of the coarsest materials, is much more convenient in use than any of these leaves.

The Siamese, for example, make two kinds of paper, the one black and the other white, from the bark of a tree called Pincus. These are fabricated in the easiest manner; but they can be used on both sides with a bobbin of fullers' earth.

The nations beyond the Ganges make their paper of the bark of many trees. The other Asiatic nations within the Ganges, excepting those toward the south, make it of old rags of cotton cloth; but from their ignorance of the proper method, and the necessary machinery, their paper is coarse. This, however, is not the case with that made in China and Japan, which
History.

which deserves attention from the beauty, the regularity, the strength, and fineness of its texture. In Europe they have discovered, or rather carried to perfection, the ingenious art of making paper with old rags, originally either from flax or hemp; and since this discovery the paper produced from our manufactures is sufficient for every purpose. And though these materials have been hitherto abundant, several philosophers have attempted to substitute other vegetable substances in their place. In the 6th volume of the Transactions of the Society for the Encouragement of Arts, we have an account of paper made by Mr Creeviss near Warrington from the back of willow-twigs; and it has been observed by a society of able critics, that hogs-beds would probably answer this purpose better. The rags in common use for paper-making are a texture of supple and strong fibres separated by a leaf from the bark of the plants. It would be in vain to employ the whole body of the plant, as this substance forms a very improper stuff for the operations of the paper-mill. From these principles we are directed in the choice of vegetable substances fit for the present purpose. The greater or less degree of purity in the materials is not absolutely necessary; for flax itself, without any preparation, could be made into paper; but it would be extremely coarse, and the bark of nettles or mallows would not bear the expense of labour. Although cotton be used in the fabrication of paper in the Levant, and perhaps in China, we are not to conclude that the down of plants in Europe, without the strength or suppleness of cotton, will answer the same purpose.

Paper.

The chief kinds of paper which merit attention in this work are, 1. The Egyptian paper; 2. The paper made from cotton; 3. Paper from the interior bark of trees or liber; 4. Chinese paper; 5. Japanese paper; 6. Paper made from asbestos; and, 7. Paper made from linen rags.

This is the famous paper used by the ancients, which was made of a kind of reed called papryrus, growing in Egypt on the banks of the Nile. According to Isidorus this paper was first used at Memphis, and Lucan seems to be of the same opinion.

Nondum flavineas Memphis connexere bidos
Novorat.

Pharsal. lib. iii. ver. 222.

Whatever truth may be in this, it is certain, that of all the kinds of paper used by the ancients, the papryrus was the most convenient, both from its flexibility and from the ease of fabrication. It was a present from nature, and required neither care nor culture. It is not certain at what particular period the ancients began to make paper of papryrus; but there are several authorities which prove the use of it in Egypt long before the time of Alexander the Great.

Pliny, lib. xiii. cap. 11, gives a full description of the method of making this paper in Egypt. They divide, says he, with a kind of needle the stem of the papryrus into thin plates or slender pellicles, each of them as large as the plant will admit. These are the elements of which the sheets of paper are composed. The pellicles in the centre are the best; and they diminish in value as they depart from it. As they were separated from the reed, they were extended on a table, and dried across each other at right angles. In this state they were moistened by the water of the Nile, and while wet were put under a press, and afterwards exposed to the rays of the sun. "It was supposed that the water of the Nile," Pliney, had a gummy quality necessary to glue these stripes together. This, says Mr Bruce, we may be assured is with a perfect foundation, no such quality being found in the water of the Nile; on the contrary, I found it of all others the most improper, till it had settled and was absolutely distilled of all the earth gathered in its turbid state. I made several pieces of this paper both in Abyssinia and Egypt; and it appears to me, that the sugar or sweetness with which the whole juice of this plant is impregnated, is the matter that causes the adhesion of these stripes together; and that the use of the water is no more than to dissolve this, and put it perfectly and equally in fusion." When there was not enough of sugar in the plant, or when the water did not sufficiently dissolve it, the pellicles were united by a paste made of the finest wheat flour, mixed with hot water and a little vinegar, and when dried they were flattened and smoothed by the beating of a mallet.

The size of this paper varied much; it seldom exceeded two feet, but it was oftentimes smaller. It had different names, according to its size and quality: The first was called Imperial, which was of the finest and largest kind, and was used for writing letters by the great men among the Romans. The second sort was called by the Romans the Livonian paper, from Livia the wife of Augustus; each leaf of this kind was 12 inches. The third sort was called the Sacerdotal paper, and was 11 inches in size.

The paper used in the amphithreatres was of the dimensions of nine inches. But what was esteemed of greatest value in it, was its strength, whiteness, and polish. The ink, however, sunk less in paper highly polished; and therefore the characters were more liable to be effaced. When it was not carefully soaked in the first preparation, the paper brought a less price; because letters were with difficulty formed upon it, and it sent forth a disagreeable smell. To remedy this defect, the paper went through a new course of sizing and hammering; and the size used on that occasion was made of light bread steeped in boiling water, and passed through a filtering cloth. By this means the paper became in the highest degree united, and smoother than the finest linen. It was this paper which gave so long a duration to the works of the Gracchi, Tiberius and Caius, in their own hand-writing. "I have seen them," says Pliney in the library of Pomponius Secundus, a poet and citizen of the first rank, near 200 years after they were written." We may add, that manuscripts of this paper still remain, which have undoubtedly been written 1000 or 1200 years ago. It appears from Pliney, that the Egyptians pasted together the pellicles of the papryrus by means of the water of the Nile; but that the polishing with ivory, and the operations of the hammer and the press, were added by the invention and industry of the Roman artists. The Egyptians seem to have known the use of size; but it is evident from the same author, that the Romans used a stronger size in the making of paper. Notwithstanding the care which was taken to give strength and consistency to the paper of Egypt, the leaves, although collected into a book, were too weak to support themselves; and for this reason it
was a common practice, after every five leaves, to insert a leaf of parchment. There still remains in the abbey of St German de-pres a fragment of the epistles of St Augustine written in this manner. The manuscript is at least 1100 years old, and in a high state of preservation.

This paper was an important branch of commerce to the Egyptians, which continued to increase towards the end of the Roman republic, and became still more extensive in the reign of Augustus. The demand from foreign nations was often so great, as to occasion a scarcity at Rome; and we read in the reign of Tiberius of a tumult among the people in consequence of this scarcity. In a letter of the emperor Adrian, the preparing of the papyrus is mentioned as one of the principal occupations at Alexandria. "In this rich and opulent city (says he) nobody is seen idle: Some are employed in the manufactory of cloth, some in that of writing paper," &c. During the time of the Antonines, this commerce continued equally to flourish. Apeleius says, that he wrote on the paper of Egypt with a reed of the Nile prepared at Memphis.

The demand for this paper was so great towards the end of the third century, that when the tyrant Firmus conquered Egypt, he boasted that he had seized as much paper and size as would support his whole army.

St Jerome informs us, that it was as much in use in the fifth century when he flourished. The duty on the importation of this commodity had grown excessive towards the end of this or the beginning of the sixth century; and being abolished by Theodoric king of Italy, Cassiodorus, in the 38th letter of his 11th book, congratulates the whole world on the discharge of an impost on a merchandise so essentially necessary to mankind.

The fathers Montfaucon and Mabillon mention several fragments written on this paper in the sixth century. One of them was a charter of the emperor Justinian, entitled Charta pleroriae securitatis. Father Montfaucon saw in 1659, in the library of Julio Justiniani, three or four fragments of paper of Egypt of the same antiquity. And Mabillon speaks of some books of the Jewish antiquities by Josephus translated into Latin, which seemed to have been written in the same century, and which were preserved in the library of St Ambrose of Milan, but he had not seen the manuscripts. The same father mentions to have seen in the library of St Martin of Tours the remains of an old Greek manuscript of the paper of Egypt, and which appeared to him to be of the seventh century. He also believes that the copy of St Mark's gospel preserved in the register-office of Venice is written on the same paper, that it is the most ancient of any of the evangelical manuscripts, and may be supposed to be written at the latest in the fourth century.

According to the same antiquarian, the paper of Egypt was used in France and Italy, and other European countries, both for books of learning and public records; and there still remains, adds he, a great number of these in the archives of the church at St Dennis, at Corbie, in the abbey De Grasse, and in other convents.

It is probable, that the invention of paper made of cotton, of which we are afterwards to treat, insensibly destroyed the reputation and manufacture of the paper of Egypt; but it is still a question at what particular period the fabrication of the latter totally ceased. Eratosthenes, the learned commentator on Homer, assures us, that in his time in 1150 it was no longer in use; but Father Mabillon maintains, that many of the papyrus bulls were written on the papyrus in the 11th century.

The Count Maffei, in his Istor. Diplomat. bibl. ii. Biblioth. Ital. tom. ii. p. 251, is decidedly of opinion, that the paper of Egypt was not in use in the fifth century. He considers all records written on this paper dated posterior to this period as not authentic; and the papyrus bulls mentioned by Father Mabillon appear to this learned person, as well as the copy of St Mark's gospel, to be written on paper manufactured from cotton. To reconcile in some measure these contradictory accounts, it may be observed, that on some particular occasions, and by some particular persons, the paper of Egypt might have been employed for several hundred years after it ceased to be of general use. Whoever wishes for a fuller account of the paper of Egypt, may consult among the ancients Pliny, lib. xiii. and Theophrastus, lib. iv. chap. ix. and among the moderns, Guilianinus, Scaliger, Saumaise, Kerchmayer, Nigroli; Father Hardouin in his edition of Pliny; Father Mabillon in his work De re Diplomat., Montfaucon in his Palaeography, and in his Collections; the illustrious Maffei in his Istor. Diplomat.; the count de Caylus in the Memoirs of the Academy of Inscriptions; and Mr Bruce in his Travels to discover the Source of the Nile.

It is generally supposed that the invention of the papyrus paper, called charta bombycina, supplanted the Egyptian from cotton paper in Greece. This paper is incomparably more lasting, and better calculated for all the purposes of writing. It is not precisely known at what period this art, which supposes a great variety of previous experiments, was first reduced to practice. The application of cotton to the purposes of paper-making requires as much labour and ingenuity as the use of linen rags; and for this reason, if we could determine the precise time when paper was made from cotton, we should also fix the invention of the art of paper-making as it is presently practised in Europe. Father Montfaucon proves, by incontestable authorities, that paper from cotton was in use in 1100. This paper, in the Greek language, is called χαρτης αμβακινος, or αμβακινος; for although αμβακας is the Greek word for silk, yet in those times it was applied, as well as χαρτης, to cotton; and hence the Italians to this day call cotton bambaccio.

The most ancient manuscript of this paper which Father Montfaucon saw with the dates, was that in the French king's library, written A. D. 1050; but as the manuscripts without date are infinitely more numerous than those which are dated, and as some conjecture can be formed concerning them from the manner of writing, this father believes some of these to have been written in the 10th century.

The researches of the same learned antiquarian amount almost to a proof that this paper was discovered towards the end of the ninth century or beginning of the tenth; for before the twelfth century it was commonly used in the eastern empire, and even in Sicily. Roger King of Sicily says, in a diploma written in 1145, that he had renewed
renewed on parchment a charter which had been written on paper of cotton, in the year 1100, and another which was dated in the year 1112. About the same time the empress Irene, in the statutes for some religious houses at Constantinople, says that she had left three copies of the same statutes, two in parchment and one in paper from cotton. From that period this paper was still more in use throughout all the eastern empire; and innumerable Greek manuscripts are found written on it in all the great libraries.

This discovery happened at a time when there seems to have been a great scarcity of parchment; for it was about this period that the Greeks erased the writings of Polybius, Diodorus of Sicily, and many valuable ancient authors, for the sake of the parchment.

It was the invention of this paper of cotton which destroyed the manufacture of the paper of Egypt; for, if we may believe Eustathius, who wrote towards the end of the 12th century, the latter paper had gone into disuse but a little before his time. We may easily believe, however, that this new invention, although of great advantage to mankind, was introduced by degrees.

The manufacture of this kind of paper has flourished in the Levant for many ages, and is carried on with great success even to this day. It is not necessary to say anything farther, than that the paper produced from cotton is extremely white, very strong, and of a fine grain.

This paper of the ancients was made from the white pellicle or inner coat found in many trees between the bark and the wood. The trees commonly in use were the maple, the plane tree, the elm, the beech, the mulberry, and most frequently the linden-tree. The ancients wrote on this inner coat after they had separated it from the bark, beat, and dried it.

The fathers Maubill and Montfaucon speak frequently of manuscripts and diplomas written on paper made from bark; and positively distinguish it from the Egyptian paper, because it was thicker, and composed of parts less adhering together.

There are many palm trees in India and America to which botanists have given the name papyrus, because the natives have written with bobbins either on the leaves or the bark. Such is the American palm, called tal by the Indians; and of the same kind is the guajara of New Spain. Every palm, the bark of which is smooth, and the leaves large and thick, may be used for this purpose.

The art of making paper from vegetables reduced to stuff was known in China long before it was practised in Europe; and the Chinese have carried it to a degree of perfection hitherto unknown to the European artis. The fine paper in China is softer and smoother than that of Europe; and these qualities are admirably adapted to the pencil, which the Chinese use in writing. Several kinds of their paper discover the greatest art and ingenuity, and might be applied with much advantage to many purposes. They are capable of receiving, for example, the impression of types; and both maps and prints have been executed with success on the Chinese paper.

The different sorts of paper vary in China according to the materials of which they are composed, and to the different manner of manufacturing those materials. Every province has its peculiar paper. That of Sechuan is made of linen rags as in Europe; that of Fu-kien, of young bamboo; that of the northern provinces, of the interior bark of the mulberry; that of the province of Kiang-nan, of the skin which is found in the webs of the silk-worm; finally, in the province of Hu-nan, the tree chu or ko-chu furnishes the materials with which they make paper.

The method of fabricating paper with the bark of different trees is nearly the same with that which is followed in the bamboo. To give an idea, therefore, of the manner of manufacturing the interior barks of the mulberry, the elm, and the cotton-tree, it will be sufficient to confine our observations to the bamboo.

The bamboo is a kind of cane or hollow reed, divided by knots; but larger, more elastic, and durable than any other reed.

The whole substance of the bamboo, composed of filaments, and a great abundance of fibrous materials, is employed in this operation. The shoots of one or two years, nearly the thickness of a man's leg, are preferred. They strip the leaves from the stem, cut them into pieces of four or five feet long, make them into parcels, and put them into water to macerate. As soon as they are softened, which generally happens in five days, they wash them in pure water; put them into a dry ditch; cover them with lime for some days, which they water for the purpose of slacking; they wash them carefully a second time; cut every one of the pieces into filaments, which they expose to the rays of the sun to dry and to bleach them. After this they are boiled in large kettles; and then reduced to stuff in mortars of wood, by means of a hammer with a long handle, which the workman moves with his foot.

The stuff being thus prepared, they take some shoots of a plant named koteng, which, steeped in water four or five days, is reduced to an unctuous or glutinous substance; and when they proceed to make the paper, this is mixed with the stuff in certain exact quantities, for on this mixture depends the goodness of the paper.

When the extract from the koteng is mixed with stuff of the bamboo, the whole mixture is beat together in mortars till it becomes a thick and viscous liquor. This is poured into large tubs or reservoirs, so exactly framed as that no part of the liquor can escape.

The workmen after this plunge their forms into the liquor; take out what is sufficient for a sheet of paper; which immediately, from the glutinous substance, becomes firm and shining; and is detached from the form by turning down the sheet on the heap of paper already made, without the interposition of pieces of woolen cloth, as in Europe.

In order to dry this paper, they have a hollow wall, the two fronts of which are smooth and extremely white. At the extremity of this wall is placed a stove, the pipes of which are carried in a circular manner through the whole empty space. The sheets of paper are laid on the surface, to which they adhere till they come over them with a soft brush; and after they are dry, it is easy to distinguish the side which received impressions from the brush from that which adhered to the wall. By means of this stove the Chinese dry their paper as fast as they can make it; but it is only in cold seasons, or in certain
The Chinese paper must be dipped in a solution of alum before it can take either ink or colours. They call this operation *faner*, from the Chinese word *fan*, which signifies alum. The following is the manner of preparing this solution: Six ounces of isinglass cut very small is put into boiling water, and constantly stirred, that it may dissolve equally. When the isinglass is wholly dissolved in the water, they throw in twelve ounces of calcined alum, which is also stirred till it is completely dissolved and mixed with the isinglass. This composition is afterwards poured into a large and deep basin, at the mouth of which is a little round piece of wood; the extremity of every sheet of paper is fixed in another piece of wood, with a slit made to receive it; by means of this equipment they plunge the sheet of paper into the composition of alum and isinglass; and when it is fully penetrated, they draw it out, making it glide over the little round piece of wood. The long piece of wood which holds the sheet by one end, and keeps it from tearing, is afterwards suspended with it on a wall till it is sufficiently dry.

The Chinese give the paper intended for different purposes different preparations. We shall confine our observations to the silver colour which they give to some paper. They take two scruples of paste made of cows hide, one scruple of alum, and a pint of water: the whole is boiled on a slow fire till the water be evaporated. The sheets of paper are then stretched on a smooth table, and covered over with two or three layers of this paste. They take afterwards a certain quantity of talle, washed and boiled in water, with the proportion of one-third of one hundred to a pound of the extreme of every sheet of paper, passed through a sieve, boiled a second time in water, dried in the sun, and again passed through the sieve. This powder is spread equally over the sheets of paper, prepared as we mentioned above; and then they are dried slowly in the shade.

The sheets of paper, covered in this manner with talle, are laid upon a table, and rubbed with a little cotton; which fixes a certain quantity of the talle in the paper, and carries off the overplus to be used on another occasion. By means of this composition the Chinese draw all manner of figures on their paper.

Formerly the Chinese wrote with a bodkin of iron on tablets of bamboo; afterwards on satin with a pencil; and during the dynasty of their tyrants, about 100 years before Christ, they discovered the art of making paper.

The paper made from the bamboo is sufficiently white, soft, closely united, without the least inequality on the surface to interrupt the motion of the pencil, or to occasion the rising of the materials which compose it. Moreover, every kind of paper made from the bamboo or the bark of trees, is residerd to crack than that made in Europe; besides, it is more susceptible of moisture, and sooner destroyed with dust and worms. To obviate this last inconvenience, they are obliged frequently to beat their books in China, and to expose them to the sun.

It may be observed, however, that the Chinese paper, employed for various purposes in Europe, has been preserved for a long time without receiving damage either from moisture or insects.

According to Kämpfer, the bark of the morus paperi, or true paper tree, is chiefly employed for making paper in Japan. Every year after the fall of the leaves, which happens in the tenth month, corresponding to our December, the Japanese cut the young shoots of this tree into pieces of about three feet, collect them into parcels, which they boil in water into which they have cast a certain quantity of ashes. If the wood is dry, they take care to steep it 23 hours in water before it is boiled. The parcels are kept in a close copper till the bark at the extremity of the shoots is separated from the stem about half an inch; they are then cooled; and the bark alone is fit for making paper. They begin by a preparation which consists of cleaning the bark, and separating the good from the bad. For this purpose they steep it in water three or four hours; and as soon as it is softened they scrape off with a knife whatever is blackish or green, and at the same time separate the strong bark of a year's growth from the slender which covers the young shoots. The first of these gives the whitest and best paper. If there is any of the bark of more than a year's growth, it is laid aside for the contract.

After the bark has been culled and cleaned in this manner, it is boiled in a clear lea till the matter is of that consistency, that, being touched gently with the finger, it draws off in the form of hairs, or like a collection of fibres. During the time of boiling it is constantly stirred with a strong reed, and the waste by evaporation supplied from time to time with additional quantities of the clear lea. To make this lea, they put two pieces of wood across the mouth of a tub, cover them with straw, on which they lay a bed of ashes a little moistened; and pouring boiling water on the ashes, the salts contained in them are carried down to the tub. This is what is called a tree or four hours; and as soon as it is softened they scrape off with a knife whatever is blackish or green, and at the same time separate the strong bark of a year's growth from the slender which covers the young shoots. The first of these gives the whitest and best paper. If there is any of the bark of more than a year's growth, it is laid aside for the contract.

After the bark is in the condition we have just now stated, it is washed with great care; for on this washing depends in a great measure the smoothness of the paper. It is put into a kind of sieve through which the water can flow freely; and great care is taken to turn it with the hand till it is sufficiently diluted, and reduced to soft and tender fibres. For the finest paper a second washing is requisite, and a piece of cloth is used instead of a sieve.

When the bark is washed, it is laid on a strong and smooth table, and beat with a kind of baton of hard wood till it is reduced to a proper consistency. It becomes indeed so soft, that it resembles paper steeped in water.

The bark prepared in this manner is put into a narrow tub, with a glutinous extract from rice and the root oreni, which is very viscous. These three substances, mixed together, are stirred with the reed till they form a liquor of an equal and uniform consistency. This composition is poured into the tub similar to those used for filling the forms in our paper mills.

As soon as the sheets are made and detached from the form, they are laid in a heap on a table covered with a double mat. A small chip of cane is placed betwixt every sheet. This piece of cane jutting out, serves to distinguish the sheets, and afterwards to raise them. Every one of the heaps is covered with a plate or thin board of the exact size of the paper. In proportion as the paper dries, or is able to bear it without danger of being compressed into one mass, they lay on

Japanese paper.
History.

on additional weights. This pressure, intended to carry off any unnecessary moisture, is continued for 24 hours, when the sheets are suspended, by means of the little pieces of reed, to long plants, in the open air, till they are completely dried.

The extract from rice is made in an unvarnished earthen pot. The pot is agitated at first gently, then more briskly: new water is poured in, and then it is filtered through a linen cloth. The finishing of the process is determined by the viscosity of the substance.

The infusion of the root oreint is made in the following manner: The root peeled and cut into small pieces, is infused into water for one night, during which time it communicates a viscosity sufficient for the purpose to which it is applied.

The Japanese paper is of such prodigious strength, that the materials of which it is composed might be manufactured into ropes. There is sold at Serje, the capital city of the province of Japan of that name, a kind of it fit for bed hangings and wearing apparel; resembling so much stuffs of wool and silk, that it is often taken for them. The following is Kempfer's catalogue of trees used in Japan for the manufactory of paper.

1. The true paper tree, called in the Japanese language kaaidi.
2. Pappus florit occurred in the form.
3. Sive morus sativa foliis urticaceae morbus cortice papiferus.
4. The false paper tree, called by the Japanese katsi kase.
5. Pappus procumbens laticrassus folio longo lanceato cortice chartaceo.
6. The plant which the Japanese call oreint is named by Kempfer malva radice viscoso flore ephemero magno panicifo.
7. The fourth tree used for paper is the futokadurai, named by Kempfer frutes viscous procumbens folio telephii vulgaris emulo fructu racemoso.

The description of these trees, given more particularly by Kempfer than the limits of this work will permit, may be of great service to lead botanists to discover the necessary plants and adapt them, like the Japanese, for the fabrication of paper.

Before finishing our reflections on this part of the subject, it will be proper to give a just idea of the attempts which have been made to increase the original materials of paper in Europe.

A slight attention to the process in China in reducing the bamboo to a paste by a careful and ingenious analysis, and to the long and proper method of the Japanese of separating the principal fibres of the bark of the mulberry, will show the absurdity not only of taking plants without any kind of choice, but of giving them no preparation except that of pounding them with mallets.

With a proper selection, and good principles, it appears not improbable that many of the European plants might be used with great advantage in constructing several kinds of paper.

It is evident that the materials used by the Chinese require less labour and preparation than the stuff of linen rags. The sheets of the Chinese paper are easily detached from the form; they are laid in heaps without the interposition of pieces of wooden cloth; the superfluous water is immediately discharged; and they require not, as in Europe, the vigorous action of presses to unite the parts more closely together.

The asbestos is a fibrous substance of little strength, the threads of which are easily broken. See Mineralogy Index. This substance has the peculiar property of supporting the action of fire without receiving any damage: whence pieces of cloth and garters made of it are incombustible. From the knowledge of this property paper has been made of the asbestos. Dr Brukman, professor at Brunswick, published the natural history of this fossil; and four copies of his book, in the library of Wolfenbuttle, are on this paper.

The manner of fabricating this paper is described by M. Lloyd in the Philosophical Transactions, N° 166. A certain quantity of the asbestos is pounded in a mortar of stone till it be reduced to a substance like cotton. All the parts of earth or stone remaining in the asbestos are then taken off by means of a fine sieve, and it is formed into sheets of paper by an ordinary paper mill. Mixing it with water reduces it to stuff; only, as it is heavier than that from linen rags it requires to be continually stirred when they are taking it up with the frames. The only excellence of this paper is, that the writing disappears when it is cast into the fire. It must be observed, at the same time, that as it is of a slender consistency, and easily torn, it is more an object of curiosity than use.

This paper is manufactured throughout Europe of linen rags collected in the cities and in the country. This kind of paper was utterly unknown to the ancients. The librini lintei mentioned by Livy, I. lib. iv. Pliny, XIII. c. xi. and by other Roman writers, are demonstrated by Guillardin, in his commentary on Pliny, &c. to have been written on pieces of linen cloth, or canvas prepared in the manner of painters.

But it is not sufficient to be certain that paper from linen is a modern invention; it is necessary to know by what nation, and at what period, it was discovered. Polydore Virgil, De Inventoribus Rerum, C. II. c. viii. confesses his ignorance of these facts. Scaliger, without any kind of proof, gives the glory to the Germans; and Count Maffei to the Italians. Other writers ascribe this honour to some Greek refugees at Basil, to whom the manner of making paper from cotton in their own country had suggested the idea. Du Halde is persuaded that Greece derived this invention from the Chinese, who, in several provinces, make paper of rags nearly in the same manner that we do. But this invention was practised by the Europeans before they had any communication with China, and before the taking of Constantinople, at which time the Greek refugees were supposed to have retired to Basil. The precise time of this discovery in Europe is not exactly known. Father Mabillon believes that it was in the twelfth century; and cites a passage of Pierre de Clugny, born A.D. 1100, to prove it. The books which we read every day, says that abbe in his treatise against the Jews, are written on sheep and calves skins; or on oriental plants; or, finally, Ex rasura veterum panormum. If these last words signify paper, such as we use, there were books of it in the twelfth century. But this citation is the more to be suspected, as Montfaucon himself, after the minutest search in France and Italy, could find no book on this paper antecedent to the death of St Louis, A.D. 1270.

The epocha of this invention was not determined till 1752, M. Mierman having proposed a reward to the person who could procure the most ancient manuscript written on this kind of paper. The collection of all the memoirs sent to him along with the manuscripts was published.
Art of Making Paper in Europe.

To give a concise view of this subject, it will be necessary to proceed with all the important parts of the operation in their order.

The selection of the rags, is the arranging of them into different lots, according to their quality and to the demand of the paper mill. In general this selection is very much neglected: The degrees of fineness and whiteness, distinguished with little care, are thought to be the only objects of importance; whereas the hardness and softness, the being more or less worn, are much more essential in this selection. It is certain, that a mixture of soft and hard rags occasions much more loss in the triturations than a difference in point of fineness or of colour. This exactness in the selection is still more necessary where cylinders are used instead of mallets. We cannot do better than to give the method practised in Holland as worthy of imitation.

They begin by a general separation of the rags into four lots; superfine, fine, middle, and coarse. These lots are given to selectors, who subdivide each of them into five chests. They have besides a bench, on which is fixed vertically a book, and a piece of scythe which is terminated by a crooked point.

The person, for example, who has the charge of the fine lot, puts into one of the chests the hard rags, or those which are little used, into another the soft, into a third the dirty, into a fourth those which are stitched or hemmed, and finally, into the fifth the superfine rags which happen to be among the fine.

After this process, the women who have the charge of it are at extreme pains to pick out every kind of sewing, and especially the knots of thread and the hems, by means of the hook or scythe which they have under their hands. They take care also by the same means to cut and reduce the rags exactly by the warp and the woof into small pieces. It is of great advantage to cut or tear the pieces of rags by a thread, whether it be by the warp, or by the woof; because if it is done obliquely, many of the ends are lost in the operation.

When they have selected a certain quantity of each of these subdivisions, they are placed on an iron grate, which covers a large chest where they are beat, and otherwise turned, till the filth and dust pass through the bars of the grate and fall into the chest.

The number of lots in the selection of rags must be proportioned to the mass from which the selection is made, and to the kinds of paper produced by the mill. Some mills, the work of which is considerable, make nine lots of their rags, five of which respect the fineness, and the rest the cleanliness and the colour. In ordinary mills there are only four lots, and in some two.

We have already observed, that the selection which regards the hardness of the materials is the most essential; because it is of great importance to obtain stuff composed of equal parts, and without any loss. But it is necessary to add, that the fineness and beauty of the paper depend in some cases on a selection not rigorous. Thus, for example, it is of great service to allow the middling to retain some part of the fine, and the fine some part of the superfine; for without this the inferior kinds of paper can never be of great value.

The most common fault is to mix the rags of the inferior lots with the superior; which though it augments the quantity of paper, is extremely injurious to the quality. It does much better to mix parts of the superior lots with the inferior. It is the want of attention to this mixture which makes some paper mills excel in the superior sorts of paper, while the inferior kinds are of a very bad quality.

The selection of rags being made with exactness, however, and the lots being fermented and triturated separately, the mixture may be made with much greater advantage when they are both reduced to stuff; always taking care that it be in the same proportion as if it were in the state of rags, and only in the manner in which we have just mentioned; for the inferior sorts gain more in beauty and quality by this mixture than is lost in stuff; whereas if the fine stuff receives a certain quantity of the inferior, the paper is more damaged in its value than increased in quantity. In this manner the interest of the manufacturer, as in all cases, is intimately connected with the goodness of his commodities.

In some mills the place for fermentation is divided into two parts, one of which serves for washing away the filth from the rags. After allowing them to steep for some time in a large stone vat, they stir them, and pour in fresh water till the impurities connected with the rags run over. When they are as clean as they possibly can be made with this kind of washing, they are laid in a heap to putrefy. In this condition they experience a degree of fermentation, which is first discovered by a mouldiness of the different pieces of cloth. Afterwards the mass grows warm; and then it is of great consequence to attend to the progress of this heat, in order to moderate its effects: for this purpose, the middle of the heap, where the fermentation is strongest, is turned out, and vice versa. In mills where mallets are used, the putrefaction is carried to a great height, which is frequently attended with two inconveniences. The first is that
that a part of the rags is reduced to an earthy substance, which is found in great abundance about the cutting table, as we shall afterwards have occasion to see. But besides this waste, excessive fermentation makes the stuff incapable of sustaining the action of the mallets till it is equally pounded. A paper made from a stuff too hard and too little fermented, is coarse and ill compacted; that made from rags too much fermented, is composed of fibres without softness and without strength.

The second inconvenience is, that the rags turn greasy by too much fermentation, and of consequence it is very difficult to separate and reduce them by all the washings of the putrefaction.

We shall not describe the form of the place for fermentation, because in different paper works these places are of different constructions: it is sufficient to say, that they are all placed in low situations and made very close. The selected rags are placed in them in heaps, and watered from time to time to bring on the fermentation. In different paper mills they practise different methods in the putrefaction of their rags.

In certain provinces in France, they lay in the place for putrefaction a heap equivalent to what the mill can triturate in a month. When this is equally and sufficiently moistened by means of moveable pipes, they cover it with an old heap, which has lain a month in a state of fermentation. When this old heap is exhausted by the mill, the new one becomes a covering to another, and so on. From this detail it is easy to perceive, that there must be near three weeks’ difference of putrefaction in the same heap, and also that in this method there is no allowance for those seasons in which the fermentation advances more rapidly.

In general the putrefaction goes on more slowly in proportion to the fineness of the rags. But when, on any occasion, it advances more rapidly than the demand from the mill, the rags are turned over and watered, to stop the fermentation and prevent the bad effects.

All the inconveniences attending the excess of putrefaction are remedied in Holland by machines which triturate the rags without having recourse to it; and their success in this manner of preparing the stuff has attracted the notice of the French artists, some of whom have adopted with advantage the Dutch machinery.

Meanwhile, it is possible to carry the method of putrefaction to much greater perfection; and several manufacturers have made attempts so well concerted, as to deserve the attention of those who study the subject.

In the neighbourhood of Brussels some paper manufacturers, who have constructed their mills after the Dutch plan, have still found it necessary to putrefy their rags; but, at the same time, they have an excellent method for moderating the effects of this putrefaction. In the great galleries connected with the buildings of the paper mill, they have constructed a continuation of chestas, capable each of them of containing a certain quantity of rags; for example, the quantity which the cylinder can triturate in one day. The number of chestas is equal to the number of days which the rags in any season require for putrefaction; and the number actually employed is greater or less according to the season. In prosecuting this plan, they lay a heap of rags in one chest, as often as they take one from another. It should also be observed, that, for the sake of the fermentation, the rags are first moistened in a large hollow stone before they are arranged into the chests.

The peculiar advantages of this method are, the equal fermentation of the rags, without any part of them being weakened; great ease in washing them; and it is even pretended, that a less degree of fermentation renders the impurities and the discoloured parts both of hemp and linen more soluble, and consequently the stuff of a purer white.

When the rags are reduced to a proper state of putrefaction, they are carried to the cutting table, which is placed on solid trestles, and enclosed on three sides to contain the rags cut in it. Before the table is erected vertically a part of the blade of a scythe, the edge of which is turned from the operator. This workman, in a situation rather elevated, takes from the left side a handful of the putrefied rags, and arranging them the long way, gives them a gentle twist, presses the half-formed rope against the blade of the scythe, and, in the manner of sawing, cuts it into three or four pieces, which he throws to the right side of the table. In this operation the rags lose part of their filth, and especially of the earthy particles occasioned by too much putrefaction.

When the rags have been submitted to all the foregoing operations, they are in a condition to be reduced into a fibrous stuff, of which the paper is made. To obtain this stuff, mills are constructed on different principles. Those which have been used for a long time over all Europe, and which by a statement in the Encyclopédie Méthodique, published at Paris in 1789, are still used in France, are mills with rollers. But the putrefaction of the rags is cut by the Dutch, and used in the north and north-western provinces, and, excepting one instance, in every part of Great Britain, are mills with cylinders or rollers. In the former of these, the rags are raised by notches fixed at convenient distances in a large circular beam of wood. The teeth fixed on the end of the roller fall into a corresponding gap made the whole breadth of the plate, and the strokes are repeated till the rags are reduced to a proper consistency. On supplying the vat with water, and carrying off all the impurities, the operation is nearly similar to that in the mills with cylinders.

Such is the nature of what may be called the old method of making paper. It was proper to speak of this old method, because at one time, and that not very distant, it universally prevailed. That it was inferior to that now in practice, seems very evident; and that the rotting of the rags was peculiarly absurd, cannot be denied, as the paper made of fermented stuff could neither be so strong nor so durable as that which is made in the modern way without putrefaction. The idea of the paper that, with any propriety, could be made from putrefied stuff, was pasteboard; but we are informed by the most intelligent papermakers in Britain, that they seldom or never even putrefy the rags or ropes of which pasteboard is made. It will now be requisite to state the method presently in practice, with the improvements lately made in the art.

The duster is made in the form of a cylinder, four and a half feet in diameter, and five feet in length. It is altogether covered with a wire net, and put in motion by its connection with some part of the machinery. A convenient
Art of Man. - Convenient quantity of rags before the selection are en-
Paper closed in the duster, and the rapidity of its motion separ-
in Europe. ates the dust from them, and forces it through the wire. It is of considerable advantage to use the duster before selection, as it makes that operation less pernici-
ous to the selectors.

The selection is performed much in the same manner as we have already described; only it is found more convenient to have the tables for cutting off the knots and stitching, and for forming them into a proper shape, in the same place with the cutting table. The surface both of these and of the cutting table is composed of a wire net, which in every part of the operation allows the remaining dust and refuse of every kind to escape.
The rags, without any kind of pretreatment are again carried from the cutting table back to the duster, and from thence to the engine, where, in general, they are in the space of six hours reduced to the stuff proper for making paper. The hard and soft of the same quality are placed in different lots; but they can be reduced to stuff at the same time, provided the soft be put somewhat later into the engine.

The engine is that part of the mill which performs the whole action of reducing the rags to paste, or, as it may be termed, of trituration. The number of the engines depends on the extent of the paper work, on the force of water, or on the construction of the machinery.

It will afford a sufficient idea of the work, to give in detail a description of the different parts of the engine. Figure 1. represents the chapter which covers the roller: it is four feet three inches in length, and two feet eight inches in breadth. The superior part is pierced with two openings running crosswise, 1, 2, 3, 4; into which enter the cheeses, or wicker frames, figures 6. and 7; the first, made of wire cloth, enters into the opening 3 and 4; the second made of hair cloth, and strengthened with several cross bars of wood, enters into the opening 1, 2, serves to retain the small pieces of rags which escape through the first, and prevents them from falling into the dalot or hole-scupper, figure 2. This hole-scupper is placed across the vat of the engine, parallel to the axle of the roller; the part g enters into the notch c of the chapter; and the extremity h enters into the opening k of the tunnel k (fig. 3.), by which means the water dashed through the wicker frames by every revolution of the roller is precipitated into the canal f, and loses itself below the engine. The figures 4, 9, and 10, represent the roller in perspective, in plane, and in profile. It is two feet in diameter, and two feet three inches in length. The trundle head A is 16 inches in diameter, about half as much in length, and furnished with seven spindles of iron, which are screwed to the end of the trundle head, made also of iron. The teeth or blades of the roller are 27 in number, and fitted strongly into the wood which composes its body, parallel to its axis. They are of that thickness as to leave as much empty space as they occupy. The exterior face of each of the blades should be made round, and divided into two parts, with a longitudinal motion, as in the profile a a a, fig. 10.

The axis AB of the roller (fig. 4. and 9.) has two parts perfectly rounded in A and in B, which perform the office of pivots. These pivots rest in the sockets A and B (fig. 8.) in the middle of the levers OAH and OBH. It is by means of these levers that they raise the roller in pleasure, or lower the axis of the roller, and fit it exactly, in Europe, and in a parallel manner, to the plate. The plates (see fig. 5.) are made of steel cut into channels, in such a manner as to correspond with the blades of the roller. Their channels are not perpendicular, but oblique; and there are two rows of them, 6 x, 6 d, consisting of seven or eight blades each on one plate. Those in 6 x, for the purpose of changing the plate, lie in an opposite direction to those in 6 d. The levers are kept in their position near the vat by bands of iron, MN and m n, between which they are made higher or lower by the cagged wheel H, which supports one of the extremities. Wedges N n are likewise employed to fix the levers at a convenient height above the plates. Finally, every vat is supplied with a small slide door, which is occasionally raised to carry the prepared stuff by means of the scuppers of wood to the general repositories.

