Before we conclude our detail of the Hebrew tongue, a few of our readers may possibly imagine that we ought to give some account of the Hutchinsonian system; a system so highly in vogue not many years ago. But as this allegorical scheme of interpretation is now in a manner exploded, we shall beg leave to remit our curious Hebraist to Mr Holloway's Originals, a small book in 2 vols 8vo, but replete with multifarious erudition, especially in the Hutchinsonian style and character.—*Fides sit penes autorem.* 39 Hutchinsonianism.

Sect. II. *The Arabic Language.*

We now proceed to give some account of the Arabian language, which is evidently one of the sister dialects of the Hebrew. Both, we imagine, were originally the same; the former highly improved and enlarged; the latter, in appearance, retaining its original simplicity and rude aspect, spoken by a people of a genius by no means inventive. In this inquiry, too, as in the former, we shall spare ourselves the trouble of descending to the grammatical minutiæ of the tongue; a method which, we are persuaded, would neither gratify our learned nor edify our unlearned readers. To those who are inclined to acquire the first elements of that various, copious, and highly improved tongue, we beg to recommend *Erpenii RudimentaLing. Arab.; Golii Gram. Arab.;* the Dissertations of Hariri, translated by the elder Schultens; Mr Richardson's Persic and Arabic Gram. &c. 40 Arabic language originally Hebrew.

We have pronounced the Hebrew and Arabian sister dialects; a relation which, as far as we know, has been seldom controverted: but we think there is authentic historical evidence that they were positively one and the same, at a period when the one as well as the

Arabic Language.

other appeared in its infant unadorned simplicity. The following detail will, we hope, fully authenticate the truth of our position.

"Unto Eber (says the Scripture †) were born two sons. The name of one was Peleg, because in his days the earth was divided; and his brother's name was Joktan," or rather Yoktan. This last, says the sacred historian, "had thirteen sons; and their dwelling reached from Mesha (Mocha) to Sephar (A)," a mount of the east. According to this account, the descendants of Yoktan possessed all the maritime coasts of Arabia from Mesha (Mocha) to Mount Sephar towards the east of that peninsula. Moses, describing the rivers of paradise, tells us, that one of the branches of that river ‡ "encompassed the whole land of Havilah, where there was great store of gold." Havilah was the twelfth son of Yoktan, whom the Arabians call Kobtan; and consequently his territory was situated towards the eastern limit of the possessions of the posterity of the youngest son of Eber. Yoktan or Kobtan was too young to be concerned in the building of the tower; and consequently retained the language of his family, which was undoubtedly the Hebrew. His descendants must have carried the same language into their respective settlements, where it must have been transmitted to succeeding generations. The original language of all the tribes of the Arabians who inhabit a vast tract of country along the southern shore, according to this deduction, was that of their father Kobtan, that is, the Hebrew. Indeed, the most learned Arabians of modern times unanimously acknowledge this patriarch as the founder of their language as well as of their nation.

† Gen. x. 25.

‡ Gen. ii. 11.

The other districts of Arabia were peopled by the offspring of Abraham. The Ishmaelites, the posterity of that patriarch by Hagar, penetrated into the very centre of the peninsula; incorporated, and in process of time became one people with the Kobtanites. Another region was possessed by the children of the same holy man by Cheturah his second wife. The Moabites, Ammonites, Edomites, Amalekites, &c. who settled in the various regions of Arabia Petræa, were all branches of Abraham's family, and used the same language with their great progenitor. The Scripture indeed speaks of people who inhabited the country last mentioned prior to the branches of Abraham's family; but these, according to the same history, were extirpated by the former. The conclusion then is, if we credit the Mosaic account, that all the inhabitants of the three divisions of Arabia did, in the earliest periods, universally use the Hebrew tongue.

There was, we are sensible, a region of Arabia inhabited by the Cushim, or descendants of Cush. This district was situated on the confines of Babylonia. Our translators have confounded this country with the modern Ethiopia; and have consequently ascribed the exploits of the Arabian Cushim to the Ethiopians. The Arabian kings of Babylon were of those Cushim. These were conquered and expelled Babylonia by the Chasidim. These spoke the Chaldean dialect, as will appear when we come to speak of that of the Abyssinians. Here the candid reader is desired to reflect that the Hebrew and Chaldaic are cognate dialects.

The foregoing proofs, deduced from the Mosaic history, will be corroborated by a mass of internal evidence in the succeeding parts of our inquiry.

41 Gradually deviated from that simplicity.

The Arabic tongue, originally pure Hebrew, was in process of time greatly transformed and altered from its simple unsophisticated state. The Arabians were divided into many different tribes; a circumstance which naturally produced many different dialects. These, however, were not of foreign growth. No foreign enemy ever conquered those independent hordes. The Persians, Greeks, and Romans, sometimes attempted to invade their territories; but the roughness of the ground, the scarcity of forage, the penury of water, and their natural bravery, always protected them. They were indeed once invaded by the Abyssinians or Ethiopians with some show of success; but these invaders were in a short time expelled the country. Their language, of consequence, was never adulterated with foreign words or exotic phrases and idioms. Whatever augmentations or improvements it received were derived from the genius and industry of the natives, and not from adventitious or imported acquisitions. From this circumstance we may justly infer, that the Arabian tongue was a long time stationary, and of course differed in no considerable degree from its Hebrew archetype. The learned Schultens, in his Commentary on Job, hath shown, to the conviction of every candid inquirer, that it is impossible to understand that sublime composition without having recourse to the Arabic idioms. That patriarch was a Chuzite. His country might be reckoned a part of Arabia. His three friends were actually Arabians, being the descendants of Ishmael and Esau. His country bordered with that of the predatory Chaldeans, who were an Arabian banditti. When we consider all these circumstances *in cumulo*, we are strongly inclined to believe that the book of Job was actually written in Arabic, as the language stood at that period; which, according to the most probable opinion, could not have been later than the age of Moses. The learned are generally agreed that this whole book, the three first chapters excepted, is a poetical composition, replete with the most brilliant and most magnificent imagery, the boldest, the justest, and most gorgeous tropes and allusions, and a grandeur of sentiment wholly divine. Whoever has read the poetical compositions of the modern Arabians, on divine subjects, with any degree of taste, will, we flatter ourselves, discover a striking similarity both of diction and sentiment. Be this as it may, we think there is no reason to conclude that the Arabic dialect deviated much from the Hebrew standard prior to the Christian era.

42 The two principal dialects of Arabia.

Of those different dialects which prevailed among the various tribes among which the peninsula of Arabia was divided, the principal were the Hemyaret and the Koreish. Though some of these were tributary to the Tobbas, or Hemyaret sovereign of Arabia Felix, yet they took no great pains to cultivate the language of that province, and of course these people did not thoroughly

(A) Sephar, in the Septuagint Σωφηρα, and in some editions Σωφηρα: hence probably Σωφιρ. *Orig. in Job* chap. xxii. ver. 14. φασιδι τινες των Ερμηνων Σωφιρ την Αφρικην ειναι.

roughly understand it. As for the independent tribes, they had no temptation to cultivate any other language than their own.

The Koreish tribe was the noblest and the most learned of all the western Arabs; and the kaaba, or square temple of Mecca, was before the era of Mohammed solely under their protection. This temple drew annually a great concourse of pilgrims from every Arabian tribe, and indeed from every other country where the Sabian religion prevailed. The language of the Koreish was studied with emulation by the neighbouring tribes. Numbers of the pilgrims were people of the first rank, and possessed all the science peculiar to their country or their age. Great fairs were held during their residence at Mecca, and a variety of gay amusements filled up the intervals of their religious duties. In these entertainments literary compositions bore the highest and most distinguished rank; every man of genius considering not his own reputation alone, but even that of his nation or his tribe, as interested in his success. Poetry and rhetoric were chiefly esteemed and admired; the first being looked upon as highly ornamental, and the other as a necessary accomplishment in the education of every leading man. An assembly at a place called *Ocadh*, had been in consequence establish-

43 The dialect of the Koreish became the politest, and why.

ed about the end of the sixth century, where all were admitted to a rivalship of genius. The merits of their respective productions were impartially determined by the assembly at large; and the most approved of their poems, written on silk, in characters of gold, were with much solemnity suspended in the temple, as the highest mark of honour which could be conferred on literary merit. These poems were called the *Moallabat*, "suspended," or *Modhahebat*, "golden." Seven of these are still preserved in many European libraries.

From this uncommon attention to promote emulation, and refine their language, the dialect of the Koreish became the purest, the richest, and the most polite, of all the Arabian idioms. It was studied with a kind of predilection; and about the beginning of the seventh century it was the general language of Arabia, the other dialects being either incorporated with it, or sliding gradually into disuse. By this singular idiomatic union the Arabic has acquired a prodigious fecundity; whilst the luxuriance of synonymes, and the equivocal or opposite senses of the same or similar words, hath furnished their writers with a wonderful power of indulging, in the fullest range, their favourite passion for antithesis and quaint allusion. One instance of this we have in the word *veli;* which signifies a *prince*, a *friend*, and also a *slave*. This same word, with the change of one letter only, becomes *vali;* which, without equivocation, imports a *sovereign*. Examples of this kind occur in almost every page of every Arabic dictionary.

44 This superiority modern.

But all these advantages of this incomparable language are merely modern, and do not reach higher than the beginning of the sixth century. Prior to that era, as we have observed above, a variety of dialects obtained; and as the Arabs were by their situation in a manner sequestered from all the rest of mankind, it may not perhaps be superfluous to inquire briefly into the cause and origin of this instantaneous and universal change.

For a course of more than 20 centuries, the Arabians had been shut up within the narrow limits of their own peninsula, and in a great measure secluded from the rest of the world. Their commerce with India was purely mercantile, and little calculated to excite or promote intellectual improvements. They traded with the Egyptians from time immemorial; but since the invasion and usurpation of the pastor kings, every shepherd, that is, every Arabian, was an abomination to the Egyptians. From that quarter, therefore, they could not derive much intellectual improvement. Besides, when an extensive territory is parcelled out among a number of petty septs or clans, the feuds and contests which originate from interfering interests and territorial disputes, leave but little time, and less inclination, for the culture of the mind. In these circumstances, the military art alone will be cultivated, and the profession of arms alone will be deemed honourable. Of consequence, we find that, in the general opinion, poetry, rhetoric, and the profession of arms, were the only sciences cultivated by the people in question. As for the science of arms, we are convinced that it was both studied and practised at a very early period; but as to the two former, we imagine they were very late acquisitions, and sprung from some circumstance external and adventitious.

The tribe of the Koreish were much engaged in commerce. They exported frankincense, myrrh, cassia, galbanum, and other drugs and spices, to Damascus, Tripoli, Palmyra, and other commercial cities of Syria and its neighbourhood. Upon these occasions the Arabian traders must have become acquainted with the Greek language, and perhaps with the more amusing and affecting parts of the Grecian literature. They might hear of the high renown of Homer and Demosthenes; and it is not impossible that some of them might be able to read their compositions. Every body knows with what unremitting ardour the learned Arabs, under the first caliphs, perused and translated the philosophical works of the Grecian sages. The very same spirit might animate their predecessors, though they wanted learning, and perhaps public encouragement, to arouse their exertions. From this quarter, we think, the Arabs may have learned to admire, and then to imitate, the Grecian worthies.

The Ptolemies of Egypt were the professed patrons of commerce as well as of learning. Under these princes all nations were invited to trade with that happy country. The Arabs, now no longer fettered by Egyptian jealousy, carried their precious commodities to Alexandria; where the Grecian literature, though no longer in its meridian splendour, shone however with a clear unfaded lustre. The court of the first Ptolemies was the retreat of all the most celebrated geniuses of Greece and of the age; in a word, Alexandria was the native land of learning and ingenuity. Here the ingenious Arab must have heard the praises of learning incessantly proclaimed; must have been often present at the public exhibitions of the poets and orators; and even though he did not understand them exactly, might be charmed with the melody of the diction, and struck with surprise at their effects on the audience. The reader will please to reflect, that the Arabian traders were the first men of the nation, both with respect to birth, learning, and fortune. These wise men, to use the language of Scripture, inspired with the natural curiosity of their race, might hear of the celebrated Olympic games, the public recitations before that assembly, and the

45 Institution at Mecca similar to the Olympic games.

Arabic Language.

the glorious prize bestowed upon the conquerors. Such information might animate them to institute something parallel at Mecca, with a view to improve their language, and at the same time to derive honour and emolument to themselves. The Koreishim might promise themselves the like advantages from the establishment of the fair and assembly at Ocadh, as the natives of Elis drew from the institution of the Olympic games. For these reasons, we conjecture, the literary competitions at the place just mentioned were instituted at so late a period, though the nation had existed more than 2000 years before the establishment of this anniversary. Upon the whole, we are inclined to believe, that the Arabs, notwithstanding all the fine things recorded of them by their own poetical historians, and believed perhaps too easily by those of other countries, were in the days of ignorance like the earliest Romans, *latrones et semibarbari*. For our part, we think it by no means probable, that a people of that character should, after so long a course of years, have stumbled upon so laudable and so beneficial an institution, without taking the hint from some foreign one of a similar complexion. This we acknowledge is only a conjecture, and as such it is submitted to the judgment of the reader.

There were, as has been observed above, two principal dialects of the original Arabic: The Hamyarite spoken by the genuine Arabs, and the Koreishite or pure Arabic, which at last became the general language of that people. The former of these inclined towards the Syriac or Chaldean; the latter being, according to them, the language of Ishmael, was deeply tinctured with the Hebrew idiom. The oriental writers tell us that Terah, the grandfather of Hamyar, was the first whose language deviated from the Syriac to the Arabic. Hence, say they, the Hamyaritic dialect must have approached near to the purity of the Syriac, and of consequence must have been more remote from the true genius of the Arabic than that of any of the other tribes. The fact seems to stand thus: The Hamyarites were neighbours to the Chaldeans and Syrians, and consequently were connected with those people by commerce, wars, alliances, &c. This circumstance introduced into their language many phrases and idioms from both these nations. That Terah was concerned in adulterating the dialect of the Hamyarites, is a mere oriental legend, fabricated by the Arabs after they began to peruse the Hebrew Scriptures. The Koreish being situated in the centre of Arabia, were less exposed to intercourse with foreigners, and therefore preserved their language more pure and untainted.

46 The Koran written in the Koreish dialect.

The learned well know, that the Koran was written in the dialect of the Koreish; a circumstance which communicated additional splendour to that branch of the Arabian tongue. It has been proved, that the language of the original inhabitants of Arabia was genuine Hebrew; but upon this supposition a question will arise, namely, whether the Arabians actually preserved their original tongue pure and unsophisticated during a space of 3000 years, which elapsed between the deluge and birth of Mohammed? or, whether, during that period, according to the ordinary course of human affairs, it underwent many changes and deviations from the original standard?

The admirers of that language strenuously maintain the former position; others, who are more moderate in their attachment, are disposed to admit the latter. Chardin observes of the oriental languages in general, that they do not vary and fluctuate with time like the European tongues.* "Çe qu'il y a de plus admirable, dit il, et de plus remarquable, dans ces langues, c'est, qu'elles ne changent point, et n'ont point changé du tout, soi à l'egard de termes, soit à l'égard du tour: rien n'y est, ni nouveau ni vieux, nulle bonne façon de parler n'a cessé *d'etre* en credit. L'Alcoran, par exemple, est aujourdhui, comme il y a mille années, le modele de plus pure, plus courte, et plus eloquente diction." It is not to our purpose to transcribe the remaining part of the author's reflection upon this subject: From the above it plainly appears that he concludes, that the Arabian tongue has suffered no change since the publication of the Koran; and at the same time insinuates, that it had continued invariable in its original purity through all ages, from the days of Kobtan to the appearance of that book. Whether both or either of these sentiments is properly authenticated will appear in the sequel.

* *Voyage*, vol. iii. p. 43.

47 Means adopted by the Arabs to preserve the purity of their language.

The learned Dr Robertson, late professor of oriental languages in the university of Edinburgh, informs us, that the Arabians, in order to preserve the purity of their language, strictly prohibited their merchants, who were obliged to go abroad for the sake of commerce, all commerce with strange women. We know not where this injunction is recorded, but certainly it was a most terrible interdict to an amorous son of the desert. If such a prohibition actually existed, we suspect it originated from some other source than the fear of corrupting their language. Be that as it may, the Doctor, as well as the great Schultens, is clearly of opinion, that the language in question, though divided into a great number of streams and canals, still flowed pure and limpid in its course.

48 The style of the Koran now obsolete.

Our readers who are acquainted with the history of the orientals are already apprized of the steady attachment of those people to ancient customs and institutions. We readily allow, that in the article of Language this same predilection is abundantly obvious; but every oriental scholar must confess, that the style of the Koran is at this day in a manner obsolete, and become almost a dead language. This fact, we believe, will not be questioned. If the Arabian has deviated so very considerably from the standard of the Koran in little more than 1000 years, and that too after an archetype is ascertained; by a pariety of reason we may infer, that much greater deviations must have affected the language in the space of 3000 years.

It is universally allowed by such as maintain the unsullied purity of the Arabian tongue, that it was originally the same with the Hebrew, or with the ancient Syriac and Chaldaic. Let any one now compare the words, idioms, and phraseology of the Koran with the remains of those three languages, and we think we may venture to affirm that the difference will be palpable. This circumstance, one would think, indicates in the strongest terms a remarkable alteration.

The Arabs themselves are agreed, that, notwithstanding the amazing fecundity of their language, vast numbers of its radical terms have been irrecoverably lost. But this loss could not be supplied without either fabricating new words or borrowing them from foreign languages. To the latter method we have seen their aversion;

Arabic Language.

sion; and must therefore conclude that they adopted the former.

The Chaldeans, Syrians, and Phœnicians, had made innovations on their language at a very early period, even before conquests were undertaken: We see no reason to suppose that the Arabs did not innovate as well as their nearest neighbours: the Hamyarites did actually innovate.

There are, we think, very strong reasons to believe, that Job was an Arabian, and flourished prior to Moses, perhaps as early as Jacob. The style, the genius, the figurative tone of the composition; the amazing sublimity of the sentiments, the allusions, the pathos, the boldness, the variety, and irregularity, the poetical enthusiasm which pervades the whole poem, strongly breathe the Arabian spirit: indeed the very diction is peculiar to that single book, and differs widely from that of the

49 and resembling the Hebrew in its phraseology.

Psalms and every poetical part of the sacred canon. If we compare this book with Mohammed's Koran, we shall scarce find any resemblance of words or phraseology; but a wonderful similarity of figures, enthusiasm, and elevation of sentiments.

We are then led to conclude, that the Arabic did actually lose and gain a multitude of vocables between the era of its first establishment among the descendants of Joktan and Ishmael, and the birth of the impostor.

The art of writing was introduced among the Arabs at a very late period: Without the assistance of this art, one would think it altogether impossible to preserve any language in its primæval purity and simplicity. Our curious readers may here expect some account of the Arabic characters: the following detail is the most probable one we have been able to collect on that subject.

* Pococke's Specim. Hist. Arab.

50 Art of writing among the Hamyarites,

It is generally agreed *, that the art of writing was known among the Hamyarites or Hemerites at a very early period. These people were sovereigns of Arabia during a course of many years. Their character was somewhat perplexed and confused. It was called *al Mosnad*, from the mutual connection of the letters. The alphabet of these people resembled that of the Hebrews both in the number and order of the letters, and is called *abgad hevâz* †, from the first ten letters of the Hebrew alphabet, artificially thrown together. "And this word (says the learned Chardin ‡) *a*, *b*, *g*, *d*, is formed of the four letters which were heretofore the first in the Arabian language, as they are still in that of the Hebrews." The same traveller is positive that these were the ancient characters of the Arabs; that they differed from Cuphite letters, which were afterwards introduced; and that they were furnished with vowel points. These, we imagine, were the first sketches of the Chaldean character, which probably the Hamyarites retained in their pristine unpolished form, after they had been polished and reduced to a more elegant size by the original inventors.

† Id. ibid.

‡ Vol. iii. p. 153.

Monuments bearing inscriptions in these characters are, they tell us, still to be seen in some places of Arabia. Some were engraved on rocks; and to these we think it probable that the patriarch Job alludes in those passages where he seems to intimate an inclination to have his sufferings recorded in a book, and graven in the rock for ever. All the Arabians agree, that the dialect of the Hamyarites inclined towards the Syriac or Chaldean. This we have imputed to the connection of that people with the Chaldeans, who lived in their neighbourhood. If the Hamyaritic dialect was infected with the Syriac or Chaldaic, there can be no doubt that they derived their letters from the same quarter.

51 in Chaldaic characters.

We conclude then, that the Hamyarites knew the art of writing from the earliest antiquity, and that the letters they employed were the rude Chaldaic in their unimproved state *. Some of the Arabians do indeed hold, that Ishmael was the first author of letters; but that his characters were rude and indistinct, without any interval between letters or words, and that these were adopted by Kedar and his other children: but this tradition hath met with little credit.

* Pococke Orat. de Ling. Arab.

With respect to the highly polished Koreishites, it is agreed on all hands, that they were unacquainted with the use of letters till a few years before the birth of Mohammed. Two difficulties here present themselves. The first is, how the Koreishite dialect, without the art of writing, happened to excel all the other dialects of the Arabic tongue, assisted by that art, apparently so necessary for preserving a language in its original purity. The second is still, we think, rather greater, namely, how the Koreish learned that most useful art at so late a period as the sixth century. It is a well known fact, that ever after the Babylonish captivity Arabia swarmed with Jewish villages, in which the art of writing was generally known; and almost at the beginning of the Christian era, multitudes of Christians retired to the same country, in order to avoid the persecutions which they suffered in the Roman empire. In these circumstances, we think it rather strange, that the Koreishites, highly polished and acute as they were, never thought of laying hold on the opportunity of learning an art so very useful. These two problems we leave to be solved by our more learned readers.

52 Art of writing among the Koreishites.

But however they be solved, it is universally acknowledged, that the Koreish were ignorant of letters till a few years before the birth of their prophet. Ebn Chalican (B), one of their most celebrated historians, informs us, that Moramer the son of Morra, an Anbarian, a native of Anbaris, a city of Irak (C), first invented alphabetical characters, and taught his countrymen to use them, from whom this noble invention was derived to the Koreishites. These letters, though neither beautiful nor convenient, were long used by the Arabs. They were denominated *Cuphite*, from *Cupha*, a city of Irak. In this character the original copy of the Koran was written. These we think were the original clumsy characters which were retained by the vulgar, after the beautiful square Chaldaic letters were invented, and probably used by priests, philosophers, and the learned

(B) See this whole detail in Dr Pococke's *Specim. Hist. Arab.* p. 250. *et seq.*

(C) *Irack*, "Babylonia," from *Erech*, one of the cities built by Nimrod. The Arabians have generally restored the ancient names of places. Thus, with them Tyre is *Tzur*, Sidon *Seyd*, Egypt *Mezri*, &c.

learned in general. These letters are often at this day used by the Arabs for the titles of books and public inscriptions.

* Roberts. Clav. Pent. p. 35, 36.

53 Improved about 300 years after Mohammed.

Abauli the son of Mocla *, about 300 years after the death of Mohammed, found out a more elegant and more expeditious character. This invention of Abauli was afterwards carried to perfection by Ebn Bowla, who died in the year of the Hegira 413, when Kader was caliph of Bagdad. This character, with little variation, obtains at this day. As we think this article of some importance, we shall, for the sake of our unlearned readers, transcribe an excellent account of this whole matter from the very learned Schultens.

"The Cuphic character, says he, which had been brought from the region of the Chaldeans to the province of Hejaz, and to Mecca its capital, in the age of Mohammed, was employed by the Koreishites, and in it the Koran was first written. But as this character was rude and clumsy, in consequence of its size, and ill calculated for expedition, Abauli Ebn Mocla devised a more elegant and expeditious one. This person was visir to Arradius the 41st caliph, who began to reign in the year of the Hegira 322. Accordingly, in the 10th century, under this emperor of the Saracens, the form of the Arabian alphabet underwent a change; and the former clumsy embarrassed character was made to give way to the polished, easy, and expeditious type. Regarding this expedition alone, the author of the invention left very few vowel characters; and as the Hebrew manner of writing admits five long ones and five short in different shapes, he taught how to express all the vowels, both long and short, suitably to the genius of the language, by three, or rather by two, small points, without any danger of a mistake: an abbreviation truly deserving applause and admiration; for by placing a very small line above he expressed *a* and *e*; and by placing the same below he meant to intimate *i* only. To the other short ones, *o* and *u*, he assigned a small *waw* above. In order to represent the long ones, he called in the *matres lectionis*, the "quiescent letters א, ו, י;" so that *phata* with *elif* intimated *a* and *o* long, i. e. *kametz* and *cholem*; *jod* placed after *kefram* became *tzeri* and *chirek* long. *Waw* annexed to *damma* made *schurek*."

'In this passage, the great orientalist acknowledges that the visir above mentioned, who carried the Arabian alphabet to the pinnacle of perfection, invented and annexed the vowel points for the sake of ease and expedition in writing; from which we may infer, that prior to the tenth century the Arabians had no vowel points; and consequently either read without vowels, or contented themselves with the *matres lectionis* above mentioned.

The design of the author of the invention, in fabricating these points, was confessedly ease and expedition in writing; a circumstance which furnishes a violent presumption that the Hebrew vowel-points were devised and annexed at some late period for the very same purposes.

Some, indeed, have gone so far as to affirm that the Arabians were the original fabricators of the vowel-points. "The Arabians † (says the learned Dr Gregory Sharp) were the original authors of the vowel points. They invented three, called *fatha*, and *damma*, and *kefra*: but these were not in use till several years after Mohammed; for it is certain that the first copies of the Koran were without them. The rabbis stole them from the Arabs." This, however, is carrying the matter too far, since it is certain that the Jews were acquainted with the points in question long before the period above mentioned.

† *Diss. on the Origin of Lan. &c.*

Though it is not our intention to enter into a minute detail of the peculiarities of this noble language, we cannot omit observing one thing, which indeed belongs to grammar, but is not generally taken notice of by the Arabic grammarians. The roots of verbs in this dialect are universally triliteral; so that the composition of the 28 Arabian letters would give near 22,000 elements of the language. This circumstance demonstrates the surprising extent of it: for although great numbers of its roots are irrecoverably lost, and some perhaps were never in use; yet if we suppose 10,000 of them, without reckoning quadriliterals, to exist, and each of them to admit only five variations, one with another, in forming derivative nouns, the whole language would then consist of 50,000 words, each of which may receive a multitude of changes by the rules of grammar.

54 Surprising extent of the Arabic language.

Again, the Arabic seems to abhor the composition of words, and invariably expresses very complex ideas by circumlocution; so that if a compound word be found in any dialect of that language, we may at once pronounce it of foreign extraction. This is indeed a distinguishing feature in the structure of this tongue, as well as of some of its sister dialects. This circumstance has, in our opinion, contributed not a little to the amazing fecundity of that language: for as every ingredient in the composition of a complex idea requires a word to express it, as many words became necessary to complete the language as there were simple ideas to be intimated by discourse. Were all the compounds of the Greek language to be dissolved, as probably once they were, the vocables of that tongue would infinitely exceed their present number.

The Arabic authors boast most unconscionably of the richness and variety of their language. No human understanding, say they, is capacious enough to comprehend all its treasures. Inspiration alone can qualify one for exhausting its sources *. Ebn Chalawalb, a most renowned grammarian of theirs, has spent a whole volume upon the various names of the lion, which amount to 500; another on the names of the serpent, which make up 200. Mohammed al Firancabodius affirms that he wrote a book on the usefulness and different denominations of honey, in which he enumerates 80 of them; and after all, he assures us that he was still far from having exhausted his subject. To excel in a language so amazingly copious, was certainly a proof of uncommon capacity, and considered as no mean talent even among the Koreishites. Hence Mohammed, when some people were expressing their admiration of the eloquence of the Koran, told them that he had been taught by the angel Gabriel the language of Ishmael, which had fallen into desuetude.

* *Pococke's Specimen.*

55 Oratory and poetry of the Arabs.

In a language so richly replenished with the choicest and most energetic terms, both oratory and poetry were cultivated with ease. All the difficulty consisted in making a choice among words and phrases equally elegant. We may compare one of those poets or orators to a young gentleman, of a taste highly refined, walking into a repository where a profusion of the richest and

and most elegant dresses are piled up in wild confusion. Our beau is here distressed with variety; but to be able to choose the most handsome and most becoming, he must have received from nature a superior good taste; which he must likewise have cultivated by assiduous industry, and by associating with the most genteel company.

The orations of the Arabs were of two kinds, metrical and prosaic. The former they compared to pearls set in gold, and the latter to loose ones. They were ambitious of excelling in both; and whoever did so, was highly distinguished. His success in either of those departments was thought to confer honour, not only on his family, but even on his tribe. In their poems were preserved the genealogies of their families, the privileges of their tribes, the memory of their heroes, the exploits of their ancestors, the propriety of their language, the magnificence of banquets, the generosity of their wealthy chiefs and great men, &c. After all, we cannot avoid being of the unpopular opinion, that this mighty parade of eloquence and poetry did not reach backward above two centuries before the birth of Mohammed, as it certainly vanished at the era of the propagation of his religious institutions. The two succeeding centuries were the reigns of superstition and bloodshed. The voice of the muses is seldom heard amidst the din of arms.

The ancient Arabs, at whatever time poetry began to be in request among them, did not at first write poems of considerable length. They only expressed themselves in metre occasionally, in acute rather than harmonious strains. The Proverbs of Solomon, and the book of Ecclesiastes seem to be composed in this species of versification. The prosody of the Arabs was never digested into rules till some time after the death of Mohammed; and this is said to have been done by Al Khalti al Farabidi, who lived in the reign of the caliph Harun al Raschid.

After so many encomiums on the copiousness of the Arabic tongue, one class of our readers may possibly expect that we should subjoin a brief detail of its genius and character; and this we shall do with all possible brevity.

56 Genius and character of the language.

All the primary or radical words of the language are composed of different combinations of consonants by *triads*; so that the various combinations and conjunctions of radicals make more than 10,000, even without including those which may arise from the meeting of guttural letters. From this quality of the language has flowed that stability of the dialect which has preserved it pure and entire for so many thousand years, and secured it from those changes and that fluctuation to which most other tongues are subject.

Perhaps, notwithstanding its copiousness and variety, no other language can vie with the one in question in point of perspicuity and precision. It is possessed of a brevity and rotundity which, amidst the greatest variety, enables it to express with clearness and energy what could not be expressed in any other tongue without tedious circumlocutions. To this purpose we shall beg leave to transcribe a passage from Bishop Pococke's oration on the Arabic language. As we imagine few of our readers who will have the curiosity to peruse this article can be unacquainted with the Latin tongue, we shall give it as it stands in the original, without a translation:

"Neque in nulla certe laudis parte, mira illa qua, non solum verborum in significando, perspicuitate, sed in prolatione, elegantiæ et dulcedini caverunt, sedulitas; quoque, non solum accurata, inter literas ex significata proportione, sensus sel intensioni, vel remissioni, prout res postulaverit, literarum appositione, subductione, vel juxta organorum, rationem prospexerunt; sed et ne quid delicatulis auribus ingratum, ne quid horridum, aut ασυμφωνον, reperiatur, effecerunt. Hoc in genere est, quod nuspiam in verbo aliquo, genuinæ apud Arabes originis, concurrunt, non intercedente vocalis alicujus motione consonantes, cum vel tres, vel plures, aliis in linguis frequenter collidantur. Immo neque, si adsint, quæ asperitati remedio sint, vocales, quas libet temerè tamen committunt consonantes; sed ita rei natura postulat, ut concurrere debeant illa, quæ se invicem, sine asperitatis inductione consequi, et inter se connecti non possint; illi vel situs, vel literarum mutatione, eas abjiciendo, inserendo, emolliendo, aliisve quibus possent modis, remedia quærunt; adeo ab omni, quod vel absonum, vel dissonum est, abhorrent. Quod si nobis secus videntur, et asperius sonare ab Arabibus prolata, illud auribus nostris, et usui, non linguæ imputandum, nec mollius illis sonare nostra, quam eorum nobis censendum. Quin et gutturalium, quæ nobis maxima asperitatis causa videntur, absentiam, ut magnum in lingua Græca defectum, arguunt Arabes."

The learned Dr Hunt, late professor of the Hebrew and Arabic languages at Oxford, is of the same opinion with the very learned prelate, part of whose oration we have transcribed above, with respect to the delicacy and elegance of the Arabian language:—"Nusquam, mihi credite, (inquit ille) auribus magis parcitur quam in Arabia; nulla lingua à κακοφωνια, alienior quam Arabica. Quamquam enim nonnullæ ejus literæ minus fortasse suaviter, immo durius etiam sonuerint, ita tamen Arabes eas temperarunt cum lenibus, duras cum mollibus, graves cum acutis miscendo, voces inde non minus auribus jucundæ, quam pronunciatu faciles confecerint, totique sermoni miram sonorum tam dulcedinem quam varietatem addiderint. Quod quidem orationis modulandæ studium in Corano adeo manifestum est, ut primi Islamismi oppugnatores eum librum magica ideo arte scriptum dixerint. Non auribus tantum gratus est Arabismus, sed et animi conceptibus exprimendis aptus, sones suos sententiis semper accommodans, et felici verborum junctura eorum naturam depingens."

To these we might add quotations from Erpenius's oration on the same subject, from Golius, Schultens, Hottinger, Bochart, and Sir William Jones; besides a whole cloud of oriental witnesses, whose extravagant encomiums would rather astonish than edify the far greater part of our readers. These panegyrics may perhaps be in some measure hyperbolical; but in general we believe them pretty well founded. At the same time we are convinced that the Arabic, however melodious in ears of a native, sounds harsh and unharmonious in that of an European.

57 Difficulty of acquiring a thorough knowledge of it.

When we consider the richness and variety of the Arabic tongue, we are led to conclude, that to acquire a tolerable degree of skill in its idioms, is a more difficult task than is generally imagined; at least some people

Arabic Language.

people who have acquired the knowledge of the Greek and Latin, and likewise of the more fashionable modern languages, with facility enough, have found it so. Be that as it may, there are two classes of men who, in our opinion, cannot handsomely dispense with the knowledge of that almost universal tongue: the gentleman, who is to be employed in the political transactions of the most respectable mercantile company upon earth, in the eastern parts of the world; and the divine, who applies himself to investigate the true purport of the sacred oracles: without this, the former will often find himself embarrassed in both his civil and mercantile negociations; and the latter will often grope in the dark, when a moderate acquaintance with that tongue would make all sunshine around him.

Bochart, Hottinger, Schultens, Pocock, Hunt, and Robertson, &c. have taken wonderful pains, and lavished a profusion of learning, in proving the affinity and dialectical cognation between the Hebrew and Arabic. Much of this labour, we think, might have been spared. We presume to affirm, that no person tolerably versed in both languages can read a single paragraph of the Arabic version of the New Testament, or indeed of the Koran itself, without being convinced of the truth of this position: it is but stripping the latter of its adventitious frippery, and the kindred features will immediately appear.

The learned professors of the university of Leyden were the first who entered upon the career of Arabian learning. To them the European students are principally indebted for what knowledge of that language they have hitherto been able to attain. Though several Italians have contributed their endeavours, yet the fruit of their labours has been rendered almost useless by more commodious and more accurate works printed in Holland.

The palm of glory, in this branch of literature, is due to Golius, whose works are equally profound and elegant; so perspicuous in method, that they may always be consulted without fatigue, and read without languor. Erpenius's excellent grammar, and his memorable dictionary, will enable the student to explain the history of *Taimur* by *Ibni Arabshah*. If he has once mastered that sublime work, he will understand the learned *Arabic* better than most of the Khatabs of Constantinople or of Mecca.

The Arabian language, however, notwithstanding all its boasted perfections, has undoubtedly shared the fate of other living languages; it has gradually undergone such considerable alterations, that the Arabic spoke and written in the age of Mohammed may be now regarded as a dead language: it is indeed so widely different from the modern language of Arabia, that it is taught and studied in the college of Mecca just as the Latin is at Rome.

The dialect of the Highlands of Yemen is said to have the nearest analogy to the language of the Koran, because these Highlanders have little intercourse with strangers. The old Arabic is through all the East, like the Latin in Europe, a learned tongue, taught in colleges, and only to be acquired by the perusal of the best authors.

"*Ut folia in sylvis pronos mutantur in annos, &c.*"

Chaldean Language, &c.

Sect. III. *Of the Chaldean, Phœnician, Ethiopian or Abyssinian, and Egyptian Languages.*

58 Connection of the Chaldean, Phœnician, Ethiopic, and Egyptian languages.

As there is a very strict connection and dialectical analogy among these languages, we have arranged them all under one section; especially since what is observed relating to one of them may, without the least straining, be extended to them all. We shall begin with the Chaldaic.

The Chaldeans, or Chasidim, as they are always called in Scripture, were the descendants of Chesed the son of Nahor, the brother of Abraham. The descendants of this patriarch drove the Cushim or Arabians out of Babylonia, and possessed themselves of that country at a very early period. As these Chasidim or Chaldeans were the posterity of Nahor, the descendant of Heber, they undoubtedly spoke the original Hebrew tongue as well as the other branches of that family. But being an ingenious inventive people, they seem to have polished their language with much care and delicacy of taste.

The only genuine remains of the ancient Chaldaic language are to be found in the Hebrew Scriptures; and those are contained in 268 verses, of which we have 200 in Daniel, reaching from verse 4th chapter 2d to chapter 8th exclusive; in Ezra 67, in chapter 4th, 17 verses; chapter 5th, the same number; chapter 6th, 18 verses; and in chapter 7th, 15: in Jeremiah, chapter 10th, these is extant only one verse. From these fragments, compared with the Hebrew, it plainly appears, that the difference between that language and the Chaldaic is scarce equal to that between the Doric and Ionic dialects of the Greek.

Whatever might have been the form of the most ancient Chaldaic letters, it is generally known that the beautiful square characters, in which the Hebrew Scriptures began to be written after the age of Ezra, were current among them at an era prior to the Babylonish captivity. Those elegant characters were probably the invention of the Chaldean academies, which were established in various parts of that extensive and fertile country.

59 Chaldean differs little from the Hebrew.

The Chaldean declensions and conjugations differ so little from the Hebrew modifications, that it would be almost superfluous to dwell upon them in this section. The most effectual way to acquire an idea of the ancient Chaldaic, is to decompound the names confessedly of that dialect, which occur in many places of Scripture. By this method of proceeding, its beautiful structure and expressive energy will be readily comprehended even by the most illiterate classes of our readers. At the same time, we must observe, that the Chaldaic and ancient Syriac bore so near a resemblance to each other, that they have generally been classed under one head.

The first Chaldaic word that occurs in the Old Testament is *bara* "*creavit.*" This word has all along been assigned to the language under consideration; for what reason, we confess we are not able to discover. The greatest part of the Hebrew tongue is now lost. The words *bar*, "a son," and *bara* "*creavit*," (rather *filiavit*), may probably be of that number. Another Scripture word which is often quoted, and always ascribed either to the Syriac or Chaldaic, is *igar* or *jegar sahadutha*,

Chaldean Language, &c.

sahadutha, which signifies "a mountain of witnesses." Every body knows, that when Jacob and Laban made their compact, the latter denominated the heap of stones reared upon that occasion in this manner; while the former called it *Galeed*, as we now write and pronounce it. This pronunciation, however, does not appear to us altogether genuine. The word is probably compounded of גל, *gal*, *cumulus*, "a heap," and עד, *chad*, *æternitas*, *seculum*, "eternity, an age:" so that גלעד, *galchad*, or *galaad* as it came to be written afterwards, signified an "everlasting heap." Laban then had respect to the end for which the monument was erected; but Jacob alluded to its duration. It appears, however, upon this and every other occasion, when Chaldaic words are mentioned, that א, *a*, was a favourite letter both with the Syrians and Chaldeans. We may likewise observe, that the same people always changed the Hebrew ש, *shin*, into ת, *thau*, in order to avoid the serpentine sound of that consonant.

60 Its proper names pure Hebrew.

The Chaldaic names of gods, men, places, &c. which occur in Scripture, appear to be no other than Hebrew polished and improved. *Bel*, *Belus* in Latin, is evidently בעל, *Baal*, or we think rather ב-על, *Bechel*. The Phœnicians, and sometimes the Hebrews, used it to signify *the most high*. The Chaldeans used their word *Bel* for the same purpose; and because this word originally imported the *High One*, they dignified their first monarch with that name. They denominated their capital city *Ba-Bel*, which imports the *temple of Bel*, and afterwards *Babylon*, which intimates *the abode or dwelling of our lord the sun*. *Nebo* was a name of the moon among the Babylonians, derived from the Hebrew נבא, *nabah*, *vaticinari*, "to prophecy." *Azer* was the planet Mars, from אזר, *Azer* or *Ezur*, *accinxit*, "to gird," alluding to the girding on of arms. *Ahad* was an Assyrian name of the sun*, a word deduced from the Hebrew אחד, *ahad*, *unus*, "one." *Netzar* was the name of an Arabian idol†, which often occurs in the composition of Babylonian names. In Arabic it signifies an *eagle*: we think, however, that the word is the Hebrew נצר, *natzar*, *custodivit*, *servavit*, "to keep, to preserve." To these names of deities many more might be added, which the nature of our design will not allow us to mention.

* *Macrob.* lib. i. c. 23.
† *Pococke Specim. Hist. Arab.*

Almost all the Chaldean proper names which occur either in sacred or profane history are evidently of Hebrew original, or cognate with that language. We shall subjoin a few examples: *Nabonassar* is evidently compounded of *Nabo* and *nazur*, both Hebrew words. *Nabopollazar* is made up of *Nabo-Pul*, the same with *Bel*, and *Azer* or *Azor*, above explained. *Belesis* is made up of *Bel* and אשא, *Esha*, "fire." Nebuchadnezzar, Belshazzar, Beltishazzar, Neriglissar, Nebuzaradan, Rabmag, Rabsaris, Nergal Sharezer, Rabshakeh, Ezarhaddon, Merodach, Evil Merodach, and numberless others, are so manifestly reducible to Hebrew vocables, when decompounded, that the oriental scholar will readily distinguish them.

Names of places in the Chaldaic are likewise so nearly Hebrew, that nothing but the dialectical tone separates them. Thus *Ur* of the Chaldeans is actually אור, *light*, that city being sacred to the sun: *Sippora* is plainly the Hebrew word *Zipporah*; *Carchemish*, a city on the Euphrates, is evidently compounded of *Kir* or *Kar*, "a city," and *Chemosh*, a name of the sun. In short, every Chaldean or old Syrian word now extant, without any difficulty, bewray their Hebrew original. As for their dialectical differences, these we remit to the Chaldaic grammars and lexicons.

61 Phœnician language derived from the Hebrew.

We now proceed to the consideration of the Phœnician language, which is known to have been that of the ancient Canaanites. That this was one of the original dialects, and consequently a cognate of the Hebrew, is universally acknowledged. Instead therefore of endeavouring to prove this position, we may refer our readers to the works of the learned Mr Bochart, where that author has in a manner demonstrated this point, by deriving almost all the names of the Phœnician colonies from the Hebrew, upon the supposition that the dialect of those people was closely connected with that tongue. St Augustine, *de Civitate Dei*, has observed, that even in his time many of the vulgar in the neighbourhood of Carthage and Hippo spoke a dialect of the old Punic which nearly resembled the Hebrew. Procopius, *de bello Goth.* informs us, that there existed even in his days in Africa a pillar with this inscription in Hebrew, "We flee from the face of Joshua the robber, the son of Nun." The names of all the ancient cities built by the Carthaginians on the coast of Africa are easily reducible to a Hebrew original. The Carthaginian names of persons mentioned in the Greek and Latin History, such as Himilco, Hamilcar, Asdrubal, Hannibal, Hanno, Dido, Anna or Hannah, Sophonisba, Gisgo, Maharbal, Adherbal, &c. all breathe a Hebrew extraction.

The Greeks borrowed a great part of their religious worship from the people of whose language we are treating; of consequence, the names of most of their gods are Phœnician. Almost every one of these is actually Hebrew, as might easily be shown. The names of persons and places mentioned in the fragments of Sanchoniathon, preserved by Eusebius, are all of Hebrew complexion. The names mentioned in the Hebrew scriptures of places which belonged to the Canaanites prior to the invasion of the Israelites under Joshua, are as much Hebrew as those which were afterwards substituted in their stead. The Punic scene in Plautus has been analysed by Bochart and several other learned men, by whom the language has been clearly proved to be deduced from the Hebrew, with some dialectical variations.

The island of Melita (now Malta) was inhabited by a colony of Phœnicians many ages before the Moors took possession of it. Among the vulgar of that island many Punic vocables are current to this day, all which may be readily traced up to the Hebrew fountain. To these we may add many inscriptions on stones, coins, medals, &c. which are certainly Phœnician, and as certainly of Hebrew extraction. We have thrown together these few hints without pursuing them to any great length, as we deemed it unnecessary to dwell long on a point so hackneyed and so generally acknowledged.

62 Origin of the Ethiopians.

Before we proceed to treat of the ancient language of the Ethiopians, we find ourselves obliged to hazard a few strictures on the origin of that ancient nation. If we can once settle that single point, the discovery will open an avenue to their primitive dialect, the article about which we are chiefly concerned in the present discussion.

In our Section concerning the Hebrew language, we were led often to mention the patriarch Cush the eldest son of Ham. The posterity of this family chief, under his

Chaldean Language, &c.

his son Nimrod, possessed themselves of Shinar, afterwards denominated *Chaldea*. These were probably the Arabians whose kings (according to Eusebius, Africanus, and other ancient chronologers) reigned in Babylon during several successive generations. Those were the Cushim or Cushites, whom the learned Mr Bryant has conducted over a great part of the world, and to whose industry and ingenuity he has ascribed almost all the inventions, arts, sciences, laws, policy, religions, &c. which distinguished mankind in the earliest ages.

In process of time, the posterity of Chasid or Chesed, called *Chasdim* or *Chasidim*, in the east, and *Chaldeans* in the west, drove out the Cushim, and seized upon their country. The Cushim retired westward, and spread themselves over that part of Arabia situated towards the south-east. They probably extended themselves over all the eastern part of that peninsula, from the sea to the wilderness between Arabia and Syria. Those were the Ethiopians mentioned in Scripture by a very unpardonable inadvertency of our translators. These, then, we think, were the primitive Cushim.

Josephus informs us †, that all the Asiatics called the Ethiopians of Africa by the name of *Cushim*. This denomination was not given them without good reason: it imports at least, that they deemed them the descendants of Cush; it being the constant practice of the orientals in the early ages to denominate nations and tribes from the name of their great patriarch or founder. The name *Cushim* must then have been given to the Ethiopians, from a persuasion that they were the progeny of the son of Ham who bore that name. By what route soever the Cushim penetrated into that region of Africa which was called by that name, it may be taken for granted that they were the descendants of Cush above mentioned.

† *Antiq. Jud.* lib. i. c. 7.

It has been observed above, that the posterity of Cush possessed the country of Shinar or Chaldea at a very early period, but were expelled by the Chasidim or Chaldeans. Upon this catastrophe, or perhaps somewhat later, a colony from the fugitive Cushim transported themselves from the south and south-east coast of Arabia over the sea which lies between that country and Ethiopia. However imperfect the art of navigation might be in that age, the distance was so small that they might easily enough make a voyage cross that narrow sea in open boats, or perhaps in canoes. However that may have been, it cannot be doubted that the tribes on both sides of that branch of the sea were kindred nations.

63
Their language originally Chaldean.

If, then, both the northern and southern Cushim sprung from the same stock, there can be no doubt that both spoke the same language. The language of the Babylonian Cushim was Chaldaic, and of consequence that of the Ethiopian Cushim was the same. We may therefore rest assured, that whatever changes the Ethiopian dialect may have undergone in the course of 3000 years, it was originally either Chaldaic, or at least a branch of that language. Scaliger informs us, that the Ethiopians call themselves Chaldeans; and that, says, he not without reason, because of those many sacred and profane books which are extant among them, the most elegant and most beautiful are written in a style near that of the Chaldean or Assyrian. Marianus Victorius, who was the first that reduced the Ethiopic tongue to the rules of grammar, tells us, in his *Proœmium*, "that the Ethiopians call their tongue Chaldaic; that it springs from the Babylonian; and is very like the Hebrew, Syriac, and Arabic: At the same time (he concludes), that this language may be easily learned by those who are masters of the Hebrew." The learned Bochart, and Bishop Walton in his *Proleg.* are clearly of the same opinion.

The vulgar letters of the Ethiopians, according to Diodorus Siculus, were the same with the sacred †† characters of the Egyptians (D). From this account, if the Sicilian may be trusted, the sacred letters of these people, concerning which so many wise conjectures have been formed, were actually Chaldaic. To carry on this investigation a little farther, we may observe, that Sir William Jones seems to have proved, by very plausible arguments, that the Sanscrit characters were deduced from the Chaldaic. This circumstance affords a presumption that the Ethiopian Cushim were likewise concerned with the Egyptians; who, as is remarked in the Section concerning the *Sanscrit*, probably introduced the religion of the Brahmans into Hindostan. This is advanced as a conjecture only; and yet when we consider the affinity between the Egyptian and Gentoo religions, we are strongly inclined to hope that this surmise may one day be verified by undeniable facts.

†† Lib. iii. p. 101. *Steph.*

The original Ethiopians were a people highly civilized; their laws, their institutions, and especially their religion, were celebrated far and wide. Homer talks in raptures of the piety of the Ethiopians, and sends his gods every now and then to revel 12 days with that devout people. The Sicilian adduces a number of very specious arguments to prove that these two nations had sprung from the same stock. He mentions a similarity of features, of manners, of customs, of laws, of letters, of the fabrication of statues, of religion, as evidences of the relation between those two neighbouring nations. There was, every body knows, a communion, as to sacred rites, between the two countries. The Egyptians sent annually a deputation of their priests, furnished with the portable statues of their gods, to visit the fanes of the devout Ethiopians. Upon this occasion, a solemn religious banquet was prepared, which lasted 12 days, and of which the priests of both nations were partakers. It was, we imagine, a kind of sacramental institution, by which both parties publicly avouched their agreement in the ceremonies of their religion respectively. These observations plainly show, that the most ancient Ethiopians were a people highly civilized; indeed so much, that the Egyptians were at one time contented to be their scholars. The tone of their language was certainly the same with that of the Chaldeans or Arabian Cushim, from whom they are descended. We know not whether there are any books in the ancient Ethiopic now extant; so that it is not easy to produce instances of its coincidence with the Chaldaic. Diogenes Laertius ‡ informs us, that Thrasyllus, in his catalogue

64
Ancient intercourse between the Ethiopians and Egyptians.

‡ Lib. ix. p. 461. *Casaub.*

(D) We find the same observation confirmed by Heliodorus (*Ethiop.* lib. x. p. 476.). "The royal letters of the Ethiopians (says he) were the sacred characters of the Egyptians." Cassiodorus likewise assures us, "That the letters inscribed upon the Egyptian obelisks were Chaldean." See Sect. *Sanscrit*.

talogue of the books composed by Democritus, mentions one, περι των εν Μεροη ιερων γραμματων, *concerning the sacred letters in the island of Meroe* (E); and another concerning the sacred letters in Babylon. Had these books survived the ravages of time, they would in this age of research and curiosity have determined not only the point under our consideration, but the affinity of sacred rites among the Chaldeans, Ethiopians, and Egyptians.

We have now shown that the Ethiopians were a colony of Cushites; that the Cushites were originally sovereigns of Shinar or Chaldea, and consequently spoke either Chaldaic, or a dialect of that tongue; that their colonists must have used the same language; that the ancient Ethiopians were a people highly polished, and celebrated in the most early ages on account of their virtue and piety. It has likewise appeared that the common letters of that people were the sacred characters of the Egyptians, These letters, we imagine, were the Cuphite; for which see the section on the *Arabic*. When they were discarded, and the modern substituted in their room, cannot be determined; nor is it, we apprehend, a matter of much importance. We shall therefore drop that part of the subject, and refer our curious and inquisitive readers to the very learned Job Ludolf's (F) excellent grammar and dictionary of the Abyssinian or Geez tongue, where they will find every thing worth knowing on that subject. We shall endeavour to gratify our readers with a very brief account of the modern Ethiopic or Abyssinian tongue; for which both they and we will be obliged to James Bruce, Esq. that learned, indefatigable, and adventurous traveller; who, by his observations on that country, which he made in person, often at the hazard of his life, has discovered, as it were, a new world both to Europe and Asia.

65 **Modern Ethiopic tongues.**

The most ancient language of Ethiopia, which we shall now call *Abyssinia* (its modern name), according to that gentleman, was the *Geez*, which was spoken by the ancient Cushite shepherds. This, we should think, approaches nearest to the old Chaldaic. Upon a revolution in that country, the court resided many years in the province of Amhara, where the people spoke a different language, or at least a very different dialect of the same language. During this interval, the *Geez*, or language of the shepherds, was dropt, and retained only in writing, and as a dead language: the sacred Scriptures being in that tongue only saved it from going into disuse. This tongue is exceedingly harsh and unharmonious. It is full of these two letters D and T, in which an accent is put that nearly resembles stammering. Considering the small extent of sea that divides this country from Arabia, we need not wonder that it has great affinity with the Arabic. It is not difficult to be acquired by those who understand any other of the oriental languages; and as the roots of many Hebrew words are only to be found here, it seems to be absolutely necessary to all those who wish to obtain a critical skill in that language.

66 **Ethiopic alphabet.**

The Ethiopic alphabet consists of 26 letters, each of which, by a *virgula* or point annexed, varies its sound in such a manner as that those 26 form as it were 62 distinct letters. At first they had but 25 of these original letters, the Latin P being wanting: so that they were obliged to substitute another letter in its place. *Paulus*, for example, they call *Taulus*, *Aulus*, or *Caulus*: *Petros*, they pronounced *Ketros*. At last they substituted T, and added this to the end of their alphabet; giving it the force of P, though it was really a repetition of a character rather than the invention of a new one. Besides these, there are 20 others of the nature of diphthongs; but some of them are probably not of the same antiquity with the letters of the alphabet, but have been invented in later times by the scribes for convenience.

The Amharic, during the long banishment of the royal family in Shoa, became the language of the court, and seven new characters were of necessity added to answer the pronunciation of this new language; but no book was ever written in any other language than *Geez*. There is an old law in the country, handed down by tradition, that whoever shall attempt to translate the Holy Scripture into Amharic or any other language, his throat shall be cut after the manner in which they kill sheep, his family sold to slavery, and their houses razed to the ground.

Before we leave this subject, we may observe, that all the ancients, both poets and historians, talk of a double race of Ethiopians; one in India, and another in Africa. What may have given rise to this opinion it is not easy to discover. Perhaps the swarthy complexion of both people may have led them to this sentiment. Eusebius indeed informs us ‡, that "a numerous colony of people emigrated from the banks of the Indus, and, crossing the ocean, fixed their residence in the country now called Ethiopia." For our part, we are rather inclined to believe, that the original Ethiopians transported themselves into India, and there perhaps co-operated with the Egyptians in digging the excavations and framing the statues, some of which are still to be seen in that country, and which we have mentioned in another Section. The Greeks called those people Αιθιοπες, *Æthiopes*, we believe, from their sun-burnt countenance; but indeed they were very little acquainted either with the country or its inhabitants.

‡ *Chron.* p. 12.

67 **Ancient language of Egypt a sister dialect of Hebrew.**

The most ancient name of Egypt was *Mizraim*, of consequence the Arabians still call it *Mesri*. It was likewise distinguished by other names, such as *Oceana*, *Aeria*, &c. It appears from the sacred historian, that it was inhabited by the descendants of Mizraim the second son of Ham. Mizraim had several sons, who, according to the Scripture account, settled respectively in that country. If we trust to the sacred records, there will be little difficulty in ascertaining the language of the Mizraim. It will appear to be one of the sister dialects of the Hebrew, Phœnician, Arabic, Chaldaic, &c.; and this, to us, appears to be the fact. But the origin of that people, their language, religion, laws, and institutions, have been so warped and confounded, both by their own historians and those of other countries, that one is scarce able to determine what to believe or what to

(E) Where the capital of Ethiopia was situated.

(F) A very learned German, who published a grammar and dictionary of the Geez in folio.

to reject. Herodotus, Diodorus Siculus, Strabo, Ptolemy, and most other ancient geographers and historians, are universally agreed, that Egypt, at least that part of it called *Delta*, was overflown by the sea, and consequently uninhabitable for many centuries after the dispersion of mankind. When we consider the low situation of the Delta, and the violent current of the tide from the coast of Phœnicia and Palestine towards that shore, we would be almost tempted to adopt this hypothesis; but the sacred records avouch the contrary. According to them, we find Egypt a populous, rich, and flourishing kingdom, as early as the age of Abraham. Had the Lower Egypt been a pool of stagnating water at any time after the general deluge, we think it could not have been drained, cleared, cultivated, and stocked with inhabitants, so early as the days of Abraham.

Diodorus Siculus, however, is positive that the Egyptians ‡ were a colony of Ethiopians; and this he endeavours to prove by the similarity of features, customs, laws, religious ceremonies, &c. between the two nations. That there was a constant intercourse of good offices between these two branches of the Hamites, cannot be questioned; and that they nearly resembled each other in many respects, is too evident to admit of contradiction. The excavations, originally dug out of the solid rocks of porphyry and marble, in which the natives resided before the plains were drained, have been observed by a most judicious traveller (G) a very few years ago. At the same time, the most accurate and judicious travellers (H) who have visited that region in modern times, are generally of opinion that the land has gained nothing on the sea since the period when Herodotus wrote his description of that country; from which circumstances we may be led to conclude, that the idea of the inundation of the Delta is not founded in fact.

‡ Lib. xiii. *passim.*

But even admitting that the Egyptian Delta has acquired nothing from the sea since the age of Herodotus to the present, it certainly does not follow that the region in question was never overflown by that element; since there are in many parts of the globe, large tracts of land, certainly once covered with sea, which have continued to this day in the very same situation in which they were 2000 years ago. We leave the decision of this point to the judgment of our readers.

We have already hinted our opinion of the nature of the Egyptian language; but because Egypt is generally thought to have been the native land of hieroglyphics, and because many are of opinion that hieroglyphical characters were prior to alphabetical, we shall hazard a few conjectures with respect to that species of writing.

68
Egyptian hieroglyphics.

The end of speech, in general, is to enable men to communicate their thoughts and conceptions one to another when present; the use of writing is to perform the same office when people are at so great a distance that vocal sounds cannot mutually reach them. Hieroglyphics are said to have been invented to supply this defect. The most ancient languages were everywhere full of tropes and figures borrowed from sensible objects. As in that stage of society men have not learned to abstract and generalize, all their ideas are borrowed from such objects as most forcibly strike their senses. This circumstance would naturally suggest to savages the idea of conveying their sentiments to each other, when absent, by delineations of corporeal objects. Thus, if a savage asked a loan of his friend's horse, he might find means to have conveyed to him the figure of that animal; and so of others. This was the very lowest species of ideal communication, and has been styled *picture-writing*.

Necessity would soon impel our savage correspondents to fabricate a method more extensively useful, which would likewise be suggested by the constant use of the metaphorical mode of speech. Some savage leader, more sagacious than the vulgar herd, would observe that certain sensible objects were fitted, according to the rules of analogy, to represent certain human passions, and even some abstract ideas; and this would be readily enough adopted by the herd as a new improvement. In this case a *horn* might be the emblem of *power*, a *sword* of *bravery*, a *lion* of *fury*, a *fox* of *cunning*, a *serpent* of *malice*, &c. By and by artificial signs might be contrived to express such ideas as could not readily be denoted by bodily objects. This might be called *symbolical writing*. Such was the foundation of the Chinese characters; and hence that prodigious number of letters of which the written language of that people is composed. Farther they could not proceed, notwithstanding their boasted inventive powers; and farther, we believe, no nation ever did proceed, who had once upon a time no other characters but hieroglyphical. The Mexicans had arrived at the very lowest stage of hieroglyphical writing, but had not taken one step towards alphabetical. The Hurons employ hieroglyphical symbols, but never entertained a single idea of alphabetical. Hieroglyphical characters are the images of objects conveyed to the mind by the organs of vision; alphabetic are arbitrary artificial marks of sound, accommodated by compact to convey to the mind the ideas of objects by the organs of hearing. In a word, we think that there is not the least analogy between these two species to conduct from the one to the other: we are therefore of opinion, that hieroglyphical characters were never the vulgar channels of ideal conveyance among civilized people.

69
Were never in vulgar use;

We know that in this point we differ from many learned, judicious, and ingenious writers; some of whom have taken much pains to investigate the intermediate stages through which the fabricators of characters must have passed in their progress from hieroglyphical to alphabetical writing. These writers have adopted a plan analogous to Bishop Wilkins's project of an artificial language. In this theory, we own, we are led to suspect that they supposed all mankind were once upon a time *savages*, and were left to hammer out words, as well as characters, by necessity, ingenuity, experience, practice, &c. For our part, we have endeavoured to prove, in our section on the Hebrew language, that alphabetical writing was an antediluvian invention; and we now lay it down as our opinion, that among all those nations which settled near the centre of civilization,

(G) See Mr Bruce's Travels, vol. i.
(H) Mr Bruce, Dr Shaw, Bishop Pococke, Savary, Volney, &c.

tion, hieroglyphics were, comparatively, a modern fabrication.

The Orientals are, at this day, extravagantly devoted to allegory and fiction. Plain unadorned truth has with them no charms. Hence that extravagant medley of fables and romance with which all antiquity is replete, and by which all ancient history is disguised and corrupted. Every doctrine of religion, every precept of morality, was tendered to mankind in parables and proverbs. Hence, says the Scripture, to understand a proverb, the words of the wise, and their dark sayings. The eastern sages involved their maxims in this enigmatical dress for several reasons: to fix the attention of their disciples; to assist their memory; to gratify their allegorical taste; to sharpen their wit and exercise their judgment; and sometimes perhaps to display their own acuteness, ingenuity, and invention.

It was among the ancients an universal opinion, that the most sacred arcana of religion, morality, and the sublime sciences, were not to be communicated to *the uninitiated rabble*. For this reason every thing sacred was involved in allegorical darkness.

Here, then, we ought to look for the origin of
70 hieroglyphical or picture writing among the civilized nations of the east, They did not employ that species of writing because they were ignorant of alphabetical characters, but because they thought fit to conceal the most important heads of their doctrines under hieroglyphical figures. The Egyptian priests were most celebrated for their skill in devising those emblematical representations; but other nations likewise employed them. We learn from the fragments of Berosus the Chaldean historian, preserved by Syncellus and Alexander Polyhistor, that the walls of the temple of Belus at Babylon were covered all over with those emblematical paintings. These characters were called ἱερα, because they were chiefly employed to represent sacred objects; and γλυφικα, because they were originally carved or engraved. Their name points to their original use. Instead of pursuing these observations, which the nature of our design will not permit, we must refer our readers to Herodotus, lib. ii. Diodorus Sic. lib. i. Strabo, lib. xvii. Plut. Isis et Osiris; and among the Christian fathers to Clem. Alex. Euseb. Præp. Evang.; but chiefly to Horapollo's Hieroglyphica.

But employed to conceal sacred doctrines from the uninitiated;

From this deduction we would conclude, that this species of writing was an adventitious mode in Egypt, peculiar to the priests, and employed chiefly to exhibit things sacred; and that among all civilized people it did not supersede the use of alphabetical characters,
71 nor did the use of the latter originate from the former. When alphabetical letters were invented, if indeed they were a human invention, they were antecedent to the other in use and extent. The Egyptian priests alone knew the true import of those sacred symbols; and communicated that knowledge first to their own children from generation to generation, then to the initiated, and last of all to the grandees of the nation, all of whom were indeed initiated. The hieroglyphics of Egypt were not then the symbols of any sacred occult language; but signs invented by the priests, and prophets or wise men, in order to represent their deities, the attributes and perfections of their deities, and the mysterious arcana of their religion, and many other circumstances relating to objects of importance, which were deemed either too sacred or too important to be imparted to the vulgar.

and posterior in time to alphabetical characters.

The Egyptians ascribed the invention of letters to a person whom they called *Thoth* *, *Theuth*, or *Thyoth*; the Greeks Ἑρμης; and the Romans *Mercurius*. Plato † calls him a god, or a godlike man; Diodorus ‡ makes him privy counsellor to Osiris; Sanchoniathon ap. Euseb. § connects him with the Phœnician Cronus or Saturn. To this Mercury the Egyptians ascribe the invention of all the arts and sciences. He was probably some very eminent inventive genius, who flourished during the first ages of the Egyptian monarchy, and who perhaps taught the rude savages the art of writing.

* Euseb. *Prop. Ev.*
† *Phædrus.*
‡ Lib. i.
§ *Prep. Ev.*

72 According to Diodorus Siculus, the Egyptians had two kinds of letters *; the one sacred, the other common: the former the priests taught their own children, the latter all learned promiscuously. In the sacred characters the rites and ceremonies of their religion were couched; the other was accommodated to the ordinary business of life. Clem. Alexand. mentions three different styles of writing employed by the Egyptians †. "The pupils, who were instructed by the Egyptians, first learned the order and arrangement of the Egyptian letters, which is called *epistolography*, that is, the manner of writing letters; next, the sacred character, which the sacred scribes employed; lastly, the hieroglyphic character, one part of which is expressed by the first elements, and is called *Cyriologic*, that is, *capital*, and the other *symbolic*. Of the symbolic kind, one part explains properly by imitation; and the other is written tropically, that is, in tropes and figures; and a third by certain enigmatical expressions. Accordingly, when we intend to write the word *sun*, we describe a circle; and when the moon, the figure of that planet appearing horned, conformable to the appearance of that luminary after the change." In this passage we have an excellent description of the three different modes of writing used by the Egyptians; the common, the sacred, and the hieroglyphic. The last he describes according to its three divisions, in exact conformity to our preceding observations.

Two kinds of alphabetical characters in Egypt.

* Lib. i.
† *Strom.* lib. v.

73 By the description above translated, it plainly appears, that the sacred character of the Egyptians was entirely different from the hieroglyphic; and by this consideration we are in a good measure justified, in supposing, as we have done all along, that the sacred letters of the Egyptians were actually the Chaldaic. The inscriptions on the obelisks mentioned by Cassiodorus, so often quoted, were certainly engraved in the sacred character; and the character in which they were drawn was that above mentioned. If the sacred letters were Chaldaic, the sacred language was probably the same.

The sacred letters and language of Egypt Chaldaic.

The Egyptians pretended, that the Babylonians derived the knowledge of the arts and sciences from them; while, on the other hand, the Babylonians maintained, that the former had been tutored by them. The fact is, they both spoke the same language; used the same religious rites; had applied with equal success to astrology, astronomy, geometry, arithmetic, and the other sciences;

sciences; of course a rivalship had arisen between the two nations, which laid the foundation of those opposite pretensions.

The most faithful specimen of the vulgar language of the Egyptians, is, we believe, still preserved in the Coptic, which, however, is so replete with Grecisms, that it must be difficult to trace it out.

Under the Ptolemies, the Greek was the language of the court, and consequently must have diffused itself over all the country. Hence, we believe, two-thirds of the Coptic are Greek words, diversified by their terminations, declensions, and conjugations only. To be convinced of the truth of this, our learned and curious readers need only consult Christian Scholtz's Egyptian and Coptic grammar and dictionary, corrected and published by Godfred Woide, Oxford, 1788.

74 The Egyptian and Phœnician languages the same.

The Egyptians and Phœnicians were in a manner cousin-germans, and consequently must have spoken the same language; that is, one of the sister dialects of the Hebrew, Chaldean, Arabian, Cushite, &c.— This is not a mere conjecture; it may be realized by almost numberless examples. It is true, that when Joseph's brethren went down to Egypt, and that ruler deigned to converse with them, they could not understand the Egyptian idiom which he spoke; nor would he, had he been actually an Egyptian, have understood them without an interpreter. The only conclusion from this circumstance is, that by this time the Egyptian had deviated considerably from the original language of mankind. The Irish and Welch, every body knows, are only different dialects of the Celtic tongue; and yet experience proves, that a native of Ireland and another of Wales cannot well comprehend each other's language, nor converse intelligibly without an interpreter. The Erse, spoken in the Highlands of Scotland, and the Irish, are known to be both branches of the old Celtic; yet a Scotch Highlander and an Irishman can hardly understand each other's speech. By a parity of reason, a Hebrew and an Egyptian might, in the age of Joseph, speak only different dialects of the same original tongue, and yet find it difficult to understand one another. The fact seems to be, the Hebrew dialect had been in a manner stationary, from the migration of Abraham to that period; whereas the Egyptian, being spoken by a powerful, civilized, and highly cultivated people, must have received many improvements, perhaps additions, in the course of near two centuries.

75 The vulgar letters of Egypt nearly the same with the Hebrew or Phœnician.

The descendants of Canaan and of Mizraim were strictly connected in their religious ceremonies: they worshipped the same objects, namely, the *Host of Heaven;* they mourned *Osiris* and *Adonis* in concert; they carried on a joint commerce, and, we think, spoke the same language: we may, therefore conclude, that their vulgar letters were nearly the same, both in form, disposition, and number. Their original number was probably 16, viz. five vowels, six mutes, simple and middle, four liquids, and the solitary σ.—With these, it is likely, was joined a mark of aspiration, or an *h*, such as we have in the Roman alphabet, and find on some Greek monuments. Cadmus was originally an Egyptian; that leader brought a new set of letters into Greece. These are generally deemed to be Phœnician. They were nearly the same with the ancient Pelasgic, as will be shown in the section of the *Greek language*. The latter, we think, were from Egypt, and consequently the former must have been from the same quarter. Danaus, Perseus, Lelex, &c. were of Egyptian extraction: they too adopted the Cadmean characters, without substituting any of their own.

The Jonim or Ionians, emigrated from Gaza, a colony of Egyptians; and their letters are known to have differed very little from those of Cadmus and the Pelasgi. The conclusion, therefore is, that the vulgar Egyptian letters were the same with the Phœnician.

We are abundantly sensible that there are found upon Egyptian monuments characters altogether different from those we have been describing. At what time, by what people, and to what language, these letters belonged, we will not pretend to determine. The Ethiopians, the Chaldeans, the Persians, the Greeks, the Romans, the Saracens, have, at different times, been sovereigns of that unhappy country. Perhaps other nations, whose memory is now buried in oblivion, may have erected monuments, and covered them with inscriptions composed of words taken from different languages, perhaps, upon some occasions, whimsically devised, with a view to perplex the curious antiquaries of future ages. Some of these are composed of hieroglyphics intermingled with alphabetical characters, artificially deranged, in order to render them unintelligible. These we do not pretend to develope; because the most inquisitive and sagacious antiquaries are not yet agreed as to their purport and signification.

76 Egyptian names of Hebrew original.

We shall now go on to show, that most part of the names of persons and places, &c. which have been conveyed down to us, may, in general, be reduced to a Hebrew, Phœnician, Syrian, or Chaldean original. As the first of these languages is most generally known, we shall employ it as our arch-type or standard, beginning with those terms which occur in Scripture.

The word *Pharaoh*, the title of the *melech* or king of Egypt, is, we think, compounded of two terms, which plainly discover a Hebrew original. According to an oriental tradition, the first who assumed this title was the sovereign of the *royal shepherds;* a race of people from Arabia and Phœnicia. They conquered Egypt at an early period, and kept possession of it for several centuries. They gloried in the title ὑκσως, or ὑκουσως, which according to Josephus *contra Apion*, signifies "royal shepherds." The word *Pharaoh* seems to be compounded of פר *Phar*, "a bullock," and רעה, *Rachah*, "to feed;" hence פרעה, *Pharachah*, as we think it ought to be written. The name given to Joseph is evidently of kin with the Hebrew; for *zaphnath* differs very little from the Hebrew verb *tzaphan*, which signifies "to hide, to keep secret;" *Paneah* or *Phaneah*, signifies much the same with the Hebrew *Phanah*, aspexit: so that the name actually intimates *one* who sees hidden things; which was certainly the very idea the prince intended to convey by giving him that name.

Potiphar, or *Potipherah*, the name of Joseph's father-in-law, has likewise a dialectical affinity with the Hebrew idiom. In that language *Patah* signifies "to open, to explain," which was one part of the sacerdotal office; and *Phar* imports "a bullock." Potiphar was then

Chaldean Language, &c.

then priest of the bullock, that is, the ox, *apis*, sacred to the *sun* (1). This person was priest or *prince of On*, which, according to Cyrillus on Hosea, was an Egyptian name of that luminary. The Hebrew word *hon* or *chon* signifies "power, wealth, sufficiency;" a very proper epithet for the *sun*, who was thought to bestow those blessings. The name of Joseph's wife was *Asenath* or *Asnath*, compounded of *Ishah*, "a woman," and *Naith* or *Neit*, an Egyptian name of Minerva, "a votary of Minerva."

Almost all the names of cities belonging to Egypt which are mentioned in Scripture are evidently Hebrew. To be satisfied as to this position, our curious readers

77 and significant in that language.

may consult Jamieson's *Spicilegia*, an excellent book very little known. The names of most of the Egyptian deities are significant in the Hebrew tongue; and in that dialect the names appear to have been imposed with great judgment and propriety, plainly indicating some office assigned them, or pointing to some peculiar attribute. We shall produce a few instances.

Osiris was the great divinity of Egypt; he was certainly the *sun*. The Egyptians gave their deities a variety of names in allusion to their various offices and attributes. Jablonski has in a manner wearied himself with tracing the signification of this name. In Hebrew we have *Oshir*, "to grow rich, to be enriched." The sun may be called the great enricher of nature, and therefore might properly be called by a name alluding to that quality. *Isis* was both the moon and the earth. *Ishah* is the Hebrew word for *woman*, and Horapollo assigns this very derivation. *Anubis* was one of the names of Mercury among the Egyptians: He was always figured with the head of a *dog*. He accompanied *Isis* in her peregrinations in quest of Osiris, and frighted away the wild beasts from attacking the princess. In Hebrew, *Nubah* signifies "to bark." Here the analogy, we think, is evident. Many Egyptian names begin with *Can*, such as *Canobus*, *Canopus*, &c. The Hebrew word *Cahen* or *Cohen*, Syr. *Con* or *Chon*, intimates both a prince and a priest. *Ob* or *Aub*, in Hebrew, imports "a bottle, a flaggon," any thing round and prominent like the human belly. In the language of Egypt it was often applied to the sun, in allusion to his rotundity. In the temple of *Jupiter Ammon or Amon*, in the desert of Libya, there was a statue of the god representing the *navel* of the human body, which was probably framed in allusion to this fancy. Hence the Pythoness, or people who, according to the Scripture, had familiar spirits, were said to prophecy by the inspiration of *Ob*, as the Delphic priestess did by that of Apollo. Again, many Egyptian names end with *siris*, as Calasiris, Termosiris. This termination is no doubt a cognate of the Hebrew and Chaldean *sar* or *zar*, signifying "a prince, or grandee, &c." The river Nile in the Ethiopic dialect is called *Siris*; that is, we believe, the *king of rivers*. The same flood seems to derive the name by which it is generally known, from the Hebrew *nehel*, "a valley, or torrent running down a valley." The same river was often called *Oceanus*, a word composed of *og*, or *oc*, or *och*, which signifies "a king, a leader," and the Hebrew *oin*, "a fountain;" so that the word imports the *king of fountains*. The Hebrews always denominated the land of Egypt the land of Mizraim; the Egyptians themselves, in later times, seemed to have called it Αιγυπτος, *Ægyptus*, "Egypt," which some think is compounded of *Ai*, Hebrew, "an island, a country, a province," and *Copt* or *Cupt*, "a famous city in that country."

From this specimen, we hope it will appear that the Egyptian language in the more early ages was one of those dialects into which that of the descendants of the postdiluvian patriarchs was divided, and perhaps subdivided, a few centuries after the deluge. Among all those, we believe, such an affinity will be found, as plainly demonstrates that they originally sprung from one common stock. Here we might easily follow the Egyptian language into Greece; and there we are persuaded we might trace a vast number of Egyptian terms into that tongue, which, however, the nature of this inquiry will not permit. If our learned readers should incline to know more of the affinity of the Egyptian tongue with the others so often mentioned, they may consult Bochart's *Chanaan*, Walton's *Proleg.* Gebelin's *Monde Prim.* Jamieson's *Spicilegia*, &c.

Sect. IV. *Of the Persian Language.*

The Persian language is divided into the ancient and modern; the former of which is at this day very imperfectly known, the latter is at present one of the most expressive, and at the same time one of the most highly polished, in the world. We shall, in treating of this language, in compliance with the plan we have all along followed, begin with the ancient.

78 At the birth of Mohammed two languages prevalent in Persia.

When Mohammed was born, and Anu'shi'rava'n, whom he calls the *just king*, sat on the throne of Persia, two languages were generally prevalent in that empire (K). The one was called *Deri*, and was the dialect of the court, being only a refined and elegant branch of the *Parsi*, so called from the province of which *Shiraz* is now the capital; and that of the learned, in which most books were composed, and which had the name of *Pahlavi*, either from the heroes who spoke it in former times, or from *pahlu*, a tract of land which included some considerable cities of *Iran*: The ruder dialects of both were spoken by the rustics of several provinces; and many of these distinct idioms were vernacular, as happens in every kingdom of considerable

79 And a more ancient language than either known only to the priests.

extent. Besides the *Parsi* and *Pahlavi*, a very ancient and abstruse tongue was known to the priests and philosophers, called the language of the *Zend*, because a book on religious and moral duties which they held sacred, and which bore that name, had been written in it; while the *Pazend* or comment on that work was composed in *Pahlavi*, as a more popular dialect. The letters of this book were called *zend*, and the language *avesta*.

The *Zend* and the old *Pahlavi* are now almost extinct in *Iran*, and very few even of the Guebres can read it; while the *Parsi* remaining almost pure in *Shabnameh*, has

(1) The Septuagint (Gen. xli. v. 45. and 50.) translate *On* by Ἡλιουπολις.

(K) The moderns call the empire of Persia *Iran*; a name unknown to the ancients.

has, by the intermixture of Arabic words, and many imperceptible changes, now become a new language, exquisitely polished by a series of fine writers both in prose and verse, analogous to the different idioms gradually formed in Europe after the subversion of the Roman empire.

80 Parsi language, and The very learned and laborious Sir William Jones is confident that the *Parsi* abounds with words from the Sanscrit, with no other change than such as may be observed in the numerous dialects of India: that very many Persian imperatives are the roots of Sanscrit verbs; and that even the moods and tenses of the Persian verb substantive, which is the model of all the rest, are deducible from the Sanscrit by an easy and clear analogy. From this he infers that the *Parsi*, like the various idiom dialects, is derived from the language of the Bramins. This conclusion, we imagine, is not altogether just, since by the same train of reasoning we may infer that the Sanscrit is derived from the *Parsi*.

The same learned gentleman adds, that the multitude of compounds in the Persian language proves that it is not of Arabic but Indian original. This is undoubtedly true; but though the *Parsi* is not of Arabic original, it does not necessarily follow that it is of Sanscrit. We might with the same propriety, and with an equal show of reason, conclude, that the Greek language is descended of the Sanscrit, because it too abounds with compounds. We may then rest assured, that neither the one nor the other argument adduced by the ingenious president proves that the *Parsi* tongue is a descendant of the Sanscrit.

The gentleman so often mentioned, assures us, that the Zend bears a strong resemblance to the Sanscrit; which, however, it might do without being actually derived from it, since we believe every oriental scholar will find that all the languages from the Mediterranean to the utmost coast of Hindostan exhibit very strong signatures of a common original. The Parsi, however, not being the original dialect of Iran or Persia, we shall pursue it no farther at present, but return to give some account of the Pahlavi, which was probably the primi-
81 the Pahlavi, tive language of the country. We have observed above, that the Pazend or comment on the Zend was composed in the Pahlavi for the use of the vulgar. This, according to Sir William, was a dialect of the Chaldaic; and of this assertion he exhibits the following proof.

By the nature of the Chaldean tongue, most words ended in the first long vowel, like *shemaiá*, "heaven;" and that very word, unaltered in a single letter, we find in the Pazend, together with *lailiá*, "night," *meyá*, "water," *nírá*, "fire," *matrá*, "rain," and a multitude of others, all Arabic or Hebrew, with a Chaldean termination; so *zamar*, by a beautiful metaphor from *pruning trees*, means in Hebrew to *compose verses*, and thence, by an easy transition, to *sing* them; now in Pahlavi we see the verb *zamarûniten*, "to sing," with its forms *zamaraunemi*, "I sing," and *zamzunid*, "he sang;" the verbal terminations of the Persian being added to the Chaldaic root. All these words are integral parts of the language; not adventitious like the Arabic nouns and verbals engrafted on the modern Persian.

From this reasoning it plainly appears, 1st, That Pahlavi was the ancient language of Persia; and, 2d, That the ancient Persian was a cognate dialect of the Chaldean, Hebrew, Arabic, Phœnician, &c. M. Anquetil has annexed to his translation of the *Zendavesta* two vocabularies in Zend and Pahlavi, which he found in an approved collection of *Rawayat* or *Traditional Pieces* in modern Persian. His vocabulary of the Pahlavi strongly confirms this opinion concerning the Chaldaic origin of that language. But with respect to the Zend, it abounded with vast numbers of pure Sanscrit words, to such a degree, that six or seven words in ten belonged to that language. 82

From this deduction it would appear, that the oldest languages of Persia were Chaldaic and Sanscrit: and that when they had ceased to be vernacular, the Pahlavi and Zend were deduced from them respectively, and the Parsi either from the Zend, or immediately from the dialect of the Brahmans: but all had perhaps a mixture of Tartarian; for the best lexicographers assert, that numberless words in ancient Persian are taken from the Cimmerians. With respect to the last of these, we cannot help being of opinion, that colonies of people from the neighbourhood of Persia did transport themselves into Crim Tartary, and perhaps into Europe. These colonists brought along with them those vocables which still occur in their dialect. Emigrants from those quarters must have found their way into Scandinavia, since numberless Persian words are still current in those regions. Perhaps Odin and his followers emigrated from the neighbourhood of Media and Persia, and brought with them the dialect of the nations from whose country they had taken their departure. derived from Chaldaic and Sanscrit, &c.

With respect to the Zend, it might well be a dialect of the Sanscrit, and was probably a sacred language; and if so, concealed from the vulgar, and reserved for the offices of religion. If Zoroastres, or Zaratusht as the orientals call him, travelled into Egypt, and was initiated in the mysteries of the Egyptian religion, as some pretend he was, he might be instructed in the sacred dialect of that people by the priests under whom he studied. When that philosopher returned into Persia, and became the apostle of a new religion, he might compose the volume of his laws and religious institutions in the sacred language of his Egyptian tutors. This language then became that of the Magi, who concealed it carefully from the knowledge of the uninitiated, as the priests did in Egypt and the Brahmans in Hindostan. 83 The Zend from the same source.

In our Section on the *Sanscrit* language, we shall give a detail of a number of particulars, which to us seem to furnish a presumption that the language in question was imported from Egypt into Hindostan. We confess there are not sufficient data to improve these presumptions into absolute certainty; but we hope the time is at hand when the worthy members of the Asiatic Society will discover abundant materials to ascertain the truth of this position. We are the rather inclined to adopt this hypothesis, when we consider the character of Zoroastres in connection with that of the Egyptian Cohens and of the Indian Brahams.

If this opinion should one day appear to be well-founded, we believe the coincidence between the language of the Zend and the Sanscrit will be easily accounted for, without making the Hindoos masters of Iran or Persia, and then driving them back to the shores of the Ganges. That the nations of Turan or Scythia did

Persian Language.

did actually overrun that country, and make themselves masters of a considerable part of it at different times, is vouched by the records and traditions of the Persians themselves. Upon those occasions a number of Tartarian words might be introduced into the country, and acquire a currency among the inhabitants. As the annals of ancient Persia have been long since destroyed and consigned to eternal oblivion, it is impossible to ascertain either the extent or duration of these irruptions. Indeed the nature of our design does not call for that investigation.

84
Proofs from Scripture of the origin of the Pahlavi.

In order to corroborate the cognation between the Chaldean and Pahlavi languages, we shall subjoin a few arguments derived from the Mosaic history, and the other writings of the Old Testament. These we believe will be admitted as irrefragable proofs of the position above advanced by such as admit the authenticity of those records.

Elam is always allowed to have been the progenitor of the Persians. This patriarch was the eldest son of Shem the son of Noah; and according to the Mosaic account, his posterity settled in the neighbourhood of the descendants of Ashur, Arphaxad, Lud and Aram, the other sons of Shem. The country where they settled was denominated *Elymais* †, as late as the beginning of the Christian era. This name was retained till the Saracens conquered and took possession of that country. If this was the case, as it certainly was, the Elamites or Persians spoke a dialect of the primary language, which, in the first Section, we have proved to have been the Hebrew.

† *Strabo*, lib. 11.

When the four eastern monarchs invaded the five cities of the plain in Canaan ‡, Chedorlaomer king of Elam was at the head of the confederacy. Amraphel king of Shinar, that is Babylon or Chaldea, was one of the allies; Arioch king of Elasar was another; and Tidal, king of some scattered nations in the same neighbourhood, was the fourth. That Chedorlaomer was principal in this expedition, is obvious from the historian's detail of the second, where that prince is placed first, and the rest are named *the kings that were with him*. This passage likewise demonstrates, that Elam, Shinar, and Elasar, lay contiguous, and were engaged in the same cause. Wherever the country in question is mentioned in Scripture prior to the era of Daniel and Ezra, it is always under the name of *Elam*. To go about to prove this would be superfluous.

‡ Gen. chap. xiv.

According to Xenophon §, the Persians knew nothing of horsemanship before the age of Cyrus: but that historian informs us, that after that monarch had introduced the practice of fighting on horseback, they became so fond of it, that no man of rank would deign to fight on foot. Here it ought to be considered, that the historian above mentioned was now writing a moral, military, and political romance; and therefore introduces this anecdote, in order to exalt the character of his hero: so that we are not to suppose that the people under consideration were unacquainted with the art of horsemanship till that period.

§ *Cyrop.* lib. 1.

The very name *Phars* or *Pharas* is certainly of Hebrew origin, and alludes to the skill that people professed in horsemanship. The original seems to be *Pharsah, ungula*, "a hoof;" and in the Arabic *Pharas* intimates a *horse*, and *Pharis* a *horseman*. Consequently the people were denominated *Parsai*, and the country *Pars*, because they were trained from their infancy to ride the *great horse*, which indeed they deemed their greatest honour. This name was perhaps first imposed upon them by the neighbouring nations, and in process of time became their gentile appellation. *Mithras* is generally known to have been the chief divinity of the Persians; a name which is plainly derived from *Mither*, "great." We find in Strabo the Persian god *Amanus*, which is plainly a cognate of *Hamah*, the "sun or fire." Hence we believe comes *Hamarim*, the "hearths or chapels," where the fire sacred to the sun was kept burning; which, we believe, the Greeks called Πυραθεια, or "fire-temples." Herodotus † mentions a custom among the Persians, according to which, when they came to engage an enemy, they cast a rope with a kind of gin at the end of it on their enemy, and by those means endeavoured to entangle and draw him into their power. The people of Persia who employed this net or gin were called *Sargates*, from *sarags*, *sherag*, or *serig*, a word which in Hebrew, Arabic, and Chaldaic, signifies to "hamper or entangle:" hence perhaps the Greek word Σαργανη, a "basket or net." *Sar* or *zar* in Hebrew, Phœnician, Syriac, &c. signifies "a lord, a prince;" and hence we have the initial syllable of the far-famed *zar-tusht*, *Zoroastres*. In a word, most of the Persian names that occur in the Grecian histories, notwithstanding the scandalous manner in which they have been disguised and metamorphosed by the Greeks, may still with a little skill and industry be traced back to a Hebrew, Chaldaic, Syriac, or Phœnician origin. In the books of Daniel, Ezra, Nehemiah, and Esther, we find a number of Persian names which are all of a Hebrew or Chaldaic complexion: to investigate these at much greater length would be foreign to the design of the present article. If our curious reader should incline to be more fully satisfied as to this point, he may consult Bochart's *Chanaan*, D'Herbelot's *Bib. Orient.* Walton's *Proleg.* &c.

† Lib. ix. cap. 85.

It now appears, we hope, to the entire satisfaction of our readers, that the Pahlavi is a remnant of the old Persian, and that the latter is a cognate branch of the Hebrew, Chaldaic, Syriac, &c. We have likewise adduced some presumptive proofs that the Zend was copied from the sacred language of the Egyptians: we shall now endeavour to explain by what changes and revolutions the language first mentioned arrived at its present summit of beauty and perfection.

85
Progress of the Persian language.

We have observed above, that the Scythians, whom the old Persians called Σακαι, *Sacæ*, and whom the modern call *Turan*, often invaded and overran Persia at a very early period. The consequence was, an infusion of Scythian or Tartarian terms, with which that language was early impregnated. This in all probability occasioned the first deviation from the original standard. The conquests of Alexander, and the dominion of his successors, must, one would imagine, introduce an inundation of Greek words. That event, however, seems to have affected the language in no considerable degree, at least very few Grecian terms occur in the modern Persian.

The empire of the *Arsacidæ* or Parthians, we apprehend, produced a very important alteration upon the ancient Persian. They were a demi-Scythian tribe; and as they conquered the Persians, retained the dominion of those parts for several centuries, and actually incorpo-

Persian Language.

rated with the natives, their language must necessarily have given a deep tincture to the original dialect of the Persians. Sir William Jones has observed, that the letters of the inscriptions at *Istakhr* or Persepolis bear some resemblance to the old Runic letters of the Scandinavians. Those inscriptions we take to have been Parthian; and we hope, as the Parthians were a Tartarian clan, this conjecture may be admitted till another more plausible is discovered. The Persians, it is true, did once more recover the empire; and under them began the reign of the Deri and Parsi tongues: the former consisting of the old Persian and Parthian highly polished; the latter of the same languages in their uncultivated vernacular dress. In this situation the Persian language remained till the invasion of the Saracens in 636; when these barbarians overran and settled in that fine country; demolished every monument of antiquity, records, temples, palaces, every remain of ancient superstition; massacred or expelled the ministers of the Magian idolatry; and introduced a language, though not entirely new, yet widely differing from the old exemplar.

But before we proceed to give some brief account of the modern Persian, we must take the liberty to hazard one conjecture, which perhaps our adepts in modern Persian may not find themselves disposed to admit. In modern Persian we find the ancient Persian names wonderfully distorted and deflected from that form under which they appear in the Scripture, in Ctesias, Megasthenes, and the other Greek authors. From this it has been inferred, that not only the Greeks, but even the sacred historians of the Jews, have changed and metamorphosed them most unmercifully, in order to accommodate them to the standard of their own language. As to the Greeks, we know it was their constant practice, but we cannot believe so much of the Hebrews. We make no doubt of their writing and pronouncing the names of the Persian monarchs and governors of that nation nearly in the same manner with the native Persians. It is manifest, beyond all possibility of contradiction, that they neither altered the Tyrian and Phœnician names of persons and places when they had occasion to mention them, nor those of the Egyptians when they occurred in their writings. The Babylonian and Chaldaic names which are mentioned in the Old Testament vary nothing from the Chaldean original. No reason can be assigned why they should have transformed the Persian names more than the others. On the contrary, in Ezra, Nehemiah, and Esther, we find the Persian names faithfully preserved throughout.

86
Nothing now existing in Persic, except the Zend, older than the Saracen conquest.

The fact, we imagine, is this: Our modern admirers of the Persic have borrowed their names of the ancient kings and heroes of that country from romances and fabulous legends of more modern date and composition. The archives of Persia were destroyed by the Saracens: nothing of importance was written in that country till two centuries after the era of Mohammed. What succeeded was all fiction and romance. The authors of those entertaining compositions either forged names of heroes to answer their purpose, or laid hold on such as were celebrated in the ballads of their country, or preserved by vulgar tradition. The names were no doubt very different from those of the ancient kings and heroes of Persia; and probably many of them had undergone considerable changes during the continuance of the Parthian empire. Upon this foundation has the learned Mr Richardson erected a very irregular fabric, new, and to use his own expression, we think built upon *pillars of ice*. He has taken much pains to invalidate the credit of the Grecian histories of the Persian empire, by drawing up in battle array against their records legions of romantic writers, who were not born till near 1000 years after the events had taken place; and to complete the probability, who lived 200 years after all the chronicles of the Medes and Persians had been finally destroyed by the fury of the Saracens.

After the decisive victory obtained over the Persians at Kadessa, their ancient government was overturned, their religion proscribed, their laws trampled under foot, and their civil transactions disturbed by the forcible introduction of the lunar for the solar kalendar; while, at the same time, their language became almost overwhelmed by an inundation of Arabic words: which from that period, religion, authority, and fashion, incorporated with their idiom.

From the seventh till the tenth century the Persian tongue, now impregnated with Arabic words, appears to have laboured under much discouragement and neglect. Bagdad, built by Almansor, became soon after the year 762 the chief residence of the caliphs, and the general resort of the learned and the ambitious from every quarter of the empire. At length the accession of the Buyah princes to the Persian throne marked in the tenth century the great epoch of the revival of Persian learning. About the year 977 the throne of Persia was filled by the great Azaduddawla; who first assumed the title of *Sultan*, afterwards generally adopted by eastern princes. He was born in Ispahan, and had a strong attachment to his native kingdom. His court, whether at Bagdad or in the capital of Persia, was the standard of taste and the favourite residence of genius. The native dialect of the prince was particularly distinguished, and became soon the general language of composition in almost every branch of polite learning. From the end of the tenth till the 15th century may be considered as the most flourishing period of Persian literature. The epic poet Firdausi, in his romantic history of the Persian kings and heroes, displays an imagination and smoothness of numbers hardly inferior to Homer. The whole fanciful range of Persian enchantment he has interwoven in his poems, which abound with the noblest efforts of genius. This bard has stamped a dignity on the monsters and fictions of the east, equal to that which the prince of epic poetry has given to the mythology of ancient Greece. His language may at the same time be considered as the most refined dialect of the ancient Persian, the Arabic being introduced with a very sparing hand: whilst Sadi, Jami, Hafiz, and other succeeding writers, in prose as well as verse, have blended in their works the Arabic without reserve; gaining perhaps in the nervous luxuriance of the one language what may seem to have been lost in the softer delicacy of the other. Hence Ebn Fekreddin Anju, in the preface to the dictionary called *Farhung Jehanguiri*, says, that the Deri and the Arabic idioms were the languages of heaven; God communicating to the angels his milder mandates in the delicate accents of the first, while his stern commands were delivered in the rapid accents of the last.

87
The most flourishing period of Persian literature.

For near 300 years the literary fire of the Persians seems

Persian Language.

seems indeed to have been almost extinguished; since, during that time, hardly any thing of that people which deserves attention has appeared in Europe: enough, however, has already been produced, to inspire us with a very high opinion of the genius of the east. In taste, the orientals are undoubtedly inferior to the best writers of modern Europe; but in invention and sublimity, they are excelled, perhaps equalled, by none. The Persians affect a rhetorical luxuriance, which to a European wears the air of unnecessary redundance. If to these leading distinctions we add a peculiar tone of imagery, of metaphor, of allusion, derived from the difference of government, of manners, of temperament, and of such natural objects as characterise Asia from Europe; we shall see, at one view, the great points of variation between the writers of the east and west. Amongst the oriental historians, philosophers, rhetoricians, and poets, many will be found who would do honour to any age or people; whilst their romances, their tales, and their fables, stand upon a ground which Europeans have not yet found powers to reach. We might here quote the Arabian Nights Entertainments, Persian Tales, Pilpay's Fables, &c.

88 The genius of the modern Persic.

We shall now annex a few strictures on the genius of that noble language; though it is our opinion that the province of the philologist is to investigate the origin, progress, and final improvement of a language, without descending to its grammatical minutiæ or peculiar idiomatic distinctions. We have already observed, that the tongue under consideration is partly Arabic and partly Persian, though the latter generally has the ascendant. The former is nervous, impetuous, and masculine; the latter is flowing, soft, and luxuriant. Wherever the Arabic letters do not readily incorporate with the Persian, they are either changed into others or thrown away. Their letters are the Arabic with little variation; these being found more commodious and expeditious than the old letters of the Deri and Parsi. Their alphabet consists of 32 letters, which, like the Arabic, are read from right to left; their form and order will be learned from any grammar of that language. The letters are divided into vowels and consonants as usual. The Arabic characters, like those of the Europeans, are written in a variety of different hands; but the Persians write their poetical works in the Talick, which answers to the most elegant of our Italic hands.

89 Resemblance between Persian and English.

There is a great resemblance between the Persian and English languages in the facility and simplicity of their form and construction: the former, as well as the latter, has no difference of terminations to mark the gender either in substantives or adjectives; all inanimate things are neuter; and animals of different sexes have either different names, or are distinguished by the words *ner*, male, and *made*, female. Sometimes indeed a word is made feminine, after the manner of the Arabians, by having ᵫ added to it.

The Persian substantives have but one variation of case, which is formed by adding a syllable to the nominative in both numbers; and answers often to the dative, but generally to the accusative, case in other languages. The other cases are expressed for the most part by particles placed before the nominative. The Persians have two numbers, singular and plural; the latter is formed by adding a syllable to the former.

The Persian adjectives admit of no variation but in the degrees of comparison. The comparative is formed by adding *ter*, and the superlative by adding *terin* to the positive.

The Persians have active and neuter verbs like other nations; but many of their verbs have both an active and neuter sense, which can be determined only by the construction. Those verbs have properly but one conjunction, and but three changes of tense: the imperative, the aorist, and the preterite; all the other tenses being formed by the help of particles or of auxiliary verbs. The passive voice is formed by adding the tenses of the substantive verb to the participle of the active.

In the ancient language of Persia there were very few or no irregularities; the imperative, which is often irregular in the modern Persian, was anciently formed from the infinitive, by rejecting the termination *eeden:* for originally all infinitives ended in *den*, till the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into *ten*, and by degrees the original infinitive grew quite obsolete; yet they still retain the ancient imperative, and the aorists which are formed from it. This little irregularity is the only anomalous part of the Persian language; which nevertheless far surpasses in simplicity all other languages ancient or modern.

With respect to the more minute and intricate parts of this language, as well as its derivations, compositions, constructions, &c. we must remit our readers to Mininskie's *Institutiones Linguæ Turcicæ, cum rudimentis parallelis linguarum Arab. et Pers.*; Sir William Jones's Persian Grammar; Mr Richardson's Arabian and Persian Dictionary; D'Herbelot's *Bibl. Orient.*; Dr Hyde *de Relig. vet. Pers.* &c. Our readers, who would penetrate into the innermost recesses of the Persian history, colonies, antiquities, connections, dialects, may consult the last mentioned author, especially chap. xxxv. *De Persia et Persarum nominibus, et de moderna atque veteri lingua Persica, ejusque dialectis.* In the preceding inquiry we have followed other authors, whose accounts appeared to us more natural, and much less embarrassing.

90 Utility of the Arabian and Persian languages.

To conclude this section, which might easily have been extended into a large volume, we shall only take the liberty to put our readers in mind of the vast utility of the Arabian and Persian languages. Numberless events are preserved in the writing of the orientals which were never heard of in Europe, and must have for ever lain concealed from the knowledge of its inhabitants, had not these two tongues been studied and understood by the natives of this quarter of the globe. Many of those events have been transmitted to posterity in poems and legendary tales like the Runic fragments of the north, the romances of Spain, or the heroic ballads of our own country. Such materials as these, we imagine, may have suggested to Firdausi, the celebrated heroic poet of Persia, many of the adventures of his *Shahnumé*; which, like Homer when stript of the machinery of supernatural beings, is supposed to contain much true history, and a most undoubted picture of the superstition and manners of the times. The knowledge of these two languages has laid open to Europe all the treasures of oriental learning, and has enriched the minds of Britons with

Persian Language.

with Indian science as much as the prudence of the regions has increased their wealth and enervated their constitution.

91 Persian poetry.

Before we conclude this section, we shall subjoin a few strictures on the nature of Persian poetry, in order to render our inquiry the more complete. The modern Persians borrowed their poetical measures from the Arabs: they are exceedingly various and complicated; they consist of 19 different kinds; but the most common of them are the *Iambic* or *Trochaic* measures, and a metre that chiefly consists of those compounded feet which the ancients called Επιτριτυς, which are composed of iambics and spondees alternately. In lyric poetry their verses generally consist of 12 or 16 syllables: they sometimes, but seldom, consist of 14. Some of their lyric verses contain 13 syllables; but the most common Persian verse is made up of 11; and in this measure are written all their great poems, whether upon heroic or moral subjects, as the works of Firdausi and Jami, the Bostar of Sadi, and the Mesnavi of Gelaleddin. This sort of verse answers to our common heroic rhyme, which was brought to so high a degree of perfection by Pope. The study of the Persian poetry is so much the more necessary, as there are few books or even letters written in that language, which are not interspersed with fragments of poetry. As to their prosody, nothing can be more easy and simple. When the student can read prose easily, he will with a little attention read poetry with equal facility.

Sect. V. *Sanscrit and Bengalese Languages.*

92 The Sanscrit one of the most ancient languages in the world.

The Sanscrit, though one of the most ancient languages in the world, was little known even in Asia till about the middle of the present century. Since that period, by the indefatigable industry of the very learned and ingenious Sir William Jones, and the other worthy members of that society of which he has the honour to be president, that noble and ancient language has at length been brought to light; and from it vast treasures of oriental knowledge will be communicated both to Europe and Asia; knowledge which, without the exertions of that happy establishment, must have lain concealed from the researches of mankind to the end of the world. In this section we propose to give to our readers such an account of that language as the limits of the present article, and the helps we have been able to procure, shall permit.

The Sanscrit language has for many centuries lain concealed in the hands of the bramins of Hindostan. It is by them deemed sacred, and is of consequence confined solely to the offices of religion. Its name imports the *perfect language*, or, according to the eastern style, *the language of perfection;* and we believe no language ever spoken by man is more justly intitled to that high epithet.

The grand source of Indian literature, and the parent of almost every dialect from the Persian gulf to the China seas, is the Sanscrit; a language of the most venerable and most remote antiquity, which, though at present shut up in the libraries of the bramins, and appropriated solely to the records of their religion, appears to have been current over most of the oriental world. Accordingly traces of its original extent may be discovered in almost every district of Asia. Those who are acquainted with that language have often found the similitude of Sanscrit words to those of Persian and Arabic, and even of Latin and Greek; and that not in technical and metaphorical terms, which refined arts and improved manners might have occasionally introduced, but in the main ground-work of language, in monosyllables, the names of numbers, and appellations of such things as would be first discriminated on the immediate dawn of civilization.

93 Traces of Sanscrit in every district of Asia and elsewhere.

Sanscrit and Bengalese Languages.

The ancient coins of many different and distant kingdoms of Asia are stamped with Sanscrit characters, and mostly contain allusions to the old Sanscrit mythology. Besides, in the names of persons and places, of titles and dignities, which are open to general notice, even to the farthest limits of Asia, may be found manifest traces of the Sanscrit. The scanty remains of Coptic antiquities afford little scope for comparison between that idiom and this primitive tongue; but there still exists sufficient ground to conjecture, that, at a very early period, a correspondence did subsist between these two nations. The Hindoos pretend, that the Egyptians frequented their country as disciples, not as instructors; that they came to seek that liberal education and those sciences in Hindostan, which none of their own countrymen had sufficient knowledge to impart. Perhaps we may examine the validity of this claim hereafter.

But though numberless changes and revolutions have from time to time convulsed Hindostan, that part of it which lies between the Indus and the Ganges still preserves that language whole and inviolate. Here they still offer a thousand books to the perusal of the curious; many of which have been religiously handed down from the earliest periods of human existence. 94 Number of books in that language.

The fundamental part of the Sanscrit language is divided into three classes: *Dhaat*, or roots of verbs, which some call primitive elements; *Shubd*, or original nouns; and *Evya*, or particles. The latter are ever indeclinable, as in other languages; but the words comprehended in the two former classes must be prepared by certain additions and inflexions to fit them for a place in composition. And here it is that the art of the grammarian has found room to expand itself, and to employ all the powers of refinement. Not a syllable, not a letter, can be added or altered but by regimen; not the most trifling variation of the sense, in the minutest subdivision of declension or conjugation, can be effected without the application of several rules: all the different forms for every change of gender, number, case, person, tense, mood, or degree, are methodically arranged for the assistance of the memory, according to an unerring scale. The number of the radical or elementary parts is about 700; and to these, as to the verbs of other languages, a very plentiful stock of verbal nouns owes its origin; but these are not thought to exceed those of the Greek either in quantity or variety. 95 Characteristics of it.

To the triple source of words mentioned above, every term of truly Indian original may be traced by a laborious and critical analysis. All such terms as are thoroughly proved to bear no relation to any one of the Sanscrit roots, are considered as the production of some remote and foreign idiom, subsequently ingrafted upon the main stock; and it is conjectured, that a judicious investigation of this principle would throw a new light

light upon the first invention of many arts and sciences, and open a fresh mine of philological discoveries. We shall now proceed to give as exact an account of the constituent parts of this language as the nature of our design will permit.

96
It is copious and nervous.

The Sanscrit language is very copious and nervous. The first of these qualities arises in a great measure from the vast number of compound words with which it is almost overstocked. "The Sanscrit (says Sir William Jones) like the Greek, Persian, and German, delights in compounds; but to a much higher degree, and indeed to such excess, that I could produce words of more than 20 syllables; not formed ludicrously like that by which the buffoon in Aristophanes describes a feast, but with perfect seriousness, on the most solemn occasions, and in the most elegant works." But the style of its best authors is wonderfully concise. In the regularity of its etymology it far exceeds the Greek and Arabic; and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules also are numerous and difficult, though there are not many anomalies. As one instance of the truth of this assertion, it may be observed, that there are seven declensions of nouns, all used in the singular, the dual, and the plural numbers, and all of them differently formed, according as they terminate with a consonant, with a long or a short vowel; and again, different also as they are of different genders: not a nominative case can be formed to any one of these nouns without the application of at least four rules, which vary likewise with each particular difference of the nouns, as above stated: add to this, that every word in the language may be used through all the seven declensions, which is a full proof of the difficulty of the idiom.

The Sanscrit grammars are called *Beeākĕrun*, of which there are many composed by different authors; some too abstruse even for the comprehension of most bramins, and others too prolix to be ever used as references. One of the shortest, named the *Sārăsootee*, contains between two and three hundred pages, and was compiled by Anoŏbhōōtēē Seroopĕnām Achārige, with a conciseness that can scarcely be paralleled in any other language.

97
Sanscrit alphabet.

The Sanscrit alphabet contains 50 letters; and it is one boast of the bramins, that it exceeds all other alphabets in this respect: but it must be observed, that as of their 34 consonants, near half carry combined sounds, and that six of their vowels are merely the correspondent long ones to as many which are short, the advantage seems to be little more than fanciful. Besides these, they have a number of characters which Mr Halhed calls connected vowels, but which have not been explained by the learned president of the Asiatic Society.

† Plate CCCCXVI.

The Sanscrit character used in Upper Hindostan † is said to be the same original letter that was first delivered to the people by Brahma, and is now called *Diewnāgur*, or the language of angels, which shows the high opinion that the bramins have entertained of that character. Their consonants and vowels are wonderfully, perhaps whimsically, modified and diversified; to enumerate which, in this place, would contribute very little either to the entertainment or instruction of our readers. All these distinctions are marked in the *Beids* (L), and must be modulated accordingly; so that they produce all the effect of a laboured recitative: but by an attention to the music of the chant, the sense of the passage recited equally escapes the reader and the audience. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody; and it is supposed that this usage has descended to them from the remotest ages.

98
Poetry.

The Sanscrit poetry comprehends a very great variety of different metres, of which the most common are these:

The *munnee hurreneh chhund*, or line of 12 or 19 syllables, which is scanned by three syllables in a foot, and the most approved foot is the anapæst.

The *cābee chhund*, or line of eleven syllables.

The *anŭshtose chhund*, or line of eight syllables.

The poems are generally composed in stanzas of four lines, called *ashlogues*, which are regular or irregular.

The most common ashlogue is that of the *anŭshtose chhund*, or regular stanza of eight syllables in the line. In this measure the greatest part of the *Māhābāret* is composed. The rhyme in this kind of stanza should be alternate; but the poets do not seem to be very nice in the observance of a strict correspondence in the sounds of the terminating syllables, provided the feet of the verse are accurately kept.

This short *anŭshtose ashlogue* is generally written by two verses in one line, with a pause between; so the whole then assumes the form of a long distich.

The irregular stanza is constantly called *anyāchhund*, of whatever kind of irregularity it may happen to consist. It is most commonly compounded of the long line *cābee chhund* and the short *anŭshtose chhund* alternately; in which form it bears some resemblance to the most common lyric measure of the English.

Perhaps our readers may feel a curiosity to be informed of the origin of this oriental tongue. If we believe the bramins themselves, it was coeval with the race of man, as was observed towards the beginning of this section. The bramins, however, are not the only people who ascribe a kind of eternity to their own particular dialect. We find that the Sanscrit in its primitive destination was appropriated to the offices of religion. It is indeed pretended, that all the other dialects spoken in Hindostan were emanations from that fountain, to which they might be traced back by a skilful etymologist. This, we think, is an argument of no great consequence, since we believe that all the languages of Europe, by the same process, may be deduced from any one of those current in that quarter of the globe. By a parity of reason, all the different dialects of Hindostan may be referred to the language in question. Indeed, if we admit the authority of the Mosaic history, all languages whatsoever are derived from that of the first man. It is allowed that the language under consideration is impregnated with Persian, Chaldaic, Phœnician, Greek, and

99
Origin of this tongue.

(L) The books which contain the religion of the bramins.

Sanscrit and Bengalese Languages.

and even Latin idioms. This, we think, affords a presumption that the Sancrit was one of those original dialects which were gradually produced among the descendants of Noah, in proportion as they gradually receded from the centre of population. What branch or branches of that family emigrated to Hindostan, it is not easy to determine. That they were a party of the descendants of Shem is most probable, because the other septs of his posterity settled in that neighbourhood. The sum then is, that the Hindoos were a colony consisting of the descendants of the patriarch Shem.

It appears, however, by almost numberless monuments of antiquity still existing, that at a very early period a different race of men had obtained settlements in that country. It is now generally admitted, that colonies of Egyptians had peopled a considerable part of Hindostan. Numberless traces of their religion occur everywhere in those regions. The very learned president himself is positive, that vestiges of those sacerdotal wanderers are found in India, China, Japan, Tibet, and many parts of Tartary. Those colonists, it is well known, were zealous in propagating their religious ceremonies wherever they resided, and wherever they travelled. There is at the same time even at this day a striking resemblance between the sacred rites of the vulgar Hindoos and those of the ancient Egyptians. The prodigious statues of Salsette and Elephanta fabricated in the Egyptian style; the vast excavations hewn out of the rock in the former; the woolly hair of the statues, their distorted attitudes, their grotesque appearances, their triple heads, and various other configurations —plainly indicate a foreign original. These phenomena suit no other people on earth so exactly as the sons of Mizraim. The Egyptian priests used a sacred character, which none knew but themselves; none were allowed to learn except their children and the choice of the initiated. All these features mark an exact parallel with the bramins of the Hindoos. Add to this, that the dress, diet, lustrations, and other rites of both sects, bore an exact resemblance to each other. Sir William Jones has justly observed, that the letters of the Sanscrit, stript of all adventitious appendages, are really the square Chaldaic characters. We learn from Cassiodorus † the following particulars: "The height of the obelisks is equal to that of the circus; now the higher is dedicated to the sun, and the lower to the moon, where the sacred rites of the ancients are intimated by Chaldaic signatures by way of letters." Here then it is plain that the sacred letters of the Egyptians were Chaldaic, and it is allowed that those of the bramins were of the same complexion; which affords a new presumption of the identity of the Sancrit with those just mentioned.

† Lib. iii. epist. 2. et 51.

That the Egyptians had at a very early period penetrated into Hindostan, is universally admitted. Osiris, their celebrated monarch and deity, according to their mythology, conducted an army into that country; taught the natives agriculture, laws, religion, and the culture of the vine, &c. He is said at the same time to have left colonies of priests, as a kind of missionaries, to instruct the people in the ceremonies of religion. Sesostris, another Egyptian potentate, likewise overran Hindostan with an army, and taught the natives many useful arts and sciences. When the pastor-kings invaded and conquered Egypt, it is probable that numbers of the priests, in order to avoid the fury of the merciless invaders, who demolished the temples and persecuted the ministers of religion, left their native country, and transported themselves into India. These, we should think, were the authors both of the language and religion of the bramins. This dialect, as imported by the Egyptians, was probably of the same contexture with the sacred language of that people, as it appeared many ages after. The Indians, who have always been an inventive and industrious race of men, in process of time cultivated, improved, diversified, and constructed that language with such care and assiduity, that it gradually arrived at that high degree of perfection in which at present it appears.