Fig. 5. is placed in the vat fig. 8. ; the roller (fig. 4. Working is placed above it in such a manner that the pivots rest of the ex-
in the sockets of the levers; the scupper (fig. 2.) and the chapter are disposed in the manner above mentioned. The vat is charged with a proper quantity of rags, and fresh water is admitted by a spigot placed at one of the corners. In this situation, when the engine is put in motion, the roller turning upon its axis draws the water and the rags by the least inclined plane, and making them pass between its blades and the channels of the plate, dashes them against the chapter and the wicker-frames; and, in short, part of them falls back into the vat, and returns into the circulation. The cause of this circulation is evidently the continual wood oc-
casioned by the movement of the roller on the other side, and the return of the water and the stuff on the other.

As all the rags are not thrown towards the part B d of the chapter, from whence they might fall back into the vat, but a part of them to a greater distance; it is necessary to have the wicker frames formerly described, not only to prevent their loss, but to allow the dirty water to escape. The spigot at the corner of the vat continually supplies this waste of water. This operation would be sufficient to whiten the rags, although the rollers were raised considerably from the plate; and therefore the force and action of the rollers reducing them to stuff must be much more effectual. It requires great skill to conduct the engine, whether it be with regard to the first quantity, to the proper time for adding the softer rags, to the augmenting or diminishing the water in proportion to the trituration; or, finally, to knowing exactly when the stuff is reduced to a proper consistency.

In the paper manufactory at Montargis, it was at-
temted to introduce rollers of the greatest strength and the least weight possible, in order to give them the great-
er rapidity; but the experiment did not succeed: the rollers of prodigious rapidity were found to produce stuff neither in greater quantity nor of superior quality. The most experienced artists have established a propor-
tion between the motion of the roller and the greater or less resistance of the rags. And the Dutch, who have arrived at very great perfection in this art, have followed a method totally different from that practised at Montargis. A roller in Holland complete in all its parts
The stuff of which the felts are made should be sufficiently strong, in order that it may be stretched exactly by the sheets without forming into folds; and, at the same time, sufficiently pliant to yield in every direction without injury to the wet paper. As the felts have to resist the reiterated efforts of the press, it appears necessary that the warp be very strong, of combed wool, and well twisted. On the other hand, as they have to imbibe a certain quantity of water, and to return it, it is necessary that the warp be of a decided, and drawn out into a slack thread. These are the utensils, together with the press, which are used in the apartment where the sheets of paper are formed.

The vat being furnished with a sufficient quantity of the fabric-stuff and of water, two instruments are employed to furnish it with these materials; the one of which is a simple pole, and the other a pole armed with a piece of board, rounded and full of holes. This operation is repeated as often as the stuff falls to the bottom. In the principal writing mills in England, they use for this purpose what is called a hog, which is a machine within the vat, that, by means of a small wheel on the outside, is made to turn constantly round, and keep the stuff in perpetual motion. When the stuff and water are properly mixed, it is easy to perceive whether the previous operations have been complete. When the stuff floats close, and in regular flakes, it is a proof that it has been well triturated; and the parts of the rags which have escaped the rollers also appear.

After this operation the workman takes one of the forms, furnished with its frame, by the middle of the short sides, and fixing the frame round the wire-cloth with his thumbs, plunges it obliquely four or five inches into the vat, beginning by the long side, which is nearest to him. After the immersion he raises it to a level: by these movements he fetches up on the form a sufficient quantity of stuff, and as soon as the form is raised the water escapes through the wire-cloth, and the superfluity of the stuff over the sides of the frame. The fibrous parts of the stuff arrange themselves regularly on the wire-cloth of the form, not only in proportion as the water escapes, but also as the workman favours this effect by gently shaking the form. Afterwards, having placed the form on a piece of board, the workman takes off the frame or deckle, and glides this form towards the coucher; who, having previously laid his felt, places it with his left hand in an inclined situation, on a plank fixed on the edge of the vat, and full of holes. During this operation the workman applies his frame, and begins a second sheet. The coucher seizes this instant, takes his left hand the form, now sufficiently dry, and laying the sheet of paper upon the felt, returns the form by gliding it along the trepan of the vat.

They proceed in this manner, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a post; and this they do with such swiftness, that, in many sorts of paper, two men make upwards of 20 posts in a day. When the last sheet of the post is covered with the last felt, the workmen about the vat unite together, and submit the whole heap to the action of the press. They begin at first to press it with a middling lever, and afterwards with a lever about fifteen feet in length. After this operation another person separates the sheets of paper from the felts, laying them...
last under the press, kept separate by a woolen felt. The press is large enough to receive two of them at once, placed one at the other's side. When the compression is judged sufficient, the heaps of paper are carried back to the table, and the whole turned sheet by sheet, in such a manner that the surface of every page is exposed to a new one; and in this situation they are again brought under the press. It is in conducting these two operations sometimes to four or five times, as often as the nature of the paper requires, that the perfection of the Dutch plan consists. If the stuff be fine, or the paper slender, the exchange is less frequently repeated. In this operation it is necessary to alter the situation of the heaps, with regard to one another, every time they are put under the press; and also, as the heaps are highest towards the middle, to place small pieces of felt at the extremities, in order to bring every part of them under an equal pressure. A single man with four or five presses may exchange all the paper produced by two vats, provided the previous pressing at the vats be well performed. The work of the exchange generally lasts about two days on a given quantity of paper.

When the paper has undergone these operations, it is not only softened in the surface, but better felted, and confirmed more plant in the interior parts of the stuff. In short, a great part of the water which it had imbibed in the operation of the vat is dissipated. By the felting of paper is understood the approximation of the fibres of the stuff, and their adhering more closely together. The paper is felted in proportion as the water escapes; and this effect is produced by the management and reiterated action of the press. Were it not for the gradual operation of the press, the paper would be porous, and composed of filaments adhering closely together. The superiority of the Dutch over the French paper depends almost entirely on this operation.

If the sheets of paper are found to adhere together, it is a proof that the business of the press has been badly conducted. To avoid this inconvenience, it is necessary to bring down the press at first gently, and by degrees with greater force, and to raise it as suddenly as possible. By this means the water, which is impelled to the sides of the heaps, and which has not yet escaped, returns to the centre; the sheets are equally dry, and the operation executed without difficulty.

According to the state of dryness in which the paper is found when it comes from the apartment of the vat, it is either pressed before or after the first exchange. The operation of the press should be reiterated and managed with great care; otherwise, in the soft state of the paper, there is a danger that its grain and transparency be totally destroyed. Another essential principle to the success of the exchange is, that the grain of the paper be originally well raised. For this purpose the wire cloth of the Dutch forms is composed of a rounder wire than those used in France, by which they gain the greatest degree of transparency, and are in no danger of destroying the grain. Besides this, the Dutch take care to proportion the wires even where the forms are equal to the thickness of the paper.

Almost every kind of paper is considerably improved by the exchange, and receives a degree of perfection which renders it more agreeable in the use. But it is necessary to observe at the same time, that all papers...
Art of Making Paper in Europe.

Sect. I.

Paper. They begin by selecting the padges in the drying houses; and after having made them supple, and having destroyed the adherence between the sheets, they separate them into handfuls in proportion to the dryness, each of them containing that number which they can dip at one time. Besides this precaution, they take care to apply two sheets of brown paper of an equal size to every handful. This brown paper, firm, solid, and already sized, is of use to support the sheets.

As soon as the paper is sized, it is the practice of some paper mills to carry it immediately to the drying house, and hang it, before it cools, sheet by sheet on the cords. The paper, unless particular attention be paid to the latitudes of the drying-house, is apt to dry too fast, whereby a great part of the size goes off in evaporation; or, if too slow, it falls to the ground. The Dutch drying-houses are the best to prevent these inconveniences:—But the exchange after the sizing, which is generally practised in Holland, is the best remedy. They begin this operation on the handfuls of paper, either while they are still hot, or otherwise, as they find it convenient. But, after the exchange, they are careful to allow the heaps to be altogether cold before they are submitted to the press. Without this precaution, the size would either be wholly squeezed out by the press of the exchange, or the surface of the paper become very irregular. It is of consequence that the paper, still warm from the sizing, grow gradually firm under the operation of the exchange, in proportion as it cools. By this method it receives that varnish which is afterwards brought to perfection under the press, and in which the excellency of the paper either for writing or drawing chiefly consists. It is in consequence of the exchanging and pressing that the Dutch paper is soft and equal, and that the size penetrates into the body of it, and is extended equally over the surface.

The exchange after the sizing ought to be conducted with the greatest skill and attention, because the grain of the paper then receives impressions which can never be eradicated. When the sized paper is also exchanged, it is possible to hang more sheets together on the cords of the drying-house. The paper dries better in this condition, and the size is preserved without any sensible waste, because the sheets of paper mutually prevent the rapid operation of the external air. And as the size has already penetrated into the paper, and is fixed on the surface, the insensible progress of a well conducted drying-house renders all the good effects more perfect in proportion as it is slowly dried.

If to these considerations be added the damage done to the paper in drying it immediately after the press of the sizing room, whether it be done in raising the hairs by separating the sheets, or in cracking the surface, it is evident that the trouble of the second exchange is infinitely overpaid by the advantage.

When the paper is sufficiently dry, it is carried to the finishing room, where it is pressed, selected, examined, folded, made up into quires, and finally into reams.—It is first put twice under the press; first, when it is at its full size, and secondly, after it is folded.

The principal labour of this place consists in assorting the paper into different lots, according to its quality and faults; after which it is made up into quires. The person who does this must possess great skill, and be capable of great attention, because he acts as a check on those who...
Art of Making Paper. He takes the sheets with his right hand, folds them, examines them, lays them over his left arm till he has the number requisite for a quire, brings the sides parallel to one another, and places them in heaps under the table. An expert workman, if proper care has been taken in assorting the lots, will finish in this manner near 600 quires in a day.

The paper is afterwards collected into reams of 20 quires each, and for the last time put under the press, which is continued for 2 or 3 hours, or as long as the demand of the paper-mill will permit.

A new method of bleaching the rags or stuff, which will undoubtedly be adopted everywhere in the preparation of writing paper, provided the expence of the process be not too great. This discovery was made by Scheele, M. Berthollet, and M. Chaptal. The first of these illustrious writers communicated to the Swedish Academy of Sciences an Essay on Manganese, containing a numerous series of experiments, intended to investigate the nature and properties of that substance. Among these experiments were several which pointed out a new state of the muriatic acid, or the acid distilled from sea-salt, otherwise known under the name of the acid or spirit of sea-salt. This state of the muriatic acid was produced by Mr Scheele, in consequence of putting the said acid into a retort or distilling vessel; and distilling over the acid into a proper receiver; it was found to have changed its nature and properties in a very remarkable manner, while at the same time the manganese remaining in the retort had suffered a very material alteration.

To the new state of the acid thus produced, in consequence of certain theoretic ideas which Mr Scheele entertained respecting the mutual action of the original muriatic acid and the manganese on each other during the process of distillation, he gave the name of depblhogisicated muriatic acid. Since the time of this original discovery, in consequence of certain changes which have occurred in the theory or philosophy of chemistry, this new state of the acid of sea-salt has been called the oxygenated muriatic acid. Among many other properties of it discovered by Mr Scheele, the most remarkable was, that it destroyed the colour of every vegetable substance which was exposed to its action; or, in other words, it bleached them; or, in the language of the dyers, it discharged their colours; that is to say, whatever happened to be the colour of any vegetable body that was submitted to the action of the oxygenated or depblhogisicated muriatic acid, it always became white, or lost its colouring matter.

In the year 1786, Dr Beddoes, then professor of chemistry in the university of Oxford, published an English translation of the Chemical Essays of Mr Scheele; and thereby made known to the chemists of Great Britain the power of the oxygenated or depblhogisicated muriatic acid, to bleach or whiten vegetable substances, or to discharge or decompose their colours. But M. Berthollet, a celebrated chemist in France, and one of the members of the Academy of Sciences at Paris, appears to have been the first who thought of rendering the above-mentioned discovery subservient to the purposes of manufacture.

In 1789, he published in the Annales de Chimie an Art of Making Paper calculated entirely for the use of manufacturers, by being divested of theoretic discussions; of which the title is, "Method of Bleaching Linen or Cotton Cloths, Threads, and Yarns, by means of oxygenated Muriatic Acid, and of some other properties of that Liquor which may be useful in Manufactures."

In the same work, and in the same year, Mr Chaptal, another French chemist, published an account of some experiments, in which, among many other applications of the oxygenated muriatic acid to purposes useful in the economical arts, he gives information of having bleached or whitened coarse rags used by the paper-makers, so as greatly to improve the quality of the paper into which they were afterwards manufactured. His preparation of this bleaching liquor differs not from Berthollet's, which is as follows: "Take six ounces of manganese and sixteen ounces of sea-salt, both reduced to fine powder; mix these accurately, and introduce into a retort or distilling vessel: Then take twelve ounces of oil of vitriol and eight ounces of water, mixed together, and allowed to cool; add these to the other ingredients in the retort, and connect the retort with a cask or receiver capable of holding twenty-seven gallons and a half of water, but only containing twenty-five gallons, which is to be impregnated with the gas or vapour of the oxygenated muriatic acid; and proceed to distillation, first without and afterwards with a fire gradually raised, till the whole acid comes over." The experiments have been made with this liquor both by some of the principal paper-makers in the neighbourhood of Edinburgh, and by Messrs Clement and George Taylors of Maidstone in Kent. By the former it was found, that paper made of rags and pulp whitened in this manner, was superior to any other made of similar materials, not only in colour but in fineness of texture. By the latter, the excellence of the liquor was found to be so great, that probably having never heard of Scheele, Berthollet, and Chaptal, and conceiving themselves to be the first inventors of it, they obtained a patent for its exclusive use, which other manufacturers will doubtless disregard. It is not to be concealed, however, that, even with all the precautions which can possibly be taken at first, various circumstances of imperfection must necessarily remain to be removed by means of farther experience, both in the perfection of the bleaching process and the economy of its application to use; but for the attaining of this experience a short time will rarely be sufficient. The above account, it must appear, refers to the time when the bleaching of rags by this process was first introduced. The practice, we find is still (1808) successfully continued by some of the manufacturers in the vicinity of Edinburgh, and has been improved by using the bleaching salt (the hyperoxydimuriate of lime), the right to the preparation of which is exclusively vested by patent in Messrs Tennant and Company of Glasgow.

Sect. II. Of the different Kinds of Paper.

The paper proper for writing should be without any knots, without any parts of the stuff not straightened, without folds, and without wrinkles, of a suitable texture, its grain uniform and regular, softened in the exchange,
Sect. II.

Paper.

Different kinds of paper. Exchange, and not destroyed by smoothing. The ground of this paper must be extremely white, or shaded with a very light blue, which adds to its natural splendour. It is of great importance that it be fully and equally sized, otherwise the writing cannot be well finished, and the turnings of the letters will be very imperfect. This paper should be made from stuff not purged, which takes a better grain, receives more benefit from the varnish, is more equally sized, and finally, is less subject to folds and wrinkles in the different operations. To make paper peculiarly fit for durable writing, Dr. Lewis recommends the impregnation of it with astrigent materials. "It is observable (says he) that writings first begin to fade or change their colour on the back of the paper, where the larger strokes have sunk in, or are visible through it; as if part of the irony matter of the vitriol was in a more subtle or dissolved state than the rest, and sunk further, on account of its not being fully disengaged from the acid, or sufficiently combined with the astrigent matter of the galls. Hence, it should seem probable, that if the paper was impregnated with astrigent matter, the colour of the ink would be more durable. To see how far this notion was well founded, I dip some paper in an infusion of galls: and, when dry, repeated the dipping a second and third time. On the paper thus prepared, and some that was unprepared, I wrote with different inks; several of which, that the effects might be more sensible, had an over-proportion of vitriol. The writings being exposed to the weather till the best of the inks on the unprepared paper had faded and changed their colour, those on the prepared paper were all found to retain their blackness. It is therefore recommended to the consideration of the paper-makers, whether a particular kind of paper might not be prepared for those uses where the long duration of the writing is of principal importance, by impregnating it with galls or other astrigents, in some of the operations it passes through before it receives the glazing; as, for instance, by using an astrigent infusion, instead of common water, in the last operation, when the matter is reduced into a pulp for being formed into sheets. The brownish hue which the paper receives from the galing, would not perhaps be any great obstacle to its use; and, if the proposal should be thought worthy of being carried into execution, further inquiries may possibly discover the means of obviating the imperfection, and communicating astrigent without colour."

The paper used for drawing, or for coloured maps, is in some mills made from one kind of white stuff, either fine or middling; in others, from a mixture of three or four kinds of stuff of different colours. The Dutch were not long ago almost wholly in possession of this manufacture. The same qualities are necessary in this paper as in that for writing. The grain, however, must be a little more raised, although softened by the exchange; for, without this grain, the pencil would leave with difficulty the traces of the objects. Great care is also necessary in the sizing of this paper, that the drawing be neatly performed, and also that the sinking of the ink or colours into the irregularities of the stuff be prevented. This paper is also made in greatest perfection by stuffs not rosted. These take a more even gloss, and are in better condition to receive all the impressions of the painter. It is also necessary that furniture paper be well softened, and submitted to the exchange, to take more exactly the outlines of the figures. The French have carried this part of the manufacture of paper to the highest state of perfection.

The British and Dutch have had the greatest success in manufacturing pasteboard, which they make either used in the manufacture of several sheets pasted together. In both cases, the sheets of pasteboard are made of stuff not rosted, and triturated with rollers furnished with blades of well tempered steel. By the operation of the exchange, and smoothing continued for a long time, the British and Dutch obtain solid and smooth stuffs, which neither break under the folds of cloth, nor adhere to them. The stuffs not purged have another advantage in this species of pasteboard, namely, that of resisting the action of heat, which they experience between the folds of cloth, without wasting or tarnishing, and of consequence they may be used for a long time.

In England they have at least equalled any other nation in the manufacture of this paper; and even in Scotland they have arrived to such a degree of perfection in this art, that great part of what they manufacture is sent into England. It requires to be made of a soft and equal stuff, without folds or wrinkles, of a natural whiteness, and with a shade of blue. It must be sized less strongly than writing paper, but sufficiently well to give neatness to the characters. The paper, thus properly prepared, yields easily to the printing press, and takes a sufficient quantity of ink. The stuff must be without grease, and wrought with that degree of slowness, as to make it spread equally over the form, and take a neat and regular grain; without this the characters will not be equally marked in every part of the page; and the smallest quantity of grease renders the sizing unequal and imperfect. Some artists with considerable success, both to mollerate the grain, and to reduce the inequalities of the surface, have submitted this paper to the exchange. And it is proper to add, that a moderate degree of exchanging and of pressing may be of great service after the sheets are printed, to destroy the hollow places occasioned by the press, and the relievo of the letters.

Engraving requires a paper of the same qualities as the last mentioned, with respect to the stuff, which must be pure, without knots, and equally reduced; the grain uniform, and the sheets without folds or wrinkles. To preserve the grain, it is necessary that it be dried slowly in the lowest place of the drying-house. If it is submitted to the exchange, the effects of it must be moderated with the greatest care, and the action of the two first presses must be equally distributed over the whole mass. Otherwise the inequality of the moisture at the middle and sides will expose it to wrinkles in the drying. The sizing of this paper must also be moderate. These circumstances are necessary to make it receive with neatness all the soft and delicate touches of the plate.

—The soft and yielding paper of Auvergne possesses all those advantages; and accordingly a great quantity of this and of printing paper were formerly imported into Britain and Holland from France, where they still continue to rot the materials from which they make engraving.
Paper for cards must be manufactured from a pretty firm stuff, in order to take that degree of smoothness which makes the cards glide easily over another in using. For this reason the cardmakers reject every kind of paper which is soft and without strength. This paper requires to be very much sized, since the sizing holds the place of varnish, to which the smoothing gives a glazed and shining surface. To answer all these purposes, the rags require to be a little rotted, and the mallets strongly armed with iron studs. Formerly Angoumois was almost the only province in France which sold card-paper to the Dutch and the other northern nations. The rags of Angoumois have the peculiar quality of not turning too soft in the putrefaction, and the mills of that province reduce them to stuff though they be not much putrefied. The French, we believe, excel every other nation in this branch of the manufacture of paper.

To preserve paper from sinking, take about the size of a nut of rock alum, dissolve it in a glass of clear water, and apply it to the paper, which has not been sufficiently sized, with a fine sponge. It is in this manner that the paper-manufacturers of Paris prepare the paper for drawing called papiers laves. When there is occasion to write on a printed book, or on paper too fresh, it is sufficient to mix a little gum with ordinary ink.

To give to writing paper a brilliant varnish, take that which is of an ordinary fineness, very smooth, without any kind of stain or hairs on its surface; stretch it on a smooth plank, and by means of a bare's foot cover it with a thin and equal layer of sandarac finely powdered. Afterwards, if a whole ream is to be varnished, take eight ounces of rock alum and one ounce of white sugar-candy; bring them to boil in six pints of water; and when the liquor is lukewarm, wet that side of the sheet which has been covered with the sandarac with a fine sponge; lay the sheets in a heap, one sheet exactly above another; and submit the ream to the press for the space of twelve hours: hang them afterwards sheet by sheet on the cords of the drying-house; put them again under the press for some days to stretch them; and finally, beat them with a bookbinder's mallet. This paper can only be used for three or four months after it is prepared.

Painters prepare their paper for drawing, and give it a dark ground, which spares them much labour of the pencil afterwards in those places where shade is necessary. For this purpose, they take white paper and pass a sponge over it, which has imbibed water impregnated with soot, leaving the light places to be formed afterwards. They use also a kind of paper for drawing, which is called tainted paper. A light colour is passed over the whole ground, which deprives the paper of its original brightness, and makes the light places of the print appear more in relief, and more luminous.

The method most common and most convenient for copying a print, is to use oiled paper. The manner of preparing this paper is to take that which is thin as Osners, and smooth, known commonly by the name of serpentine paper, and moisten it with a composition, two parts of the oil of walnuts and one part of the oil of turpentine mixed well together. A sheet of pasteboard and a sheet of paper are laid on a smooth table; above them are placed two sheets of paper to be prepared; and a layer of the oil applied to the uppermost is sufficient to penetrate both. This may be done to any number of sheets, and a strong sheet of pasteboard is placed over the whole. The heap is afterwards submitted to the press, under which it remains for two or three days till the oil be completely dry. Paper prepared in this manner serves to copy very readily and exactly all kinds of figures and plans; because, being altogether transparent, all the parts of the drawing, whether of light or shade, are easily distinguished.

Besides the paper made from the asbestos, it is now necessary for wrapping up gunpowder and valuable writings, to have a paper that will not easily take fire. The manner in which this is prepared is extremely simple. Ordinary paper is dipped into boiling liquid, consisting of three-fourths of water, and one-fourth of dissolved alum. This salt, which is not inflammable, covers the surface of the paper, and renders it in some measure incombustible.

In the season of verjuice, a little of it diluted with water is sufficient for obliterating any fresh spot of sealing ink. The salt of the verjuice dissolved in water answers the purpose equally well, and the salt of sorrel or oxals acid is also employed with this view. If the spots be dry, and the above acids are insufficient to eradicate them, a little aquafortis diluted in water, and applied with the feather of a quill or a fine hair pencil, will make them entirely disappear.

Books and manuscripts are sometimes defaced by accidental stains with oil. To remove such blemishes, for taking burn sheep's bones and reduce them to a fine powder; lay a quantity of this powder on each side of the stain, place it between two sheets of white paper, and submit it for 12 hours to the press. If the stains have not disappeared, it will be necessary to reiterate the process.

To make oiled papers take colours; mix with the coequal a very small quantity either of the gall of a pig or of making carp; and, as these substances are of the nature of soap, take to them a small quantity of oil, and it will dissolve the grease that is in the paper, and permit the colours to be spread over the surface.

Emery paper, which is employed for taking the rust from iron without wasting it, is made by impregnating the coarse paper with gummed water or any other tenacious substance, and then covering it over with the finest emery.

The colours proper for paper are not different from those used for other substances, and are enumerated under the article Colour-Making. They are applied with soft brushes, after being tempered to a due degree with size or gum-water. If the paper on which they are to be laid is soft, so that the colours are apt to go through, it must also be sized before they are laid on, or a proportionally larger quantity must be used along with the colours themselves. If a considerable extent of the paper is to be done over with one colour, it

PAPER.

care must be taken, after the first, to let the print fall exactly in the same part of the paper as that which went before; otherwise the figure of the design would be brought into irregularity and confusion. In common paper of low price, it is usual, therefore to print only the outlines, and lay on the rest of the colours by stencilling; which both saves the expense of cutting more prints, and can be practised by common workmen, not requiring the great care and dexterity necessary to the using several prints.

The manner of stencilling the colours is this. The figure, which all the parts of any particular colour make in the design to be painted, is to be cut out, in a piece of thin leather or oil-cloth, which pieces of leather or oil-cloth are called stencils; and being laid flat on the sheets of paper to be printed, spread on a table or floor, are to be rubbed over with the colour, properly tempered, by means of a large brush. The colour passing over the whole is consequently spread on those parts of the paper where the leather or cloth is cut away, and give the same effect as if laid on by a print. This is nevertheless only practicable in parts where there are only detached masses or spots of colours: for where there are small continued lines, or parts that run one into another, it is difficult to preserve the connection or continuity of the parts of the cloth, or to keep the smaller corners close down to the paper: and therefore, in such cases, prints are preferable. Stencilling is indeed a cheaper method of ridging coarse work than printing; but without such extraordinary attention and trouble as render it equally difficult with printing, it is far less beautiful and exact in the effect. For the outlines of the spots of colour want that sharpness and regularity that are given by prints, besides the frequent extralineations, or deviations from the just figure, which happen by the original misplacing of the stencils, or the shifting the place of them during the operation.

Pencilling is only used in the case of nicer work, such as the better imitations of the India paper. It is performed in the same manner as other paintings in water or varnish. It is sometimes used only to fill the outlines already formed by printing, where the price of the colour, or the exactness of the manner in which it is required to be laid on, render the stencilling or printing it less proper; at other times, it is used for forming or delineating some parts of the design, where a spirit of freedom and variety, not to be had in printed outlines, are desired to be had in the work.

The paper designed for receiving the flock is first prepared with a varnish-ground with some proper colour, or by that of the paper itself. It is frequently practised to print some mosaic, or other small running figure in colours, on the ground, before the flock be laid on; and it may be done with any pigment of the colour desired, tempered with varnish, and laid on by a print correspondently to that end.

The method of laying on the flock is this. A wooden print being cut, as is above described, for laying on the colour in such manner that the part of the design which is intended for the flock may project beyond the rest of the surface, the varnish is put on a block covered with the leather or oil-cloth, and the print is to be used also in the same manner, to lay the varnish on all
all the parts where the flock is to be fixed. The sheet, thus prepared by the varnished impression, is then to be removed to another block or table, and to be strawed over with flock; which is afterwards to be gently compressed by a board, or some other flat body, to make the varnish take the better hold of it: and then the sheet is to be hung on a frame till the varnish be perfectly dry; at which time the superfluous part of the flock is to be brushed off by a soft camel’s hair brush; and the proper flock will be found to adhere in a very strong manner.

The method of preparing the flock is, by cutting woolen rags or pieces of cloth with the hand, by means of a large bill or shearing knife; or by means of a machenie worked by a horse-mill.

There is a kind of counterfeit flock-paper, which, when well managed, has very much the same effect to the eye as the real, though done with less expense. The manner of making this sort is, by laying a ground of varnish on the paper; and having afterwards printed the design of the flock in varnish, in the same manner as for the true; instead of the flock, some pigment, or dry colour, of the same hue with the flock required by the design, but somewhat of a darker shade, being well powdered, is strawed on the printed varnish, and produces nearly the same appearance.

PAP

Paper-Money is a term frequently made use of for bank-hills, which pass currently in trade instead of gold and silver.

Concerning this species of currency, the national utility of which has been controverted by some, we have the following observations in Dr Smith’s Treatise on the Wealth of Nations: “The substitution of paper in the room of gold and silver money replaces a very expensive instrument of commerce with one much less costly, and sometimes equally convenient. Circulation comes to be carried on by a new wheel, which it costs less both to erect and maintain than the old one.

“When the people of any particular country are endowed with such confidence in the fortune, probity, and prudence of a particular banker, as to believe that he is always ready to pay upon demand such of his promissory notes as are likely at any time to be presented to him, those notes come to have the same currency as gold and silver money, from the confidence that such money can at any time be had for them.

A particular banker lends among his customers his own promissory notes, to the amount, we shall suppose, of 100,000l. As those notes serve all the purpose of money, his debtors pay him the same interest as if he had lent them so much money. This interest is the source of his gain. Though some of those notes are continually coming back upon him for payment, part of them continue to circulate for months and years together. Though he has generally in circulation, therefore, notes to the amount of 100,000l. 20,000l. in gold and silver may frequently be a sufficient provision for answering occasional demands. By this operation, therefore, 20,000l. in gold and silver perform all the functions which 100,000l. could otherwise have performed. Eighty thousand pounds of gold and silver can therefore, in this manner, be spared from the circulation of the country; and if different operations of the same kind should at the same time be carried on by many different banks and bankers, the whole circulation may be thus conducted with a fifth part only of the gold and silver.

Let us suppose, for example, that the whole circulating money of some particular country amounted, at a particular time, to 1,000,000l. sterling, that sum being then sufficient for circulating the whole annual produce of their land and labour. Let us suppose too, that some time thereafter, different banks and bankers issued promissory notes, payable to the bearer, to the extent of 1,000,000l. reserving in their different coffers 200,000l. for answering occasional demands. There would remain, therefore, in circulation 800,000l. in gold and silver, and 1,000,000l. of bank notes, or 1,800,000l. of paper and money together. But the annual produce of the land and labour of the country had before required only 1,000,000l. to circulate and distribute it to its proper consumers, and that annual produce cannot be immediately augmented by those operations of banking. One million, therefore, will be sufficient to circulate it after them. The goods to be bought and sold being precisely the same as before, the same quantity of money will be sufficient for buying and selling them. The channel of circulation, if I may be allowed such an expression, will remain precisely the same as before. One million we have supposed sufficient to fill that channel. Whatever, therefore, is poured into it beyond this sum, cannot run in it, but must overflow. One million eight hundred thousand pounds are poured into it. Eight hundred thousand pounds, therefore, must overflow, that sum being over and above what can be employed in the circulation of the country. But though this sum cannot be employed at home, it is too valuable to be allowed to lie idle. It will therefore be sent abroad, in order to seek that profitable employment which it cannot find at home. But the paper cannot go abroad; because, at the distance from the banks which issue it, and from the country in which payment of it can be exacted by law, it will not be received in common payments. Gold and silver, therefore, to the amount of 800,000l. will be sent abroad, and the channel of home circulation still remain filled with 1,000,000l. of paper instead of 1,000,000l. of those metals which filled it before.

But though so great a quantity of gold and silver is thus sent abroad, we must not imagine that it is sent abroad for nothing, or that its proprietors make a present of it to foreign nations. They will exchange it for foreign goods of some kind or another, in order to supply the consumption either of some other foreign country or their own.

If they employ it in purchasing goods in one foreign country in order to supply the consumption of another,
another, or in what is called the carrying trade, whatever profit they make will be an addition to the next revenue of their own country. It is like a new fund, created for carrying on a new trade; domestic business being now transacted by paper, and the gold and silver being converted into a fund for this new trade.

If they employ it in purchasing foreign goods for home consumption, they may either first purchase such goods as are likely to be consumed by idle people who produce nothing, such as foreign wines, foreign silks, &c.; or, secondly, they may purchase an additional stock of materials, tools, and provisions, in order to employ an additional number of industrious people, who reproduce, with a profit, the value of their annual consumption.

So far as it is employed in the first way, it promotes prodigality, increases expense and consumption without increasing production, or establishing any permanent fund for supporting that expense, and is in every respect hurtful to the society.

So far as it is employed in the second way, it promotes industry; and though it increases the consumption of the society, it provides a permanent fund for supporting that consumption. The people who consume, reproducing, with a profit, the whole value of their annual consumption. The gross revenue of the society, the annual produce of their land and labour, is increased by the whole value which the labour of these workmen adds to the materials upon which they are employed; and their next revenue by what remains of this value, after deducting what is necessary for supporting the tools and instruments of their trade.

That the greater part of the gold and silver which, being forced abroad by those operations of banking, is employed in purchasing foreign goods for home consumption, is, and must be employed for purchasing those of this second kind, seems not only probable, but almost unavoidable. Though some particular men may sometimes increase their expense very considerably, though their revenue does not increase at all, this may be overcome by the class or order of men ever does so; because, though the principles of common prudence do not always govern the conduct of every individual, they always influence that of the majority of every class or order. But the revenue of idle people, considered as a class or order, cannot in the smallest degree be increased by those operations of banking. Their expense in general, therefore, cannot be much increased by them, though that of a few individuals among them may, and in reality sometimes is. The demand of idle people, therefore, for foreign goods, being the same, or very nearly the same, as before, a very small part of the money, which being forced abroad by those operations of banking, is employed in purchasing foreign goods for home consumption, is likely to be employed in purchasing those for their use. The greater part of it will naturally be destined for the employment of industry, and not for the maintenance of idleness.

When we compute the quantity of industry which the circulating capital of any society can employ, we must always have regard to those parts of it only which consist in provisions, materials, and finished work: the other, which consists in money, and which serves only to circulate those three, must always be deducted. In order to put industry into motion, three things are requisite: materials to work upon, tools to work with, and the wages or recompense for the sake of which the work is done. Money is neither a material to work upon, nor a tool to work with, nor the wages of the workmen; but the wages of the workmen are commonly paid to him in money, his real revenue, like that of all other men, consists, not in the money, but in the money's worth; nor in the metal pieces, but in what can be got for them.

"The quantity of industry which any capital can employ, must evidently be equal to the number of workmen whom it can supply with materials, tools, and a maintenance suitable to the nature of the work. Money may be requisite for purchasing the materials and tools of the work, as well as the maintenance of the workmen. But the quantity of industry which the whole capital can employ, is certainly not equal both to the money which purchases, and to the materials, tools, and maintenance, which are purchased with it; but only to one or other of those two values, and to the latter more properly than to the former.

When paper is substituted in the room of gold and silver money, the quantity of the materials, tools, and maintenance, which the whole circulating capital can supply, may be increased by the whole value of gold and silver which used to be employed in purchasing them. The whole value of the great wheel of circulation and distribution is added to the goods which are circulated and distributed by means of it. The operation, in some measure, resembles that of the undertaker of some great work, who, in consequence of some improvement in mechanics, takes down his old machinery, and adds the difference between its price and that of the new to his circulating capital, to the fund from which he furnishes materials and wages to his workmen.

"What the proportion is which the circulating money of any country bears to the whole value of the annual produce circulated by means of it, it is perhaps impossible to determine. It has been computed by different authors at a fifth, at a twentieth, and at a thirtieth part of that value. But how small soever the proportion which the circulating money may bear to the whole value of the annual produce, as but a part, and frequently but a small part, of that produce, is ever destined for the maintenance of industry, it must always bear a very considerable proportion to that part. When, therefore, by the substitution of paper, the gold and silver necessary for circulation is reduced to perhaps a fifth part of the former quantity, if the value of only the greater part of the other four fifths be added to the funds which are destined for the maintenance of industry, it must make a very considerable addition to the quantity of that industry, and consequently to the value of the annual produce of land and labour.

That part of his capital which a dealer is obliged to keep by him unemployed, for answering occasional demands, is so much dead stock, producing nothing either to him or to his country. The judicious operations of banking enable him to make it active and productive. The gold and silver money which circulates in any country, and by means of which the produce of its land and labour is annually circulated and distributed to the proper consumers, is in the same manner as the ready money of the dealer, all dead stock. It
is a very valuable part of the capital of the country, which produces nothing to the country. The judicious operations of banking, by substituting paper in the room of a great part of it, enables the country to make a great part of this dead stock active and productive. The gold and silver money which circulates in any country, may very properly be compared to a highway, which, while it circulates and carries to market all the grass and corn of the country, produces itself not a single pile of either. The judicious operations of banking, by providing, if I may be allowed so violent a metaphor, a sort of waggon-way through the air, enable the country to convert, as it were, a great part of its highways into good pastures and corn fields, and thereby to increase very considerably the annual produce of its lands and labour. The commerce and industry of the country, however, it must be acknowledged, though they may be somewhat augmented, cannot be altogether so secure, when they are thus, as it were, suspended upon the Dædalian wings of paper money, as when they travel about upon the solid ground of gold and silver.

"The whole paper money of every kind which can easily circulate in any country, never can exceed the value of the gold and silver, of which it supplies the place, or which (the commerce being supposed the same) would circulate there if there was no paper money. If twenty shilling notes, for example, were the lowest paper money current in Scotland, the whole of that currency, which can easily circulate there, cannot exceed the sum of gold and silver which would be necessary for transacting the annual exchanges of twenty shillings value and upwards, usually transacted within that country. Should the circulating paper at any time exceed that sum, as the excess could neither be sent abroad, nor be employed in the circulation of the country, it must immediately return upon the banks to be exchanged for gold and silver. Many people would immediately perceive that they had more of this paper than was necessary for transacting their business at home, and as they could not send it abroad, they would immediately demand payment of it from the banks. When this superfluous paper was converted into gold and silver, they could easily find a use for it by sending it abroad; but they could find none while it remained in the shape of paper. There would immediately, therefore, be a run upon the banks to the whole extent of this superfluous paper, and, if they showed any difficulty or backwardness in payment, to a much greater extent; the alarm which this would occasion necessarily increasing the run." See Banking and Exchange, Supplement.

PAPER MACHE. This is a substance made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced to a kind of paste, and then boiled with a solution of gum arabic or of size, to give tenacity to the paste, which is afterwards formed into different toys, &c. by pressing it into oiled moulds. When dry, it is done over with a mixture of size and lamp black, and afterwards varnished. The black varnish for these toys, according to Dr Lewis, is prepared as follows: some colophon, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vessel, and thence as much amber in fine powder sprinkled in by degrees, with the addition of a little spirit or oil of turpentine now and then: when the amber is melted, sprinkle in the same quantity of sarcocolla, continuing to stir them, and to add more spirit of turpentine, till the whole becomes fluid; then strain out the clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory black in fine powder, is applied, in a hot room, on the dried paper paste; which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let stand each time till the oven grows cold. The paste thus varnished is hard, durable, glossy, and bears liquor hot or cold.

PAPHLAGONIA, in Ancient Geography, a country of the Hither Asia, beginning at Parthenius, a river of Bithynia, on the west, and extending in length to the Halys eastward, with the Euxine to the north, and Galatia to the south. Pliny enlarges the limits on the west side to the river Billis, on this side the Parthenius. It is called Pylemenia by some (Pliny). Paphlagonia, the people, mentioned by Homer, and therefore of no small antiquity. A superstitious and silly people (Lucian); a brave people (Homer); taking their name from Phaleg (Bocchart).

PAPHOS, in Ancient Geography, two adjoining islands on the west side of the island of Cyprus; the one called Haliea Paphos (Strabo, Ptolemey, Pliny); the other Nea Paphos; and when mentioned without an adjunct, this latter is always understood. Both dedicated to Venus, and left undistinguished by the poets (Virgil, Horace). Hence Venus is surnamed Paphia. Paphos, the people, (Coins, Stephanus). It was restored by Augustus, after a shock of an earthquake, and called Augusta (Dio).