Had the learned president of the Asiatic Society (M), when he instituted a comparison between the deities of Hindostan on the one side and of Greece and Italy on the other, examined the analogy between the gods of Hindostan and those of Egypt, we think he would have performed a piece of service still more eminent. Having first demonstrated the similarity between the divinities of India and Egypt, he might then have proceeded to investigate the resemblance of the Egyptian and Phoenician with those of Greece and Rome. By this process a chain would have been formed which would have conducted his reader to comprehend at one view the identity of the Zabian worship almost throughout the world.

We foresee that it will be objected to this hypothesis, that all the dialects of Hindostan being clearly reducible to the Sanscrit, it is altogether impossible that it could have been a foreign language. To this we answer, that at the early period when this event is supposed to have taken place, the language of the posterity of the sons of Noah had not deviated considerably from the primitive standard, and consequently the language of the Egyptians and the Hindoos was nearly the same. The Sanscrit was gradually improved: the language of the vulgar, as is always the case, became more and more different from the original archetype; but still retained such a near resemblance to the mother-tongue as proved the verity of its extraction. 100

Bengalese language derived from the Sanscrit.

To the preceding account of the Sanscrit language we shall annex a few strictures on the language of Bengal, which we believe is derived from the other, and is in most common use in the southern parts of Hindostan.

Though most of the ancient oriental tongues are read from right to left, like the Hebrew, Chaldaic, Arabic, &c. yet such as properly belong to the whole continent of India proceed from left to right like those of Europe. The Arabic, Persian, &c. are the grand sources whence the former method has been derived; but with these, the numerous original dialects of Hindostan have not the smallest connection or resemblance.

The great number of letters, the complex mode of combination, and the difficulty of pronunciation, are considerable

(M) See that gentleman's discourse, *Researches*, vol. i.

2

Sanscrit and Bengalese Languages.

considerable impediments to the study of the Bengal language; and the carelessness and ignorance of the people, and the inaccuracy of their characters, aggravate these inconveniences. Many of their characters are spurious; and these, by long use and the hurry of business, are now almost naturalized into the language.

101 Bengal alphabet.

The Bengal alphabet, like that of the Sanscrit, from which it is derived, consists of 50 letters, whose form, order, and sound, may be learned from Mr Halhed's grammar of the Bengal language. The vowels are divided into long and short, the latter of which are often omitted in writing. Most of the oriental languages are constructed upon the same principle, with respect to the omission of the short vowel. The Hebrews had no sign to express it before the invention of the Masoretic points; in Arabic it is rarely inserted unless upon very solemn occasions, as in the Koran; in the modern Persian it is universally omitted: so to all the consonants in the Sanscrit, the short vowel is an invariable appendage, and is never signified by any diacritical mark; but where the construction requires that the vowel should be dropped, a particular stroke is set under the letter. It is in vain to pretend, in a sketch like this, to detail the sound and pronunciation of these letters: this must be acquired by the ear and by practice.

102 Genders, &c. of this language.

In the Bengal language, there are three genders, as in Greek, Arabic, &c. The authors of this threefold division of genders, with respect to their precedence, appear to have considered the neuter as a kind of residuum resulting from the two others, and as less worthy or less comprehensive than either (see section of the *Greek*). The terminations usually applied upon this occasion are *aa* for the masculine, and *ee* for the feminine. In Sanscrit, as in Greek and Latin, the names of all things inanimate have different genders, founded on vague and incomprehensible distinctions: the same is the case with the Bengal.

103 Peculiarities of Sanscrit and Bengalese nouns.

A Sanscrit noun, on its first formation from the general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative; nor is impressed with any of those modifications which mark the relation and connection between the several members of a sentence. In this state it is called an *imperfect* or *crude* noun. To make a nominative of a word, the termination must be changed and a new form supplied. Thus we see, that, in the Sanscrit at least, the nominative has an equal right with any other inflection to be called a case. Every Sanscrit noun has seven cases, exclusive of the vocative; and therefore comprehends two more than even those of the Latin. Mr Halhed above mentioned details all the varieties of these with great accuracy, to whose grammar we must refer our readers. The Bengal has only four cases beside the vocative; in which respect it is much inferior to the other.

It would be difficult to account for the variety of words which have been allotted to the class of pronouns by European grammarians. The first and second person are chiefly worthy of observation; these two should seem to be confined to rational and conversable beings only: the third supplies the place of every object in nature; wherefore it must necessarily be endued with a capacity of shifting its gender respectively as it shifts the subject; and hence it is in Sanscrit frequently denominated an adjective. One of the demonstratives *hic* or *ille* usually serves for this purpose; and generally the latter, which in Arabic has no other name than *dhemeer el ghaayb*, "the pronoun of the absentee," for whose name it is a substitute.

104 Bengalese pronouns.

In most languages where the verb has a separate inflection to each person, that inflection is sufficient to ascertain the personality; but in Bengal compositions, though the first and second persons occur very frequently, nothing is more rare than the usage of the pronoun of the third; and names of persons are inserted with a constant and disgusting repetition, to avoid, as it should seem, the application of the words HE and SHE. The second person is always ranked before the first, and the third before the second. The personal pronouns have seven cases, which are varied in a very irregular manner. Leaving these to the Bengalian grammar, we shall proceed to the *verb*.

The Sanscrit, the Arabic, the Greek and Latin verbs, are furnished with a set of inflections and terminations so comprehensive and so complete, that by their form alone they can express all the different distinctions both of persons and time. Three separate qualities in them are perfectly blended and united. Thus by their root they denote a particular act, and by their inflection both point out the time when it takes place and the number of the agents. In Persian, as in English, the verb admits but of two forms, one for the present tense and one for the aorist; and it is observable, that while the past tense is provided for by a peculiar inflection, the future is generally supplied by an additional word conveying only the idea of time, without any other influence on the act implied by the principal verb. It is also frequently necessary that the different state of the action, as perfect or imperfect, be further ascertained in each of the tenses, past, present, and future. This also, in the learned languages, is performed by other variations of inflections, for which other verbs and other particles are applied in the modern tongues of Europe and Persia.

105 Middle voice of Sanscrit verbs.

Every Sanscrit verb has a form equivalent to the middle voice of the Greek, used through all the tenses with a reflective sense, and the former is even the most extensive of the two in its use and office: for in Greek the reflective can only be adopted intransitively when the action of the verb descends to no extraneous subject; but in Sanscrit, the verb is both reciprocal and transitive at the same time.

Neither the Sanscrit, nor the Bengalese, nor the Hindostanic, have any word precisely answering to the sense of the verb *I have*, and consequently the idea is always expressed by *est mihi*; and of course there is no auxiliary form in the Bengal verb correspondent to *I have written*, but the sense is conveyed by another mode. The very substantive, in all languages, is defective and irregular, and therefore the Sanscrit calls it a *semi-verb*. It is curious to observe that the present tense of this verb, both in Greek and Latin, and also in the Persian, appears plainly to be derived from the Sanscrit. In the Bengalese, this verb has but two distinctions of time, the present and the past; the terminations of the several persons of which serve as a model for those of the same tense in all other verbs respectively.

106 Characteristics of the Bengalese verbs.

Verbs of the Bengal language may be divided into three classes, which are distinguished by their penultimate letter. The simple and most common form has an

Sanscrit and Bengalese Languages.

an open consonant immediately preceding the final letter of the infinitive. The second is composed of those words whose final letter is preceded by another vowel or open consonant going before it. The third consists entirely of causals derived from verbs of the first and second conjugations. The reader will easily guess at the impossibility of prosecuting this subject to any greater length: we shall therefore conclude with a few remarks collected from the grammar so often mentioned, which we apprehend may be more amusing, if not more instructing.

The Greek verbs in μι are formed exactly upon the same principle with the Sanscrit conjugations, even in the minutest particulars. Instances of this are produced in many verbs, which from a root form a new verb by adding the syllable *mi*, and doubling the first consonant. This mode furnishes another presumption of the Egyptian origin of the Sanscrit. Many Greeks travelled into Egypt; many Egyptian colonies settled in Greece. By one or other of those channels the foregoing innovation might have been introduced into the Greek language.

To form the past tense, the Sanscrit applies a syllabic augment, as is done in the Greek: the future has for its characteristic a letter analogous to that of the same tense in the Greek, and it omits the reduplication of the first consonant. It may be added, that the reduplication of the first consonant is not constantly applied to the present tense of the Sanscrit more than to those of the Greek.

The natural simplicity and elegance of many of the Asiatic languages are greatly debased and corrupted by the continual abuse of auxiliary verbs; and this inconvenience has evidently affected the Persian, the Hindostan, and the Bengal idioms.

The infinitives of verbs in the Sanscrit and Bengalese are always used as substantive nouns. Every body knows that the same mode of arrangement very often occurs in the Greek.

In the Sanscrit language, as in the Greek, there are forms of infinitives and of participles comprehensive of time; there are also other branches of the verb that seem to resemble the gerunds and supines of the Latin.

All the terms which serve to qualify, to distinguish, or to augment, either *substance* or *action*, are classed by the Sanscrit grammarians under one head; and the word used to express it literally signifies *increase* or *addition*. According to their arrangement, a simple sentence consists of three members; the *agent*, the *action*, the *subject;* which, in a grammatical sense, are reduced to two; the *noun* and the *verb*. They have a particular word to specify such words as amplify the noun which imports quality, and answers to our *adjectives* or *epithets:* Such as are applied to denote relation or connection, are intimated by another term which we may translate *preposition*.

107 Sanscrit and Bengalese adjectives.

The adjectives in Bengalese have no distinction of gender or number; but in Sanscrit these words preserve the distinction of gender, as in the Greek and Latin.

Prepositions are substitutes for cases, which could not have been extended to the number necessary for expressing all the several relations and predicaments in which a noun may be found, without causing too much embarrassment in the form of a declension. Those are too few in the Greek language, which occasions much inconvenience. See sect. *Greek*.

The Latin is less polished than the Greek, and of consequence bears a much nearer resemblance to the Sanscrit, both in words, inflections, and terminations.

The learned are now convinced that the use of numerical figures was first derived from India. Indeed the antiquity of their application in that country far exceeds the powers of investigation. All the numerals in Sanscrit have different forms for the different genders, as in Arabic. There appears a strong probability that the European method of computation was derived from India, as it is much the same with the Sanscrit, though we think the Europeans learned it from the Arabians. The Bengalese merchants compute the largest sums by *fours;* a custom evidently derived from the original mode of computing by the fingers.

The Sanscrit language, among other advantages, has a great variety in the mode of arrangement; and the words are so knit and compacted together, that every sentence appears like one complete word. When two or more words come together *in regimine*, the last of them only has the termination of a case; the others are known by their position; and the whole sentence so connected, forms but one compound word, which is called a *foot*.

Sect. VI. *Of the Chinese Language.*

108 Antiquity of the Chinese.

The Chinese, according to the most authentic accounts, are a people of great antiquity. Their situation was such, as, in the earliest ages of the world, in a great measure secured them from hostile invasion. Their little commerce with the rest of mankind precluded them the knowledge of those improvements which a mutual emulation had often generated among other nations, who were situated in such a manner, with relation to each other, as served to promote a mutual intercourse and correspondence. As China is a large and fertile country, producing all the necessaries, conveniencies, and even the luxuries of life, its inhabitants were not under the necessity of looking abroad for the two former, nor exposed to the temptation of engaging in foreign commerce, in order to procure the latter. Perfectly satisfied with the articles which their own country produced, they applied themselves entirely to the practice of agriculture and other arts connected with that profession; and their frugality, which they retain even to this day, taught them the lesson of being contented with little; of consequence though their population was almost incredible, the produce of their soil was abundantly sufficient to yield them a subsistence. Their inventions were their own; and as they borrowed nothing from other people, they gradually began to despise the rest of mankind, and, like the ancient Egyptians, branded them with the epithet of *barbarians*.

Those people had at an early period made amazing proficiency in the mechanical arts. Their progress in the liberal sciences, according to the latest and indeed the most probable accounts, was by no means proportioned. In mathematics, geometry, and astronomy, their knowledge was contemptible; and in ethics, or moral philosophy, the complexion of their laws and customs

Chinese Language.

customs proves their skill to have been truly superficial. They value themselves very highly at present upon their oratorial talents; and yet of all languages spoken by any civilized people, theirs is confessedly the least improved. To what this untowardly defect is owing, the learned have not yet been able to determine.

109 Their language an original tongue.

The language of the Chinese is totally different from those of all other nations, and bears very strong marks of an original tongue. All its words are monosyllabic, and compositions and derivations are altogether unknown. Their nouns and verbs admit of no flexions; in short, every thing relating to their idioms is peculiar, and incapable of being compared with any other dialect spoken by any civilized people. Most barbarous languages exhibit something that resembles an attempt towards those diacritical modifications of speech; whereas the Chinese, after a space of 4000 years, have not advanced one step beyond the very first elements of ideal communication. This circumstance, we think, is a plain demonstration that they did not emigrate from that region where the primitive race of mankind is thought to have fixed its residence. Some have imagined, we believe with good reason, that they are a *Tartarian* race, which, breaking off from the main body of that numerous and widely extended people, directed their march towards the south-east. There, falling in with delightful and fertile plains which their posterity now inhabit, they found themselves accommodated so much to their liking, that they dropped all desire of changing their habitations. The country of China is, indeed, so environed with mountains, deserts, and seas, that it would have been difficult for men in their primitive state to have emigrated into any of the neighbouring regions. Thus secluded from the rest of mankind, the Chinese, in all probability, were left to the strength of their own inventive powers to fabricate a language, as well as the other arts and improvements necessary for the support and convenience of life.

It is indeed obvious that their stock of vocables, when they emigrated from Tartary, was neither ample nor properly accommodated to answer the purposes of the mutual conveyance of ideas. With this slender stock, however, they seem to have been satisfied; for it does not appear that any additions were afterwards made to that which was originally imported. Instead of framing a new race of terms by compounding their primitive ones; instead of diversifying them by inflections, or multiplying them by derivatives, as is done in every other language; they rather chose to retain their primitive words, and by a variety of modifications introduced upon their orthography or pronunciation, to accommodate them to a variety of significations. Were it possible to scrutinize all the Tartarian dialects, and to reduce them to their primitive monosyllabic character, perhaps the original language of the Chinese might be investigated and ascertained. We know that attempts have been made to compare it with some of the other Asiatic languages, especially the *Hebrew:* This labour has, however, proved unsuccessful, and no primeval identity has been discovered. Before this comparison could be instituted with the most distant prospect of success, the language last mentioned must be stripped of all its adventitious qualities; and not only so, but it must be reduced to the monosyllabic tone, and then contrasted with the Chinese monosyllables; an undertaking which we are persuaded would not be readily executed. After all, we are convinced that no resemblance of any importance would be discovered.

110 Process of its fabrication.

The Chinese language must then, in our opinion, have been a Tartarian dialect, as the people themselves were colonists from Tartary. We have observed above, that those people have not hitherto found out the art of composition of words. This is the more surprising, when we consider that, in the characters which form their written language, they employ many compositions. For example, the character by which they represent *misfortune*, is composed of one hieroglyphic which represents a *house*, and another which denotes *fire;* because the greatest misfortune that can befal a man is to have his house on fire. With respect to the language which they use in speech, though they very often employ many words to express one thing, yet they never run them together into one word, making certain changes upon them that they may incorporate the more conveniently, but always preserve them entire and unaltered.

111 Paucity of its words.

The whole number of words in the Chinese language does not exceed 1200: the nouns are but 326. It must certainly appear surprising, that a people whose manners are so highly polished and refined, should be able to express so many things as must of necessity attend such a course of life by so small a number of words, and those too monosyllables. The difficulties which attend this singular mode must be felt almost every instant; circumstances which, according to the ordinary course of things, should have induced them to attempt both an augmentation of the number of their words and an extension of those which they had by composition and derivation. We learn from Du-Halde * that the Chinese have two different dialects: the one vulgar, which is spoken by the vulgar, and varies according to the different provinces; the other is called the *Mandarin language*, and is current only among the learned. The latter is properly that which was formerly spoken at court in the province of *Kiang-nan*, and gradually spread among the polite people in the other provinces. Accordingly, this language is spoken with more elegance in the provinces adjoining to *Kiang-nan* than in any other part of the kingdom. By slow degrees it was introduced into all parts of the empire, and consequently became the universal language.

* *Hist. of China*, vol ii.

It then appears that the modern language of China was originally the court dialect, and utterly unknown to the bulk of the people. From this circumstance we think it may fairly be concluded that this dialect was deemed the royal tongue, and had been fabricated on purpose to distinguish it from the vulgar dialects. We learn from Heliodorus, that the † Ethiopians had a royal language which was the same with the sacred idiom of the Egyptians. This Mandarin tongue was originally an artificial dialect fabricated with a view to enhance the majesty of the court, and to raise its very style and diction above that of the rest of mankind. The Chinese, a wonderfully inventive people, might actually contrive a language of that complexion, with an intention to render it obscure and

† *Ethiop.* lib. vi.

Chinese Language

and enigmatical (N). Such a plan would excite their admiration, and would at the same time greatly exceed their comprehension. In process of time, when the Chinese empire was extended, the Mandarins who had been brought up at court, and understood nothing of the provincial dialects, found it convenient to have the most eminent persons in every province taught the language employed by themselves, in order to qualify them for transacting the affairs of government with them in a language which both understood. By this means the royal dialect descended to the vulgar, and in process of time become universal. The Tartar dialect formerly in use vanished; only a few vestiges of it remained; which gradually incorporating with the royal language, occasioned the variation of provincial tongues above mentioned.

We are therefore clearly of opinion, that the modern language of the Chinese was deduced from the original Mandarin, or court dialect, and that this last was an artificial speech fabricated by the skill and ingenuity of that wonderful people. The learned have long held it up as the primary dialect, because, say they, it bears all the signatures of an original unimproved language. In our opinion, nothing appears more ingeniously artificially. It is universally allowed that, in its structure, arrangement, idioms, and phraseology, it resembles no other language. Is not every learned man now convinced that all the Asiatic languages yet known, discover unequivocal symptoms of their cognation and family resemblance? The Ethiopians, Chaldeans, Arabians, Persians, Egyptians, Hebrews, Phœnicians, the Brahmans, Bengalese, the Hindoos bordering upon China, all speak only different dialects of one language, varying from the original in dialect only, some in a greater some in a lesser degree: why should the Chinese alone stand altogether insulated and unallied?

The languages of the North all wear congenial features. The Tartar or Tatar dialects of every clan, of every canton, of every denomination, exhibit the most palpable proofs of a near affinity: the Gothic and Sclavonian dialects, which pervade a great part of Europe and some parts of Asia, are obviously brethren, and may easily be traced up to an Asiatic original. Even some of the American jargon dialects contain vocables which indicate an Asiatic or European original. Our readers, we flatter ourselves, will agree with us, that had the language of the Chinese been the original language, a resemblance must have still existed between it and its descendants. If it had originated from any other language, it would have retained some characteristic features of its parent archetype. As neither of these is to be found in the fabric of the language under consideration, the conclusion must be, that it is a language entirely different from all other tongues; that it is constructed upon different principles, descended from different parents, and framed by different artists.

The Chinese themselves have a common and immemorial tradition, that their language was framed by *Yao* their first emperor, to whom they attribute the invention of every thing curious, useful, and ornamental. Traditional history, when it is ancient, uniform, and universal, is generally well founded: upon this occasion we think the tradition above mentioned may be fairly admitted as a collateral evidence.

112 A proof of its artificial structure.

The paucity of vocables contained in this singular language, we think another presumption of its artificial contexture. The Chinese *Onomathetæ* would find it an arduous task to devise a great number of new terms, and would therefore rest satisfied with the smallest number possible. In other languages we find the like economy was observed. Rather than fabricate new words, men chose sometimes to adapt old words to new, and, upon some occasions, even to contrary significations. To spare themselves the trouble of coining new terms, they contrived to join several old ones into one; whence arose a numerous race of compounds. Derivatives too were fabricated to answer the same purpose. By this process, instead of creating new vocables, old ones were compounded, diversified, deflected, ramified, metamorphosed, and tortured into a thousand different shapes.

The Greek is deservedly esteemed a rich and copious language; its radical words have been curiously traced by several learned men, who, after the most laborious and exact scrutiny, have found that they do not amount to more than 300. The Sanscrit language is highly compounded; its radical terms, however, are very few in number. Upon the whole, we think we may conclude, that the more any language abounds in compounds and derivatives, the smaller will be the number of its radical terms. The Arabic admits of no composition, and of consequence its words have been multiplied almost *in infinitum;* the Sanscrit, the Persian, and the Greek, abound with compounds, and we find their radicals are few in proportion.

113 Three different methods of enriching a language.

There are, we think, three different methods which may be employed in order to enrich and extend the range of a language. 1st, By fabricating a multitude of words; the plan which has been pursued by the Arabs. 2d, By framing a multitude of compounds and derivatives; the artifice employed by the Greeks and the authors of the Sanscrit. 3d, By varying the signification of words without enlarging their number; the method practised by the Chinese and their colonists. The Arabians, we think, have shown the most fertile and inventive genius, since they have enriched their language by actually creating a new and a most numerous race of words. The fabricators of the Sanscrit and the collectors of the Greek have exhibited art, but *comparatively* little fertility of genius. Leaving, therefore, the Arabians, as in justice we ought, masters of the field in the contest relating to the formation of language, we may range the Greek and Sanscrit on the one side, and the Chinese on the other; and having made this arrangement, we may attempt to discover on which side the largest proportion of genius and invention seems to rest.

The

(N) An attempt of this nature, among a people like the Chinese, is by no means improbable; nor is its success less probable. For a proof of this, we need only have recourse to Bishop Wilkins's Artificial Language, and Psalmanazar's Dictionary of the language of Formosa.

Chinese Language.

The Greek and Sanscrit (for we have selected them as most highly compounded) exhibit a great deal of art in modifying, arranging, and diversifying their compounds and derivatives, in such a manner as to qualify them for intimating complex ideas; but the Chinese have performed the same office by the help of a race of monosyllabic notes, simple, inflexible, invariable, and at the same time few in number. The question then comes to be, whether more art is displayed in new-modelling old words by means of declensions, compounds, and derivatives; or by devising a plan according to which monosyllabic radical terms, absolutely invariable, should, by a particular modification of sound, answer all the purposes performed by the other. The latter appears to us much more ingeniously artificial. The former resembles a complicated machine composed of a vast number of parts, congenial indeed, but loosely connected; the latter may be compared to a simple, uniform engine, easily managed, and all its parts properly adjusted. Let us now see in what manner the people in question managed their monosyllabic notes, so as to qualify them for answering all the purposes of speech.

114 That adopted by the Chinese.

Though the number of words in the Chinese language does not amount to above 1200; yet that small number of vocables, by their artificial management, is sufficient to enable them to express themselves with ease and perspicuity upon every subject. Without multiplying words, the sense is varied almost *in infinitum* by the variety of the accents, inflections, tones, aspirations, and other changes of the voice and enunciation; circumstances which make those who do not thoroughly understand the language frequently mistake one word for another. This will appear obvious by an example.

The word *teou* pronounced slowly, drawing out the *u* and raising the voice, signifies a *lord* or *master*. If it is pronounced with an even tone, lengthening the *u*, it signifies a *hog*. When it is pronounced quick and lightly, it imports a *kitchen*. If it be pronounced in a strong and masculine tone, growing weaker towards the end, it signifies a *column*.

By the same economy, the syllable *po*, according to the various accents, and the different modes of pronunciation, has eleven different significations. It signifies *glass*, *to boil*, *to winnow rice*, *wise or liberal*, *to prepare*, *an old woman*, *to break or cleave*, *inclined*, *a very little*, *to water*, *a slave or captive*. From these examples, and from almost numberless others which might be adduced, it is abundantly evident that this language, which at first sight appears so poor and confined, in consequence of the small number of the monosyllables of which it is composed, is notwithstanding very copious, rich, and expressive.

Again, the same word joined to various others, imports a great many different things; for example *mou*, when alone, signifies a *tree*, *wood;* but when joined with another word, it has many other significations. *Mou leao*, imports "wood prepared for building;" *mou lan* is "bars, or wooden grates;" *mou hia*, "a box;" *mou sang*, "a chest of drawers;" *mou tsiang*, "a carpenter;" *mou eul*, "a mushroom;" *mou nu*, "a sort of small orange;" *mou sing*, "the planet Jupiter;" *mou mien*, "cotton," &c. This word may be joined to several others, and has as many different significations as it has different combinations.

Thus the Chinese, by a different arrangement of their monosyllables, can compose a regular and elegant discoure, and communicate their ideas with energy and precision; nay even with gracefulness and propriety. In these qualities they are not excelled either by the Europeans or Asiatics, who use alphabetical letters. In fine, the Chinese so naturally distinguish the tones of the same monosyllable, that they comprehend the sense of it, without making the least reflection on the various accents by which it is determined.

115 Consequences of this method on pronunciation.

We must not, however, imagine, as some authors have related, that those people cant in speaking, and make a sort of music which is very disagreeable to the ear; these different tones are pronounced so curiously, that even strangers find it difficult to perceive their difference even in the province of *Kiang-nan*, where the accent is more perfect than in any other. The nature of it may be conceived by the guttural pronunciation in the Spanish language, and by the different tones that are used in the French and Italian; these tones are almost imperceptible; they have, however, different meanings, a circumstance which gave rise to the proverb, that *the tone is all.*

If the fineness and delicacy of their tones are such as to be scarce perceptible to a stranger, we must suppose that they do not rise high, but only by small intervals; so that the music of their language must somewhat resemble the music of the birds, which is within a small compass, but nevertheless of great variety of notes. Hence it will follow, that strangers will find it very difficult, if not impossible, to learn this language; more especially if they have not a delicate ear and a flexible voice, and also much practice. The great difference then between the Chinese and Greek accents consists in this, that the Greeks had but two accents, the grave and acute, distinguished by a large interval, and that not very exactly marked: for the acute, though it never rises above a fifth higher than the grave, did not always rise so high, but was sometimes pitched lower according to the voice of the speaker. The Chinese must have many more accents, and the intervals between them must be much smaller, and much more carefully marked: for otherwise it would be impossible to distinguish them. At the same time, their language must be much more musical than the Greek, and perhaps more so than any language ought to be; but this becomes necessary for the purposes above mentioned. Du Halde is positive, that notwithstanding the perpetual variation of accents in the Chinese tongue, and the almost imperceptible intervals between these tones, their enunciation does not resemble singing: many people, however, who have resided in China, are equally positive that the tone with which they utter their words does actually resemble *canting;* and this, when we consider the almost imperceptible intervals by which they are perpetually raising and lowering the tone of their voice, appears to us highly probable.

As the people of whose language we are treating at present communicate a variety of different significations to their monosyllabic words by their different accentuation, so they employ quantity for the very same purpose. By lengthening or shortening the vowels of their words, they employ them to signify very different things. The same they perform by giving their words different aspirations, Chinese, Language rations, as likewise by sounding them with different degrees of roughness and smoothness, and even sometimes by the different motion, posture, or attitude, with which their enunciation is accompanied. By these methods of diversifying their monosyllables (says Du Halde), they make 330 of them serve all the purposes of language, and these too not much varied in their termination; since all the words in that language either terminate with a vowel or with the consonant *n*, sometimes with the consonant *g* annexed.

From this account, we think it is evident that the Chinese, by a wonderful exertion of ingenuity, do, by different tones and prosodical modifications, by means of a very inconsiderable number of words, all invariable radicals, actually perform all that the most polished nations have been able to achieve by their compounds, derivatives, &c. diversified by declensions, conjugations, and flexions of every kind; circumstances which, in our opinion, reflect the greatest honour on their inventive powers.

116 Grammar of the Chinese.

With respect to the grammar of this language, as it admits of no flexions, all their words being indeclinable, their cases and tenses are all formed by particles. They have no idea of genders; and even the distinction of numbers, which in almost all other languages, even the most unimproved, is marked by a particular word, is in the Chinese only indicated by a particle. They have only the three simple tenses, namely, the past, present, and future; and for want of different terminations, the same word stands either for the verb or the verbal substantive, the adjective or the substantive derived from it, according to its position in the sentence.

The Chinese language being composed of monosyllables, and these indeclinable, can scarce be reduced to grammatical rules: we shall, however, attempt to lay before our readers as much of the texture of that singular dialect as may enable them to form some vague idea of its genius and constitution. We shall begin with the letters, and proceed regularly to the remaining parts as they naturally succeed each other.

117 Chinese letters or characters

The art of joining the Chinese monosyllables together is extremely difficult, and requires a very long and laborious course of study. As they have only figures by which they can express their thoughts, and have no accents in writing to vary the pronunciation, they are obliged to employ as many different figures or characters as there are different tones, which give so many different significations to the same word. Besides some single characters signify two or three words, and sometimes even a whole period. For example, to write these words, *good morrow, Sir*, instead of joining the characters which signify *good* and *morrow* with that of *Sir*, a different character must be used, and this character alone expresses these three words. This circumstance greatly contributes to multiply the Chinese characters.

This method of joining the monosyllables is indeed sufficient for writing so as to be understood; but it is deemed trifling, and is used only by the vulgar. The style that is employed, in order to shine in composition, is quite different from that which is used in conversation, though the words are in reality the same. In writings of that species, a man of letters must use more elegant phrases, more lofty expressions, and the whole must be dignified with tropes and figures which are not in general use, but in a peculiar manner adapted to the nature of the subject in question. The characters of Cochin-china, of Tong-king, of Japan, are the same with those of the Chinese, and signify the same things; though, in speaking, these nations do not express themselves in the same manner: of consequence the language of conversation is very different, and they are not able to understand each other; while, at the same time, they understand each other's written language, and use all their books in common.

The learned must not only be acquainted with the characters that are employed in the common affairs of life, but must also understand their various combinations, and the numerous and multiform dispositions and arrangements which of several simple strokes make the compound characters. The number of their characters amounts to 80,000; and the man who knows the greatest number of them is of course the most learned. From this circumstance we may conclude, that many years must be employed to acquire the knowledge of such a prodigious number of characters, to distinguish them when they are compounded, and to remember their shape and import. After all, a person who understands 10,000 characters may express himself with tolerable propriety in this language, and may be able to read and understand a great number of books. The generality of their learned men do not understand above 15,000 or 20,000, and few of their doctors have attained to the knowledge of above 40,000. This prodigious number of characters is collected in their great vocabulary called *Hai-pien*. They have radical letters, which show the origin of words, and enable them to find out those which are derived from them: for instance, the characters of mountains, trees, man, the earth, of a horse, under which must be sought all that belongs to mountains, trees, man, &c. In this search one must learn to distinguish in every word those strokes or figures which are above, beneath, on the sides, or in the body of the radical figure.

118 exceedingly numerous.

Clemens Alexandrinus (see Section *Chaldean*, &c.) informs us, that the Egyptians employed three sorts of characters: The first was called the *epistolary*, which was used in writing letters; the second was denominated *sacred*, and peculiar to the sacerdotal order; the last *hieroglyphical*, which was appropriated to monumental inscriptions and other public memorials. This mode of representation was twofold: one, and the most simple, was performed by describing the picture of the object which they intended to represent, or at least one that resembled it pretty nearly; as when they exhibited the sun by a circle and the moon by a crescent: the other was properly symbolic; as when they marked *eternity* by a serpent with his tail in his mouth, the *air* by a man clothed in an azure robe studded with stars, &c.

The Chinese, in all probability, had the same variety of characters. In the beginning of their monarchy, they communicated their ideas by drawing on paper the images of the objects they intended to express; that is, they drew the figure of a bird, a mountain, a tree, waving lines, to indicate birds, mountains, forests, rivers, &c.

There were, however, an infinite number of ideas to be communicated, whose objects do not fall under the cognizance of the senses; such as the soul, the thoughts, the

Chinese Language.

the passions, beauty, deformity, virtues, vices, the actions of men and other animals, &c. This inconvenience obliged them to alter their original mode of writing, which was too confined to answer that purpose, and to introduce characters of a more simple nature, and to invent others to express those things which are the objects of our senses.

119 and truly hieroglyphical.

These modern characters are, however, truly hieroglyphical, since they are composed of simple letters which retain the signification of the primitive characters. The original character for the sun was a circle, thus ⊙; this they called *ga*: They now represent that luminary by the figure 日, to which they still give the original name. But human institutions having annexed to these last framed characters the very same ideas indicated by the original ones, the consequence is, that every Chinese letter is actually significant, and that it still retains its significancy, though connected with others. Accordingly the word *tsai*, which imports "misfortune, calamity," is composed of the letter *mien*, "a house," and the letter *ho*, "fire;" so that the symbolical character for misfortune is the figure of a house on fire. The Chinese characters, then, are not simple letters without any signification, like those of the Europeans and other Asiatics; but when they are joined together, they are so many hieroglyphics, which form images and express thoughts.

Upon the whole, the original characters of the Chinese were real pictures (see Section of the *Egyptian* language); the next improvement was the symbolical character; the third and last stage is the present mode, in which artificial signs have been fabricated, in order to represent such thoughts or ideas as could not be represented by one or other of the methods above described. Du Halde, vol. ii. p. 400, *et seq.* has furnished us with rules for pronouncing the Chinese vowels and consonants; a piece of information which, we apprehend, would be of little consequence to our readers, and which we shall therefore pass over, and proceed to give a brief account of their grammar. As the whole language is composed of monosyllables, and these indeclinable, its grammatical structure must be simple and obvious: we shall only mention what to us appears singular and important.

120 Peculiarities of the Chinese parts of speech.

In the Chinese language there is no diversity of genders or cases, and of consequence no declensions. Very often the noun is not distinguished from the verb; and the same word which in one situation is a substantive, in another may become an adjective, and even a verb.

The adjective always goes before the substantive; but if it follow it, it becomes a substantive.

The cases and numbers are known only by the composition. The plural number is distinguished by the particle *men*, which is common to all nouns; but when the noun is preceded by some word that signifies number, the particle *men* is not annexed.

The Chinese genitive, both singular and plural, when it comes after nouns, is often made by *ti*; and there is no other case in that language. The same particle is sometimes placed after pronouns, as if they were derivatives.

The comparative degree is formed by adding the particle *keng*, which is always set before the noun, and signifies *much*. The particle *to* is sometimes used, which likewise imports *much*.

The Chinese have only three personal pronouns, *nqo*, "I," *ni*, "thou," and *ta*, "he:" these become plural by adding the syllable *men*. They are made possessive by adding the syllable *ti*, as *nqo ti*, "mine," *ni ti*, "thine," *ta ti*, "his." The patronymics are formed by putting the name of the city, country, &c. after the pronoun: *chon* is the pronoun relative *who*, *what*, *which*.

Chinese verbs have only three tenses, the preterperfect, the present, and the future. When there is no particle added to the verb, it is the present: the preterperfect is made by adding the particle *leao*: to distinguish the future tense they use the particle *tsiang* or *hoei*; and these are all the varieties incident to their verbs.

The Chinese language has no words that are properly adverbs; they only become so by custom, or by the place they possess in discourse. They are often obliged to employ several words to express the adverbs of other languages: they have none that are demonstrative, or proper for calling or exhorting; but in their stead they are obliged to use nouns and verbs.

121 Their numerals.

Perhaps our readers may wish to know the Chinese numerals; and may imagine that they bear a resemblance to those of the European or other Asiatic dialects. In this, however, they will be disappointed.

They stand as follows:

Y	One
Eut	Two
San	Three
Sace	Four
Ou	Five
Lou	Six
Tsi	Seven
Po	Eight
Kieou	Nine
Che	Ten
Che y	Eleven
Eut che	Twelve
San che	Thirteen
Pe	One hundred
Eut pe	Two hundred
Y tsien	One thousand
Y ouan	Ten thousand
Che ouan	Twenty thousand
Eut ouan	One hundred thousand
Che ouan	Two hundred thousand
Y pe ouan	One million

There are a great many particles proper to numbers in the Chinese language: they are frequently used, and in a way peculiar to it; for every numeral has a particle importing the object to which it is attached. Thus *co* is used for man, and *y co* for a woman, &c.; *hoei* is used for illustrious men; *tche* or *tchi* is used for ships, dogs, hens; *mey* is used for pearls and precious things; *pen* is used for books; *teng* is appropriated to oxen and cows; *too* is used for letters and little bundles of paper; *oo* is employed for corn and pulse. Those distinctions indicate a language manufactured on purpose to be employed

ployed by people who were too high and too haughty to converse with the vulgar.

122 Style of the Chinese writers.

The style of the Chinese, in their elaborate compositions, is mysterious, concise, and allegorical, after the eastern manner. It is often obscure to those who do not understand the language thoroughly; and it requires a considerable degree of skill to avoid mistakes in reading an author of elegance and sublimity. Their writers express a great deal in few words; and their expressions are lively, full of spirit, intermingled with bold comparisons and lofty metaphors. They affect to insert in their compositions many sentences borrowed from their five canonical books; and as they compare their books to pictures, so they liken these quotations to the five principal colours employed in painting; and in this their eloquence chiefly consists.

They prefer a beautiful character to the most finished picture; and nothing is more common than to see a single page covered with old characters, if they happen to be fair and elegant, sold at a very high price. They honour their characters in the most common books; and when they happen to light by chance upon a printed leaf, they gather it up with the greatest care and respect.

In China there are three varieties of language; that of the common people, that of the people of fashion, and that employed in writing books. Though the first is not so elegant as either of the other two, it is not however inferior to our European languages; though those who are but superficially acquainted with the Chinese may, in fact, imagine it uncouth and barbarous. This low and rude language is pronounced and written many different ways, as is generally the case in other countries.

But a more polished, and at the same time a much more energetic, language, is employed in an almost infinite number of novels; some perhaps true, but many more the vehicles of fiction. These are replete with lively descriptions, characters highly finished, morality, variety, wit, and vivacity, in such a degree as to equal in purity and politeness the most celebrated authors of Europe. This was the language of the Mandarins; and though exquisitely beautiful in its kind, was still inferior to the language of books. This last might be styled the *hypersublime;* and of this there are several degrees and intervals before an author can arrive at what they call the language of the *king*. This mode of writing cannot be well understood without looking upon the letters; but when understood, it appears easy and flowing. Each thought is generally expressed in four or six characters: nothing occurs that can offend the nicest ear; and the variety of the accents with which it is pronounced produces a soft and harmonious sound.

The difference between the *king* and their other books consists in the difference of the subjects upon which they are written. Those of the former are always grand and sublime, and of course the style is noble and elevated: those of the latter approach nearer to the common affairs and events of life, and are of consequence detailed in the Mandarin tongue. In writing on sublime subjects no punctuations are used. As these compositions are intended for the learned only, the author leaves to the reader to determine where the sense is complete; and those who are well skilled in the language readily find it out.

The copiousness of the Chinese language is in a great measure owing to the multitude of its characters. It is likewise occasioned, in some degree, by the difference of their signification, as also by the artificial method of their conjunction, which is performed most commonly by uniting them two and two, frequently three and three, and sometimes four and four.

123 Their books numerous and bulky.

Their books are very numerous and bulky, and of course exceeding cumbrous. A dictionary of their language was compiled in the 18th century. It consisted of 95 large volumes. An appendix was annexed of 25 volumes. Their other books are voluminous in proportion. The Chinese, one may say, are a nation of learned men. Few people of rank neglect the belles lettres; for ignorance in a man of any degree of eminence is deemed an indelible stain on his character.

For their manner of writing, the implements with which they write, and the materials upon which they draw their characters, we must refer our readers to the article WRITING. It would, we believe, afford our readers some pleasure, could we discover and explain the reasons which have hitherto prevented the Chinese from adopting the letters employed from time immemorial by the other nations of Europe and Asia.

124 Obstacles to their improvement in science and literature.

The Chinese have ever looked upon themselves as greatly superior to the rest of mankind. In ancient times they entertained such contemptible notions of foreigners, that they scorned to have any further commerce with them than to receive their homage. They were indeed, at a very early period, highly revered by the Indians, Persians, and Tartars. In consequence of this veneration, they looked upon themselves as the favourites of heaven. They imagined they were situated in the middle of the earth, in a kind of paradise, in order to give laws to the rest of mankind. Other men they looked upon with contempt and disdain, and deemed them deformed in body and defective in mind, cast out into the remote corners of the world as the dross and refuse of nature. They boasted that themselves only had received from God rational souls and beautiful bodies, in order to qualify them for being sovereigns of the species.

Such are the sentiments of the Chinese; and with such sentiments it is by no means surprising that their improvements in *language*, in *writing*, and other appendages of the belles lettres, have not been proportioned to their progress in mechanics. When people are once fully persuaded that they have already arrived at the summit of perfection, it is natural for them to sit down contented, and solace themselves with the idea of their own superior attainments. The Chinese had early entertained an exalted opinion of their own superiority to the rest of mankind; and therefore imagined that they had already carried their inventions to the *ne plus ultra* of perfection; the consequence was, that they could make no exertions to carry them higher.

The Chinese, for the space of 3000 years, had almost no intercourse with the rest of mankind. This was the consequence of their insulated situation.—They of course, *compared themselves with themselves;* and finding that they excelled all their barbarian neighbours,

Chinese Language.

bours, they readily entertained an opinion that they excelled all the rest of mankind in an equal proportion. This conceit at once stifled the emotions of ambition, and deprived them of all opportunities of learning what was going forward in other parts of the world.

They despised every other nation. People are little disposed to imitate those whom they despise; and this perhaps may be one reason why they are at this day so averse from adopting the European inventions.

A superstitious attachment to the customs of the ancients, is the general character of the Asiatic nations. This is evidently a kind of diacritical feature among the Chinese. The institutions of *Fohi* are looked up to among them with equal veneration as those of *Thoth* were among the Egyptians. Among the latter, there was a law which made it capital to introduce any innovation into the music, painting, or statuary art, instituted by that legislator. We hear of no such law among the former; but custom established, and that invariably, for a space of 3000 years, might operate as forcibly among them as a positive law did among the people first mentioned. An attachment to ancient customs is often more powerful and more coercive than any law that can be promulgated and enforced by mere human authority. These reasons, we think, may be assigned as the impediments to the progress of the Chinese in the belles lettres, and perhaps in the cultivation of the other sciences.

125 Chinese words found in various other languages.

Though the language of the Chinese is confessedly different from all the other known languages in its character and construction, it contains, however, a great number of words evidently of the same origin with those which occur in other dialects, used by people, who, according to the natural course of things, could never have been connected with that remote country. A few of those we shall produce before we conclude this section. We shall begin with the import of the name *China*.

China, or, as the orientals write it, *Sin*, is perhaps the Latin *sinus*, "the bosom, the heart, the middle." The Chinese actually imagine that their country is situated in the very middle of the earth, and of consequence call it *Cham*, "the middle, the heart;" a denomination which exactly suits their opinion.

Tu, in Chinese, intimates every thing that falls under the cognizance of the senses, every thing that strikes the sight; in Latin, *tueor*.

Ta, a table, a plank, a figure that renders every thing sensible: 2. To see, to look upon, to appear; Greek ται ταια, whence τεινω, *tendo*.

Tue, to examine attentively, to inspect carefully.

Tui, the most apparent, chief, principal, first; 2. Lightning, thunder.

Teu, a sign by which we know one, letter of acknowledgment. All these ideas are contained in the Hebrew תו, *thu*, *signum*, which we believe has produced the Egyptian *thouth*, the god or godlike man who invented letters, geometry, music, astronomy, &c.

Tai, a dye, a theatre; Greek of old Θεαω, then Θεαομαι, "to see, to look."

Tam, Latin *tantum*, "so much."

Tan, land, country, region, a syllable annexed to the end of a great number of words. *Aqui tan*, *Aquitania*, "a land of water;" *Mauri tan*, *Mauritania*, "the land of the Moors." The orientals prefix *s*, whence *Farsi stan*, *Farsistan*, "the land or country of the Persians:" *Chusi stan*, *Chusistan*, "the country of Chuz;" *Turque stan*, *Turquestan*, "the land of the Turks."

Chinese Language.

Ti, a chief, an emperor, a title of dignity; whence the Greek τιω, "to honour;" hence, too, the word *di*, "bright, glorious;" whence Δις, "Jupiter," "Διος, divine;" the Latin *Dius*, now *Deus*, "God," and *Divus*, with the *digamma Æolicum* inserted; the Celtic *Dhia*, &c. It signified originally "bright, glorious," and was an epithet of the Sun.

Tum, Latin *tumeo*, "to swell."

Liven, "to love;" Hebrew לב, *leb*, "the heart;" Latin, *libet*. This word pervades all the dialects of the Gothic tongue, still retaining either the same or a nearly analogous signification.

Li, "letters;" Latin, *lino*, "to daub," as the Chinese actually do in forming their letters.

Lo, "to contain, that which contains;" Celtic, *log*; French, *loge*, *logis*, *loger*.

Lim, "a rule;" hence Latin, *linea*, "a line."

Su, "with;" Greek, συν, "with;" Celtic, *cyn*, *cym*; whence Latin, *cum*, *con*, &c.

Xim, "very high, elevated, sacred, perfect;" Latin, *eximius*.

Sin, "the heart;" Persian, *Sin*, "the heart."

Sien, "chief, first;" Celtic, *can*, *cean*, *san*, "the head;" metaphorically, the chief, the first, the principal; Thibet, *sen*, or *ken*, "great, elevated;" Arabic, *sane*, "to be elevated or raised."

Sim, or *Sing*, "a constellation, a star, an element;" Hebrew, *shem*: Greek, σημειον, σημα; Latin, *signum*.

Sie, "a man of learning;" Goth. Sax. Engl. "see; to see, seer."

Cem, "a priest:" Hebr. *cohen*; Syr. *con*; Egypt. *can*, *cun*.

Quin, "a king;" Celtic, *ken*, *kend*, "head, chief;" Gothic, *koanig*; Germ. Flem. Engl. *king*, also *queen*.

Hu, "a door;" Goth. Germ. Engl. *hus*, *hausen*, *house*.

Min, "a river;" Welch, *men*, "the water of a river;" Latin, *mano*, "to flow," and perhaps *amoenus*, "pleasant."

Hen, "hatred;" Greek, αινος, "cruel, horrible, odious."

Kiven, "a dog;" Greek κυων, *id.*

Ven, "beauty;" Latin, *Venus*, *venustas*; Iceland. Swed. *wen*, "pleasant;" Scotch, *winsome*.

Han, "the soul, breath;" Greek, ανεμος; Latin, *anima*, *animus*.

To these instances of the analogy between the Chinese language and those of the other people of Asia and Europe many more might be added; but the preceding, it is hoped, will serve as a specimen, which is all that can be expected from an inquiry of the nature of the present.

Sect. VII. *Of the Greek Language.*

126 Origin of the Greeks

Before we enter upon the consideration of the essential and constituent parts of this noble language, we must beg leave to settle a few preliminaries, which, we trust,

trust, will serve to throw some light upon many points which may come under consideration in the course of the following disquisition.

The Greeks, according to the most authentic accounts, were descended of Javan or Jon, the fourth son of Japhet, the eldest son of the patriarch Noah. The Scriptures of old, and all the orientals to this day, call the Greeks *Jonim*, or *Jaunam*, or *Javenoth*. We have already observed, in the beginning of the article concerning the Hebrew language, that only a few of the descendants of Ham, and the most profligate of the posterity of Shem and Japhet, were concerned in building the tower of Babel. We shall not now resume the arguments then collected in support of that position; but proceed to investigate the character of that branch of the posterity of Javan which inhabited Greece and the neighbouring regions.

At what period the colonists arrived in these parts cannot be certainly determined; nor is it of great importance in the question before us. That they carried along with them into their new settlements the language of Noah and his family, is, we think, a point that cannot be controverted. We have endeavoured to prove that the Hebrew, or at least one or other of its sister-dialects, was the primæval language of mankind. The Hebrew, then, or one of its cognate branches, was the original dialect of the Jonim or Greeks.

Be that as it may, before these people make their appearance in profane history, their language deviates very widely from this original archetype. By what means, at what period, and in what length of time this change was introduced, is, we believe, a matter not easy to be elucidated. That it was progressive, is abundantly certain both from the rules of analogy and reason.

The colonies, which traversed a large tract of country before they arrived at their destined settlements, must have struggled with numberless difficulties in the course of their peregrinations. The earth, during the period which immediately succeeded the universal deluge, must have been covered with forests, intersected with swamps, lakes, rivers, and numberless other impediments. As the necessaries, and a few of the conveniences of life, will always engross the first cares of mankind, the procuring of these comforts will, of necessity, exclude all concern about arts and sciences which are unconnected with these pursuits. Hence we think it probable, that most of those colonies which migrated to a very great distance from the plains of Shinar, which we believe to have been the original seat of mankind, in a great measure neglected the practice of the polite but unnecessary modes of civilization which their ancestors were acquainted with, and practised before the era of their migration. Certain it is, that those nations which continued to reside in the neighbourhood of that centre of civilization, always appear in a cultivated state; while, at the same time, the

127 who were long a barbarous people.

colonists who removed to a considerable distance appear to have sunk into barbarism, at a period more early than the annals of profane history can reach.—This appears to have been the situation of the primary inhabitants of Greece. Their own historians, the most partial to their own countrymen that can well be imagined, exhibit a very unpromising picture of their earliest progenitors. Diodorus Siculus, in delineating the character of the original men, we believe sketches his draught from the first inhabitants of Greece *. He represents them as absolute savages, going out in small parties to make war upon the wild beasts of the field, which (according to him) kept them in continual alarm. "Necessity obliged them to band together for their mutual security; they had not sagacity enough to distinguish between the wholesome and poisonous vegetables; nor had they skill enough to lay up and preserve the fruits of autumn for their subsistence during the winter." The scholiast on Pindar describes the situation of the inhabitants of Peloponnesus in the following manner †. "Now some have affirmed that the nymphs, who officiated in performing the sacred rites, were called *Melissæ*. Of these Mnaseas of Patara gives the following account. They prevailed upon men to relinquish the abominable practice of eating raw flesh torn from living animals, and persuaded them to use the fruits of trees for food.—

128 Progress of their civilization.

Melissa, one of them, having discovered bee-hives, ate of the honey-combs, mingled the honey with water for drink, and taught the other nymphs to use the same beverage. She called bees Μελισσαι, *Melissæ*, from her own name, and bestowed much care on the management of them.

"These things (says he) happened in Peloponnesus; nor is the temple of Ceres honoured without nymphs, because they first pointed out the mode of living on the fruits of the earth, and put an end to the barbarous practice of feeding on human flesh. The same ladies, too, from a sense of decency, invented garments made of the bark of trees."

Hecatæus the Milesian, treating of the Peloponnesians, affirms *, "that before the arrival of the Hellenes, a race of barbarians inhabited that region; and that almost all Greece was, in ancient times, inhabited by barbarians †. In the earliest times (says Pausanias) (o) barbarians inhabited most part of the country called *Hellas*." The original Greeks, if we may believe an author of deep research and superior ingenuity ‡, were strangers to all the most useful inventions of life. Even the use of fire was unknown till it was found out and communicated by Prometheus, who is thought to have been one of the first civilizers of mankind. Hence Æschylus §, introduces Prometheus commemorating the benefits which he had conferred upon mankind by his inventions, in a strain that indicates the uncultivated state of the world prior to the age in which he flourished. For the entertainment of our readers, we shall translate as much of that passage as suits our present purpose.

——————"Of the human race
Now hear the tale, how foolish erst they were:
I taught them thought and exercise of reason:
If aught they saw before, they saw in vain.
Hearing, they heard not; all was shapeless dreams
For a long space of time, at random mixt.

In

* Lib. i.

(o) The Greeks borrowed this contemptuous epithet from the Egyptians. See *Herod.* lib. ii. cap. 158.

Greek Language.

In wild confusion: for they neither knew
Tile-cover'd houses standing in the sun,
Nor timber work; but, like the earth-bred ant,
They lodg'd in sunless caves dug under ground:
No certain sign had they of winter cold,
Nor of the flow'ry spring, or summer store,
But blindly manag'd all; till I them taught
What time the stars appear, what time they set,
Hard to be scan'd: then arithmetic rare,
That queen of arts, by dint of patient thought
Descry'd, I taught them; and how vocal sounds
From letters join'd arose."

This character, though applied to mankind in general, was in reality that of the most ancient Greeks. These forbidding features had been transmitted to the poet by tradition as those of his ancestors: he was a Greek, and of consequence imputes them to all mankind without distinction.

Phoroneus, the son and successor of Inachus*, is said to have civilized the Argives, and to have taught them the use of some new inventions. This circumstance raised his character so high among the savage aborigines of the country, that succeeding ages † deemed him the first of men. Pelasgus obtained the like character, because he taught the Arcadians to live upon the fruit of the *fagus*, to build sheds to shelter them from the cold, and to make garments of the skins of swine.

* *Plato.*

† *Pausan.* lib. viii. c. 1.

But what clearly demonstrates the unpolished character of the most ancient Greeks is, the extravagant honours lavished by them upon the inventors of useful and ingenious arts. Most of these were advanced to divine honours, and became the objects of religious worship to succeeding generations. The family of the Titans affords a most striking instance of this species of adulation. Jupiter, Juno, Mars, Apollo, Venus, Diana, &c. were sprung of this family. By the useful inventions which these personages communicated to the uncultivated nations of Greece, they obtained such lasting and such extravagant honours, that they justled out the sidereal divinities of the country, and possessed their high rank as long as Paganism prevailed in those regions. To these testimonies of the savagism of the original Greeks, others almost without number might be added; but those adduced in the preceding part of this inquiry will, we hope, satisfy every candid reader as to the truth of the position advanced.

129
A new colony arrives in Greece called *Pelasgi*.

While matters were in this situation with respect to the primitive Jonim or Greeks, a new colony arrived in those parts, which in a few years considerably changed the face of affairs. The people who composed this colony were called *Pelasgi;* concerning whose origin, country, character, and adventures, much has been written, and many different opinions exhibited by the learned. It is not our province to enter into a detail of their arguments and systems; we shall only inform our readers, that the general opinion is, that they were natives either of Egypt or Phœnicia. We have seen a dissertation in manuscript upon this subject, from which we are allowed to extract the following particulars.

The author, we think, has proved by very plausible arguments, that these people could not be descendants of the Egyptians nor Phœnicians. He maintains, that the Pelasgi were a great and numerous tribe; that they overspread all the coast of Asia Minor from Mount Mycale to Troas; that they were masters at one time of all the Asiatic and Grecian islands; that they overran Greece and many of the neighbouring countries; and all this in less than half a century.—These facts he seems to have proved from Homer, Herodotus, Diodorus Siculus, Pausanias, and other Greek authors of approved authenticity. He shows, that they were a civilized generation; that they were well acquainted with military affairs, legislation, agriculture, navigation, architecture, letters, &c. He insists, that Phœnicia could not at any given period have furnished such a numerous body of emigrants, even supposing the whole nation had emigrated, and left their native country a desart. He believes that this event took place before the invasion of Canaan by the Israelites; that consequently the Pelasgic migration was not occasioned by that catastrophe. He has shown, we think by very probable arguments, that the Egyptians in the earliest ages were averse to foreign expeditions, especially by sea; because that people hated this element, and besides could be under no temptation to emigrate: add to this, they were accustomed to live on small matters, and their country was exceedingly fertile and easily cultivated. It appears (says he) from Herodotus, that the Pelasgi were not acquainted with the religion of the Zabians, which could not have been the case had they emigrated from either of these countries. He makes it appear, at least to our satisfaction, that Herodotus is mistaken when he supposes that the deities of Greece were derived from Egypt. He demonstrates, that the names of the greatest part of those deities are of Phœnician extraction; and this opinion he establishes by a very plausible etymological deduction. He asserts, that had the Pelasgi been natives of either of the countries above mentioned, it would be absurd to suppose them ignorant of the names and religious rites of their respective nations. He finds, that the Egyptian and Phœnician colonies, which afterwards settled in Greece, were enemies to the Pelasgi, and either subdued or expelled them the country, which, he imagines, would scarce have been the case had both parties sprung from the same ancestors. After settling these points, he concludes, that the people in question were the progeny of the Arabian shepherds, who, at a very early period, invaded and subdued both the Lower and Upper Egypt. After possessing that country about a century and a half, they were conquered by Amenophis king of the Upper Egypt, who drove them out of the country. Upon this the fugitives retired to Palestine, where Manetho the Egyptian historian loses sight of them, and either through malice or ignorance confounds them with the Israelites. This writer supposes that those fugitives gradually directed their course for the west and north-west coasts of Asia Minor, whence they conveyed themselves over to Greece.