The abbé Mariti, in his Travels through Cyprus, gives the following account of the island of Paphos. "It is situated (say he) on the southern side: it contained the celebrated temple of Venus; which, together with the city, was destroyed by an earthquake, so that the least vestige of it is not now to be seen. A lake in the neighbourhood, which even in summer overflows with stagnant and corrupted water, renders the air in some degree unwholesome. On the western coast is the new Paphos, called by some of the modern geographers Bafos; a name which is unknown in the island of Cyprus. That we may not positively ascribe to the latter every thing that history tells us of Paphos in general, it may not be here improper to mention that it has been several times destroyed. This city had a port, where vessels trading upon that coast still cast anchor: but this happens only in summer; for, being exposed to every wind, it is extremely dangerous. The bottom of it is full of sharp rocks; which sometimes destroy the cables so much, that mariners are obliged to keep them afloat on the surface of the water, by means of empty casks fixed to them at certain distances. In the neighbourhood there are two castles; one on the borders of the sea, and the other on the summit of a little hill: but the latter is at present in ruins. The government of Paphos consists of a digdaban or commissary; a cadi; and an aqai, who presides over the custom-house. Of all the Christian edifices,
Paphos edifices, there is none remaining but the church of St George, in which service is performed by the Greek ministers. The productions of this part of the island, which are all of an excellent quality, are silk, barley, and other kinds of grain. To discover the origin of the Old and New Paphos, would be carrying light into the midst of the thickest darkness. When we have added conjecture to conjecture, we are still in the same situation. As this is an attempt superior to my abilities, I shall leave it to the divining, though uncertain, knowledge of our antiquaries. I must, however, observe, that there was here formerly a temple dedicated to Venus, which was entirely destroyed by an earthquake. In this island St Paul by his eloquence converted Sergius, a Roman proconsul. He here likewise conferred the deaconship on his disciple and colleague Titus, who soon after suffered martyrdom. Paphos was an episcopal city in the time of the Lusignans; and it is still the seat of a bishop, who is a suffragan to the archbishop of Nicosia. On the western side of the island there are a great number of scattered villages; but they are not worthy of notice, being either abandoned or in ruins.

Mr Bruce informs us, that in the neighbourhood of this place many silver medals of excellent workmanship are dug up; they are, however, but of little estimation among the antiquarians, being chiefly of towns of the size of those found at Crete and Rhodes, and in all the islands of the Archipelago. There are some excellent Greek intaglios; generally upon better stones than usual in the islands. This illustrious traveller informs us, that he has seen some heads of Jupiter, remarkable for bushy hair and a beard, which were of excellent workmanship, and worthy of any price. All the inhabitants of the island are subject to fevers, but especially those in the neighbourhood of Paphos. The same traveller observes, that Cyprus was very long undiscovered; for though ships had been sailing on the Mediterranean 1700 years before Christ, and though the island is only a day’s sailing from the continent of Asia on the north and east, and little more from that of Africa on the south, it was not known at the building of Tyre, a little before the Trojan war, that is, 500 years after the neighbouring seas had been navigated. Its first discovery, and our author is of opinion, that it was not well known even at the time of building of Solomon’s temple; because we do not find that Hiram king of Tyre, though just in its neighbourhood, ever had recourse to it for wood: though the carriage would undoubtedly have been easier from thence, than to have brought it down from the top of Mount Lebanon. Eratosthenes informs us, that in ancient times the island was so overgrown with wood, that it could not be tilled; so that they first cut down the timber to be used in the furnaces for melting silver and copper; that after this they built fleets with it: but finding even this insufficient, they gave liberty to all strangers to cut it down for whatever purpose they pleased; and not only so, but they gave them afterwards the property of the ground they had cleared. Matters are now quite altered; and the want of wood is a principal complaint in most parts of the island. About Acremas, however, on the west side of the island, the wood is still thick and impervious, inhabited by large stags and wild boars of a monstrous size. Mr Bruce was informed, that a live elephant had lately been seen there, but gave no credit to the account.

PAPIAS, bishop of Hierapolis, a city of Phrygia, was the disciple of St John the Evangelist, and the companion of Polycarp, as St Jerome observes, and not of John the Ancient, as some other authors have maintained. He composed a work in five books, entitled Expositions of the Discourses of our Lord, of which there are only some fragments now remaining. He it was who introduced the opinion of the Millennium.

PAPILIO, the BUTTERFLY, a genus of insects belonging to the order of lepidoptera. See ENTOMOLOGY INDEX.

PAPILLONACEOUS, among Botanists, an appellation given to the flowers of plants belonging to various classes, from their resembling the wings of a butterfly.

PAPINIAN, a celebrated Roman lawyer of the third century, under the emperor Severus; who had so high an opinion of his worth, that he recommended his sons Caracalla and Geta to his care. Caracalla having first murdered his brother, ordered Papinian to compose a discourse to excuse this murder to the senate and people; which when he refused to undertake, the brutal emperor ordered him to be beheaded; and his body was dragged through the streets of Rome. Papinian wrote several treatises in the line of his profession.

PAPISTS, are those who believe the pope or bishop of Rome to be the supreme pastor of the universal church, who profess to believe all the articles of Pope Pius’s creed, and who promise implicit obedience to the edicts of the church, especially the decrees of the council of Trent. See POPE and TRENTO.

PAPPERNEHEIM, a town of Germany, in the kingdom of Bavaria; and capital of a county of the same name, with a castle, where the counts reside. It is seated near the river Altmühl, 17 miles north-west of Neuburg, and 32 south of Nuremberg; and is subject to its own count. E. Long. 10. 31. N. Lat. 48. 38. The count of Pappenheim was hereditary marshal of the empire, and performed his office at the coronation of the emperor.

PAPPUS, an eminent philosopher of Alexandria, said by Suidas to have flourished under the emperor Theodosius the Great, who reigned from A. D. 379 to 395. His writings show him to have been a consummate mathematician: Many of them are lost; the rest continued long in manuscript, detached parts having only been occasionally published in the last century, until Carolus Maneleins published his remains entire at Bologna, in 1660, in folio.

PAPPUS, in Botany, a soft downy substance that grows on the seeds of certain plants, as thistles, hawkweed, &c. serving to scatter and buoy them up in the air.

PAPYRUS, the famous reed from which was made the far-famed paper of Egypt. Before entering on the description of the papyrus, it is natural to say a word or two on the opinion generally received in Europe concerning the loss of this plant. Supposing this loss possible, the date of it must be fixed at no distant period; for it is not 200 years since Guinandin and Prosper Alpin observed the papyrus on the banks of the
the Nile. Guiraldin saw the inhabitants of the country eating the inferior and succulent part of the stem in the manner of the ancients; a fact which alone shows it to be the papyrus, and of which other travellers seem not to have availed themselves. This practice, together with those related by Prosper Alpin, are sufficient to convince us, that this plant is not wholly useless, although it is not now employed in the fabrication of paper. The alteration on the soil of Egypt, and on the methods of agriculture, have in all probability removed this plant less common; but causes altogether local could not occasion the destruction of the papyrus, especially as its residence in the marshes would prevent their operation. But it is needless to reason from probabilities or analogy: Mr Bruce not only saw the papyrus growing both in Egypt and Abyssinia, but actually made paper of it in the manner in which it was made by the ancients. He tells us likewise, that, so far from any part of it being useless, the whole plant is at this day used in Abyssinia for making boats, a piece of the acaica tree being put in the bottom to serve as a keel. That such were the boats of ancient Egypt, we know from the testimony of Pliny, who informs us, that the plants were first sewed together, and then gathered up at stem and stern, and tied fast to the keel: "Conservatur bibula Mempithis cymba papyro." "The bottom, root, or woody part of this plant was likewise of several uses before it turned absolutely hard; it was chewed in the manner of liquorice, having a considerable quantity of sweet juice in it. This we learn from Dioscorides; it was, I suppose, chewed, and the sweetness sucked out in the same manner as is done with sugar cane. This is still practised in Abyssinia, where they likewise chew the root of the Indian corn, and of every kind of cyperus: and Herodotus tells us, that about a cubit of the lower part of the stalk was cut off, and roasted over the fire, and eaten. "From the scarcity of wood, which was very great in Egypt, this lower part was likewise used in making cups, moulds, and other necessary utensils: we need not doubt, too, one use of the woody part of this plant was, to serve for what we call boards or covers for binding the leaves which were made of the bark; we know that this was anciently one use of it, both from Alcaeus and Anacreon." The papyrus, says Pliny, grows in the marshes of Egypt, or in the stagnant places of the Nile, made by the flow of that river, provided they are not beyond the depth of two cubits. Its roots are tortuous, and in thickness about four or five inches: its stem is triangular, rising to the height of ten cubits. Prosper Alpin gives it about six or seven cubits above the water; the stem tapers from the bottom, and terminates in a point. Theophrastus adds, that the papyrus carries a top or plume of small hairs, which is the thyrsus of Pliny. Guiraldin informs us, that its roots throw to the right and left a great number of small fibres, which support the plant against the violence of the wind, and against the waters of the Nile. According to him, the leaves of the plant are obtuse, and like the typhus of the marshes. Mr Bruce, on the other hand, assures us, that it never could have existed in the Nile. "Its head (says he) is too heavy; and in a plain country the wind must have had too violent a hold of it. The stalk is small and feeble, and withal too tall; the root too short and slender to stay it against the violent pressure of the wind and current; therefore I do constantly believe it never could be a plant growing in the river Nile itself, or in any very deep or rapid river;" but in the calisbes or places where the Nile had overflowed and was stagnant.

The Egyptians made of this plant paper fit for writing (see PAPER), which they call colias or philaris, and also papyrus, and hence the Latin charta; for in general the word charta is used for the paper of Egypt.

The papyrus was produced in so great quantities on the banks of the Nile, that Cassiodorus (lib. xi. 30.) compares it to a forest. There, says he, rises to the view, this forest without branches, this thicket without leaves, this harvest of the waters, this ornament of the marshes. Prosper Alpin is the first who gives us a plate of the papyrus, which the Egyptians call berdi. This corresponds in some degree with the description of the plant mentioned by Theophrastus; but the best drawing of it has been given by Mr Bruce.

The ancient botanists placed the papyrus among the graminous plants or dog grass; ignorant of the particular kind to which it belonged, they were contented to specify it under the name of papyrus, of which there were two kinds, that of Egypt, and that of Sicily. The moderns have endeavoured to show, that these two plants are one and the same species of cyperus. It is under this genus that they are found in the catalogues and descriptions of plants published since the edition of Marmion's work, where the papyrus is called cyperus nicus Syriacus maximus papparcesus.

In the manuscripts of the letters and observations of M. Lippi physician at Paris, who accompanied the envoy of Louis XIV. to the emperor of Abyssinia, we find the description of a cyperus which he had observed on the banks of the Nile in 1704. After having described the flowers, he says that many ears covered with young leaves are supported by a pretty long pedicle; and that many of those pedicles, equally loaded and coming from one joint, form a kind of parasol. The disk of this parasol is surrounded with a quantity of leaves which form a crown to the stem which supports it. The stem is a pretty long prism, the corners of which are a little rounded; and the leaves, not at the top, but at the side, are formed like the blade of a sword; the roots are black and full of fibres; and this plant is called cyperus Nitidus major, umbella multiplica.

The same Lippi describes another kind which rises not so high; the stem and leaves correspond with the former, but the ears form rather a kind of head than any thing like the spreading of an umbrella; this head was very soft, shining, and gilded, rich and airy, much loaded, supported by pedicles which were joined together at the bottom like the knitting of a parasol. It is called by him cyperus Nitidus major aureo, divis punctata. These two kinds of cyperus have a marked resemblance in their leaves, their stem, their foliage, and the marshy places where they grow. The only difference consists in their size, and in the position of the ears, which serve to distinguish them; and they seem to bear a resemblance to the papyrus and the sari, described
PAP

Papyrus, described by ancient authors. The first is perhaps the papyrus, and the second the sari; but this is only conjecture.

The papyrus, which grew in the waters, is said to have produced no seed; but this Mr Bruce very properly calls an absurdity. The form of the flower (says he) sufficiently indicates, that it was made to resolve itself into the covering of one, which is certainly very small, and by its exalted situation and thickness of the head of the flower, seems to have named the extraordinary covering it has had to protect it from the violent hold the wind must have had upon it. For the same reason, the bottom of the filaments composing the head are sheathed in four concave leaves, which keep them close together, and prevent injury from the wind getting in between them. Its plume was composed of slender pedicles, very long, and somewhat like hair, according to Theophrastus. The same peculiarity exists in the papyrus of Sicily; and the same is found to exist in another kind of papyrus sent from Madagascar by M. Poivre, correspondent of the Academy of Sciences. It is impossible to determine whether the papyrus of Sicily was used in any way by the Romans. In Italy it is called papiro, and, according to Cesalpin, piperno. This papyrus of Sicily has been cultivated in the garden of Pisa; and if we can depend on the authority of Cesalpin, who himself examined the plant, it is different from the papyrus of Egypt.

The papyrus, says he, which is commonly called piperno in Sicily, has a longer and thicker stem than the plant cyperus. It rises sometimes to four cubits; the angles are obtuse, and the stem at the base is surrounded with leaves growing from the root; there are no leaves on the stem even when the plant is at the greatest perfection, but it carries at the top a large plume which resembles a great tuft of dishevelled hairs; this is composed of a great number of terminal pedicles, in the form of reeds; at the extremity of which are placed the flowers, between two small leaves of a reddish colour like the cyperus. The roots are woody, about the thickness of reeds, jointed, and they throw out a great number of branches which extend themselves in an oblique direction. These are scented somewhat like the cyperus, but their colour is a lighter brown; from the lower part issue many small fibres, and from the higher a number of stems shoot up, which in proportion as they are tender contain a sweet juice.

The plume of the papyrus of Sicily is pretty well described in a short account of it in the second part of the Museum de Boccane. This plume is a tuft or assemblage of a great number of long slender pedicles, which grow from the same point of division, are disposed in the manner of a parasol, and which carry at the top three long and narrow leaves, from which issue other pedicles, shorter than the former, and terminating in several knots of flowers. Meech, in his Nova Plantarum Genera, printed at Florence 1728, has given an engraving of one of the long pedicles in its natural length; it is surrounded at the base with a case of about one inch and a half in height; towards the extremity it carries three long and narrow leaves, and four pedicles, to which are fixed the knots of flowers. Every pedicle has also a small case surrounding its base. In short, we find in the Grasso Graphia of Scheuchzer a very particular description of the plume of a kind of cyperus, which appears to be a Sicilian plant. From this account it appears that the papyrus of Sicily is well known to botanists. It were to be wished that we had an particular description of the papyrus of Egypt; but meanwhile it may be observed, that these two plants have a near affinity to one another; they are confounded together by many authors; and, according to Theophrastus, the sari and the papyrus nilotica have a decided character of resemblance. It is only in this, that the papyrus sends forth thick and tall stems, which being divided into slender plates, are fit for the fabrication of paper; whereas the sari has small stems, considerably shorter, and altogether useless for any kind of paper.

The papyrus, which served anciently to make paper, must not be confounded with the papyrus of Sicily, found also in Calabria; for, according to Strabo, the papyrus was to be found in no place excepting Egypt and India. The greatest part of botanists have believed that the Sicilian plant is the same with the sari of Theophrastus; others have advanced that the papyrus of Egypt and the sari were the same plant in two different stages of its existence, or considered with respect to the greater or less height, which, according to them, might depend on the qualities of the soil, the difference of the climate, or other accidental causes. In proof of this, it is maintained, that there is an essential difference between the papyrus growing in the waters and the same plant growing on the banks of rivers and in marshes. The first of these has thick and tall stems, and a plume in the form of a tuft of hair very long and slender, and without any seed: the second differs from the first in all these particulars; it has a shorter and more slender stem, its plume is loaded with flowers, and of consequence it produces seed. In whatever way we consider these facts, it is sufficient for us to know, that the difference between the papyrus and the sari neither depends on climate, nor soil, nor on situation. The plants whose difference depended on these circumstances, both grew in Egypt, and were both employed in the manufacture of paper. But it is an established fact, that the sari cannot be employed for this purpose.

Finally, The papyrus of Sicily began to be known by botanists in 1570, 1572, and 1583, at which periods the works of Lobel, of Guilandin, and of Cesalpin, first appeared. The ancients had no manner of knowledge of this plant. Pliny makes no mention of it in his Natural History; from which it is evident that it was neither used in Rome nor in Sicily. If he had seen this plant, he must have been struck with its resemblance to the papyrus and the sari, as they were described by Theophrastus; and since he gives a particular description of these last mentioned, he would have most naturally hinted at their conformity to the Sicilian papyrus.

Among many dried plants collected in the East Indies by M. Poivre, there is a kind of papyrus very different from that of Sicily. It carries a plume composed of a considerable tuft of pedicles, very long, weak, slender, and delicate, like single threads, terminating most frequently in two or three small narrow leaves, without any knot of flowers between them; hence this plume must be altogether barren. Those pedicles or threads are furnished with a pretty long membranous case, in which
PAPYRUS. which they are inserted; and they issue from the same point of direction, in the manner of a parasol. The plume, at its first appearance, is surrounded with leaves like the radii of a crown. The stem which supports it is, according to M. Poivre, about ten feet in height, where there is two feet under water; it is of a triangular form, but the angles are rounded; its thickness is about the size of a walking staff which fills the band.

The interior substance, although soft and full of fibres, is solid, and of a white colour. By this means the stem possesses a certain degree of strength, and is capable of resistance. It bends without breaking; and as it is extremely light, it serves in some sort for a cane: The same M. Poivre used no other during a residence of several months at Madagascar. This stem is not of equal thickness in its whole length; it tapers insensibly from the thickest part towards the top. It is without knots, and extremely smooth. When this plant grows out of the waters, in places simply moist, it is much smaller, the stems are lower, and the plume is composed of shorter pedicles or threads, terminating at the top in three narrow leaves, a little longer than those at the plume when the plant grows in the water. From the base of these leaves issue small knots of flowers, arranged as they are in the cyperus; but these knots are not elevated above the pedicles, they occupy the centre of the three leaves, between which they are placed, and form themselves into a small head. The leaves which spring from the root and the lower part of the stem resemble exactly those in the cyperus. This plant, which the inhabitants call sanga-sanga, grows in great abundance in their rivers and on their banks, but particularly in the river Tartas, near the Foule-point in Madagascar. The inhabitants of these cantons use the bark of this plant for mats; they make it also into sails, into cordage for their fishing houses, and into cords for their nets.

This kind of papyrus, so lately discovered, and different from the papyrus of Sicily by the disposition of its flowers, shows, that there are two kinds of the cyperus which might easily be confounded with the papyrus of Egypt; whether we consider, on the one hand, to what purposes the inhabitants of the places where they grow have made them subservient; or, on the other compare their form, their manner of growth, and the points in which they resemble each other. This comparison can be easily made from the accounts which Pliny and Theophrastus gave of the papyrus of Egypt, and by the figure and description given by Prosper Alpinus, after having observed the plant on the banks of the Nile. But if we can depend on the testimony of Strabo, who affirms that the papyrus is found nowhere but in Egypt and in India, it is perhaps possible that the papyrus of the isle of Madagascar is the same with that of Egypt.

Whatever truth may be in this conjecture, the inhabitants of this island have never derived from it those advantages which have immortalized the papyrus of Egypt. They have not made that celebrated paper, quo un maxime humanitas, vita, constat et memoria. Mr Russell, a recent traveller (1817), mentions, that a nobleman at Syracuse had succeeded in making paper of the Sicilian papyrus by a process similar to that described by Pliny.

PAR, in Commerce, signifies any two things equal in value. See EXCHANGE.

PARABLE, a fable or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn by comparing it with something in which the people are more immediately concerned; such are the parables of Divus and Lazarus, of the Prodigal Son, of the Ten Virgins, &c. Dr Blair observes, that "4 of parables, which form a part of allegory, the prophetical writings are full; and if to these sometimes appear obscure, we must remember, that in those early times it was universally the mode throughout all the eastern nations to convey sacred truths under mysterious figure and representations."

PARABOLA. See CONIC SECTIONS.

PARABOLE. See ORATORY, No 84.

PARACELSUS, AURELIUS PHILIP THEOPHRASTUS BOMBASTUS DE HOHENHEIM, a famous physician, born at Einfelden, a town in the canton of Schwetz in Switzerland. He was educated with great care by his father, who was the natural son of a prince, and in a little time made a great progress in the study of physic. He afterwards travelled into France, Spain, Italy, and Germany, in order to become acquainted with the most celebrated physicians. At his return to Switzerland, he stayed at Basle, where he read lectures on physic in the German tongue. He was one of the first who made use of chemical remedies with success, by which he acquired a very great reputation. Paracelsus gloried in destroying the method established by Galen, which he believed to be very uncertain; and by this means drew upon himself the hatred of the other physicians. It is said, that he boasted of being able, by his remedies, to preserve the life of man for several ages: but he himself experienced the vanity of his promises, by his dying at Saltzburg, in 1545, at 37 years of age according to some, and at 48 according to others. The best edition of his works is that of Geneva in 1658, in 3 vols. folio.

PARACENTESIS, an operation in surgery, commonly called tapping. See SURGERY.

PARACLET, the Comforter, a name given to the Holy Ghost.

PARADE, in a military sense, the place where troops assemble or draw together, to mount guard, or for any other purpose.

PARADE, in fencing, implies the action of parrying or turning off any thrust.

PARADISE, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

As to this terrestrial paradise, there have been many inquiries about its situation. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the place possessed by the Caspian sea, and under the arctic pole. The learned Huetius places it upon the river that is produced by the conjunction of the Tigris and Euphrates, now called the river of the Arabs, between this conjunction and the division made by the same river before it falls into the Persian sea. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxes, and the Phasis, which they suppose to be the four rivers described...
PAR

described by Moses. But concerning the exact place we must necessarily be very uncertain, if indeed it can be thought at all to exist at present, considering the many changes which have taken place on the surface of the earth since the creation. "Learned men (says Mr. Milne) have laboured to find out the situation of Paradise, which seems to be but a vague and uncertain inquiry; for the Mosaic description of it will not suit any place on the present globe. He mentions two rivers in its vicinity, viz. Pison and Gihon, of which no vestiges can now be found. The other two still remain, viz. the Hiddekel, supposed to be the Tigris, and the Euphrates, whose streams unite together at a considerable distance above the Persian gulf; in some part of which, it is highly probable the happy garden once lay (A). This gulf is eastward both of the land of Midian and the wilderness of Sinai; in one of which places Moses wrote his history. But since the formation of this earth, it has undergone great changes from earthquakes, inundations, and many other causes. The garden, however, seems to have been a peninsula, for the way or entrance into it is afterwards mentioned: We are told that a 'river went out of it,' which, according to some, should be rendered 'run on the outside of it,' and thus gave it the form of a horseshoe: for had the Euphrates run through the middle of the garden, one half of it would have been useless to Adam, without a bridge or boat wherewith to have crossed it."

The learned authors of the Universal History, in their account of rarities natural and artificial in Syria, mention "a spot which is still shown as the place where once stood the garden of Eden, or Terrestrial Paradise. And indeed it is in all respects so beautiful and rich, and yields so delightful a prospect from the adjacent hills, that there is hardly another place in the world that has a fairer title to the name it bears. Its proximity to Damascus, the capital of Syria, near the fountain head of the Jordan; its situation between the Tigris or Hiddekel, the Euphrates, the Phasis or Pison, the Araxes or Gihon (which last has those names from its vast rapacity above all other known rivers), its bordering on the land of the Chaldees, famed for its fine gold; all these and many other marks specified by Moses, together with its charming and surprising fruitfulness, and constant verdure, have induced a great number of commentators to settle that celebrated and so much sought after spot here, and to deem it the most valuable of all the natural rarities of this country.

Christians, we presume, need not betold, that however curious or amusing this inquiry may be, the determination of it is of no importance, since we are all well assured that the celestial paradise is that place of pure and refined delight in which the souls of the blessed enjoy everlasting happiness. It may not be improper, however, in this place to give a description of the paradise of the Mohammedans. The sensuality and absurdity of that impostor must be apparent to all men. Their religion has no consistency in its parts, and the descriptions of the future enjoyments of the faithful are miserable instances of human weakness and folly. "The paradise of the Mohammedans is said by them to be situated above the seven heavens, or in the seventh, and next under the throne of God; and to express the amplitude of the place, they tell us that the earth of it is of the finest wheat flour, or of the purest musk, or of saffron; and that its stones are pearls and jacinths, the walls of it building enriched with gold and silver, and the trunks of all its trees of gold, among which the most remarkable is the tree tuba, or tree of happiness. They pretend that this tree stands in the palace of Mohammed, though a branch of it will reach to the houses of every believer, loaded with pomegranates, dates, grapes, sunlight, and all sorts of food, bigness, and delicious tastes, unknown to mortals. If a man desires to eat of any particular kind of fruit, it will immediately be presented to him; or if he chooses flesh, birds ready dressed will be set before him, and such as he may wish for. They add, that this tree will supply the blessed not only with fruit, but with silk garments also, and beasts to ride on, adorned with rich trappings, all which will burst forth from the fruit; and that the tree is so large, that a person mounted on the fleetest horse would not be able to gallop from one end of its shade to the other in 100 years. Plenty of water being one of the greatest additions to the pleasantness of any place, the Alcoran often speaks of the rivers of paradise as the principal ornament. Some of these rivers are said to flow with water, some with milk, some with wine, and others with honey: all of them have their sources in the root of this tree of happiness; and, as if these rivers were not sufficient, we are told that the garden of this paradise is also watered by a great number of lesser springs and fountains, whose waters are rubies and emeralds, their earth of camphor, their beds of musk, and their sides of saffron. But all these glories will be eclipsed by the resplendent and exquisite beauty of the girls of paradise, the enjoyment of whose company will constitute the principal felicity of the faithful. These (they say) are not formed of clay, as mortal women, but of pure musk; and are, as their prophet often affirms, in his Alcoran, free from all the natural defects and inconveniences incident to the sex. Being also of the

(A) "God (we are told) placed at the east of the garden of Eden cherubims and a flaming sword, which turned every way, to keep the way of the tree of life. In Scripture, the extraordinary judgments of God are said to be executed by his angels, who are sometimes compared to flames of fire. Therefore the cherubim and the flaming sword may probably mean nothing more than that a large portion of ground on the eastward of Paradise was set on fire during the above awful occasion, and continued burning with such violence, that the flame thereof at a distance appeared like a brandished sword, turning every way with the wind. Now if the soil of Eden was bituminous, like that of Gomorrah (which was once so fertile as to be compared to the garden of the Lord), the fire would continue burning till it produced the same effect in the one place as it did in the other, and turned a great part of that tract into sea: which seems to countenance the opinion of those who place the situation of Paradise in some part of the Persian gulf."
strictest modesty, they keep themselves secluded from public view in pavilions of hollow pears, so large, that as some traditions have it, one of them will be no less than 16, or, as others say, 60 miles long, and as many broad. With these the inhabitants of paradise may taste pleasures in their height; and for this purpose will be endowed with extraordinary abilities, and enjoy a perpetual youth.

PARADISE LOST, the name of a modern epic poem, the first and finest of those composed by Milton.

The subject of this poem is extraordinary; it had never before been attempted, and seemed to be above the efforts of human genius. Angels and devils are not the machinery, but the principal actors in it; so that what would appear marvellous in any other composition, is in this only the natural course of events. The poet's intention was, as he expresses it himself, to vindicate the ways of God to men. How far Milton was happy in the choice of his subject, may be questioned. It has led him into difficult ground, though it certainly suited the daring sublimity of his genius. It is a subject for which he alone was fitted; and, in the conduct of it, he has shown a stretch both of imagination and invention which is perfectly wonderful.

Bird of PARADISE. See the following article.
PARADISEA, a genus of birds belonging to the order of picus. See Ornithology Index.

PARADOX, a proposition, in philosophy, a proposition seemingly absurd, as being contrary to some received opinions, but yet true in fact.

The vulgar and illiterate take almost every thing, even the most important, upon the authority of others, without ever examining it themselves. Although this implicit confidence is seldom attended with any bad consequences in the common affairs of life, it has nevertheless, in other things, been much abused; and in political and religious matters has produced fatal effects. On the other hand, knowing that learned men, to avoid this weakness have fallen into the contrary extreme: some of them believe every thing to be unreasonable or impossible, that appears so to their first apprehension; not adhering to the narrow limits of the human understanding, and the infinite variety of objects, with their mutual operations, combinations, and affections, that may be presented to it.

It must be owned, that credulity has done much more mischief in the world than incredulity has done, or ever will do; because the influences of the latter extend only to such as have some share of literature, or affect the reputation thereof. And since the human mind is not necessarily impelled, without evidence, either to belief or unbelief, may but suspend its assent to, or dissent from, any proposition, till after a thorough examination; it is to be wished that men of learning, especially philosophers, would not hastily, and by the first appearances, determine themselves with respect to the truth or falsehood, possibility or impossibility of things.

A person who has made but little progress in the mathematics, though in other respects learned and judicious, would be apt to pronounce it impossible that two lines, which were nowhere two inches asunder, may continually approach towards one another, and yet never meet though continued to infinity: and yet the truth of this proposition may be easily demonstrated. And many, who are good mechanics, would be as apt to pronounce the same, if they were told, that though the teeth of one wheel should take equally deep into the teeth of three others, it should still affect them in such a manner, that, in turning it in any way round its axis, it should turn them one of the same way, another the contrary way, and the third no way at all.

No science abounds more with paradoxes than geometry; thus, that a right line should continually approach to the hyperbola, and yet never reach it, is a true paradox; and in the same manner a spiral may continually approach to a point, and yet not reach it in any number of revolutions, however great.

The Copernican system is a paradox to the common people; but the learned are all agreed as to its truth. Geometricians have of late been accuscd of maintaining paradoxes; and some do indeed use very mysterious terms in expressing themselves about asymptotes, the sums of infinite progressions, the arcs comprehended between curves and their asymptotes, and the solids generated from these arcs, the length of some spirals, &c. But all these paradoxes and mysteries amount to no more than this; that the line or number may be continually acquiring increments, and those increments may decrease in such a manner that the whole line or number shall never amount to a given line or number.

The necessity of admitting it is obvious from the nature of the most common geometrical figures: thus, while the tangent of a circle increases, the area of the corresponding sector increases, but never amounts to a quadrant. Neither is it difficult to conceive, that if a figure be concave towards a base, and have an asymptote parallel to the base (as it happens when we take a parallel to the asymptote of the logarithmic curve, or of the hyperbola, for a base), that the ordinate in this case always increases while the base is produced, but never amounts to the distance between the asymptote and the base. In like manner, a curvilinear area may increase while the base is produced, and approach continually to a certain finite space, but never amount to it; and a solid may increase in the same manner, and yet never amount to a given solid. See Mr. Laurin's Elements. See Logarithmic Curve.

PARADOXI, a sort of mimes or buffoons among the ancients, who entertained the people with exquisite effusions of drollery. They were also called Parasciologi, Ordonarii, Neoncologi, and Aratologi. See AIM.

PARAGAUDA, among the Romans, were spheres of gold, or silk and gold, interwoven in, not sewed to their garments. The garment was sometimes of one colour with one paragaude; sometimes of two colours, with two paragaude; of three colours, with three paragaude, &c. They were worn both by men and women.

PARAGOGE, in grammar, a figure whereby a letter or syllable is added to the end of a word, as med, for me; dicier, for dicit, &c.

PARAGRAM, in general, denotes a section or division of a chapter; and in references is marked thus, §.

PARAGUAY, or LA PLATA, a province of Spanish America, bounded on the north by the river of the Amazons; on the east, by Brazil; on the south, by Patagonia; and on the west, by Chili and Peru. This
the river Uruguay and Parana, and others a hundred leagues higher up in the country to the north-west of Guayra. The Portuguese frequently came upon them, and by force carried away as many as they thought proper to their plantations, and made slaves of them. Offended by such treatment, the Guaraneses resolved to quit their settlements in the neighbourhood of the Portuguese, and to remove into the province of Paraguay. Accordingly a migration of 20,000 persons, great and small, ensued. These the Jesuits soon converted; and having had the like success in converting about an equal number of the natives of Tape, a district in Paraguay, they united the two nations, and laid the foundation of their future dominion. These fathers seem to have trod in the steps of the first Incas, and to have civilized nations and converted souls in order to acquire subjects. According to a very exact account taken in the year 1734, there were then 32 towns of the Guaraneses, which were reckoned to contain above 20,000 families; and as the new converts were continually increasing, they were then about laying the foundations of three new towns. There were also then seven very populous towns inhabited by the converted Chiquito Indians, and they were preparing to build others for the reception of the new converts of that nation which were daily made.

The missions of Paraguay are surrounded on all sides with wild or unconverted Indians; some of whom live in friendship with the towns, but others harass them by frequent incursions. The fathers missionaries frequently visit those Indians, and preach to them; and from these expeditions they seldom return without bringing along with them some new converts to incorporate with their civilized subjects. In the performance of this duty they sometimes penetrate 100 leagues into those uncultivated tracts where wild Indians range; and it is observed that they meet with the least success amongst those nations with whom any fugitive Mestizos, or Spanish criminals, have taken refuge. The diligence of these fathers is certainly worthy the imitation of the Protestant clergy.

Every town has its curate, who is assisted by one, and very often by two priests of the same order, according to the largeness and extent of the town and its district. These two or three priests, together with six boys who assist them in the service of the church, form a small college in every town, wherein the hours and other exercises are regulated with the same formality and exactness as in the large colleges in the cities of Peru and Chili. The most troublesome part of the duty of

The climate of Paraguay differs but little from that of Spain; and the distinctions between the seasons are much the same. In winter, violent tempests of wind and rain are very frequent, accompanied with such dreadful claps of thunder and lightning as fill the inhabitants with terror and consternation. In summer, the excessive heats are mitigated by gentle breezes, which constantly begin at eight or nine in the morning.

It produces maize, manioc, and potatoes, besides many fruits and simples unknown in Europe. Vines, however, do not thrive, except in some particular places. Wheat has also been tried; but it is only used for cakes, and other things of that kind. There are great numbers of poisonous serpents, and others of enormous size, many of which live on fish. It produces also abundance of sugar, indigo, pimento, ipecacuanha, and variety of other drugs; and above all the herb Paraguay, which it exports to the value of 100,000l. annually, to the provinces of Chili and Peru. The manner of using it is, to dry and reduce it almost to powder, then put it into a cup with lemon juice and sugar; boiling water is then poured on it, and the liquor drank as soon as may be. It is supposed to be serviceable in all disorders of the head, breast, and stomach; it preserves the miners from the noxious mineral steams with which they would otherwise be suffocated; it is a sovereign remedy in putrid fevers and the scurvy; allays hunger; and purifies all kind of water, by infusing it therein.
of the assistant priests are the personal visitations which they are obliged to make to the Indians to prevent their giving themselves up to idleness; for such is the slothfulness of the Guaranies, that if they were not very carefully looked after, the society would receive no benefit or advantage from them. They also attend the public shambles, where the cattle necessary for the sustenance of the Indians are daily slaughtered, and distribute the flesh amongst all the families in the town, in proportion to the number of persons whereof each family consists; so that all may have what is necessary, none what is superfluous. They also visit the sick, and see that they are properly taken care of. They are generally employed the whole day in these affairs, so that they have seldom time to assist the curate in his spiritual functions. All the boys and girls in the parish go to church every day in the week (except on festivals and Sundays), where they are instructed by the curate. On Sundays the whole parish goes to church to be instructed. The curate is besides obliged to go to confess the sick, and to administer the viaticum to those who desire it, and also to perform all the other functions peculiar to this office. In strictness the curate should be appointed in this manner. The society should nominate three persons to the governor of Buenos Ayres (in whose government the missions of Paraguay are included), as being vice patron of the missions, that he may choose one of them for curate; and the curates should be instructed in the duties of their office by the bishop: but as the provincials of the order can best judge who are properly qualified for the office, the governor and bishop have ceded their rights to them, and by them the curates are always appointed. The missions of the Guaranies and the missions of the Chiquitos, into which the missions of Paraguay are divided, have each their distinct father-superior, by whom the coadjutors or assistant curates of the several towns in the respective divisions are appointed. These superiors are continually visiting the towns, to see that they be well governed, and to endeavour to improve and augment them. They likewise from time to time take care to send out some fathers of the order into the countries of the wild Indians to make new converts. The better to enable him to discharge these duties, the superior of the Guaranies is assisted by two vice-superiors; one of whom resides in Parana, the other upon the banks of the river Uruguay, and the superior himself resides in the town of Candelaria. The post of superior of the Chiquitos is not so troublesome as that of the superior of the Guaranies: for the Chiquitos are not only less numerous, but much more docile and industrious than the Guaranies, so that they need not be continually watched and attended in order to prevent their idleness. The king allows an annual stipend of 300 pezas to each curate of the Guaranies, for the maintenance of himself and his assistants. The money is paid to the superior, who issues out monthly to each curate as much as is necessary for his subsistence; and when they want any thing extraordinary, their wants are supplied upon application to him. But the Chiquitos maintain their own curates. In every town there is a plantation set apart for the maintenance of the curate, which is cultivated by the joint labour of all the inhabitants. The produce of these plantations is generally more than sufficient for the subsistence of the curates, and the surplus is sold to buy ornaments for the churches. Nor are the curates the spiritual rectors of the towns only; they are also in effect the civil governors. It is true there are in every town of the missions a governor, regidores, and alcaldes, as there are in the other towns and cities under the Spanish government. But though the governor is elected by the Indians, he must be approved by the curate before he enters upon his office; nor can he chaste or punish delinquents without the curate's permission. The curate examines those who are accused of offences; and if he finds them guilty, delivers them to the governor to be punished, according to the nature and quality of the offence committed. He sometimes orders them to be imprisoned for a few days, sometimes to fast, and, when the fault is considerable, to be whipped, which is the severest punishment that is ever inflicted; for the regulations and instructions of the curates have been so efficacious, that murder and such like heinous crimes are never here committed. And even before they undergo these gentle corrections, the curate discourses the offenders in a mild friendly manner; and endeavours to excite in them a due sense of their crime, and of the ill consequences they might flow from it, and to convince them that they merit a much greater punishment than that which they have suffered. This mild treatment prevents tumults and insurrections, and acquires the curates universal veneration and esteem. The alcaldes are chosen annually by the regidores. The governor, regidores, and alcaldes are all Indians of the best capacities; and are in effect only so many overseers appointed by the curate, and dignified with these empty titles.

Every town has its armoury or magazine, in which are lodged the fire-arms or other weapons wherewith the militia are armed when they take the field to repel the irruptions of the Portuguese and wild Indians. The militia are very dexterous and expert in the management of their arms; and are exercised on the eve of festivals in the squares or public places of the towns. The militia is composed of all those who are able to bear arms: they are formed into companies, which have each a proper number of officers, chosen from amongst those who are most distinguished for judgment and conduct. The dress of them is white, adorned with gold and silver, and the devices of the town to which they belong: they always appear in their uniforms on festivals, and on the days of military exercise. The governor, alcaldes, and regidores have also proper robes and dresses suitable to their respective offices, in which they appear on public occasions. There are schools in every town, in which the common people are taught reading and writing, and also music and dancing; in which arts they become very skilful. The Jesuits are very careful in consulting the natural bent and genius of their scholars, and in directing their studies and application accordingly. The lads of the most promising genius are taught the Latin tongue with great success. In one of the court yards of every curate's house are various shops or workhouses of painters, carvers, gilders, silversmiths, carpenters, weavers, and clockmakers, and of several other mechanics and artisans, who daily work for the public under the direction of the coadjutors, and at the same time teach the youth their respective arts and occupations.

The churches are large, well built, finely decorated
Paraguay, and enlightened, and not inferior to the richest in Peru. Each church has a choir of music, composed of instruments of all sorts, and very good voices; so that divine service is conducted here with as much pomp and solemnity as in cathedrals: nor are the public processions less splendid, especially that of the host; which, whenever it is carried abroad, is attended by the governor, alcaldes, and regidores, in their robes, and also by the militia in a body. The houses of the Indians are as well built and as well furnished as most of the Spanish houses in Peru. The greatest part indeed have mud walls, others are built with brick, and some with stone, but all are covered with tiles. In every town there is a house where gunpowder is made, that they may never want it when they are obliged to take arms, and always have it ready to make artificial fireworks on rejoicing days: for all festivals are here observed with as great ceremony and exactness as in the greatest cities. Upon the proclamation of a new king of Spain, the governors, alcaldes, regidores, and officers of the militia, appear dressed in new robes and uniforms of a different fashion from those they wore before. There is a sort of convenl in every town; in one part whereof are confined women of an ill life, and the other part is destined for the reception of married women who have no family, and who retire thither when their husbands are absent. For the maintenance of this house, and for the support of orphans, of old and infirm people, all the inhabitants of the town work two days in every week; and the profits of their labour, which is called the labour of the community, are set apart for the purpose. If the produce of this labour be more than is necessary for their subsistence, the surplus is laid out to buy ornaments for the churches, and clothes for the orphans and aged and infirm people; so that here are no beggars, nor any who want the necessary of life. In short, by the wise policy and prudent regulations of the Jesuits, the whole community enjoys peace and happiness.

The Guaranes are so profuse and negligent, that the curates are obliged to take into their hands all their goods and stuffs as soon as they are manufactured and made ready for sale; otherwise they would waste and destroy them, and not be able to maintain themselves. They are ignorant, as this matter is a task to them, so that the curates have no other trouble with them than the assisting them in the disposal of their goods, and procuring returns for them. For this purpose the society keeps a factor or procurator at Santa Fé and Buenos Ayres, to whom the merchandise of the missions is sent to be disposed of; and these factors return the value to the fathers in such sort of European commodities as are wanted. The goods of every town are kept separate; and the royal taxes are taken out of them without any other discount or allowances, save the stipends of the curates of the Guaranes and the pensions of the caiques. The fathers choose to manage the commerce of their subjects themselves, lest they should contract vices by their communication with other people. In this respect the fathers are so careful, that they will not suffer any of the people of Peru, whether they be Spaniards, Mestizos, or Indians, to enter into the territories of the missions. However, there are some who suspect that these are all specious pretences; and that the society's real motive for prohibiting all intercourse with strangers, is the fear of rivals in the beneficial commerce of Paraguay, which is now entirely in their hands.

Such is the account they themselves have given us of their own conduct: but others have treated their characters with more severity; accusing them of pride, haughtiness, and abusing their authority to the greatest degree; insomuch that they would have caused the magistrates to be whipped in their presence, and obliged persons of the highest distinction within their jurisdiction to kiss the hem of their garment, as the greatest honour at which they could possibly arrive. To this might be added, the utter abolition of all ideas of property; which indeed was rendered useless by the general magazines and storehouses, which they established, and from which, together with the herds of cattle kept for the public use, they supplied the wants of individuals as occasion required; yet still it was objected to the character of the fraternity, that they possessed large property themselves, and claimed the absolute disposal of the meanest effects in Paraguay. All manufactures belonged to them; every natural commodity was brought to them: and the treasures annually remitted to the superior of the order were thought to be a proof that zeal for religion was not the only motive by which they were influenced.

Besides the parochial or provincial governments, there was a kind of supreme council, composed of an annual meeting of all the fathers, who concerted the measures necessary for promoting the common concerns of the mission, framed new laws, corrected or abolished old ones, and, in a word, adapted every thing to circumstances. It is said to have been one of the great objects of the annual councils to take such measures as should effectually deprive strangers of all intelligence concerning the state of the mission. Hence the natives were restrained from learning the Spanish tongue, and were taught, that it was dangerous for their salvation to hold any conversation with a subject of Spain or Portugal. But the circumstance that rendered their designs most suspicious, was the establishment of a military force. Every parish had its corps of horse and foot, who were duly exercised every Sunday; and it was said, that the whole amounted to a body of 70,000 or 80,000 troops, well disciplined.

The city of Buenos Ayres, the metropolis of this vast province, was taken by the naval and military forces of his Britannic majesty, under the command of Sir Home Popham and Major-general Beresford, on the 26th of June 1806. It was attacked on the 9th of August the same year, by a detachment of Spanish troops from Monte Video, and obliged to surrender on the 12th under a capitulation, the terms of which were not afterwards observed; and General Beresford, the officers, troops, marines of the squadron, and a few seamen, remained prisoners of war. A more considerable force, under the command of Lieutenant-general Whitelocke, was afterwards sent to reduce it. That officer, after a number of skirmishes and partial engagements with the enemy, in which the officers and troops under his command exhibited abundant proofs of great bravery, thought proper to abandon the idea of reducing the town. The reason assigned by him for this mysterious conduct, the dread that all the prisoners would be massacred by an exasperated mob, might have done honour to his humanity, but it is extremely doubtful whether or not that was founded on fact. The British government
PARAEPHIS. See Oratory, No. 87.
PARALLACTIC, in general, something relating to the parallax of heavenly bodies. See Parallax.
PARALLAX, in Astronomy, is the difference between the places of any celestial object, as seen from the surface and from the centre of the earth at the same instant.

Let E in figure of parallax, represent the centre of illustration.

earth, O the place of an observer on its surface, whose visible horizon is OH, and true horizon EF: Now let ZDT be a portion of a great circle in the heavens, and A the place of any object in the visible horizon; join EA, and produce it to C; then C is the true place of the object, and H is its apparent place, and the angle CAH is the parallax; or, because the object is in the horizon, it is called the horizontal parallax. But OAE, the angle which the earth's radius subtends at the object, is equal to CAH: Hence the horizontal parallax of an object may be defined to be the angle which the earth's radius subtends at that object. For the various methods hitherto proposed to find the quantity of the horizontal parallax of an object, see Astronomy.

The whole effect of parallax is in a vertical direction: For the parallactic angle is in the plane passing through the observer and the earth's centre; which plane is necessarily perpendicular to the horizon, the earth being considered a sphere.

The more elevated an object is above the horizon, the parallax is the parallax, its distance from the earth's centre continuing the same. When the object is in the zenith, it has no parallax; but when in the horizon, its parallax is greatest. The horizontal parallax being given, the from the parallax at any given altitude may be found by the following rule.

To the logarithmic cosine of the given altitude, add twice the sine of the log. sine of the horizontal parallax, the sum, rejecting 10 from the index, will be the log. sine of the parallax in altitude.

Demonstration. Let B be the place of an object; produce OB, ED to F and D; then the angle BOEZ will be the apparent altitude of the object, BEZ the true altitude, and OBE the parallax in altitude. Now in the triangle AOE.

R : sine OAE :: EA : EO.

And in the triangle OBE.

BE (=EA : EO :: sine BOE : sine OBE).

Hence R : cosine BOA :: sine OAE : sine OBE.

As the two last terms are generally small quantities, the arch may be substituted in place of its sine without any sensible error.

Example. Let the apparent altitude of the moon's centre be 30° 25', and the moon's horizontal parallax 56° 54''. Required the parallax in altitude.

Moon's apparent alt. 39° 25' cosice 0.8879260
Moon's horizontal par. 56° 54'' sine 8.2188166

Moon's par. in altitude 43° 57', sine 8.167446

Or, to the secant of the moon's apparent altitude, add the proportional logarithms of the parallax in altitude.

As the apparent place of an object is nearer the horizon than its true place, the parallax is therefore to be added to the apparent altitude, to obtain the true altitude. Hence also an object will appear to rise later and set sooner.

The
The sine of the parallax of an object is inversely as its distance from the earth's centre.

Demonstration. Let A be the place of an object, and H the place of the same object at another time, or that of another object at the same instant; join EH, then in the triangles $\triangle AOE, \triangle HOE$,

\[
R : \text{sine OAE} :: \text{AE} : \text{OE} \quad \text{sine OHE} : R :: \text{OE} : \text{EH}.
\]

Hence sine OHE : sine OAE :: AE : EH.

The parallax of an object makes it appear more distant from the meridian than it really is.

Demonstration. The true and apparent places of an object are in the same vertical, the apparent place being lower than the true; and all verticals meet at the zenith. Hence the apparent place of an object is more distant from the plane of the meridian than the true place.

The longitude, latitude, right ascension, and declination of an object are affected by a parallax. The difference between the true and apparent longitudes is called the parallax in longitude; in like manner, the difference between the true and apparent latitudes, right ascensions, and declinations, are called the parallax in latitude, right ascension, and declination, respectively.

When the object is in the nonagesimal, the parallax in longitude is nothing, but that in latitude is greatest: and when the object is in the meridian, the parallax in right ascension vanishes, and that in declination is a maximum. The apparent longitude is greater than the true longitude, when the object is east of the nonagesimal, otherwise less; and when the object is in the eastern hemisphere, the apparent right ascension exceeds the true, but is less than the true right ascension when the object is in the western hemisphere. The apparent place of an object is more distant from the elevated poles of the ecliptic and equator than the true place: hence, when the latitude of the place and elevated pole of the ecliptic are of the same name, the apparent latitude is less than the true latitude, otherwise greater; and the apparent declination will be less or greater than the true declination, according as the latitude of the place, and declination of the object, are of the same or of a contrary denomination.

The parallaxes in longitude, latitude, right ascension, and declination, in the spheroidal hypothesis, may be found by the following formulae; in which $L$ represents the latitude of the place, diminished by the angle contained between the vertical and radius of the given place; $P$ the horizontal parallax for that place; $a$ the altitude of the nonagesimal at the given instant; $\lambda$ the true and apparent latitudes of the object; $D$ the true and apparent declinations respectively; and $m$ the distance of the object from the meridian.

Then $\text{par. in long.} = P \cdot \text{sine } a \cdot \text{sine } d \cdot \text{secant } \lambda \cdot \text{radius unity}$; and $\text{par. in lat.} = P \cdot \text{cosine } a \cdot \text{cosine } \lambda = p \cdot \text{cosine } d \cdot \text{secant } a \cdot \text{sine } \lambda$.

The sign $+$ is used when the apparent distance of the object from the nonagesimal and from the elevated pole of the ecliptic are of the same affection, and the sign $-$ if of different affection. If the greatest precision be required, the following quantity $= 0.0000121216$; $p \cdot \text{long.}, \text{sine } a$, is to be applied to the parallax in latitude found as above, by addition or subtraction.

Vol. XV. Part II.

According as the true distance of the object from the elevated pole of the ecliptic is greater or less than 90°.

Again, $\text{par. in right ascen.} = P \cdot \text{cosine } L \cdot \text{secant } D \cdot \text{radius unity}$; and $\text{par. in declination} = P \cdot \text{sin } L \cdot \text{cosine } \varphi = P \cdot \text{cosine } L \cdot \text{sin } \varphi$, cosine $m$.

The upper or lower sign is to be used, according as the distance of the object from the meridian and from the elevated pole of the equator are of the same or different affection. Part 2d of par. in declination $= 0.0000121216$; $\text{par. in right ascen.}, \text{sine } 2 \varphi$, which is additive to, or subtractive from, part first of parallax in declination, according as the true distance of the object from the elevated pole of the equator is greater or less than 90°.

For the moon's parallax, see Astronomy.

There is also a curious paper in the first volume of Asiatic Researches, p. 320, &c. on the same subject, to which we refer our readers.

Parallax of the Earth's annual Orbit, is the difference between the places of a planet as seen from the sun and earth at the same instant. The difference between the longitudes of the planets as seen from the sun and earth is called the parallax in longitude; and the difference between its latitude is the parallax in latitude.

Parallax of the Fixed Stars. See Astronomy, art. 268, which contains an account of the method used by Dr. Herschel, to ascertain the parallax of a star which appears to be double, from observations made at opposite points of the orbit of the earth. M. Piazzi, the discoverer of the planet Ceres, has made many observations of the zenith distances of ζ Lyrae, Arcturus, Procyon, and Aquilæ, &c. at those times when the effects of parallax ought to be the greatest. His observations are published in the 10th volume of the Italian Society.

Let $p$ be the absolute parallax, consequently,

\[
\text{parallax of Arcturus in declination will be } 0.595 \, p,
\]

and that in right ascension, $0.055 \, p$; hence, he observes, that observations of the right ascension of this star are preferable to those of the declination, for determining the parallax of this star.

M. Calendrelli, in a work printed at Rome in 1806, has given the result of his observations of the zenith distances of ζ Lyraæ, made with the sector of Mess. Maire and Boscovich. By comparing five observations in June, with four in December 1805, and five in March with the same number in June, he deduced the parallax of ζ Lyraæ in declination to be 4.7, and that in right ascension 6.35. According to M. Piazzi, the parallax is less than half of these quantities; and, hence, the required quantity not exceeding the unavoidable differences attending observations, it appears difficult to determine it, so as to be free from doubt.

Mess. Delambre and Mechain have made many observations of the pole star, and θ Ursæ minoris, being those stars which ought to have the greatest parallax in declination, at the times most proper to discover their parallax; but from the comparison, which M. Delambre made, of the zenith distances of these stars, he discovered nothing that could give the least suspicion of a parallax; and the small anomalies which he observed are often in a contrary direction. M. Delambre adds, 5 D that
Parallax that these stars being of the second magnitude, may be too far distant from us to have a parallax; however, although this may be the case, yet it appears to him that the fixed stars have no parallax.

The parallax of Venus affords the most correct method, hitherto proposed, of finding the distance of the earth from the sun; and, hence the distances of the other planets, and also their magnitudes. For this discovery we are indebted to the celebrated Dr. Halley. From observations of the transits of this planet, in 1761 and 1769, the parallax of the sun has been more accurately determined than previous thereto. The parallax of Mars has also been employed for the same purpose.

Parallax, is also used to denote the change of place in any object arising from viewing it obliquely with respect to another object. Thus the minute hand of a watch is said to have a parallax when it is viewed obliquely; and the difference between the instants shown by it, when viewed directly and obliquely, is the quantity of parallax in time.

Parallel, in Geometry, an appellation given to lines, surfaces, and bodies, everywhere equidistant from each other. See Geometry.

Parallel Sphere, that situation of the sphere wherein the equator coincides with the horizon, and the poles with the zenith and nadir.

Parallel of Latitude, in Astronomy, are lesser circles of the sphere parallel to the equator, imagined to pass through every degree and minute of the colures.

Parallel of Altitude, or Almucantar, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, having their poles in the zenith.

Parallel of Destination, in Astronomy, are the same with parallels of latitude in geography.

Paralleloiped, in Geometry, a regular solid comprehended under six parallelograms, the opposite ones of which are similar, parallel, and equal to each other.

Paralogism, in Logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false, or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

Paralysis, the Palsy. See Medicine Index.

Paramaribo, the capital of the former Dutch settlement of Surinam, situated about 18 miles from the mouth of a river of the same name. See SURINAM.

Paramount, (compounded of two French words, par, i.e. per, and monter, ascendere), signifies in our law the "highest lord of the fee, of lands, tenements, and hereditaments." As there may be a lord wherein lands are held of an inferior lord, who holds them of a superior under certain services; so this superior lord is lord paramount. Also the king is the chief lord, or lord paramount, of all the lands in the kingdom. Co. Litt. 1.

Parnymph, among the ancients, the person who waited on the bridegroom, and directed the nuptial solemnities; called also promus and outheus, because the ceremonies began by taking auspices. As the parnymph officiated only on the part of the bridegroom, a woman called promus officiated on the part of the parnymph bride.

Parapet, in Fortification, an elevation of earth designed for covering the soldiers from the enemy's cannon or small shot. See Fortification.

Paraphernalia, or Parapherna, in the civil law, those goods which a wife brings her husband besides her dower, and which are still to remain at her disposal exclusive of her husband, unless there is some provision made to the contrary in the marriage contract. Some of our English civilians define the paraphernalia to be such goods as a wife challenges over and above her dower or jointure, after her husband's death; as furniture for her chamber, wearing apparel, and jewels, which are not to be put into the inventory of her husband's goods; and a French civilian calls paraphernalia the moveables, linen, and other female necessities, which are adjudged to a wife in prejudice of the creditors, when she renounces the succession of her husband.

Paraphimosis, a disorder of the penis, wherein the prepuce is shrunk, and withdrawn behind the glans, so as not to be capable of being brought to cover the same; which generally happens in venereal disorders. See Surgery.

Paraphrase, an explanation of some text in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject. Such are esteemed Erasmus's Paraphrase on the New Testament, the Chaldee Paraphrase on the Pentateuch, &c.

Paraphrenitis, an inflammation of the diaphragm. See Diaphragm, Medicine Index.

Paraphrosyne, a word used by medical writers to denote a delirium, or an alienation of mind in fevers, or from whatever other cause.

Paraplegia, a species of palsy. See Medicine Index.

Parasang, an ancient Persian measure, different at different times, and in different places; being usually 30, sometimes 40, and sometimes 50 stadia or furlongs. The word, according to Littleton, has its rise from parasch angarius, q. d. the space a postman rides from one station, angaria, to another.

Parascenium, in the Grecian and Roman theatres, was a place behind the scenes whither the actors withdrew to dress and undress themselves. The Romans more frequently called it Postasenium. See Theatre.

Paraseleune, in Natural Philosophy, a mock moon; a meteor or phenomenon encompassing or adjacent to the moon, in form of a luminous ring; wherein are observed sometimes one and sometimes two or more images of the moon.

Parasemon, among the Greeks, was the figure carved on the prow of the ships to distinguish them from each other. This figure was generally that of a bull, lion, or other animal; sometimes the representation of a mountain, tree, flower, &c.

Parasite, among the Greeks, was originally a very reputable title; the parasites being a kind of priests, at least ministers, of the gods, in the same manner as the epulones were at Rome. They took care of the sacred corn, or the corn destined for the service of the temples and the gods, viz. sacrifices, feasts, &c. They had
PAR

PARASITE

PARASITES, or Parasitical Plants, in Botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow on the ground. Such are the mistletoe, &c.

PARASTATÆ, in Anatomy. See Prostate.

PARATALASSIA. See Primrose.

PARBUNCLE, in a ship, the name of a rope almost like a pair of strings: it is seized both ends together, and then put almost double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it, to hoist it up by.

PARÈ, in heathen mythology, goddesses who were supposed to preside over the accidents and events, and to determine the date or period, of human life.

The Paræ were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us, the Paræ spun the thread of men’s lives; that Clotho held the distaff, and drew the thread; Lachesis twirled the spindle, and spun it; and Atropos cut it. Clotho colis retinet, Lachesis set, Atropos secat.

The ancients represent the Paræ divers ways: Lucian, in the shape of three poor old women, having large locks of wool, mixed with dalladlils on their heads; one of which holds a distaff, the other a wheel, and the third a pair of scissors, wherewith to cut the thread of life. Others represent them otherwise: Clotho appearing in a long robe of divers colours, wearing a crown upon her head adorned with seven stars, and holding a distaff in her hand; Lachesis in a robe beset with stars, with several spindles in her hand; and Atropos, clad in black, cutting the thread with a pair of large scissors.

The ancients imagined that the Paræ used white wool for a long and happy life, and black for a short and unfortunate one. See Necessity, in Mythology.

PARCHMENT, the skins of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

The word comes from the Latin pergamenæ, the ancient name of this manufacture; which is said to have been taken from the city Pergamos, to Eumenes king whereof its invention is usually ascribed; though, in reality, that prince appears rather to have been the improver than the inventor of parchment. For the Persians of old, according to Diodorus, wrote all their records on skins; and the ancient Ionians, as we are told by Herodotus, made use of sheep skins and goat skins in writing, many ages before Eumene’s time. Never doubt we doubt that such skins were prepared and dressed for that purpose, after a manner not unlike that of our parchment; though probably not so artificially.—The manufacture of parchment is begun by the skinner, and finished by the parchment maker.

The skin having been stripped of its wool, and placed in the lime pit, in the manner described under the article Shammy, the skinner stretches it out upon a kind of frame, and pares off the flesh with an iron instrument; this done, it is moistened with a rag; and powdered chalk being spread over it, the skinner takes a large pumice stone, flat at bottom, and rubs over the skin, and thus scours off the flesh; he then goes over it again with an iron instrument, moistens it as before, and rubs it again with the pumice stone without any chalk underneath: this smooths and softens the flesh side very considerably. He then drains it again, by passing over it the iron instrument as before. The flesh side being thus drained, by scraping off the moisture, he in the same manner passes the iron over the wool or hair side: then stretches it on a frame, and scrapes the flesh side again: this finishes its draining; and the more it is drained the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb skin that has the wool on; and this smooths it still further. It is now left to dry, and when dried, taken off the frame by cutting it all round. The skin thus far prepared by the skinner, is taken out of his hands by the parchment maker, who first, while it is dry, pares it on a summer, (which is a calf skin stretched in a frame), with a sharper instrument than that used by the skinner; and working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin thus equally pared on the flesh side, is again rendered smooth, by being rubbed with the pumice stone, on a bench covered with a sack stuffed with flocks; which leaves the parchment in a condition fit for writing upon. The parings thus taken off the leather, are used in making glue, size, &c. See the article GLUE, &c.

What is called vellum is only parchment made of the skins of abortives, or at least sucking graves. This has a much finer grain, and is whiter and smoother than parchment; but is prepared in the same manner, except its not being passed through the lime pit.

PARDALIS, Ignatius Gaétan, a learned Jesuit, born at Paris in 1636. He taught polite literature for several years; during which time he composed several small pieces, both in prose and verse, with peculiar delicacy of thought and style. At length he devoted himself entirely to mathematics and natural philosophy, and read all authors, ancient as well as modern, in those branches of knowledge. He died in 1673, of an infectious disorder contracted by confessing and preaching to the prisoners in the Bicêtre during the Easter holidays. Father Pardies published several works; of which his Elements of Geometry are well known in this country, where a translation of them has gone through several editions. In 1672 he had a dispute with Sir Isaac Newton respecting the Theory of Light and Colours; which may be seen in the Philosophical Transactions for that year.

PARDON, in Criminal Law, is the remitting or forgiving an offence committed against the king.

Law (says an able writer) cannot be framed on principles of compassion to guilty, yet justice, by the constitution of England, is bound to be administered in mercy: this is promised by the king in his coronation oath; and it is that act of his government which is the most personal and most entirely his own. The king condemns no man; that rugged task he leaves to his courts.

5 D 2
Pardon

Pardon. — The great operation of his sceptre is mercy. His power of pardoning was said by our Saxon ancestors to be derived a lege suecitiglitatus: and it is declared in parliament, by stat. 27 Hen. VIII. c. 24: that no other person hath power to pardon or remit any treason or colonies whatsoever; but that the king hath the whole and sole power thereof, united and knit to the imperial crown of this realm.

This is indeed one of the greatest advantages of monarchy in general above any other form of government, that there is a magistrate who has in his power to extend mercy wherever he thinks it is deserved; holding a court of equity in his own breast, to soften the rigour of the general law, in such criminal causes as merit an exemption from punishment. Pardons (according to some theorists) should be excluded in a perfect legislation, where punishments are mild, but certain; for that the clemency of the prince seems a tacit disapprobation of the laws. But the exclusion of pardons must necessarily introduce a very dangerous power in the judge or jury; that of construing the criminal law by the spirit instead of the letter; or else it must be held, what no man will seriously avow, that the situation and circumstances of the offender (though they alter not the essence of the crime) ought to make no distinction in the punishment. In democracies, however, this power of pardon can never subsist; for there nothing higher is acknowledged than the magistrate who administers the laws: and it would be impolitic for the power of judging and of pardoning to centre in one and the same person. This (as the president Montesquieu observes) would oblige him very often to contradict himself, to make and to unmake his decisions: it would tend to confound all ideas of right among the mass of people; as they would find it difficult to tell, whether a prisoner were discharged by his innocence, or obtained a pardon through favour. In Holland, therefore, if there be no stadtholder, there is no power of pardoning lodged in any other member of the state. But in monarchies the king acts in a superior sphere; and though he regulates the whole government as the first mover, yet he does not appear in any of the disagreeable or invidious parts of it. Whenever the nation see him personally engaged, it is only in works of legislation, munificence, or compassion. To him therefore the people look up as the fountain of nothing but bounty and grace; and these repeated acts of goodness, coming immediately from his own hand, endear the sovereign to his subjects, and contribute more than any thing to root in their hearts that filial affection and personal loyalty which are the sure establishment of a prince.

The king may pardon all offences merely against the crown or the public; excepting, 1. That, to preserve the liberty of the subject, the committing any man to prison out of the realm, is, by the habeas corpus act, 31 Car. II. c. 2, made a prerogative, unpardonable even by the king. Nor, 2. can the king pardon, where private justice is principally concerned in the prosecution of offenders: Non potest rex gratiam facere cum injuria et damnno aliorum. Therefore, in appeals of all kinds (which are the suit, not of the king, but of the party injured), the prosecutor may release; but the king cannot pardon. Neither can he pardon a common nuisance, while it remains unredressed, or so as to prevent an abatement of it; though afterwards he may remit the fine: because the prosecution is vested in the king to avoid the multiplicity of suits, yet (during its continuance) this offence is more of the nature of a private injury to each individual in the neighbourhood, than of a public wrong. Neither, lastly, can the king pardon an offence against a popular or penal statute; after information brought: for thereby the informer hath acquired a private property in his part of the penalty.

There is also a restriction of a peculiar nature, that affects the prerogative of pardoning, in case of parliamentary impeachments, viz. that the king's pardon cannot be pleaded to any such impeachment, so as to impede the inquiry, and stop the prosecution of great and notorious offenders. Therefore, when in the reign of Charles II. the earl of Danby was impeached by the house of commons of high treason and other misdemeanors, and pleaded the king's pardon in bar of the same, the commons alleged, "That there was no precedent that ever any pardon was granted to any person impeached by the commons of high treason, or other high crimes, depending the impeachment?" And thereupon resolved, "That the pardon so pleaded was illegal and void, and ought not to be allowed in bar of the impeachment of the commons of England." For which resolution they assigned this reason to the house of lords, "That the setting up a pardon to be a bar of an impeachment defeats the whole use and effect of impeachments: for should this point be admitted, or stand doubted, it would totally discourage the exhibit of any for the future; whereby the chief institution for the preservation of the government would be destroyed." Soon after the Revolution, the commons renewed the same claim, and voted, "That a pardon is not pleadsable in bar of an impeachment." And at length, it was enacted by the act of settlement, 12 and 13 W. III. c. 2, "That no pardon under the great seal of England shall be pleadsable to an impeachment by the commons in parliament." But, after the impeachment has been solemnly heard and determined, it is not understood that the king's royal grace is farther restrained or abridged: for, after the impeachment and attainer of the six rebel lords in 1715, three of them were from time to time reprieved by the crown; and at length received the benefit of the king's most gracious pardon.

The effect of such pardon by the king, is to make the offender a new man; to acquit him of all corporal penalties and forfeitures annexed to that offence for which he obtains his pardon; and not so much to restore his former, as to give him a new credit and capacity. But nothing can restore or purify the blood when once corrupted, if the pardon be not allowed till after attainer, but the high and transcendent power of parliament. Yet if a person attainted receive the king's pardon, and afterwards hath a son, that son may be heir to his father; because the father being made a new man, might transmit new inheritable blood; though, had he been born before the pardon, he could never have inherited at all.

Such is the nature of pardons in this kingdom. These, like other good things, may doubtless be abused; and if they are in any instance, their abuse deserves censure: but that in their nature they should be counted absurd, arbitrary, and destructive of morality, can, we suspect,
We are told, however, by a late champion for the Rights of Man, that "the very word to a reflecting mind is fraught with absurdity. What is the rule that ought in all cases to pre-crible my conduct?" Surely justice: understanding by justice the greatest utility of the whole mass of things that may be influenced by my conduct. What then is clemency? It can be nothing but the pitiable egotism of him who imagines he can do something better than justice. Is it right that I should suffer constraint for a certain offence? The rectitude of my suffering must be founded in its tendency to promote the general welfare. He therefore that pardons me, iniquitously prefers the imaginary interest of an individual, and utterly neglects what he owes to the whole. He bestows that which I ought not to receive, and which he has no right to give. Is it right, on the contrary, that I should not undergo the suffering in question? Will he, by rescuing me from suffering, do a benefit to me, and no injury to others? He will then be a notorious delinquent, if he allow me to suffer. There is indeed a considerable defect in this last supposition. If, while he benefits me, he do no injury to others, he is infallibly performing a public service. If I suffered in the arbitrary manner which the supposition includes, the whole would sustain an unquestionable injury in the injustice that was perpetrated. And yet the man who prevents this odious injustice, has been accustomed to arrogate to himself the attribute of clemency, and the apparently sublime, but in reality tyrannical, name of forgiveness. For, if he do more than has been here described, instead of glory he ought to take shame to himself, as an enemy to the interest of human kind. If every action, and especially every action in which the happiness of a rational being is concerned, be susceptible of a certain rule, then caprice must be in all cases excluded: there can be no action, which, if I neglect, I shall have discharged my duty; and, if I perform, I shall be entitled to applause."

Such is the reasoning of this singular writer; reasoning which, in our opinion, betrays want of feeling or ignorance of human nature. That human nature is such, as, in the aggregate, to need control, no one who is acquainted with it will deny; and there appears to be no other method of controlling mankind but by general laws; and these laws may, through the natural imperfection of human affairs, be cruel in one case, where they are just in another. Cases may likewise occur where the sentence of the law, without its execution, will answer every purpose which could be expected from it: and where the execution of it would be extreme cruelty, though it might in strict unfeeling language be called justice, because in conformity with the letter of the law: Yet though such cases may and do often occur, it would indeed be absurd to abolish any of those laws which the security of civil society has required; and therefore the only natural remedy against legal injustice is the system of pardons.

Our author next goes on to trace the origin of pardons; and instead of a definite system of law, we are told that it is necessary to have a court of reason, to which the decisions of a court of law shall be brought for revision: a remedy apparently too vague and indeterminate to produce any lasting or good effect; and the proposal of which results from supposing mankind more virtuous and more knowing than they really are. We are next led to consider the abuses of pardons: from whence our author would draw an argument for their abolition; a species of reasoning unfair and unphilosophical. He tells us, that the authority in this case is placed first in the judge, and next in the king and council. "Now (says he), laying aside the propriety or impropriety of this particular selection, there is one grievous abuse which ought to strike the most superficial observer. These persons with whom the principal trust is reposed, consider their functions in this respect as a matter purely incidential, exercise them with supineness, and in many instances with the most scanty materials to guide their judgment. This grows in a considerable degree out of the very name of pardon, which imparts a work of supererogatory benevolence."

Now it is obvious to remark, that pardons are in general granted in consequence of an application from people who have more than scanty materials to guide their judgements, and on whose fidelity in relating the circumstances of the case, confidence is placed or not according to their several characters. Our author next proceeds to the arbitrary character of pardons. "Such a system (he says), to speak it truly, is a lottery of death, in which each man draws his ticket for reprieve or execution, as undefinable accidents shall decide." The allusion here to a lottery ticket is peculiarly unfortunate and indecent, nor does the whole sentence show any great degree of candour. It is impossible to define a particular crime, and to annex a particular punishment to the commission of it; but the nature of morality consists not in the external action, but in the motives which prompted to it. Definite law cannot, however, always make this distinction; and after the sentence of the law is pronounced, it comes to be considered whether there are any alleviating circumstances in the case; and whether there are or not, must depend on the particulars or accidents of the case: and it is indeed impossible to suppose that these accidents could be previously defined; their nature does not admit of it. To particularize and define every mode of an action which imagination can conceive, or which experience has shown us may happen, would indeed be an Herculean labour; and we might literally say with the apostle, that the world could not contain the books that might be written. We are, however, told, that "reason is a thousand times more explicit and intelligible than law; and when we are accustomed to consult her, the certainty of her decisions would be such, as men practised in our present courts are totally unable to conceive."

Were reason, however, appointed to be appealed to in all cases, and to be the final criterion, it would leave far greater room for villany than any mode at present in practice. Reason is a very uncertain and indefinite term, and may be made any thing, according to the circumstances or passions of men. Our reforming neighbours the French have raised a statute to reason and to truth; but what claim they have to either, Mr Godwin must himself decide.

We are next told that pardons are destructive to morality. "Another very important consequence (says our author) grows out of the system of pardons. A system of pardons is a system of unmitigated slavery. I am taught
PARDON Parenychyma

Parenychyma to the pith or pulp, or that inner part of a fruit or plant through which the juice is supposed to be distributed. See FLAVES.

PARENT, a term of relation applicable to those from whom we immediately derive our being. See Moral Philosophy, N° 129. and 137.

To this article belongs an inquiry into, 1. The legal duties of parents to their legitimate children. 2. Their power over them.

I. The duties of parents to legitimate children consist in three particulars; their maintenance, their protection, and their education.

1. The duty of parents to provide for the maintenance &c. of their children, is a principle of natural law; an obligation, says Pufendorf, laid on them not only by nature herself, but by their own proper act, in bringing them into the world; for they would be in the highest manner injurious to their issue, if they only gave their children life, that they might afterwards see them perish. By begetting them, therefore, they have entered into a voluntary obligation, to endeavour, as far as in them lies, that the life which they have bestowed shall be supported and preserved. And thus the children will have a perfect right of receiving maintenance from their parents. And the president Montesquieu has a very just observation upon this head, that the establishment of marriage, in all civilized states, is built on this natural obligation of the father to provide for his children; for that ascertainment and makes known the person who is bound to fulfil this obligation; whereas, in promiscuous and illicit conjunctures, the father is unknown; and the mother finds a thousand obstacles in her way; shame, remorse, the constraint of her sex, and the rigour of laws, that stifle her inclinations to perform this duty; and besides, she generally wants ability.

The municipal laws of all well regulated states have taken care to enforce this duty; though Providence has done it more effectually than any laws, by implanting in the breast of every parent that natural regard, or in-superable degree of affection, which not even the deformity of person or mind, not even the wickedness, ingratitude, and rebellion of children, can totally suppress or extinguish.

The civil law obliges the parent to provide maintenance for his child; and if he refuse, JUDESE DE EAO RCONNOIR. Nay, it carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing; and there are 14 such reasons reckoned up, which may justify such disinherison. If the parent alleged no reason, or a bad, or a false one, the child might set the will aside, TANQUAM TESTAMENTUM INEFFICIOREM, a testament contrary to the natural duty of the parent. And it is remarkable under what colour the children were to move for relief in such a case; by suggesting, that the parent had lost the use of his reason when he made the ineflicious testament. And this, as Pufendorf observes, was not to bring into dispute the testator’s power of disinheriting his own offspring; but to examine the motives upon which he did it; and if they were found defective in reason, then to set them aside. But perhaps this is going rather too far; every man has, or ought to have, by the laws of society, a power over his own property; and as Grotius very well distinguishes, natural right obliges to give a necessary
cessuary maintenance to children; but what is more than that, they have no right to, than as it is given by the favour of their parents, or the positive constitutions of the municipal law.

Let us next see what provision our own laws have made for this natural duty. It is a principle of law, that there is an obligation on every man to provide for those descended from his loins; and the manner in which this obligation shall be performed, is thus pointed out. The father, and mother, grandfather and grandmother, of poor impotent persons, shall maintain them at their own charges, if of sufficient ability, according as the quarter sessions shall direct; and, if a parent runs away, and leaves his children, the church wardens and overseers of the parish shall seize his rents, goods, and chattels, and dispose of them towards their relief. By the interpretations which the courts of law have made upon these statutes, if a mother or grandmother marries again, and was before such second marriage of sufficient ability to keep the child, the husband shall be charged to maintain it; for this being a debt of her's, when single, shall, like others, extend to charge the husband. But, at her death, the relation being dissolved, the husband is under no further obligation.

No person is bound to provide a maintenance for his issue, unless where the children are impotent and unable to work, either through infancy, disease, or accident; and then is only obliged to find them with necessaries, the penalty on refusal being no more than 20s. a month. For the policy of our laws, which are ever watchful to promote industry, did not mean to compel a father to maintain his idle and lazy children in ease and indolence; but thought it unjust to oblige the parent, against his will, to provide them with superfluities, and other indulgencies of fortune; imagining they might trust to the impulse of nature, if the children were deserving of such favours. Yet, as nothing is so apt to stifle the calls of nature as religious bigotry, it is enacted, that if any Popish parent shall refuse to allow his Protestant child a fitting maintenance, with a view to compel him to change his religion, the lord chancellor shall by order of court constrain him to do what is just and reasonable. But this did not extend to persons of another religion, of no less bitterness and bigotry than the Popish: and therefore, in the very next year, we find an instance of a Jew of immense riches, whose only daughter having embraced Christianity, he turned her out of doors; and on her application for relief, it was held she was entitled to none. But this gave occasion to another statute, which ordains, that if Jewish parents refuse to allow their Protestant children a fitting maintenance, suitable to the fortune of the parent, the lord chancellor, on complaint, may make such order therein as he shall see proper.

Our law has made no provision to prevent the disinheriting of children by will; leaving every man's property in his own disposal, upon a principle of liberty in this as well as every other action; though perhaps it had not been amiss if the parent had been bound to leave them at the least a necessary subsistence. Indeed, among persons of any rank or fortune, a competence is generally provided for younger children, and the bulk of the estate settled upon the eldest by the marriage articles. Heirs also, and children, are favorites of our courts of justice, and cannot be disinherit-
Popish religion; or shall contribute any thing towards their maintenance when abroad by any pretext whatever, the person both sending and sent shall be disabled to sue in law or equity, or to be executor or administrator to any person, or to enjoy any legacy or duty of gift, or to bear arms by sea or land, and shall for-}

doer the purposes for which he is employed.