Such are the arguments by which the author of the dissertation above mentioned supports his hypothesis. It is, for aught we know, altogether new, and to us it appears by no means improbable. If our curious readers should wish to know more of this subject, they may consult Gebelin's preliminary Discourse to his Greek Dictionary, Lord Monboddo's Inquiry into the Origin and Progress of Language, vol. i. towards the end, and Mr Bryant's Analysis of Ancient Mythology, *passim.*

Be this as it may, nothing is more certain than that the Pelasgi were the first people who in some degree civilized the savages of ancient Greece. It is not our business

Greek Language.

business at present to enumerate the many useful inventions which they communicated to the Greeks, at that time worse than barbarians. We deem it, however, absolutely necessary, as an introduction to our subject, to hazard a few conjectures on the language and letters of those adventurers; a point strictly connected with the subject soon to fall under consideration.

130 Who introduce letters into that country.

Whether we suppose the Pelasgi to have been the offspring of the Phœnicians, Egyptians, or Arabian shepherds, it will make little difference as to their language; every man of learning and research is convinced that those three nations, especially at that early period, spoke a dialect of the Hebrew. The Pelasgi, then, must have spoken a dialect of that language when they arrived in Greece. Perhaps it might have undergone several changes, and acquired some new modifications, during so many years as had passed since they began to be a separate nation, and in the course of so many peregrinations. Some monuments of theirs still extant prove this fact beyond all contradiction. As these people incorporated with the aborigines of Greece, the remains of the original language of mankind, or at least so much of it as had been retained by them, gradually coalesced with that of the new settlers. From this, we think, it is obvious, that prior to the arrival of the new colonists from the East, the language now current among the two united tribes must have been a dialect of the Phœnician, Arabian, Hebrew, &c. Be that as it may, Herodotus * affirms that the Pelasgi in his time spoke a barbarous language, quite unintelligible to the modern Greeks.

* Lib. i. cap. 59.

The reason of this difference between the language of the Hellenes or Greeks in the age of Herodotus, and that of the remains of the Pelasgi at that period, seems to be this: Prior to the time of that historian, the Greek language had, from time to time, undergone many changes, and received vast improvements; whereas, on the contrary, that of the remnant of the Pelasgi, who were now reduced to a very low state, had remained stationary, and was then just in the same predicament in which it had been perhaps a century after their arrival in the country.

As the Pelasgi, as was observed above, were a people highly civilized and well instructed in the various arts at that time known in the eastern world, they were skilled in agriculture, architecture, music, &c. (P). The presumption then is that they could not be unacquainted with alphabetical writing. This most useful art was well known in the countries from which they emigrated; and of course it is impossible to imagine that they did not export this art as well as the others above-mentioned. Diodorus Siculus imagines that † the Pelasgi knew not the use of alphabetical letters, but that they received them from Cadmus and his Phœnician followers; that those letters were afterwards called *Pelasgic*, because the Pelasgi were the first people of Greece who adopted them. This account must go to the score of national vanity, since very soon after he acknowledges ‡ that Linus wrote the exploits of the first Bacchus and several other romantic fables in Pelasgic characters; and that Orpheus, and Pronapides the master of Homer, employed the same kind of letters. Zenobius likewise informs us † that Cadmus slew Linus for teaching characters different from his. These letters could be none other than the Pelasgic ‡.

† Lib. iii.

‡ Ibid.

† Apud Dr Gregory Sharp's Strict. Greek Language

‡ See Plate XVI.

Pausanias, in his Attics, relates ‖, that he himself saw an inscription upon the tomb of Corœbus, who lived at the time when Crotopus, who was contemporary with Deucalion, was king of the Argives. This inscription then was prior to the arrival of Cadmus; and consequently letters were known in Greece before they were introduced by this chief. It likewise appears from Herodotus himself, that the Ionians were in possession of alphabetical characters before the coming of the Phœnicians. "For (says he) § the Ionians having received letters from the Phœnicians, changing the figure and sound of some of them, ranged them with their own, and in this manner continued to use them afterwards." If, then, the Ionians (Q) ranged the Phœnician characters with their own, it is obvious that they had alphabetical characters of their own.

‖ Lib. i. cap. 49.

§ Lib. i. c. 58.

Besides these historical proofs of the existence of Pelasgic characters, monuments bearing inscriptions in the same letters have been discovered in several parts of Greece and Italy, which place this point beyond the reach of controversy. What characters these were may be easily determined. As the Pelasgi emigrated from Arabia, the presumption is that their letters were Phœnician. They are said by Dr Swinton to have been 13 in number, whereas the Phœnician alphabet consists of 16. The three additional letters were probably invented by the latter people after the Pelasgi had left the eastern quarters. The Phœnician letters imported by the Pelasgi were, no doubt, of a coarse and clumsy contexture, unfavourable to expedition in writing, and unpleasant to the sight. Besides, the Phœnician characters had not as yet received their names; and accordingly the Romans, who derived their letters from the Arcadian Pelasgi †, had no names for theirs. The probability is, that prior to this era the Pelasgic letters had not been distinguished by names. These were of course no other than the original letters of the Phœnicians in their first uncouth and irregular form: and for this reason they easily gave way to the Cadmean, which were more beautiful, more regular, and better adapted to expedition.

† Livii, lib. i. c. 7.

Plate XV.

Hitherto we have seen the Pelasgi and the Ionim incorporated, living under the same laws, speaking the same language, and using the same letters. But another nation, and one too of vast extent and populousness, had at an early period taken possession of a considerable part of the country afterwards distinguished by the name of *Hellas* or *Greece*. The Thracians were a great and mighty nation; inferior to none except the Indians ‡, says the father of Grecian history. These people at a very early period, had extended their quarters over all the northern parts of that country. They were, in ancient times, a learned and polished nation. From them,

‡ Herod. lib. v. c. 3.

131 The Thracians a powerful nation at a very early period.

(P) The Arcadians, who were a Pelasgic tribe, were highly celebrated for their skill in music. They introduced this art into Italy. See *Dion. Halicar.* lib. i.

(Q) The Athenians were originally called *Ionians*.

in succeeding ages, the Greeks learned many useful and ornamental sciences. Orpheus (R) the musician, the legislator, the poet, the philosopher, and the divine, is known to have been of Thracian extraction. Thamyris and Linus were his disciples, and highly respected among the Greeks for their learning and ingenuity. That these people spoke the same language with the Greeks, is abundantly evident from the connection between them and these Thracian bards. The Thracian language, then, whatever it was, contributed in a great proportion towards forming that of the Greeks. From the remains of the Thracian dialect there appears to have been a very strong resemblance between it and the Chaldean. This position we could readily support by the most plausible etymological deduction, did the limits prescribed us in this article admit such an inquiry. It appears, however, that the * Thracians, Getæ, and Daci or Davi, spoke nearly the same language. The Goths, so much celebrated in the annals of the lower empire, were the descendants of the Getæ and Daci, and consequently retained the dialect of their ancestors. The reader, therefore, must not be surprised, if in tracing the materials of which the Greek language is composed, we should sometimes have recourse to the remains of the Gothic.

* Strabo, lib. i. & vii.

131
The Greek language composed of three different dialects.

We have now found out three branches of the Greek language; that of the Ionim or *Aborigines*, that of the Pelasgic tribe, and that of the Thracians. These three, we imagine, were only different dialects of the very same original tongue. This assertion we could readily prove by the comparison of a great number of words taken from the two last, were this a proper place for such a discussion.

132
Arrival of Cadmus in Greece.

Some centuries after the arrival of the Pelasgi, Cadmus, an Egyptian (S) by birth, and a sojourner in Phœnicia, arrived in Bœotia with a multitude of followers. This colony-chief and his countrymen introduced letters and several other useful improvements into the country in question. As these people were natives of Phœnicia and its environs, their alphabet was that of their native country, consisting of 16 letters. That the Phœnician alphabet was nearly the same with the Samaritan and Hebrew, has been so often and so clearly demonstrated by the learned of this and the former century, that it would be altogether superfluous to insist upon it in this short inquiry. The Phœnicians, as is generally known, wrote from right to left, and the old Grecian characters, inverted, exactly resemble the other.

The names of the Cadmean characters are Syrian †, which shows the near resemblance between that language and the Phœnician. They stand thus: *alpha, beta, gamla, delta*, &c. The Syrians used to add *a* to the Hebrew vocables; hence alph becomes alpha, beth, betha or beta, &c. In the Cadmean alphabet we find the vowel letters, which is an infallible proof that this was the practice of the Phœnicians in the age of Cadmus; and this very circumstance furnishes a presumption that the Jews did the same at the same period.

† *Scaliger.*

133
The letters introduced by him.

After all, it is evident that the oldest Greek letters, which are written from right to left, differ very little from those of the Pelasgi. The four double letters θ, φ, ξ, χ, are said to have been added by Palamedes about 20 years before the war of Troy. Simonides is generally supposed to have added the letters ζ, η, ψ, though it appears by some ancient inscriptions that some of these letters were used before the days of Palamedes and Simonides.

In the year of our Lord 1456 seven brazen tables were discovered at Engubium, a city of Umbria in the Apennines, of which five were written in Pelasgic or Etruscan characters and two in Latin. The first of these tables is thought to have been composed about 168 years after the taking of Troy, or 1206 years before Christ. By comparing the inscription on these tables with the old Ionic characters, the curious have been enabled to discover the resemblance.

134
The old Ionic character.

The old Ionic character wrote from right to left continued in general use for several centuries: It was composed of the Cadmean and Pelasgic characters, with some variations of form, position, and sound. The Athenians continued to use this character till the year of Rome 350. The old Ionic was gradually improved into the new, and this quickly became the reigning mode. After the old Ionic was laid aside, the * (Βουστροφηδον) Bustrophodon came into custom, which goes backwards and forwards as the ox does with the plough. They carried the line forward from the left, and then back to the right. The words were all placed close together, and few small letters were used before the fourth century. If our curious readers would wish to know more of letters and alphabets, we must remit them to Chishul, Morton, Postellus, the great Montfaucon, Gebelin, Astle, &c. For our part we are chiefly concerned at present with the Phœnician and Cadmean systems; and on these perhaps we may have dwelt too long. Having now, we hope sufficiently proved that the Greek alphabet was derived from the Phœnician, in order to convince our curious but illiterate readers of the certainty of our position, as it were by ocular demonstration, we shall annex a scheme of both alphabets, to which we shall subjoin some strictures upon such letters of the Greek alphabet as admit any ambiguity in their nature and application.

* *Pausan.* lib. viii. cap. 17.

135
The Greek alphabet derived from the Phœnician.

A, *alpha*, had two sounds, the one broad like *a* in the English word *all;* the other slender, as *e* in *end, spend, defend.* The Hebrews certainly used it so, because they had no other letter to express that sound; the Arabs actually call the first of their alphabet *elif;* and they as well as the Phœnicians employ that letter to express both the sound of A and E promiscuously. The Greeks call their letter E ε-ψιλον, that is E slender, which seems to have been introduced to supply the place of A slender.

H, *eta*, was originally the mark of the *spiritus asper*, and no doubt answered to the Hebrew ח. It is still retained in that capacity in the word Ηκατον, and in words with the *spiritus asper* beginning books, chapters, sections,

(R) Orpheus seems to be compounded of two oriental words, *or*, "light," and *phi*, "the mouth." Though some deduce it from the Arabian *arif*, a learned man."

(S) Joseph Scaliger's account of the origin of the Ionic letters. *Euseb. Chron.*

tions, &c. Ε originally marked both the sound of Εψιλον and Ητα; that is, it was sometimes sounded short as at present, and sometimes long, where it is now supplied by Η. As it was found convenient to distinguish these two different quantities of sound by different letters, they adopted Η, the former *spiritus asper*, to denote the long sound of Ε, and substituted the present *spiritus asper* [ʽ] in its place.

Ι, *iota*, is the Hebrew or Phœnician *jod* or *yod*. We imagine it originally served the purpose of both iota and ypsilon. It had two different sounds; the one broad and full, the other weak and slender. The latter had the sound of the modern υψιλον. That this was actually the case, appears in several monumental inscriptions: And upon this depends the variation of some cases of the demonstrative pronoun and of the second declension.

Ο, *omicron*, or small *o*, in the original Greek had three different sounds. It sounded *o* short, as at present; and likewise *o* long, now denoted by Ω or large *O*. It likewise marked the sound of the improper diphthong ου, sounded like the English diphthong *oo*. The Ω was taken from the Phœnician wau or *V*.

Υ, *ypsilon*, we have observed before, was adopted to supply a mark for the sound of I slender.

Ζ, *zeta*, is compounded of δς. Dion. Halic. however, informs us, that this letter should be pronounced σδ, according to the Doric plan.

Θ, *theta*, was not known in the old Greek. It is compounded of τ and the *spiritus asper*, both which were of old written separately thus TH.

Ξ, *xi*, is compounded of γς, κς, χς. These letters, too, were originally written separately.

Φ, *phi*. This letter is compounded of β, π, and the *spiritus asper*; thus BH, PH.

Χ, *chi*, like the foregoing, is compounded of γ, κ, and the *spiritus asper* as above.

Ψ, *psi*, like some of the rest, is made up of βς, πς, which, too, were originally written in separate characters.

These observations are thrown together purely for the use of students who may not choose to inquire into the *minutiæ*. We are sorry that the nature of the work will not permit us to extend our researches to greater length. The reader will find an ancient inscription on Plate CCCCXVI. in which the powers of the letters are exemplified as they were in the first stage of the Greek language. Every language, we believe, was originally composed of inflexible words; the variations which now distinguish nouns and verbs were the effects of progressive improvements. What might have been the state of the Greek language with respect to these variations in its original form, it is not now possible to discover. That it was rude and irregular, will not, we imagine, be controverted. One of the first attempts towards forming the variations, now denominated *declensions* and *conjugations*, would probably be made upon the *demonstrative* article and the *substantive* verb. This observation will be found to hold good in most polished languages. In the Greek tongue, this was evidently the method.

136
Origin and flexion of the article.

The original Greek article was imported from the east. It was the Hebrew or Phœnician ה *ha*. This particle sometimes signifies *one*, and sometimes it answers to our demonstrative *the*; both in its adverbial and demonstrative capacity it imports demonstration. In the earliest stages of the two oriental languages, it was probably written apart, as *ha-melech*, "the king." In process of time it came to be joined with the following word, as *Hammelech*. From this we think the Greek article was deduced. It is still retained in the Doric dialect in its pristine character. The difference between *ho* and *ha* in the eastern language is nothing. Here then we have the articles ὁ masculine and ἁ feminine. Upon these several changes were superinduced, in order to render them more useful for the purposes of language. For those changes we know of no archetype.

The Greeks then having adopted the Hebrew, or Phœnician, or Chaldean article *ha*, and changed it into *ho* for the masculine, seem to have arranged its variations in the following manner:

	Sing.	*Plu.*
Nom.	ὁ	ὁι
Gen.	ὁυ	ὁν
Dat.	ὁι	ὁις
Acc.	ὁν	ὁυς

137
Its use in the flexion of nouns of the first and second declensions.

In the earliest stages of the Greek language, ι and υ were sounded in the same manner, or nearly so, as was observed above. The accusative was at first like the nominative; for distinction's sake it was made to terminate in ν, which letter was likewise adopted to characterize the genitive plural; ς was annexed to the dative plural, to distinguish it from the dative singular. The radical word was still without inflexion.

When the article was inflected in this manner, the process stood as follows: we take λογος for an example.

	Sing.	*Plu.*
Nom.	ὁ λογ *speech*	ὁι λογ *speeches*
Gen.	ὁυ λογ *of speech*	ὁν λογ *of speeches*
Dat.	ὁι λογ *to speech*	ὁις λογ *to speeches*
Acc.	ὁν λογ *speech*	ὁυς λογ *speeches*

In this arrangement our readers will observe, that in the time under consideration, ω was not yet introduced; and therefore ομικρον or little ο was the same letter in the genitive plural as in the accusative singular; but in the latter case it was sounded long by way of distinction.

The article *ha*, which is still retained in the Doric dialect, was varied as follows:

	Sing.	*Plu.*
Nom.	ἁ	ἁι
Gen.	ἁς	ἁν
Dat.	ἁι	ἁις
Acc.	ἁν	ἁς

These variations differ a little from those of the masculine; and they were no doubt made for the sake of distinction, as is usual in such cases. We shall now give an example of the feminine as it must have stood before variations were introduced. We shall employ τιμη.

	Sing.	*Plu.*
Nom.	ἁ τιμ *honour*	ἁι τιμ *honours*
Gen.	ἁς τιμ *of honour*	ἁν τιμ *of honours*
Dat.	ἁι τιμ *to honour*	ἁις τιμ *to honours*
Acc.	ἁν τιμ *honour*	ἁς τιμ *honours*

Afterwards,

Afterwards, when the Chaldean article *du* was adopted for the neuter gender, the letter ד or *d* was changed into τ, and prefixed to it; and then the Greeks, who, in their declension of adjectives, always followed the neuter gender, began to prefix it to the oblique cases.

In this manner we think the Greek nouns stood originally; the only change being made upon the article. At length, instead of prefixing that word, and expressing it by itself, they found it convenient to affix a fragment of it to the noun, and so to pronounce both with more expedition. Thus ὁς-λογ, e. g. became λογ-ὁς, ὁν λογ became λογ ον, and of course λογος and λογον, &c. The *spiritus asper*, or rough breathing, was thrown away, in order to facilitate the coalition. Nouns of the neuter gender, as was necessary, were distinguished by using ν instead of ς. In oriental words the Greeks often change ς into ν, and *vice versa*.

138 In this mode of flexion the Greeks copied from the Orientals.

In this case the Greeks seem to have copied from an eastern archetype. In Hebrew we find an arrangement exactly similar. To supply the place of the pronouns possessive, they affix fragments of the personals: Thus, they write *ben-i*, "my son," instead of *ben-ani*, and *debir-nu*, "our words," instead of *debir-anu*, &c. The persons of their verbs are formed in the same manner. In this way, in our opinion, the variations of the first and second declensions were produced.

139 Formation of the third declension and of its cases.

After that a considerable number of their nouns were arranged under these two classes, there remained an almost infinite number of others which could not conveniently be brought into these arrangements; because their terminations did not readily coalesce with the articles above mentioned. These, like nouns of the neuter gender, were in a manner secluded from the society of the two other classifications. It is probable that these for a long time continued indeclinable. At last, however, an effort was made to reduce them into a class as well as the others. All these excluded nouns originally terminated with ς, which appears from their genitives as they stand at present. By observing this case, we are readily conducted to the termination of the pristine vocable. The genitive always ends in ος, which ending is formed by inserting ο between the radical word and ς. By throwing out ο we have the ancient nominative: Thus, Τιταν, genitive Τιτανος; taking out ο we have Τιτανς, the original inflexible termination. Λητω, genitive Λητοος; throw out ο and you have Δητος. Παλλας, genitive Παλλαδος; take away ο and there remains παλλαδς. Ορνις, genitive Ορνιθος; by throwing out ο we have Ορνιθς. Αναξ, genitive Ανακτος, Ανακτς. Κερατος, genitive Κερατιος, Κερατις; originally Κερατος, because originally ι had the sound of η, as was observed above. Μελι, genitive Μελιτος, Μελιτς. Ειδος, genitive Ειδεος, Ειδες, the old noun. In short, the genitive is always formed by inserting ο immediately before ς, which is always the termination of the nominative; and by this rule, we easily discover the noun such as it was in its original form.

The dative of this declension was closed with ι *ascriptum*; the same with that of the second, namely, ι *subscriptum*. The accusative commonly terminates with α; but was originally ended with ν. The Romans imitated the Æolian dialect, and they commonly ended it with *em* or *im*. The Greeks, perhaps in this imitated their progenitors, for *a* was their favourite vowel. The nominative plural ended in ες, which nearly resembles the English plural, and was possibly borrowed from the Thracians. The genitive plural in all the declensions ends in ων; the dative ends in σι, the σ being inserted to distinguish it from the dative singular. When a strong consonant, which would not easily coalesce with ς, comes immediately before it, that consonant is thrown out to avoid a harsh or difficult sound. The sum then is; the cases of nouns of the first and second declensions consist of the radical word with fragments of the articles annexed, and these were the first classifications of nouns. The other nouns were left out for some time, and might be denominated *neuters*; at length they too were classified, and their variations formed as above. In this process the Greeks deviated from the oriental plan; for these people always declined their nouns by particles prefixed. Whether the Greeks were gainers by this new process, we will not pretend positively to determine. We are, however, inclined to imagine that they lost as much in perspicuity as they gained by variety.

It is generally believed that the Greeks have no ablative; to this opinion, however, we cannot assent. It is true, that the dative, and what we would call the *ablative*, are always the same: yet we think there is no more reason to believe that the latter is wanting in Greek, than that the ablative plural is wanting in Latin, because in that language both these cases are always alike. 140 Greek ablative.

In the eastern languages there are only two genders, analogous to the established order of nature, where all animals are either male or female. But as the people of the east are, to this day, strongly addicted to personification, they ranged all objects of which they had occasion to speak, whether animate or inanimate, under one or other of these two classes. Hence arose what is now called the *masculine* and *feminine* genders. The orientals knew nothing of a neuter gender, because, indeed, all objects were comprehended under the foregoing classes. The Phœnician feminine was formed from the masculine, by adding אה, *ah*. In this the Greeks in many cases imitated them. The Greeks and Latins left a vast number of substantives, like a kind of outcasts, without reducing them to any gender; this process gave rise to the neuter gender, which imports, that such substantives were of *neither gender*. This has the appearance of a defect, or rather a blemish, in both. Sometimes, too, they make words neuter, which, according to the analogy of grammar, ought to be either masculine or feminine. And again, they range words under the masculine or feminine, which by the same rule ought to have been neuter. In short, the doctrine of generical distribution seems to have been very little regarded by the fabricators of both tongues. The beauty which arises from variety seems to have been their only object. 141 Genders.

The use of the article in the Greek language is, we think, rather indeterminate; it is often prefixed to proper names, where there is no need of demonstration nor generical distinction. On the contrary, it is often omitted in cases where both the one and the other seem to require its assistance. In short, in some cases it seems to be a mere expletive. Though both Lord Monboddo and Mr Harris have treated of this part of speech, neither the one nor the other has ascertained its proper use. (See *Origin and Progress of Language*, vol. ii. p. 53. *Hermes*, p. 214. *et seq.*)—We know not any objection to 142 Farther observations on the article.

Greek Language

to the early use of articles among the Greeks so plausible as the total neglect of them among the Romans. But it ought to be considered, that after the flexions were introduced, the use of the article was in a great measure neglected. Accordingly, Lord Monboddo observes that it is very seldom used as such by Homer, but commonly in place of the relative pronoun ὅς, ἥ, ὅ.—Thus it would appear, that at the time when the Roman language was reduced to the Grecian standard, the article was not commonly used by the Greeks; and of course the Latins never employed it. There can be no doubt but the pronoun *who*, in the northern languages, is the same with the Greek ὁ, and the Hebrew *hua*. This among the northern people is always a relative, which affords a presumption that the Greeks originally used the article in the same manner as we do at present. The fact is, that the articles having once got into vogue, were often positively used as mere expletives to fill up a gap; and that, on the other hand, when there was no occasion for pointing out an object, it being fully determined by the tenor of the discourse, it was often omitted.

143 Adjectives.

In forming adjectives, they followed the same plan that they had done with substantives. Their great effort was to make their adjectives agree with their substantives in gender, number, and case. This arrangement improved the harmony of speech; and nothing could be more natural than to make the word expressing the quality correspond with the subject to which it belonged.

As adjectives denote qualities, and thus are susceptible of degrees, nature taught them to invent marks for expressing the difference of these degrees. The qualities may exceed or fall below each other by almost numberless proportions; it was, however, found convenient to restrict these increases and decreases to two denominations. The positive is, properly speaking, no degree of comparison at all; therefore we need only point out the formation of the comparative and superlative.

The former is generally thought to be fabricated, by first adding the Hebrew word יתר, *excellent*, to the positive, and then affixing the Greek termination ος; and the latter, by affixing the Syrian word *tath* and the syllable ος, in the same manner.

144 Greek numerals.

Every nation, even the most uncivilized, have early acquired the notion of number. Numerical characters and names are the same in many different languages. These terms were discovered, and in use, long before grammar came to any perfection; and therefore remain either inflexible or irregular. The first way of computing among the Greeks was by the letters of the alphabet; so that Α signified *one* and Ω *twenty-four:* in this manner the rhapsodies of Homer are numbered; and so are the divisions of some of the Psalms, as is generally known. But a more artificial plan of computation was obviously necessary. They divided the letters of the alphabet into *decades* or tens, from Α to Ι=10. To express the number 6, they inserted ϛ *baw*=6; so that by this means the first decade amounted to 10. In the next decade every letter increased by tens, and so Ρ denoted 100. In this decade they inserted ϙ κοππα=90. In the third, every letter rose by 100; so that ϡ σαμπι=900. By inserting these three Phœnician characters they made their alphabet amount to 900. To express chiliads or thousands, they began with the letters of the alphabet as before; and to make the distinction, they placed a dot under each character, as the units, tens, hundreds, were distinguished by an acute accent over them.

But in monumental inscriptions, and in public instruments, a larger and more lasting numerical character was fabricated. The began with Ι, and repeated that letter till they arrived at Π=5. This is the first letter of πεντε, *five*. Then they proceeded, by repeating Ι till they came to 10 Δ, the first letter of δεκα, 10. Then they repeated Δ over and over, so that four Δ=40. To express 50, they used this method; they inclosed Δ in the belly of |Δ|=50, |Η|=500, |Μ|=50,000, &c. Often, however, Χ signifies 1000, and then we have δις Χιλιοι, 2000; τρεις Χιλιοι, 3000; and so of the rest.

The word *pronoun* signifies a word placed instead of a noun or name; and indeed the personal pronouns are really such: this needs no explication. The pronoun of the first person is one of those words which have continued invariable in all languages; and the other personals are of the same character. The relatives, possessives, demonstratives, and gentiles, are generally derived from these, as may be discerned by a very moderate adept in the language. Our readers will therefore, we hope, easily dispense with our dwelling upon this part of speech. 145 Pronouns.

Verb. In most ancient languages, verbs, according to the order of nature, have only three tenses or times, namely, the *past*, *present*, and *future*. The intermediate tenses were the invention of more refined ages.—The Greek, in the most early periods, had no other tenses but those above mentioned. The manner of forming these we shall endeavour to point out, without touching upon the nature of the rest, since an idea of them may be acquired from any common grammar. 146 Greek verbs, how formed.

We have observed above, that the flexion of nouns of the first and second declensions are formed by annexing fragments of the articles to the radical words; and that the variation of the tenses was produced by joining the substantive verb, according to the same analogy. Every Greek verb was originally an inflexible biliteral, triliteral, quadriliteral or dissyllabic radix. The variations were formed a long while after in the manner above intimated.

The Greeks had their substantive or auxiliary verb, from the Phœnician or Chaldean verb הוה, *fuit*. This verb, taking away the gentle aspirate from both beginning and end, actually becomes ευ. This vocable the Greeks brought along with them from the East, and manufactured after their own manner, which appears to have been thus:

Pres.	εω, εις, ει,	εομεν, εετε, εοντι,
Cont.	ω, ως, ω,	ουμεν, ειτε, ουντι,
Fut.	εσω, εσεις, εσει,	εσομεν, &c.

We place οντι in the third person plural, because for many centuries ομικρον supplied the sound of the diphthong ου. By these variations it will appear that the radical verb was rendered capable of inflection. We have observed that Greek verbs were a collection of biliteral,

Greek Language.

literal, triliteral, or quadriliteral, radical words.—The following may serve for examples: τι, λεγ, Μαρ, τυπ, φαν, ταν, ραπ, Δαμ, Δηλ, Δεικ.

These radicals are taken at random; and we believe our Grecian student, by adding the terminations, will readily find them all significant verbs. With these radicals, then, and the substantive verb, we suppose the present and future tenses were formed.

147 Original present that which is now the second future.

But it is now generally admitted that the modern present was not the original one of the verb. The second, or Attic future, appears plainly to have been the most ancient present. When the language was improved, or rather in the course of being improved, a new present was invented, derived indeed from the former, but differing widely from it in its appearance and complexion. Upon this occasion, the old present was degraded, and instead of intimating what was *doing at present*, was made to import what was immediately to be done hereafter. By this means, γραφω, contracted into γραφῶ, *I am writing*, came to intimate, *I am just going to write*. This change was probably made for the sake of enriching the language, for variety, for energy. Thus, τυπτω contracted τυπῶ became τυπτω, τιμῶ, τινω, &c. According to this theory, we find, that such verbs as now have no second future retain their original form, only the circumflex has been removed in order to accommodate them to the general standard. Grammarians have now chosen the three characteristic letters of active verbs from the present, first future, and perfect. The true characteristic of the original verb was that of the present second future. Many verbs are now destitute of that tense, because since the invention of the new present, those have fallen into disuse.

148 Formation of the modern present.

Let us now take the verb λεγω, *dico*, in order to make a trial; and let us write the radix and the auxiliary, first separately, and then in conjunction: Thus,

λεγ-εω, λεγ-εις, λεγ-ει, λεγ-εομεν, λεγ-εετε, λεγ-εουσι. Then we will have contracted λεγῶ, λεγεῖς, λεγεῖ, λεγοῦμεν, λεγεῖτε, λεγουσι. Here, we believe, every thing is self-evident.

The English would run thus: Saying *I am*, saying *thou art*, saying *he is*, &c. At first the radix and the auxiliary were pronounced separately, as we do our helping verbs in English, and would have been written in the same manner had words been then distinguished in writing.

149 First future, and

The present first future occupied the same place that it now does, and concurred in its turn to complete the future in conjunction with the radix. That the substantive verb was inflected in the manner above laid down, is obvious from its future middle εσομαι, and from the future of the Latin verb *sum*, which was of old *eso*, *esis*, &c. Verbs in λω, μω, νω, ρω, often take σω in the first future. See *Fœd. Cret. ap. Marm. Oxon.* lib. 87. Verbs in λω and ρω assume σ by analogy, as κελλω, κελσω, *Eurip. Hecub.* v. 1057. κελσαι, *Hom. Od.* x. v. 511. τελλω, τελσω, *unde* τελσον, *Il.* x. v. 707. ορω. ορσομεν, *Pind. Nem. Od.* 9. *Duodec.* 2. τυρω, τυρσω, *Theoc. Idyll.* 22. v. 63. In fine, the Æolic dialect after the liquids often inserts σ.

It must be observed, that the Greeks, in order to accelerate the pronunciation, always throw out the ε and ο, except in verbs ending in αω, εω, οω; where they generally change them into η and ω. When the last letter of the radix can coalesce with σ after ε is thrown out, they transform it, so as to answer that purpose; if not, they sometimes throw it out. We shall once more take λεγω for an example:

λεγ-εσω, λεγ-εσεις, λεγ-εσει, &c.

Throwing out ε, it would stand λεγ-σω, λεγ-σεις, &c. by changing γς into ξ it becomes λεξω. Δ θ and τ cannot coalesce with σ, therefore they throw them out: thus, Αδω, future first ασω; πληθω, future first πλησω; Ανυτω, Ανυσω, &c.

These are the general rules with respect to the formation of the present and future of active verbs in the earliest stages of the Greek language. The limits prescribed will not allow us to pursue these conjectures; but the reader may, if he thinks proper, carry them a great way.

150 preterite tense.

The preterite tense falls next under consideration. If we may trust analogy, this, as well as the other two, must have owed its conformation to the radix of the verb, and some other word fitted to eke out its terminations. It has been thought by some critics, that this addition was taken from the Hebrew word היה; and we should be of the same opinion did not another auxiliary present itself nearer home, which appears to us much more congruous to such a purpose. Perhaps, indeed, the people from whom we suppose it borrowed, derived it from the eastern quarters. We have already observed, that the Thracians were masters of a great part of Greece in the very earliest ages. At that time they were a polite and learned people. From them a considerable part of the Greek language was derived. If, therefore, we should find a word in their language employed for the same purpose, and accommodated to coalesce with the radical verb, we feel ourselves very much inclined to prefer such a word.

151 Origin of the auxiliary verb.

The word *ha* pervades many different languages as an auxiliary verb. From it we have the Italian *ho*, the Spanish *he*, the French *ai*; and in one shape or other it appears in all the German and Scandinavian dialects. It is the Gothic auxiliary; and, we believe, it forms the termination of the perfect active of the first conjugation in the Latin tongue: For there *am* is the radix of *amo*; in the preterite *am-avi*, *amavi*: and the preterperfect *am-hav-eram*, i. e. *amaveram*, compounded of *am*, *hav*, and *eram*, the imperfect of the indicative of the substantive verb. This process, in the formation of the preterite of Latin verbs, will scarce be questioned, and forms certainly a presumptive proof that the Greeks pursued the same line. From this verb is likewise derived the Latin *habeo*, by changing *v* and *b*, which are indeed the same letter. Our readers, after this detail, will not be surprised if we should now hazard a conjecture, and declare it as our opinion, that this same Gothic auxiliary *ha* is actually the additional part of the preterite of Greek verbs, and that part upon which the conjugation depends.

In forming this combination between the radix and the auxiliary, the Greeks were obliged to fabricate several devices. As often as the last letter of the radix could not unite with the aspirate in *ha*, they metamorphosed it into one of the double letters, which are capable of coalescing with it. In the verb λεγω, γ was changed into χ; thus, λεγ *ha* became λεγχα, τυπτω preterite τυπ *ha*, was combined into τυφα. In verbs which

Greek Language.

which had a radix that would not admit this conjunction, they hardened the *h* into κ, as in τιω, preterite τι-κα, Ακου-κα. Many other ways were contrived to facilitate this re-union. These are detailed in every Greek grammar, and so need not be mentioned.—What has been said with respect to this configuration, we offer as a pure conjecture, without the most remote intention of obtruding it upon our readers.

If it is admitted, that the auxiliary *ha* formed the conjugating termination of the active verb among the Greeks, it will likewise be admitted, that the radical verb and the other made originally two distinct words: that, according to this scheme, the preterite would proceed thus, λεγ *ha*, said *I have;* λεγ *has*, said *thou hast;* λεγ *he*, said *he hath*, &c. This process to us appears rational, elegant, and advantageous. The pluperfect was not then invented, and therefore it does not come under our consideration. The other tenses were all deduced from those described; and in forming these intermediate distinctive tenses, we believe that both critics and grammarians, and perhaps philosophers too, were employed. See GRAMMAR.

The eastern nations have diversified their verbs, by affixing fragments of the personal pronouns to the radix, by which they gained only the advantage of exhibiting the genders of the persons engaged in being, acting, and suffering; but a perpetual repetition of these was unavoidable. The Greeks, by their artificial combination of the radix with the two auxiliaries, avoided the necessity of repeating their personal pronouns, as we and the other modern inhabitants of Europe are obliged to do; and at the same time, by diversifying the terminations of their nouns and verbs, wonderfully improved the beauty and harmony of their language. The arrangement above insisted on is so very different from that of the orientals, and so entirely Gothic, that we think there can be no doubt that the Greeks borrowed this manœuvre from the Thracians. Every person moderately acquainted with the Greek language will, upon examination, discover a wonderful coincidence between the structure, idioms, and phraseology, of the English and Greek languages; so many congenial features must engender a strong suspicion that there once subsisted a pretty intimate relation between them.

In the preceding deduction, we find ourselves obliged once more to differ from the very learned author of the *Origin and Progress of Language*. As we took the liberty to question his originality of the Greek language, and at the same time presumed to attack the goodly structure raised by philosophers, critics, and grammarians; so we now totally differ from that learned writer as to his theory of the creation of verbs out of the inhabile matter of αω, εω, &c. This whole fabric, in our opinion, leans on a feeble foundation.

The apparatus of intermediate tenses, of augments, derivation of tenses, with their formation, participles, and idiomatical constructions, and other essentials or appendages, we omit, as not coming within the verge of the disquisition.

The derivation and formation of the middle and passive voices, would certainly afford matter of curious speculation; but the labour necessary to investigate this connection would greatly overbalance the benefit expected.

152 Derivation and formation of the middle voice.

However, to complete our plan, we shall subjoin a few strictures with respect to the formation of the middle voice, which was, in our opinion, immediately formed from the active.

We have seen already, that the active voice in its original state was formed by annexing fragments of the substantive or auxiliary verb to the radix. The same economy was observed in fabricating the flexible parts of the verb of the middle voice. To demonstrate this, we shall first conjugate the present tense of the auxiliary passive upon the principles above laid down.

Present, Εομαι, εεαι, εεται, εομεθα, εεσθε, εονται. Such was the passive-present of the auxiliary. We shall now take our example from the verb τυπτω; second future τυπ-εομαι, *struck I am*, τυπ-εεαι, *struck thou art*, τυπ-εεται, *struck he is*, &c. contracted τυπουμαι, τυπη, τυπειται. The conjunction and formation here is obvious. Perhaps, in the second person, σ was inserted, which, however, is thrown out in the process of the persons. The future middle is clearly formed, by affixing the future-passive of the verb εω, only as η was introduced into the language for ε long, it was generally (T) substituted instead of that vowel in verbs ending in αω and εω, and ω for ο in verbs ending in οω; the two vowels ε and ο being originally long as well as short, till η was adopted to denote the long sound of the former, and ω that of the latter. In many verbs, before the conjunction of the radix and auxiliary, ε was thrown out: thus, τυπ-εσομαι became τυψομαι, λεγ-εσομαι, λεξομαι, &c. Plate CCCCXVI.

The preterite was deduced from that of the active by a very slight variation, so trifling, indeed, that it need not be mentioned; only we may observe, that the aspirate *h* is never retained in this tense, which originally seems to have been the only distinguishing character by which that tense of the middle voice differed from the same tense of the active.

From the strict analogy between the mode of forming the three primary tenses of the active and middle voice, we are led to suspect that what is now the middle was originally the passive voice.

The immediate formation of the former, by annexing the passive auxiliary, is obvious. The middle voice still partakes of the passive signification, since it has sometimes a passive, though more frequently an active. There are several parts of the present passive quite analogous to the same tenses in the middle: and, lastly, it is the common progress, in the course of improvement, to proceed step by step, and by approximation. What is most simple and easy is the first object, then succeeds what is only a little more difficult, and so on till we arrive at the last stage, when human ingenuity can go no farther. Now, it will readily be admitted, that the passive voice is much more embarrassed and intricate in its texture than the middle; and, therefore, the

(T) We say generally, because in verbs ending in εω, the ε is sometimes retained, as τελεω, τελεσω, αρκεω-εσω.

Greek Language. the former should have been posterior in point of time to the latter.

We are well aware, that the very learned Kuster, and most other moderns, deeply skilled in the origin, progress, and structure, of the Greek language, have thought otherwise. The general opinion has been, that the Greek middle voice answered exactly to the Hebrew conjugation *hithpachal*, and in its pristine signification imported a reciprocality, or when the *agent acts upon itself*. For our part, we only intended a few hints upon the subject, which our learned readers may pursue, approve, or reject, at pleasure.

153 and of the passive.

If we might pretend to investigate the formation of the passive voice, we should imagine that the modern present was formed from the ancient one, by inserting such letters as were found necessary for beauty, variety, energy, &c.; the first future from the second future middle of the verb τιθημι, once θεω. This future is θησομαι; and, joined to the radix, always occupies that place, τι-θησομαι, πιλεθησομαι, φλεχθησομαι, τυφθησομαι, and so of the rest: whether μαι, σαι, ται, which occur so frequently as the terminations of the middle and passive voices, are fragments of some obsolete verb, we will not pretend to determine.

From verbs in αω, εω, οω, υω, are formed verbs in μι; which in the present, imperfect, and second aorist, as it is called, only have a different form, by assuming μι with a long vowel preceding it, in the present active; which vowel is preserved in each person singular. This collection of irregular verbs seems to be formed from the verb ειμι, which in some dialects might be ημι. Indeed the imperfect ην, ης, η, seems to imply as much: in this, however, we dare not be positive.

In the whole of this analysis of the formation of verbs, we have laid down what to us appears most plausible. That metaphysical critics may discover inaccuracies in the preceding detail we make no doubt; but our candid readers will doubtless reflect, that no language was ever fabricated by philosophers, and that the elements of language were hammered out by peasants, perhaps by savages. Critics have created a philosophy of language we admit, and have a thousand times discovered wonderful acuteness and ingenuity in the mechanism of words and sentences, where the original onomathetæ never apprehended any, and which possibly never existed but in their own heated imagination. If our more enlightened readers should find any thing in the preceding detail worthy their attention, so much the better; if the contrary should happen, we presume they will take up with the hackneyed system. We have all along neglected the dual number, because it regularly follows the type of the other numbers.

Be that as it may, before we drop this subject we must take the liberty to subjoin an observation or two with respect to the consequences of the practice of new modelling the present, and of course the imperfect, tenses of verbs. 1st, After this arrangement they commonly retained all the other tenses exactly as they had stood connected with the primitive verb: this needs no example. 2d, They often collected the tenses of verbs, whose present and imperfect were now obsolete, in order to supply this defect. Thus we have φερω-Οισω, ενεγκα, ηνεχα. 3d, They often formed present and imperfect tenses without any other tenses annexed: The poets in particular seem to have fabricated these two tenses at pleasure. Greek Language.

If this procedure was convenient for the poets, it was certainly most incommodious with respect to the vulgar, as well as to foreigners who had an inclination to learn the language. The vulgar, some ages after Homer and Hesiod, must have found it as difficult to understand their poems as our people do to comprehend those of Chaucer and Spenser. By this disposition, too, the etymology of verbs was almost entirely confounded. The present second future being, as has been observed, the ancient present, the attention of the curious etymologist was naturally diverted to the modern present, where it was utterly impossible to discover the radical word. A few examples will elucidate this point: τεινω, *to stretch, to extend*, old present τανω; ταν is the radix, which at once appears to be a Persian word signifying *a large tract of country*. Hence *Mauritania* "the land of the Mauri," Aquitania, Bretania; and with s prefixed, Hindo-stan, Chusi-stan, Turque-stan. The obsolete verb οπω, whence οπτομαι, is evidently derived from *op*, an Egyptian name of the moon: φαινω, second future φανῶ, *to show*, from the Egyptian word *phan* or *pan*, a name of the sun: τυπτω, future second τυπῶ; τυπ is obviously the offspring of תף, *thaph*," a drum or timbrel," from beating or striking, &c. In such etymological researches, the student must be careful to turn the Ionic η into the Doric α; because the Dores were latest from the coast of Palestine, and consequently retained the largest share of the Phœnician dialect: thus γηθεω, *to rejoice*, turning η into α becomes γαθεω. This word, throwing away the termination, becomes *gath*, plainly signifying a *wine press* (H). It is likewise to be observed, that the Æolians often change α into υ, as συρξ instead of σαρξ, &c.

It is not our intention to enter into the arrangement and peculiar constructions of the Greek language. There is, however, one, which we cannot well pass over 154

Greek infinitives used as nouns.

in silence. As that tongue is destitute of those words which the Latins call *gerunds*, to supply this defect they employ the infinitive with the article prefixed: thus, Εις το ειναι αυτους φιλους, *in order to their being friends*: απο του ἑλεσθαι αυτους βασιλεα, *from their having elected a king*; Εκ του απο φευγειν αυτους εκ της πολεως, *from their flying out of the city*. In these phrases the infinitive is said to assume the nature of a substantive noun; agreeing with the article before it, exactly as if it were a noun of the neuter gender. Idioms of this kind occur in our own tongue; only with us the verb, instead of being expressed in the infinitive, is turned into the participle. According to this arrangement, the first of the preceding phrases, which, according to the Greek, would stand *toward to be friends*, in English is, *in order to their being friends*. This anomaly, then, if indeed it be such, is of no manner of consequence. The French, if we are not mistaken, would express it in the very same manner with the Greek, that is, *pour etre amis*.

From treating of verbs, we should naturally proceed to

(H) Hence it came to signify rejoicing, from the mirth and revelry attending the treading of the vine-press.

Greek Language.

to the consideration of adverbs, which are so denominated, because they are generally the concomitants of verbs. Every thing relating to that part of speech, in the Greek tongue, may be seen in the Port Royal or any other Greek grammar. Instead therefore of dwelling upon this beaten topic, we shall hazard a conjecture upon a point to which the critics in the Greek tongue, as far as we know, have not hitherto adverted.

155
Greek particles of oriental extraction.

The most elegant and most admired writers of Greece, and especially Homer, and after him Hesiod, abound with small particles, which appear to us pure expletives, created as it were to promote harmony, or fill up a blank without sense or signification. How those expletive particles should abound in that language beyond any other, we think, is a matter not easy to be accounted for. It has been said by the Zoili, that if you extract these nonentities from the poems of that bard, *qui solus meruit dici poeta*, a *magnum inane*, a mighty blank, would be left behind. We would willingly do justice to that pigmy race of words, and at the same time vindicate the prince of poets from that groundless imputation. Plato likewise, the prince of philosophers, has been often accused of too frequently employing these superfluous auxiliaries.

Those particles were no doubt imported from the east. It would be ridiculous to imagine that any description of men, however enthusiastically fond they might be of harmonious numbers, would sit down on purpose to fabricate that race of monosyllables purely to eke out their verses; mere sounds without significancy. In the first place, it may be observed, that there is a very strict connection among the particles of all cognate languages. To this we may add, that the not understanding the nature, relations, signification, and original import of those seemingly unimportant terms, has occasioned not only great uncertainty, but numberless errors in translating the ancient languages into the modern. The Greek language in particular loses a considerable part of its beauty, elegance, variety, and energy, when these adverbial particles with which it is replete are not thoroughly comprehended. An exact translation of these small words, in appearance insignificant, would throw new light not only on Homer and Hesiod, but even upon poets of a much posterior date. Particles, which are generally treated as mere expletives, would often be found energetically significant. It is however, altogether impossible to succeed in this attempt without a competent skill in the Hebrew, Chaldaic, Arabian, Persian, and old Gothic languages. We shall here take the liberty to mention a few of these particles which are most familiar, one or other of which occur in almost every line of Homer, and which we believe are either not understood or misunderstood. Such are Δα, δη, μεν, ητοι, μαν, γε, περ, αρα, ρα, γυν. Δα is nothing else but the Chaldaic particle δα, the parent of the English *the*. It likewise signifies *by turns, in your turn;* δη is the same word in the Ionic dialect; μεν is a particle of the Hebrew affirmative אמן *amen, fides, veritas*. Μαν, a kind of oath by the moon, called *mana*, almost over all the east; hence Dor. μανα; γε, an oath by γεα, that is, *the earth;* αρα, another oath by the same element, probably from the oriental word of the same import; ρα is a fragment of αρα mentioned before; γυν, of γεα the *earth*, and ον or ων, an Egyptian name of the sun; ως, *as*, a particle which pervades all the dialects of the Gothic language. In this manner we believe all these small words that occur so frequently in the Greek tongue, and which have hitherto been held inexplicable, may be easily rendered in significant terms: and were this done, we believe they would add both beauty and energy to the clauses in which they stand. But this discussion must be left to more accomplished adepts.

Greek Language.

156
Prepositions.

We shall not explain the nature of prepositions, because we are convinced that few people will take the trouble to peruse this disquisition who are not already acquainted with their import in language. The Greek prepositions are eighteen in number, which need not be enumerated here. Most of these might be easily shown to be particles, or fragments deduced from oriental or Gothic words. The use of these words is to connect together terms in discourse, and to show the relation between them. In languages where, as in English, all these relations are expressed without any change on the termination of the nouns to which they are prefixed, the process is natural and easy. The whole is performed by juxtaposition. But in the Greek and Latin tongues, this effect is produced, partly by prefixing prepositions and partly varying the terminations of nouns. Had the Greeks been able to intimate all those relations by varying the terminations, or had they multiplied their prepositions to such a number as would have enabled them to express these relations without the casual variations, as the northern languages have done; in either case their language would have been less embarrassing than it is in its present state. According to the present arrangement both prepositions and the casual variations are used promiscuously to answer that purpose; a method which appears to us not altogether uniform. Though this plan might occasion little embarrassment to natives, it must, in our opinion, have proved somewhat perplexing to foreigners. The difficulty would be, as to the latter, when to adopt the one and when the other expedient.

Another inconveniency arises from the exceeding small number of prepositions in that language, which bear too small a proportion to the great variety of relations which they are appropriated to express. This deficiency obliged them often to employ the same preposition to denote different relations: For instance, Επι intimates, 1st, *upon;* as επι τȣ λιθȣ, *upon the stone;* and then it takes the genitive. 2d, It denotes *near upon;* as ἐπι τῳ λιθῳ, and then it governs the dative. 3d, The same preposition signifies *motion towards;* as Επεσεν ἐπι τον λιθον, *he fell upon the stone*. In these instances the same preposition intimates three different relations; and, which is still more embarassing, each of these requires a different case. The difficulty in this instance is so considerable, that even the most accurate of the Greek writers themselves often either forget or neglect the true application. Many examples of this might be adduced, did the limits assigned us admit such illustrations. Every man who has carefully perused the Grecian authors will readily furnish himself with examples.

157
irregularly used,

Again, some prepositions, which indicate different relations, are prefixed to the same case. Thus, εξ signifies *from;* as, Εκ Διος αρχομεθα, *from Jupiter we begin;* ἀπ εμου βιου, *from my life*, or *my course of life;* προ των θυρων, *before the doors;* προ νικης εγκωμιον, *an encomium before the victory;* αντι αγαθων αποδιδοναι κακα, *to render evil.*

Greek Language.

evil for good; αντι σου, against you. In these examples, and indeed every where, those prepositions intimate different relations, and yet are prefixed to the same cases. Sometimes the same preposition seems to assume two opposite significations: this appears from the preposition αντι just mentioned, which intimates both *for, instead of,* and *against* or *opposite to.*

What has been observed with respect to the prepositions above mentioned, the reader will readily enough apply to κατα, μετα, δια, περι. These incongruities certainly imply something irregular; and seem to intimate that those anomalies were so deeply incorporated with the constitution of the language, that the subsequent improvers found it impossible to correct them. Indeed to prefix a preposition to a case already distinguished by the affixed termination, appears to us a superfluity at least, if not an absurdity; for certainly it would have been more natural to have said εκ Ζευς αρχομεθα, than εκ Διος αρχωμεθα. Some very learned men, who have inquired into *the origin of language*, have been of opinion that prepositions were the last invented species of words. If this opinion be well founded, we may suppose (and we think that this supposition is not altogether improbable) that the casual terminations of the Greek language were first affixed to the radix, in the manner above exhibited; and that prepositions were afterwards fabricated and prefixed to the cases already in use.

The syntax or construction of the Greek language does not, according to our plan, come within the compass of our present inquiry. This the curious Greek student will easily acquire, by applying to the grammars composed for that purpose. We have already hazarded a few conjectures with respect to the formation of the most important and most distinguished classes of words into which it has been divided by the most able grammarians, without, however, descending to the minutiæ of the language. As prepositions are the chief materials with which its other words, especially verbs, are compounded, we shall briefly consider the order in which they probably advanced in this process.

158 used in composition.

Complex ideas are compounded of a certain number or collection of simple ones. Of those complex notions, some contain a greater and some a smaller number of simple conceptions. In language, then, there are two ways of expressing those complex ideas, either by coining a word to express every simple idea separately, according to the order in which they stand in the mind; or by trying to combine two or more simple terms into one, and by that method to intimate one complex idea by one single word. The Arabians, notwithstanding all the boasted excellencies of their language, have never arrived at the art of compounding their words, in order to answer this noble purpose; and the sister dialects are but slenderly provided with this species of vocables. The Greeks, of all other nations (except perhaps those who spake the Sanscrit language), are unrivalled in the number, variety, propriety, elegance, energy, and expression of their compound terms, The Greeks, like the Arabians, in the earliest stages of their language, had only a collection of radical disjointed words, consisting of the jargons of the aboriginal Greeks, of the Pelasgi, Thracians, &c. How these words were arranged and constructed, we have no data remaining upon which we can found a critical investigation. We must therefore remain satisfied with such probable conjectures as the nature of the case, and the analogy of the language, seem to suggest.

The prepositions were originally placed before the nouns, whose relations they pointed out. For example, let us take the ξυναπεθνησκετο τοις αλλοις, *he died along with the rest,* or *he died out of hand along with the others.* These words were arranged thus: απεθνησκετο συν τοις αλλοις; and απο-θνησκει συν τοις αλλοις. In this manner the parts of every compound word were placed separately, at least as much as other words which had no connection.

159 The first compound words in Greek.

The first compound words of the Greek language were the radical nouns with the article, and the radical part of the substantive or auxiliary verb. The success of this experiment encouraged them to attempt the same in other words. By this noble invention they found themselves able to express, in one word, with ease and significancy, what in other languages, and formerly in their own, required a tedious ambages or circumlocution. In process of time, as their language was gradually mellowed, they increased the number of their compounds, till their language, in that respect, infinitely excelled all its parent dialects. In this process they were careful to unite such letters as not only prevented asperity and difficulty of pronunciation, but even promoted harmony and elegance. But this was the labour of posterior ages.

The Greeks were entirely ignorant of the derivation or etymology of their language: for this we need only consult Plato's Cratylus, Aristotle's Rhetoric, Demetrius Phalereus, Longinus, &c. In deducing patronymics, abstracts, possessives, gentiles, diminutives, verbals, &c. from radicals of every kind, they have shown the greatest art and dexterity. Examples of this occur almost in every page of every Greek author. But this extended no farther than their own language; every foreign language was an abomination to the Greeks. But more of this in the sequel.

160 Original materials of the Greek language;

The original materials of the Greek tongue were undoubtedly rough and discordant, as we have described them above. They had been collected from different quarters, were the produce of different countries, and had been imported at very distant periods. It would therefore be an entertaining, if not an instructing, speculation, if it were possible to discover by what men and by what means, this wonderful fabric was founded, erected, and carried to perfection. The writers of Greece afford us no light. Foreigners were unacquainted with that originally insignificant canton. Every thing beyond Homer is buried in eternal oblivion. Orpheus is indeed reported to have composed poems; but these were soon obliterated by the hand of time. The verses now ascribed to that philosophical hero are none of his *. Linus wrote, in the Pelasgic dialect, the achievements of the first Bacchus; Thamyris the Thracian wrote; and Pronapides the master of Homer was a celebrated poet. The works of all these bards did not long survive; and it is a certain fact that the Greek tongue was highly polished even more early than the age in which these worthies flourished. Homer, no doubt, imitated their productions, and some are of opinion that he borrowed liberally from them. The Greeks knew no more of the original character of their language, than of the original character and complexion of

* *Pausan.* lib. i. cap. 22.

of their progenitors. They allowed, indeed, that their language was originally barbarous and uncouth; but by what means or by what persons it was polished, enriched, and finally arranged, was to them an impenetrable secret.

We have already demonstrated that the Ionim or aborigines of Greece were a race of barbarians; that consequently their language, or rather their jargon, was of the same contexture. The Pelasgi found both the people and their speech in this uncultivated state. These people arrived in Greece about the year before Christ 1760. It was then that the language of Greece began to be cultivated. Before the age of Homer the work seems to have been completed. Nothing of consequence was afterwards added to the original stock; on the contrary, not a few moieties were deducted from the Homeric treasure. The Pelasgi, as was said before, arrived in Greece *an. ant. Chr.* 1760. Homer is thought to have been born *an. ant. Chr.* 1041; consequently the cultivation of the Greek tongue was completed in a period of about 700 years. But upon the supposition that Orpheus, Linus, Thamyris, &c. wrote long before Homer, as they certainly did, that language had arrived nearly at the standard of perfection two centuries before; by which computation the period of its progress towards its stationary point is reduced to 500 years. But as the Pelasgi were a colony of foreigners, we ought to allow them one century at least to settle and incorporate with the natives, and to communicate their language, laws, manners, and habits, to the aborigines of the country. By this deduction we shall reduce the term of cultivation to less than four centuries.

161 which was carried to its utmost perfection at a very early period.

During this period Greece was furiously agitated by tumults and insurrections. That country was divided into a number of independent states, which were perpetually engaged in quarrels and competitions. The profession of arms was absolutely necessary for the protection and preservation of the state; and the man of conduct and prowess was honoured as a demi-god, and his exploits transmitted with eclat to posterity. The Greek tongue was then rough and unpolished; because, like the ancient Romans, the bravest men were more disposed to act than to speak. Every language will take its colour from the temper and character of those who employ it; and had it not been owing to one class of men, the Greek tongue would have continued equally rough to the era of Homer as it had been a century after the arrival of the Pelasgi.

There has appeared among barbarous or half civilized people a description of men whose profession it has been to frequent the houses or palaces of the great, in order to celebrate their achievements, or those of their ancestors, in the sublimest strains of heroic poetry. Accordingly, we find that the Germans had their *bards*, the Gauls their *fads*, the Scandinavians their *scalds* or *scaldres*, the Irish their *fileas*, all retained for that very purpose. They lived with their chieftains or patrons; attended them to battle; were witnesses of their heroic deeds; animated them with martial strains; and celebrated their prowess, if they proved victorious; or, if they fell, raised the song of woe, and chanted the mournful dirge over their sepulchres. These bards were always both poets and musicians. Their persons were held sacred and inviolable. They attended public entertainments, and appeared in all national conventions. The chief of them were employed in the temples of the gods; and the less illustrious, like our minstrels of old, strolled about from place to place, and exercised their functions wherever they found employment.

162 by the poets, who made a

Among the ancient Greeks there was a numerous tribe of men of the very same description who were at once poets and musicians, and whose office it was to celebrate the praises of the great, and to transmit their exploits to posterity in the most exaggerated encomiums. These poetical vagrants were styled Αοιδοι or songsters. Some of these lived in the houses of great men; while others, less skilful or less fortunate, strolled about the country in the manner above described. The more illustrious of these Αοιδοι who were retained in the temples of the gods, were certainly the first improvers of the language of the Greeks. Among the Hebrews we find the first poetical compositions were hymns in honour of Jehovah, and among the Pagans the same practice was established. In Greece, when all was confusion and devastation, the temples of the gods were held sacred and inviolable. There the Αοιδοι improved their talents, and formed religious anthems on those very models which their progenitors had chanted in the east.

The language of the Greeks was yet rugged and unmellowed: their first care was to render it more soft and more flexible. They enriched it with vocables suited to the offices of religion; and these, we imagine, were chiefly imported from the east. Homer every where mentions a distinction between the language of gods and men. The language of gods imports the oriental terms retained in the temples, and used in treating of the ceremonies of religion; the language of men intimates the ordinary civil dialect which sprung from the mixed dialects of the country. The priests no doubt concurred in promoting this noble and important purpose. From this source the strolling Αοιδοι drew the rudiments of their art; and from these last the vulgar deduced the elements of a polished style.

163 distinction between the language of gods and of men.

To these Αοιδοι of the superior order we would ascribe those changes mentioned in the preceding part of this inquiry, by which the Greek tongue acquired that variety and flexibility, from which two qualities it has derived a great share of that ease, beauty, and versatility, by which it now surpasses most other languages. The diversity of its terminations furnishes a most charming variety, while at the same time the sense is communicated to the reader or hearer by the relation between them. By this economy the poet and orator are left at liberty to arrange their vocables in that order which may be most soothing to the ear, and best adapted to make a lasting impression on the mind.

Few colonies have emigrated from any civilized country without a detachment of priests in their train. The supreme powers, whoever they were, have always been worshipped with music and dancing. The Hebrews, Phœnicians, and Egyptians, delighted in these musical and jocund festivals. The priests who attended the Iones, Dores, Æolians, Thebans, Athenians, &c. from the east, introduced into Greece that exquisite taste, those delicate musical feelings, which distinguish the Greeks from all the neighbouring nations. Hence that numerous race of onomatapœas, by which the Greek language is invested with the power of expressing almost every passion of the human soul, in such terms as oblige it to feel and actually to assimilate to the passion it would excite. Numberless instances of this occur in every page of Homer, Hesiod, Pindar, Sophocles, Euripides, and even of Aristophanes: to quote instances would be to insult the Greek student.

Every body knows that the practice of writing in verse was antecedent to the date of prosaic composition. Here, then, the Αοιδοι and the ministers of religion chiefly displayed their skill and discernment. By a judicious mixture of short and long syllables; by a junction of consonants which naturally slide into each other; by a careful attention to the rhythm, or harmony resulting from the combination of the syllables of the whole line—they completed the metrical tone of the verse, guided by that delicacy of musical feeling of which they were possessed before rules of prosody were known among men.

Much liberty was certainly used in transposing letters, in varying terminations, in annexing prefixes and affixes, both to nouns and other kinds of words where such adjuncts were possible: and upon this occasion we think it probable, that those particles of which we have spoken above were inserted like filling stones thrust in to stop the gaps or chinks of a building. Verses were then clumsy and irregular, as the quantity of vowels was not duly ascertained, and the collision of heterogeneous consonants not always avoided. Probably these primitive verses differed as widely from the finished strains of Homer and his successors, as those of Chaucer and Spencer do from the smooth polished lines of Dryden and Pope.

164 Earliest poets of Greece.

The poetical compositions of the earliest Greeks were not, we think, in the hexameter style. As they were chiefly calculated for religious services, we imagine they resembled the Hebrew iambics preserved in the song of Aaron and Miriam, Deborah and Barak, Psalms, Proverbs, &c. which were indeed calculated for the same purpose. Archilochus perhaps imitated these, though the model upon which he formed his iambics was not generally known. The later dramatic poets seem to have copied from the same archetypes. Hexameters, it is probable, were invented by Orpheus, Linus, Thamyris, Musæus, &c. The first of these travelled into Egypt, where he might learn the hexameter measure from that people, who used to bewail *Maneros* and *Osiris* in elegiac strains. This species of metre was first consecrated to theology, and the most profound sciences of moral and natural philosophy; at length it was brought down to celebrate the exploits of kings and heroes.

Res gestas regumque, ducumque, et fortia bella,
Quo scribi possent numero monstravit Homerus.

We have hazarded a conjecture above, importing that the earliest poetical compositions of the Greeks were consecrated to the service of the gods. We shall now produce a few facts, which will furnish at least a presumptive evidence of the probability of that conjecture.

165 Orpheus.

Orpheus begins his poem with ancient chaos, its transformations and changes, and pursues it through its various revolutions. He then goes on to describe the offspring of Saturn, that is time, the æther, love, and light. In short, his whole poem is said to have been an oriental allegory, calculated to inspire mankind with the fear of the gods, and to deter them from murder, rapine, unnatural lusts, &c.

166 Musæus.

Musæus was the favourite scholar of Orpheus, or perhaps his son. He composed prophecies and hymns, and wrote sacred instructions, which he addressed to his son. He prescribed atonements and lustrations; but his great work was a Theogony, or History of the Creation, &c.

167 Melampus.

Melampus brought the mysteries of Proserpine from Egypt into Greece. He wrote the whole history of the disasters of the gods. This seer is mentioned by Homer himself.

168 Olen.

Olen came from Lycia, and composed the first hymn that was sung in Delos at their solemnities; he probably emigrated from Patara a city of Lycia, where Apollo had a celebrated temple and oracle.

The Hyperborean damsels used to visit Delos, where they chaunted sacred hymns in honour of the Delian god.

169 Homer and Hesiod.

To these we add the great Homer himself, if indeed the hymns commonly annexed to the Odyssey are his composition. Hesiod's Theogony is too well known to need to be mentioned.

From these instances we hope it appears, that the origin of the poetry of Greece is to be found in the temples; and that there, its measure, numbers, rhythm, and other appendages, were originally fabricated.

170 Different dialects, with their origin.

The Grecian poets, however, enjoyed another advantage which that class of writers have seldom possessed, which arose from the different dialects into which their language was divided. All those dialects were adopted indifferently by the prince of poets; a circumstance which enabled him to take advantage of any word from any dialect, provided it suited his purpose. This, at the same time that it rendered versification easy, diffused an agreeable variety over his composition. He even accommodated words from Macedonia, Epirus, and Illyricum, to the purposes of his versification: Besides, the laws of quantity were not then clearly ascertained; a circumstance which afforded him another conveniency. Succeeding poets did not enjoy these advantages, and consequently have been more circumscribed both in their diction and numbers.

The Greek language, as is generally known, was divided into many different dialects. Every sept, or petty canton, had some peculiar forms of speech which distinguished it from the others. There were, however, four different dialectical variations which carried it over all the others. These were the Attic, Ionic, Æolic, and Doric. These four dialectical distinctions originated from the different countries in the east from which the tribes respectively emigrated. The Attics consisted, 1st, of the barbarous aborigines; 2d, of an adventitious colony of Egyptian Saïtes; 3d, a branch of Ionians from the coast of Palestine. These last formed the old Ionian dialect, from which sprung the Attic and modern Ionic. The Æolians emigrated from a different quarter of the same coast; the inhabitants of which were a remnant of the old Canaanites, and consequently different in dialect from the two first-mentioned colonies. The Dores sprang from an unpolished race of purple fishers on the same coast, and consequently spoke a dialect more coarse and rustic than any of the rest. These four nations emigrated from different regions; a circumstance which, in our opinion, laid the foundation of the different dialects by which they were afterwards distinguished.

It is impossible in this short sketch to exhibit an exact view of the distinguishing features of each dialect. Such an analysis would carry us far beyond the limits of the article

Greek Language.

article in question. For entire satisfaction on this head, we must refer the Grecian student to Mattaire's *Græcæ Linguæ Dialecti*, where he will find every thing necessary to qualify him for understanding that subject. We shall content ourselves with the few observations following.

The Athenians being an active, brisk, volatile race, delighted in contractions. Their style was most exquisitely polished. The most celebrated authors who wrote in that dialect were the following: Plato, Thucydides, Xenophon, Demosthenes, and the other orators; Æschylus, Euripides, Sophocles, Aristophanes, Menander, Diphilus, with the other comic and tragic poets. That dialect was either ancient or modern. The ancient Attic was the same with the Ionic.

The Ionic, as was said, was the ancient Attic; but when that nation emigrated from Attica and settled on the coast of Asia Minor, they mingled with the Carians and Pelasgi, and of course adopted a number of their vocables. They were an indolent, luxurious, and dissolute people; of course their style was indeed easy and flowing, but verbose, redundant, and without nerves. This, however, is the leading style in Homer; and after him a prodigious number of writers on every subject have used the same dialect, such as Herodotus of Halicarnassus the celebrated historian; Ctesias of Cnidus the historian of Persia and India; Hecatæus of Miletus; Megasthenes the historian, who live under Seleucus Nicator; Hippocrates the celebrated physician of Coos; Hellanicus the historian often mentioned with honour by Polybius; Anacreon of Teia, Alcæus, Sappho of Lesbos, excellent poets; Pherecydes Syrus the philosopher, and a multitude of other persons of the same profession, whom it would be superfluous to mention upon the present occasion.

The Æolic and Doric were originally cognate dialects. When the Dorians invaded Peloponnesus, and settled in that peninsula, they incorporated with the Æolians, and their two dialects blended into one produced the new Doric. The original Dores inhabited a rugged mountainous region about Ossa and Pindus, and spoke a rough unpolished language similar to the soil which they inhabited. Andreas Schottus, in his observations on poetry, lib. ii. cap. 50. proves from an old manuscript of " Theocritus, that there were two dialects of the Doric tongue, the one ancient and the other modern; that this poet employed Ionic and the modern Doric; that the old Doric dialect was rough and cumbrous; but that Theocritus has adopted the new as being more soft and mellow." A prodigious number of poets and philosophers wrote in this dialect, such as Epicharmus the poet; Ibycus the poet of Rhegium; Corinna the poetess of Thespis, or Thebes, or Corinth, who bore away the prize of poetry from Pindar; Erynna a poetess of Lesbos; Moschus the poet of Syracuse; Sappho the poetess of Mitylene; Pindarus of Thebes, the prince of lyric poets; Archimedes of Syracuse, the renowned mathematician; and almost all the Pythagorean philosophers. Few historians wrote in that dialect; or if they did, their works have not fallen into our hands. Most of the hymns sung in temples of the gods were composed in Doric; a circumstance which evinces the antiquity of that dialect, and which, at the same time, proves its affinity to the oriental standard.

After that the Greek tongue was thoroughly polished by the steps which we have endeavoured to trace in the preceding pages, conscious of the superior excellency of their own language, the Greeks, in the pride of their heart, stigmatized every nation which did not employ their language with the contemptuous title of *barbarians*. Such was the delicacy of their pampered ears, that they could not endure the untutored voice of the people whom the called **Βαρβαροφωνοι**. This extreme delicacy produced three very pernicious effects; for, 1st, It induced them to metamorphose and sometimes even to mangle, foreign names, in order to reduce their sound to the Grecian standard; and, 2d, It prevented their learning the languages of the east, the knowledge of which would have opened to them an avenue to the records, annals, antiquities, laws, customs, &c. of the people of those countries, in comparison of whom the Greeks themselves were of yesterday, and knew nothing. By this unlucky bias, not only they, but even we who derive all the little knowledge of antiquity we possess through the channel of their writings, have suffered an irreparable injury. By their transformation of oriental names they have in a manner stopped the channel of communication between the histories of Europe and Asia. This appears evident from the fragments of Ctesias's Persian history, from Herodotus, Xenophon, and all the other Grecian writers who have occasion to mention the intercourse between the Greeks and Persians. 3d, It deprived them of all knowledge of the etymology of their own language, without which it was impossible for them to understand its words, phraseology, and idioms, to the bottom. We mentioned Plato's Cratylus above. In that dialogue, the divine philosopher endeavours to investigate the etymology of only a few Greek words. His deductions are absolutely childish, and little superior to the random conjectures of a school-boy. Varro, the most learned of all the Romans, has not been more successful. Both stumbled on the very threshold of that useful science; and a scholar of very moderate proficiency in our days knows more of the origin of these two noble languages, than the greatest adepts among the natives did in theirs. By prefixes, affixes, transpositions of letters, new conjunctions of vowels and consonants for the sake of the music and rhythm, they have so disguised their words, that it is almost impossible to develope their original. As a proof of this, we remember to have seen a manuscript in the hands of a private person where the first twelve verses of the Iliad are carefully analysed; and it appears to our satisfaction, that almost every word may be, and actually is traced back to a Hebrew, Phœnician, Chaldean, or Ægyptian original: And we are convinced that the same process will hold good in the like number of verses taken from any of the most celebrated poets of Greece. This investigation we found was chiefly conducted by reducing the words to their original invariable state, which was done by stripping them of prefixes, affixes, &c. These strictures are, we think, well founded; and consequently need no apology to protect them.

171 The partiality of the Greeks to their own tongue, and its evil consequences.

172 Beauty of the Greek language.

These imperfections, however, are counterbalanced by numberless excellencies: and we are certainly much more indebted to that incomparable people for the information they have transmitted to us through the medium of their writings, than injured by them in not conveying to us and to themselves more authentic and more ample communications of ancient events and occurrences. Without fatiguing our readers with superfluous encomiums on a language which has long ago been extolled perhaps to to an extravagant degree by the labours of men of the most enlarged capacity and the most refined taste, we shall now proceed to make a few observations on *spirits* and *accents*; which being rather appendages than essentials of the language, we have on purpose reserved for the last place.

173 The spiritus asper and lenis.

Every word in the Greek language beginning with a vowel is marked with a spirit of breathing: This aspiration is double, namely *lenis et asper*, "the gentle, and rough or aspirated." The gentle accent, though always marked, is not now pronounced, though in the earliest periods of the language it was undoubtedly enounced, though very softly. Both these aspirations were imported from the east. They were actually the Hebrew ה *he* and ח *heth*. The former denoted the *spiritus lenis*, and and latter the *spiritus asper*. The Hebrew prefixed *ha* or *he* to words beginning with a vowel, and of course the Greeks followed their example. These people seem to have delighted in aspirates; and of consequence the letter ς is, some think, rather too often affixed to the terminations of their words. Every word beginning with ρ had the aspirate joined to ρ, probably with a design to render the aspiration still more rough.

174 The accents.

The Greek accents are three in number; the acute, the grave, and the circumflex. The acute raises and sharpens the voice; the grave depresses and flattens it; the circumflex first raises and sharpens the voice, and then depresses and flattens it. It is obviously composed of the other two. The learned author of the *Origin and Progress of Language* has taken much pains to prove that these accents were actually musical notes, invented and accommodated to raise, depress, and suspend the voice, according to a scale of musical proportions. It is scarce possible, we think, for a modern Greek scholar to comprehend distinctly the ancient theory of accents. These the native Greeks learned from their infancy, and that with such accuracy, that even the vulgar among the Athenians would have hissed an actor or actress off the stage or an orator off the pulpitum *, on account of a few mistakes in the enunciation of those notes.

* See Pulpitum.

The elevations, depressions, and suspensions of the voice upon certain syllables, must have made their language sound in the ears of foreigners somewhat like recitative, or something nearly resembling *cant*. But the little variety of these syllabic tones, and the voice not resting upon them, but running them on without interruption, sufficiently distinguished them from music or cant. Be that as it may, we think it highly probable, that the wonderful effects produced by the harangues of the orators of Greece on the enraptured minds of their hearers, were owing in a good measure to those artificial musical tones by which their syllables were so happily diversified.

To this purpose we shall take the liberty to transcribe a passage from Dion. Halic. *De Structura Orationis*, which we find translated by the author of the *Origin and Progress of Language*, vol. ii. book 3d, part ii. chap. 7. page 381. "Rhetorical composition is a kind of music, differing only from song or instrumental music, in the degree, not in the kind; for in this composition the words have melody, rythm, variety, or change, and what is proper or becoming: So that the ear in it, as well as in music, is delighted with the melody, moved by the rythm, is fond of variety, and desires with all these what is proper and suitable. The difference, therefore, is only of greater and less."

With respect to accents, it may be observed that only one syllable of a word is capable of receiving the acute accent, however many there be in the word. It was thought that the raising the tone upon more than one syllable of the word, would have made the pronunciation too various and complicated, and too like chanting.

The *grave accent* always takes place when the acute is wanting. It accords with the level of the discourse; whereas the acute raises the voice above it.

The *circumflex accent* being composed of the other two is always placed over a long syllable, because it is impossible first to elevate the voice and then to depress it on a short one. Indeed among the Greeks a long syllable was pronounced like two short ones; and we apprehend it was sometimes written so, especially in later times. It is altogether obvious from two learned Greek authors, Dion. Halic. and Aristoxenus, that the Greek accents were actually musical notes, and that these tones did not consist of loud and low, or simply elevating and depressing the voice; but that they were uttered in such a manner as to produce a melodious rythm in discourse.

In a word, the acute accent might be placed upon any syllable before the antepenult, and rose to a *fifth* in the diatonical scale of music; the grave fell to the third below it. The circumflex was regulated according to the measure of both, the acute always preceding. The grave accent is never marked except over the last syllable. When no accent is marked, there the grave always takes place. Some words are called *enclitics*. These have no accent expressed, but throw it back upon the preceding word. The circumflex, when the last syllable is short, is often found over the penult, but never over any other syllable but the last or the last but one.

175 The ancient Greeks had no accentual marks.

The ancient Greeks had no accentual marks. They learned those modifications of voice by practice from their infancy; and we are assured by good authority, that in pronunciation they observe them to this day. The accentual marks are said to have been invented by a famous grammarian, Aristophanes of Byzantium, keeper of the Alexandrian library under Ptolemy Philopater, and Epiphanes, who was the first likewise who is supposed to have invented punctuation. Accentual marks, however, were not in common use till about the seventh century; at which time they are found in manuscripts. If our curious readers would wish to enter more deeply into the theory of accents, we must remit them to Origin of Language, vol. ii. lib. 2. *passim*; and to Mr Foster's Essay on the different Nature of Accent and Quantity.

Such, in general, are the observations which we thought the nature of our design obliged us to make on the origin and progress of the Greek language. Some of our more learned readers may perhaps blame us for not interspersing the whole disquisition with quotations from the most celebrated writers in the language which has been the object of our researches. We are well aware that this is the general practice in such cases. The books were before us, and we might have transcribed from them more quotations than the nature of an article of this kind would permit. In the first part there were no books in that

Greek Language.

that language to quote from, because the Greeks knew nothing of their own origin, nor of that of their language, and consequently have recorded nothing but dreams and fictions relating to that subject. Even when we had made considerable progress in our inquiry, the nature of the plan we have adopted excluded in a great measure the use of quotations. When we drew near the conclusion, we imagined that our learned readers would naturally have recourse to the passages alluded to without our information, and that the unlearned would not trouble themselves about the matter. The Greek student who intends to penetrate into the depths of this excellent language, will endeavour to be thorough-
176 ly acquainted with the books after mentioned.

Books to be studied by every one who wishes to be a master of this language.

Aristotle's Rhetoric and Poetics, his book *De Interpretatione*, especially with Ammonius's Commentary. Ammonius was a native of Alexandria, and by far the most acute of all the ancient grammarians.

Dion. Halic. *De Structura Orationis*, where, amidst abundance of curious and interesting observations, will be found the true pronunciation of the Greek letters.

Demetrius Phalereus *De Elocutione;* a short essay indeed, but replete with instruction concerning the proper arrangement of words and members in sentences.

Longinus, the prince of critics, whose remains are above commendation. Theodorus Gaza ‡ and the other refugees from Constantinople, who found an hospitable reception from the munificent family of the Medici, and whose learned labours in their native language once more revived learning and good taste in Europe. These, with some other critics of less celebrity, but equal utility, will unlock all the treasures of Grecian erudition, without however disclosing the source from which they flowed. To these one might add a few celebrated moderns, such as Mons. Fourmont the Elder, Mons. Gebelin, Abbé Pezron, Salmasius, and especially the learned and industrious Lord Monboddo.

‡ See *Gaza*.

We shall now give a very brief account of the vast extent of the Greek language even before the Macedonian empire was erected; at which period, indeed, it became in a manner universal, much more than ever the Latin language could accomplish notwithstanding
177 the vast extent of the Roman empire.

Vast extent of the Greek language.

Greece, originally Hellas, was a region of small extent, and yet sent out many numerous colonies into different parts of the world. These colonies carried their native language along with them, and industriously diffused it wherever they formed a settlement. The Iones, Æoles, and Dores, possessed themselves of all the west, and north-west coast of the Lesser Asia and the adjacent islands; and there even the barbarians learned that polished language. The Greek colonies extended themselves along the south coast of the Euxine sea as far as Sinope, now Trebizund, and all the way from the west coast of Asia Minor: though many cities of barbarians lay between, the Greek tongue was understood and generally spoken by people of rank and fashion.

There were Greek cities on the north coast of the Euxine sea to the very eastern point, and perhaps beyond even those limits; likewise in the Taurica Chersonesus, or Crim Tartary; and even to the mouth of the Danube, the straits of Caffa, &c. In the neighbourhood of all these colonies, the Greek language was carefully propagated among the barbarians, who carried on commerce with the Greeks.

A great part of the south of Italy was planted with Greek cities on both coasts; so that the country was denominated *Magna Græcia*. Here the Greek tongue universally prevailed. In Sicily it was in a manner vernacular. The Ionians had sent a colony into Egypt in the reign of Psammitichus; and a Greek settlement had been formed in Cyrenia many ages before. The Phocians had built Massilia or Marseilles as early as the reign of Cyrus the Great, where some remains of the Greek language are still to be discovered. Cæsar tells us, that in the camp of the Helvetii registers were found in Greek letters. Perhaps no language ever had so extensive a spread, where it was not propagated by the law of conquest. 178

Greek spoken at present.

The Greek tongue, at this day, is confined within very narrow limits. It is spoken in Greece itself, except in Epirus, and the western parts of Macedonia. It is likewise spoken in the Grecian and Asiatic islands, in Candia or Crete, in some parts of the coast of Asia Minor, and in Cyprus: but in all these regions, it is much corrupted and degenerated.

As a specimen, we shall insert a modern Greek song, and the advertisement of a quack medicine, which with other plunder, was brought by the Russians from Chocsim or Chotzim in 1772.

Song in modern Greek.

ΜΙ δυστιχίαις πολιμῶ μί βάσανα ὡς τὸ λεμό
Εἶμαι, και κιντινύω, καὶ νὰ χαθω κοντεύω
Στὸ πέλαγος των συμφορῶν μι ἐπικινδυνον καιρὸν
Μ' ανέμυς ὀλάθριυς σφοδρυς και ιναντιυς.
Μι κύματα πολλῶν καὶ μαῦ τυφανὶ ανεστιασμῶν.
Θαλασσα φυσκομένη, πόλλα ἀγριομένη,
Ὅπῦ ἀφριζι καί φησὰ γι σαγανάκια πιρισσά
Σύνιφα σκοτισμένα καὶ κατασυγχισμένα,
Και νὰ φανῆ μια σωτηρία, νὰ ιδῦν τά μάτιά μυστιριά.
Γλίχα νιρα νὰ εὕρω, κάσχα καί δεν ἠξιύρῶ,
Ν' ἀραξω και δεν ἠμπορῶ γιατι λιμένα δεν θορῶ.
Μ' ἀπιλπισίαι θρέχω οτα ἅρμινα πῦ ίχω.
Πῦ μὶ αὐτὰ κὰν νὰ πνυγῶ ἤ σιλαμέτινα εὐγῶ,
Καὶ τυτα ἂν βασαξυν, ἐμποςῦν νὰ μὶ φυλαξυν.

Translation.

With dire misfortunes, pains, and woes,
O'erwhelm'd, ingulph'd, I struggling fight;
O'er my frail bark proud billows close,
To plunge her deep in lasting night.
Rough seas of ills incessant roar,
Fierce winds adverse, with howling blast,
Heave surge on surge. Ah! far from shore
My found'ring skiff shall sink at last.
Involv'd in low'ring darksome clouds,
'Mid sultry fogs, I pant for breath;
Huge foaming billows rend my shrouds,
While yawning gulfs extend beneath.
From bursting clouds loud thunders roll,
And deaf'ning peals terrific spread;
Red lightnings dart from pole to pole,
And burst o'er my devoted head.
When shall the friendly dawning rays
Guide me to pleasures once possest;
And breezy gales, o'er peaceful seas,
Waft to some port of endless rest?

In

In dark despair, with tempests tost,
I veer my sail from side to side.
Conduct me, Heav'n! to yond' fair coast,
Or plunge me in the 'whelming tide.

The Quack Bill.

ΒΑΛΣΑΜΟΝ ΤΗΣ ῾ΙΕΡΟΥΣΑΛΗΜ, ΑΠΟ ΤΑΙΣ, ΚΑΙ ΝΟΥΡΙΑΙΣ, ΚΑΙ ΠΑΛΕΑΙΣ ΡΕΤΖΕΤΑΙΣ.

ΤΟΥΤΟ *τὸ μπαλσαμον ὠφελεῖ εις τὸ ἀδυνατόν τομαχι, καὶ βοηθεῖ τὴν χονευσιν δυναμώνει τὴν καρδίαν. συκώνει ὅλας τὰς ἐμφράξεις τῆς κοιλιας ωφελεῖ εἰς τὴν στνωσιν καὶ βῆχα παλαιὸν. ῾Ιατρέυει τὰς ἐσωτερικὰς πληγὰς τȣ̃ σήθȣς, καὶ τȣ̃ πνύμονες ἤγουν πλεμονίȣ. κινεῖ τα καταμήνια τῶν γυναικῶν. ᾿Εις τὰς ἐξωτεριкὰς πληγὰς πρέπει νὰ βάζεται μὲ τὸ ξανθὸ τόσον ὲις παλαιὰς. Οσον καὶ ὲονεας, καθὼς εἶναι ἡ σπαθιαῖς, καὶ μαχαιριαῖς, καὶ ἀλλα κοψίματα ιατρευει κάθελογῆς Φισολα, καὶ ὁλας τὰς βρομεραὰς πληγὰς ὀπȣ̃ ἔφθασαν ὲις τὸ κȣ̃καλον θαυμάσιως, ὠφελεῖ εἰς τὰ ἀυτία ὀπȣ̃ τρέχουν ἔμπυον νά σαζεται δὺο ἢ τρεῖς κόμπȣς ἤχουν σαλαγματίας μεϐαμπάκι βρεμμένον εἰς ἀυτὸ, βάνεται εἰς τὰς πληγωμενας δοντοκοιλιαῖς καὶ θέλουν ῾ατρευθῆ. καὶ ἀκόμι δυναμώνει τὰ ὀδόντια ὀπȣ̃ κινοῦν ται δε θελουν νὰ πέσουν. βοηθᾶ καὶ ἀπὸ τὴν πανύκλαν.*

῾Η *δόσις ἐσωτεριкῶς ἂς εἶναι δέκα ἢ καὶ δώδεκα κόμπȣς εἰς ὀλίγον κρασὶ, ἢ καὶ νερον, τὸ κάθε ταχυ καὶ βράδυ. ἂς τὸ μεταχειρίζεται, καὶ ἐινα θαυμάσιον μὲτὴν δοκιμὴν βεϐαιωμενον.*

᾿Αληθὲς βάλσαμον τȣ̃ Βασιλεως.

Instead of giving a literal and bald translation of this advertisement, which runs exactly in the style of other quack bills, it may be sufficient to observe, that the medicine recommended is said, when taken inwardly, to raise the spirits, remove costiveness and inveterate coughs; to cure pains of the breast and bellyaches; to assist respiration, and remove certain female obstructions. When applied externally, it cures wounds and sores, whether old or fresh, removes ringing of the ears, fastens the teeth when loose, and strengthens the gums.

All this, and much more, it is said to do in a wonderful manner; and is declared to be the true royal balsam of Jerusalem, and an universal specific.

It is indeed next to a miracle that so many monuments of Grecian literature are still to be found among men. Notwithstanding the burning of the famous library of Alexandria, and the almost numberless wars, massacres, and devastations, which have from time to time in a manner desolated those countries where the Greek language once flourished; we are told that there still remain about 3000 books written in that language.

179 Distinguished stages of the Greek language.

We shall now conclude this section with a brief detail of the most distinguished stages and variations through which this noble tongue made its progress from the age of Homer to the taking of Constantinople, *anno Chr.* 1453; a period of more than 2000 years.

Homer gave the Greek poetry its colour and consistency, and enriched, as well as harmonized, the language. It seems, from the coincidence of epithets and cadence in Homer and Hesiod, that the Greek heroic verse was formed spontaneously, by the old Αοιδοι, a sort of *improvisatori;* and that Homer and his first followers adopted their versification. The Iliad and Odyssey have much of the air of extempore compositions; an epithet is never wanting to fill up a verse; and a set of expressions are mechanically annexed to such ideas as were of frequent recurrence. Hence that copiousness and waste of words in the old Greek bard, which forms such a contrast to the condensed and laboured composition of Virgil.

The Greek prose was of a more difficult structure; and it may be distributed into different styles or degrees of purity. Of the prose authors now extant, the first and best style is that of Herodotus, and of Plato in the florid or mixed kind, of Xenophon in the pure and simple, of Thucydides and Demosthenes in the austere. Nothing, perhaps, is so conducive to form a good taste in composition as the study of these writers.

The style of Polybius forms a new epoch in the history of the Greek language: it was the idiotic or popular manner of expression, especially among military men, in his time, about the 150th Olympiad. It became the model of succeeding writers, by introducing a simple unstudied expression, and by emancipating them from the anxious labour of the Old Greeks respecting the cadence and choice of words. The style of the New Testament, being plain and popular, frequently resembles that of Polybius, as has been shown by Raphelius, and by Kirchmaier, *de parallelismo* N. T. *et Polybii*, 1725.

Before this historian, the Alexandrian Jews had formed a new or Hellenistic style, resulting from the expression of oriental ideas and idioms in Greek words, after that language had lost of its purity, as it gained in general use, by the conquests of Alexander. The Hellenistic is the language of the Septuagint, the Apocrypha, the New Testament, and partly of Philo and Josephus. This mixture in the style of the evangelists and apostles, is one credential of the authenticity of the best of all books, a book which could not have been written but by Jewish authors in the first century. See the fine remarks of Bishop Warburton, Doctrine of Grace, book i. ch. 8—10. Critics lose their labour in attempting to adjust the Scripture-Greek to the standard of Atticism.

The diction of the Greek historians, and geographers of the Augustan age, is formed on that of Polybius; but improved and modernized, like the English of the present age, if compared with that of Clarendon or Bacon. More perspicuous than refined, it was well suited to such compilations as were then written by men of letters, such as Dionysius, Diodorus, and Strabo, without much experience or rank in public life.

The ecclesiastical style was cultivated in the Christian schools of Alexandria, Antioch, and Constantinople; rank and luxuriant, full of oriental idioms, and formed in a great measure on the Septuagint version. Such is, for instance, the style of Eusebius. After him, the best Christian writers polished their compositions in the schools of rhetoric under the later sophists. Hence the popular and flowing purity of St Chrysostome, who has more good sense than Plato, and perhaps as many good words.

On the Greek of the Byzantine empire, there is a good dissertation by Ducange, *de causis corruptæ Græcitatis*, prefixed to his Glossary, together with Portius's Grammar of the modern Greek. This last stage of the Greek language is a miserable picture of Turkish barbarism.

Greek Language.

barism. And, which is most surprising, there is no city of Greece where the language is more different from the ancient than at Athens. The reason of that is, because it has been long inhabited by a mixed multitude of different nations.

To conclude, the Greeks have left the most durable monuments of human wisdom, fortitude, magnificence, and ingenuity, in their improvement of every art and science, and in the finest writings upon every subject necessary, profitable, elegant, or entertaining.

The Greeks have furnished the brightest examples of every virtue and accomplishment, natural or acquired, political, moral, or military: they excelled in mathematics and philosophy; in all the forms of government, in architecture, navigation, commerce, war: as orators, poets, and historians, they stand as yet unrivalled, and are like to stand so for ever; nor are they less to be admired for the exercises and amusements they invented, and brought to perfection, in the institution of their public games, their theatres, and sports.

180 No perfect translation of any Greek author.

Let us further observe, that in vain our readers will look for these admired excellencies in any of the best translations from the Greek: they may indeed communicate some knowledge of what the originals contain; they may present you with propositions, characters, and events: but allowing them to be more faithful and more accurate than they really are, or can well be, still they are no better than copies, in which the spirit and lustre of the originals are almost totally lost. The mind may be instructed, but will not be enchanted: The picture may bear some faint resemblance, and if painted by a masterly hand give pleasure; but who would be satisfied with the canvass, when he may possess the real object? who would prefer a piece of coloured glass to a diamond? It is not possible to preserve the beauties of the original in a translation.—The powers of the Greek are vastly beyond those of any other tongue. Whatever the Greeks describe is always felt, and almost seen; motion and music are in every tone, and enthusiasm and inchantment possess the mind:

Graiis ingenium, Graiis dedit ore rotundo,
Musa loqui. HORACE.

SECT. VIII. *Of the Latin Language.*

181. Origin of the Romans, and of their language.

THIS language, like every other spoken by barbarians, was in its beginning rough and uncultivated.—What people the Romans were, is a point in which antiquarians are not yet agreed. In their own opinion they were sprung from the Trojans *; Dion. Halicar. derives them from the Greeks †; and Plutarch informs us ‡ that some people imagined that they were sprung from the Pelasgi. The fact is, they were a mixture of people collected out of Latium and the adjacent parts, which a variety of accidents had drawn together, to establish themselves on that mountainous region, in order to secure their own property, and plunder that of their neighbours. They were in all probability composed of Arcadians, Sabines, Latins, Hetruscans, Umbrians, Oscans, Pelasgi, &c.; and if so, their language must have been a mixture of the different dialects peculiar to all these discordant tribes.

* *Tit. Liv.* lib 1. cap 1. &c.
† *Antiq. Rom.* lib. i.
‡ *Vita Romul.*

Latin Language.

The Latin language ought then to be a mingled mass of the Arcadian, that is, the Æolian || Greek, the Pelasgic, Hetruscan, and Celtic dialects. These jarring elements, like the people to whom they belonged respectively, gradually incorporated, and produced what was afterwards called the *Latin* tongue.

|| *Strabo,* lib v. *Dionys. Halicarn. Antiq.* lib i.

The Arcadians were a Pelasgic § tribe, and consequently spoke a dialect of that ancient Greek produced by the coalition of this tribe with the savage aborigines of Greece. This dialect was the ground-work of the Latin. Every scholar allows, that the Æolian Greek, which was strongly tinctured with the Pelasgic, was the model upon which the Latin language was formed. From this deduction it appears, that the Latin tongue is much more ancient than the modern Greek; and of course we may add, that the Greek, as it stood before it was thoroughly polished, bore a very near resemblance to that language. Hence we think we may conclude, that the knowledge of the Latin language is necessary in order to understand the Greek. Let us not then expect to find the real ingredients of the Greek tongue in the academic groves of Athens, or in Smyrna, or in Rhodope, or in Hæmos; but on the banks of the Tiber and on the fields of Laurentum.

§ *Strabo et Herodotus.*

A very considerable part of the Latin tongue was derived from the Hetruscan. That people were the masters of the Romans in every thing sacred. From them they learned the ceremonies of religion, the method of arranging games and public festivals, the art of divination, the interpretation of omens, the method of lustrations, expiations, &c. It would, we believe, be easy to prove, that the Pelasgi * and Hetrusci (x) were the same race of people; and if this was the case, their languages must have differed in their dialect only.

* *Thucydides,* lib vi.

The Umbrian or Celtic enters deeply into the composition of the Latin tongue. For proof of this, we need only appeal to *Pelloutier, Bullet's Memoires de la Langue Celtic, partie premiere, Abbé Pezron's Origin of Ancient Nations,* &c. Whether the old Celtic differed essentially from the Pelasgic and Hetruscan, would be a matter of curious investigation, were this a proper subject for the present article.

The Latin abounds with oriental words, especially Hebrew, Chaldaic, and Persian. These are certainly remains of the Pelasgic and Hetruscan tongues, spoken originally by people who emigrated from regions where those were parts of the vernacular language.—The Greeks,

(x) The Hetrusci were variously denominated by the Greeks and Romans. The former called them τυῤῥηνοι; which was their true name, for they actually emigrated from Tarshish, or the western coast of Asia Minor, and consequently Herodotus every where calls them τυρσηνοι. The Æolians changed α into υ; hence in that dialect they were called τυρσηνοι, from *Tarsus.* The Romans styled them *Tusci,* probably from the Greek verb θυω, *sacrifico,* alluding to the skill which that people professed in the ceremonies of religion. They called their country *Hetruria,* we think from the Chaldaic word *heretum,* "a magician or sorcerer; a name deduced from their skill in divination.

Latin Language.

Greeks, in polishing their language, gradually distorted and disfigured vast numbers of the rough eastern vocables, which made a very great part of it. (See the preceding section).

The Romans, of less delicate organs, left them in their natural state, and their natural air readily bewrays their original. We had collected a large list of Latin words still current in the east; but find that Thomassin † and Ogerius (Y), and especially Mons. Gebelin, in his most excellent Latin Dictionary, have rendered that labour superfluous.

† *Glossary.*

In this language, too, there are not a few Gothic terms. How these found their way into the Latin, it is not easy to discover, unless, as Pelloutier supposes, the Celtic and Gothic languages were originally the same: or perhaps we may conjecture, that such words were part of a primitive language, which was at one time universal.

182 How far the Latin resembles the Greek.

There are, besides, in the Latin a great number of obsolete Greek words, which were in process of time obliterated, and others substituted in their room; so that, upon the whole, we are persuaded, that the most effectual method to distinguish the difference between the early and modern Greek, would be to compare the ancient Latin with the latter; there being, we imagine, very little difference between the ancient Greek and Latin in the earliest periods.

However that may be, it is certain that the Roman letters were the same with the ancient Greek.—*Formæ literis Latinis quæ veterrimis Græcorum*, says Tacitus ‡; and Pliny § says the same thing, and for the truth of his assertion he appeals to a monument extant in his own times.

‡ *Tacitus, Anal.* lib. ii.
§ *Nat Hist.* lib. vii. cap. 58.

These old Greek letters were no other than the Pelasgic, which we have shown from Diodorus Siculus (see preceding Section) to have been prior to the Cadmean. For the figure of these letters, see Astle, Postellus, Montfaucon, Palægraphia Græca, Mons. Gebelin, and our Plates XV. and XVI.

That the Latins borrowed the plan of their declensions from the Greeks, is evident from the exact resemblance of the terminations of the cases throughout the three similar declensions. In nouns of the first declension, the resemblance is too palpable to stand in need of illustration. In the second, the Greek genitive is ου. In Latin the *o* is thrown out, and the termination becomes *i*. In the Greek section, we have observed, that the sounds of ι and υ differed very little; therefore the Latins used ι instead of υ. The Latin dative ends in *o*, which is the Greek dative, throwing away ι *subscriptum*, which was but faintly sounded in that language. No genuine Greek word ended in μ or *m*.

The Hellenes seemed to have abhorred that bellowing liquid; it is, however, certain that they imported it from the east, as well as the other letters, and that they employed it in every other capacity, except in that of closing words. In the termination of flexions, they changed it into ν.

The Latins retained *m*, which had been imported to them as a terminating letter at an era before the Greek language had undergone its last refinement.—Hence the Latin accusative in *um*, instead of the Greek ον. The vocative case, we imagine, was in this declension originally like the nominative. The Latins have no dual number, because, in our opinion, the Æolian dialect, from which they copied, had none. It would be, we think, a violent stretch of etymological exertion, to derive either the Latin genitive plural of the second declension from the same case of the Greek, or that of the latter from the former; we therefore leave this anomaly, without pretending to account for its original formation. The third declensions in both languages are so exactly parallel, that it would be superfluous to compare them. The dative plural here is another anomaly, and we think a very disagreeable one, which we leave to the conjectures of more profound etymologists.

For the other peculiarities of Latin nouns, as they are nearly similar to those of the Greek, we must beg leave to remit our readers to that section for information. 183

The Latins have no articles, which is certainly a defect in their language. The Pelasgic, from which they copied, had not adopted that word in the demonstrative sense. Homer indeed seldom uses it; and the probability is, that the more early Greek used it less frequently, at least in the sense above mentioned. Thus in Latin, when I say, *video hominem*, it is impossible to find out by the bare words whether the word *hominem* intimates "a man," or "the man;" whereas in Greek it would be Βλεπω ανθρωπον, *I see a man*, Βλεπω τον ανθρωπον, *I see the man*. Hence the first expression is indefinite, and the second definite. Deficiency of articles.

The substantive verb *sum* in Latin seems to be partly formed from the Greek and partly not. Some of the persons of the present tense have a near resemblance to the Greek verb εω or ειμι, while others vary widely from that archetype. The imperfect præterite and præterperfect have nothing common with the Greek verb, and cannot, we think, be forced into an alliance with it. The future *ero*, was of old *eso*, and is indeed genuine Greek. Upon the whole, in our apprehension, the Latin substantive verb more nearly resembles the Persian verb *hesten* than that of any other language we are acquainted with. 184 Origin of the substantive verb.

From what exemplar the Latin verbs were derived, is not, we think, easily ascertained. We know that attempts have been made to deduce them all from the Æolic Greek, and that the Romans themselves were extremely fond of this chimera; but the almost numberless irregularities, both in the formation and conjugation of their verbs, induce us to believe that only a part of them were formed upon that model. We are apt to think that the terminations in *bam*, *bas*, *bat*, *bamus*, &c. are produced by their union with a fragment of some obsolete verb, which is now wholly lost. In the verb *amo*, e. g. we are sure that the radix *am* is the Hebrew word *mother*; but how *am-abam*, *am-abo*, *am-arem* were fabricated, and connected with the radical *am*, is not so easily determined. That Latin verbs are composed of an inflexible radix and another flexible verb, as well as the Greek, cannot be doubted; but what this flexible 185 and of other verbs.

(Y) *Græca et Latina lingua Hebraizantes*, Venice 1763. If these books are not at hand, Dr Littleton's Dictionary will, in a good measure, supply their place.

flexible auxiliary was, we think, cannot now be clearly ascertained. It is not altogether improbable that such parts of the verbs as deviate from the Greek archetype were supplied by fragments of the verb *ha*, which pervades all the branches of the Gothic language, and has, we think, produced the Latin verb *habeo*. When the Greeks began to etymologize, they seldom overpassed the verge of their own language: the Latins pursued nearly the same course. If their own language presented a plausible etymology, they embraced it; if not, they immediately had recourse to the Greek; and this was the *ne plus ultra* of their etymological researches. Cicero, Quintilian, Festus, &c. and even Varro, the most learned of all the Romans, stop here; all beyond is either doubt or impenetrable darkness. Their opinion above mentioned we offer only as a conjecture; the decision we leave to more able critics.

186 Deficiencies in Latin verbs.

The want of aorists or indefinite tenses seems to us a palpable defect in the Latin language. The use of these among the Greeks entitled the writer to express the specific variations of time with more accuracy and precision than the Latins, who never attempted to specify them by any other tenses but the imperfect and pluperfect. Indeed we should imagine, that both the Greeks and Latins were much inferior to the English in this respect. The Latin word *lego*, for example, may be translated into English three different ways: 1st, *I read;* 2d, *I do read;* 3d, *I am reading*.

187 Irregularities in the conjugations.

The Latins, in reducing verbs to their four conjugations, formed their inflexions in a very irregular manner. Many very of the first class inflect their præterite and supine like those of the second: thus *domo*, instead of giving *avi* and *atum*, has *ui* and *itum*, like *monui* and *monitum*. Again, not a few verbs of the third conjugation have *ivi* and *atum*, as if they belonged to the fourth; e. g. *peto*, *petivi*, *petitum*. Then, some verbs have *io* in the present, *ivi* in the præterite, and *itum* in the supine, while, contrary to the rules of analogy, they in reality belong to the third: such are *cupio*, *cupivi*, *cupitum*, *cupere*, &c. Some verbs of the second conjugation have their præterite and supine as if they belonged to the third; thus, *jubeo, jussi, jussum, jubere; augeo, auxi, auctum, augere*. Some verbs, which are actually of the fourth conjugation, have their præterite and supine as if they were of the third; thus *sentio, sensi, sensum, sentire; haurio, hausi, haustum, haurire*, &c. If these are not manifest irregularities, we cannot say what deserves the name. The fact seems to stand thus: The Romans were originally a banditti of robbers, bankrupts, runaway slaves, shepherds, husbandmen, and peasants of the most unpolished character. They were engaged in perpetual broils and quarrels at home, and seldom enjoyed repose abroad. Their profession was robbery and plunder. Like old Ishmael, their hands were against every man, and every man's hand against them. In such a state of society no time was left for cultivating the sciences. Accordingly the arts of war and government were their sole profession. This is so true, that their own poet characterizes them in the following manner:

Excudunt alii spirantia mollius æra, &c.

188 The Latin deficient in participles.

Another blemish in the Latin tongue is occasioned by its wanting a participle of the præterite sense in the active voice. This defect is perpetually felt, and is the cause of an awkward circumlocution wherever it happens to present itself. Thus, "The general having crossed the river drew up his army;" *Imperator, cum transiisset flumen, aciem instruxit.* Here *cum transiisset flumen* is a manifest circumlocution, which is at once avoided in the Greek ὁ ἡγεμων περασας τον ποταμον, &c. This must always prove an incumbrance in the case of active intransitive verbs. When active deponent verbs occur, it is easily avoided. Thus, "Cæsar having encouraged the soldiers, gave the signal for joining battle;" *Cæsar cohortatus milites, prœlii committendi signum dedit.*

Another palpable defect in this language arises from the want of a participle of the present passive. This again must produce an inconveniency upon many occasions, as will be obvious to every Latin student almost every moment.

189 Supines and gerunds.

The two supines are universally allowed to be substantive nouns of the fourth declension. How these assumed the nature of verbs it is not easy to determine. When they are placed after verbs or nouns, the matter is attended with no difficulty; but how they should acquire an active signification, and take the case of the verb with which they are connected, implies, we should think, a stretch of prerogative.

The Latin gerunds form another unnatural anomaly. Every Latin scholar knows that those words are nothing but the neuters of the participles of the future passive. The fabricators of the Latin tongue, however, elevated them from their primary condition, giving them upon many occasions an active signification. In this case we must have recourse to

———————— *Si volet usus,*
Quem penes arbitrium est et jus et norma loquendi.

Another inconveniency, perhaps more severely felt than any of the preceding, arises from the want of the use of the present participle of the verb *sum*. Every body knows what a conveniency is derived from the frequent use of the participle ὢν in Greek; and indeed it appears to us somewhat surprising that the Latins neglected to introduce the participle *ens* into their language. In this we believe they are singular. Here again a circumlocution becomes necessary in such a case as the following: "The senate being at Rome, passed a decree." Instead of saying *senatus ens Romæ, legem tulit*, we are obliged to say *cum senatus Romæ esset*, &c. If the words *ens* or *existens* had been adopted, as in the Greek, this odious circumlocution would have been avoided.

Many other defects of the like kind will occur to every person who shall choose to search for them, and those in the most approved classical authors. Perhaps our mentioning so many may be deemed invidious by the admirers of that language; but we write from conviction, and that must be our apology.

190 Different genius of the Latin and Greek languages.

If one take the trouble to compare the structure of the Greek and Latin languages, he will, we think, quickly be convinced that their characteristic features are extremely different. The genius of the former seems easy and natural; whereas that of the latter, notwithstanding the united efforts of poets, orators, and philosophers, still bears the marks of violence and restraint. Hence it appears that the Latin tongue was pressed into the service, and compelled almost against its will to bend to the laws of the Grecian model. Take a sentence of Hebrew,

Latin Language.

Hebrew, Chaldean, Arabian, &c. and try to translate it into Greek without regarding the arrangement of the words, and you will find it no difficult attempt; but make the same trial with respect to the Latin, and you will probably find the labour attended with considerable difficulty. To translate Greek into English is no laborious task; the texture of the two languages is so congenial, that the words and phrases, and even the idiomatic expressions, naturally slide into each other. With the Latin the case is quite otherwise; and before elegant English can be produced, one must deviate considerably from the original. Should we attempt to translate a piece of English into Greek, and at the same time into Latin, the translation of the former would be attended with much less difficulty than that of the latter, supposing the translator equally skilled in both languages.

191 Causes of this difference.

This incongruity seems to spring from the following cause. Before any man of considerable abilities, either in the capacity of a poet, grammarian, or rhetorician, appeared at Rome, the language had acquired a strong and inflexible tone, too stubborn to be exactly moulded according to the Grecian standard. After a language has continued several centuries without receiving a new polish, it becomes like a full grown tree, incapable of being bent to the purposes of the mechanic. For this reason, it is highly probable, that the tongue in question could not be forced into a complete assimilation with the Greek. Notwithstanding all these obstructions, in process of time it arrived at such an exalted pitch of perfection, as to rival, perhaps to excel, all the other European languages, the Greek only excepted. Had men of the taste, judgment, and industry of Ennius, Plautus, Terence, Cicero, and the worthies of the Augustan age, appeared in the early stages of the Roman commonwealth, we may believe that their language would have been thoroughly reduced to the Grecian archetype, and that the two dialects might have improved each other by a rivalship between the nations who employed them.

Without pretending to entertain our readers with a pompous and elaborate account of the beauties of that imperial language which have been detailed by writers almost without number, we shall endeavour to lay before them as briefly as possible its pristine character, the steps and stages by which it gradually rose to perfection, the period when it arrived at the summit of its excellence, and by what means it degenerated with a rapid career till it was lost among those very people to whom it owed its birth.

192 The Latin tongue composed chiefly of Pelasgic and Celtic words.

We have observed already, that the Latin tongue was a *colluvies* of all the languages spoken by the vagrant people who composed the first elements of that republic. The prevailing dialects were the Pelasgic or Hetruscan, which we think were the same; and the Celtic, which was the aboriginal tongue of Italy. Hence the primary dialect of the Romans was composed of discordant materials, which in our opinion never acquired a natural and congenial union. Be that as it may, this motley mixture was certainly the original dialect of the Romans. The Pelasgic or Hetruscan part of it retained a strong tincture of the oriental style. The Celtic part seems to have been prevalent, since we find that most of the names of places (z), especially in the middle and northern parts of Italy, are actually of Celtic original. It is therefore clear that the style of the first Romans was composed of the languages above mentioned. Who those first Romans were, we believe it is impossible to determine with any degree of certainty. The Roman historians afford us as little information upon that subject, as their etymologists do upon the origin of their language. Their most celebrated writers upon this point were Ælius Gallus, Quintus Cornificius, Nonius Marcellus, Festus, and some others of less note. At the head of these we ought to place Terentius Varro, whom Cicero styles the most learned of all the Romans. From these writers we are to expect no light. Their etymologies are generally childish and futile. Of the language of the most ancient Romans we can only reason by analogy; and by that rule we can discover nothing more than what we have advanced above.

In the first place we may rest assured that the dual number, the articles, the participle above mentioned, the aorists, and the whole middle voice, never appeared in the Latin tongue; and accordingly were not current in those languages from which it was copied, at least at the time when it was first fabricated.

Besides all this, many circumstances concur to make it highly probable that, in the earliest period of the language, very few inflexions were introduced. 1st, When the Pelasgi left Greece, the Greek language itself was not fully polished. 2d, The Arcadians were never thoroughly cultivated. They were a rustic pastoral people, and little minded the refinements of a civilized state; consequently the language they brought into Italy at that era must have been of a coarse and irregular contexture. 3d, When the Thessalian * Pelasgi arrived in Italy about the time of Deucalion, the Greek itself was rude and barbarous; and, which is still of more consequence, if we may credit Herodotus quoted in the former section, that people had never adopted the Hellenic tongue. Hence it appears, that the part of the Latin language derived from the Pelasgic or Hetruscan (for these we believe to have been the same) must have taken a deep tincture from the oriental tongue. (See preceding Section). If we may judge of the Celtic of that age by that of the present, the same character must likewise have distinguished its structure.

* *Dionys. Halicarn.* lib. i.

193 Hence little inflected in its original state.

From these circumstances, we think it appears that the earliest language of the Romans was very little diversified with inflections. It nearly resembled the oriental exemplar, and consequently differed widely from the modern Latin. The effect of this was, that the modern Romans could not understand the language of their early progenitors. Polybius †, speaking of the earliest treaty between the Romans and Carthaginians, makes the following observation: "Believe me (says he), the Roman language has undergone so many changes since that time

† Lib. 3. *sub initio.*

(z) For proof of this our readers may consult Abbé Pezron, Pelloutier, Bullet's *Mem.* Gebelin, *Pref. Dict. Lat.* and many others.

Latin Language.

time (A) to the present, that even those who are most deeply skilled in the science of antiquities cannot understand the words of that treaty but with the greatest difficulty."

From this source we make no doubt has flowed that vast number of oriental words with which the Latin language is impregnated. These were originally inflexible. like their brethren of the east. They were not disguised as they now are with prefixes, affixes, metatheses, syncopas, antitheses, &c. but plain and unadorned in their natural dress.

194 Bent afterwards into the Grecian model.

After the Romans became acquainted with the Æolian Greeks, who gradually seized upon both coasts of Italy towards the south, which they called *Magna Græcia*, they began to affect a Grecian air, and to torture their language into that foreign contexture. It appears, however, that at first the Grecian garb sat rather awkwardly, and several marks of violence were easily discerned. The most ancient specimen of this kind that we can recollect consists of the remains of the *twelve tables*. Here every thing is rude and of a clumsy cast; for though by this time considerable progress had been made in refinement, and the language of Rome had begun to appear in a Grecian uniform, still those changes were not altogether natural. Soon after appeared Marcus Fabius Pictor and Sisenna; historians often quoted by Livy, but whose works are long since irrecoverably lost. The Fasti Capitolini are often mentioned; but they too perished in the burning of the Capitol during the civil wars between Marius and Sylla. Had those monuments escaped the ravages of time, we should have been able to mark the progress of the Latin tongue from stage to stage, and to ascertain with the greatest accuracy its gradual configuration in the course of its progress towards the Grecian standard. We must therefore leave the Latin tongue during those periods rude and barbarous, and descend to others better known and more characteristically marked. Those commenced after that

Græcia capta ferum victorem cepit, et artes
Intulit agresti Latio.

195 The principal authors by whom it was gradually polished.

In this period we find Ennius, who wrote a Roman history in hexameter verse in 18 books, which he called *Annals;* most part of which is now lost. He likewise translated *Euhemerus de Origine Deorum;* a work often mentioned by the Christian fathers in their disputes with the Pagans. It is sometimes quoted by Cicero. Then followed Caius Lucilius the famous satirist, and a number of other writers, such as Accius, Valerius, Æedituus, Alpinus, &c. whose fragments were published by the Stephens, Paris, 1564. All these imitated the writers of Greece or translated from them. By their perseverance and active exertions, the spirit of these authors was transfused into the Latin tongue, and its structure accommodated to the Grecian plan.