In the Gentleman's Magazine for 1755, we have the following case of conscience. "A person has his own parents and his own children living, both parties equally indigent, both equally incapable of assisting themselves, and both equally earnest in calling upon him for relief. Things are so circumstances, that he can possibly assist but one party, and not both. Query, Which party has the greatest claim to his assistance, and to which is he obliged, by all ties human and divine, to give the preference?" One solves this difficulty, by informing us of a pretty print done at Rome, representing a young woman suckling her aged father, on which the following lines are noted:

My child and father vital nurture crave,
Parental, filial, fondness both would save,
But if a nursing only one can live,
I choose to save the life I cannot give.

Here we find the preference given to the parent; and another correspondent gives the same decision in these words. "The obligations arising from nature, and natural affection, seem to be in this case reciprocal and equivalent; the child is as strongly attracted to the parent, as the parent to the child. But will not filial gratitude operate and decide in favour of the parents? Does not the person, either mediate or immediately, owe his present power and abilities to relieve, to his parents? and are they not on that account best entitled to relief? Does not the fifth commandment declare more strongly in favour of the parents, than any other divine precept does in favour of the children? If a person had an opportunity given him of delivering either his parent or his child (but not both) from certain death, I dare say the voice of nature and of mankind would applaud him that saved his parent, and condemn him that should prefer his child. There is more of selfishness in preferring the child; and to save the parent seems to me to be much the more generous, noble and exalted conduct. It is indeed, upon the whole, a melancholy alternative; but if both parties continue importunate, and neither will relinquish their claims in favour of the other, I say relieve the parent." There are two correspondents, however, who think differently, and their reasons are as follows: "A person's children have the greatest claim to his assistance, and he is obliged by all ties to prefer them, in that respect, to his parents. It is true, when a man's parents are in want, they have a claim to his assistance; but that claim is not equal to that which his children have. His parents he has of necessity; his children, of choice. It is his duty before he get children, to consider how he is to provide for them: and by being wisely the cause of their existence, he comes under such an obligation to provide for their comfortable subsistence, as must be stronger than any obligation of that kind he can be under to persons with whom his connexion is involuntary. But nature and reason point it out as the duty of all parents to provide for their children; but not vice versa. If a man's parents happen to be indigent, and he himself able, he is bound to maintain them out of respect and gratitude: but his obligation to provide for his children
Par. is a debt of strict justice; and therefore ought to be preferred. Nevertheless the description of the case to which the query is subjoined, is so general, that it is easy to figure a case according to that description in which the person ought to prefer his parents. This obligation to provide for his children may have been dissolved by monstrous ingratitude, such as their plotting against his life; or he may have given them proper education, and ample provisions, which they have riotously squandered away: in either of which cases it is thought he is undoubtedly discharged from his obligation. But if they have lost their portion purely by misfortunes, without their fault, it is thought his obligation to assist them is not wholly extinguished; and in that case their claim to his assistance, or that of his parents, is preferable."

"I find (says the author of the last answer) that all your correspondents agree, that the life of the parents is to be preserved. It is very certain, that the relation between me and my child is exactly equal to that which is between me and my parent; and therefore relation cannot decide in favour of the one or the other: I must then be determined by a different consideration; and I know of none more weighty than the following: If I preserve the life of my child, I am instrumental in giving life to all his descendants, which may, perhaps, be very numerous; but if I preserve the life of my parent, I preserve a single life only, and that a short one. I therefore say, relieve the child. But it is thought that the voice of nature will applaud the person who preserves the parent: if so, nature must applaud a rule which she herself does not observe: it is natural for old men to die before young ones. Besides, the command, Be fruitful and multiply, and replenish the earth, may be opposed to the fifth commandment." Still, however, it is doubtless difficult to determine in such cases when they occur, as there are no fixed rules whereby to decide. With respect to the power of parents and the duty of children, much may be said. Between me, however, surely any instances where both are often absent than the child, and is subject to marriage. This, as it is the most important event in the civil life either of a man or woman, so it is often rendered peculiarly unfortunate, to precipitate folly and want of duty in children; and as often through the unreasonable severity of parents. As a child is bound not to give unreasonable offence to a parent in the choice of a partner; so neither ought the parent to impose any improper or arbitrary restraint upon the child.

The power of a parent in China is very great; for a father, while living, has the power of an absolute despotic tyrant, and after his death is worshipped as a god. Let a son become ever so rich, and a father ever so poor, there is no submission, no point of obedience, that the latter cannot command; or that the former can refuse. The father is absolute master, not only of his son's estate, but also of his concubines and children, who, whenever they displease him, he may sell to strangers. If a father accuses his son before a mandarin, there needs no proof of his guilt; for they cannot believe that any father can be so unnatural as to bring a false accusation against his own son. But should a son be so insolent as to mock his father, or arrive at such a pitch of wickedness as to strike him, all the province where this shameful act of violence is committed is alarmed; it even becomes the concern of the whole empire; the emperor himself judges the criminal. All the mandarins near the place are turned out of their posts, especially those of the town where he lived, for having been so negligent in their instructions; and all the neighbours are reprimanded for neglecting, by former punishments, to put a stop to the wickedness of the criminal before it arrived at such flagitiousness. As to the unhappy wretch himself, they cut him into a thousand pieces, burn his bones, level his house to the ground, and even those houses that stand near it, and set up monuments and memorials of the horrid deed.

The emperor of China, who is one of the most powerful and despotic monarchs upon earth, pays the greatest attention to his mother. An instance of this Pere Amyot relates as having happened at Pekin, A. D. 1752, when the emperor's mother entered her 60th year, which, among the Chinese, is accounted a very remarkable period. Crozat likewise particularly describes the homage the emperor pays his mother every new-year's day in the palace, at which ceremony all the great officers of his court assist. See CHILDREN, Fyial Pity, Parental Affection, &c.

Par. Anthony, a mathematician, was born at Paris in 1666. He showed an early propensity to mathematics. He accustomed himself to write remarks upon the margins of the books which he read; and he had filled a variety of books with a kind of commentary at the early age of thirteen. At fourteen he was put under a master, who taught rhetoric at Chartres. It was here that he happened to see a dodenation. upon every face of which was delineated a sun dial, except the lowest whereon it stood. Struck as it were instantaneously with the curiosity of these dials, he attempted drawing one himself: but having a book which only showed the practical part without the theory, it was not till after his master came to explain the doctrine of the sphere to him that he began to understand the projection of the circle on the plane of the dials. He then undertook to write a Treatise upon Gnomonics. The piece was indeed rude and unfinished; but it was entirely his own, and not borrowed. About the same time he wrote a book of Geometry, in the same taste, at Beauvais. His friends then sent for him to Paris to study the law; and, in obedience to them, he studied a course in that faculty; which was no sooner finished, than, urged by his passion for mathematics, he shut himself up in the college of Dornans, that no avocation might take him from his beloved study: and, with an allowance of less than 200 livres a-year, he lived content in this retreat, from which he never stirred but to the Royal College, in order to hear the lectures of M. de la Hire or M. Sauveur. When he found himself capable of teaching others, he took pupils: and fortification being a branch of mathematics which the war had brought into particular notice, he turned his attention to it; but after some time began to entertain scruples about teaching what he had never seen, and knew only by the force of imagination. He imparted this scruple to M. Sauveur, who recommended him to the marquis d'Aligre, who luckily at that time wanted to have a mathematician with him. Parent made two campaigns with the marquis, by which
he instructed himself sufficiently in viewing fortified places; of which he drew a number of plans, though he had never learned the art of drawing. From this period he spent his time in a continual application to the study of natural philosophy, and mathematics in all its branches, both speculative and practical; to which he joined anatomy, botany, and chemistry. His genius managed every thing, and yet he was incessant and indefatigable in his application. M. de Billettes, who was admitted into the Academy of Sciences at Paris in 1699, with the title of their mechanician, nominated for his disciple Parent, who excelled chiefly in this branch. It was soon discovered in this society, that he engaged in all the various subjects which were brought before them; and indeed that he had a hand in every thing. But this extent of knowledge, joined to a natural impetuosity of temper, raised in him a spirit of contradiction, which he indulged on all occasions; sometimes to the abuse of an argument, highly culpable, and often with but little regard to decency. Indeed the same behaviour was shown to him, and the papers which he brought to the academy were often treated with much severity. He was charged with obscurity in his productions; and he was indeed so notorious for this fault, that he perceived it himself, and could not avoid correcting it. The king had, by a regulation in 1716, suppressed the class of scholars of the academy, which seemed to put too great an inequality betwixt the members. Parent was made a joint or assistant member for geometry: but he enjoyed this promotion but a short time; for he was taken off by the small-pox the same year, at the age of 50. He was author of a great many pieces, chiefly on mechanics and geometry.

PARENTAL, something belonging to the relation of parent. See Parent.

PARENTAL Affection, the endearing attachment of parents to their children, including in it love; a desire of doing no hurt; a wish of their prosperity, and with all the act of anxiety highly depend upon us for all that they enjoy. Nature even excites this affection in brutes: but in them it continues only so long as it is necessary for the preservation of their offspring; for when these are able to provide for themselves, it ceases, and the relation is forgotten. In man, however, though it lessen, or at least becomes less anxious as the dependence of the child becomes less, it never entirely ceases, except in some few instances of extreme depravity. Authors, however, have imagined, and Lord Kames among the rest, that after the child is provided for, and no more depends on the parent, all affection would cease, were it not artificially preserved and confirmed by habit. Whether his lordship, in this opinion, be right or wrong, we shall not pretend to say. One thing, however, is certain, that be it natural or not, it is one of the greatest comforts of life, even when all dependence has ceased. It matters not that there are many instances where this comfort is not felt. Human depravity has often obliterated the finest feelings of the mind; and it is just to be wondered at if in some instances it do so in the case before us. A good heart certainly can enjoy no greater satisfaction than that arising from grateful returns of kindness and affection to an aged parent. As the vexations which parents receive from their children hasten the approach of age, and double the force of years; so the comforts which they reap from them are balm to all other sorrows, and disappoint the injuries of time.

Parents repeat their lives in their offspring; and their concern for them is so near, that they feel all their sufferings, and taste all their enjoyments, as much as if they regarded their own persons. However strong we may suppose the fondness of a father for his children, yet they will find more lively marks of tenderness in the bosom of a mother. There are no ties in nature to compare with those which unite an affectionate mother to her children, when they repay her tenderness with obedience and love.

We have a remarkable instance of parental affection in Zaleucus the prince of the Locrines, who made a decree, that whoever was convicted of adultery should be punished with the loss of both his eyes. Soon after this establishment, the legislature's own son was apprehended in the very fact, and brought to a public trial. How could the father acquit himself in so tender and delicate a conjuncture? Should he execute the law in all its rigour, this would be worse than death to the unhappy youth: should he pardon so notorious a delinquent, this would defeat the design of his salutary institution. To avoid both these inconveniences, he ordered one of his own eyes to be pulled out and one of his son's.

Diocles also relates a surprising instance of the same warm affection. Cambalus, a young gentleman of character and fortune in the city of Mullamat, being one day out coursing, was way-laid, and very near being robbed and murdered by the banditti who infested that part of the country. Curious, the young gentleman's father, happened to come by at the very instant, to whom Cambalus related the danger he was in. The son was on foot, the father on horseback; but no sooner had he heard the melancholy tale, than he leapt from his horse, desired his son to mount, and make the best of it to the city: but Cambalus, for preserving his father's safety, refused him, and so means consent to it; on the contrary, conjured his father to leave him, and take care of himself. The father, struck with the generosity and affection of his son, added tears to entreaties, but all to no purpose. The contest between them is better conceived than described — while bathed in tears, and beseeching each other to preserve his own life, the banditti approached and stabbed them both.

Amongst the ancient Greeks, the sentiments of parental affection were exceedingly strong and ardent. The mutual tenderness of the husband and the wife was communicated to their offspring; while the father viewed in his child the charme of its mother, and the mother perceived in it the many graces of its father. As parental kindness is the most simple and natural expansion of self-love, so there are innumerable instances of it in all countries savage and civilized.

PARENTALIA, in antiquity, funeral obsequies, or the last duties paid by children to their deceased parents.

PARENTHESES, in Grammar, certain intercalary words inserted in a discourse, which interrupt the sense or thread, but seem necessary for the better understanding of the subject.

PARENZO, a small but strong town of Italy, and in Istria, with a bishop's see and a good harbour; seat
PARHELION, or PARHELION, formed from παρέχειν, near, and ἅλφις, sun, in Natural Philosophy, a mock sun or meteor, in form of a very bright light, appearing on the one side of the sun.

Appearances of this kind have been made mention of by both the ancients and moderns. Aristotle observes, that in general they are seen only when the sun is near the horizon, though he takes notice of two that were seen in Bosphorus from morning to evening; and Pliny has related the times when such phenomena were observed at Rome. Cassendi says, that in 1635 and 1636 he often saw one mock sun. Two were observed by M. de la Hire in 1689; and the same number by Cassini in 1693, Mr Grey in 1700, and Dr Halley in 1702: but the most celebrated appearances of this kind were seen at Rome by Scheiner, by Muschenbroeck at Utrecht, and by Hevelius at Sedan. By the two former, four mock suns were observed, and by the latter seven.

Parhelia are apparently of the same size with the sun, though not always of the same brightness, nor even of the same shape; and when a number appear at once, there is some difference in both these respects among them. Externally they are tinged with colours like the rainbow; and many have a long fiery tail opposite to the sun, but paler towards the extremity. Parhelia are generally accompanied with coronas, some of which are tinged with rainbow colours, but others are white. They differ in number and size; but all agree in breadth, which is that of the apparent diameter of the sun.

A very large white circle, parallel to the horizon, generally passes through all the parhelia; and, if it were entire, it would go through the centre of the sun. Sometimes there are arcs of lesser circles concentric to this, touching those coloured circles which surround the sun. They are also tinged with colours, and contain other parhelia. There are also said to have been other circles obliquely situated with respect to all those we have mentioned; but of this we have met with no authentic account. The order of the colours in these circles is the same as in the rainbow; but on the inside, with respect to the sun, they are red, as is also observed in many other coronas.

Parhelia have been visible for 3, 2, 3, and 4 hours together; and in North America, they are said to continue some days, and to be visible from sunrise to sunset.

When the parhelia disappear, it sometimes rains, or there falls snow in the form of oblong spicule, as Maraldi, Weidler, Kraft, and others, have observed; and because the air in North America abounds with such frozen spicule, which are even visible to the eye, according to Ellis and Middleton, such particles have been thought to be the cause of all coronas and parhelia.

Mr Ellis says, that, at Churchill in Hudson's Bay, the rising of the sun is always preceded by two long streams of red light, one on each side of him, and about 20° distant from him. These rise as the sun rises; and as they grow longer begin to bend towards each other, till they meet directly over the sun, just as he rises, forming there a kind of parhelion or mock sun. These two streams of light, he says, seem to have their source in two other parhelia, which rise with the true sun; and in the winter season, when the sun never rises above the haze or fog, which he says is constantly found near the horizon, all these accompany him the whole day, and set with him in the same manner as they rise. Once or twice he saw a fourth parhelion directly under the true sun; but this, he says, is not common. These facts being constant, are very valuable, and may throw great light on the theory of these remarkable phenomena.

Sometimes parhelia appear in a different manner; as when three suns have been seen in the same vertical circle, well defined, and touching one another. The true sun was in the middle, and the lowest touched the horizon; and they set one after the other. This appearance was seen by M. Malezieuw in 1722. Other appearances similar to this are recited by M. Muschenbroeck.

Sometimes the sun has risen or set with a luminous tail projecting from him, of the same breadth with his diameter, and perpendicular to the horizon. Such an appearance was seen by Cassini in 1672 and 1692, by De la Hire in 1702, and by Mr Ellis in Hudson's Bay.

As M. de l'Isle was walking on the banks of the river La Plata, he saw the sun rising over the river with a luminous tail projecting downwards, which continued till he was six degrees high.

Paraselenae, or mock moons, have also been seen, accompanied with tails and coloured circles, like those which accompany the parhelia. An account of several, and a particular description of a single appearance of this kind, may be seen in Muschenbroeck.

The Roman phenomenon, observed by Scheiner, is famous on account of its having been the first appearance of the kind that engaged the attention of philosophers. It is represented in fig. 1.; in which A is the place of the observer, B his zenith, C the true sun, AB a plane passing through the observer's eye, the true sun, and the zenith. About the sun C, there appeared two concentric rings, not complete, but diversified with colours. The lesser of them, DEF, was fuller, and more perfect; and though it was open from D to F, yet those ends were perpetually endeavouring to unite; and sometimes they did so. The outer of these rings was much fainter, so as scarcely to be discernible. It had, however, a variety of colours; but was very inconstant. The third circle, KL.MN, was very large, and all over white, passing through the middle of the sun, and every where parallel to the horizon. At first this circle was entire; but towards the end of the appearance it was weak and ragged, so as hardly to be perceived from M towards N.
In the intersection of this circle, and the outward iris GKI, there broke out two parhelia or mock suns N and K, not quite perfect; K being rather weak, but N shone brighter and stronger. The brightness of the middle of them was something like that of the sun; but towards the edges they were tinged with colours like those of the rainbow; and they were uneven and ragged. The parhelion N was a little wavering, and sent out a spiked tail, NP, of a colour somewhat fiery, the length of which was continually changing.

The parhelia at L and M in the horizontal ring were not so bright as the former; but were rounder, and white, like the circle in which they were placed. The parhelion N disappeared before K; and while M grew fainter, K grew brighter, and vanished the last of all.

It is to be observed farther, that the order of the colours in the circles DEF, GKN, was the same as in the common halos, namely, red next the sun; and the diameter of the third circle was also about 45 degrees; which is the usual size of a halo.

The reverend Dr Hamilton sent the following account of parhelia, seen at Cookstown, to the Royal Irish Academy.

'Wednesday, September 24th, 1783, as I was preparing to observe the sun passing the meridian, before the first limb touched the centre wire, it was obscured by a dark well defined cloud, about 10° in diameter. Upon going to the door of the transit room, to see if it was likely soon to pass off the disk of the sun, I observed the following phenomena: From the western edge of the cloud issued a luminous parallel to the horizon, perfectly well defined, extending exactly to the northern meridian; it was about 30° broad, white, and ended in a blunted termination. On it were two parhelia; the nearest to the sun displaying the prismatic colours; the remote one white, and both ill defined. In a short time the cloud had passed off, and showed the luminous almucantar, reaching perfect to the true sun. While things were thus situated, I measured with an accurate sextant the distances of the parhelia; I found the coloured one 26°, the remote one 90°, from the true sun. Just as I had done this, a new and prismatic circle surrounded the sun immediately with the prismatic parhelion. And now another coloured parhelion appeared on the eastern board. The sextant with its face up and down, exactly measured this and the former at the original distance of 26°; the luminous almucantar still remaining perfect. In about 10 or 12 minutes whitish hazy clouds came on, and obscured all these uncommon appearances.—I did not observe that the atmospheric phenomena before or after were at all uncommon. The wind a light breeze at SSW. Bar. 29. 6. rising. Thermometer 55°.

Fig. 2. SM represents the south meridian; NM the north meridian; PP the prismatic circle, with two prismatic suns or parhelia, at 26° distance on each side the true sun; W the white parhelion, at 90° distance from the true sun; LA the luminous almucantar; and HO the horizon.

Various hypotheses have been framed by philosophers to account for this phenomenon, particularly by M. Marbiot, Descartes, and Huygens. None of them, however, are satisfactory: but those readers who wish to become acquainted with them may consult Huygens's Dissertation on this subject, in Smith's Optics, book i. chap. xi. Muschenbroek's Introduction, &c. vol. xi. p. 1538, &c. 4to.; but especially Dr Priestley's History of Vision, Light, and Colours, vol. ii. p. 613, &c.

PARIA, or NEW ANDALUSIA, a country of Terra Firma in South America; bounded on the north by the North sea; on the east by Surinama; on the west by New Granada and the Caraccas; and on the south by Guiana. It produces colouring drugs, gums, medicinal roots, Brazil wood, sugar, tobacco, and some valuable timber; the inland pastures being woody and mountainous, but interspersed with fine valleys that yield corn and pasturage. Caracas is the capital town.

PARIAN CHRONICLE. See ARUNDELIAN Marble, and PARIAN CHRONICLE.

Under the article Parian Chronicle, we have been as full as the subject seemed to require, or as the nature of our work would admit. It is unnecessary, therefore, to resume it in this place. Such of our readers, however, as wish for further information on this subject (which is equally interesting to the scholar and to the antiquarian) we must refer to Robertson's attack upon its authenticity, and to Gough's learned and judicious vindication of the authenticity, published in Archaeologia for 1789. The extent of his learning, and the solidity of his arguments, appear upon the whole to outweigh the objections of his sensible and plausible opponent. Hewlett's book upon the same side of the question may command some degree of attention. It is ingenious. See SANDWICH Marble.

Parian Marble, among the ancients, the white marble used by them, and to this day, for carving statues, &c. and called by us at this time stannary marble.

Too many of the later writers have confounded all the white marbles under the name of the Parian; and among the workmen, this and all the other white marbles have the common name of alabasters; so that it is in general forgotten among them, that there is such a thing as alabaster different from marble; which, however, is truly the case. Almost all the world also have confounded the Carrara marble with this, though they are really very different; the Carrara kind being of a texture and clearer white than the Parian; but less bright and splendid, harder to cut, and not capable of so glittering a polish.

The true Parian marble has usually somewhat of a faint bluish tinge among the white, and often has blue veins in different parts of it. It is supposed by some to have had its name from the island Paros, one of the Cyclades in the Ægean sea, where it was first found; but others will have it to have been so called from Agrarcticus Parius, a famous statuary, who adorned it by cutting a statue of Venus in it.

PARiAS, or PERREAS, a tribe of Hindoos, so peculiarly distinguished from all others, that they live by themselves in the outskirts of towns; and, in the country, build their houses apart from the villages, or rather have villages of their own, furnished with wells; for they dare not so much as fetch water from those which flow other families make use of; and, lest these latter should inadvertently go to one of theirs, they are obliged to scatter the bones of dead cattle about their wells, that they may be known. They dare not in cities pass through
through the streets where the Brahmans live; nor set foot in the villages where they dwell.—They are likewise forbidden to enter a temple, either of their god Wisthow or Esvar, because they are held impure. They get their bread by sowing, digging, and building the walls of mud houses; most of those inhabited by the common people being raised by these Parias; who also do such kinds of dirty work as other people do not care to meddle with. Nor is their diet much more cleanly; for they do not scuffle to eat cows, horses, fowl, or other carrion, which die of themselves, and are even putrid. One would scarce imagine, that contents for precedence should ever enter into the thoughts of a people who have renounced all cleanliness, and, like swine, wallow in filth; and yet pride has divided the Parias into two classes: the first are simply called Paria, the other Ceripara. The employment of these latter is to go about selling leather, which they dress; also to make bridles, and so kind of things: some of them likewise serve for soldiers. The Parias, who reckon themselves the better family, will not eat in the house of the Ceripara; but the Ceripara will readily eat with the Paria. For this reason they are obliged to pay them respect, by lifting their hands above, and standing the right hand behind their backs. These Ceripara, when they marry, cannot set up a pandel, a kind of garland, before their doors, made with more than three stakes or trees; should they exceed that number, the whole city would be in motion. The Ceripara are likewise subject to some sort of slavery; for when any person of credit or authority dies in the families of the Komitis, Sittis, Palis, farriers, or goldsmiths, and the friends have a mind to be at the expense of some clothes to give the Ceripara, these latter must suffer their beards to be shaved; and when the corpse is carried out of town to be burned or interred, they must do that office; for which each receives a formum, or one piece and a half of silver, worth three sous and a half. These are the same sort of people who are called at Surat Halachors; that is, in the Persian language, 'eat-alls, or eaters at large.' Nothing can offend an Hindoo more than to be called a Halachor: yet these poor people are not offended, cringe and bow to all they pass, and go through their drudgery without noise or concern.

The Parias are very vicious, stupid, and ignorant, occasioned by their wretched way of life: The Bramins and nobility shun them as if they had the plague, and look on the meeting a Parias as the greatest misfortune. To come near one of them is a sin, to touch them a sacrifice. If a Paria were dying, it is infamy to visit him, or to give him the least assistance, in the utmost danger or distress. A Bramin who unavoidably should touch a Paria, immediately washes himself from the impurity. Even their shadow and breath being reckoned contagious, they are obliged to live on the east side of their towns, that the westerly winds which prevail in this country may keep back their breath. And it is lawful for a Bramin to kill one of these unhappy creatures, if he does not avoid it by getting out of his way: In short, they think them reproved by God, and believe the souls of the damned enter into the Parias, to be punished for their crimes.—Yet the mission have found among these dogs of the people very active zemist catechists, who by their labours have very much contributed to the conversion of their countrymen, particularly one Rajanaiken a Paria soldier, who, of all the inferior missionaries, has distinguished himself most by his labours and sufferings.

PARIAH Ossa. See Anatomy Index.

PARITARIA, PELLITORY of the Wall: A genus of plants belonging to the polygonia class; and in the natural method ranking under the 53rd order, Scæbridice. See Botany Index.

PARIES, in Anatomy, a term used for the enclosures or membranes that stop up or close the hollow parts of the body; especially those of the heart, the thorax, &c. The paries of the two ventricles of the heart are of unequal strength and thickness; the left exceeding the right, because of its office, which is to force the blood through all parts of the body; whereas the right only drives it through the lungs.

PARIS, MATTHEW, one of our best historians from William the Conqueror to the latter end of the reign of Henry III. but of his life few particulars have been transmitted to us. Leland his original biographer, without determining whether he was born in France or England, informs us, that he was a monk of St Alban's, and that he was sent by Pope Innocent to reform the monasteries of the convent at Holm in Norway. Bishop Bale, the next in point of time, adds to the above relation, that, on account of his extraordinary gifts of body and mind, he was much esteemed, particularly by King Henry III. who commanded him to write the history of his reign. Fuller makes him a native of Cambridgeshire, because there was an ancient family of his name in that county. He also mentions his being sent by the pope to visit the monks in the diocese of Norwich. Bishop Tanner, Bishop Nicholson, Doctor Du Pin, and the Nouveau Dictionnaire Historique, add not a single fact to those above related. Matthew Paris died in the monastery of St Alban's in the year 1259. He was doubtless a man of extraordinary knowledge for the 13th century; of an excellent moral character, and, as an historian, of strict integrity. His style is unpolished; but that defect is sufficiently atoned for by the honest freedom with which he relates the truth, regardless of the dignity or sanctity of the persons concerned. His works are: 1. Historia ab Adamo ad Congressum anglorum. Lib. I. manuscript, col. C. C. Cantab. c. ix. Most of this book is transcribed, by Matthew of Westminster, into the first part of his Florilegium. 2. Historia major, seu rerum Anglicarum historia à Gul. Conquestoris adventu ad annum 43 Henrii III. &c. several times printed. The first part of this history, viz. to the year 1235, is transcribed almost verbatim from the Chronicle of Roger Wendover; and the Appendix, from the year 1260, is the work of William Rashinger, who was also a monk of St Alban's. 3. Vita duorum Offororum, Merici regum, S. Albiani fundatorum. 4. Gesta 22 abbatis S. Albani. 5. Additamenta chronicorum ad hist. majorem; printed. 6. Historia minor; nunc epistome majoris historiae; manuscript. Besides many other things in manuscript.

PARIS, son of Priam, king of Troy, by Hecuba, also named Alexander. He was deceased, even before his birth, to become the ruin of his country; and when his mother, in the first months of her pregnancy, had dreamt that she should bring forth a terror, who, had he set foot into her palace, the soothsayers foretold the calamities which were to be expected from the impiety of her future
Paris, future son, and which would end in the ruin of Troy. Priam, to prevent so great and so alarming an evil, ordered his slave, Archelaus to destroy the child as soon as he was born. The slave, either touched with humanity, or influenced by Hecuba, did not obey, but was satisfied to expose the child on Mount Ida, where the shepherds of the place found him, and educated him as their own. Some attribute the preservation of his life, before he was found by the shepherds, to the maternal tenderness of a she-bear who suckled him. Young Paris, though educated among shepherds and peasants, gave very early proofs of courage and intrepidity; and from his care in protecting the flocks of Mount Ida from the rapacity of the wild beasts, he was named Alexander, “helper or defender.” He gained the esteem of all the shepherds; and his graceful countenance and manly deportment recommended him to the favours of Oenone, a nymph of Ida, whom he married, and with whom he lived with the most perfect tenderness. Their conjugal peace was, however, of no long duration. At the marriage of Peleus and Thetis, the goddess of discord, who had not been invited as a partner to the entertainment, showed her displeasure by sending into the assembly of the gods who were at the celebration of the nuptials, a golden apple, on which were written the words *Deliv pulchrius.* All the goddesses claimed it as their own; the contention at first became general; but at last only three, Juno, Venus, and Minerva, wished to dispute their respective right to beauty. The gods, unwilling to become arbiters in an affair so tender and so delicate in its nature, appointed Paris to adjudge the prize of beauty to the fairest of the goddesses; and indeed the shepherd seemed sufficiently qualified to decide so great a contest, as his wisdom was so well established, and his prudence and sagacity so well known. The goddesses appeared before their judge without any covering or ornament, and each endeavoured by promises and entreaties to gain the attention of Paris, and to influence his judgment. Juno promised him a kingdom; Minerva military glory; and Venus the fairest woman in the world for his wife, as Ovid expresses it, *Hosidion* 17, v. 118.

*Unaque cum regnaua; bellii daret altera laudem; Tyndaridis conjux, tertia dixit, eris.*

After he had heard their several claims and promises, Paris adjudged the prize to Venus, and gave her the golden apple, which perhaps she seemed entitled as the goddess of beauty. This decision of Paris drew upon the judge and his family the resentment of the two other goddesses. Soon after, Priam proposed a contest among his sons and other princes, and promised to reward the conqueror with one of the finest bulls of Mount Ida. His emissaries were sent to procure the animal, and it was found in the possession of Paris, who reluctantly yielded it. The shepherd was anxious to retain his favourite, and he went to Troy and entered the lists of the combatants. He was received with the greatest applause, and obtained the victory over his rivals, Nestor, the son of Neleus, Ceymus son of Neptune, Polites, Helenus, and Deiphobos, sons of Priam. He likewise obtained a superiority over Hector himself, which prince, enraged to see himself conquered by an unknown stranger, pursued him closely; and Paris must have fallen, a victim to his brother’s rage, had he not fled to the altar of Jupiter. This sacred retreat preserved his life; and

Cassandra, the daughter of Priam, struck with the similarity of the features of Paris with those of her brothers, inquired his birth and age. From these circumstances she soon discovered that he was her brother, and as such she introduced him to her father and to her brothers. Priam acknowledged Paris as his son, forgetful of the alarming dreams which had caused him to meditate his death, and all jealousy ceased among the brothers. Paris did not long suffer himself to remain inactive; he equipped a fleet, as if willing to redeem Hesione his father’s sister, whom Hercules had carried away and obliged to marry Telemon the son of Aeacus. This was the pretended motive of his voyage, but the causes were far different. Paris remembered that he was to be the husband of the fairest of women; and, if he had been led to form those expectations while he was an obscure shepherd of Ida, he had now every plausible reason to see them realized, since he was the acknowledged son of the king of Troy. Helen was the fairest woman of the age, and Venus had promised her to him. On these grounds, therefore, he went to Sparta, the residence of Helen, who had married Menelaus. He was received with great respect; and the hospitality of Menelaus, and while the husband was absent in Crete, Paris persuaded Helen to elope with him, and to fly to Asia. Helen consented; and Priam received her into his palace without difficulty, as his sister was then detained in a foreign country, and as he wished to show himself as hostile as possible to the Greeks. This affair was soon productive of serious consequences. When Menelaus had married Helen, all her suitors had bound themselves by a solemn oath to protect her person, and therefore the injured husband reminded them of their engagements, and called upon them to recover her. Upon this all Greece took up arms in the cause of Menelaus; Agamemnon was chosen general of all the combined forces, and a regular war was begun. Paris, meanwhile, who had refused Helen to the petitions and embassies of the Greeks, armed himself, with his brothers and subjects, to oppose the enemy; but the success of the war was neither hindered nor accelerated by his means. He fought with little courage, and at the very sight of Menelaus, whom he had so recently injured, all his resolution vanished, and he retired from the front of the army, where he walked before like a conqueror. In a combat with Menelaus, which he undertook by means of his brother Hector, Paris must have perished, had not Venus interfered, and stolen him from the resentment of his antagonist. He wounded, however, in another battle, Machaon, Euryphila, and Diomedes; and, according to some opinions, he killed with one of his arrows the great Achilles.

The death of Paris is differently related: some say that he was mortally wounded by one of the arrows of Philoctetes, which had been once in the possession of Hercules; and that when he had himself lanced an account of his wounds, he ordered himself to be carried to the feet of Oenone, whom he had basely abandoned, and who in the years of his obscurity had foretold him that he would solicit her assistance in bidding moments. He expired before he came into the presence of Oenone; and the nymph, still mindful of their former love, threw herself upon his body, and stabbed herself to the heart, after she had plentifully bathed it with her tears.

According to others, Paris did not immediately go to Troy.
Troy when he left the Peloponnese, but he was driven on the coasts of Egypt, where Proteus, who was king of the country, detained him; and when he heard of the violence which had been offered to the king of Sparta, he kept Helen at his court, and permitted Paris to retire. Whatever was the mode of his death, it took place, we are told, about 1188 B.C. See TROY, &c.

PARIS, the capital of the kingdom of France, is situated on the river Seine, in the department of the Seine, at the distance of 120 miles from the sea, and is one of the largest and finest cities in Europe. It derived its modern name from the ancient Parisii, and is supposed by some to have had the Latin name of Lutetia, from lutum, "mud," the place where it now stands, having been anciently very marshy and muddy. Ever since the reign of Hugh Capet, that is, for nearly 800 years, this city has been the usual residence of the kings of France. It is of a circular form; its extent along the river is about four miles and a half, its breadth three and a half, and its circumference about 16 miles. The number of its inhabitants in 1817, was 913,500. Paris is the see of an archbishop of the court of France, and of 15 other dioceses and public bodies in the kingdom. Before the revolution, it contained 46 parish churches, 22 subsidiary churches, 11 abbeys, 13 monasteries and convents, 13 colleges, 15 public schools, and 26 hospitals. Of the convenants and monasteries, the greater number were suppressed in the course of the revolution. Three have been converted into commodious prisons, four into hospitals, three into barracks, and several others into markets and manufactories of various kinds. The Seine, upon which Paris stands, is much smaller than the Thames. It forms two islands, the Isle of St. Louis, and the Isle of Notre Dame. The former was the site of the ancient city. In the oldest part of Paris, as in London, the streets are narrow, dark, and dirty. Few of them have pavements for foot passengers, who are exposed to be trodden down or crushed by the carriages plying back and forward. The gutter, which is in the centre, is generally filled with a stream of mud even in summer, which the pedes are often finds it good to step into, and from which he is sure to be bespattered by the drivers of the cabriolets. There are few of those splendid equipages which crowd the streets of London to be seen in Paris, the higher classes in the latter being comparatively poor; but fiacres and cabriolets are very numerous. The houses are generally of stone, six or seven stories high, with one gable or wing to the street, and with the lower windows barricaded with iron. The street entrance is often by a massive gate which opens into a court, and out of this court there is one common entrance into a large building called a hotel, the first floor of which is probably occupied by a person of rank, who pays 300l. per annum of rent; above him are tenants in different gradations of fashion or opulence, to the sixth or seventh floor, which is inhabited by the milkman, the cobler, or the scavenger, paying only ten pounds of rent. The whole of this ill-assorted community use the same magnificent staircase, decorated with marble columns and bas-reliefs, and embowered by the foliage of a hundred dirty feet. When a hotel (or large house) is inhabited by one opulent or noble family, it is not unusual to make the upper story the receptacle for the hay and provender for the horses. The lamps are suspended by cords across the middle of the street, but usually afford more light than those of London. The shops are generally small and dark, without projectsing windows for the display of goods, or any other mark to distinguish them except a sign-board. In viewing the city from a distance, nothing strikes an Englishman more than the great transparency of the atmosphere, and absence of that cloud of smoke which hovers over our cities, in consequence of the use of pitch on fuel: the Parisians scarcely use anything else than wood.

Paris surpasses all the other capitals of Europe in the number and splendour of its public edifices. Of these one of the most distinguished is the Palace of the Thulleries, founded by Catherine de Medicis. The front consists of five pavilions comprising that of the centre, with four ranges of buildings connecting them together, and forming one grand facade, adorned with columns of the various orders, and with vases and statues. In front of the building stands a beautiful triumphal arch erected by Napoleon. Behind it are extensive gardens laid out with exquisite taste by Lenostre, embellished with orange trees, statues, fountains, and basins of the greatest beauty. In the morning the healthiest and most enterprising of the Parisians, who is accommodated with a chair and newspaper for four souvs; in the evening they are crowded with gay and fashionable company. 2. The Palais Royal, originally built by Cardinal Richelieu, is a magnificent edifice adorned with Doric and Ionic columns, with a garden, basin, and fountain. The arcades of the ground story are occupied by innumerable shops, of small dimensions, but elegantly fitted up. Beneath are apartments where various groups are dancing, regaling with liquor, engaged in play, or in scenes of vice and debauchery. Other apartments are occupied by restaurateurs, lecturers on belles lettres and philosophy, or literary societies. It is in short a little world within itself. 3. The Luxembourg, or Palace of the Chamber of Peers, is one of the most magnificent palaces in Paris. It consists of one vast court of a square form, 360 feet by 300, surrounded by porticos, and flanked by square buildings called pavilions. The garden is fine, and from its elevated situation commands many delightful views of the city. 4. The Palace of Justice is a large and handsome building, forming three sides of a square, and occupied partly by some of the tribunals. 5. The Hotel de Bourbon, or Palace of the Representatives, is chiefly distinguished by its noble portico, with a colonnade of the Corinthian order surmounted by a pediment. It is delightfully situated on the banks of the Seine. 6. The Louvre is connected by a gallery with the Thulleries. The facade of this building, called the colonnade, is justly regarded as one of the most perfect pieces of architecture to be found anywhere. In this building was the celebrated museum, which was strait of so many works of art after the battle of Waterloo. 7. The Palace of the Fine Arts, formerly called the College of the Four Nations, is an elegant edifice of a semicircular form, with a dome which is much admired. It contains two libraries; and the school of fine arts, and the meetings of the institute, now called the royal academy, are held here. 8. The Royal Observatory, erected in 1667, is distinguished by the simplicity of its design and the harmony of its parts. It is vaulted throughout, and has neither wood nor iron in its construction. It has a well 170 feet deep, to the bottom of which there is a descent by a stair; and the stair
Paris. The stair is so constructed as to leave a vacuity in the middle, through which the stars are seen from the bottom of the well at midday. Three astronomers are always resident here. 9. The Hotel de Ville, or town hall, is worthy of notice both for its antiquity and its architecture. It is rich in beauty and ornament. An equestrian statue of Henry IV. in bas relief is placed over the principal entrance.Hitler Rohdesperre retreated after he was outlawed. In front of the Hotel de Ville is the famous lamp iron, and within it is preserved the still more famous guillotine. 10. The Mint is one of the finest ornaments of the banks of the Seine. It is 350 feet long by 84 in height, and combines simplicity of design, with a tasteful display of ornament. 11. The cathedral of Notre Dame, the mother church of France, was built about the year 1010, or according to others 1177. Its architecture, though Gothic, is singularly bold and delicate, and it has ever been esteemed one of the handsomest structures in the kingdom. It is 414 feet long, 144 wide, and 102 high. 12. Abbaye de Val de Grace, now converted into an hospital; it has a fine dome decorated in the inside with some excellent fresco paintings. 13. The church of St Eustache, is a model of the boldness and lightness of the Gothic style. 14. The Pantheon, a large and magnificent temple, 330 feet long by 253 broad, with a dome rising to the height of 228 feet. The portal, formed by 22 Corinthian columns 38 feet high, is 112 feet long and 36 deep, and is crowned with a grand bas relief, sculptured by Coustou. It was originally built on a plan too light to sustain its own weight, and the alterations rendered necessary to support it, have injured its beauty; but it is still a grand and imposing structure. It was designed to commemorate men whose talents or achievements had reflected honour on their country. There are four Protestant churches in Paris, of which that in the Rue St Honore is much admired for its elegance; and, two Jewish synagogues. Several of the remaining convents are worth visiting. The Catacombs of Paris are justly classed among the curiosities of the place. These are very extensive quarries excavated in ancient times in the limestone rock under the city, and used at a later period as a depository for the bones of the dead. For many centuries the inhabitants of Paris buried their dead in large trenches, into which the corpses were thrown in heaps, and thinly covered with earth. From the small extent of the burying grounds, these trenches were soon opened again, and the putrid mass often spread contagion over the town. At length the government forbid all burials within the walls, and had these immense masses of corruption which had been accumulating for ten centuries, taken up, the bones separated and cleaned, and deposited in these catacombs. They are placed along the walls in rows, those of one size kind being placed together. There are a many of the apartments resembling chapels, in which are vases and altars sometimes formed of human bones, and sometimes having skulls of different sizes disposed about them as ornaments. Some of the altars are cut out of the solid rock; and it is believed that, in a very early age, they were frequented as places of Christian worship. The descent to these caverns is by a narrow staircase of eighty steps, and the visitor is conducted out at another passage more than half a mile distant. The guide as well as the stranger bears a torch; the former traces his course by a black line marked on the roof. Without this, there would be a risk of losing the way amidst the labyrinth of passages and chambers.

There are upwards of seventy squares in Paris, many of which are well deserving of attention for the beauty, richness, and uniformity of the buildings, and for the columns and statues that adorn them. Among these may be mentioned the Place des Victoires, Place Vendome, Place de Louis XV. There are sixty fountains, some of which exhibit very beautiful specimens of architecture. The Fountain of the Elephant, in which the water was to have been thrown out from the trunk of a bronze status of an elephant 72 feet high, was begun by Napoleon, but was left unfinished at his overthrow, and the work has not since been resumed. The bridges of Paris cannot vie with those of London. The most remarkable are, the Pont Neuf, completed by Henry the fourth, 996 feet long, and 90 broad. The Pont Royal; Pont Louis XVI; Pont au Change; Pont St Michael; Pont Notre Dame; Pont de la Tournelle; Pont de Austerlitz, completed in 1807; Pont de Jena, lately finished; Pont des Arts, consisting of nine cast metal arches. Paris contains also a number of triumphal arches. Those called the Gate of St Dennis and the Gate of St Martin were erected in the reign of Louis XIV, and are very fine pieces of architecture. The triumphal arch of the Thurleries erected by Bonaparte, is also of exquisite workmanship; but the bronze bases which were placed over it have been restored to Venice, and the statue of Napoleon has been cast down.

The hospitals and charitable institutions of Paris which are numerous, and many of them on an extensive scale, are supported by the government. More than 15,000 beds are found at the different hospitals, and the annual expenditure is computed at 300,000l. sterling. The Hotel des Invalids, or hospital for disabled and superannuated soldiers, is a magnificent building, in a fine situation near the Seine. The colours taken from the different nations which were suspended here, were burnt by the veterans, when the allies were before Paris, to prevent them from being retaken. We can only mention the Hotel Dieu, or hospital for the sick, the Hospice de Salpetriere, which is a charity workhouse for women, the Hospital de Charite, Maison de Santé, the Hospital de Maternité for lying-in women and foundling children. There is besides a foundling hospital.

The Royal University of Paris, suppressed in 1792, since re-established, consists of four faculties, viz. theology, in which there are six professors; law, of which there are seven; surgery, in which there are about twenty lecturers, many of whom are men of distinguished abilities; and lastly, letters and science, which includes professorships on philosophy, belles-lettres, poetry, history, and geography. At the royal college of France, lectures are given gratuitously on many branches of science and literature; and among the readers are the names of Delambre, Biot, Portal, and Cuvier. At the polytechnic school, about 300 young men, selected from those who have distinguished themselves at the inferior schools, are furnished with the higher branches of education gratuitously. They go chiefly into the service of the artillery. There are besides a school of the fine arts, a school of mines, and a variety of others.
institution for the blind, and that for the deaf and
dumb, are meritorious establishments, and extremely
well conducted. The museums and libraries of various
kinds in Paris, are too numerous to admit of separate
description here. The museum of natural history in-
cludes a botanic garden, a menagerie, a collection of
minerals, of animal remains, of anatomy, with a lib-
ary, all on the most extensive scale, and in the most
perfect order. The museum of French monuments con-
tains many interesting remains of antiquity, along with
those of a late period. The Louvre, though it has been
despoiled of many of its choicest pieces, still presents
1104 pictures, with 355 specimens of sculpture. Of the
1200 paintings of the great gallery, however, about 950
were carried away. Those with which it is now filled
have been furnished from other galleries, and from private
collections. The royal library was founded by King
John, and has ever since been increasing. It is now
the most magnificent library in Europe, containing
365,000 printed books, besides 60,000 MSS. Tables
are placed in the rooms for the accommodation of vis-
tors, who may call for whatever books they please, and
are immediately supplied with them. There are several
other public libraries upon a less extensive scale.

At one period of the revolution there were thirty
theatres in Paris opened nightly. At present the num-
ber is limited to ten, four large, and six smaller. The
first of these in point of rank is the Theatre Français,
where the exhibitions are chiefly confined to the clas-
cical productions of the French stage. The opera is un-
rivalled for the beauty and splendour of the ballets, and
the excellence of the dancing; but the singing is not
above mediocrity.

Paris, Herb Paris, or True-love, a genus of plants
belonging to the octandria class, and in the natural
method ranking under the 11th order, Sarratentacea. See
Botany Index.

Herb Paris of Canada, a genus of plants belonging
to the hexandria class. See TWILLIA, Botany Index.

Paris, or Parisium, the first and last name being derived from the
place where it is found in great abundance, is a substance
composed of lime and sulphuric acid, which, on account
of its property of rapidly absorbing water, after being
calcined, is much employed in making casts and models.
See GYPSUM, MINERALOGY, AND GEOLOGY Index.

Parish, the precinct of a parochial church, or a
circuit of ground inhabited by people who belong to
one church, and are under the particular charge of its
minister.

The word comes from the Latin paroecia, the Greek
παροεικα, habitat; composed of παρα, near, and
οικείος, house.—Accordingly Du Cange observes, that
the name παροεικα was anciently given to the whole terri-
try of a bishop, and derives it from neighborhood;
because the primitive Christian, not daring to assemble
openly in cities, were forced to meet secretly in neigh-
bouring houses.

In ancient church there was one large edifice in
each city for the people to meet in; and this they
called paroecia, or Parish. But the signification of the
word was afterwards enlarged, and by a parish was
meant a diocese, or the extent of the jurisdiction of a
bishop, consisting of several churches, unless we will
suppose, as some do, that those bishops were only pas-
tors of single churches. Du Pin observes, that country
parishes had not their origin before the 4th century; but
those of cities are more ancient. The city of Alex-
dria is said to have been the first that was divided
into parishes.

Of the first division of parishes there is no certain
information; for in the early ages of Christianity in
this island, parishes were unknown, or at least signified
the same that a diocese now does. There was then no
appropriation of ecclesiastical dues to any particular
church; but every man was at liberty to contribute
his tithes to any priest or church he pleased, but he
was obliged to do it to some; or if he made no spe-
cial appropriation thereof, they were paid to the bishop,
whose duty it was to distribute them among the clergy,
and for other pious purposes, according to his own dis-
cretion. Camden says England was divided into parishes by Archebishop Honorius about the year 630. Sir
Henry Hobart maintains that parishes were first erected by the council of Lateran, held in 1179. But Mr.
Selden proves, that the clergy lived in common without
any division of parishes, long after the time mentioned
by Camden; and it appears from the Saxons laws, that
parishes were in being long before the council of Late-
ran in 1179. The distinction of parishes occurs in the
laws of King Edgar, about the year 970. It seems
very clear and certain, says Judge Blackstone (Com-
vol. ii. p. 112.) that the boundaries of parishes were first
ascertained by those of a manor or manor; because it
very seldom happens that a manor extends itself over
more than one parish, though there are often many ma-
ors in one parish. The lords, he adds, as Christianity
spread, began to build churches upon their own domes-
ties or wastes, in order to accommodate their tenants
in one or two adjoining lordships; and that they might
have divine service regularly performed therein, obliged
all their tenants to appropriate their tithes to the main-
tenance of the one officiating minister, instead of leaving
them at liberty to distribute them among the clergy of
the diocese in general; and this is the origin of the
churches, of which the tithes were appropriated, formed a distinct parish;
and this accounts for the frequent intermixture of par-
ishes one with another. For if a lord had a parcel of
land detached from the main of his estate, but not suf-
cient to form a parish of itself, it was natural for him
to endow his newly erected church with the tithes of
such lands. Extra-parochial wastes and marsh lands,
when improved and drained, are by 17 Geo. II. cap.
37, to be assessed to all parochial rates in the parish next
adjoining. Camden reckons 9284 parishes in England;
and Chamberlaynes makes 9953. They are now gen-
ernally reckoned about 10,000.

Parish-Clerk. In every parish the person, vicar, &c.,
held a parish clerk under him, who is the lowest office
of the church. These were formerly clerks in ordure,
and their business at first was to officiate at the altar;
for which they had a competent maintenance by offi-
cings; but they are now laymen, and have certain fees
with the person on christenings, marriages, burials, &c.; besides wages for their maintenance. The law
looks upon them as officers for life: and they are chosen
by the minister of the parish, unless there is a cus-
tom for the parishioners or churchwardens to choose
them; in which case the canon cannot abrogate such
custom; and when chosen it is to be signified, and

5 F.
PAR

they are to be sworn into their office by the archdeacon, for which the court of king's bench will grant a mandamus.

PARISH, in Ancient Geography, a people of Gallia Celtica, inhabiting the country about the Sequana and Matrona. Now a great part of the Isle of France.—Parisii (Prolemy), a people of Britain, having the Britons to the north and west, the German sea to the west, and the Gauls to the south, from whom they were separated by the Humber. Now Holderness, a peninsula of the east riding of Yorkshire.

PARISIUM civitas. See LUTETIA.

PARIUM, in Ancient Geography, a noble city of Mysia Minor, with a port on the Propontis; called Aedracus by Homer, according to Pliny; but Strabo distinguishes them: according to others, the Peacost of Homer. Pariisii, the people (Strabo). The birthplace of Neopolis surnamed Glossographus (Strabo). Here stood a Cupid equal in exquisite workmanship to the Cidian Venus.

PARK (French parc, i.e., locus inclusus), is a large quantity of ground enclosed and privileged for wild beasts of chase, by the king's grant or prescription. See CHASE and FOREST.

Manwood defines a chase to be “a privileged place, for beasts of venery, and other wild beasts of the forest and chase, tans sulvestres quam comasses;” and differs from a chase or warren, in that it must be enclosed: for if it lies open, it is good cause of seizure into the king's hand, as a thing forfeited; as a free chase, if it be enclosed: besides, the owner cannot have an action against such as hunt in his park, if it lies open. No man can erect a park without license under the broad seal; for the common law does not encourage matter of pleasure, which brings no profit to the commonwealth. But there may be a park in reputation erected without any lawful warrant; and the owner may bring his action against persons killing his deer.

To a park three things are required. 1: A grant thereof. 2: Enclosures by pale, wall, or hedge. 3: Beasts of a park; such as the buck, doe, &c. Where all the deer are destroyed, it shall no more be accounted a park; for a park consists of vert, venison, and enclosure: and if it is determined in any of them, it is a total disbanding.

Parks as well as chases are subject to the common law, and are not to be governed by the forest laws.

PARK, as connected with gardening. See GARDENING.

A park and a garden are more nearly allied than a farm and a garden, and can therefore be accommodated to each other without any disparagement to either. A farm loses some of its characteristic properties by the connexion, and the advantage is on the part of the garden: but a park thus bordered retains all its own excellencies; they are only enriched, not counteracted, by the intermixture. The most perfect composition of a place that can be imagined, consists of a garden opening into a park, with a short walk through the latter to a farm, and ways along its glades to ridings in the country; but to the farm and the ridings the park is no more than a passage; and its woods and its buildings are but circumstances in their views; its scenes can be communicated only to the garden.

The affinity of the two objects is so close, that it would be difficult to draw the exact line of separation between them. Gardens have lately encroached very much both in extent and in style on the character of a park; but still there are scenes in the one which are out of the reach of the other. The small sequestered spots which are agreeable in a garden would be trivial in a park; and the spacious lawns which are among the noblest features of the latter, would in the former fatigue by their want of variety; even such as, being of a moderate extent, may be admitted into either, will seem bare and naked, if not broken in the one; and lose much of their greatness, if broken in the other. The proportion of a part to the whole is a measure of its dimensions: it often determines the proper size for an object, as well as the space fit to be allotted to a scene; and regulates the style which ought to be assigned to either.

But whatever distinctions the extent may occasion between a park and a garden, a state of highly cultivated nature is consistent with each of their characters; and may in both be of the same kind, though in different degrees.

The excellencies both of a park and of a garden are happily blended at Hagley (A), where the scenes are equally elegant and noble. It is situated in the midst of a fertile and lovely country, between the Clent and the Wychberry hills; neither of which are within the pale but both belong to the place. The latter rise in three beautiful swells. One of them is covered with wood; another is an open sheep walk, with an obelisk on the summit; on the third, the portico of the temple of Theseus, exactly on the model of that of Athens, and little less in the dimensions, stands boldly out upon the brow, backed by the dark ground of a fir plantation, and has a most majestic appearance above the steep which fall before and beside it. The house is seen to the greatest advantage from these eminences, and every point of them commands some beautiful prospect. The busy town of Stourbridge is just below them; the ruins of Dudley castle rise in the off-ship; the country is full of industry and inhabitants; and a small portion of the moor, where the minerals manufactured in the neighbourhood, are dug, breaking in upon the horizon, accounts for the richness, without derogating from the beauty, of the landscape. From the Clent hills the views are still greater: they extend on one side to the black mountains in Wales, a long ridge which appears, at 60 miles distance, in the interval between the unwieldy heap of the Malvern hills and the solitary peak of the Wrekin, each 30 miles off, and as many sunder. The smoke of Worcester, the churches in Birmingham, and the houses in Stourbridge, are distinctly visible. The country is a mixture of hill and dale, and strongly enclosed; except in one part, where a heath, varied by rising grounds, pieces of water, and several objects, forms an agreeable contrast to the cultivation.

(A) Near Stourbridge, in Worcestershire, the seat of Lord Lyttleton.
The house, though low in the park, is yet above the adjacent country, which it overlooks to a very distant horizon. It is surrounded by a lawn of fine uneven grounds, and diversified with large clumps, little groups, and single trees. It is open in front, but covered on one side by the Witchberry hills; on the other side, and behind, by the banks and steep, all overspread with a lofty hanging wood. The lawn pressing to the foot, or creeping up the slopes of these hills, and sometimes winding along glades into the depth of the wood, traces a beautiful outline to a sylvan scene, already rich to luxuriance in massiness of foliage and staleness of growth.

But though the wood appears to be entire, it in reality opens frequently into lawns, which occupy much of the space within it. In the number, the variety, and the beauty of these lawns, in the shades of the separation between them, in their beauties also, and their varieties, the glory of Hagley consists. No two of the openings are alike in dimensions, in shape, or in character. One is of no more than five or six acres; another of not less than fifty; and others are of all the intermediate sizes. Some stretch out into lengthened glades; some widen every way: they are again distinguished by buildings, by prospects, and often by the style only of the ground them and the wood. The garden is described by a few careless lines; that of another is composed of many parts, very different, and very irregular; and the ground is never flat, but falls sometimes in steep descents, sometimes in gentle declivities, waves along easy swells, or is thrown into broken inequalities, with endless variety.

An octagon seat, sacred to the memory of Thomson, and erected on his favourite spot, stands on the brow of a steep; a mead winds along the valley beneath, till it is lost on either hand behind some trees. Opposite to the seat, a noble wood crowns the top, and feathers down to the bottom of a large oval swelling hill. As it descends on one side, the distant country becomes the offskip. Over the fall, on the other side, the Clint hills appear. A dusky antique tower stands just below them, at the extremity of the wood; and in the midst of it is seen a Doric portico, called Pope's Building, with part of the lawn before it. The scene is very simple; the principal features are great; they prevail over all the rest, and are intimately connected with each other.

The next opening is small, circling about a rotunda on a knoll, to the foot of which the ground rises every way. The trees which surround it are large; but their foliage is not very thick; and their stems appearing beneath, their ramifications between the boughs are, in so confined a spot, very distinguished and unpreceable circumstances. It is retired; has no prospect; no visible outlet but one, and that is short and narrow, to a bridge with a portico upon it, which terminates a piece of water.

The grove behind the rotunda separates this from a large, airy, forest glade, thinly skirted with wood, careless of dress, and much overgrown with fern. The wildness is an acceptable relief in the midst of so much elegance and improvement as reign in the neighbouring lawns: and the place is in itself pleasant; in no part confined; and from a Gothic seat at the end is a perspective view of that wood and tower which were seen before in front, together with the Witchberry hills, and a wide range of country.

The tower, which in prospect is always connected with wood, stands, however, on a piece of down, which stretches along the broad ridge of a hill, and spreads out on each hand for some way down the sides. Thick groves catch the falls. The descent of a fall is right, but lost under the trees; but that on the left being steeper and shorter, it may be followed to the bottom. A wood hangs on the declivity, which is continued in the valley beneath. The tower overlooks the whole: it seems the remains of a castle, partly entire, partly in ruins, and partly overgrown with bushes. A finer situation cannot be imagined: It is placed in an exposed unfrequented spot; commands an extensive prospect; and is everywhere an interesting object.

At the end of the valley below it, in an obscure corner, and shut out from all view, is a hermitage, composed of roots and of moss: high banks, and a thick covert darkened with horse chestnuts, confine the sequestered spot: a little rill trickles through it, and two small pieces of water occupy the bottom. They are seen on one side through groups of trees; the other is open, but covered with fern. This valley is the extremity of the park; and the Clint hills rise in all their irregularity immediately at the boundary alone.

The other descent from the castle is a long declivity, covered like the rest with noble woods, in which fine lawns are again embosomed, differing still from the former, and from each other. In one, the ground is very rough, the boundary is much broken, and marked only by the trunks of the trees which shoot up high before the branches begin. The next is more simple; and the ground falls from an even brow into one large hollow, which stops towards the glen, where it sinks into the covert. This has a communication through a short glade, and between two groves, with another called the Timian lawn, from the resemblance which it is said to bear to those of that celebrated island: it is encompassed with the staliest trees, all fresh and vigorous, and so full of leaf, that not a stem, not a branch, appears, but large masses of foliage only describe an undulating outline; the effect, however, is not produced by the boughs feathering down to the bottom, they in appearance shoot out horizontally, a few feet above the ground, to a surprising distance, and form underneath an edging of shade, into which the retreat is immediate at every hour of the day. The verdure of
the turf is as luxuriant there as in the open space: the
round gently waves in both over easy swells and little
dips, just varying, not breaking, the surface. No strong
lines are drawn; no striking objects are admitted; but all is of an even temper, all mild, placid, and serene; in
the gayest season of the day not more than cheerful, in
the stillest watch of night not gloomy. The scene is in
deed peculiarly adapted to the tranquillity of the latter,
when the moon seems to repose her light on the thick
foliage of the grove, and steadily marks the shade of
every bough. It is delightful then to saunter here, and
see the grass, and the gosamer which entwines it, glist
ening with dew; to listen and hear nothing stir, ex
ccept perhaps a withered leaf dropping gently through a
tree; and, sheltered from the chill, to catch the fresh
ness of the evening air: a solitary urn, chosen by Mr
Pope for the spot, and now inscribed to his memory,
when shown by a gleam of moonlight through the trees,
fixes that thoughtfulness and composure to which the mind is insensibly led by the rest of this elegant
scene.

The Doric portico, which also bears his name, though
not within sight, is near: it is placed on the declivity of
a hill; and Thomson, uniting with its site and heads
among the grass, sees a resemblance in the prospect before it.
In the valley beneath is a bench, which com
mands a variety of short views; one is up the ascent to
the portico, and others through openings in the wood to
the bridge and the rotunda.

The next lawn is large: the ground is steep and ir
regular, but inclines to one direction, and falls from
every side into the general declivity: the outline is di
versified by many groups of trees on the slopes; and
frequent glimpses of the country are seen in perspec
tive through openings between them. In the brow is a
seat, in the proudest situation of all Hasley; it com
mands a view down the bold sweep of the lawn, and
over a valley filled with the noblest trees, up to the
heights beyond. One of those heights is covered with
a hanging wood; which opens only to show Thom
son's seat, and the groves and the steep above it; the
others are the Witchberry hills, which seem to press
forward into the landscape; and the heavy height of
the trees, when seen into a continued surface, form
a broad base to the temple of Thesus, hide the swell
on which it is built, and crown up to the very
foundation. Farther back stands the obelisk; before
it is the sheep walk; behind it the Witchberry wood.
The temple is backed by the first; and both these plan
tations are connected with that vast sylvan scene which
overspreads the other hill and all the intermediate
valley. Such extent of wood; such variety in the dis
position of it; objects so illustrious in themselves, and
ennobled by their situations, each contrasted to each,
every one distinct, and all happily united; the parts
so beautiful of a whole so great, seen from a charming
lawn, and surrounded by a delightful country, com
pose all together a scene of real magnificence and
grandeur.

The several lawns are separated by the finest trees;
which sometimes grow in airy groves, chequered with
gleams of light, and open to every breeze; but more
often nestled in long groves, branches meeting and appen
ing each other, cast a deep impenetrable shade. Large
boughs feathering down often intercept the sight; or a
vacant space is filled with coppice wood, not, however,
and hornbeam, whose twined heads mixing with the fol
age, and whose little stems clustering about the trunks
of the trees, thicken and darken the plantation. Here
and there the division is of such coppice wood only,
which then being less constrained and oppressed, springs
up stronger, spreads further, and joins in a low vaulted
covering; in other places the shade is high, overshot
by the tallest ash, or spreads under the branches of the
most venerable oaks. They rise in every shape, they are
dispersed in every form in which trees can grow. The
ground beneath them is sometimes almost level; some
times a gentle swell but generally very irregular and
broken. In several places, large hollows wind down
the sides of the hills, worn in the stormy months by
water courses, but worn many ages ago. Very old oaks
in the midst of the channels prove their antiquity: some
of them are perfectly dry most part of the year; and
some are watered by little rills all the summer: they are
deep and broad; the sides are commonly steep; often
abrupt and hollow; and the trees on the bank sometimes
extend their roots, all covered with moss, over the chan
nels of the water. Low down in one of these glens, a
thick shade of trees is in a plain, the midst of several little curren\nand water falls, running among large loose stones, and the stumps of
de trees, with which the ground is broken. On the brink
of another glen, which is distinguished by a numerous
rookery, is a seat in a still wilder situation, near a deeper
hollow, and in a darker gloom: the falls are nearly
perpendicular; the roots of some of the trees are almost
bare, from the earth having crumbled away; large
boughs of others, sinking with their own weight, seem
ready to break from the trunks they belong to; and the
finest ash, still growing, lie all aslant the water course
below, which, though the streams run in winter only, yet
constantly retains the black tinge of damp, and casts
a chill all around.

Gravel walks are conducted across the glens, through
the woods, the groves, or the thickets, and along the
sides of the lawns, concealed generally from the sight,
but always ready for the communication, and leading to
the principal scences. The frequency of these walks, the
number and the style of the buildings, and the high pre
servation in which all the place is kept, give to the whole
park the air of a garden. There is, however, one spot
more peculiarly adapted to that purpose, and more arti
cially disposed than the rest; it is a narrow vale, di
vided into three parts: one of them is quite filled with
water which leaves no room for a path, but thick trees
on either side come down quite to the brim; and be
tween them the sight is conducted to the bridge with
a portico upon it, which closes the view: another part of
this vale is a deep gloom, overhung with large ash and
cocks, and darkened below by a number of yews: there
are scattered over very uneven ground, and open under
neath; but they are encompassed by a thick covert, un
der which a stream falls from a stony channel, down a
rock; other rills drop into the current, which after
wards pours over a second cascade into the third divi
sion of the vale, where it forms a piece of water, and is last
under the bridge. The view from this bridge is a per
fect opera scene, through the divisions of the vale up
to the rotunda. Both those buildings, and the other
decorations of the spot, are of the species generally confi
ned
The hermitage also, which has been described, and its appendages, are in a style which does not belong to a park; but through all the rest of the place, the two characters are intimately blended. The whole is one subject; and it was a bold idea to conceive that one to be capable of so much variety; it required the most vigorous efforts of a fertile fancy to carry that idea into execution. See Gardening.

Park of Artillery. See Artillery.

Park of Provisions, in military affairs, the place where the sutlers pitch their tents in the rear, and sell their provisions to the soldiers. Likewise that place where the bread waggons are drawn up, and where the troops receive their ammunition bread, being the store of the army.

Parker, Matthew, the second Protestant archbishop of Canterbury, was born at Norwich in the year 1504, the 19th of Hen. VII. His father, who was a man in trade, died when our author was about twelve years old; but his mother took special care of his education, and at the age of 17 sent him to Corpus Christi College in Cambridge, where, in 1523, he took his bachelor's degree. In 1527 he was ordained, created master of arts, and chosen fellow of the college. Having obtained a license to preach, he frequently held forth at St. Paul's cross in London, and in other parts of the kingdom. In 1533 or 1534 he was made chaplain to Queen Anne Boleyn, who obtained for him the deanery of Stoke Clare in Suffolk, where he founded a grammar school. After the death of the queen, King Henry made him his own chaplain, and in 1541 prebendary of Ely. In 1544, he was, by the king's command, elected master of Corpus Christi College, and the following year vice-chancellor of the university. In 1547 he lost the deanery of Stoke, by the dissolvation of that college. In the same year he married the daughter of Robert Harlestone, a Norfolk gentleman.

In the year 1553 he was nominated, by Edward VI., to the deanery of Lincoln, which, with his other preferments, enabled him to live in great affluence: but Mary had scarcely succeeded to the throne before he was deprived of every thing he held in the church, and was then obliged to live in obscurity, frequently changing his place of abode to avoid the fate of the other reformers.

Queen Elizabeth ascended the throne in 1558; and in the following year Dr. Parker, from indigence and obscurity, was at once raised to the see of Canterbury; an honour which he neither solicited nor desired. In this high station he acted with spirit and propriety. He visited his cathedral and diocese in 1560, 1565, and 1573. He repaired and beautified his palace at Lambeth at vast expense. The sum which the repairs of the palace and great hall at Canterbury cost him was upwards of 1400l. sterling, which is at least equal to ten times the sum now a-days. Both the palace and great hall were, however, exposed through the injuries of time, and partly through that of fire. The hall, built by Archbishop Huber in the 12th century, was famous in history for the great feasts that had been given there by archbishops and abbots in former times; in particular, at the nuptial feasts of King Edward I. in 1290; at the installation of the abbot of St. Austin's in 1309; at the enthronization of George Nevill, archbishop of York, in 1364; and of Archbishop Warham in 1504, when Edward duke of Buckingham acted as lord high steward of his household; and lastly, for the entertainment given by that archbishop in 1519 to the emperor Charles V. of Henry VIII. Queen Catherine, &c. In 1565 Archbishop Parker gave three entertainments in this hall at Whitsuntide (which lasted three days), on Trinity Sunday, and in Mineersaie time. At the two first of these the archbishop himself sat in the midst of the uppermost table; on his left hand the mayor, &c. and on one side of the hall a continued row of men according to their rank filled the other tables; and on his right hand sat only some noble women and ladies of quality, the whole length of the hall, corresponding to the row of men on the other side: which order of placing the women was observed in honour of the queen. The first rank of guests having risen, and the tables cleared, they were furnished again, and filled the second time. At the last feast which was grander than all the rest, the archbishop entertained the two judges who went that circuit (b), the attorney-general, the high-sheriff, with all who met at these assizes, as justices of the peace, advocates, and common lawyers, and all the rest of proctors and attorneys; who all (with a promissious company) in troops came in. The hall was set forth with much plate of silver and gold, adorned with much tapestry of Flanders; and dainties of all sorts were served in excellent order by none but the archbishop's servants, the table being often the same day furnished a fresh with new guests; while the ladies were nobly entertained in inner parlours by Mrs. Parker, the hall being now filled with gentlemen. Otherwise, at these feasts, it was the archbishop's custom, in honour of matrimony, to entertain both men and their wives. Of this noble hall and palace, now within 200 years, there is little or nothing left except a few ruins. On Whitsunday 1570, and the two following days, this archbishop feasted the citizens of Canterbury and their wives in the same manner as he had done before: and on Trinity Sunday (after consecrating Bishop Curteis of Chichester) he made another most archiepiscopall feast, inviting another archbishop (viz. Grindal of York, who came thither for confirmation) to be his guest: besides whom were present Hora bishop of Winchester, and Curteis bishop of Chichester. At the lower tables sat all the ministers and servants whatsoever, even the children, who belonged to that church; and at the remotest tables, but in the same hall, in sight, sat the pope of both sexes of the hospitals of St. John's and Harbledown. On July 11th, being assizes time, the judges, high-sheriff, gentlemen, and the common sort, were all feasted by the archbishop in a splendid manner as before. Soon after Bishop Sands of Worcester, else of London, came to Canterbury to be confirmed. The archbishop, on his return, lodged the first night at Sittingbourne, and the next night (after dining at Graveshend)

(b) This proves that the judges of assize then came to Canterbury, though it was then a county in itself, being so made in 1481.
Parker. (send) came to Lambeth in barges by Thames, with all
his family. Sept 7. 1573, being Q. Elizabeth’s birthday.
Archbishop Parker entertained her majesty, and as
many noblemen, &c. as were present at Archbishop
Warham’s entertainment in the same hall 54 years be-
fore.

The archbishop (to use his own words, in a letter
to Archbishop Grindal of York) “met her highness,
as she was coming to Dover, upon Falconstone Down. I
left her at Dover, and came home to Bekesborn that
night; and after that went to Canterbury to receive her
majesty there. Which I did, with the bishops of Lin-
coln and Rochester, and my suffragan (of Dover), at
the west door; where, after the grammarian had made
his oration to her upon her horse-back, she alighted.
We then kneeled down, and said the psalm Deus misera-
atur, in English, with certain other collects briefly;
and that in our chimes and rochet. The quire, with the
dean and prebendaries, stood on either side of the church,
and brought her majesty up with a song; she going un-
der a square canopy, borne by four of her temporal
knights, to her traverse, placed by the communion
board, where she heard evening song; and after depart-
ed to her lodging at St Austin’s, whither I waited upon
her. From thence I brought certain of the council, and
divers of the court, to my house to sup, and gave them
14 or 15 dishes, furnished with two messes, at my
long table, whereat sat about 20; and in the same cham-
er a third mess, at a square table, whereat sat 10 or
12; my less hall having three long tables furnished
with my officers, and with the guard, and others of the
court: and so her majesty came every Sunday to church
to hear the sermon. And upon one Monday it pleased
her highness to dine in my great hall, thoroughly furn-
ished with the council, Frenchmen, ladies, gentlemen,
and the mayor of the town, with his brethren, &c.;
her highness sitting in the midst, having two French
ambassadors (Gendius and Mothe-Fenelon) at the end
of the table, and four ladies of honour at the other
end. And so three messes were served by her nobility
at washing, her gentleman and guard bringing her
dishes, &c.” On which the archbishop of York, in
his answer, made this reflection: “Your grace’s large
description of the entertainment at Canterbury did so
likely set forth the matter, that in reading thereof I
almost thought myself to be one of your guests there,
and as it were beholding the whole order of all things
done there. Sir, I think it shall be hard for any of
our coast to do the like for one hundred years, and how
long after God knoweth.” In this progress Lord
Treasurer Burleigh was lodged with Mr Pearson,
the eleventh prebendary, who, the archbishop says,
“had a fine house.”

He founded several scholarships in Beonset or Corpus-
Christi college in Cambridge, and gave large presents
of plate to that and to other colleges in this university.
He gave 100 volumes to the public library. He like-
wise founded a free school at Rochdale in Lancashire.
He took care to have the seals filled with pious and
learned men; and, considering the great want of Bibles
in many places, he, with the assistance of other learned
men, improved the English translation, had it printed
on a large paper, and dispersed through the kingdom.
This worthy prelate died in the year 1575, aged 72;
and was buried in his own chapel at Lambeth. He
was pious without affection or austerity, cheerful and
contented in the midst of adversity, moderate in the
height of power, and beneficent beyond example. He
wrote several books; and also published four of our
best historians, Matthew of Westminster, Matthew
Paris, Asser’s Life of King Alfred, and Tho. Waling-
ham. The learned archbishop also translated the Par-
ley. This version was printed, but without a name;
and has been attributed to an obscure poet of the same
name of Keeper. This was Wood’s opinion; but it is mo-
t than probable that the learned author of the Athene
Oxoniensis, was wrong. See Gentleman’s Magazine for
1781, p. 566. where Parker is proved to be the author
of a version of the Psalms.

PARKINSONIA, a genus of plants, belonging to the
decandria class; and in the natural method ranking
under the 33d order, Lomentaceae. See BOTANY
Index.

PARLEY, a conference with an enemy. Hence,
to beat or sound a parley, is to give a signal for hold-
ing such a conference by beat of drum, or sound of trump.

PARLIAMENT, the grand assembly of the three
houses of this kingdom, summoned together by the king’s
authority, to consider of matters relating to the public
welfare, and particularly to enact and repeal laws.

The original or first institution of parliament is one of
those matters which lie so far hidden in the dark ages,
and though a subject of antiquity, that the tracing of it out is a thing equally
difficult and uncertain. The word parliament itself (or
colloquentium, as some of our historians translate it) is, com-
paratively, of modern date; derived from the French,
and Signifying the places they met and conferred to-
gether.” It was first applied to general assemblies of
the states under Lewis VII. in France, about the middle
of the 12th century. But it is certain, that long before
the introduction of the Norman language into England,
all matters of importance were debated and settled in
the great councils of the realm. A practice which seems to
have been universal among the northern nations, par-
cularly the Germans; and carried by them into all the
countries of Europe, which they overran at the dissolu-
tion of the Roman empire. Relics of which constitu-
tion, under various modifications and changes, are still
to be met with in the diets of Poland, Germany, and
Sweden, and lately in the assembly of the estates in
France: for what is there now called the parrlement,
is only the supreme court of justice, consisting of the peers,
certain dignified ecclesiastics, and judges; which either is in practice, nor is supposed to be in theory, a
general council of the realm.

In England, however, this general council hath been
Antiquely held immemorially, under the several names of mekde of, in Syn-
med, or “great council;” michel gemcet; or “great
meeting;” and more frequently usittena-geome, or “the
meeting of wise men.” It was also styled in Latin,
commune concilium regni, magnum concilium regis,
urcia magna, conventus magnatum vel procercum, assis
generalis, and sometimes communitas regni Angliae. We
have instances of its meeting to order the affairs of the
kingdom, to make new laws, and to amend the old, or,
as Flata expresses it, nova injurye emerit nova constit-
ture remedie, so early as the reign of Ina king of the
West Saxons, Ofka king of the Mercians, and Ethelbert
king of Kent, in the several realms of the heptarchy.
And after their union, the Mirror informs us, that King
Alfred ordained for a perpetual usage, that these cou-
ccies
Parliament should meet twice in the year, or oftener, if need be, to treat of the government of God's people; how they should keep themselves from sin, should live in quiet, and should receive right. Our succeeding Saxon and Danish monarchs held frequent councils of this sort, as appears from their respective codes of laws; the titles whereof usually speak them to be enacted, either by the king with the advice of his witenagemote, or wise men, as, Hiec sunt instituta, quas Edwarlus rex consilio supervenientium suaorum instituuit; or to be enacted by those sages with the advice of the king: as Hiec sunt judicia quas sopicientes consilio regis Ethelstan instituerunt; or, lastly, To be enacted by them both together, as Hec sunt institutiones, quas rex Edmundus et episcopi sui cum sopicientibus suis instituerunt.

There is also no doubt but these great councils were occasionally held under the first princes of the Norman line. Glanvil, who wrote in the reign of Henry II. speaking of the particular amount of an amercement in the sheriff's court, says, it had never yet been ascertained by the general assize or assembly, but was left to the custom of particular counties. Here the general assize is spoken of as a meeting well known, and its statutes or decisions are put in a manifest contradistinction to custom, or to the common law. And in Edward III.'s time, an act of parliament, made in the reign of William the Conqueror, was proved in the case of the abbey of St. Edmund's Bury, and judicially allowed by the court.

Hence it indisputably appears, that parliaments, or general councils, are coeval with the kingdom itself. How those parliaments were constituted and composed, is another question, which has been matter of great dispute among our learned antiquarians; and particularly, whether the commons were summoned at all; or, if summoned, at what period they began to form a distinct assembly. But without entering into controversies of this sort, it may be sufficient to observe, that it is generally agreed, that in the main the constitution of parliament, as it now stands, was marked out so long ago as the 17th year of King John, A.D. 1215, in the great charter granted by that prince; wherein he promises to summon all archbishops, bishops, abbots, earls, and greater barons, personally; and all other tenants in chief under the crown, by the sheriff and bailiffs; to meet at a certain place, with 40 days notice, to assess aids and scutages when necessary. And this constitution has subsisted in fact at least from the year 1266, 49 Henry III. there being still extant writs of that date, to summon knights, citizens, and burgesses, to parliament. We proceed therefore to inquire wherein consists this constitution of parliament, as it now stands, and has stood, for the space of at least 500 years. And in the prosecution of this inquiry, we shall consider, first, The manner and time of its assembling: Secondly, Its constituent parts: Thirdly, The laws and customs relating to parliament: Fourthly, The methods of proceeding, and of making statutes, in both houses: And, lastly, The manner of the parliament's adjournment: prerogative, and dissolution.