Plautus and Terence, by translating the comedies of Menander and Diphilus into their own language, taught the Latin muses to speak Attic Greek. To speak that language was then the *ton* of the times, as it is now with us to chatter French. Greek tutors were retained in every reputable family; and many Romans of the first rank were equally qualified to speak or write both in Greek and Latin. The original jargon of Latium was now become obsolete and unintelligible; and Cato the Ancient condescended to learn the Greek language at 80.

196 The golden age of Rome.

To pretend to enumerate the various, and we may add inimitable, examples of the Augustan or golden age of the Roman tongue, would be an insult to the understanding of our readers: we shall only take the liberty to translate a few lines from a most excellent historian *, who, had his honesty been equal to his judgment, might have rivalled the most celebrated writers of his country. Having observed, that the Greek authors, who excelled in every province of literature, had all made their appearance nearly about the same space of time, confined within very narrow limits, he adds, "Nor was this circumstance more conspicuous among the Greeks than among the Romans; for unless we go back to the rough and unpolished times, which deserve commendation only on account of their invention, the Roman tragedy is confined to Accius and the period when he flourished. The charming wit of Latin elegance was brought to light by Cecilius, Terentius, and Afranius, nearly in the same age. As for our historians (to add Livy also to the age of the former), if we except Cato and some old obscure ones, they were all confined to a period of 80 years; so neither has our stock of poets extended to a space much backward or forward. But the energy of the bar, and the finished beauty of prose eloquence, setting aside the same Cato (by leave of P. Crassus, Scipio, Lælius, the Gracchi, Fannius, and Ser. Galba, be it spoken), broke out all at once under Tully the prince of his profession; so that one can be delighted with none before him, and admire none except such as have either seen or were seen by that orator."

* *Velleius Paterculus,* lib. i. cap. *ult.*

From this quotation it plainly appears, that the Romans themselves were convinced of the short duration of the golden age of their language. According to the most judicious critics, it commenced with the era of Cicero's oratorical productions, and terminated with the reign of Tiberius, or perhaps it did not reach beyond the middle of that prince's reign. It is generally believed that eloquence, and with it every thing liberal, elevated, and manly, was banished Rome by the despotism of the Cæsars. We imagine that the transition was too instantaneous to have been entirely produced by that unhappy cause. Despotism was firmly established among the Romans about the middle of the reign of Augustus; and yet that period produced such a group of learned men as never adorned any other nation in so short a space of time. Despotism, we acknowledge, might have affected the eloquence of the bar; the noble and important objects which had animated the republican orators being now no more: but this circumstance could not affect poetry, history, philosophy, &c. The style employed upon these subjects did not feel the fetters of despotism. The age of Louis XIV. was the golden period

197 Causes of the degeneracy of the Latin tongue.

(A) This treaty, according to the same historian, was concluded in the consulship of Lucius Junius Brutus and Marcus Valerius, 28 years before Xerxes made his descent upon Greece.

riod of the French tongue; and we think that age produced a race of learned men, in every department superior in number and equal in genius to the literati who flourished under the noble and envied constitution of Britain during the same age, though the latter is universally allowed to have been the golden period of this country. The British isles, we hope, enjoy still as much liberty as ever; yet we believe few people will aver, that the writers of the present age are equal either in style or in genius to that noble group who flourished from the middle of the reign of Charles I. to the middle of the reign of George II.; and here despotism is quite unconcerned.

In the east the same observation is confirmed. The Persians have long groaned under the Mohammedan yoke; and yet every oriental scholar will allow, that in that country, and under the most galling tyranny, the most amazing productions of taste, genius, and industry, that ever dignified human nature, have been exhibited. Under the Arabian caliphs, the successors of Mohammed, appeared writers of a most sublime genius, though never was despotism more cruelly exercised than under those fanatics. The revival of letters at the era of the Reformation was chiefly promoted and cherished by petty despotical princes.

We cannot therefore be persuaded, that the despotism of the Cæsars banished eloquence and learning from Rome. Longinus indeed has attributed this misfortune to that cause, and tells us, θρεψαι τε γαρ ἱκανη τα φρονηματα των μεγαλοφρονων ἡ ΕΛΕΥΘΕΡΙΑ, &c. "It is liberty that is formed to nurse the sentiments of great geniuses, to push forward the propensity of contest, to inspire them with hopes, and the generous ambition of being the first in rank." When Longinus wrote this, he did not reflect that he himself was a striking instance of the unsoundness of his observation.

198 The writers of the silver age greater masters of science than their predecessors.

As to science, the fact is undoubtedly on the other side. That Seneca was superior to Cicero in philosophy, cannot be reasonably contradicted. The latter had read, and actually abridged, the whole extent of Grecian philosophy: this displayed his reading rather than his learning. The former had addicted himself to the stoic sect; and though he does not write with the same flow of eloquence as Tully, he thinks more deeply and reasons more closely. Pliny's Natural History is a wonderful collection, and contains more useful knowledge than all the writings of the Augustan age condensed into one mass. We think the historical annals of Tacitus, if inferior to Livy in style and majesty of diction, much superior in arrangement and vigour of composition. In short, we discover in these productions a deep insight into human nature, an extensive knowledge of the science of government, a penetration which no dissimulation could escape, together with a sincere attachment to truth both with respect to events and characters; nor is he inferior in the majesty, energy, and propriety of his harangues, wherever an equal opportunity presents itself. Quintilian, Pliny the younger, Suetonius, Petronius Arbiter, and Juvenal, deserve high esteem; nor are they inferior to their immediate predecessors. We think there is good reason to conclude, that the loss of liberty among the Romans did not produce the extinction of eloquence, science, elevation of sentiment, or refinement of taste. There were, we believe, other circumstances which chiefly contributed to produce that revolution.

The same Velleius Paterculus whom we have quoted assigns some plausible and very judicious reasons for this catastrophe. "Emulation (says he) is the nurse of genius; and one while envy, and another admiration, fires imitation. According to the laws of nature, that which is pursued with the greatest ardour mounts to the top: but to be stationary in perfection is a difficult matter; and by the same analogy, that which cannot go forward goes backward. As at the outset we are animated to overtake those whom we deem before us, so when we despair of being able to overtake or to pass by them, our ardour languishes together with our hope, and what it cannot overtake it ceases to pursue; and leaving the subject as already engrossed by another, it looks out for a new one upon which to exert itself. That by which we find we are not able to acquire eminence we relinquish, and try to find out some object *elsewhere* upon which to employ our intellectual powers. The consequence is, that frequent and variable transitions from subject to subject proves a very great obstacle to perfection in any profession."

This perhaps was the case with the Romans. The heroes of the Augustan age had borne away the prize of eloquence, of history, of poetry, &c. Their successors despaired of being able to equal, much less to surpass them, in any of these walks. They were therefore laid under the necessity of striking out a new path by which they might arrive at eminence. Consequently Seneca introduced the *stile coupé*, as the French call it; that is, a short, sparkling, figurative diction, abounding with antitheses, quaintnesses, witticisms, embellished with flowers and meretricious ornaments; whereas the style of the Augustan age was natural, simple, solid, unaffected, and properly adapted to the nature of the subject and the sentiments of the author.

The historian Sallust laid the foundation of the unnatural style above mentioned. Notwithstanding all the excellencies of that celebrated author, he everywhere exhibits an affectation of antiquity, an antithetical cast, an air of austerity, an accuracy, exactness, and regularity, contrary to that *air degagé* which nature displays in her most elaborate efforts. His words, his clauses, seem to be adjusted exactly according to number, weight, and measure, without excess or defect. Velleius Paterculus imitated this writer; and, as is generally the case with imitators, succeeded best in those points where his archetype had failed most egregiously. Tacitus, however excellent in other respects, deviated from the Augustan exemplars, and is thought to have imitated Sallust; but affecting brevity to excess, he often falls into obscurity. The other contemporary writers employ a cognate style; and because they have deviated from the Augustan standard, their works are held in less estimation, and are thought to bear about them marks of degeneracy.

That degeneracy, however, did not spring from the despotic government under which these authors lived, but from that affectation of singularity into which they were led by an eager but fruitless desire of signalizing themselves in their mode, as their predecessors had done in theirs. But the mischiefs of this rage for innovation did not reach their sentiments, as it had done their

Latin Language.

style; for in that point we think they were so far from falling below the measure of the writers of the former age, that in many instances they seem to have surpassed them.

With respect to sentiment and mental exertions, the authors in question preserved their vigour, till luxury and effeminacy, in consequence of power and opulence, enervated both the bodies and minds of the Romans. The contagion soon became universal; and a listlessness, or intellectual torpor, the usual concomitant of luxury, spread indolence over the mental faculties, which rendered them not only averse to, but even incapable of, industry and perseverance. This lethargic disposition of mind seems to have commenced towards the conclusion of the silver age; that is, about the end of the reign of Adrian. It was then that the Roman eagle began to stoop, and the genius of Rome, as well in arts as in arms, began to decline. Once more, the declension of the intellectual powers of the writers of that nation did not arise from the form of the government, but from the causes above specified.

As the Roman genius, about that period, began to decline, so the style of the silver age was gradually vitiated with barbarisms and exotic forms of speech. The multitudes of barbarians who flocked to Rome from all parts of the empire; the ambassadors of foreign princes, and often the princes themselves, with their attendants; the prodigious numbers of slaves who were entertained in all the considerable families of the capital, and over all Italy; the frequent commerce which the Roman armies upon the frontiers carried on with the barbarians; all concurred to vitiate the Latin tongue, and to interlard it with foreign words and idioms. In such circumstances, it was impossible for that or any other language to have continued pure and untainted.

This vitiated character both of style and sentiment became more and more prevalent, in proportion as it descended from the reign of Adrian towards the era of the removal of the imperial seat from Rome to Constantinople. Then succeeded the iron age, when the Roman language became absolutely rude and barbarous.

199 Writers of great talents during the silver and brazen ages.

Towards the close of the silver, and during the whole course of the brazen age, there appeared, however, many writers of no contemptible talents. The most remarkable was Seneca the stoic, the master of Nero, whose character both as a man and a writer is discussed with great accuracy by the noble author of the *Characteristics*, to whom we refer our readers.

About the same time lived Persius the satirist, the friend and disciple of the stoic Cornutus; to whose precepts he did honour by his virtuous life; and by his works, though small, he showed an early proficiency in the science of morals.

Under the mild government of Adrian and the Antonines lived Aulus Gellius, or (as some call him) Agellius; an entertaining writer in the miscellaneous way, well skilled in criticism and antiquity. His works contain several valuable fragments of philosophy, which are indeed the most curious part of them.

With Aulus Gellius we may rank Macrobius; not because he was a contemporary (for he is supposed to have lived under Honorius and Theodosius), but from his near resemblance in the character of a writer. His works, like those of the other, are miscellaneous; filled with mythology and ancient literature, with some philosophy intermixed.

In the same age with Aulus Gellius flourished Apuleius of Madaura in Africa; a Platonic writer, whose matter in general far exceeds his perplexed and affected style, too conformable to the false rhetoric of the age in which he lived.

Boethius was descended from one of the noblest of the Roman families, and was consul in the beginning of the sixth century. He wrote many philosophical works; but his ethic piece on the Consolation of Philosophy deserves great encomiums, both for the matter and the style; in which latter he approaches the purity of a far better age than his own. By command of Theodoric king of the Goths this great and good man suffered death; and with him the Latin tongue, and the last remains of Roman dignity, may be said to have sunk in the western world.

There were besides a goodly number both of poets and historians who flourished during this period; such as Silius Italicus, Claudian, Ausonius, &c. poets and historians to a very great number, for whom our readers may consult *Joh. Alberti Fabricii Bibl. Lat.*

200 Elegant ecclesiastical writers in Latin.

There flourished, too, a number of ecclesiastical writers, some of whom deserve great commendation. The chief of these is Lactantius, who has been deservedly dignified with the title of the *Christian Cicero.*

The Roman authors amount to a very small number in comparison of the Greek. At the same time, when we consider the extent and duration of the Roman empire, we are justly surprised to find so few writers of character and reputation in so vast a field. We think we have good reason to agree with the prince of Roman poets in the sentiment already quoted.

201 Excellency and usefulness of the Latin tongue.

Upon the whole, the Latin tongue deserves our attention beyond any other ancient one now extant. The grandeur of the people by whom it was spoken; the lustre of its writers; the empire which it still maintains among ourselves; the necessity we are under of learning it in order to obtain access to almost all the sciences, nay even to the knowledge of our own laws, of our judicial proceedings, of our charters; all those circumstances, and many others too numerous to be detailed, render the acquisition of that imperial language in a peculiar manner at once improving and highly interesting. Spoken by the conquerors of the ancient nations, it partakes of all their revolutions, and bears continually their impression. Strong and nervous while they were employed in nothing but battles and carnage, it thundered in the camps, and made the proudest people to tremble, and the most despotic monarchs to bend their stubborn necks to the yoke. Copious and majestic, when, weary of battles, the Romans inclined to vie with the Greeks in science and the graces, it became the learned language of Europe, and by its lustre made the jargon of savages disappear who disputed with it the possession of that quarter of the globe. After having controuled by its eloquence, and humanized by its laws, all those people, it became the language of religion. In short, the Latin language will be studied and esteemed as long as good sense and fine taste remain in the world.

Celtic Language.

SECT. IX. *Celtic, Gothic, and Sclavonian Languages.*

§ 1. *Of the Celtic Language.*

IN treating of the origin of the Latin tongue (see Sect. VIII.), we observed that a great part of it is derived from the Celtic. We shall now endeavour to give some account of the origin and extent of that ancient language; still leaving the minutiæ to grammars and dictionaries, as we have done with respect to the other dialects which have fallen under our consideration. Our candid readers, it is hoped, will remember, that we are acting in the character of philologers, not in that of grammarians and lexicographers.

202 Origin of the Celts, The descendants of Japhet having peopled the western parts of Asia, at length entered Europe. Some broke into that quarter of the globe by the north, others found means to cross the Danube near its mouth. Their posterity gradually ascended towards the source of that river; afterwards they advanced to the banks of the Rhine, which they passed, and thence spread themselves as far as the Alps and the Pyrenees.

These people, in all probability, were composed of different families; all, however, spoke the same language; their manners and customs bore a near resemblance; there was no variety among them but that difference which climate always introduces. Accordingly they were all known, in the more early times, by the general name of *Celto-scythæ*. In process of time, becoming exceedingly numerous, they were divided into several nations, which were distinguished by different names and territorial appellations. Those who inhabited that large country bounded by the ocean, the Mediterranean, the Rhine, the Alps, and the Pyrenees, were denominated *Gauls* or *Celts*. These people multiplied so prodigiously in the space of a few centuries, that the fertile regions which they then occupied could not afford them the means of subsistence. Some of them now passed over into Britain; others crossed the Pyrenees, and formed settlements in the northern parts of Spain. Even the formidable barriers of the Alps could not impede the progress of the Gauls: they made their way into Italy, and colonized those parts which lie at the foot of the mountains, whence they extended themselves towards the centre of that rich country.

203 part of whom were denominated Gauls.

By this time the Greeks had landed on the eastern coast of Italy, and founded numerous colonies in those parts. The two nations vying as it were with each other in populousness, and always planting colonies in the course of their progress, at length rencountered about the middle of the country. This central region was at that time called *Latium*. Here the two nations formed one society, which was called *the Latin people*. The languages of the two nations were blended together; and hence, according to some, the Latin is a mixture of Greek and Gaelic.

As the Gauls were a brave and numerous people, they certainly maintained themselves in their pristine possessions, uninvaded, unconquered, till their civil animosities and domestic quarrels exposed them as a prey to those very Romans whom they had so often defeated, and sometimes driven to the brink of destruction. They were not a people addicted to commerce; and upon the whole, considering their situation both in their primary seats and afterwards in Italy, they had little temptation or opportunity to mingle with foreigners. Their language, therefore, must have remained unmixed with foreign idioms. Such as it was when they settled in Gaul, such it must have continued till the Roman conquests. If therefore there is one primitive language now existing, it must be found in the remains of the Gaelic or Celtic. It is not, then, surprising, that some very learned men, upon discovering the coincidence of very great numbers of words in some of the Greek dialects with other words in the Celtic, have been inclined to establish a strict affinity between those languages. The ancient Pelasgic and the Celtic at least must have nearly resembled each other, admitting a dialectical difference only, and that discrimination which climate and a long period of time must always produce. 204 Resemblance between their language and that of the Pelasgi.

Some have thought that the Gauls lost the use of their native language soon after their country was conquered by the Romans; but *Monsieur Bullet*, in his *Memoires de la Langue Celtique*, has proved almost to a demonstration, that the vulgar among those people continued to speak it several centuries after that period. When a great and populous nation has for many ages employed a vernacular tongue, nothing can ever make them entirely relinquish the use of it, and adopt unmixed that of their conquerors.

Many learned men, among whom is the lexicographer above mentioned, have shown that all the local names in the north of Italy are actually of Celtic extraction. These names generally point out or describe some circumstances relating to the nature of their situation: such as exposure, eminence, lowness, moistness, dryness, coldness, heat, &c. This is a very characteristic feature of an original language; and in the Celtic it is so prominent, that the Erse names of places all over Scotland, are, even to this day, peculiarly distinguished by this quality. We have heard a gentleman, who was well skilled in the dialect of the Celtic still spoken in the Highlands of Scotland, propose to lay a bet at very great odds, that if one should pronounce the name of any village, mountain, river, gentleman's seat, &c. in the old Scottish dialect, he should be able, by its very name, to give a pretty exact description of its local situation.

To discover the sources from which the Celtic tongue is derived, we must have recourse to the following expedients.

1. We must consult the Greek and Latin authors, who have preserved some Gaelic or Celtic terms in their writings.

2. We must have recourse to the Welsh and *Basse Bretagne* dialects; in which, indeed there are many new words, but these are easily distinguished from the primitive stock.

3. If one would trace another source of the Celtic, he must converse with the country people and peasants, who live at a distance from cities, in those countries where it was once the vernacular tongue. We have been credibly informed, that a Highland gentleman crossing the Alps for Italy, accidentally fell in with an old woman, a native of those parts, who spoke a language so near akin to his native Erse, that he could understand her with little difficulty; and that she on the other hand, understood most of his words. That an event of this nature should actually take place is by no means

Celtic Language.

means surprising, when we consider that the Erse spoken in the Highlands of Scotland is perhaps the most genuine remnant of the Celtic now existing, and at the same time reflect that there may be some remote cantons among those wild and inaccessible mountains, the Alps, where some remains of that tongue may still be preserved.

205
The most genuine remains of the Celtic in the Highlands of Scotland.

4. We have said that the most genuine remains of the Gaelic tongue are to be found in the Highlands of Scotland; and the reason is obvious. The Scottish Highlanders are the unmixed unconquered posterity of the ancient Britons, into whose barren domains the Romans never penetrated; not, we imagine, because they were not able, since they subdued both North and South Wales, equally inaccessible, but because they found no scenes there either to fire their ambition or allure their avarice. Amidst all the revolutions that from time to time shook and convulsed Albion, those mountainous regions were left to their primitive lords, who, like their southern progenitors, hospitable in the extreme, did not, however, suffer strangers to reside long among them. Their language, accordingly, remained unmixed, and continues so even unto this day, especially in the most remote parts and unfrequented islands.

The Norwegians subdued the western islands of Scotland, at a time when the Scottish monarchy was still in its minority. They erected a kind of principality over them, of which the isle of Man was the capital. Though they maintained the sovereignty of those islands for some centuries, built many forts, and strengthened them with garrisons, and in fine were the lawgivers and administrators of justice among the natives; yet we have been informed by the most respectable authority, that there is not at this day a single vocable of the Norse or Danish tongue to be found among these islanders. This fact affords a demonstration of that superstitious attachment with which they were devoted to their vernacular dialects.

206
The Welsh dialect not pure, nor the Irish.

The Welsh dialect cannot, we think, be pure and unsophisticated. The Silures were conquered by the Romans, to whom they were actually subject for the space of three centuries. During this period a multitude of Italian exotics must have been transplanted into their language; and indeed many of them are discernible at this day. Their long commerce with their English neighbours and conquerors hath adulterated their language, so that a great part of it is now of an English complexion. The Irish is now spoken by a race of people whose morality and ingenuity is nearly upon a level. Their latest historians have brought them from the confines of Asia, through a variety of adventures, to people an island *extra anni solisque vias*. However this genealogical tale may please the people for whom it was fabricated, we may still suspect that the Irish are of Celtic extraction, and that their forefathers emigrated from the western coast of Britain at a period prior to all historical or even traditional annals. Ireland was once the *native land of saints*. The chief actors on this sacred stage were Romanists, and deeply tinctured with the superstition of the times. They pretended to improve the language of the natives; and whatever their success was, they improved it in such a manner as to make it deviate very considerably from the original Celtic; so that it is not in Ireland that we are to look for the genuine characters of the dialect under consideration.

Though the Hibernian tongue, in our opinion, differs considerably from the original Celtic, some very ingenious essays have been lately published by the learned and laborious members of the *Antiquarian Society of Dublin*; in which the coincidence of that tongue with some of the oriental dialects, has been supported by very plausible arguments. In a dissertation published in the year 1772, they have exhibited a collection of *Punico-Maltese* words compared with words of the same import in Irish, where it must be allowed the resemblance is palpable. In the same dissertation they have compared the celebrated *Punic* scene in Plautus with its translation into the Irish; in which the words in the two languages are surprisingly similar. If those criticisms are well founded, they will prove that the Celtic is coeval and congenial with the most ancient languages of the east; which we think highly probable. Be that as it may, the Danes and Norwegians formed settlements in Ireland; and the English have long been sovereigns of that island. These circumstances must have affected the vernacular idiom of the natives; not to mention the necessity of adopting the language of the conquerors in law, in sciences, in the offices of religion.

207
Coincidence between the Celtic and Phœnician.

The inhabitants of the highlands and islands of Scotland are the descendants of those Britons who fled from the power of the Romans, and sheltered themselves among the fens, rocks, and fastnesses of those rugged mountains and sequestered glens. They preferred those wastes and wilds, with liberty and independence, to the pleasant and fertile valleys of the south, with plenty embittered by slavery. They no doubt carried their language along with them; that language was a branch of the Celtic. With them, no doubt, fled a number of the druidical priests, who unquestionably knew their native dialect in all its beauties and varieties. These fugitives in process of time formed a regular government, elected a king, and became a considerable state. They were sequestered by their situation from the rest of the world. Without commerce, without agriculture, without the mechanical arts, and without objects of ambition or emulation, they addicted themselves wholly to the pastoral life as their business, and to hunting and fishing as their diversion. Those people were not distinguished by an innovating genius; and consequently their language must have remained in the same state in which they received it from their ancestors. They received it genuine *Celtic*, and such they preserved it.

When the Scots became masters of the low country, and their kings and a great part of the nobility embraced the Saxon manners, and adopted the Saxon language, the genuine Caledonians tenaciously retained their native tongue, dress, manners, clanships, and feudal customs, and could never cordially assimilate with their southern neighbours. Their language, therefore, could not be polluted with words or idioms borrowed from a people whom they hated and despised. Indeed it is plain from the whole tenor of the Scottish history, that neither Caledonian chieftains, nor their vassals, were ever steadily attached to the royal family after they fixed their residence in the low country, and became *Saxons*, as the Highlanders called them by way of reproach. Indeed the commerce between them and those of the south, till about a century and a half ago, was only transient and

Celtic Language.

and accidental; nor was their native dialect in the least affected by it.

208 Causes of the purity of the Scotch dialect of this ancient language.

Their language, however, did not degenerate, because there existed among them a description of men whose profession obliged them to guard against that misfortune. Every chieftain retained in his family a bard or poet laureat, whose province it was to compose poems in honour of his lord, to commemorate the glorious exploits of his ancestors, to record the genealogy and connections of the family; in a word, to amuse and entertain the chief and his guests at all public entertainments and upon all solemn occasions. Those professors of the Parnassian art used to vie with each other; and the chiefs of families often assembled their respective bards, and encouraged them by considerable premiums to exert their poetic talents. The victor was rewarded and honoured; and the chieftain deemed it an honour to himself to entertain a bard who excelled his peers. The ancient Gauls, as we learn from Diodorus Siculus, Strabo, Tacitus, Lucan, &c. entertained persons of that profession; and certainly the ancient Britons did the same. Those bards were highly revered; their persons were deemed sacred; and they were always rewarded with salaries in lands or cattle (see Section *Greek*). Those poetic geniuses must have watched over their vernacular dialect with the greatest care and anxiety; because in their compositions no word was to be lost, but as many gained as possible.

The use of letters was not known among the ancient *Celtæ;* their druidical clergy forbade the use of them. All their religious rites, their philosophical dogmas, their moral precepts, and their political maxims, were composed in verses which their pupils were obliged to commit to memory. Accordingly letters were unknown to the Caledonian Scots, till they learned them either from their southern neighbours or from the Romans. The Irish, indeed, pretend to have letters of a very ancient date; the Highlanders of the country in question make no claim to the use of that invention. Their bards, therefore, committed every thing to memory; and of course the words of their language must have been faithfully preserved. We find that the celebrated poems of Ossian, and others of an inferior character, or at least fragments of such poems (see OSSIAN), have thus been preserved from father to son for more than 1000 years. The beauty, significancy, harmony, variety, and energy of these verses, strike us even in a prose translation: how infinitely more charming must they appear in their native form and poetical attire!

In order to exhibit the genius of the Celtic in as striking a light as the nature of our present design will permit, we shall lay before our readers a very contracted sketch of the Gaelic or Caledonian dialect as it now stands; which we hope will go a great way to convince them that this is the genuine offspring of the other. In doing this we shall borrow many hints from a gentleman * whose learning seems to equal his zeal for his native language; which, in compliance with the modern practice, we shall for the future distinguish by the name of *Gaelic*.

* Essays, &c. by James Grant, Esq. advocate.

The Gaelic is not derived from any other language as far as we know, being obviously reducible to its own roots. Its combinations are formed of simple words of a known signification; and those words are resolvable into the simplest combinations of vowels and consonants, and even into simple sounds. In such a language we may expect that some traces will be found of the ideas and notions of mankind living in a state of primeval simplicity; and if so, a monument is still preserved of the primitive manners of the Celtic race while as yet under the guidance of simple nature, without any artificial restraint or controul.

The sudden sensations of heat and cold, and bodily pain, are expressed by articulate sounds, which, however, are not used in this language to denote heat, cold, or bodily pain. A sudden sensation of heat is denoted by an articulate exclamation *hait;* of cold, by *id;* of bodily pain, by *oich*. All these sounds may be called *interjections*, being parts of speech which discover the mind to be seized with some passion. Few of the improved languages of Europe present so great a variety of sounds which instantaneously convey notice of a particular passion, bodily or mental feeling.

The pronouns *he* and *she* are expressed by the simple sounds *e* and *i*, and these are the marks of the masculine and feminine genders; for a neuter gender is unknown in the *Gaelic*. The compositions of rude and barbarous ages are universally found to approach to the style and numbers of poetry; and this too is a distinguishing character of the *Gaelic*. Bodily subsistence will always be the principal concern of an uncultivated people. Hence *ed* or *eid* is used upon discovery of any animal of prey or game: it is meant to give notice to the hunting companion to be in readiness to seize the animal: and hence we believe *edo* "to eat" in Latin, and *ed* in Irish, signifies "cattle;" likewise in Scotch *edal* "cattle," literally signifies "the offspring or generation of cattle." *Cord* or *cued*, "share or portion of any subject of property," literally "common food." *Faoed* "hunting," literally "gathering of food." *Edra* "the time of the morning when cattle are brought home from pasture to give milk," literally "meal-time." These are words importing the simplicity of a primitive state, and are common in the Gaelic idiom.

Traces of imitative language remain in all countries. The word used for *cow* in the Gaelic language is *bo*, plainly in imitation of the lowing of that animal.

209 Excellency of Gaelic compounds.

In joining together original roots in the progress of improving language and rendering it more copious, its combinations discover an admirable justness and precision of thought, which one would scarce expect to find in an uncultivated dialect. It will, however, be found, upon examination, that the Gaelic language, in its combination of words, specifies with accuracy the known qualities, and expresses with precision the nature and properties which were attributed to the object denominated.

An appears to have been a word of frequent use in this language, and seems to have been originally a name applied indefinitely to any object. According to Bullet, it was used to signify "a planet;" hence the *sun* had the name of *grian*, which is a compound of *gri* "hot," and *an* "a planet." *Re* signifies originally and radically "division." The changes of the moon and the variety of her phases were early employed to point out the divisions of time. The present name for the *moon* is *gealach:* a word derived from her whiteness of colour. To these we might add a vast number more whose signification precisely indicates their shape, colour, effects, &c. Many of these would be found exactly similar to Greek

Greek and Latin words of the same sound and signification. In order to satisfy our curious readers, we shall annex a few, though some of them may perhaps be questionable.

The *Venus* of the Latins is said to be a compound of *ben* and *jus*, which literally signify the "first woman," the letter *b* in Gaelic being softened into *v*. Εδας and ειδας signify "food." These words are compounded of the Gaelic words *ed* or *eid* and *ar*; the former denotes *food* simply, and the latter *ploughed land*. These are the roots of the Greek and Latin words εδω, *edo*; αρω, *aro*. Εδρα, which signifies "a seat," has an evident reference to food. It is compounded of two Gaelic words *ed* and *ira*, which literally signifies "meal-time." Εδνα, which signifies "the presents which a bridegroom made to his bride," is a compound of two Gaelic words *ed* and *na* or *nuah*, literally signifying "raw food." From *ar* there are many Greek derivatives. Αρουρα signifies "ploughed land," also "crop of corn;" Αρτος, "bread." In Gaelic *a crop of corn* and *bread* are expressed by *arbhar*, commonly pronounced *arar* and *aran*; all being equally derivatives of the root *ar*. So the Greek and Latin words αροτος, *arabilis*, "arable;" αροτρον, *aratrum*, "a plough;" αροτης, *arator*, "a ploughman;" and many others, are evidently derived from the same source. We would not, however, suggest, in consequence of this coincidence, that either the Greek or Latin languages was derived from the Gaelic; we rather believe that these are remains of a primeval tongue, which are still retained in all the three; and we produce them upon the present occasion as presumptions that the Gaelic is an original, underived language, and of course the most pure and unadulterated relick of the Celtic now existing. If our readers should incline to know more of this subject, they may consult Pezron's *Origin of Ancient Nations*, Bullet's *Mem. de la Langue Celtique*, Parson's *Rem. of Japhet*, Gebelin's *Monde prim.* &c.

210 Copiousness and antiquity of the Celtic.

When the Celtic language was generally spoken over Europe, it seems to have been amazingly copious. By consulting Bullet's *Memoires*, it appears that its names for the common and various objects of nature were very numerous. The words denoting water, river, wood, forest, mountain, lake, &c. were most precisely accommodated to specify each modification and variety, with such peculiar exactness as even the Greek, with all its boasted idiomatical precision and copiousness, has not been able to equal. The appearances which diversify the visible face of animated nature, arrest the attention of men in an uncultivated state. Unaccustomed to thought and abstract reasoning, their minds expand and exercise their powers upon sensible objects, and of course mark every *minutia* and almost imperceptible distinction with an accuracy to us seemingly impossible.

We hope it now appears to every reader, that the Celtic was one of the dialects of the primitive language; that it once overspread by far the greatest part of Europe; that the Gaelic now spoken in the northern parts of Scotland and the adjacent islands is the most pure and unmixed relick of that tongue now anywhere existing. We would willingly refer our readers to some well composed grammar of that language; but indeed we know of none that deserves our recommendation. Some years ago we were flattered with the prospect of seeing one published by a gentleman whose deep skill in that language is universally acknowledged. We have likewise heard of an intended dictionary of the same tongue; but hitherto our hopes have been disappointed.

We are, however, happy to find that there is now publishing an excellent translation of both the Old and New Testaments into Gaelic, which has hitherto been a desideratum among those who speak this language. Such a translation will at once contribute to preserve that ancient tongue, and disseminate the knowledge of the truth among the natives of that country.

Every assistance towards acquiring the knowledge of a tongue which was once universal over a great part of Europe, will certainly be an acceptable present to the public. The antiquary, who is desirous of tracing the affinity of languages, and wishes to mark the migrations of people, ought certainly to apply himself to the study of its remaining branches; and, if we mistake not, he will soon be convinced, that they all breathe a spirit congenial to the manners and sentiments of a people who are just entering upon the first stage of improvement and civilization.

211 Origin of the words Gaul and Gal.

Perhaps it may be expected, that, before we conclude this short sketch of the Celtic tongue, we should give some account of the origin of the words *Gaul* and *Gal*, the two names by which this people was distinguished by the Greeks and Romans. Mr M'Pherson imagines, that the appellation of *Celt* is an adjective derived from *Gael*, the aboriginal name of the inhabitants of ancient Gaul. For our part, we can see no connection between *Gael* and *Kelt*, nor do we think that the latter is an adjective. We believe that those people called themselves *Cael* and not *Gael*. We are sure that *Caledonia*, or *Cal-don* or *dun*, was an ancient name of the mountainous parts of Scotland.

Though many different opinions have been advanced with relation to the etymology of this word, we imagine that none is so probable as that which supposes that it is compounded of the two Celtic words *Cal* or *Kal*, that is, "Gal or Gaul," and *dun*, which signifies "a hill or mountain." Upon this ground, the Caledonii will import the Gauls of the mountains, or which is the same, the Highland Gauls. The Irish and Highlanders reciprocally denominate themselves by the general title of *Cael*, *Gael*, or *Gauls*. They also distinguish themselves, as the Welsh originally did, and as the Welsh distinguish them both at present, by the appellation of *Guidhill*, *Guethel*, and *Gathel*. The intermediate *th*, they say, is left quiescent in the pronunciation, as it is in many words of the British language; in which case *Gathel* would immediately be formed into *Gael*; and Gathel is actually sounded like *Gael* by both the Irish and Highlanders at present. The appellation of *Gathel*, therefore, say they, was originally the same with *Gael*, and the parent of it. The quiescent letters in British are frequently transferred from the middle to the conclusion of the word; by which manœuvre, *Gathel* is changed into *Galath*, *Galat*, *Galt*, and *Celt*. It is true, that *Gael* of the continent is universally denominated *Galatæ* and *Celtæ* by the Grecians, and *Gallt* and *Gallta* by the Irish. The appellations, therefore, of *Gathel-i*, *Gall-i*, *Gallat-æ*, *Calet-es*, *An-calit-es*, and *Celt-æ*, are all one and the same denomination, only varied by the astonishing ductility of the *Celtic*, and disguised by the alterations ever incident to a language that has been merely oral for ages.

It may perhaps appear presumptuous in us to differ

fer from two such respectable authorities as M'Pherson and Whitaker: we must, however, acknowledge, that neither the one nor the other appears to us well founded. Besides, they convey no idea of the signification of the words, though in the Celtic language they must have been significant. The name *Cael*, the same with *Gal*, was probably giving them in the East from the Greek καλ, which in many oriental languages denotes *fair*; and γαλατια may be easily derived from γαλ or γαλαθ, *Gal* or *Galuth*.—This denomination might be given them by their neighbours, in allusion to their fair complexion.

§ 2. *Of the Gothic Language.*

THE Celtic and Gothic tongues at one time divided Europe between them. Both were of equal antiquity, both originated in Asia, both were dialects of the original language of mankind. The Celtic, however,

212 Ancient Gothic.

was first imported into Europe. The Gauls or Celts had penetrated farthest towards the west; a circumstance which plainly intimates the priority of their arrival. In the population of countries, we believe it may be held as a maxim, that the colonies who emigrated first were generally impelled by succeeding emigrants; and that of consequence the most early were pushed forward to the parts most distant. The Celts, then, having overspread the most western parts of Europe, must have arrived more early in those regions.

The Goths and Getæ were the same race of people, according to Procopius *, *de bello Goth.*; and Strabo † (B) informs us, that they spoke the same language with the Thracians, from whose confines they had spread themselves northward as far as the western banks of the Danube. Vopiscus, in the History of Probus tells us, that this emperor ‡ obliged "the Thracians, and all the Getic tribes, either to surrender or accept of his friendship." This expression indicates, that the Thracians and the Getic tribes were deemed the same race of people. From this deduction it is clear, that the Getæ and Thracians were brethren; that they spoke the same language: and that their laws, manners, customs, and religious tenets, were the same, might easily be shown, were this a proper place for an inquiry of that nature.

* Lib. i. cap. 2.
† Lib. ii. cap. 23.
‡ Lib. 7.

213 The same with the language of the Thracians.

The Thracian language, as might be demonstrated from names of persons, offices, places, and customs, among that people, was nearly related to the Chaldean and other oriental languages.

214 Origin of the Goths.

They are thought to have been the descendants of Tiras, one of the sons of Japhet, and consequently must have preserved the speech of the Noachic family. The Gothic language abounds with *Pahlavi*, or old Persic words, which are no doubt remains of the primeval dialect of mankind. The Thracians peopled a considerable part of the northern coast of Asia Minor; and consequently we meet with many names of cities, mountains, rivers, &c. in those parts, exactly corresponding with many names in Europe, evidently imposed by our Gothic progenitors. Any person tolerably acquainted with the remains of the Gothic tongue, will be able to trace these with little difficulty.

We learn from Herodotus *, that Darius in his expedition against the wandering Scythians who lived on the other side of the Ister or Danube, in his progress subdued the Getæ; and in the same passage the historian informs us, that these people held the immortality of the human soul, and that they were the bravest and most just of all the Thracians. After this period, we find them mentioned by almost every Greek writer, even familiarly; for Geta, in the comedies of that nation, is a common name for a slave. The Getæ then occupied all that large tract of country which extended from the confines of Thrace to the banks of the Danube; were a brave and virtuous people; and spoke the same language with the Thracians, with whom they are often confounded both by Greek and Roman historians.

* Lib. iv. passim.

But the name of *Goths* is by no means so ancient. It was utterly unknown both to the ancient Greeks and Romans. The first time that the name *Goth* is mentioned is in the reign of the emperor Decius, about the year of Christ 250. About that time they burst out of Getia, and, rushing like a torrent into the empire, laid waste every thing with fire and sword. The name of their leader or king was *Cneva*. Decius, endeavouring to expel them from Thrace, was vanquished and slain.

After this irruption, we find them frequently in the Latin authors under the name of *Getæ* or *Gothi*; though the Greeks generally denominate them *Scythæ*. Torfæus tells us, that *get* † and *got* are actually the same word, which anciently, according to him denoted a "soldier." *Got* in Icelandic signifies a "horse or horseman," and *gata* a "wanderer;" and this last was perhaps the import of the term *Geta*, they being originally an unsettled vagrant people. As nations generally assume to themselves some high auspicious denomination, we may believe the Goths did the same. We may therefore rest satisfied, that the Getæ assumed the Icelandic name above mentioned as their national one: or perhaps, notwithstanding their Greek denomination, they called themselves *Gots* or *Goths* from the beginning.

† *History of Norway*, lib. i.

215 Their primary seat.

The orginal seat of the Goths was the country now called *Little Tartary*, into which they had extended themselves from the frontiers of Thrace. This country was called *Little Scythia* by the Greek writers; and it was the station whence those innumerable swarms advanced, which, in conjunction with the Alani and other barbarous tribes, at length overran and subverted the western empire. One part of the Gothic nation was allowed by Constantine to settle in Mœsia. Before the year 420 most of the Gothic nations who had settled within the limits of the Roman empire had been converted to the Christian faith; but,

(B) Lib. vii. page 295, B.; ibid. page 305. G. (Casaubon). From this passage it appears, that the Greeks were of opinion that the Getæ were Thracians. *Plin. Nat. Hist.* lib. iv. cap. 11. mentions a tribe of the Getæ called *Gaudæ*.

Gothic Language.

but, unhappily, the greater part of the apostles by whom they had been proselyted, were Arians, which proved fatal to many of the orthodox Christians; for the Arian Goths persecuted them with unrelenting cruelty.

216 Remains of genuine Gothic.

About the year 367, Ulphilas bishop of the Mœsian Goths, translated the New Testament into the Gothic language. The remains of this translation furnish a genuine, and at the same time venerable, monument of the ancient Gothic dialect. Nor more is now extant of that valuable translation than the four Gospels, and another fragment containing part of the epistle to the Romans. The Gospels have been repeatedly published since the first edition by Junius 1665, down to that of Mr Lye. Other fragments of the Gothic language have also been found, which our curious readers may see in Lye's Notes to his Edition of the Gothic Gospels. The fragment of the Epistle to the Romans was lately discovered in the library at Wolfenbuttle, and published by Knitel archdeacon of Wolfenbuttle.

The Goths, prior to the age of Ulphilas, were ignorant of the use of alphabetical characters. The bishop fabricated an alphabet for them, which is a medley of Greek and Roman letters, but rather inclining to the former.

217 Gothic alphabet.

This alphabet consists of 25 letters (see Plate XV.). Junius has carefully analyzed those letters, and pointed out their powers and sounds in his Gothic alphabet, prefixed to his *Glossarium Gothicum*. They were long retained in all the European languages derived from the Gothic source, which will be enumerated in the sequel.

What kind of language the ancient Gothic was, is plain from the fragments above mentioned; but in what respects it agrees with the oriental tongues, or differs from them, is not easy to ascertain with precision. We have observed in our section on the Greek, that a considerable part of that language must have been derived from the Thracian; which, according to Strabo there quoted, was the same with the Getic, or Gothic. The Thracian tongue will, we are convinced upon comparison, be found analogous to the Chaldean or Syrian. The German, which is a genuine descendant of the Gothic, is full of Persian words: the old Persian or Pahlavi appears to be a dialect of the Chaldean. The learned Junius, near the beginning of his Gothic alphabet, remarks that a very considerable part of the language in question is borrowed from the most ancient Greek.

218 Gothic language derived from the Chaldean, &c.

Both the learned Ihre in his *Glossarium Suio-Gothicum*, and Wachter in his excellent German and Latin Dictionary, often remark the coincidence of Gothic and German words with oriental vocables of the like sound and of the same signification. In the old Saxon, which is another ramification of the Gothic tongue, numberless terms of the very same complexion appear. From this deduction we hope it will follow, that the Gothic tongue, in its original unmixed state as it was spoken by the ancient Getæ, was a dialect of the primeval language; that language which the sons of Tiras brought with them from the plains of Shinar or from Armenia, or from any other region, where the primitive mortals had fixed their residence. To confirm this position, we shall annex a few instances.

The Thracian tribes, in all probability, first took possession of those tribes of Asia Minor which stretch towards the east. Thence they crossed the Hellespont, and spread themselves far and wide northward. Strabo supposes that they first settled in the regions to the north of those straits, and thence transported numerous colonies into Asia Minor. The reverse was probably the case; but be that as it may, it is universally agreed, that both sides of the Hellespont were peopled with Thracians.

In Asia Minor we meet with the city Perga, which, throwing away the *a*, is *Perg*. In every tongue descended from the Gothic, the word *Berg* signifies "a rock," and metaphorically a "town or burgh;" because towns were originally built on rocks for the sake of defence. Hence likewise *Pergamos*, the fort or citadel of Troy. *Beira* in Thracian signified a "city;" the Chaldaic and Hebrew word *Beer* imports a "well," and is possibly the original of the Gothic word *beer, ale*. In ancient times, especially in the East, it was customary to build cities in the neighbourhood of fountains. The ancients called the Phrygians Βρυγες, *Bryges*, or *Bruges*; the Gothic word coinciding is obvious. *Dyndymus*, the name of a city sacred to Cybele, is compounded of two Gothic words *dun* and *dum*, both signifying "a height, an eminence;" and hence *a town, an inclosure*. The word *tros* seems to be the very Gothic *trosh*, "brave, valiant." The words *fader, mader, dochter, bruder*, are so obviously Persian, that every etymologist has assigned them to that language.

Many futile etymologies have been given of the sacred name *God*, which is in reality the Persian word *Choda*, commonly applied by them to their *Hormuzd* or *Oromazes*. The Persian *bad* or *bod* signifies a "city;" the same word in Gothic imports a "house, a mansion, an abode." *Band*, in Persic, a "strait place;" in Gothic, "to bend." *Heim* or *ham*, "a house," is generally known to be of Persian original. Much critical skill has been displayed in tracing the etymology of the Scotch and old English word *Yule*, "Christmas." *Yule*, derived from *iul*, was a festival in honour of the sun, which was originally celebrated at the winter solstice. *Wick* or *wich* is a Gothic term still preserved in many names of towns; it signifies "a narrow corner, or small strip of land jutting into the sea, or into a lake or river:" hence the Latin *vicus*, and Greek φοικος. In Spanish, we have many old Gothic words; among others *hijo* a "son," the same with the Greek υιος. In some places of Scotland, we call any thing that is little, small, *wee*; originally spelt *wi*, if we mistake not, from the very same word.

These few examples we have thrown together, without any regard to order, persuaded that almost every word of the language, truly Gothic, may with a little pains and judgment be traced to some oriental root or cognate. We may observe in passing, that many Gothic nouns end in *a*, like the Chaldaic and Syriac; that their substantive verb very much resembles that of the Persian, Greek, and Latin; and that their active and auxiliary verb has furnished the common preterperfect tense of Greek verbs in the active voice: that verb is *haban*, Gothic Language. *haban*, but originally *ha*, as the common people pronounce it at this day, especially in the north of Scotland, and among the Swedes, Danes, Norwegians, and Icelanders.

219 Modern tongues deduced from the Gothic.

We shall now leave the other inferior arrangements of this ancient language to grammarians and lexicographers, and proceed to inquire what modern tongues are deduced from it as their stock, and which of them makes the nearest approaches to its simplicity and rusticity.

We have already observed that the Goths, formerly Getæ, were possessed of a vast extent of country, reaching from the frontiers of Thrace to the banks of the Ister or Danube. We have seen that a colony of them settled in Mœsia under Constantine II. They then spread themselves into Dacia, and from thence into Germany. All these countries were situated in such a manner, that the progress of population was forward, and according to the natural course of emigration. From Germany they extended themselves into Scandinavia, that is, Sweden, Denmark, and Norway. Their whole ancient *Edda*, *Sagas*, "Chronicles," show that the Goths arrived in Scandinavia by this route, without, however fixing the era of that event with any tolerable degree of accuracy. By the Germans, we believe the ancients understood all the nations eastward, westward, and northward, reaching from the Danube on the south up to the extremity of Scandinavia on the Northern ocean; and from the Rhine and German ocean on the west, to the river Chronus or Niemen on the east. All those nations spoke one or other of the Gothic dialects, some approaching nearer, and others deviating farther from, the parent language.

The Francic is a dialect of the Teutonic, *Tudesque*, or old German; and the Gospels of Ulphilas bear such a resemblance to the Francic, fragments of which are preserved in the early French historians, that some learned men have pronounced those gospels to be part of an old Francic version; but others of equal respectability have refuted this opinion, both from history and comparison of the dialects. Schilter has given us large monuments of the Tudesque or old German from the seventh century, which evidently prove that the Gothic of Ulphilas is the same language. Wachter's learned Glossary of the ancient German likewise confirms this position. Mr Ihre, after hesitating whether the Gospels of Ulphilas bear most resemblance to the German or Scandinavian dialect of the Gothic, declares at last in favour of the former. The Anglo-Saxon is also known to be a venerable dialect of the Tudesque; and is so intimately connected with the gospels, that some valuable works on this subject are wholly built upon that supposition.

The Icelandic is the oldest relick of the Scandinavian. It begins with Arius Frode in the eleventh century, and is a dialect of the German. The remains we have of it are more modern by four centuries than those of the German: they are more polished than the other. The words are shortened, not only because they are more modern than the German, but because the Icelandic was polished by a long succession of poets and historians almost equal to those of Greece and Rome. Hence the Icelandic, being a more polished language than the German, has less affinity with the parent Gothic. The Swedish is more nearly related to the Icelandic than either the Danish or Norwegian. That the Swedish is the daughter of the Gothic, is fully shown by Mr Ihre above mentioned, in his *Glossarium Suio-Gothicum*. There is, therefore, no manner of doubt as to the identity of the Gothic, preserved in Ulphilas and other ancient remains, with the German and Scandinavian tongue. Gothic Language.

The modern German, a language spoken in a far greater extent than any other of modern Europe, resembles the Gothic Gospels more than the present Danish, Norwegian, or Swedish; and has certainly more ancient *stamina*. Its likeness to the Asiatic tongues, in harshness and inflexible thickness of sound, is very apparent.

Busbequius shows, that the clowns of Crim Tartary, remains of the ancient Goths, speak a language almost German. These clowns were no doubt descendants of the ancient Goths, who remained in their native country after the others had emigrated. It is therefore apparent from the whole of this investigation, that the Gothic was introduced into Europe from the East, and is probably a dialect of the language originally spoken by men.

§ 3. *Of the Sclavonian Language.*

There is another language which pervades a considerable part of Europe, and this, like the Gothic, seems to have originated in the east. The language we mean is the Sclavonic or rather Slavonic, which prevails far and wide in the eastern parts of this division of the globe. It is spoken by the Dalmatians, by the inhabitants of the Danubian provinces, by the Poles, Bohemians, and Russians. The word *slab*, that is, "slave," (whence the French word *esclave*, and our word *slave*), signifies "noble, illustrious;" but because in the lower ages of the Roman empire, vast multitudes of these people were spread over all Europe in the quality of slaves, that word came to denote the servile tribe by way of distinction, in the same manner as the words *Geta*, *Davus*, and *Syrus*, did among the Greeks at a more early period. 220 Sclavonic language,

The Slavi dwelt originally on the banks of the Borysthenes, now the Dnieper or Nieper. They were one of the tribes of the European Sarmatians who in ancient times inhabited an immense tract of country, bounded on the west by the Vistula, now the Weisel; on the south-east by the Euxine sea, the Bosphorus Cimmerius, the Palus Mœotis, and the Tanais or Don, which divides Europe from Asia. 221 spoken by the Slavi one of the tribes of the Sarmatians.

In this vast tract of country, which at present comprehends Poland, Russia, and a great part of Tartary, there dwelt in ancient times many considerable tribes. To enumerate these, we believe, would not much edify our readers: we shall only inform them, that among these Sarmatian clans were the Roxolani, now the Russians, and likewise the Slavi, who dwelt near the Borysthenes, as was observed above.

The Slavi gradually advanced towards the Danube; and in the reign of Justinian having passed that river, they made themselves masters of that part of Illyricum which lies between the Drave and the Save, and is to this day from them called *Sclavonia*. These barbarians by degrees overran Dalmatia, Liburnia, the western parts of Macedonia, Epirus; and on the east they extended their quarters all along to the western bank

bank of the Danube, where that river falls into the Euxine. In all these countries, the Sclavonian was deeply impregnated with the Greek, which was a thing of course, since the barbarian invaders settled in those regions, and mingled with the aborigines, who spoke a corrupt dialect of that language.

222 the Poles,

The Poles are the genuine descendants of the ancient Sarmatæ (c), and consequently speak a dialect of their language, but much adulterated with Latin words, in consequence of the attachment the Polanders have long professed to the Roman tongue.

223 Silesians, and

The Silesians and Bohemians have corrupted their dialects in the very same manner. In those countries, then, we are not to search for the genuine remains of the ancient Sarmatian.

224 Russians descended from the Slavi.

The modern Russians, formerly the Rhoxani or Roxolani, are the posterity of the Sarmatæ, and are a branch of the Slavi: they inhabit a part of the country which that people possessed before they fell into the Roman provinces; they speak the same language, and wear the very same dress; for, on the historical pillar at Constantinople, the Sclavonians are dressed like the Russian boors. If then the Slavi are Sarmatæ, the Russians must of course be the descendants of the same people. They were long a sequestered people, and consequently altogether unconnected with the other nations of Europe, They were strangers to commerce, inhospitable to strangers, tenacious of ancient usages, averse to improvements of every kind, wonderfully proud of their imaginary importance; and, in a word, a race of people just one degree above absolute savagism. A people of this character are, for the most part, enemies to innovations; and if we may believe the Russian historians, no nation was ever more averse to innovations than the one in question. From the ninth century, at which era they embraced Christianity, it does not appear that they moved one step forward towards civilization, till Peter the Great, not a century ago, in consequence of his despotic authority, compelled them to adopt the manners and customs of their more polished neighbours.

We may then conclude, that the Russians made as little change in their language during that period, as they did in their dress, habits, and manner of living. Whatever language they spoke in the ninth century, the same they employed at the beginning of the 18th. They were, indeed, according to *Appian de bel. Mithrid.* once conquered by Diophantus, one of Mithridates's generals, but that conquest was for a moment only: they were likewise invaded, and their country overrun, by the great Timor or Tamerlane; but this invasion was like a torrent from the mountains, which spreads devastation far and wide while it rages, but makes little alteration on the face of the country.

We find likewise, that upon some occasions they made incursions upon the frontiers of the Roman empire; but we hear of no permanent settlements formed by them in these quarters. Upon the whole, we take the Russians to have been, with respect to their language, in the very same predicament with the highlanders and islanders of Scotland, who, according to the general opinion, have preserved the Celtic dialect pure and entire, in consequence of their having never mingled with foreigners.

225 The Russian language genuine Sclavonic.

From this deduction we may infer two things; first, that the Russian language is the genuine Sclavonian; and, secondly, that the latter is the same, or nearly the same, with the ancient Sarmatian.

In the Russian, there are found a great number of words resembling the old simple roots of the Greek both in sound and signification; its grammatical genius is nearly the same; and we are informed by the very best authority, that there is in this language a translation of Epictetus, in which there are whole pages, in both original and translation, without one single transposition. Mons. Leveque, who has published a translation of a history of Russia, is so entirely convinced of the strict analogy between the ancient Greek and the modern Russe, that he is positive that the former is derived from the latter. Mons. Freret, a very learned French academician, is clearly of the same opinion. We are, however, persuaded that this opinion is ill founded. We rather imagine, that those coincidences arise from the relicks of the primitive language of mankind; vestiges of which, we believe, are to be found almost in every tongue now existing.

It is, however, we allow, uncommonly difficult to render a reason for the syntaxical analogy of the two languages, without admitting the truth of the one or the other hypothesis. We have examined with some care a good number of Russian vocables, and compared them with Greek ones of the same signification. We have not, however, found such a resemblance as we think necessary to support the position advanced above.

226 Resemblance between Russian and oriental words.

We have indeed found a very strong resemblance between the former and many oriental words, especially Hebrew, Chaldean, and old Persian, of which we could produce several instances, did the nature of our present inquiry admit such a deviation. Every body knows that the Sarmatæ were divided into two great nations, the Asiatic and European; the former extended very far eastward, behind the mountain Caucasus, the northern shore of the Euxine sea, and so forth. These, we may believe, derived their language from the original tongue long before the Greek language existed. This, in comparison of the Hebrew, Phœnician, Egyptian, Arabian, Chaldean, &c. was but of yesterday. The Greek, most learned men are now convinced, was a late composition of many different dialects, incorporated with the jargon of the aboriginal Ionim or Greeks. The Sarmatian, on the contrary, was the tongue of a great and populous nation, civilized, in all appearance, long before the Greeks began to emerge from a state of savagism. We are, therefore, by no means disposed to allow, either that the Greek is derived from the Russian, or the Russian from the Greek. We believe there is just the same reason for this conclusion, that the Abbé Pezron and Mons. Gebelin pretend to have discovered, in order to support their position that the Greek is derived from the Celtic. Certain it is, that the resemblance among the oriental

(c) This appears by their character, their laws, their manners, their form of government, their military equipage, their impetuosity, their aristocratic splendour.

Sclavonian Language.

oriental languages, of which we take the Sarmatian to have been one, is so palpable, that any person of a moderate capacity who is perfectly master of one, will find little difficulty in acquiring any other. If, therefore, the coincidence between the Greek and Russian should actually exist, we think this circumstance will not authenticate the supposition, that either of the two is derived from the other.

In the course of this argument, our readers will be pleased to observe, that we all along suppose, that the Sclavonian, of which we think the Russian is the most genuine remain, is the same with the old Sarmatian. We shall now take the liberty to hazard a conjecture with respect to the syntaxical coincidence of that language with the Greek; for we acknowledge that we are not so profoundly versed in the Russian dialect of the Sclavonian as to pretend to pronounce a definitive sentence.