I. As to the manner and time of assembling. The parliament is regularly to be summoned by the king's writ or letter, issued out of chancery by advice of the privy council, at least 40 days before it begins to sit. It is a branch of the royal prerogative, that no parliament can be convened by its own authority, or by the authority of any except the king alone. And this prerogative is founded upon very good reason. For, supposing it had a right of sitting spontaneously, without being called together, it is impossible to conceive that all the members, and each of the houses, would agree unanimously upon the proper time and place of meeting; and if half of the members met, and half absented themselves, who should determine which is really the legislative body, the part assembled, or that which stays away? It is therefore necessary, that the parliament should be called together at a determinate time and place; and, highly becoming its dignity and independence, that it should be called together by none but one of its own constituent parts: and of the three constituent parts, this office can only appertain to the king; as he is a single person, whose will may be uniform and steady; the first person in the nation, being superior to both houses in dignity; and the only branch of the legislature that has a separate existence, and is capable of performing any act at a time when no parliament is in being. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor: for this revived parliament must have been originally summoned by the crown.

It is true, that the convention parliament which restored King Charles II. met above a month before his return; the lords, by their own authority, and the commons in pursuance of writs issued in the name of the crown, to keepers of the liberty of England by authority of parliament, and that the said parliament sat till the 9th of December, full seven months after the Restoration; and enacted many laws, several of which are still in force. But this was for the necessity of the thing, which superseded all law; for if they had not so met, it was morally impossible that the kingdom should have been settled in peace. And the first thing done after the king's return was, to pass an act declaring this to be a good parliament, notwithstanding the defect of the king's writ. So that as the royal prerogative was chiefly wounded by their so meeting, and as the king himself, who alone had a right to object, consented to waive the objection, this cannot be drawn into an example in prejudice of the rights of the crown. Besides, we should also remember, that it was at that time a great doubt among the lawyers, whether even this healing act made it a good parliament, and held by very many in the negative; though it seems to have been too nice a scruple. And yet, out of abundant caution, it was thought necessary to confirm its acts in the next parliament, by statute 15 Car. II. c. 7. and c. 14.

It is likewise true, at the time of the Revolution of 1688, the lords and commons by their own authority, and upon the summons of the prince of Orange (afterwards King William), met in a convention, and, ex necessitate rei, therein disposed of the crown and kingdom. But it must be remembered, that this assembling was upon a like principle of necessity as at the Restoration; that is, upon a full conviction that King James II. had abdicated the government, and that the throne was thereby vacant; which supposition of the individual members was confirmed by their concurrent resolution, when they actually came together. And in such a case as the palpable vacancy of a throne, it follows, ex necessitate rei, that the
The king is obliged to convok parliament.as often as circumstances require.

And this, by the ancient statutes of the realm, he is bound to do every year, or oftener if need be. Not that he is, or ever was, obliged by these statutes to call a new parliament every year; but only to permit a parliament to sit annually for the redress of grievances, and dispatch of business, if need be. These last words are so loose and vague, that such of our monarchs as were inclined to govern without parliaments, neglected the convoking them, sometimes for a very considerable period, under pretense that there was not need of them. But to remedy this, by the statute 16 Car. II. c. 1. it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most. And by the statute 1 W. and M. st. 2. c. 2. it is declared to be one of the rights of the people, that for redress of all grievances, and for the amending, strengthening, and preserving, the laws, parliaments ought to be held frequently. And this indefinite frequency is again reduced to a certainty by statute 6 W. & M. c. 2. which enacts, as the statute of Charles II. has done before, that a new parliament shall be called within three years after the determination of the former.

II. The constituent parts of a parliament are, the king's majesty, sitting there in his royal political capacity, and the three estates of the realm; the lords spiritual, the lords temporal (who sit together with the king in one house); and the commons, who sit by themselves in another. And the king and these three estates together form the greater corporation or body politic of the kingdom, of which the king is said to be caput, principium, et finis. For upon their coming together the king meets them, either in person or by representation; without which there can be no beginning of a parliament; and he also has alone the power of dissolving them.

It is highly necessary for preserving the balance of the constitution, that the executive power should be a branch, though not the whole, of the legislature. The total union of them, we have seen, would be productive of tyranny: the total disjunction of them for the present, would in the end produce the same effects, by causing that union against which it seems to provide. The legitimacy of the legislature would soon become tyrannical, by making continual encroachments, and gradually assuming to itself the rights of the executive power. Thus the long parliament of Charles I. while it acted in a constitutional manner, with the royal concurrence, redressed many heavy grievances and established many salutary laws. But when the two houses assumed the power of legislation, in exclusion of the royal authority, they soon after assumed likewise the reins of administration; and, in consequence of these united powers, overturned both church and state, and established a worse oppression than any they pretended to remedy. To hinder therefore such encroachments, the king is himself a part of the parliament; and as this is the reason of his being so, very properly therefore the share of legislation which the constitution has placed in the crown, consists in the power of rejecting, rather than resolving; this being sufficient to answer the end proposed. For we may apply to the royal negative, in this case, what Cicero observes of the negative of the Roman tribunes, that the crown has not any power of doing wrong, but merely of preventing wrong from being done. The crown cannot begin of itself any alterations in the present established law; but it may approve or disapprove of the alterations suggested and consented to by the two houses. The legislature therefore cannot abridge the executive power of any rights which it now has by law, without its own consent; since the law must perpetually stand as it now does, unless all the powers will agree to alter it. And herein indeed consists the true excellence of the British government, that all the parts of it form a mutual check upon each other. In the legislature, the people are a check upon the nobility, and the nobility a check upon the people, by the mutual privilege of rejecting what the other has resolved; while the king is a check upon both, which preserves the executive power from encroachments. And this very executive power is again checked and kept within due bounds by the two houses, through the privilege they have of impeaching into, impeaching, and punishing the conduct (not indeed of the king, which would destroy his constitutional independence; but which is more beneficial to the public) of his evil and pernicious counsellors. Thus every branch of our civil polity supports and is supported, regulated and restrained, by the rest; for the two houses mutually drawing in two directions of opposite interest, and the prerogative in another still different from them both, they mutually keep each other from exceeding their proper limits; while the whole is prevented from separation, and artificially connected together by the mixed nature of the crown, which is a part of the legislature, and the sole executive magistrate. Like three distinct powers in machines, they jointly impel the machine of government in a direction different from what either, acting by itself, would have done; but at the same time in a direction pursuing of each, and formed out of all; a direction which constitutes the true line of the liberty and happiness of the community.

Having already considered these constituent parts of the
Parliament the sovereign power, or parliament, each in a separate view, under the articles King, Lords, and Commons, to which the reader is referred, we proceed.

III. To examine the laws and customs relating to parliament, united together and considered as one aggregate body. The power and jurisdiction of parliaments, says Sir Edward Coke, is so transcendent and absolute, that it cannot be confined either for causes or persons within any bounds. And of this high court be add Knox, 3: antiquitatem spectes, est virtutisima, id dignitatem, est honoratissimae; si jurisdicti, est caputissimae. It hath sovereign and uncontrollable authority in making, confirming, enlarging, restraining, abrogating, repealing, reviving, and expounding laws, concerning matters of all possible denominations, ecclesiastical or temporal, civil, military, maritime, or criminal: this being the place where that absolute despotic power, which must in all governments reside somewhere, is intrusted by the constitution of these kingdoms. All mischiefs and grievances, operations and remedies, that transcend the ordinary course of the laws, are within the reach of this extraordinary tribunal. It can regulate or new-model the succession to the crown; as was done in the reigns of Henry VIII. and William III. It can alter the established religion of the land; as was done in a variety of instances in the reigns of King Henry VIII. and his three children. It can change and create afresh even the constitution of the kingdom and of parliaments themselves; as was done by the act of Union, and the several statutes for triennial and septenniel elections. It can, in short, do every thing that is not naturally impossible; and therefore some have not scrupled to call its power, by a figure rather too bold, the omnipotence of parliament. True it is, that what the parliament doth, no authority upon earth can undo. So that it is a matter most essential to the liberties of this kingdom, that such members be delegated to this important trust as are most eminent for their probity, their fortitude, and their knowledge; for it was a known apostrophe of the great lord treasurer Burleigh, "That England could never be ruined but by a parliament;" and, as Sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in the kingdom, if by any means a misgovernment should anyway fall upon it, the subjects of this kingdom are left without all manner of remedy. To the same purpose, the President Montesquieu, though we trust too hastily, presages, that as Rome, Sparta, and Carthage, have lost their liberty and perished; so the constitution of England will in time lose its liberty, will perish: it will perish whenever the legislative power shall become more corrupt than the executive.

It must be owned, that Mr. Locke, and other theoretical writers, have held, that "there remains still inherent in the people a supreme power to remove or alter the legislature, when they find the legislature act contrary to the trust reposed in them: for when that trust is abused, it is thereby forfeited, and devolves to those who gave it." But however just this conclusion may be in theory, we cannot adopt it, or argue from it, under any dispensation of government at present actually existing. For this devolution of power, to the people at large, includes in it a dissolution of the whole form of government established by that people; reduces all the members to their original state of equality; and by annihilating the sovereign power, repeals all positive laws whatsoever before enacted. No human laws will therefore suppose a case, which at once must destroy all law, and compel men to build afresh upon a new foundation; nor will they make provision for so desperate an event, as must render all legal provisions ineffectual. So long therefore as the English constitution lasts, we may venture to affirm, that the power of parliament is absolute and without control.

In order to prevent the mischiefs that might arise, by placing this extensive authority in hands that are either incapable or else improper to manage it, it is provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be of the age of 21 years of age. This is also expressly declared by statute 7 & 8 W. III. c. 25: with regard to the house of commons, doubts have arisen, from some contradictory adjudications, whether or not a minor was incapacitated from sitting in that house. It is also enacted by statute 7 Jac. I. c. 6, that no member be permitted to enter the house of commons till he hath taken the oath of allegiance before the lord steward or his deputy: and by 30 Car. II. st. 2, and 1 Geo. I. c. 13, that no member shall vote or sit in either house, till he be, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, and subscribed and repeated the declaration against transubstantiation, and invocation of saints, and the sacrifice of the mass. Aliens, unless naturalized, were likewise by the law of parliament incapable to serve therein: and now it is enacted, by statute 12 & 13 W. III. c. 2, that no alien, even though be naturalized, shall be capable of being a member of either house of parliament. And there are not only these standing incapacities; but if any person is made a peer by the king, or elected to serve in the house of commons by the people, yet may the respective houses, upon complaint of any crime in such person, and proof thereof, adjudge him disabled and incapable to sit as a member: and this by the law and custom of parliament.

For as every court of justice hath laws and customs for its direction, so some have the civil and common, some the common law, others their own peculiar laws and customs; so the high court of parliament hath also its own peculiar law, called lex et consuetudo parliamento; a law which Sir Edward Coke observes is ad unciam quaesitum et ad multa ignotum, ad paucos cognitum. It will not therefore be expected that we should enter into the examination of this law with any degree of minuteness; since, as the same learned author assures us, it is much better to be learned out of the rolls of parliament and other records, and by precedents and continual experience, than can be expressed by any one man. It will be sufficient to observe, that the whole of the law and custom of parliament has its original from this one maxim, "That whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere." Hence, for instance, the lords will not suffer the commoners to interfere in the settling the election of a peer in Scotland; the commons will not allow the lords to judge of the election of a burgess; nor will either house permit the subordinate courts of law to examine the merits of either case. But the maxim on
The privileges of parliament are likewise very large and indefinite; and therefore, when in 31st Hen. VI. the house of lords propounded a question to the judges concerning them, the chief justice, Sir John Fortescue, in the name of his brethren, declared, "That they ought not to make answer to that question; for it hath not been used aforesight, that the justices should in any wise determine the privileges of the high court of parliament; for it is so high and mighty in its nature, that it may make law; and that which is law, it may make no law; and the determination and knowledge of that privilege belong to the lords of parliament, and not to the justices." Privileges of parliament was principally established, in order to protect its members not only from being molested by their fellow-subjects, but also more especially from being oppressed by the power of the crown. If therefore all the privileges of parliament were once to be set down and ascertained, and no privilege to be allowed but what was so defined and determined, it was easy for the executive power to devise some new case not within the line of privilege, and under pretence thereof to harass any refractory member, and violate the freedom of parliament. The dignity and independence of the two houses are therefore in great measure preserved by keeping their privileges indefinite. Some, however, of the more notorious privileges of the members of either house are, privileges of speech, of person, of their domestics, and of their lands and goods. As to the first, privilege of speech, it is declared by the statute 1 W. and M. st. 2. c. 2. as one of the liberties of the people, "That the freedom of speech, and debates, and proceedings in parliament, ought not to be impeached or questioned in any court or place out of parliament." And this freedom of speech is particularly demanded of the king in person, by the speaker of the house of commons, at the opening of every new parliament. So likewise are the other privileges, of person, servants, lands, and goods; which are immunities as ancient as Edward the Confessor: in whose laws we find this precept, "ad synodos venientibus, sive sermonis sinit, sive per se quid agendum habebint, sit omnino pacis;" and so too in the old Gothic constitutions, "Extinditur harpres et secrectorum ad quotwocdecim dies, convocato regni senatu." This included formerly not only privilege from illegal violence, but also from legal arrests and seizures by process from the courts of law. But member of either house, or his menial servants, is a high contempt of parliament, and there punished with the utmost severity. It has likewise peculiar penalties annexed to it in the courts of law by the statutes 5 Hen. IV. c. 6. and 11 Hen. VI. c. 11. Neither can any member of either house be arrested and taken into custody without a breach of the privilege of parliament.

But all other privileges which derogate from the common law are now at an end, save only as to the freedom of the member's person; which in a peer (by the privilege of peerage) is far more secured, and inviolable; and in a commoner (by the privilege of parliament) for forty days after every prorogation, and forty days before the next appointed meeting; which is now in effect as long as the parliament subsists, it seldom being prorogued for more than 80 days at a time. As to all other privileges which obstruct the ordinary course of justice, they were restrained by the statutes 12 W. Ill. c. 3. and 3 Ann. c. 18. and 11 Geo. II. c. 24. and are now totally abolished by statute 10 G. III. c. 50.; which enacts, that no suit may at any time be brought against any peer or member of parliament, their servants, or any other person entitled to privilege of parliament; which shall not be impeached or delayed by pretence of any such privilege, except that the person of a member of the house of commons shall not thereby be subjected to any arrest or imprisonment. Likewise, for the benefit of commerce, it is provided by statute 4 Geo. III. c. 33. that any trader, having privilege of parliament, may be served with legal process for any just debt (to the amount of 100l.): and unless he makes satisfaction within two months, it shall be deemed an act of bankruptcy; and that commissions of bankruptcy may be issued against such privileged traders in like manner as against any other.

The only way by which courts of justice could anciently take cognizance of privilege of parliament was by writ of privilege, in the nature of a supersedeas, to prevent the delivery of the party out of custody when arrested in a civil suit. For when a letter was written by the speaker to the Lord Chancellor, or to any of the judges, to stay proceedings against a privileged person, they rejected it as contrary to their oath of office.

But since the statute 12 Will. Ill. c. 3. which enacted that no privileged person shall be subject to arrest or imprisonment, it hath been held, that such arrest is irregular ab initio, and that the party may be discharged upon motion. It is to be observed, that there is no precedent of any such writ of privilege, but only in civil suits; and that the statute of 1 Jac. I. c. 13. and that of King William (which remedy some inconveniences arising from privilege of parliament), speak only of civil actions. And therefore the claim of privilege hath been usually guarded with an exception as to the case of indictable crimes; or, as it hath been frequently expressed, of treason, felony, and breach (or surety) of the peace. Whereby it seems to have been understood, that no privilege was allowable to the members, their families, or servants, in any crime, whatsoever: for all crimes are treated by the law as being contra pacem domini regis. And instances have not been wanting, wherein privileged persons have been committed, and committed, or prosecuted to outlawry, even in the middle of a session; which proceeding has afterwards received the sanction and approbation of parliament. To which may be added, that a few years ago, the case of writing and publishing seditious libels was resolved by both houses not to be entitled to privilege; and that the reasons upon which that case proceeded, extended equally to every-indictable offence. So that the chief, if not the only, privilege of parliament in such cases, seems to be the right of receiving immediate information of the imprisonment or detention of any member, with the reason for which he is detained: a practice that is daily used upon the slightest military accusations, preparatory to a trial by a court-martial; and which is recognised by the several temporary statutes for suspending the habeas corpus act: whereby it is provided, that no member of either house shall be detained, till the matter of which he stands suspected be first communicated to the house of which he is a member, and the consent of the
Parliament said house obtained for his commitment or detaining. But yet the usage has uniformly been, ever since the Revolution, that the communication has been subsequent to the arrest.

These are the general heads of the laws and customs relating to parliament, considered as one aggregate body. The laws and customs relating to each branch in particular being explained under the articles already referred to, viz., King, Lords, and Commons, we shall proceed to IV. To the method of making laws; which is much the same in both houses. But for this, too, we have to refer the reader to the article Bill; and shall only observe in this place, that for despatch of business, of the house of each house of parliament has its speaker. The speaker of the house of lords, whose office it is to preside there, and manage the formality of business, is the lord chancellor, or keeper of the king's great seal, or any other appointed by the king's commission: and if none be so appointed, the house of lords (it is said) may elect.

The speaker of the house of commons is chosen by the house; but must be approved by the king. And here, in the usage of the two houses differs, that the speaker of the house of commons cannot give his opinion or argue any question in the house; but the speaker of the house of lords, if a lord of parliament, may. In each house the act of the majority binds the whole; and this majority is declared by votes openly and publicly given; not, as at Venice, and many other senatorial assemblies, privately, or by ballot. This latter method may be serviceable, to prevent intrigues and unconstitutional combinations; but it is impossible to be practised with us, at least in the house of commons, where every member's conduct is subject to the future censure of his constituents, and therefore should be openly submitted to their inspection.

V. There remains only, in the last place, to add a word or two concerning the manner in which parliament may be adjourned, prorogued, or dissolved.

An adjournment is no more than a continuance of the session from one day to another; as the word itself signifies; and this is done by the authority of each house separately every day; and sometimes for a fortnight, or a month together, as at Christmas or Easter, or upon other particular occasions. But the adjournment of one house is no adjournment of the other. It hath also been usual, when his majesty hath signified his pleasure, that both or either of the houses should adjourn themselves to a certain day, to obey the king's pleasure so signified, and to adjourn accordingly. Otherwise, besides the indecorum of a refusal, a prorogation would assuredly follow; which would often be very inconvenient to both public and private business. For prorogation puts an end to the session; and then such bills as are only begun, and not perfected, must be resumed de novo (ii at all) in a subsequent session; whereas, after an adjournment, all things continue in the same state as at the time of the adjournment made, and may be proceeded on without any fresh commencement.

A prorogation is the continuance of the parliament from one session to another; as an adjournment is a continuation of the session from day to day. This is done by the royal authority, expressed either by the lord chancellor in his majesty's presence, or by commission from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time; it not being a prorogation of the house of lords or commons, but of the parliament. The session is never understood to be at an end until a prorogation; though, unless some act be passed, or some judgment given in parliament; it is in truth no session at all. And formerly the usage was for the king to give the royal assent to all such bills as he approved at the end of every session, and then to pro rogue the parliament, though sometimes only for a day or two; after which all business then depending in the houses was to be begun again. Which custom obtained so strongly, that it once became a question, whether giving the royal assent to a single bill did not of course put an end to the session? And though it was then resolved in the negative, yet the notion was so deeply rooted, that the statute 1 Car. I. c. 7. was passed to declare, that the king's assent to that and some other acts should not put an end to the session; and even so late as the reign of Charles II. we find a proviso frequently tacked to a bill, that his majesty's assent thereto should not determine the session of parliament. But it now seems to be allowed, that a prorogation must be expressly made, in order to determine the session. And if at the time of an actual rebellion, or imminent danger of invasion, the parliament shall be separated by adjournment or prorogation, the king is empowered to call them together by proclamation, with 14 days notice of the time appointed for their reassembly.

A dissolution is the civil death of the parliament; and this may be effected three ways: 1. By the king's will, expressed either in person or by representation. For as the king has the sole right of convening the parliament, so also it is a branch of the royal prerogative, that he may (whenever he pleases) prorogue the parliament for a time, or put a final period to its existence. If nothing had a right to prorogue or dissolve a parliament but itself, it might happen to become perpetual. And this would be extremely dangerous if at any time it should attempt to encroach upon the executive power, as was fatally experienced by the unfortunate King Charles I.; who, having unadvisedly passed an act to continue the parliament then in being till such time as it should please to dissolve itself, at last fell a sacrifice to that inordinate power which he himself had consented to give them. It is therefore extremely necessary that the crown should be empowered to regulate the duration of these assemblies, under the limitations which the English constitution has prescribed: so that, on the one hand, they may frequently and regularly come together for the despatch of business and redress of grievances; and may not, on the other, even with the consent of the crown, continue to an inconvenient and unconstitutional length.

2. A parliament may be dissolved by the demise of or in conse of the crown. This dissolution formerly happened immediately upon the death of the reigning sovereign: for he was considered in law as the head of the parliament, (caput, principium, et finis), that failing, the whole body was held to be extinct. But the calling a new parliament immediately on the inauguration of the successor being found inconvenient, and dangers being apprehended from having no parliament in being in case of a disputed succession, it was enacted by the statutes 7 and 8 Wm. III. c. 15, and 6 Ann. c. 7, that the parliament in being shall continue for six months after the death of any king or queen, unless sooner prorogued or dissolved.
Parliament. 

Parliament, or through length of time.

1. Lastly, A parliament may be dissolved or expire by length of time. For if either the legislative body were perpetual, or might last for the life of the prince who convened them as formerly, and were so to be supplied, by occasionally filling the vacancies with new representatives; in these cases, if it were once corrupted, the evil would be past all remedy; but when different bodies succeed each other, if the people see cause to disapprove of the present, they may rectify its faults in the next. A legislative assembly also, which is sure to be separated again, (whereby its members will themselves become private men, and subject to the full extent of the laws which they have enacted for others,) will think themselves bound in interest as well as duty, to make only such laws as are good. The utmost extent of time that the same parliament was allowed to sit, by the statute 6 W. and M. c. 3, was three years: after the expiration of which, reckoning from the return of the first summons, the parliament was to have no longer continuance. But by the statute 1 Geo. I. stat. 2. c. 38. (in order, professedly, to prevent the great and continued expences of frequent elections, and the violent heats and animosities consequent thereupon, and for the peace and security of the government then just recovering from the late rebellion), this term was prolonged to seven years; and, what above is an instance of the vast authority of parliament, the same house that was chosen for three years, enacted its own continuance for seven. So that, as our constitution now stands, the parliament must expire, or die a natural death, at the end of every seventh year, if not sooner dissolved by the royal prerogative.

We shall conclude this article with an account of some general forms not taken notice of under any of the above heads.

In the house of lords, the princes of the blood sit by themselves on the sides of the throne; at the wall, on the king's right hand, the two archbishops sit by themselves on a form. Below them, the bishops of London, Durham, and Winchester, and all the other bishops, sit according to the priority of their consecration. On the king's left hand, the lord treasurer, lord president, and lord privy seal, sit upon forms above all dukes, except the royal blood; then the dukes, marquises, and earls, according to their creation. Across the room are wool sacks, continued from an ancient custom; and the chancellors, or keepers, being of course the speaker of the house of lords, sits on the first wool sack before the throne, with the great seal or mace lying by him; below these are forms for the viscounts and barons. On the other wool sacks are seated the judges, masters in chancery, and king's council, who are only to give their advice in points of law; but they all stand up till the king gives them leave to sit.

The commons, sit promiscuously; only, the speaker has a chair at the upper end of the house, and the clerk and his assistant sit at a table near him. When a member of the house of commons speaks, he stands up, uncovered, and directs his speech to the speaker only. If what he says be answered by another, he is not allowed to reply the same day, unless personal reflections have been cast upon him: but when the commons, in order to have a greater freedom of debate, have resolved themselves into a committee of the whole house, every member may speak to a question as often as he thinks necessary. In the house of lords, they vote, beginning at the presence or lowest baron, and so up orderly to the highest, every one answering Content or Not content. In the house of commons they vote by ayes and noes; and if it be dubious which are the greater number, the house divides. If the question be about bringing any thing into the house, the year goes out, but if it be about any thing the house already has, the noes go out. In all divisions the speaker appoints four tellers, two of each opinion. In a committee of the whole house, they divide by changing sides, the person taking the right and the noes the left of the chair; and then there are but two tellers. If a bill pass one house, and the other demur to it, a conference is demanded in the painted chamber, where certain members are deputed from each house, and here the lords sit covered, and the commons stand bare, and debate the case. If they disagree, the affair is null: but if they agree, this, with the other bills that have passed both houses, is brought down to the king in the house of lords, who comes thither clothed in his royal robes; before him the clerk of the parliament reads the title of each bill, and as he reads, the clerk of the crown pronounces the royal assent or dissent. If it be a public bill, the royal assent is given in these words, Le roy le veut; "The king will have it so." if private, Soit fait comme il est destine; "Let the request be complied with," if the king is about to see the bill, the answer is, Le roy s'accordera, "The king will think of it;" and if it be a money bill, the answer is, Le roy remercie ses loyaux sujets, accepte leur benevolence, et en saisit le veut; "The king thanks his loyal subjects, accepts their benevolence, and therefore grants his consent."

High Court of Parliament, is the supreme court in the kingdom, not only for the making, but also for the execution of laws; by the trial of great and numerous offenders, whether lords or commoners, in the method of parliamentary impeachment. As for acts of parliament to attain particular persons of treason or felony, or to inflict pains and penalties, beyond or contrary to the common law, to serve a special purpose, we speak not of them; being to all intents and purposes new laws, made pro re nata, and by no means an execution of such as are already in being. But an impeachment before the lords by the commons of Great Britain, in parliament, is a prosecution of the already known and established law, and has been frequently put in practice; being a presentment to the most high and supreme court of criminal jurisdiction by the most solemn grand inquest of the whole kingdom. A commoner cannot, however, be impeached before the lords for any capital offence, but only for high misdemeanors; a peer may be impeached for any crime. And they (usually in case of an impeachment of a peer for treason) address the crown to appoint a lord-high-steward, for the greater dignity and regularity of their proceedings, which lord-high-steward was formerly elected by the peers themselves, though he was generally commissioned by the king; but death of late years has been strenuously maintained, that the appointment
Parliament. The articles of impeachment are a kind of bills of indictment, found by the house of commons, and afterwards tried by the lords; who are in cases of misdemeanors considered not only as their own peers, but as the peers of the whole nation. This is a custom derived to us from the constitution of the ancient Germania; who in their great councils sometimes tried capital accusations relating to the public: Licet apud concilium accusare quoque, et discribem capitis intendere. And it has a peculiar propriety in the English constitution; which has much improved upon the ancient model imported hither from the continent. For though in general the union of the legislative and judicial powers ought to be most carefully avoided, yet it may happen that a subject, intrusted with the administration of public affairs, may infringe the rights of the people, and be guilty of such crimes as the ordinary magistrate either dares not or cannot punish. Of these the representatives of the people, or house of commons, cannot properly judge; because their constituents are the parties injured, and can therefore only impeach. But before what court shall this impeachmant be tried? Not before the ordinary tribunals, which would naturally be swayed by the authority of so powerful an accuser. Reason therefore will suggest, that this branch of the legislature, which represents the people, must bring its charge before the other branch, which consists of the nobility, who have neither the same interests, nor the same passions, as popular assemblies. This is a vast superiority which the constitution of this island enjoys over those of the Grecian or Roman republics; where the people were at the same time both judges and accusers. It is proper that the nobility should judge, to ensure justice to the accused; as it is proper that the people should accuse, to ensure justice to the commonwealth. And therefore, among other extraordinary circumstances attending the authority of this court, there is one of a very singular nature, which was insisted on by the house of commons in the case of the earl of Danby in the reign of Char. II. and is now enacted by statute 12 and 13 W. III. c. 2. that no pardon under the great seal shall be pleadable to an impeachment by the commons of Great Britain in parliament.

Such is the nature of a British parliament, and in theory at least we should presume it were nearly perfect; but some of our fellow countrymen, more zealous perhaps than wise, see prodigious faults in it, such indeed as they think must inevitably prove fatal. The consequence of this presumption, has been a loud and incessant call for parliamentary reform. That abuses ought to be reformed, is certain; and that few institutions are so perfect as not to need amendment, is a fact equally indisputable. We shall even suppose that there are many abuses in our parliament which would require to be amended, but, granting all this, and something more if it were necessary, we would recommend in the mean time to the serious consideration of those who call themselves the Friends of the People, whose sincerity in their professions it would be unwise to question, the example of France, and that they would allow it to be a warning to Britain. France wanted reform indeed, and that which was first proposed had the consequence of the coolest and the best of men; but the consequences have been dreadful; and if ever a free and stable government Parliament, take place in it, which we sincerely wish may be soon, it will have been purchased at an immense price, by enormities which will disgrace it whilst the remembrance of them lasts.

The former parliaments of France were sovereign courts established by the king, finally to determine all disputes between particular persons, and to pronounce on appeals from sentences given by inferior judges. There were ten of these parliaments in France, of which that of Paris was the chief, its privileges and jurisdiction being of the greatest extent. It consisted of eight chambers: the grand chamber, where causes of audience were pleaded; the chamber of written law; the chamber of counsel; the Tournelle criminal, for judging criminal affairs; the Tournelle civil, in aid of the grand chamber; and three chambers of inquests, where processes were adjudged in writing: besides these, there were also the chamber of vacations, and those of requests. In 1771 the king thought fit to branch the parliament of Paris into six different parliaments, under the denomination of superior courts, each parliament having similar jurisdiction. Under their second rate of kings, this parliament, like that of England, and was the king's council; it gave audience to ambassadors, and consulted of the affairs of war and government. The king, like ours, at that time presided in them, without being at all master of their resolutions. But in after times their authority was abridged; as the kings reserved the decision of the grand affairs of the public to their own councils; leaving none but private ones to the parliaments. The parliament of Paris also enjoyed the privileges of verifying and registering the king's arrests or edicts, without which those edicts were of little or no value.

Parliament of Sweden, consists of four estates, with the king at their head. These estates are, 1. The nobility and representatives of the gentry; with whom the colonels, lieutenant colonels, majors, and captains of every regiment, sit and vote. 2. The clergy; one of which body is elected from every rural deanery of ten parishes; who, with the bishops and superintendents, amount to about 200. 3. The burgheers, elected by the magistrates and council of every corporation as their representatives, of whom there are four for Stockholm, and two for every other town, amounting in the whole to about 150. 4. The peasants, chosen by the peasants out of every district; who choose one of their own rank, and not a gentleman, to represent them: these amount to about 250.

All these generally meet at Stockholm: and after the state affairs have been represented to them from the throne, they separate, and sit in four several chambers or houses, in each of which affairs are carried on by majority of votes; and every chamber has a negative in the passing any law.

Parma, an ancient, rich, populous, and handsome town of Italy, capital of the duchy of the same name, with a citadel, a bishop's see, and an university. The number of inhabitants is about 36,000. It has a magnificent cathedral, and the largest opera house in Europe, which has seats for 8000 people; but as it required a vast number of candles, which occasioned great expense, they have contrived another which has room for 3000 spectators. The dome and the church of St John are painted by the famous Corregio, who was a native of
PAR

PARMA [790]

of this place. The citadel, which is very near the city, is built in the same taste as that at Antwerp. In 1734 there was a bloody battle fought here; and in 1741, by the treaty of Aix-la-Chapelle, the duchies of Parma, Placentia, and Guastalla, were given to Don Philip, brother to Don Carlos above mentioned. In 1814 these duchies were bestowed upon Maria Louisa late empress of France, with the right of succession to her son Napoleon Charles. It is 30 miles south-east of Cremona, and 60 south east of Milan. E. Long. 10. 51. N. Lat. 44. 50.

PARMA, the duchy of, a province of Italy, bounded on the north by the Po; on the north-east by the Mantuan; on the east by the duchy of Modena; on the south by Tuscany; and on the west by the duchy of Placentia. The air is very wholesome, on which account the inhabitants live to a great age. The soil is very fertile in corn, wine, oil, and hemp; the pastures feed a great number of cattle, and the cheese is in very high esteem. Here are considerable mines of copper and silver.

PARMESAN CHEESE, a sort of cheese much esteemed among the Italians; so named from the duchy of Parma where it is made, and whence it is conveyed to various parts of Europe.

The excellent pasture grounds of this country are watered by the Po; and the cows from whose milk this cheese is made yield a great quantity of it. Of this cheese there are three sorts; the fromaggio di forma, about two palms in diameter, and seven or eight inches thick; and the fromaggio di ribolte and di ribolite, which are not so large. This cheese is of a saffron colour; and the best is kept three or four years. See CHEESE.

PARMIGIANO, a celebrated painter, whose true name was Francesco Mazzuoli; but he received the former from the city of Parma, where he was born, in 1504. He was brought up under his two uncles, and was an eminent painter when but 16 years of age. He was famous all over Italy at 19; and at 23 performed such wonders, that when the general of the emperor Charles V. took Rome by storm, some of the common soldiers having, in sacking the town, broke into his apartments, found him intent upon his work, and were instantly so struck with the beauty of his pieces, that instead of involving him in the plunder and destruction in which they were then employed, they resolved to protect him from all manner of violence; which they actually performed. His works are distinguished by the beauty of the colouring, the invention, and drawing. His figures are spirited and graceful, particularly with respect to the choice of attitude, and in their dresses. He also excelled in music, in which he much delighted.

In large compositions Parmigianu did not always reach a high degree of excellence; but in his holy families, and other similar subjects, the gracefulness of his heads, and the elegance of his attitudes, are peculiarly delightful. For the celebrity of his name he seems to be chiefly indebted to his numerous drawings and etchings; for his life being short, and a great part of it consumed in the idle study of alchemy, in pursuit of the philosopher's stone, and in the seducing avocations of music and gambling, there was but little time left for application to the laborious part of his business. His paintings in oil are few in number, and held in high esteem, as are also his drawings and etchings; good impressions of these last being very rarely to be found. He was the first that practised the art of etching in Italy; and probably he did not at first know, that it had been for some years practised in Germany. When he set out for Rome, he was advised to take some of his pictures with him, as a means of getting himself introduced into the acquaintance of the nobility and artists in that celebrated city. One of them is mentioned by his biographers as a masterpiece. It was his own portrait painted upon a piece of wood of a convex form, in imitation of a convex mirror. The surface is said to have been so wonderfully executed, that it had the appearance of real glass, and the head, as well as every part of the furniture of the chamber in which he was supposed to sit, was so artfully managed, that the whole formed a very complete piece of deception. At Rome he was employed by Pope Clement VII. who was highly pleased with his performances, and rewarded him liberally. A Circumcision which he painted for him was particularly esteemed as a capital work. In it Parmigianu was successful in introducing a variety of lights, without destroying the general harmony. When Charles V. came to Bologna to be crowned emperor of the Romans, Parmigianu failed not to be present at that singular ceremony; and so accurately marked the countenance of the emperor, that at his return home, he was enabled from memory to make out a surprising likeness. In the same piece he introduced the figure of Fame placing a crown of laurel on the head of the emperor, whilst a young Hercules presented him with a globe of the world. Before it was quite finished, the painter and his piece were introduced to Charles by the Pope, but to little purpose; for the emperor left Bologna a few days after, without ordering him any recompense for his labour. In the church of Madonna della Stercato at Parma are still to be seen several of the works of this artist; among which one of Sibyls, and two others of Moses, and of Adam and Eve, are much admired. So also is a Dead Christ, with the Virgin in sorrow, in the church of the Dominicans at Cremona. In the Houghton collection of pictures, now in possession of the empress of Russia, is one of his best pictures, representing Christ laid in the sepulchre, for which he is said to have been knighted by the duke of Parma. His principal works are at Parma, where he died poor in 1540.

PARNASSIA, grass of Parnassus; a genus of plants belonging to the pentandria class. See BUTANT Indcr.

PARNASSUS (Strabo, Pindar, Virgil), a mountain of Phocis, near Delphi, and the Mount Cithera and Helicon, with two tops (Ovid, Lucan); the one called Cerebha, sacred to Apollo; and the other Nax, sacred to Bacchus, (Juvenal). It was covered with bay trees (Virgil); and originally called Larnassus, from Deucalion's larnax or ark, thither conveyed by the flood, (Stephanus, Scholiast on Apollonius); after the flood, Parnassus; from Har Nahas, changing the A into p, the hill of divination or augury (Pausus); the oracle of Delphi standing at its foot.

Chandler *; who visited it, thus describes it: "Par * Travelling northward from about Delphi toward the Oetean mountains, separated the western Locri from those who possessed the sea coast before Euboea. It was a place of refuge
PAR

Parthenes. refuge to the Delphians in times of danger. In the
delay, which happened under Deucalion, the natives were
saved upon it by following the cry of wolves. On the
invasion by Xerxes, some transported their families over
to Achaia, but many concealed them in the mountain,
and in Corycium, a grotto of the Nymphs. All Par-
thenes was renowned for sanctity, but Corycium was
the most noted among the hallowed caves and places. 4
On the way to the summit of Parthenes, says Pausanius,
as much as 60 stadia beyond Delphi, is a brazen image;
and from thence the ascent to Corycium is easier for a
man on foot, and for mules and horses. Of all the caves
in which I have been, this appeared to me the best
worth seeing. On the coasts, and by the sea side, are
more can be numbered; but some are very famous
both in Greece and in other countries. The Corycian
cave exceeds in magnitude those I have mentioned,
and for the most part may be passed through without a light.
It is sufficiently high: and has water, some springing
up, and yet more from the roof, which petrifies; so that
the bottom of the whole cave is covered with sparry ice-
cles. The inhabitants of Parthenes esteem it sacred to
the Corycian Nymphs, and particularly to Pan. — From
the cave to reach the summits of the mountain is dif-
cult even to a man on foot. The summits are above the
clouds, and the women called Thyiades madden on them
in the rites of Bacchus and Apollo. 5 Their frantic or-
gies were performed yearly. Wheler and his company
ascended Parthenes from Delphi, some on horses, by a
track between the stadium and the clefts of the moun-
tain. Stairs were cut in the rock, with a strait channel,
perhaps a water duct. — In a long hour, after many tra-
cverses, they gained the top, and entering a plain turned
to the right, towards the summits of Castalia, which are
divided by deep precipices. From this eminence they
had a fine prospect of the gulf of Corinth, and of the
coast; Mount Cirphis appearing beneath them as a
plain, bounded on the east by the bay of Aspromita,
and on the west by that of Salono. A few shepherds
had huts there. They returned to the way which they
had quitted, and crossed a hill covered with pines and
snow. On their left was a lake, and beyond it a peak,
exceedingly high, white with snow. They travelled to
the foot of it through a valley, four or five miles in
compass; and rested by a plentiful fountain called Dro-
sonippe, the stream boiling up a foot in diameter, and
nearly as much above the surface of the ground. It
runs into the lake, which is about a quarter of a mile
distant to the south-east. They did not discover Cory-
cium, or proceed farther on, but keeping the lake on
their right, came again to the brink of the mountain,
and descended by a deep and dangerous track to Baco-
vlo, a village four or five miles eastward from Delphi.
It was the opinion of Wheler, that no mountain in
Greece was higher than Parthenes; that it was not in-
superior to Mount Cenis among the Alps; and that, if
detached, it would be seen at a greater distance than even
Mount Athos. The summits are perpetually increasing,
every new fall of snow adding to the perennial heap,
while the sun has power only to thaw the superficies.
Castalis, Pleistus, and innumerable springs are fed, some
invisibly, from the lakes and reservoirs, which, without
these drains and subterraneous vents, would swell, espe-
cially after heavy rains and the melting of snow, so as
to fill the valleys, and run over the tops of the rocks
down upon Delphi, spreading wide an inundation, sim-
lar, as has been surmised, to the Deucalian del-
luge."