227
Origin of the syntaxical coincidence between this language and the Greek.

As the Russians were a generation of savages, there is no probability that they were acquainted with the use of letters and alphabetical writing till they acquired that art by intercourse with their neighbours. It is certain, beyond all contradiction, that few nations had made less proficiency in the fine arts than that under consideration: and we think there is little appearance of their having learned this art prior to their conversion to Christianity. Certain it is, that the Slavi, who settled in Dalmatia, Illyria, and Liburnia, had no alphabetical characters till they were furnished with them by St Jerome. The Servian character, which very nearly resembles the Greek, was invented by St Cyril; on which account the language written in that character is denominated *Chiurilizza*. These Sclavonic tribes knew nothing of alphabetic writing prior to the era of their conversion. The Mœsian Goths were in the same condition till their bishop Ulphilas fabricated them a set of letters.

If the Slavi and Goths, who resided in the neighbourhood of the Greeks and Romans, had not learned alphabetical writing prior to the era of their conversion to Christianity, it must hold, *à fortiori*, that the Russians, who lived at a very great distance from those nations, knew nothing of this useful art antecedent to the period of their embracing the Christian faith.

The Russians pretend that they were converted by St Andrew; but this is known to be a fable. Christianity was first introduced among them in the reign of the grand duke Wolodimar, who marrying the daughter of the Grecian emperor Basilius, became her convert about the year 989. About this period, we imagine, they were taught the knowledge of letters by the Grecian missionaries, who were employed in teaching them the elements of the Christian doctrines. Their alphabet consists of 31 letters, with a few obsolete additional ones; and these characters resemble those of the Greeks so exactly, that there can be no doubt of their being copied from them. It is true, the shape of some has been somewhat altered, and a few barbarian ones have been intermingled. The Russian liturgy, every body knows, was copied from that of the Greeks; and the best specimen of the old Russian is the church offices for Easter, in the very words of Chrysostom, who is called by his name *Zlato ustii*. "golden-mouthed." The power of the clergy in Russia was excessive; and no doubt their influence was proportioned to their power. The first race of clergy in that country were undoubtedly Greeks. We know how active and industrious those people were in propagating their language as well as their religion. The offices of religion might be at first written and pronounced in the Greek tongue, but it would soon be found expedient to have them translated into Russian. The persons employed in this work must have been Greeks, who understood both languages.

Sclavonian Language.

As it is confessedly impossible that a people so dull and unattentive as the Russians originally were, could ever have fabricated a language so artificially constructed as their present dialect; and as it is obvious, that, till Christianity was introduced among them by the Greeks, they could have no correspondence with that people—it must appear surprising by what means their language came to be fashioned so exactly according to the Greek model. We have observed above, that the Russian letters must have been invented and introduced into that country by the Greek missionaries. We think it probable, that those apostles, at the same time that they taught them a new religion, likewise introduced a change into the idiom of their language. The influence of those ghostly teachers over a nation of savages must have been almost boundless; the force of their precepts and example almost incontrollable. If the savage converts accepted a new religion from the hands of those Grecian apostles, they might with equal submission adopt improvements in their language. Such of the natives as were admitted to the sacerdotal function must have learned the Greek language, in order to qualify them for performing the offices of their religion. A predilection for that language would be the immediate consequence. Hence the natives, who had been admitted into holy orders, would co-operate with their Grecian masters in improving the dialect of the country; which, prior to the period above mentioned, must have greatly deviated from the original standard of the Sarmatian tongue.

Upon this occasion, we imagine the Greek apostles, in conjunction with their Russian disciples, reduced the language of the country to a resemblance with the Greek idiom. They retained the radical vocables as they found them; but by a variety of flections, conjugations, derivations, compositions, and other modifications, transformed them into the Grecian air and apparel. They must have begun with the offices of the church; and among a nation of savages newly converted, the language of the new religion would quickly obtain a very extensive circulation. When the Grecian garniture was introduced into the church, the laity would in process of time assume a similar dress. The fabric of the Grecian declensions, conjugations, &c. might be grafted upon Russian stocks without affecting the radical parts of the language. If the dialect in question, like most others of a very ancient date, laboured under a penury of vocables, this manœuvre would contribute exceedingly to supply that defect. By this expedient the Greek language itself had been enlarged from about 300 radical terms to the prodigious number of words of which it now consists.

The Latin tongue we have seen above in its original constitution differed widely from the Greek; and notwithstanding this incongruity, the improvers of the former have pressed it into a very strict agreement with the

 latter.

latter. This, we think, was still a more difficult task; as, in our opinion, the genius of the Latin differs in a much greater degree than that of the Russian does from the Greek. We know, that the genius of the Gothic tongue and those of all its descendants are much more in unison with the Greek than with that of the Latin. The Spanish, Italian, and French, have cudgelled many of their Gothic, Teutonic, and Celtic verbs, into a kind of conjugations, imitating or rather aping those of the Latin. The Persians have formed most elegant and energetic declensions and conjugations, upon inflexible roots borrowed from the Pahlavi and Deri, and even from Tartar originals.

Upon the grounds above mentioned we have taken the liberty to hazard the following conjectures, which we cheerfully submit to the cognizance of our more enlightened readers.

1. That the Sarmatian was a dialect of the original language of mankind.

2. That the Sclavonian was a dialect of the Sarmatian.

3. That the Russe is the most genuine unsophisticated relick of the Sclavonian and Sarmatian.

4. That the Russians had no alphabetic characters prior to the era of the introduction of Christianity, that is, towards the end of the tenth century.

5. That they were converted by Grecian missionaries.

6. That those missionaries copied their present letters from those of Greece; and in conjunction with the more enlightened natives, reduced the original unimproved Russe to its present resemblance to the Greek standard.

228 Russian nouns. The Russian language, like most others, contains eight parts of speech, noun, pronoun, &c. Its nouns have three genders, masculine, feminine, and neuter; it has also a common gender for nouns, intimating both sexes. It has only two numbers, singular and plural. Its cases are seven, nominative, genitive, dative, accusative, vocative, instrumental, and prepositive. These cases are not formed by varying the termination, as in Greek and Latin; but generally by placing a vowel after the word, as, we imagine, was the original practice of the Greeks (See *Greek* Section). Thus in Russe, рук, *ruk*, "the hand;" nominative, рук-а, "the hand;" genitive, рук-N` "of the hand," &c. See *Les Elem. de la Langue Russe par Charpentier*. Nouns substantive are
229 Adjectives. reduced to four declensions, and adjectives make a fifth. These agree with their substantives in case, gender, and number. They have three degrees of comparison, as is common in other languages; the positive, comparative, and superlative. The comparative is formed from the feminine of the nominative singular of the positive, by changing *a* into *te*, that is, *aie* in English; the superlative is made by prefixing пре, *pre*, before the positive. These rules are general; for the exceptions, recourse must be had to the Russian grammar above mentioned.

The numeral adjectives in Russe have three genders like the rest, and are declined accordingly. Their pronouns have nothing peculiar, and are divided and arranged in the same manner as in other languages. Verbs
230 Verbs, in the Russian language are comprehended under two conjugations. The moods are only three; the indicative, the imperative, and the infinitive: the subjunctive is formed by placing a particle before the indicative. Its tenses are eight in number; the present, the imperfect, the preterite simple, the preterite compound, the pluperfect, the future indeterminate, the future simple, the future compound. The verbs have their numbers and persons as in other languages. To enter into a detail of their manner of conjugating their verbs would neither be consistent with our plan, nor, we are persuaded, of much consequence to our readers. Their other parts of speech differ nothing from those of other languages. Their syntax nearly resembles that of the Greek and Latin. All these articles must be learned from a grammar of the language. Whether there is any grammar of the Russian language composed in English we know not. That of Mons. Charpentier in French, printed at Petersburgh in 1768, is the only one we have seen, and which appears to us a very excellent one. We could wish to be able to gratify our readers with a more authentic account of the origin of the Sclavonian language; but this we find impossible, in consequence of the want of memorials relating to the state of the ancient Sarmatæ. Towards the era of the subversion of the western empire, the nations who inhabited the countries in question were so blended and confounded with each other, and with Huns and other Scythian or Tartar emigrants, that we believe the most acute antiquarian would find it impossible to investigate their respective tongues, or even their original residence or extraction. We have selected the Russe as the most genuine branch of the old Sclavonian, and to this predilection we were determined by the reasons above mentioned. We are sorry that we are not so well acquainted with the idiom of the Russian language as to be able to compare it with those of the east; but upon such a comparison, we are persuaded that the radical materials of which it is composed would be found to have originated in the oriental regions. The word *Tsar*, for example, is probably the Phœnician and Chaldean *Sar*, or *Zar*, "a prince, a grandee." Diodorus Siculus calls the queen of the Massagetæ, who, according to Ctesias, cut off Cyrus's head, *Zarina*; which was not many years ago the general title of the empress of all the Russias. Herodotus calls the same princess *Tomyris*, which is the very name of the famous Timor or Tamur, the conqueror of Asia. The former seems to have been the title, and the latter the proper name, of the queen of the Massagetæ. In the old Persian or Pahlavi, the word *Gard* signifies "a city;" in Russian, *Gorad* or *Grad* intimates the very same idea: hence *Constantinople* in old Russe is called *Tsargrad* or *Tsargorad*. These are adduced as a specimen only; and able etymologists might, we believe, discover a great number. 231 Phœnician and Chaldean words in Russe.

The Sclavonian language is spoken in Epirus, the western part of Macedonia, in Bosnia, Servia, Bulgaria, in part of Thrace, in Dalmatia, Croatia, in Poland, Bohemia, Russia, and Mingrelia, in Asia, whence it is frequently used in the seraglio at Constantinople. Many of the great men of Turkey understand it, and frequently use it; and most of the janizaries having been stationed in garrisons on the Turkish frontiers in Europe, use it as their vulgar tongue. The Hungarians, however, and the natives of Wallachia, speak a different language: and this language bears evident signatures of the Tartarian dialect, which was the tongue of the original Huns. Upon the whole, the Sclavonian is by much the most extensive language in Europe, and extends far into Asia.

Modern Languages.

SECT. X. *Modern Languages.*

If we call all the different dialects of the various nations that now inhabit the known earth, languages, the number is truly great; and vain would be his ambition who should attempt to learn them, though but imperfectly. We will begin with naming the principal of them: There are four, which may be called original or mother-languages, and which seem to have given birth to all that are now spoken in Europe. These are the *Latin, Celtic, Gothic*, and *Sclavonian.* It will not, however, be imagined, from the term *original* given to these languages, that we believe them to have come down to us, without any alteration, from the confusion of tongues at the building of the tower of Babel. We have repeatedly declared our opinion, that there is but one truly original language, from which all others are derivatives variously modified. The four languages just mentioned are original only as being the immediate parents of those which are now spoken in Europe.

232 Parent dialects of Europe, with their respective offspring.

I. From the *Latin* came,

1. The Portuguese.
2. Spanish.
3. French.
4. Italian.

From the *Celtic*,

5. The Erse, or Gaelic of the Highlands of Scotland.
6. The Welsh.
7. The Irish.
8. Basse Bretagne.

From the *Gothic*,

9. The German.
10. The Low Saxon or Low German.
11. The Dutch.
12. The English; in which almost all the noun-substantives are German, and many of the verbs French, Latin, &c. and which is enriched with the spoils of all other languages.
13. The Danish.
14. The Norwegian.
15. Swedish.
16. Icelaudic.

From the *Sclavonian*,

17. The Polonese.
18. The Lithuanian.
19. Bohemian.
20. Transylvanian.
21. Moravian.
22. The modern Vandalian, as it is still spoken in Lusatia, Prussian Vandalia, &c.
23. The Croatian.
24. The Russian or Muscovite; which, as we have seen, is the purest dialect of this language.
25. The language of the Calmucs and Cossacs.
26. Thirty-two different dialects of nations who inhabit the north-eastern parts of Europe and Asia, and who are descended from the Tartars and Huno-Scythians. There are polyglott tables which contain not only the alphabets, but also the principal distinct characters of all these languages.

II. The languages at present generally spoken in Asia are,

233 Asiatic languages.

27. The Turkish and Tartarian, with their different dialects.
28. The Persian.
29. The Georgian or Iberian.
30. The Albanian or Circassian.
31. The Armenian.

These languages are spoken by the Greek Christians in Asia under the patriarch of Constantinople.

32. The modern Indian.
33. The Formosan.
34. The Indostanic.
35. The Malabarian.
36. The Warugian.
37. The Tamulic or Damulic.

The Danish missionaries who go to Tranquebar, print books at Hall in these languages.

38. The modern Arabic.
39. The Tangusian.
40. The Mungalic.
41. The language of the Nigarian or Akar Nigarian.
42. The Grusinic or Grusinian.
43. The Chinese.
44. The Japanese.

We have enumerated here those Asiatic languages only of which we have some knowledge in Europe, and even alphabets, grammars, or other books than can give us information concerning them. There are doubtless other tongues and dialects in those vast regions and adjacent islands; but of these we are not able to give any account.

III. The principal languages of Africa are,

234 African languages.

45. The modern Egyptian.
46. The Fetuitic, or the language of the kingdom of Fetu.
47. The Moroccan; and,
48. The jargons of those savage nations who inhabit the desert and burning regions. The people on the coast of Barbary speak a corrupt dialect of the Arabic. To these may be added the Chilhic language, otherwise called *Tamazeght;* The Negritian, and that of Guinea; the Abyssinian; and the language of the Hottentots.

IV. The languages of the American nations are but little known in Europe. Every one of these, though distant but a few days journey from each other, have their particular language or rather jargon. The languages of the Mexicans and Peruvians seem to be the most regular and polished. There is also one called *Poconchi* or *Pocomana*, that is used in the bay of Honduras and towards Guatimal, the words and rules of which are most known to us. The languages of North America are in general the Algonhic, Apalachian, Mohegic, Savanahamic, Virginic, and Mexican: and in South America, the Peruvian, Caribic, the language of Chili, the Cairic, the Tucumanian, and the languages used in Paraguay, Brasil, and Guiana.

235 American languages.

V. We have already said, that it would be a vain and senseless undertaking for a man of letters to attempt the study of all these languages, and to make his head an universal dictionary; but it would be still more absurd in us to attempt the analysis of them in this place: some general reflections therefore must here suffice. Among the modern languages of Europe, the French seems to merit great attention; as it is elegant and pleasing in itself; as it is become so general, that with it we may travel from one end of Europe to the other without

236 General reflections on modern languages.

Modern Languages.

without scarce having any occasion for an interpreter; and as in it are to be found excellent works of every kind, both in verse and prose, useful and agreeable. There are, besides, grammars, and dictionaries of this language which give us every information concerning it, and very able masters who teach it; especially such as come from those parts of France where it is spoken correctly; for with all its advantages, the French language has this inconvenience, that it is pronounced scarce anywhere purely but at Paris and on the banks of the Loire. The language of the court, of the great world, and of men of letters, is moreover very different from that of the common people; and the French tongue, in general, is subject to great alteration and novelty. What pity it is, that the style of the great Corneille, and that of Moliere, should already begin to be obsolete, and that it will be but a little time before the inimitable *chefs d'œuvres* of those men of sublime genius will be no longer seen on the stage: The most modern style of the French, moreover, does not seem to be the best. We are inclined to think, that too much conciseness, the epigrammatic point, the antithesis, the paradox, the sententious expressions, &c. diminish its force; and that, by becoming more polished and refined, it loses much of its energy.

VI. The German and Italian languges merit likewise a particular application; as does the English, perhaps above all, for its many and great excellencies (See LANGUAGE). Authors of great ability daily labour in improving them; and what language would not become excellent, were men of exalted talents to make constant use of it in their works! If we had in Iroquois books like those which we have in English, Italian, French, and German, should we not be tempted to learn that language? How glad should we be to understand the Spanish tongue, though it were only to read the Araucana of Don Alonzo D'Ercilia, Don Quixote, some dramatic pieces, and a small number of other Spanish works, in the original; or the poem of Camoens in Portuguese.

VII. The other languages of Europe have each their beauties and excellencies. But the greatest difficulty in all living languages constantly consists in the pronunciation, which it is scarce possible for any one to attain unless he be born or educated in the country where it is spoken: and this is the only article for which a master is necessary, as it cannot be learned but by teaching or by conversation: all the rest may be acquired by a good grammar and other books. In all languages whatever, the poetic style is more difficult than the prosaic: in every language we should endeavour to enrich our memories with great store of words (*copia verborum*), and to have them ready to produce on all occasions: in all languages it is difficult to extend our knowledge so far as to be able to form a critical judgment of them. All living languages are pronounced rapidly, and without dwelling on the long syllables (which the grammarians call *moram*): almost all of them have articles which distinguish the genders.

VIII. Those languages that are derived from the Latin have this further advantage, that they adopt without restraint, and without offending the ear, Latin and Greek words and expressions, and which by the aid of a new termination appear to be natives of the language. This privilege is forbidden the Germans, who in their best translations dare not use any foreign word, unless it be some technical terms in case of great necessity.

PHI

Philomathes, Philomela.

PHILOMATHES, a lover of learning or science.

PHILOMELA, in fabulous history, was a daughter of Pandion king of Athens, and sister to Procne, who had married Tereus king of Thrace. Procne separated from Philomela, to whom she was much attached, spent her time in great melancholy till she prevailed upon her husband to go to Athens and bring her sister to Thrace. Tereus obeyed; but he had no sooner obtained Pandion's permission to conduct Philomela to Thrace, than he fell in love with her, and resolved to gratify his passion. He dismissed the guards whom the suspicions of Pandion had appointed to watch him; offered violence to Philomela; and afterwards cut out her tongue, that she might not discover his barbarity, and the indignities she had suffered. He confined her in a lonely castle; and having taken every precaution to prevent a discovery, he returned to Thrace, and told Procne that Philomela had died by the way, and that he had paid the last offices to her remains. At this sad intelligence Procne put on mourning for the loss of Philomela; but a year had scarcely elapsed before she was secretly informed that her sister was not dead. Philomela, in her captivity, described on a piece of tapestry her misfortunes and the brutality of Tereus, and privately conveyed it to Procne. She was going to celebrate the orgies of Bacchus when she received it, but she disguised her resentment; and as during those festivals she was permitted to rove about the country, she hastened to deliver her sister Philomela from her confinement, and concerted with her on the best measures of punishing the cruelty of Tereus. She murdered her son Itylus, then in the sixth year of his age, and served him up as food before her husband during the festival. Tereus, in the midst of his repast, called for Itylus; but Procne immediately informed him that he was then feasting on his flesh, when Philomela, by throwing on the table the head of Itylus, convinced the monarch of the cruelty of the scene. He drew his sword to punish Procne and Philomela; but as he was going to stab them to the heart, he was changed into a hoopoe, Philomela into a nightingale, Procne into a swallow, and Itylus into a pheasant. This tragedy happened at Daulis in Phocis; but Pausanias and Strabo, who mention the whole of the story, are silent about the transformation; and the former observes, that Tereus, after this bloody repast, fled to Megara, where he laid violent hands on himself. The inhabitants of the place raised a monument to his memory, where they offered yearly sacrifices, and placed small pebbles instead of barley. It was on this monument that the birds called hoopoes were first seen; hence the

the fable of his metamorphosis. Procne and Philomela died through excessive grief and melancholy; and as the nightingale's and the swallow's voice is peculiarly plaintive and mournful, the poets have embellished the fable by supposing that the two unfortunate sisters were changed into birds.

PHILONIUM, in *Pharmacy*, a kind of anodyne opiate, taking its name from Philo the inventor.

Ancient Universal History, vol. vi.

PHILOPOEMEN, a celebrated general of the Achæan league, was born in Megalopolis, a city of Arcadia, in Peloponnesus; and from his very infancy discovered a strong inclination to the profession of arms. He was nobly educated by Cassander of Mantinea; a man of great probity, and uncommon abilities. He was no sooner able to bear arms than he entered among the troops which the city of Megalopolis sent to make incursions into Laconia, and in these inroads never failed to give some remarkable instance of his prudence and valour. When there were no troops in the field, he used to employ his leisure time in hunting and such other manly exercises. When Cleomenes king of Sparta attacked Megalopolis, Philopœmen displayed much courage and greatness of soul. He signalized himself no less some time after, in the battle of Sellasia, where Antigonus gained a complete victory over Cleomenes. Antigonus, who had been an eye-witness of his prudent and intrepid behaviour, made very advantageous offers to gain him over to his interest; but he rejected them, having an utter aversion to a court life, which he compared to that of a slave, saying, that a courtier was but a slave of a better condition. As he could not live idle and inactive, he went to the isle of Crete, which was then engaged in war, and served there as a volunteer till he acquired a complete knowledge of the military art; for the inhabitants of that island were in those days accounted excellent warriors, being scarce ever at peace among themselves. Philopœmen, having served some years among the troops of that island, returned home, and was upon his arrival appointed general of the horse; in which command he behaved so well, that the Achæan horse, heretofore of no reputation, became in a short time famous all over Greece. He was soon after appointed general of all the Achæan forces, when he applied himself to the re-establishing of military discipline among the troops of the republic, which he found in a very low condition, and universally despised by their neighbours. Aratus, indeed, was the first that raised the Achæan state to that pitch of power and glory to which it arrived; but the success of his enterprises was not so much owing to his courage and intrepidity as to his prudence and politics. As he depended on the friendship of foreign princes, and their powerful succours, he neglected the military discipline at home; but the instant Philopœmen was created prætor, or commander in chief, he roused the courage of his countrymen, in order to put them into a condition to defend themselves without the assistance of foreign allies. With this view he made great improvements in the Achæan discipline; changing the manner of their exercise and their arms, which were both very defective. He had thus, for the space of eight months, exercised his troops every day, making them perform all the motions and evolutions, and accustoming them to manage with dexterity their arms, when news was brought him that Machanidas was advancing, at the head of a numerous army, to invade Achaia. He was glad of this opportunity to try how the troops had profited by his discipline; and accordingly, taking the field, met the enemy in the territories of Mantinea, where a battle was fought. Philopœmen, having killed Machanidas with his own hand, struck off his head, and carried it from rank to rank, to encourage his victorious Achœans, who continued the pursuit, with great slaughter, and incredible ardour, to the city of Tegea, which they entered together with the fugitives. The Lacedæmonians lost on this occasion above 8000 men, of which 4000 were killed on the spot, and as many taken prisoners. The loss of the Achæans was very inconsiderable, and those that fell were mostly mercenaries. This happened about the year before Christ 204.

But what most of all raised the fame and reputation of Philopœmen was his joining the powerful city of Lacedæmon to the Achæan commonwealth; by which means the Achæans came to eclipse all the other states of Greece. This memorable event happened in the year 191. In this transaction we cannot help taking notice of one circumstance, which, in our opinion, reflects greater lustre on Philopœmen than all his warlike exploits. The Lacedæmonians, overjoyed to see themselves delivered from the oppressions they had long groaned under, ordered the palace and furniture of Nabis to be sold; and the sum accruing from thence, to the amount of 120 talents, to be presented to Philopœmen, as a token of their gratitude. Deputies therefore were to be appointed, who should carry the money, and desire Philopœmen, in the name of the senate, to accept of the present. On this occasion it was that the virtue of the generous Achæan appeared in its greatest lustre; for so great was the opinion which the Spartans had of his probity and disinterestedness, that no one could be found who would take upon him to offer the present: struck with veneration, and fear of displeasing him, they all begged to be excused. At last they obliged, by a public decree, one Timolaus, who had formerly been his guest, to go to Megalopolis, where Philopœmen lived, and offer him this testimony of their regard. Timolaus, with great reluctance, set out for Megalopolis, where he was kindly received and entertained by Philopœmen. Here he had an opportunity of observing the strictness of his whole conduct, the greatness of his mind, the frugality of his life, and the regularity of his manners; which struck him with such awe, that he did not dare once to mention the present he was come to offer; insomuch that, giving some other pretence to his journey, he returned home with the money. The Lacedæmonians sent him again; but he could no more prevail upon himself now than the first time to mention the true cause of his journey. At last, going a third time, he ventured, with the utmost reluctance, to acquaint Philopœmen with the offer he had to make in the name of the Lacedæmonians. Philopœmen heard him with great calmness; but the instant he had done speaking, he set out with him for Sparta, where, after having acknowledged his obligation to the Spartans, he advised them to lay out their money in reforming or purchasing those miscreants who divided the citizens, and set them at variance by means of their seditious discourses; to the end that, being paid for their silence, they might not occasion so many distractions in the government: "for it is much more advisable (said he) to stop an enemy's mouth than a friend's; as for me, I shall always be your friend, and you

Philopœmen ‖ Philosopher's Stone.

you shall reap the benefit of my friendship without expence." Such was the disinterestedness of this noble Achæan!

About two years after this, the city of Messene withdrew itself from the Achæan league. Philopœmen attacked them; but was wounded, taken prisoner, and poisoned by the magistrates. Thus died one of the greatest heroes that Greece or any other country ever produced. He was no way inferior in valour, military knowledge, and virtue, to any of the boasted heroes of Rome. Had Achaia been nearer to an equality with Rome, he would have preserved his country from the yoke which the Roman republic forced it to bear. Both the Greek and Roman writers put him upon the level with Hannibal and Scipio, who were his contemporaries, and happened to die the same year. They allow him to have been not only one of the greatest commanders, but also one of the greatest statesmen of his age. To his valour and prudence Achaia owed her glory, which upon his death began to decline, there being none after him in that republic able to oppose her enemies with the like steadiness and prudence: whence Philopœmen was called the last of the Greeks, as Brutus was afterwards styled the last of the Romans.

PHILOSOPHER, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature.

PHILOSOPHER's Stone, the greatest object of alchemy, is a long sought for preparation, which, when found, is to convert all the true mercurial part of metal into pure gold, better than any that is dug out of mines or perfected by the refiner's art.

Some Greek writers in the fourth and fifth centuries speak of this art as being then known; and towards the end of the 13th century, when the learning of the East had been brought hither by the Arabians, the same pretensions began to spread through Europe. It is supposed that this art, called *Alchemy*, was of Egyptian origin; and that when the ancient Greek philosophers travelled into Egypt, they brought back some of the allegoric language of this Egyptian art, ill understood, which afterwards passed into their mythology. Alchemy was the earliest branch of chemistry, considered as a philosophical science: in the other parts of chemical knowledge, facts preceded reasoning or speculation; but alchemy was originally speculative.

The alchemists supposed the general principles of metals to be chiefly two substances, which they called mercury and sulphur; they apprehended also, that the pure mercurial, sulphureous, or other principles of which they imagined gold to be composed, were contained separately in other bodies; and these principles, therefore, they endeavoured to collect, and to concoct and incorporate by long digestions; and by thus conjoining the principles of gold, if they could be so produced and conjoined, it might be expected that gold would be produced. But the alchemists pretend to a product of a higher order, *called the elixir, the medicine for metals, the tincture, the philosopher's stone;* which by being projected on a large quantity of any of the inferior metals in fusion, should change them into fine gold; which being laid on a plate of silver, copper, or iron, and moderately heated, should sink into the metal, and change into gold all the parts to which it was applied; which, on being properly heated with pure gold, should change the gold into a substance of the same nature and virtue with itself, so as thus to be susceptible of perpetual multiplication; and which, by continued coction, should have its power more and more exalted, so as to be able to transmute greater and greater quantities of the inferior metals, according to its different degrees of perfection.

Alchemists have attempted to arrive at the making of gold by three methods: the first by separation; for every metal yet known, it is affirmed, contains some quantity of gold; only, in most, the quantity is so little as not to defray the expence of getting it out.

The second is by maturation; for the alchemists think mercury is the basis and matter of all metals; that quicksilver purged from all heterogeneous bodies would be much heavier, denser, and simpler, than the native quicksilver; and that by subtilizing, purifying, and digesting it with much labour, and long operations, it is possible to convert it into pure gold.

This method is only for mercury. With respect to the other metals, it is ineffectual, 1. Because their matter is not pure mercury, but has other heterogeneous bodies adhering to it; and, 2. Because the digestion, whereby mercury is turned into gold, would not succeed in other metals, because they had not been long enough in the mines.

Weight is the inimitable character of gold, &c. Now mercury, they say, has always some impurities in it, and these are lighter than mercury. Could they be purged away, which they think is not impossible, mercury would be as heavy as gold, and what is as heavy as gold is gold, or at least might very easily be made gold.

The third method is by transmutation, or by turning all metals readily into pure gold, by melting them in the fire, and casting a little quantity of a certain preparation into the fused matter; upon which the fæces retire, are volatilized and burnt, and carried off, and the rest of the mass is turned into pure gold. That which works this change in the metals is called the *philosopher's stone.*

Whether this third method be possible or not, it is difficult to say. We have so many testimonies of it from persons who on all other occasions speak truth, that it is hard to say they are guilty of direct falsehood, even when they say that they have been masters of the secret. We are told, that it is only doing that by art which nature does in many years and ages. For as lead and gold differ but little in weight, therefore there is not much in lead beside mercury and gold. Now, if we had any body which would so agitate all the parts of lead as to burn all that is not mercury therein, and had also some sulphur to fix the mercury, would not the mass remaining be converted into gold? There is nothing in nature so heavy as lead except gold, mercury, and platina, which was not known to these reasoners; it is evident, therefore, there is something in lead that comes very near to gold. But in lead there is likewise some heterogeneous matter different both from mercury and gold. If therefore 19 ounces of lead be dissolved by the fire, and 8 ounces be destroyed by these means, it is argued that we shall have the rest good gold; the ratio of lead to gold being as 11 to 19. If then the philosopher's stone can purify the mercurial matter in lead, so as that nothing shall remain but the pure mercurial body, and you can fix

Philosopher's Stone.

fix and coagulate this by means of sulphur, out of 19 ounces of lead you will have 11 of gold: or, if you reduce the lead from 18 to 14, you will then have converted it into mercury; and if you farther purify this mercury to the proper standard, you will have gold; provided you have but a sulphur with which to fix and coagulate it. Such is the foundation of the opinion of the philosopher's stone; which the alchemists contend to be a most subtile, fixed, concentrated fire, which, as soon as it melts with any metal, does, by a magnetic virtue, immediately unite itself to the mercurial body of the metal, volatilize and cleanse off all that is impure therein, and leave nothing but a mass of pure gold. Many frauds and artifices have unquestionably been practised in this operation, and there might be political reasons why princes and others should encourage those who pretended to a power of furnishing this inexhaustible source of wealth; but it would be wrong to censure as impostors all those who have declared themselves convinced, from their own experiments, of the transmutability of base metals into gold. There are strong reasons, however, to believe that the authors have been deceived themselves by fallacious appearances. Mr Boyle gives an account of a process by which he imagines part of the substance of gold to have been transmuted into silver. He also relates a very extraordinary experiment, under the title of the degradation of gold by an anti-elixir, which was published in his own life-time, and since reprinted in 1739. Hence many have been led to conclude in favour of the alchemical doctrine of the transmutability of metals. See an account of this experiment, with remarks upon it by Dr Lewis, in his *Commerce of Arts*, sect. 12. p. 297, &c.

Characters of the Kings and Queens of England.

"The opinion (says Holt) that one metallic or other foreign substance might be changed into another, was, it seems, at this time (reign of Henry VI. of England) propagated by certain chemists, whose observations on the surprising effects and alterations produced in certain substances by the force of heat carried their imaginations beyond what sound judgment might warrant. The first instance of which on record is in vol. xi. p. 68. of the *Fœdera;* wherein Henry VI. grants a licence to John Cobbe, freely to work in metals; he having, by philosophical art, found out a method of transferring imperfect metals into perfect gold and silver.

Philosopher's Stone ‖ Philosophizing.

"This pretended secret, known afterwards by the name of the *Philosopher's stone* or *powder*, was encouraged by four licences, granted to different projectors during this reign, and at sundry times after, during this century particularly, and in succeeding times, all over Europe. The frenzy has not entirely ceased even to this day, although it meets with neither public encouragement nor countenance from men of sober reason; the projectors having yet found nothing from their airy schemes in this mode of search but certain ruin to their property." See CHEMISTRY.

The same author, when speaking of the commerce of the kingdom, and the wonderful increase and riches of commercial cities, speaks thus: "This is the true philosopher's stone, so much sought after in former ages, the discovery of which has been reserved to genius, when studying to improve the mechanic arts. Hence a pound of raw materials is converted into stuffs of fifty times its original value. And the metals too are not, indeed, transmuted into gold—they are more: for the labour of man has been able to work the baser metals, by the ingenuity of art, so as to become worth more than many times its weight in gold."

PHILOSOPHIC, or PHILOSOPHICAL, something belonging to PHILOSOPHY.

PHILOSOPHICAL EGG, among chemists, a thin glass body or bubble, of the shape of an egg, with a long neck or stem, used in digestions.

PHILOSOPHIZING, rules of. See NEWTONIAN *Philosophy*, N° 16. and the following article.

PHILOSOPHY

1 Definitions of philosophy.

IS a word derived from the Greek, and literally signifies the *love of wisdom* (A). In its usual acceptation, however, it denotes a science, or collection of sciences, of which the universe is the object; and of the term thus employed many definitions have been given, differing from one another according to the different views of their several authors. By Pythagoras, philosophy is defined ἐπιστήμη τῶν ὄντων, "the knowledge of things existing;" by Cicero, after Plato, *scientia rerum divinarum et humanarum cum* CAUSIS; and by the illustrious Bacon, *interpretatio naturæ*. Whether any of these definitions be sufficiently precise, and at the same time sufficiently comprehensive, may be questioned; but if philosophy in its utmost extent be capable of being adequately defined, it is not here that the definition should be given. "Explanation (says an acute writer *), is the first office of a teacher; definition, if it be good, is the last of the inquirer after truth; but explanation is one thing, and definition quite another." It may be proper, however, to observe, that the definition given by Cicero is better than that of Pythagoras, because the chief object of the philosopher is to ascertain the *causes* of things; and in this consists the difference between his

History of philosophy.

* *Tatham's Chart and Scale of Truth*, v. i. p. 8.

(A) The origin usually attributed to the term *philosophy* has been already assigned in the article PHILOLOGY. M. Chauvin gives it a turn somewhat different. According to him, the term is derived from φιλια, *desire* or *study*, and σοφια *wisdom;* and therefore he understands the word to mean *the desire or study of wisdom:* for (says he) Pythagoras, conceiving that the application of the human mind ought rather to be called *study* than *science*, set aside the appellation of *wise* as too assuming, and took that of *philosopher*.

History of Philosophy.

his studies and those of the natural historian, who merely enumerates phenomena, and arranges them into separate classes.

2 Its objects.

The principal objects of philosophy are, God, nature, and man. That part of it which treats of God is called *theology;* that which treats of nature, *physics* and *metaphysics;* and that which treats of man, *logic* and *ethics.* That these are not separate and independent sciences, but, as Bacon expresses it (B), branches from the same trunk, we shall endeavour to show, after we have given, agreeably to our usual plan, a short history of philosophy from the earliest ages to the present day.

To attempt to assign an *origin* to philosophy, would be ridiculous; for every man endeavours to ascertain the causes of those changes which he observes in nature; and even children themselves are inquisitive after that which produces the sound of their drums and their rattles. Children, therefore, and the most illiterate vulgar, have in all ages been philosophers. But the first people among whom philosophy was cultivated as a profession, was probably the Chaldeans. We certainly read of none earlier; for though we have more authentic accounts of the Hebrews than of any other nation of remote antiquity, and have reason to believe that no people was civilized before them, yet the peculiar circumstances in which they were placed, rendered all philosophical investigation to them useless, and even tended to suppress the very spirit of inquiry. The Egyptians indeed pretended to be the first of nations, and to have spread the blessings of religion and the light of science among every other people; but, from the earliest records now extant, there is reason to believe that the Chaldeans were a civilized and powerful nation before the Egyptian monarchy was founded.

3 Philosophy of the Chaldeans.

Of the Chaldean philosophy much has been said, but very little is known. Astronomy seems to have been their favourite study; and at the era of Alexander's conquest of their country, they boasted that their ancestors had continued their astronomical observations through a period of 470,000 years. Extravagant claims to antiquity have been common in all nations (C). Calisthenes, who attended the Macedonian conqueror, was requested by Aristotle to inform himself concerning the origin of science in Chaldea; and upon examining into the grounds of this report, he found that their observations reached no farther backwards than 1903 years, or 2234 years before the Christian era. Even this is a remoter antiquity than Ptolemy allows to their science; for he mentions no Chaldean observations prior to the era of Nabonassar, or 747 years before Christ. That they cultivated something which they called philosophy at a much earlier period than this, cannot be questioned; for Aristotle †, on the credit of the most ancient records, speaks of the Chaldean magi as prior to the Egyptian priests, who were certainly men of learning before the time of Moses. For any other science than that of the stars, we do not read that the Chaldeans were famous; and this seems to have been cultivated by them merely as the foundation of judicial astrology. Persuading the multitude that all human affairs are influenced by the stars, and professing to be acquainted with the nature and laws of this influence, their *wise men* pretended to calculate nativities, and to predict good and bad fortune *. This was the source of idolatry and various superstitions; and whilst the Chaldeans were given up to such dotages, true science could not be much indebted to their labours. If any credit be due to Plutarch and Strabo, Vitruvius, who quote Berosus, (see BEROSUS), it was the opinion of the Chaldean *wise men* that an eclipse of the moon happens when that part of its body which is destitute of fire is turned towards the earth. "Their cosmogony, as given by Berosus, and preserved by Syncellus, seems to be this, that all things in the beginning consisted of darkness and water; that a divine power dividing this humid mass, formed the world; and that the human mind is an emanation from the Divine nature †.

† *Apud Laert.* lib. I. § 8.

* *Sext. Emp. ad Math.* lib. 4. § 2. *Strabo,* lib. 100. *Cic. de Div.* lib. I. § I.

† *Enfield's Hist. Phil.* vol. i.

The large tract of country which comprehended the empires of Assyria and Chaldea, was the first peopled region on earth. From that country, therefore, the rudiments of science must have been propagated in every direction through the rest of the world; but what particular people made the earliest figure, after the Chaldeans, in the history of philosophy, cannot be certainly known. The claim of the Egyptians is probably best founded; but as their science was the immediate source of that of the Greeks, we shall defer what we have to say of it on account of the connection between the parent and the offspring, and turn our attention from Chaldean to Indian philosophy, as it has been cultivated from a very early period by the Brachmans and Gymnosophists. We pass over Persia, because we know not of any science peculiar to that kingdom, except the doctrines of the magi, which were religious rather than philosophical; and of them the reader will find some account under the words MAGI, POLYTHEISM, and ZOROASTER.

4 Indian philosophy.

From whatever quarter India received its wisdom, we are certain that its philosophers were held in high repute at a period of very remote antiquity, since they were visited by Pythagoras and other sages of ancient Greece, who travelled in pursuit of knowledge. Yet they seem to have been in that early age, as well as at present, more distinguished for the severity of their manners than for the acquisition of science; and, as Dr Enfield observes, to have more resembled modern monks than ancient

(B) Convenit igitur partiri *philosophiam* in *doctrinas* tres; *doctrinam* de *numine*, *doctrinam* de *naturâ*, *doctrinam* de *homine*. Quoniam autem partitiones *scientiarum* non sunt lineis diversis similes, quæ coeunt ad unum angulum; sed potius ramis arborum, qui conjunguntur in uno trunco, qui etiam truncus ad spatium nonnullum integer est et continuus, antequam se partiatur in ramos. *De aug. Scient.* lib. iii. cap. I.

(C) This claim of the Babylonians is thus rejected with contempt by Cicero; "Contemnamus Babylonios, et eos, qui è Caucaso cœli signa servantes, numeris, et motibus, stellarum cursus persequuntur; Condemnemus, inquam, hos aut *stultitiæ*, aut *vanitatis*, aut *imprudentiæ*, qui 470 millia annorum, ut ipsi dicunt, monumentis comprehensa continent, et mentiri judicemus, nec *seculorum* reliquorum *judicium*, quod de ipsis futurum sit, *pertimescere*." *De Divinatione*, lib. i. § 19.

cient philosophers. The brachmans or bramins, it is well known, are all of one tribe; and the most learned of them are in their own language called *Pundits* or *Pandits*. The Greek writers, however, mention a society called *Sumanæans*, who, voluntarily devoting themselves to the study of divine wisdom, gave up all private property, committed their children to the care of the state, and their wives to the protection of their relations. This society was supported at the public expence; and its members spent their time in contemplation, in conversation on divine subjects, or in acts of religion.

5
Ingrafted on religion.

The philosophy of the Indians has indeed from the beginning been engrafted on their religious dogmas, and seems to be a compound of fanatic metaphysics and extravagant superstition, without the smallest seasoning of rational physics. Very unlike the philosophers of modern Europe, of whom a great part labour to exclude the agency of mind from the universe, the Pandits of Hindostan allow no powers whatever to matter, but introduce the Supreme Being as the immediate cause of every effect, however trivial. "Brehm, *the Spirit of God*, (says one of their most revered Bramins), is absorbed in self-contemplation. The same is the mighty lord, who is present in every part of space, whose omnipresence, as expressed in the Reig Beid or Rigveda, I shall now explain. Brehm is one, and to him there is no second; such is truly Brehm. His omniscience is self-inspired or self-intelligent, and its comprehension includes every possible species. To illustrate this as far as I am able; the most comprehensive of all comprehensive faculties is omniscience; and being self-inspired, it is subject to none of the accidents of mortality, *conception*, *birth*, *growth*, *decay*, or *death*; neither is it subject to passion or vice. To it the three distinctions of time, *past*, *present*, and *future*, are not. To it the three modes of being (D) are not. It is separated from the universe, and independent of all. This omniscience is named *Brehm*. By this omniscient Spirit the operations of God are enlivened. By this Spirit also the 24 powers (E) of nature are animated? How is this? As the eye by the sun, as the pot by the fire, as iron by the magnet (F), as variety of imitations by the mimic, as fire by the fuel, as the shadow by the man, as dust by the wind, as the arrow by the spring of the bow, and as the shade by the tree; so by this Spirit the world is endued with the powers of intellect, the powers of the will, and the powers of action; so that if it emanates from the heart by the channel of the ear, it causes the perception of sounds; if it emanates from the heart by the channel of the skin, it causes the perception of touch; if it emanates from the heart by the channel of the eye, it causes the perception of visible objects; if it emanates from the heart by the channel of the tongue, it causes the perception of taste; if it emanates from the heart by the channel of the nose, it causes the perception of smell. This also invigorating the five members of action, and invigorating the five members of perception, and invigorating the five elements, and invigorating the five senses, and invigorating the three dispositions of the mind, &c. causes the creation or the annihilation of the universe, while itself beholds every thing as an indifferent spectator *."

From this passage it is plain that all the motions in the universe, and all the perceptions of man, are, according to the Bramins, caused by the immediate agency of the Spirit of God, which seems to be here considered as the soul of the world. But it appears from some papers in the Asiatic Researches, that the most profound of these oriental philosophers, and even the authors of their sacred books, believe not in the existence of matter as a separate substance, but hold an opinion respecting it very similar to that of the celebrated Berkeley. The Vêdantis (says Sir William Jones), unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of Supreme Goodness was left a moment to itself, imagine that the Deity is ever present to his work, and constantly supports a series of perceptions, which in one sense they call *illusory*, though they cannot but admit the reality of all created forms, as far as the happiness of creatures can be affected by them.

6
Admits not the separate existence of matter, and

* Prelimi. nary Disc. to Halhed's Gentoo Laws.

This is the very immaterialism of Berkeley; and in proof that it is the genuine doctrine of the Bramins, the learned president quotes the *Bhágavat*, which is believed to have been pronounced by the Supreme Being, and in which is the following sentence.

"Except the *first cause*, whatever may appear, and may not appear, in the mind, know that to be the mind's *Máyá*, or 'delusion,' as light, as darkness."

7
Teaches the metempsychosis.

We have shown elsewhere (see METAPHYSICS, N° 269.) that the metaphysical doctrines of the Bramins, respecting the human soul, differ not from those of Pythagoras and Plato; and that they believe it to be an emanation from the great soul of the world, which, after many transmigrations, will be finally absorbed in its parent substance. In proof of their believing in the metempsychosis, Mr Halhed gives us the following translation of what (he says) is a beautiful stanza in the Gëëtā: "As throwing aside his old clothes, a man puts on others that are new; so our lives, quitting the old, go to other newer animals."

8
Physics of the Bramins.

From the Bramins believing in the soul of the world not only as the *sole agent*, but as the immediate cause of every motion in nature, we can hardly suppose them to

(D) To be awake, to sleep, and to be absorbed in a state of unconsciousness—a kind of trance.

(E) The 24 powers of nature, according to the Bramins, are the five elements, *fire*, *air*, *earth*, *water*, and *akash* (a kind of subtile æther); the five members of action, the *hand*, *foot*, *tongue*, *anus*, and *male organ of generation*; the five organs of perception, the *ear*, *eye*, *nose*, *mouth*, and *skin*; the five senses, which they distinguish from the organs of sensation; the three dispositions of the mind, *desire*, *passion*, and *tranquillity*; and the power of *consciousness*.

(F) If the work from which this extract is quoted be of as great antiquity as Mr Halbed supposes, the Bramins must have been acquainted with the phenomena of magnetism at a much earlier period than any other philosophers of whom history makes mention.

History of Philosophy.

to have made any great progress in that science which in Europe is cultivated under the name of *physics*. They have no inducement to investigate the laws of nature; because, according to the first principles of their philosophy, which, together with their religion, they believe to have been revealed from heaven, every phenomenon, however regular, or however anomalous, is produced by the voluntary act of an intelligent mind. Yet if they were acquainted with the use of fire-arms 4000 years ago, as Mr Halhed seems to believe, he who made that discovery must have had a very considerable knowledge of the powers of nature; for though gunpowder may have been discovered by accident in the East, as it certainly was in the West many ages afterwards, it is difficult to conceive how mere accident could have led any man to the invention of a gun. In astronomy, geometry, and chronology too, they appear to have made some proficiency at a very early period. (See ASTRONOMY, N° 4.). Their chronology and astronomy are indeed full of those extravagant fictions which seem to be essential to all their systems; but their calculation of eclipses, and their computations of time, are conducted upon scientific principles.

9 Their astronomy.

"It is sufficiently known (says Mr Davis *) that the Hindoo division of the ecliptic into signs, degrees, &c. is the same as ours; that their astronomical year is sidereal, or containing that space of time in which the sun, departing from a star, returns to the same; that it commences on the instant of his entering the sign Aries, or rather the Hindoo constellation Mesha; that each astronomical month contains as many even days and fractional parts as he stays in each sign; and that the civil differs from the astronomical account of time only in rejecting those fractions, and beginning the year and month at sunrise, instead of the intermediate instant of the artificial day or night. Hence arises the unequal portion of time assigned to each month dependent on the situation of the sun's apsis, and the distance of the vernal equinoctial colure from the beginning of Mésha in the Hindoo sphere; and by these means they avoid those errors which Europeans, from a different method of adjusting their kalendar by intercalary days, have been subject to."

* Asiatic Researches, vol. ii.

Mr Davis observes, that an explanation of these matters would have led him beyond his purpose, which was only to give a general account of the method by which the Hindoos compute eclipses, and to show that the science of astronomy is as well known among them now as ever it was among their ancestors. This he does very completely; but in the present short historical sketch, we can neither copy nor abridge his memoir. Suffice it to say, that he has shown the practical part of the Hindoo astronomy to be founded on mathematical principles; and that the learned Pandits appear to have truer notions of the form of the earth, and the economy of the universe, than those which are ascribed to their countrymen in general.

The same writer shows likewise, that the prodigious duration which the Hindoos attribute to the world, is the result of a scientific calculation, founded indeed on very whimsical principles. "It has been common with astronomers to fix on some epoch, from which, as from a radix, to compute the planetary motions; and the ancient Hindoos chose that point of time counted back, when, according to their motions as they had determined them, they must have been in conjunction in the beginning of Mésha or Aries, and coeval with which circumstance they supposed the *creation*. This, as it concerned the planets only, would have produced a moderate term of years compared with the enormous antiquity that will be hereafter stated: but having discovered a slow motion of the nodes and apsides also, and taken it into computation, they found it would require a length of time corresponding with 1955884890 years now expired, when they were so situated, and 2364115110 years more before they would return to the same situation again, forming together the grand anomalistick period denominated a *Calpa*, and fancifully assigned as the day of Brahmá."

But though the mathematical part of the astronomy of the Pandits is undoubtedly respectable, their physical notions of the universe are in the highest degree ridiculous and extravagant. In the Vedas and Puranas, writings of which no devout Hindoo can dispute the divine authority, eclipses are said to be occasioned by the intervention of the monster *Rahu*; and the earth to be supported by a series of animals. "They suppose (says Mr Halhed) that there are 14 spheres, seven below and and six above the earth. The seven inferior worlds are said to be altogether inhabited by an infinite variety of serpents, described in every monstrous figure that the imagination can suggest. The first sphere above the earth is the immediate vault of the visible heavens, in which the sun, moon, and stars, are placed. The second is the first paradise, and general receptacle of those who merit a removal from the lower earth. The third and fourth are inhabited by the souls of those men who, by the practice of virtue and dint of prayer, have acquired an extraordinary degree of sanctity. The fifth is the reward of those who have all their lives performed some wonderful act of penance and mortification, or who have died martyrs for their religion. The highest sphere is the residence of Brahma and his particular favourites, such as those men who have never uttered a falsehood during their whole lives, and those women who have voluntarily burned themselves with their husbands. All these are absorbed in the divine essence."

10 Strange notions of the universe.

11 Ethics of the Hindoos.

On ethics, the Hindoos have nothing that can be called philosophy. Their duties, moral, civil, and religious, are all laid down in their *Vedas* and *Shasters;* and enjoined by what they believe to be divine authority, which supersedes all reasoning concerning their fitness or utility. The business of their Pandits is to interpret those books, which are extremely ancient, and written in a language that has long been unintelligible to every other order of men; but no Pandit will alter the text, however impossible to be reconciled to principles established in his own practice of astronomy. On such occasions, the usual apology for their sacred books is, that "such things may have been so formerly, and may be so still; but that for astronomical purposes, astronomical rules must be followed *." The great duties of morality have been prescribed in every religious code; and they are not overlooked in that of the Hindoos, though the highest merit that a Bramin can have consists in voluntary acts of abstinence and mortification, and in contempt of death.

* Davis's Memoir, Asiatic Researches, vol. ii.

Of

12
Philosophy of the Arabians and Chinese.

Of the ancient philosophy of the Arabians and Chinese nothing certain can be said; and the narrow limits of such an abstract as this, do not admit of our mentioning the conjectures of the learned, which contradict each other, and are all equally groundless.

There is indeed sufficient evidence that both nations were at a very early period observers of the stars; and that the Chinese had even a theory by which they foretold eclipses (see ASTRONOMY, N° 2, 3.); but there is reason to believe that the Arabians, like other people in their circumstances, were nothing more than judicial astrologers, who possessed not the smallest portion of astronomical science.

Pliny makes mention of their magi, whilst later writers tell us, that they were famous for their ingenuity in solving enigmatical questions, and for their skill in the arts of divination: but the authors of Greece are silent concerning their philosophy; and there is not an Arabian book of greater antiquity than the Koran extant (see PHILOLOGY, Section II.).

13
Early science of the Phœnicians.

Leaving therefore regions so barren of information, let us pass to the Phœnicians, whose commercial celebrity has induced many learned men to allow them great credit for early science. If it be true, as seems highly probable, that the ships of this nation had doubled the Cape and almost encompassed the peninsula of Africa long before the era of Solomon (See OPHIR, N° 10.), we cannot doubt that the Phœnicians had made great proficiency in the art of navigation, and in the science of astronomy, at a period of very remote antiquity. Nor were these the only sciences cultivated by that ancient people: the learned Cudworth has, in our opinion, sufficiently proved that *Moschus* or *Mochus* a Phœnician, who, according to Strabo, flourished before the Trojan war, was the author of the atomic philosophy afterwards adopted by Leucippus, Democritus, and others among the Greeks; and that it was with some of the successors of this sage that Pythagoras, as Jamblichus tells us, conversed at Sidon, and from them received his doctrine of *Monads* (See PYTHAGORAS). Another proof of the early progress of the Phœnicians in philosophy may be found in the fragments of their historian Sanchoniatho which have been preserved by Eusebius *. We are indeed aware that men of great celebrity have called in question the authenticity of those fragments, and even the very existence of such a writer as Sanchoniatho; but for this scepticism we can discover no foundation (See SANCHONIATHO). His history may have been interpolated in some places by the translator Philo-Byblius; but Porphyry, Eusebius, and Theodoret, speak of it as a work of undoubted credit, and affirm that its author flourished before the Trojan war. Now this ancient writer teaches that, according to the *wise men* of his country, all things arose at first from the necessary agency of an active principle upon a passive chaotic mass which he calls *mot*. This chaos Cudworth thinks was the same with the elementary *water* of Thales, who was also of Phœnician extraction; but Mosheim justly observes that it was rather *dark air*, since Philo translates it αερα ζοφωδη. Be this as it may, nothing can be more evident than that the Phœnicians must have made some progress in what must surely be considered as philosophy, however false, so early as the era of Sanchoniatho; for speculations about the origin of the world never occur to untaught barbarians. Besides Mochus and Sanchoniatho, Cadmus, who introduced letters into Greece, may undoubtedly be reckoned among the Phœnician philosophers; for though it is not pretended that the alphabet was of his invention, and though it is by no means certain that the Greeks, at the time of his arrival among them, were wholly destitute of alphabetic characters (See PHILOLOGY, N° 130.); yet the man who could prevail with illiterate savages to adopt the use of strange characters, must have been a great master of the science of human nature. Several other Phœnician philosophers are mentioned by Strabo; but as they flourished at a later period, and philosophized after the systematic mode of the Greeks, they fall not properly under our notice. We pass on therefore to the philosophy of Egypt.

* Prep. Ev.

14
Egyptian philosophy.

It has been already observed that the Egyptians boasted of being the first of nations, and the authors of all the science which in separate rays illuminated the rest of the world. But though this claim was undoubtedly ill-founded, their high antiquity and early progress in the arts of civil life cannot be controverted. The Greeks with one voice confess that all their learning and wisdom came from Egypt, either imported immediately by their own philosophers, or brought through Phœnicia by the sages of the east; and we know from higher authority than the histories of Greece, that at a period so remote as the birth of Moses, the wisdom of the Egyptians was proverbially famous. Yet the history of Egyptian learning and philosophy, though men of the first eminence both ancient and modern have bestowed much pains in attempts to elucidate it, still remains involved in clouds of uncertainty. That they had some knowledge of physiology, arithmetic, geometry, and astronomy, are facts which cannot be questioned; but there is reason to believe that even these sciences were in Egypt pushed no farther than to the uses of life. That they believed in the existence of incorporeal substances is certain; because Herodotus assures us that they were the first assertors of the immortality, pre-existence, and transmigration of human souls, which they could not have been without holding those souls to be at least *incorporeal*, if not *immaterial*.

The author of Egyptian learning is generally acknowledged to have been *Thoth*, *Theut*, or *Taaut*, called by the Greeks *Hermes*, and by the Romans *Mercury*; but of this personage very little is known. Diodorus Siculus says that he was chief minister to Osiris, and that be improved language, invented letters, instituted religious rites, and taught astronomy, music, and other arts. The same thing is affirmed by *Sanchoniatho*, whose antiquity has been already mentioned; by *Manetho* an Egyptian priest, who flourished during the reign of Ptolemy Philadelphus; and by Plato, whose authority, as he resided long in Egypt, and was himself an eminent philosopher, is perhaps more to be depended upon than that of the other two. In the Philebus we are told that Thoth was the inventor of letters; and lest we should suppose that by those letters nothing more is meant than picture writing or symbolical hieroglyphics, it is added, that he distinguished between *vowels* and *consonants*, determining the number of each. The same philosopher, in his Phædrus, attributes to Thoth the invention of *arithmetic*, *geometry*, *astronomy*, and *hieroglyphic* learning; and subjoins a disputation

disputation said to have been held between him and *Thamus* then king of Egypt, concerning the advantage and disadvantage of his newly invented letters. Thoth boasted that the invention, by aiding memory, would greatly contribute to the progress of science; whilst the monarch contended, that it would enervate men's natural faculties by making them trust to written characters without exerting the powers of their own minds.