PARNEW, DR THOMAS, a very ingenious divine
and poet in the early part of the 18th century. He
was archdeacon of Clogher, and the intimate friend of Mr
Pope; who published his works, with an elegant copy
of recommendatory verses prefixed. He died in 1718,
age 39.

Johnson† says, "The life of Dr Parnell is a task of
which I should very willingly decline, since it has been
the Poet's lately written by Goldsmith, a man of such variety
of powers, and such facility of performance, that he always
seemed to do best that which he was doing; a man who
had the art of being minute without tediousness, and gen-
eral without confusion; whose language was copious
without exuberance, exact without constraint, and easy
without weakness.

"What such an author has told, who would tell a
again? I have made an extract from his larger narrative;
and shall have this gratification from my attempt, that
it gives me an opportunity of paying due tribute to the
memory of a departed genius.

'To yea γεράνς τοις Σακράλίς,'

"The general character of Parnell is not great ex-
tent of comprehension, or fertility of mind. Of the lit-
tle that appears still less is his own. His praise must be
derived from the easy sweetness of his diction: in his
verses there is more happiness than pains; he is srylic-
ly without effort, and always delights though he never
ravishes; every thing is proper, yet every thing seems
sexual. If there is some appearance of elaboration in
the Hermit, the narrative, as it is less airly, is less plea-
sing. Of his other compositions, it is impossible to say
whether they are the productions of Nature so excellent
as not to want the help of Art, or of Art so refined as
to resemble Nature."

PARODICAL DEGREES, in an equation, a term
sometimes used to denote the several regular terms in a
quadratic, cubic, biquadratic, &c. equation, when the
indices of the powers ascend or descend orderly in an
arithmetical progression. Thus, \( x^2 + mx + n = p \) is
a cubic equation where no term is wanting, but having
all its parodic degrees; the indices of the terms regularly
descending thus, 3, 2, 1, 0.

PARODY, a popular maxim, adage, or proverb.

PARODY, is also a poetical pleasantry, consisting in
applying the verses written on one subject, by way of
ridicule, to another; or in turning a serious work into
a burlesque, by affecting to observe as near as possible
the same rhymes, words, and cadences.

The parody was first set on foot by the Greeks; from
whom we borrow the name. It comes near to what
some of our late writers call travesty. Others have
more accurately distinguished between a parody and bur-
lesque; and they observe, that the change of a single
word may parody a verse; or of a single letter a word.
Thus, in the last case, Cato exposed the inconstant dis-
position of Marcus Fulvius Nobilior, by changing No-
ibilior into Mobilior. Another kind of parody consists
in the mere application of some known verse, or part of
a verse of a writer, without making any change in it,
with a view to expose it. A fourth instance is that of
writing verses in the taste and style of authors little ap-
proved,
proven. The rules of parody regard the choice of a subject, and the manner of treating it. The subject should be a known and celebrated work: as to the manner, it should be by an exact imitation, and an intermixture of good-natured pleasantness.

Parole, in a military sense, the promise made by a prisoner of war, when he has leave to go anywhere, of returning at a time appointed, if not exchanged.

Parole, means also a word given out every day in orders by the commanding officer, both in camp and garrison, in order to know friends from enemies.

Paronomasia, in Rhetoric, a pun; or a figure whereby words nearly alike in sound, but of very different meanings, are affectedly or designedly used. See Oratory, No. 76.

Paronychia, the Whitlow, in Surgery, is an abscess at the end of the fingers. According as it is situated more or less deep, it is differently denominated, and divided into species. See Surgery Index.

Paros, in Ancient Geography, an island of the Egean sea, one of the Cyclades, with a strong clogonomial town, 38 miles distant from Delos (Pliny, N. E. I.), Anciently called Paetec and Minea (Pliny); also Demetrias, Zacynthus, Hyria, Hysubseteq, and Cabornis (Nicanor). The country of Archilochus the iambic poet (Strabo). An island famous for its white marble (Virgil, Horace, Ovid), called lycnites, because dug with lamps (Pliny). The name of Cabornis is borrowed, according to Stephanus, from one Cabarnus, who first informed Ceres of the rape of her daughter Proserpine; or, according to Hesychius, from the Cabarni, the priests of Ceres being so called by the inhabitants of this island. The name of Minea is borrowed from Minos king of Crete, who subdued this, as he did most of the other islands of the Egean sea: It was called Paros, which name it retains to this day, from Paros the son of Parthachus, or as Stephanus will have it, of Jason the Argonaut. Paros, according to Pliny's computation, is distant from Naxos seven miles and a half, and 28 from Delos. Some modern travellers suppose that it is 80, others only 50 miles in compass. Pliny says it is half as large as Naxos, that is, between 36 and 37 miles in compass. It was a rich and powerful island, being termed the most wealthy and happy of the Cyclades, and by Cornelius Nepos an island elated with its riches. The city of Paros, the metropolis, is styled by Stephanus a potent city, and one of the largest in the Archipelago: the present city of Paros, now Parichia, is supposed to have been built upon its ruins, the country abounding with valuable monuments of antiquity. The very walls of the present city are built with columns, architraves, pedestals, mingled with pieces of ancient marble of a surprising magnitude, which were once employed in more noble edifices. Paros was indeed formerly famous for its marble, which was of an extraordinary whiteness, and in such request among the ancients that the best statuaries used no other (A). The island is provided with several capacious and safe harbours, and was anciently much resorted to by traders. It was, according to Thucydides, originally peopled by the Phenicians, who were the first masters of the sea. Afterwards the Carians settled here, as we are told by Thucydides and Diodorus. But these two authors differ as to the time when the Carians came first into the island; for Thucydides tells us, that the Carians were driven out by the Cretans under the conduct of Minos; and Diodorus writes, that the Carians did not settle here till after the Trojan war, when they found the Cretans in possession of the island. Stephanus thinks that the Cretans, mixed with some Arcadians, were the only people that ever possessed this island. Minos himself, if we believe Pliny, resided some time in the island of Paros, and received here the melancholy news of the death of his son Androgeus, who was killed in Athens, after he had distinguished himself at the public games. We find the inhabitants of this island chosen from among all the Greeks by the Milesians to compose the differences which had for two generations rent that unhappy state into parties and factions. They acquitted themselves with great prudence, and reformed the government. They assisted Darius in his expedition against Greece with a considerable squadron; but after the victory obtained by Miltiades at Marathon, they were reduced to great straits by that general. However, after blocking up the city for 26 days, he was obliged to quit the entrepise, and return to Athens with disgrace. Upon his departure, the Persians were informed that Timo, a priestess of the national gods, and then his prisoner, had advised him to perform some secret ceremony in the temple of Ceres, near the city; assuring him that he would thereby gain the place. Upon this information they sent deputies to consult the oracle of Delphi, whether they should punish her with death, for endeavouring to betray the city to the enemy, and discovering the sacred mysteries to Miltiades. The Pythian answered that Timo was not the adviser; but that the gods, having resolved to destroy Miltiades, had only made her the instrument of his death. After the battle of Salamis, Themistocles subjected Paros and most of the other neighbouring islands to Athens, exacting large sums from them by way of punishment for having favoured the Persians. It appears from the famous monument of Adulas, which Cosmus of Egypt has described with great exactness, that Paros and the other Cyclades were once subject to the Ptolemies of Egypt. However, Paros fell again under the power of the Athenians, who continued masters of it till they were driven out by Mithridates.

(A) Sutherland says, "that while its marble quarries continued to be worked, Paros was one of the most flourishing of the Cyclades; but on the decline of the eastern empire they were entirely neglected, and are now converted into caves, in which the shepherds shelter their flocks. We have been in several of these subterraneous folds, which put me much in mind of Homer's description of Polyphemus. The common walls are almost entirely composed of marble; and in examining a very small part of one, we found several pieces of cornice and base relief. Several fine blocks of marble (fragments of columns) are lying close to the water's edge; and seem to have been brought there by travellers, who, for want of a proper purchase to get them on board, have not been able to carry them farther."
PAR

PAR

thridates the Great. But that prince being obliged to
yield to Sylla, to Lucullus, and to Pompey, this and
the other islands of the Archipelago submitted to the
Romans, who reduced them to a province with Lydia,
Phrygia, and Caria.

Mr Sutherland, who lately visited Paros, says, that
"the water in it is excellent; and as that which we got
at Messina has been complained of, as being too hard
to make proper pesse sugar for the people, all the casks
are ordered to be emptied and refilled. The Russians
made the place their grand arsenal; their powder maga-
nines, and several other buildings, are still standing;
and the island is considerably indebted to them for
improving the convenience for water, and for the trade
which the cash they expended introduced among the
inhabitants."

PAROTIDES, or Parotides, are glands situated
on each side of the head. See Anatomy Index.

PAROXYSM, in Medicine, the severe fit of a dis-
case, under which it grows higher or exasperated; as
of the gout, &c.

PARR, CATHERINE, queen of England, was the el-
dester daughter of Sir Thomas Parr of Kendal. She
was first married to John Nevil, Lord Latimer; after whose
death, by her marriage with Henry VIII, she was raised
to the throne. The royal nuptials were solemnized at
Hampton Court on the 22d of July 1543. Being reli-
giously disposed, she was, in the early part of her life,
a zealous observer of the Reformed rites and ceremonies;
but in the dawning of the Reformation, she became as
zealous a promoter of the Lutheran doctrine; yet with
such prudence and circumspection as her perilous situa-
tion required. Nevertheless, we are told, that she was
in great danger of falling a sacrifice to the Papish fac-
tion, the chief of whom was Bishop Gardiner: he drew
up articles against her, and prevailed on the king to sign
a warrant to remove her to the Tower. This warrant
was, however, accidentally dropped, and immediately
conveyed to her majesty. What her apprehensions
must have been on this occasion may be easily imagined.
She knew the monarch, and she could not help recol-
clecting the fate of his former queens. A sudden illness
was the natural consequence. The news of her indis-
pension brought the king to her apartment. He was
laviish in expressions of affection, and sent her a physi-
ian. His majesty being soon after also somewhat indis-
pensed, she prudently returned the visit; with which the
king seemed pleased, and began to talk with her on re-
ligious subjects, proposing certain questions, concerning
which he wanted her opinion. She answered, that such
profound speculations were not suited to her sex; that
it belonged to the husband to choose principles for his
wife; the wife's duty was, in all cases, to adopt im-
plicitly the sentiments of her husband; and as to her-
selv, it was doubly her duty, being blessed with a
husband who was qualified, by his judgment and learn-
ing, not only to choose principles for his own family,
but for the most wise and knowing of every nation.
"Not so, by St Mary," replied the king; "you are
now become a doctor, Kate, and better fitted to give
than receive instruction." She meekly replied, that
she was sensible how little she was entitled to these
praises; that though she usually declined not any con-
versation, however sublime, when proposed by his ma-
jectly, she well knew that her conceptions could serve
to no other purpose than to give him a little momentary
amusement; that she found the conversation a little ap-
to languish when not revived by some opposition, and
she had ventured sometimes to feign a variety of senti-
ments, in order to give him the pleasure of refuting her;
and that she also proposed, by this innocent arti-
ifice, to engage him into topics whence she had observed,
by frequent experience, that she reaped profit and in-
struction. "And is it so, sweet-heart?" replied the king;
"then we are perfect friends again." He embraced her
with great affection, and sent her away with assurances
of his protection and kindness.

The time being now come when she was to be sent
to the Tower, the king, walking in the garden, sent
for the queen, and met her with great good humour;
when lo the chancellor, with forty of the guards, ap-
proached. He fell upon his knees, and spoke softly
with the king, who called him knave, arrant knave,
beast, fool, and commanded him instantly to depart.
Henry then returned to the queen, who ventured to
intercede for the chancellor: "Ah, poor soul," said
the king, "thou little knowest how evil he deserveth
this grace at thy hands. Of my word, sweet-heart,
he hath been toward thee an arrant knave; and so let
him go." The king died in January 1547, just three
years and a half after his marriage with this second
Catherine; who in a short time was again espoused to
Sir Thomas Seymour lord-admiral of England; and in
September 1548 she died in childbed. The historians
of this period generally insinuate that she was poisoned
by her husband, to make way for his marriage with the
lady Elizabeth.

That Catherine Parr was beautiful is beyond a
doubt: that she was pious and learned is evident from
her writings; and that her prudence and sagacity were
not inferior to her other accomplishments, may be
concluded from her holding up the passion of a capri-
cious tyrant as a shield against her enemies; and that
at the latter end of his days, when his passions were
enfeebled by age, and his peevish austerity increased
by disease. She wrote, 1. Queen Catherine Parr's la-
mentation of a sinner, bewailing the ignorance of her
blind life; Lond. 8vo. 1548, 1563. 2. Prayers or me-
ditations, wherein the mynd is stirred patiently to suffer
all afflictions here, to set at nought the vain prospe-
ritie of this worlde, and alwayes to long for the everlastyng
felicitie. Collected out of holy works, by the most
virtuous and gracious princesse Katherine, Queen of
England, France, and Irelande. Printed by John
Wayland, 1545, 4to, 1561, 12mo. 3. Other Medita-
tions, Prayers, Letters, &c. unpublished.

PARR, THOMAS, or Old Parr, a remarkable En-
lishman, who lived in the reigns of ten kings and
queens; married a second wife when he was 120, and
had a child by her. He was the son of John Parr,
a husbandman of Wimington, in the parish of Aiderby,
in the county of Salop, where he was born in the year
1483. Though he lived to the vast age of upwards
of 152 years, yet the tenor of his life admitted but of
little variety; nor can the detail of it be considered of
importance, further than what will arise from the gra-
tification of that curiosity which naturally inquires after
the mode of living which could lengthen life to such
extreme
extreme old age. Following the profession of his father, he laboured hard, and lived on coarse fare. Taylor the water poet says of him:

Good wholesome labour was his exercise,
Down with the lamb, and with the lark would rise;
In mire and toiling sweat he spent the day,
And to his team he whistled time away:
The cock his night-clock, and till day was done,
His watch and chief sun-dial was the sun.
He was of old Pythagoras' opinion,
That green cheese was most wholesome with an onion;
Coarse messin bread, and for his daily swig,
Milk, butter milk, and water, whey, and whig:
Sometimes metheglin, and by fortune happy,
He sometimes sipp'd a cup of ale most nappy,
Cyder or perry, when he did repair
To a Whitsun ale, wake, wedding, or a fair,
Or when in Christmas time he was a guest
At his good landlord's house among the rest:
Else he had little leisure time to waste,
Or to the alehouse huff-cap ale to taste.
Nor did he ever hunt a tavern fox;
Nor knew a coach, tobacco, or the.
His physic was good better, which the soil
Of Salop yields, more sweet than Candy oil;
And garlic he esteem'd above the rate
Of Venice treacle or best mithridate.
He entertain'd no gout, no ache he felt,
The air was good and temperate where he dwelt;
While mavisises and sweet-toned nightingales
Did chant him roundelay and madrigals.
Thus living within bounds of Nature's laws,
Of his long lasting life may be some cause.

And the same writer describes him in the following two lines:

From head to heel, his body had all over
A quick set, thick set, natural hair cover.

The manner of his being conducted to London is also noticed in the following terms: "The right honourable Thomas earl of Arundel and Surrey, earl marshal of England, on being lately in Shropshire to visit some lands and manors which his lordship holds in that county, or for some other occasions of importance which caused his lordship to be there, the report of this aged man was signified to his honour, who hearing of so remarkable a piece of antiquity, his lordship was pleased to see him; and in his innate, noble, and Christian piety, he took him into his charitable tuition and protection, commanding that a litter and two horses (for the more easy carriage of a man so feeble and worn with age) to be provided for him; also, that a daughter of his, named Lucy, should likewise attend him, and have a horse for her own riding with him: and to cheer up the old man, and make him merry, there was an antique-faced fellow, with a high and mighty no-beard, that had also a horse for his carriage. These were all to be brought out of the

country to London by easy journeys, the charge being allowed by his lordship; likewise one of his lordship's own servants, named Bryan Kelly, to ride on horseback with them, and to attend and defray all manner of reckonings and expenses. All which was done accordingly as follows:"

"Winnington is a parish of Alderbury, near a place called the Welch Pool, eight miles from Shrewbury; from whence he was carried to Wem, a town of the earl's aforesaid; and the next day to Shifnal, a manor-house of his lordship's, where they likewise stayed one night: from Shifnal they came to Wolverhampton, and the next day to Birmingham, and from thence to Coventry. Although Master Kelly had much to do to keep the people off, that pressed upon him in all places where he came, yet at Coventry he was most oppressed, for they came in such multitudes to see the old man, that those that defended him were almost quite tired and spent, and the aged man in danger of being stifled; and, in a word, the rabble were so unruly, that Bryan was in doubt he should bring his charge no farther; so greedy are the vulgar to hearken to or gaze after novelties. The trouble being over, the next day they passed to Daintree, to Stony Stratford, to Radburne, and so to London; where he was well entertained and accommodated with all things, having all the aforesaid attendance at the sole charge and cost of his lordship." When brought before the king, his majesty, with more acuteness than good manners, said to him, "You have lived longer than other men, what have you done more than other men?" He answered, "I did penance when I was a hundred years old." This journey, however, proved fatal to him; owing to the alteration in his diet, to the change of the air, and his general mode of life, he lived but a very short time, dying the 4th of November 1635 (A); and was buried in Westminster Abbey. After his death, his body was opened; and an account was drawn up by the celebrated Dr Harvey, part of which we shall lay before our readers.

"Thomas Parr was a poor country man of Shropshire, whence he was brought up to London by the right honourable Thomas earl of Arundel and Surrey; and died after he had outlived nine princes, in the tenth year of the tenth of them, at the age of 152 years and nine months.

"He had a large breast, lungs not fungous, but sticking to his ribs, and distended with blood; a liveliness in his face, as he had a difficulty of breathing a little before his death, and a long lasting warmth in his armpits and breast after it; which sign, together with others, was so evident in his body, as they use to be on those that die by suffocation. His heart was great, thick, fibrous, and fat. The blood in the heart blackish and diluted. The cartilages of the sternum not more bony than in others, but flexible and soft. His viscera were sound and strong, especially the stomach; and it was observed of him, that he used to eat often by night and day, though contented with old

(A) The author of a book entitled Long Livers, 8vo. 1722, which Oldys in his MS. notes on Fuller ascribes to one Robert Samber, against all evidence says, p. 89, that Parr died sixteen years after he had been presented to the king, 24th of November 1651."
old cheese, milk, coarse bread, small beer, and whey; and, which is more remarkable, that he ate at midnight a little before he died. His kidneys were covered with fat, and pretty sound; only on the interior surface of them were found some aqueous or serous abscesses, whereof one was near the bigness of a hen egg, with a yellowish water in it, having made a roundish cavity, impressed on that kidney; whence some thought it came that a little before his death a suppression of urine had befal- ten him; though others were of opinion, that his urine was suppressed upon the regurgitation of all the serosity into his lungs. Not the least appearance there was of any stony matter either in the kidneys or bladder. His bowels were also sound, a little whitish without. His spleen very little, hardly equaling the bigness of one kidney. In short, all his inward parts appeared so healthy, that if he had not changed his diet and air, he might perhaps have lived a good while longer. The cause of his death was imputed chiefly to the change of food and air; forasmuch as coming out of a clear, thin, and free air, he came into the thick air of London; and after a constant plain and homely country diet, he was taken into a splendid family, where he fed high and drank plentifully of the best wines, whereupon the natural functions of the parts of his body were overcharged, his lungs obstructed, and the habit of the whole body quite disordered; upon which there could not but ensue a dissolution. His brain was sound, entire, and firm; and though he had lost the use of his eyes, nor much of his memory, several years before he died, yet he had his hearing and apprehension very well; and was able, even to the 130th year of his age, to do any husbandman's work, even thrashing of corn.

The following summary of his life is copied from Oldys's MS. notes on Fuller's Worthies: Old Parr was born 1483; lived at home until 1500, set. 17, when he went out to service. 1518, set. 35, returned home from his master. 1522, set. 39, spent four years on the remainder of his father's lease. 1543, set. 60, ended the first lease he renewed of Mr. Lewis Porter. 1563, set. 80, married Jane, daughter of John Tyler, a merchant, by whom he had a son and a daughter, who both died very young. 1564, set. 81, ended the second lease which he renewed of Mr. John Porter. 1585, set. 102, ended the third lease he had renewed of Mr. Hugh Porter. 1588, set. 105, did penance in Alderbury church, for lying with Katharine Milton, and getting her with child. 1595, set. 112, he buried his wife Jane; after they had lived 32 years together. 1605, set. 122, having lived 10 years a widower, he married Jane, widow of Anthony Adda, daughter of John Lloyd of Gilsells, in Montgomeryshire, who survived him. 1635, set. 152, he died; after they had lived together 50 years, and after 50 years possession of his last lease. See Longevity.

PARA, a genus of birds belonging to the order of grallae. See Ornithology Index.

PARRELS, in a ship, are frames made of truck, ribs, and ropes, which having both their ends fastened to the yards, are so contrived as to go round about the masts, that the yards by their means may go up and down upon the mast. These also, with the breast ropes, fasten the yards to the masts.

PARRET, or PARR RED RIVER, has its rise in the southern part of Somersetshire in England, and being joined by several other small rivers, the Evel; and about four miles from this junction, it is joined by the Tone or Thone, a pretty large river, rising among the hills in the western parts of this county. About two miles below the junction, it passes by the town of Bridgewater, and falls into the Bristol channel in Bridgewater bay.

PARRHASIUS, a famous ancient painter of Ephesus, or, as some say, of Athens; he flourished about the time of Socrates, according to Xenophon, who hath introduced him into a dialogue discoursing with that philosopher. He was one of the best painters in his time. Pliny says, that it was he who first gave symmetry and just proportions in that art; that he was likewise the first who knew how to express the truth and life of characters, and the different airs of the face; that he discovered a beautiful disposition of the head, and heightened the grace of the visage. It is allowed even by the masters in the art, that he far outshone them in the glory of succeeding in the outlines, in which consists the grand secret of painting. But it is also remarked by Pliny, that Parrhasius became insupportable with pride; and was so very vain as to give himself the most flattering epithets; such as, the tenderest, the softest, the grandest, the most delicate, and the perfector of his art. He boasted that he was sprung from Apollo, and that he was born to paint the gods; that he had actually drawn Hercules touch by touch, that hero having often appeared to him in dreams. When the plurality of voices was against him at Samos in favor of Timanthes, in the opinion of a picture of Ajax provoked against the Greeks, for adjudging to Ulysses the arms of Achilles, he answered a person who comforted him on his check, "For my part I don't trouble myself at the sentence; but I am sorry that the son of Telamon hath received a greater outrage than that which was formerly put upon him so unjustly." Ælian relates this story, and tells us that Parrhasius affected to wear a crown of gold upon his head, and to carry in his hand a baton, studded with nails of the same metal. He worked at his art with pleasure, often indeed singing. He was very licentious and loose in his pictures; and he is said, by way of amusement, to have represented the most infamous objects. His Atlantias, with her spouse Meleager, was of this kind. This piece was afterwards devised as a legacy to the emperor Tiberius, upon condition that, if he was displeased with the subject, he should receive a million sesterces instead of it. The emperor, covetous as he was, not only preferred the picture to that sum, but even placed it in his most favorite apartment. It is also said, that, though Parrhasius was excelled by Timanthes, yet he excelled Zeuxis. Among his pictures is a celebrated one of Theseus; and another representing Meleager, Hercules, and Perseus, in a group together; as also Æneas, with Castor and Pollux, in a third.

PARRHASIUS, Janus, a famous grammarian in Italy, who was born at Cosenza in the kingdom of Naples, 1470. He was intended for the law, the profession of his ancestors; but he refused it, and cultivated classical learning. His real name was Johannes Paulus Vaticanus; but according to the order of the grammarians of the age, he took instead of it Parrhasius. He taught at Milan with much reputation, being admired for a grace...

Parrhasius ful delivery, in which he chiefly excelled other professors. — It was this charm in his voice, which brought a vast concourse of people to his lectures; and among others he had the pleasure to see General Trimmolos, who was then three score years old. He went to Rome when Alexander VI. was pope; and was like to be involved in the misfortunes of Bernardino Cajetan and Silius Savello, with whom he had some correspondence; but he escaped the danger, by the information of Thomas Phedrus, professor of rhetoric, and canon of St John Lateran, whose advice he followed in retiring from Rome. Soon after, he was appointed public professor of rhetoric at Milan; but the liberty he took to censure the teachers there as arrant blockheads, provoked them in return to asperse his morals. They said he had a criminal converse with his scholars: which being a crime extremely abhorred by the Milanese, our professor was obliged to leave Milan. He went to Vicenza, where he obtained a larger salary; and he held this professorship till the states of the Venetians were laid waste by the troops of the League: upon which he went to his native country, having made his escape through the army of the enemy. He was at Cosenza, when his old friend Phedrus persuaded Julius to send for him to Rome; and though that design proved abortive by the death of the pope, yet, by the recommendation of John Lascaris, he was called thither under his successor Leo X. Leo was before favourably inclined to him; and on his arrival at Rome, appointed him professor of polite literature. He had been some time married to a daughter of Demetrius Chalcondylas; and he took with him to Rome, Basil Chalcondylas, his wife's brother, and brother of Demetrius Chalcondylas, professor of the Greek tongue at Milan. He did not long enjoy this office conferred upon him by the pope; for, worn out by his studies and labours, he became so afflicted with the gout, that for some years he had no part of his body free, except his tongue: having almost lost the use of both his legs and both his arms. He laboured besides under so great a degree of poverty, as put him out of all hopes of being ever in a better situation; so that he left Rome, and returned into Calabria, his native country, where he was tormented a long while with a fever, and at last died in the greatest misery. He left his library to his friend Seripandus, brother to Cardinal Jerome Seripandus, who built him a tomb in the convent of the Austin friars at Naples. There are several books ascribed to him; and in the dedication of one of them, his character is drawn to great advantage by Henry Stephens.

PARRHESIA. See ORATORY, No 88.

PARRICIDE, the murder of one's parents or children. By the Roman law, it was punished in a much severer manner than any other kind of homicide. After being scourged, the delinquents were sewed up in a leather sack, with a live dog, a cock, a viper, and an ape, and so cast into the sea. Solon, it is true, in his laws, made none against parricide; apprehending it impossible that one should be guilty of so unnatural a barbarity. And the Persians, according to Herodotus, entertained the same notion, when they adjudged all persons who killed their reputed parents to be bastards. And upon some such reason as this must we account for the omission of an exemplary punishment for this crime in our English laws; which treat it no otherwise than as simple murder, unless the child was also the servant of the parent.

For though the breach of natural relation is unobserved, yet the breach of civil or ecclesiastical connexion, when coupled with murder, denominates it a new offence; no less than a species of treason, called parrucca prodicta, or petit treason; which, however, is nothing else but an aggravated degree of murder; although, on account of the violation of private allegiance, it is stigmatized as an inferior species of treason. And thus, in the ancient Gothic constitution, we find the breach both of natural and civil relations ranked in the same class with crimes against the state and sovereign.

PARROT. See Psittacus, Ornithology Index.

PARSHORE, a town of England in Worcestershire, seven miles from Worcester, and 102 from London, situated on the north side of the Avon, near its junction with the river Bow, being a considerable thoroughfare in the lower road from Worcester to London. A religious house was founded here in 604, a small part of which now remains, and is used as the parish church of Holy Cross, the whole of which contained above 10 acres. The Abbey church was 250 feet long, and 120 broad. The parish of Par Shore is of great extent, and hath within its limits many manors and chapels. At present it has two parishes, Holy Cross and St. Andrew. In Holy Cross church are several very antique monuments. Its chief manufacture is stockings. It contained 2479 inhabitants in 1811.

PARSLEY. See Apium, Botany Index.

PARSNIP. See Pastinaca, Botany Index.

PARSON and VICAR. A parson, persona ecclesia, is one that hath full possession of all the rights of a parochial church. He is called parson, personas, because by his person the church, which is an invisible body, is represented; and he is in himself a body corporate, in order to protect and discharge the rights of the church (which he personates) by a perpetual succession. He is sometimes called the rector or governor of the church; but the appellation of parson (however it may be depreciated by familiar, clownish, and indiscriminate use) is the most legal, most beneficial, and most honourable title that a parish priest can enjoy; because such a one (Sir Edward Coke observes), and he only, is said exem seu personam ecclesiae gerere. A parson has, during his life, the freehold in himself of the parsonage house, the glebe, the tithes, and other dues. But these are sometimes appropriated; that is to say, the benefice is perpetually annexed to some spiritual corporation, either sole or aggregate, being the patron of the living; whom the law esteems equally capable of providing for the service of the church as any single private clergyman.

The appropriating corporations, or religious houses, properiter, were wont to depute one of their own body to perform divine service, and administer the sacraments, in those parishes of which the society was thus the parson. This officiating minister was in reality no more than a curate, deputy, or viceregent of the appropriator, and therefore called vicarius, or "vicar." His stipend was at the discretion of the appropriator, who was, however, bound of common right to find somebody, qui illi de temporalibus, episcopo de spiritualibus, debet respondere. But this
Parson. this was done in so scandalous a manner, and the parishioners suffered so much by the neglect of the appropriators, that the legislature was forced to interpose: and accordingly it is enacted, by statute 30 Rich. II. c. 6, that in all appropriations of churches the diocesan bishop shall ordain (in proportion to the value of the church) a competent sum to be distributed among the poor parishes annually; and that the vicarage shall be sufficiently endowed. It seems the parishioners were frequently sufferers, not only by the want of divine service, but also by withholding those aids for which, among other purposes, the payment of tithes was originally imposed: and therefore in this act a pension is directed to be distributed among the poor parishes, as well as a sufficient stipend to the vicar. But he, being liable to be removed at the pleasure of the appropriator, was not likely to insist too rigidly on the legal sufficiency of the stipend; and therefore, by statute 4 Hen. IV. c. 12, it is ordained, that the vicar shall be a secural person, not a member of any religious house; that he shall be vicar perpetual, not removable at the caprice of the monastery; and that he should be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary; for these three express purposes, to do divine service, to inform the people, and to keep hospitality. The endowments, in consequence of these statutes, have usually been by a portion of the glebe, or land belonging to the parsonage, and a particular share of the tithes, which the appropriators found it most troublesome to collect, and which are therefore generally called petty or small tithes; the greater, or prelial tithes, being still reserved to their own use. But one and the same rule was not observed in the endowment of all vicarages. Hence some are more liberally, and some more scantily, endowed; and hence the tithes of many things, as wood in particular, are in some parishes rectorial, and in some vicarial tithes.

The distinction therefore of a parson and vicar is this: The parson has for the most part the whole right to all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, entitled to the best part of the profits, to whom he is in effect perpetual curate, with a standing salary. Though in some places the vicarage has been considerably augmented by a large share of the great tithes; which augmentations were greatly assisted by the statute 27 Car. II. c. 8, enacted in favour of poor vicars and curates, which rendered such temporary augmentations (when made by the appropriators) perpetual.

The method of becoming a parson or vicar is much the same. To both there are four requisites necessary; holy orders, presentation, institution, and induction. The method of conferring the holy orders of deacon and priest, according to the liturgy and canons, is foreign to the present purpose; any farther than as they are necessary requisites to make a complete parson or vicar. By common law, a deacon, of any age, might be instituted and inducted to a parsonage or vicarage; but it was ordained, by statute 13 Eliz. c. 12, that no person under twenty-three years of age, and in deacon's orders, should be presented to any benefice with cure; and if he were not ordained priest within one year after his induction, he should be ipso facto deprived: and now, by statute 13 and 14 Car. II. c. 4, no person is capable to be admitted to any benefice, unless he hath been first ordained a priest; and then he is, in the language of the law, a clerk in orders. But if he obtains orders, or a license to preach, by money or corrupt practices, (which seems to be the true, though not the common, notion of simony), the person giving such orders forfeits 40l. and the person receiving, 10l. and is incapable of any ecclesiastical preferment for seven years after.

Any clerk may be presented to a parsonage or vicarage; that is, the patron, to whom the advowson of the church belongs, may offer his clerk to the bishop of the diocese to be instituted. But when he is presented, the bishop may refuse him upon many accounts. As, 1. If the patron is excommunicated, and remains in contempt 40 days; or, 2. If the clerk be unfit: which unfitness is of several kinds. First, With regard to his person; as if he be a bastard, an outlaw, an excommunicate, an alien, under age, or the like. Next, With regard to his faith or morals: as for any particular heresy, or vice that is malum in se; but if the bishop alleges only in general, as that he is schismatically inveteratus, or objects a fault that is malum prohibitum merely, as haunting taverns, playing at unlawful games, or the like, it is not good cause of refusal. Or, lastly, The clerk may be unfit to discharge the pastoral office for want of learning. In any of which cases, the bishop may refuse the clerk. In case the refusal is for heresy, schism, inability of learning, or other matter of ecclesiastical cognizance, there the bishop must give notice to the patron of such his cause of refusal, who being usually a layman, is not supposed to have knowledge of it; else he cannot present by lapse; but if the cause be temporal, there he is not bound to give notice.

If an action at law be brought by the patron against the bishop for refusing his clerk, the bishop must assign the cause. If the cause be of a temporal nature, and the fact admitted (as, for instance, outlawry), the judges of the king's courts must determine its validity, or whether it be sufficient cause of refusal; but if the fact be denied, it must be determined by a jury. If the cause be of a spiritual nature, (as heresy, particularly alleged) the fact, if denied, shall also be determined by a jury; and if the fact be admitted or found, the court, upon consultation and advice of learned divines, shall decide its sufficiency. If the cause be of want of learning, the bishop need not specify in what points the clerk is deficient, but only allege that he is deficient; for the statute 9 Edw. II. st. 1. c. 13, is express, that the examination of the fitness of a person presented to a benefice belongs to the ecclesiastical judges. But because it would be nugatory in this case to demand the reason of refusal from the ordinary, if the patron were bound to abide by his determination, who has already pronounced his clerk unfit; therefore if the bishop return the clerk to be minus sufficiens in litterarum, the court shall write to the metropolitan to re-examine him, and certify his qualifications; which certificate of the archbishop is final.

If the bishop hath no objections, but admits the patron's presentation, the clerk so admitted is next to be instituted by him; which is a kind of investiture of the spiritual part of the benefice; for by institution, the care of the souls of the parish is committed to the charge of the clerk. When a vicar is instituted, he (besides the usual
of the crown, of holding such livings in commendam. Commenda
or ecclesia commendata, is a living commended
by the crown to the care of a clerk, to hold till a
proper pastor is provided for it. This may be temporary
for one, two, or three years, or perpetual, being a kind
of dispensation to avoid the vacancy of the living, and
is called a commendanda retinere. There is also a commen
de recipere, which is to take a benefice de novo, in the
bishop’s own gift, or the gift of some other patron con
senting to the same; and this is the same to him as an
institution and induction are to another clerk. 4. By re
signation. But this is of no avail till accepted by the
ordinary, into whose hands the resignation must be
made. 5. By deprivation, either by canonical censures,
or in pursuance of divers penal statutes, which declare
the benefice void, for some nonreance or neglect, or
else some malefeasance or crime: as for simony; for
maintaining any doctrine in derogation of the king’s
supremacy, or of the thirty-nine articles, or of the book
of common prayer; for neglecting after institution to
read the liturgy and articles in the church, or make the
declarations against Pepero, or to take the adjuration
oath; for using any other form of prayer than the liturgy
of the church of England; or for absenting himself 60
days in one year from a benefice belonging to a Popish
patron, to which the clerk was presented by either of
the universities: in all which, and similar cases, the
benefice is ipso facto void, without any formal sentence
of deprivation.

PARSONAGE, a rectory, or parish church, endowed
with a glebe, house, lands, tithes, &c. for the main
tenance of a minister, with cure of souls within such
parish. See PARSON.

PART, a portion of some whole, considered as divi
ded or divisible.

Logical PART, is a division for which we are indebt
ted to the schoolmen. It refers to some universal as
its whole; in which sense the species are parts of a
genus, and individuals or singulars are parts of the
species.

Physical PART, is that which, though it enter the
composition of a whole, may yet be considered apart,
and under its own distinct idea; in which sense, a con
tinuum is said to consist of parts. Physical parts, again,
are of two kinds, homogeneous and heterogeneous; the
first are those of the same denomination with some other;
the second of a different one: See Homogeneous, &c.
Parts, again, are distinguished into subjective, essential,
and integrant. The schoolmen were also the authors of
this division.

Aliquot PART, is a quantity which, being repeated
any number of times, becomes equal to an integer.
Thus 6 is an aliquot part of 24, and 5 an aliquot part
of 30, &c.

Aliquant PART, is a quantity, which, being repeated
any number of times, becomes always either greater or
less than the whole. Thus 5 is an aliquant part of 17,
and 9 an aliquant part of 10, &c.

The aliquant part is resolvable into aliquot parts.
Thus 15, an aliquant part of 20, is resolvable into 10,
a half, and 5 a fourth part of the same.

Parts of Speech, in Grammar, are all the sorts of
words which can enter the composition of a discourse.
See Grammar.

PARTERRE, in Gardening, a level division of
ground,
Parterre, ground, which for the most part faces the south, or best front of a house, and is generally furnished with evergreens, flowers, &c. There are two kinds of these, the plain ones and the parterres of embroidery.

Plain parterres are most valuable in England, because of the firmness of the English turf, which is superior to that of any other part of the world; and the parterres of embroidery are cut into shell and scroll work, with alleys between them. An oblong, or long square, is accounted the most proper figure for a parterre; and a parterre should indeed be always twice as long as it is broad, because, according to the known laws of perspective, a long square always sinks to a square; and an exact square always appears less than it really is. As to the breadth of parterre, it is to be proportionable to the front of the house; but less than 100 feet in breadth is too little.

There should be on each side the parterre a terrace walk raised for a view, and the flat of the parterre between the terraces should never be more than 300 feet, at the utmost, in breadth; and about 140 feet in width, with twice and a half that in length, is esteemed a very good size and proportion.

Parthenium, a genus of plants, belonging to the monoeccia class, and in the natural method ranking under the 49th order, Composite. See Botany Index.