All this, if real, must have happened before the era of Moses; and since it is almost certain that alphabetical characters were in use prior to the *exod* of the Israelites from Egypt (see PHILOLOGY, N° 24, 25.) we may as well allow the invention to Thoth, as give it to an earlier author of unknown name. That arithmetic, geometry, and astronomy, were cultivated in Egypt from the most remote antiquity, is affirmed by all the ancients, and made in the highest degree probable by the situation of the country. The first elements of astronomy have certainly been discovered by various nations, whose habits of life led them to the frequent observation of the heavens; and it is observed by Cicero, that the Egyptians and Babylonians, dwelling in open plains where nothing intercepted the view of the heavenly bodies, naturally devoted themselves to the study of that science. The annual overflowing of the Nile, which broke up the boundaries of their land, would lay the Egyptians under the necessity of adopting some method of settling those boundaries anew; and necessity we know to be the parent of invention. Hence their early acquaintance with practical geometry cannot well be doubted. Their custom of embalming their dead, and the perfection to which they carried that art (G), shows infallibly their knowledge of the properties of natural substances, and gives some reason to believe that they were not altogether strangers to anatomy: but if we allow them to have been at this early period anatomists acquainted with the power of drugs, we can hardly refuse them some skill in the art of physic, which they themselves traced up to their gods and demigods, to *Serapis*, *Isis*, and her son *Horus or Apollo*.

The art of alchymy has been said to have been known by the ancient Egyptians; and from the author of the Egyptian philosophy it has been called the *Hermetic* art. But though this is unquestionably a fiction, there is evidence that they were possessed of one art which is even yet a *desideratum* in the practice of chemistry. "Moses (we are told *) took the golden calf, which his brother had made for idolatrous purposes, and *burnt it in the fire*, and *ground it to powder*, and strewed it on the water, and made the children of Israel drink of it." Had this fact been related by Herodotus or Diodorus Siculus, it would have been deemed sufficient evidence that the Egyptians were even at that early period no strangers to the art of chemistry: and surely the evidence should not be the worse for coming from the pen of the Hebrew lawgiver, who was himself educated in the court of Egypt.

* Exod. xxxii. 20.

15 Not carried to high perfection.

But though it is thus evident that the rudiments of almost every useful science were known in Egypt from the remotest antiquity, it does not appear that any of them was carried to a great degree of perfection, unless perhaps chemistry alone must be excepted. One would think that no science could have been more indispensably requisite to them than geometry. And yet though Pythagoras is said to have spent 22 years in Egypt studying that science and astronomy, he himself discovered (H) the famous 47th Prop. of Euclid's first book after his return to Samos. This, though a very useful, is yet a simple theorem; and since it was not reached by the Egyptian geometry, we cannot suppose that those people had then advanced far in such speculations. The same conclusion must be drawn with respect to astronomy; for Thales is said to have been the first that calculated an eclipse of the sun; and we nowhere read that the *Egyptians* pretended to dispute that honour with him.

16 Their knowledge of the solar system.

To this it may be replied, that Pythagoras was in Egypt undoubtedly taught the true constitution of the solar system, and what is more extraordinary, the doctrine of comets in particular, and of their revolutions, like the other planets, round the sun (I). We grant that he was taught all this; but it was not scientifically, but dogmatically, as facts which the priests had received by tradition from their early ancestors, and of which they had never questioned the truth nor enquired into the reasons. Of this we need no better proof than that the Pythagorean system of the sun was totally neglected by the Greeks as soon as they began to frame hypotheses and to speculate in philosophy (K).

But

(G) It is true that the dissection of some mummies has lessened the high opinion long entertained of the skill of the ancient Egyptians in the art of embalming; yet it must be granted that their knowledge of antiseptic drugs was great, since it is now certainly known, even from these dissections, that by means of such drugs they contrived to preserve rags of cloth from corruption for upwards of 3000 years.

(H) This discovery he claimed; and his claim was admitted by the Greek writers without having been *directly* controverted since. An excellent mathematician, however, has shown that the equality between the square of the hypothenuse of a right-angled triangle, and the sum of the squares on the other two sides, was known to the astronomers of India at a period long prior to that of Pythagoras. Notwithstanding this, it is certainly possible that the sage of Samos may have made the discovery himself, though we think the contrary much more probable; for we agree with the able writer already mentioned, that Pythagoras, who is generally believed to have conversed with Indian brahmans as well as Egyptian priests, may have derived from them "some of the solid as well as the visionary speculations with which he delighted to instruct or amuse his disciples." See *Transactions of the Royal Society of Edinburgh*, vol. ii. Memoir xiii. Physic Class.

(I) This is recorded by Aristotle and Plutarch; and thus expressed by Ammianus Marcellinus.—" Stellas quasdam, *ceteris similes*, quarum *ortus orbitusque*, quibus sint temporibus *præstituti* humanis mentibus ignorari, lib. xxv. cap. 10.

(K) *Fixas* in supremis mundi partibus immotas persistere, et planetas his inferiores circa solem revolvi, terram pariter moveri cursu annuo, diurno vero circa axem propriam, et solem ceu focum universi in omnium centro quiescere,

History of Philosophy.

But it may seem strange, and certainly is so, that the Egyptian priests, in the days of Pythagoras, should have preserved so great a discovery of their ancestors, and at the same time have totally forgotten the principles and reasoning which led to a conclusion apparently contrary to the evidence of sense. This is a difficulty which we pretend not to remove, though the fact which involves it seems to be beyond the reach of controversy. Perhaps the following observations may throw upon it a feeble light, According to Manetho, the written monuments of the first Thoth were lost or neglected in certain civil revolutions or natural calamities which befel the kingdom of Egypt. After many ages great part of them were recovered by an ingenious interpretation of the symbols which he had inscribed upon ancient columns: and the man who made this interpretation was called the second *Thoth* or *Hermes Trismegistus*. But *thrice illustrious* as this personage was, it is at least possible that he may have been much inferior to the former Hermes, and have read his writings and transcribed his conclusions without being able to comprehend the principles or reasoning which led to those conclusions. Any man who understands Latin might translate into his own tongue the conclusions of Newton; but much more would be requisite to make him comprehend the demonstrations of his sublime geometry. By what mode of reasoning the first Hermes (L) was led to the true idea of the solar system, or whether it was by reasoning at all, cannot now be known; but it seems very evident, that when the intercourse between the Egyptians and Greeks first commenced, the wisdom of the former people consisted chiefly in the science of legislation and civil policy, and that the philosopher, the divine, the legislator, and the poet, were all united in the same person. Their cosmogony (for all the ancients who pretended to science framed cosmogonies) differed little from that of the Phœnicians already mentioned. They held that the world was produced from chaos by the energy of an intelligent principle; and they likewise conceived that there is in nature a continual tendency towards dissolution. In Plato's Timæus, an Egyptian priest is introduced describing the destruction of the world, and asserting that it will be effected by means of water and fire. They conceived that the universe undergoes a periodical conflagration; after which all things are restored to their original form, to pass again through a similar succession of changes.

17 Their moral science. *Enfield's History of Philosophy.*

"Of preceptive doctrine the Egyptians had two kinds, the one sacred, the other vulgar. The former, which respected the ceremonies of religion and the duties of the priests, was doubtless written in the sacred books of Hermes, but was too carefully concealed to pass down to posterity. The latter consisted of maxims and rules of virtue, prudence, or policy. Diodorus Siculus relates many particulars concerning the laws, customs, and manners of the Egyptians; whence it appears that superstition mingled with and corrupted their notions of morals. It is in vain to look for accurate principles of ethics among an ignorant and superstitious people. And that the ancient Egyptians merited this character is sufficiently evident from this single circumstance, that they suffered themselves to be deceived by impostors, particularly by the professors of the fanciful art of astrology; concerning whom Sextus Empiricus justly remarks, that they have done much mischief in the world, by enslaving men to superstition, which will not suffer them to follow the dictates of right reason." See EGYPT, MYSTERIES, MYTHOLOGY, &c.

18 Grecian philosophy.

From Egypt and Phœnicia philosophy passed into Greece; where it was long taught without system, as in the countries from which it was derived. Phoroneus, Cecrops, Cadmus, and Orpheus, were among the earliest instructors of the Greeks; and they inculcated Egyptian and Phœnician doctrines in detached maxims, and enforced them, not by strength of argument, but by the authority of tradition. Their cosmogonies were wholly Phœnician or Egyptian, disguised under Grecian names; and they taught a future state of rewards and punishments. The planets and the moon Orpheus conceived to be habitable worlds, and the stars to be fiery bodies like the sun: but he taught that they are all animated by divinities; an opinion which prevailed both in Egypt and the east: and it does not appear that he gave any other proof of his doctrines than a confident assertion that they were derived from some god. See ORPHEUS.

Hitherto

cere, antiquissima fuit philosophantium sententia. Ab Ægyptiis autem astrorum antiquissimis observationibus propagatam esse hanc sententiam verisimile est. Et etiam ab illis et à gentibus conterminis ad Græcos, gentem magis philologicam quam philosophicam, philosophia omnis antiquior juxta et senior manasse videtur. Subinde docuerunt Anaxagoras, Democritus, et alii nonnulli, terram in centro mundi immotam stare, et astra omnia in occasum, aliqua celerius, alia tardius moveri, idque in spatiis liberrimis. Namque orbis solidi postea ab Eudoxo, Calippo, Aristotele, introducti sunt; declinante indies philosophia primitus introducta, et novis Græcorum commentis paulatim prævalentibus. Quibus *vinculis* ANTIQUI planetas in spatiis liberis retineri, deque cursu rectilineo perpetuo retractas in orbem regulariter agi docuere, non constat. *Newton de Mundi Systemate.*

(L) Some authors, deeply skilled in the Hebrew language, have thought that the true system of the sun and planets may be perceived in the Scriptures of the Old Testament, and that it is only from ignorance or carelessness of the translators that it does not appear in the English bible and other versions. The writer of this article confesses that his knowledge of the Hebrew is very limited, which is probably the reason that to him the arguments of these men appear weak and their criticisms fanciful. No man, however, has a higher veneration than he for the sacred volume, which he believes to have been given for nobler purposes that to teach its readers the science of astronomy; but could the principles of that science be found in it, he should be strongly inclined to think that the first Thoth was Joseph, and that the monarch to whom he was minister was the far-famed Osiris. Were there any solid foundation for this supposition, it would be easy to conceive how Thoth acquired his science, and how the Egyptian priests might retain just notions of the solar system in general, long after they had forgotten the evidence upon which he communicated those notions to their ancestors.

Hitherto we have seen philosophy in its state of infancy and childhood, consisting only of a collection of sententious maxims and traditionary opinions; but among the Greeks, an ingenious and penetrating people, it soon assumed the form of profound speculation and systematic reasoning. Two eminent philosophers arose nearly at the same period, who may be considered as the parents not only of Grecian science, but of almost all the science which was cultivated in Europe prior to the era of the great Lord Bacon: These were Thales and Pythagoras; of whom the former founded the Ionic school and the latter the Italic; from which two sprung the various sects into which the Greek philosophers were afterwards divided. A bare enumeration of these sects is all that our limits will admit of; and we shall give it in the perspicuous language and just arrangement of Dr Enfield, referring our readers for a fuller account than we can give of their respective merits to his abridged translation of Brucker's history.

19 The Ionic school.

Of the Ionic School were, 1. The Ionic sect proper, whose founder Thales had as his successors Anaximenes, Anaxagoras, Diogenes Apolloniates, and Archelaus. 2. The Socratic school, founded by Socrates, the principal of whose disciples were Xenophon, Æschines, Simon, Cebes, Aristippus, Phædo, Euclid, Plato, Antisthenes, Critias, and Alcibiades. 3. The Cyrenaic sect, of which Aristippus was the author; his followers were, his daughter Arete, Hegisias, Anicerris, Theodorus, and Bion. 4. The Megaric or Eristic sect, formed by Euclid of Megara; to whom succeeded Eubulides, Diodorus, and Stilpo, famous for their logical subtlety. 5. The Eliac or Eretriac school, raised by Phædo of Elis, who, though he closely adhered to the doctrine of Socrates, gave name to his school. His successors were Plistanus and Menedemus; the latter of whom, being a native of Eretria, transferred the school and name to his own country. 6. The Academic sect, of which Plato was the founder. After his death, many of his disciples deviating from his doctrine, the school was divided into the old, new, and middle academies. 7. The Peripatetic sect, founded by Aristotle, whose successors in the Lyceum were Theophrastus, Strato, Lycon, Aristo, Critolaus, and Diodorus. Among the Peripatetics, besides those who occupied the chair, were also Dicæarchus, Eudemus, and Demetrius Phalereus. 8. The Cynic sect, of which the author was Antisthenes, whom Diogenes, Onesicritus, Crates, Metrocles, Menippus, and Menedemus, succeeded. In the list of Cynic philosophers must also be reckoned Hipparchia, the wife of Crates. 9. The Stoic sect, of which Zeno was the founder. His successors in the porch were Persæus, Aristo of Chios, Herillus, Sphærus, Cleanthus, Chrysippus, Zeno of Tarsus, Diogenes the Babylonian, Antipater, Panætius, and Posidonius.

20 The Italic school.

Of the Italic School were, 1. The Italic sect proper: it was founded by Pythagoras, a disciple of Pherecydes. The followers of Pythagoras were Aristæus, Mnesarchus, Alcmæon, Ecphantus, Hippo, Empedocles, Epicharmus, Ocellus, Timæus, Archytas, Hippasus, Philolaus, and Eudoxus. 2. The Eleatic sect, of which Xenophanes was the author: his successors, Parmenides, Melissus, Zeno, belonged to the metaphysical class of this sect; Leucippus, Democritus, Protagoras, Diagoras, and Anaxarchus, to the physical. 3. The Heraclitean sect, which was founded by Heraclitus, and soon afterwards expired: Zeno and Hippocrates philosophised after the manner of Heraclitus, and other philosophers borrowed freely from his system. 4. The Epicurean sect, a branch of the Eleatic, had Epicurus for its author; among whose followers were Metrodorus, Polyænus, Hermachus, Polystratus, Basilides, and Protarchus. 5. The Pyrrhonic or Sceptic sect, the parent of which was Pyrrho: his doctrine was taught by Timon the Phliasian; and after some interval was continued by Ptolemy a Cyrenean, and at Alexandria by Ænesidemus.

Of the peculiar doctrines of these sects, the reader will in this work find a short account either in the lives of their respective founders, or under the names of the sects themselves. We shall only observe at present, that though many of them were undoubtedly absurd, and many wicked, it would yet perhaps be going too far to say with some, that the philosophy of Greece became impious under Diagoras, vicious under Epicurus, HYPOCRITICAL UNDER ZENO, impudent under Diogenes, covetous under Demochares, voluptuous under Metrodorus, fantastical under Crates, scurrilous under Menippus, licentious under Pyrrho, and quarrelsome under Cleanthes. Of the truth of this heavy charge every reader must judge for himself. We are strongly inclined to think, that there were virtues and vices peculiar to each sect; "and that the sects themselves had an affinity more or less direct with the different temperaments of man; whence the choice of sectators often depended on physical influence, or a peculiar disposition of their organs. Nothing appears more natural than that those men who were born with great force of mind and strong nerves should discover a predilection for stoicism; while mortals, endowed by nature with more delicacy of fibres and keener sensibility, fled for refuge to the myrtles of Epicurus. People whose temperaments partook of no extremes, were always inclined either for the Lyceum or the Academy. Such as possessed solidity of understanding ranged themselves with Aristotle; and those who had only genius, or even pretensions to that endowment, went to augment the crowd of Platonists."

Pauw's Philosophical Dissertation, &c.

21 Grecian mode of philosophizing.

All the systematical philosophers, however, pursued their inquiries into nature by nearly the same method. Of their philosophy, as well as of ours, the universe, with all that it contains, was the vast object; but the individuals things which compose the universe are infinite in number and ever changing; and therefore, according to an established maxim of theirs, incapable of being the subjects of human science *. To reduce this infinitude, and to fix those fleeting beings, they established certain definite arrangements or classes, to some of which every thing past, present, or to come, might be referred; and having ascertained, as they thought, all that could be affirmed or denied of these classes, they proved, by a very short process of syllogistic reasoning, that what is true of the class must be true of every individual comprehended under it. The most celebrated of these arrangements is that which is known by the name of *categories;* which Mr Harris thinks at least as old as the era of Pythagoras, and to the forming of which mankind would, in his opinion, be necessarily led by the following considerations: Every subject of human thought is either *substance* or *attribute;* but *substance* and *attribute* may each of them be

22 The categories.

* *Boeth. in Prædic. et Arist. Physic. lib. i.*

4

be modified under, the different characters of *universal* or *particular*. Hence there arises a quadruple arrangement of things into *substance universal* and *substance particular*; into *attribute universal* and *attribute particular*; to some one of *which four* not only our words and ideas, but every individual of that immense multitude of things which compose the universe, may be deduced. This arrangement, however, the learned author thinks too limited; and he is of opinion, that, by attending to the substances with which they were surrounded, the Grecian schools must soon have distinguished between the attributes *essential* to all substances and those which are only *circumstantial*; between the attributes proper to *natural* substances or bodies, and those which are peculiar to *intelligible* substances or minds. He likewise thinks, that the *time* and *place* of the existence of substances not present, must soon have attracted their attention; and that in considering the place of this or that substance, they could hardly avoid thinking of its *position* or *situation*. He is of opinion, that the superinduction of one substance upon another would inevitably suggest the idea of *clothing* or *habit*, and that the variety of *co-existing substances* and *attributes* would discover to them another attribute, viz. that of *relation*. Instead therefore of confining themselves to the simple division of *substance* and *attribute*, they divided *attribute* itself into nine distinct sorts, some *essential* and others *circumstantial*; and thus by setting substance at their head, made ten *comprehensive universal genera*, called, with reference to their Greek name, *categories*, and with reference to their Latin name *predicaments*. These categories are, SUBSTANCE, QUALITY, QUANTITY, RELATION, ACTION, PASSION, WHEN, WHERE, POSITION, and HABIT; which, according to the systematic philosophy of the Greeks, comprehend every human science and every subject of human thought. *History*, natural and civil, springs, says Mr Harris, out of SUBSTANCE; *mathematics* out of QUANTITY; *optics* out of QUALITY and QUANTITY; *medicine* out of the *same*; *astronomy* out of QUANTITY and MOTION; *music* and *mechanics* out of the *same*; *painting* out of QUALITY and SITE; *ethics* out of RELATION; *chronology* out of WHEN; *geography* out of WHERE; *electricity*, *magnetism*, and *attraction*, out of ACTION and PASSION; and so in other instances.

To these categories, considered as a mere arrangement of science, we are not inclined to make many objections. The arrangement is certainly not complete: but this is a matter of comparatively small importance; for a complete arrangement of science cannot, we be-
23 and predicables. lieve, be formed. The greatest objection to the categories arises from the use that was made of them by almost every philosopher of the Grecian schools; for those sages having reduced the objects of all human science to ten general heads or general terms, instead of setting themselves to inquire by a painful induction into the nature and properties of the real objects before them, employed their time in conceiving what could be predicated of *substance* in general, of this or that *quality*, *quantity*, *relation*, &c. in the abstract: and they soon found, that of such general conceptions as the *categories* there are but five *predicables* or *classes* of *predicates* in nature. The first class is that in which the *predicate* is the *genus* of the *subject*; the second, that in which it is the *species* of the *subject*; the third, is when the *predicate* is the *specific difference* of the *subject*; the fourth, when it is a *property* of the *subject*; and the fifth, when it is something *accidental* to the *subject* (see LOGIC, Part II. chap. ii. and iii.). Having proceeded thus far in their system, they had nothing to do with individuals but to arrange them under their proper categories, which was commonly done in a very arbitrary manner; and then, with the formality of a syllogism, to predicate of each the predicable of the genus or species to which it belonged. But by this method of proceeding, it is obvious that no progress whatever could be made in physical, metaphysical, or ethical science; for if the individual truly belongs to the
category under which it is arranged, we add nothing to 24 are no instruments of science.
our stock of knowledge by affirming or denying of it what we had before affirmed or denied of the whole genus: and if it belong not to the category under which we arrange it, our syllogising will only give the appearance of proof to what must, from the nature of things, be an absolute falsehood. It is only by experiments made on various substances apparently of the same kind that they can be certainly known to belong to the same category; and, when this is done, all syllogistic reasoning from the genus to the species, and from the species to the individual, is but solemn trifling, as every proposition in this retrograde course takes for granted the thing to be proved.

Yet this mode of philosophizing spread from Greece 25 This philosophy disseminated through the whole world.
almost over the whole world. It was carried by Alexander into Asia, by his successors into Egypt, and it found its way to Rome after Greece became a province of the empire. It was adopted by the Jews, by the fathers of the Christian church, by the Mahommedan Arabs during the caliphate, and continued to be cultivated by the schoolmen through all Europe, till its futility was exposed by Lord Bacon (M). The professors of this philosophy often displayed great acuteness; but their systems were built on mere hypotheses, and supported by syllogistic wrangling. Now and then indeed a superior genius, such as Alhazen and our countryman Roger Bacon, broke through the trammels of the schools, and, regardless of the authority of the Stagyrite and his *categories*, made real discoveries in physical science by experiments judiciously conducted on individual substances (see BACON, *Roger*; and OPTICS, N° 6.); but the science in repute still continued to be that of *Generals*.

It was indeed a combination of absurd metaphysics with more absurd theology; and that which is properly called *physics*, had in Europe no place in a liberal education from the end of the eighth century to the end of the fourteenth. Towards the beginning of this period of darkness, the whole circle of instruction, or the

(M) Scientiæ, quas habemus, fere à Græcis fluxerunt. Quæ enim scriptores Romani, aut Arabes, aut recentiores addiderunt, non multa aut magni momenti sunt: et qualiacunque sint, fundata sunt super basin eorum quæ inventa sunt à Græcis. *Bacon.*

History of Philosophy. the liberal arts as they were called, consisted of two branches, the *trivium* and the *quadrivium*; of which the former comprehended *grammar*, *rhetoric*, and *dialectics*; the latter *music*, *arithmetic*, *geometry*, and *astronomy*, to which was added, about the end of the eleventh century, the study of a number of *metaphysical subtleties* equally useless and unintelligible.

Hitherto the works of the ancient Greek philosophers had been read only in imperfect Latin translations; and before the scholastic system was completely established, Plato and Aristotle had been alternately looked up to as the oracle in science. The rigid schoolmen, however, universally gave the preference to the Stagyrite; because his analysis of body into matter and form is peculiarly calculated to keep in countenance the most incredible doctrine of the Romish church (see TRANSUBSTANTIATION): and upon the revival of Greek learning, this preference was continued after the school philosophy had begun to fall into contempt, on account of much useful information contained in some of his writings on subjects of natural history, and his supposed merit as a natural philosopher. At last the intrepid spirit of Luther and his associates set the minds of men free from the tyranny of ancient names, as well in human science as in theology; and many philosophers sprung up in different countries of Europe, who professed either to be *eclectics*, or to study nature, regardless of every authority but that of reason. Of these the most eminent beyond all comparison was Francis Bacon Lord Verulam.

26 exposed as futile by Lord Bacon; This illustrious man having read with attention the writings of the most celebrated ancients, and made himself master of the sciences which were then cultivated, soon discovered the absurdity of pretending to account for the phenomena of nature by syllogistic reasoning from hypothetical principles; and with a boldness becoming a genius of the first order, undertook to give a new chart of human knowledge. This he did in his two admirable works, intitled, 1. *De dignitate et augmentis scientiarum*; and, 2. *Novum organum scientiarum*, sive *Judicia vera de interpretatione Naturæ*. In the former of these works, he takes a very minute survey of the whole circle of human science, which he divides into three great branches, *history*, *poetry*, and *philosophy*, corresponding to the three faculties of the mind, *memory*, *imagination*, and *reason*. Each of these general heads is subdivided into minuter branches, and reflections are made upon the whole, which, though we can neither copy nor abridge them, will amply reward the perusal of the attentive reader.

27 who establishes a better method of inquiry. The purpose of the *Novum Organum* is to point out the proper method of interpreting nature; which the author shows can never be done by the logic which was then in fashion, but only by a painful and fair induction. "Homo naturæ minister (says he) et interpres tantum facit et intelligit, quantum de naturæ ordine re, vel mente observaverit; nec amplius scit aut potest. Syllogismus ad principia scientiarum non adhibetur, ad media axiomata frustra adhibetur, cum sit subtilitati naturæ longe impar. Assensum itaque constringit, non res. Syllogismus ex propositionibus constat, propositiones ex verbis, verba notionum tesseræ sunt. Itaque si notiones ipsæ (id quod basis rei est) confusæ sint et temere à rebus abstractæ, nihil in iis quæ superstruuntur, est firmitudinis. Itaque spes est una in *inductione vera*."

View of Bacon's Philosophy. To hypotheses and preconceived opinions, which he calls *idola theatri*, this great man was not less inimical than to syllogisms; and since his days almost every philosopher of eminence, except Descartes and his followers (see DESCARTES and CARTESIANS) has professed to study nature according to the method of induction so accurately laid down in the *Novum Organum*. On this method a few improvements have perhaps been made; but notwithstanding these, Lord Bacon must undoubtedly be considered as the author of that philosophy which is now cultivated in Europe, and which will continue to be cultivated as long as men shall have more regard for matters of fact than for hypothetical opinions. Of this mode of philosophising we shall now give a short, though we hope not inaccurate, view, by stating its objects, comparing it with that which it superseded, explaining its rules, and pointing out its uses; and from this view it will appear, that its author shares with Aristotle the empire of science.

THE universe, that unbounded object of the contemplation, the curiosity, and the researches of man, may be considered in two different points of view. 28 View of his philosophy.

In the first place, it may be considered merely as a collection of existences, related to each other by means of resemblances and distinction, situation, succession, and derivation, as making parts of a whole. In this view it is the subject of pure description.

To acquire an acquaintance with, or a knowledge of, the universe in this point of view, we must enumerate all the beings in it, mention all their sensible qualities, and mark all these relations for each. But this would be labour immense; and when done, an undistinguishable chaos. A book containing every word of a language would only give us the materials, so to speak, of this language. To make it comprehensible, it must be put into some form, which will comprehend the whole in a small compass, and enable the mind to pass easily from one word to another related to it. Of all relations among words, the most obvious are those of resemblance and derivation. An etymological dictionary, therefore, in which words are classed in consequence of their resemblances, and arranged by means of their derivative distinctions, will greatly facilitate the acquisition of the language.

Just so in nature: The objects around us may be grouped by means of their resemblance, and then arranged in those groups by means of their distinctions and other relations. In this classification we are enabled to proceed by means of our faculty of abstracting our attention from the circumstances in which things differ, and turning it to those only in which they agree. By the judicious employment of this faculty we are able not only to distribute the individuals into classes, but also to distribute those classes into others still more comprehensive, by discovering circumstances of resemblance among them: for the fewer the circumstances are which concur to form that resemblance which has engaged our attention, the greater is the number of similar circumstances which are neglected; and the more extensive will be the class of individuals in which the resemblance is observed. Thus 29 Natural history. a number of individuals resembling each other in the single

View of Bacon's Philosophy.

single circumstance of life, composes the most extensive KINGDOM of ANIMALS. If it be required, that they shall further resemble in the circumstance of having feathers, a prodigious number of animals are excluded, and we form the inferior *class* of BIRDS. We exclude a great number of birds, by requiring a further similarity of web feet, and have the *order* of ANSERES. If we add lingua ciliata, we confine the attention to the *genus* of ANATES. In this manner may the whole objects of the universe be grouped, and arranged into kingdoms, classes, orders, genera, and species.

Such a classification and arrangement is called NATURAL HISTORY; and must be considered as the only foundation of any extensive knowledge of nature. To the natural historian, therefore, the world is a collection of existences, the subject of descriptive arrangement. His aim is threefold.

1. To observe with care, and describe with accuracy, the various objects of the universe.

2. To determine and enumerate all the great classes of objects; to distribute and arrange them into all their subordinate classes, through all degrees of subordination, till he arrive at what are only accidental varieties, which are susceptible of no farther distribution; and to mark with precision the principles of this distribution and arrangement, and the characteristics of the various assemblages.

3. To determine with certainty the particular group to which any proposed INDIVIDUAL belongs.

DESCRIPTION, therefore, ARRANGEMENT, and REFERENCE, constitute the whole of his employment; and in this consists all his science.

30 distinguished from philosophy.

Did the universe continue unchanged, this would constitute the whole of our knowledge of nature: but we are witnesses of an uninterrupted succession of changes, and our attention is continually called to the EVENTS which are incessantly happening around us. These form a set of objects vastly more interesting to us than the former; being the sources of almost all the pleasures or pains we receive from external objects.

We are therefore much interested in the study of the events which happen around us, and strongly incited to prosecute it: but they are so numerous and so multifarious, that the study would be immense, without some contrivance for abbreviating and facilitating the task. The same help offers itself here as in the study of what may be called *quiescent nature*. Events, like existences, are susceptible of classification, in consequence of resemblances and distinction; and by attention to these, we can acquire a very extensive acquaintance with active nature. Our attention must be chiefly directed to those circumstances in which many events resemble each other, while they differ perhaps in a thousand others. Then we must attend to their most general distinctions; then to distinctions of smaller extent, and so on.

It is in this way accordingly that we have advanced in our knowledge of active nature, and are gradually, and by no means slowly, forming assemblages of events more and more extensive, and distributing these with greater and greater precision into their different classes.

In the zealous and attentive prosecution of this task a very remarkable and interesting observation occurs: In describing those circumstances of similarity among events, and particularly in distributing them according to those similarities, it is impossible for us to overlook that constancy which is observed in the changes of nature in the events which are the objects of our contemplation. Events which have once been observed to accompany each other are observed always to do so.

31 Constancy in the changes of nature

The rising of the sun is always accompanied by the light of day, and his setting by the darkness of night. Sound argument is accompanied by conviction, impulse by motion, kindness by a feeling of gratitude, and the perception of good by desire. The unexcepted experience of mankind informs us, that the events of nature go on in certain regular trains; and if sometimes exceptions seem to contradict this general affirmation, more attentive observation never fails to remove the exception. Most of the spontaneous events of nature are very complicated; and it frequently requires great attention and penetration to discover the simple event amidst a crowd of unessential circumstances which are at once exhibited to our view. But when we succeed in this discovery, we never fail to acknowledge the perfect uniformity of the event to what has been formerly observed.

32 universally expected.

But this is not all: We firmly *believe* that this uniformity will *still continue*; that fire will melt wax, will burn paper, will harden clay, as we have formerly observed it to do; and whenever we have undoubted proofs that the circumstances of situation are precisely the same as in some former case, though but once observed, we expect with irresistible and unshaken confidence that the event will also be the same.

It is not surely necessary to adduce many proofs of the universality of this law of human thought. The whole language and actions of men are instances of the fact. In all languages there is a mode of construction which is used to express this relation as distinct from all others, and the conversation of the most illiterate never confounds them, except when the conceptions themselves are confounded. The general employment of the active and passive verb is regulated by it. *Turris eversa est à militibus; turris eversa est terræ motu*, express two relations, and no schoolboy will confound them. The distinction therefore is perceived or felt by all who can speak grammatically. Nor is any language without general terms to express this relation, cause—effect—to occasion. Nay, it is a fact in the mind of brutes, who hourly show that they expect the same uses of every subject which they formerly made of it; and without this, animals would be incapable of subsistence, and man incapable of all improvement. From this alone memory derives all its value; and even the constancy of natural operation would be useless if not matched or adapted to our purposes by this expectation of any confidence in that constancy.

After all the labours of ingenious men to discover the foundation of this irresistible expectation, we must be contented with saying that such is the constitution of the human mind. It is an *universal fact* in human thought; and for any thing that has been yet discovered, it is an *ultimate* fact, not included in any other still more general. We shall soon see that this is sufficient for making it the foundation of true human knowledge; all of which must in like manner be reduced to ultimate facts in human thought.

We must consider this undoubted feeling, this persuasion of the constancy of nature, as an *instinctive* anticipation of events similar to those which we have already

View of Bacon's Philosophy.

already experienced. The general analogy of nature should have disposed philosophers to acquiesce in this, however unwelcome to their vanity. In no instance of essential consequence to our safety or well-being are we left to the guidance of our boasted reason; God has given us the surer conduct of natural instincts. No case is so important as this: In none do we so much stand in need of a guide which shall be powerful, infallible, and rapid in its decisions. Without it we must remain incapable of all instruction from experience, and therefore of all improvement.

Our sensations are undoubtedly feelings of our mind. But all those feelings are accompanied by an instinctive reference of them to something distinct from the feelings themselves. Hence arises our perception of external objects and our very notions of this externeity (pardon the term). In like manner, this anticipation of events, this irresistible connection of the idea of fire with the idea of burning, is also a feeling of the mind: and this feeling is by a law of human nature referred, without reasoning, to something external as its cause; and, like our sensation, it is considered as a *sign* of that external something. It is like the conviction of the truth of a mathematical proposition. This is referred by us to something existing in nature, to a necessary and external relation subsisting between the ideas which are the subjects of the proposition. The conviction is the sign or indication of this relation by which it is brought to our view. In precisely the same manner, the irresistible connection of ideas is interpreted as the sensation or sign of a *necessary connection* of external things or events. These are supposed to include something in their nature which renders them inseparable companions.

33 Our knowledge of causation.

To this bond of connection between external things we give the name of CAUSATION. All our knowledge of this relation of cause and effect, is the knowledge or consciousness of what passes in our own minds during the contemplation of the phenomena of nature. If we adhere to this view of it, and put this branch of knowledge on the same footing with those called the *abstract sciences*, considering only the *relations* of ideas, we shall acquire *demonstrative science*. If we take any other view of the matter, we shall be led into inextricable mazes of uncertainty and error.

We see then that the natural procedure of our faculty of abstraction and arrangement, in order to acquire a more speedy and comprehensive knowledge of natural events, presents them to our view in another form. We not only see them as *similar* events, but as events naturally and necessarily *conjoined*. And the expression of *resemblance* among events is also an expression of *concomitancy*; and this arrangement of events in consequence of their resemblance is in fact the *discovery* of those accompaniments. The trains of natural appearance being considered as the appointments of the Author of Nature, has occasioned them to be considered also as consequences of *laws* imposed on his works by their great author, and every thing is said to be regulated by fixed laws. But this is the language of analogy.

34 Laws of nature explained.

When a sovereign determines on certain trains of conduct for his subjects, he issues his orders. These orders are laws. He inforces the observance of them by his authority; and thus a certain regularity and constancy of conduct is produced. But should a stranger, ignorant of the promulgation of these laws, and of the exerted authority of the magistrate, observe this uniformity of conduct, he would ascribe it to the genius and disposition of the people; and his observation would be as useful to him for directing the tenor of his own conduct, as the knowledge of the subject himself of the real source of this constancy is for directing his.

Just so in nature, while the theologian pretends, from his discoveries concerning the existence and superintendance of God, to know that the constant accompaniment of events is the consequence of laws which the great Author and Governor of the universe has imposed on his works, the ordinary philosopher, a stranger to this scene, and to the unsearchable operations of the SUPREME MIND, must ascribe this constancy to the nature of the things. There is a great resemblance between the expression *natural law* and *grammatical rule*. Rule in strict language implies command; but in grammar it expresses merely a generality of *fact*, whether of flexion or construction. In like manner, a LAW OF NATURE is to the philosopher nothing but the expression of a generality of fact. A natural or physical law is a generally observed fact; and whenever we treat any subject as a generally observed fact, we treat it physically. It is a physical law of the understanding that argument is accompanied by conviction; it is a physical law of the affection that distress is accompanied by pity; it is a physical law of the material world that impulse is accompanied by motion.

And thus we see that the arrangement of events, or the discovery of those general points of resemblance, is in fact the discovery of the laws of nature; and one of the greatest and most important is, that the laws of nature are constant.

There is no question that this view of the universe is incomparably more interesting and important than that which is taken by the natural historian; contemplating every thing that is of value to us, and, in short, the whole life and movement of the universe. This study, therefore, has been dignified with the name of PHILOSOPHY and of SCIENCE; and natural history has been considered as of importance only in so far as it was conducive to the successful prosecution of philosophy. 35 Object of philosophy.

But the philosopher claims a superiority on another account: he considers himself as employed in the discovery of causes, saying that philosophy is the study of the objects of the universe as related by causation, and that it is by the discovery of these relations that he communicates to the world such important knowledge. Philosophy, he says, is the science of causes. The vulgar are contented to consider the prior of two inseparably conjoined events as the cause of the other; the stroke on a bell, for instance, as the cause of sound. But it has been clearly shown by the philosopher, that between the blow on the bell and the sensation of sound there are interposed a long train of events. The blow sets the bell a trembling; this agitates the air in contact with the bell; this agitates the air immediately beyond it; and thus between the bell and the ear may be interposed a numberless series of events, and as many 36 Causes. more between the first impression on the ear and that last impression on the nerve by which the mind is affected. He can no longer therefore follow the nomenclature of the vulgar. Which of the events of this train therefore is the cause of the sensation? None of them:

View of Bacon's Philosophy.

them: It is that *something* which inseparably connects any two of them, and constitutes their bond of union. These bonds of union or causes he considers as residing in one or both of the connected objects: diversities in this respect must therefore constitute the most important distinctions between them. They are therefore with great propriety called the *qualities*, the *properties* of these respective subjects.

As the events from which we infer the existence of these qualities of things resemble in many respects such events as are the consequences of the exertion of our own powers, these qualities are frequently denominated POWERS, forces, energies. Thus, in the instance just now given of the sound of a bell, we infer the powers of impulse, elasticity, nervous irritability, and animal sensibility.

In consequence of this inference of a necessary connection between the objects around us, we not only infer the posterior event from the prior, or, in common language, the effect from the cause, but we also infer the prior from the posterior, the cause from the effect. We not only expect that the presence of a magnet will be followed by certain motions in iron-filings, but when we observe such motions, we infer the presence and agency of a magnet. Joy is inferred from merriment, poison from death, fire from smoke, and impulse from motion. And thus the appearances of the universe are the indications of the powers of the objects in it. Appearances are the language of nature, informing us of their causes. And as all our knowledge of the sentiments of others is derived from our confidence in their veracity; so all our knowledge of nature is derived from our confidence in the constancy of natural operations. A veracity and credulity necessarily resulting from that law of our mental constitution by which we are capable of speech, conduct us in the one case; and the constancy of nature, and the principle of induction, by which we infer general laws from particular facts, conduct us in the other. As human sentiment is inferred from language, and the existence of external things from sensation; so are the laws of nature, and the powers of natural objects, inferred from the phenomena. It is by the successful study of this language of nature that we derive useful knowledge. The knowledge of the influence of motives on the mind of man enables the statesman to govern kingdoms, and the knowledge of the powers of magnetism enables the mariner to pilot a ship through the pathless ocean.

37 inferred from effects.

Such are the lofty pretensions of philosophy. It is to be wished that they be well founded; for we may be persuaded that a mistake in this particular will be fatal to the advancement of knowledge. An author of great reputation † gives us an opportunity of deciding this question in the way of experiment. He says that the ancients were philosophers, employed in the discovery of causes, and that the moderns are only natural historians, contenting themselves with observing the laws of nature, but paying no attention to the causes of things. If he speak of their *professed* aim, we apprehend that the assertion is pretty just in general. With very few exceptions indeed it may be affirmed of his favourite Aristotle, the philosopher κατ' 'εξοχην, and of Sir Isaac Newton. We select these two instances, both because they are set in continual opposition by this author, and because it will be allowed that they were the most eminent students of nature (for we must not yet call them philosophers) in ancient and modern times. Aristotle's professed aim, in his most celebrated writings, is the investigation of causes; and in the opinion of this author, he has been so successful, that he has hardly left any employment for his successors beside that of commenting upon his works. We must on the other hand acknowledge that Newton makes no such pretensions, at least in that work which has immortalized his name, and that his professed aim is merely to investigate the *general* laws of the planetary motions, and to apply these to the explanation of particular phenomena. Nor will we say that he has left no employment for succeeding inquirers; but on the contrary, confess that he has only begun the study, has discovered but one law, and has enabled us to explain only the phenomena comprehended in it alone. But he has not been unsuccessful; his investigation has been complete; and he has discovered, beyond all possibility of contradiction, a *fact* which is observed through the whole extent of the solar system; namely, that every body, nay, that every particle in it, is continually DEFLECTED toward every other body; and that every deflection is, in every instance, proportional to the quantity of matter in that body toward which the deflection is directed, and to the reciprocal of the square of the distance from it. He has therefore discovered a physical law of immense extent. Nor has he been less successful in the explanation of particular phenomena. Of this there cannot be given a better instance than the explanation of the lunar motions from the theory of gravity begun by Newton "Mathesi sua facem præferente;" and now brought to such a degree of perfection, that if the moon's place be computed from it for any moment within the period of two thousand years back, it will not be found to differ from the place on which she was actually observed by one hundredth part of her own breadth.

† *Ancient Metaphysics.*

38 Discoveries of Aristotle and Newton compared.

Discimus hinc tandem qua causa argentea Phœbe
Passibus haud æquis eat, et cur, subdita nulli
Hactenus astronomo, numerorum frena recusat.
Quæ toties animos veterum torsere sophorum,
Quæque scholas hodie rauco certamine vexant,
Obvia conspicimus, nube pellente mathesi;
Qua superos penetrare domos, et ardua cœli
Newtoni auspiciis jam dat contingere templa.

We may now desire the champions of the science of causes to name any one cause which has really been discovered by their great master, whether in the operations of mind or of body. But they must not on this occasion adduce the investigation of any natural law, in which he has sometimes succeeded. With still greater confidence may we challenge them to produce any remarkable instance of the explanation of natural phenomena either of mind or body. By explanation we mean an account of the production, and an appreciation of all the circumstances, susceptible of a scrupulous comparison with fact, and perfectly consistent with it. It is here that the weakness of this philosopher's pretensions is most conspicuous; and his followers candidly acknowledge, that in the inquiries which proceed by experiment, we have not derived great assistance from Aristotle's philosophy. But this, say they, does not derogate from the pre-eminence of his philosophy, because he has shown that the *particular* fields of observation are to be cultivated only by means of experiment. But surely every field of *observation* is particular. There is no abstract

View of Bacon's Philosophy.

abstract object of philosophical research, the study of which shall terminate in the philosophy of universals. In every kind of inquiry, that cause alone must be supposed to act which we understand so far as to be able to appreciate its effects in particular circumstances, and compare them with fact, and see their perfect coincidence. If we have discovered causes, they are *known* as far as they are discovered. Their genuine effects are known, and therefore the phenomena which result from their agency are understood. When therefore it is acknowledged, as it must be acknowledged, that mankind have made but little advances in the knowledge of nature, notwithstanding the pretended discovery of causes by Aristotle, and the conducting clue of his philosophy, till of late years; and when it is also allowed that *now*, while we are every day making great additions to this subordinate knowledge, the causes which Aristotle has discovered are forgotten, and his philosophy is neglected; there is great room for suspecting (to say the least), that either the causes which philosophy pretends to have discovered are not real, or that Aristotle and his followers have not aimed at the discovery of causes, but only at the discovery of natural laws, and have failed in the attempt.

39 Philosophical causes discovered

There seems here to be a previous question: *Is it possible to discover a philosophical cause*, that something which is neither the prior nor the posterior of the two *immediately* adjoining events, but their bond of union, and this distinct from the union itself? It is evident that this is an inquiry purely experimental. It is of *human knowledge* we speak. This must depend on the nature of the human mind. This is a matter of contingency, known to us only by experiment and observation. By observing all the feelings and operations of the mind, and classing and arranging them like any other object of science, we discover the general laws of human thought and human reasoning; and this is all the knowledge we can ever acquire of it, or of any thing else.

Much has been written on this subject. The most acute observation and sound judgment have been employed in the study; and we may venture to say, that considerable progress has been made in pneumatology. Many laws of human thought have been observed, and very distinctly marked; and philosophers are busily employed, some of them with considerable success, in the distribution of them into subordinate classes, so as to know their comparative extent, and to mark their distinguishing characters with a precision similar to what has been attained in botany and other parts of natural history; so that we may hope that this study will advance like others. But in all these researches, no phenomena have occurred which look like the perception or contemplation of these separate objects of thought, these philosophical causes, this POWER in abstracto. No philosopher has ever pretended to state such an object of the mind's observation, or attempted to group them into classes.

40 in the events.

We may say at once, without entering into any detail, that those causes, those bonds of necessary union between the naturally conjoined events or objects, are not only perceived *by means* of the events alone, but are perceived solely *in* the events, and cannot be distinguished from the conjunctions themselves. They are neither the objects of separate observation, nor the productions of memory, nor inferences drawn from reflection on the laws by which the operation of our own minds are regulated; nor can they be derived from other perceptions in the way of argumentative inference. We cannot infer the paroxysm of terror from the appearance of impending destruction, or the fall of a stone when not supported, as we infer the incommensurability of the diagonal and side of a square. This last is *implied* in the very conception or notion of a square; not as a consequence of its other properties, but as one of its essential attributes: and the contrary proposition is not only false, but incapable of being distinctly conceived. This is not the case with the other phenomenon, or any matter of fact. The proofs which are brought of a mathematical proposition, are not the reason of its being true, but the steps by which this truth is brought into our view; and frequently, as in the instance now given, this truth is perceived, not directly, but consequentially, by the inconceivableness of the contrary proposition.

41 Mr Hume's theory a *petitio principii.*

Mr Hume derives this irresistible expectation of events from the known effect of custom, the association of ideas. The corelated event is brought into the mind by this well known power of custom, with that vivacity of conception which constitutes belief or expectation. But without insisting on the futility of his theory of belief, it is sufficient to observe, that this explanation begs the very thing to be proved, when it ascribes to custom a *power* of any kind. It is the origin of this very power which is the subject in dispute. Besides, on the genuine principles of scepticism, this custom involves an acknowledgement of past events, of a something different from present impressions, which, in this doctrine (if doctrine it can be called), are the only certain existences in nature: and, lastly, it is known that *one* clear experience is a sufficient foundation for this unshaken confidence and anticipation. General custom can never, on Mr Hume's principles, give superior vivacity to any particular idea.

42 Another hypothesis respecting causal connection.

This certain nonentity of it as a separate object of observation, and this impossibility to derive this notion of necessary and causal connection between the events of the universe from any source, have induced two of the most acute philosophers of Europe, Mr Leibnitz and Father Malebranche, to deny that there is any such connection, and to assert that the events of the universe go on in corresponding trains, but without any causal connection, just as a well regulated clock will keep time with the motions of the heavens without any kind of dependence on them. This harmony of events was pre-established by the Author of the Universe, in subserviency to the purposes he had in view in its formation.

All those purposes which are cognisable by us, may certainly be accomplished by this perfect adjustment. But without insisting on the fantastic wildness of this ingenious whim, it is quite enough to observe, that it also is a begging of the question, because it supposes causation when it ascribes all to the agency of the Deity.

Thus have we searched every quarter, without being able to find a source from which to derive this perception of a necessary connection among the events of the universe, or of this confident expectation of the continuance of physical laws; and yet we are certain of the feeling, and of the persuasion, be its origin what it may: for we speak intelligibly on this subject; we speak familiarly of cause, effect, power, energy, necessary connection, motives and their influence, argument and conviction,

viction, reasons and persuasion, allurements and emotions, of gravity, magnetism, irritability, &c.; and we carry on conversations on these subjects with much entertainment and seeming instruction. Language is the expression of thought, and every word expresses some notion or conception of the mind; therefore it must be allowed, that we have such notions as are expressed by cause, power, energy. But it is here, as in many cases, we perceive a distinction without being able to express it by a definition; and that we do perceive the relation of causation as distinct from all others, and in particular as distinct from the relation of contiguity in time and place, or the relation of agent, action, and patient, must be concluded from the uniformity of language, which never confounds them except on purpose, and when it is perceived. But even here we shall find, that none of the terms used for expressing those powers of substance which are conceived as the causes of their characteristic phenomena, really express any thing different from the phenomena themselves. Let any person try to define the terms gravity, elasticity, sensibility, and the like, and he will find that the definition is nothing but a description of the phenomenon itself. The words are all derivatives, most of them verbal derivatives, implying action, gravitation, &c. As the general resemblances in shape, colour, &c. are expressed by the natural historian by generic terms, so the general resemblances in event are expressed by the philosopher in generic propositions, which, in the progress of cultivation, are also abbreviated into generic terms.

This abundantly explains the consistency of our language on this subject, both with itself and with the operations of nature, without however affording any argument for the truth of the assumption, that causes are the objects of philosophic research as separate existences; or that this supposed necessary connection is a *necessary truth*, whether supreme or subordinate. But since the perception of it has its foundation in the constitution of the human mind, it seems intitled to the name of a *first principle*. We are hardly allowed to doubt of this, when we consider the importance of it, and the care of nature to secure us in all things essential to our safety and well-being, from all danger, from inattention, ignorance, or indolence, by an instinct infallible in its information, and instantaneous in its decisions. "It would not be like her usual care (says Hume), if this operation of the mind, by which we infer like effects from like causes, and *vice versa*, were entrusted to the fallacious deduction of our reason, which is slow in its operations, appears not in any degree during the first years of infancy, and in every age and period of human life is extremely liable to error. It is more conformable to her *ordinary caution* (mark the acknowledgement) to secure so necessary an act of the mind by some instinct, or blind tendency, which may be infallible and rapid in all its operations, may discover itself at the first appearance of life, and may be independent of all the laboured deductions of reason. As she has taught us the use of our limbs, without giving us any knowledge of the nerves and muscles by which they are actuated; so she has implanted in us an instinct, which carries forward the thought in a course conformable to that established among external objects, though we be ignorant of the powers and forces on which this regularity depends."

43 The perception of this connection a first principle.

Such a knowledge is quite unnecessary, and therefore causes are no more cognisable by our intellectual powers than colours by a man born blind; nay, whoever will be at the pains to consider this matter agreeably to the received rules and maxims of logic, will find that necessary connection, or the bond of causation, can no more be the subject of philosophical discussion by man, than the ultimate nature of truth. It is precisely the same absurdity or incongruity, as to propose to examine light with a microscope. Other rational creatures may perceive them as easily as we hear sounds. All that we can say is, that their existence is probable, but by no means certain. Nay, it may be (and we may never know it) that we are not the efficient causes of our own actions, which may be effected by the Deity or by ministering spirits; and this may even be true in the material world. But all this is indifferent to the real occupation of the philosopher, and does not affect either the certainty, the extent, or the utility of the knowledge which he may acquire.

44 The object of the philosopher the discovery of physical laws.

We are now able to appreciate the high pretensions of the philosopher, and his claim to scientific superiority. We now see that this can neither be founded on any scientific superiority of his object, nor of his employment. His object is not causes; and his discoveries are nothing but the discovery of general facts, the discovery of physical laws: and his employment is the same with that of the descriptive historian. He observes and describes with care and accuracy the events of nature; and then he groups them into classes, in consequence of resembling circumstances, detected in the midst of many others which are dissimilar and occasional. By gradually throwing out more circumstances of resemblance, he renders his classes more extensive; and, by carefully marking those circumstances in which the resemblance is observed, he characterises all the different classes: and, by a comparison of these with each other, in respect to the number of resembling circumstances, he distributes his classes according to their generality and subordination; thus exhausting the whole assemblage, and leaving nothing unarranged but accidental varieties. In this procedure it is to be remarked, that every grouping of similar events is, *ipso facto*, discovering a general fact, a physical law; and the expression of this assemblage is the expression of the physical law. And as every observation of this constancy of fact affords an opportunity for exerting the instinctive inference of natural connection between the related subjects, every such observation is the discovery of a power, property, or quality, of natural substance. And from what has been said, this observation of event is all we know of the connection, all we know of the natural power. And when the philosopher proceeds farther to the arrangement of events, according to their various degrees of complication, he is, *ipso facto*, making an arrangement of all natural powers according to their various degrees of subordinate influence. And thus his occupation is perfectly similar to that of the descriptive historian, classification and arrangement; and this constitutes all the science attainable by both.

45 Philosophy defined.

PHILOSOPHY may therefore be defined, the study of the phenomena of the universe, with a view to discover the general laws which indicate the powers of natural substances, to explain subordinate phenomena, and to

improve

View of Bacon's Philosophy.

improve art: Or, in compliance with that natural instinct so much spoken of, Philosophy is the study of the phenomena of the universe, with a view to discover their causes, to explain subordinate phenomena, and to improve art.

The task is undoubtedly difficult, and will exercise our noblest powers. The employment is manly in itself, and the result of it important. It therefore justly merits the appellation of *philosophy*, although its objects are nowise different from what occupy the attention of other men.

46 The employment of the philosopher.

The employment of the philosopher, like that of the natural historian, is threefold; DESCRIPTION, ARRANGEMENT and REFERENCE; while the objects are not *things* but *events*.

The description, when employed about events, may be more properly termed *history*. A philosophical history of nature consists in a complete or copious enumeration and narration of facts, properly selected, cleared of all unnecessary or extraneous circumstances, and accurately narrated. This constitutes the materials of philosophy. We cannot give a better example of this branch of philosophical occupation than astronomy.

From the beginning of the Alexandrian school to this day, astronomers have been at immense pains in observing the heavenly bodies, in order to detect their true motions. This has been a work of prodigious difficulty: for the appearances are such as might have been exhibited although the real motions had been extremely different. Not that our senses give us false information; but we form hasty, and frequently false judgments, from these informations; and call those things deceptions of sense, which are in fact errors of judgment. But the true motions have at last been discovered, and have been described with such accuracy, that the history may be considered as nearly complete. This is to be found in the usual systems of astronomy, where the tables contain a most accurate and synoptical account of the motion; so that we can tell with precision in what point of the heavens a planet *has been* seen at any instant that can be named.

47 Phenomeneology.

Sir Isaac Newton's Optics is such another perfect model of philosophical history, as far as it goes. This part of philosophy may be called PHENOMENOLOGY.

Having in this manner obtained the materials of philosophical description, we must put them into a compendious and perspicuous form, so that a general knowledge of the universe may be easily acquired and firmly retained. This is to be done by classification and arrangement, and this classification must proceed on resemblances *observed* in the events; and the subsequent arrangement must be regulated by the distinctions of which those resemblances are still susceptible. This assemblage of events into groups must be expressed. They are facts; therefore the expression must be propositions. These propositions must be what the logicians call *general* or *abstract propositions;* for they express, not any individual fact of the assemblage, but that circumstance in which they all resemble. Such propositions are the following: Proof is accompanied by belief; kindness is accompanied by gratitude; impulse is accompanied by motion.

48 Investigation.

These are usually called *general facts;* but there are none such; every fact is individual. This language, however inaccurate, is very safe from misconstruction, and we may use it without scruple. These propositions are NATURAL OF PHYSICAL LAWS; and then the detecting and marking those resemblances in event, is the investigation of physical laws; and we may denominate this employment of the philosopher INVESTIGATION.

In the prosecution of this task, it will be found that the similarities of fact are of various extent: and thus we shall form physical laws of various extent; and we shall also find that some are subordinate to others; for the resemblance of a number of facts in one circumstance does not hinder a part of them from also resembling in another circumstance: and thus we shall find subordinations of fact in the same way as of quiescent qualities. And it is found here, as in natural history, that our assemblage of resembling events will be the more extensive as the number of resembling circumstances is smaller; and thus we shall have kingdoms, classes, orders, genera, and species of phenomena, which are expressed by physical laws of all those different ranks.

It has been already observed, that this observation of physical laws is always accompanied by a reference of that uniformity of event to a natural bond of union between the concomitant facts which is conceived by us as the *cause* of this concomitancy; and therefore this procedure of the philosopher is considered as the discovery of those causes, that is, the discovery of those powers of natural substances which constitute their physical relations, and may justly be called their distinguishing *qualities* or *properties*. This view of the matter gives rise to a new nomenclature and language. We give to those powers generic names, such as *sensibility*, *intelligence*, *irritability*, *gravity*, *elasticity*, *fluidity*, *magnetism*, &c. These terms, without exception, mark resembling circumstances of event; and no other definition can be given of them but a description of these circumstances. In a few cases which have been the subjects of more painful or refined discussion, we have proceeded farther in this abbreviation of language.

We have framed the verb "to gravitate," and the verbal noun "gravitation," which purely expresses the fact, the phenomenon; but is conceived to express the *operation* or energy of the cause or natural power. It is of importance to keep in mind this metaphysical remark on these terms; for a want of attention to the pure meaning of the words has frequently occasioned very great mistakes in philosophical science.

We may with propriety call this part of the philosopher's employment AITIOLOGY. 49 Aitiology.

We shall give an instance of its most successful application to the class of events already adduced as an example of philosophic history or phenomenology.

Kepler, a celebrated Prussian astronomer, having maturely considered the phenomena recorded in the tables and observations of his predecessors, discovered, amidst all the varieties of the planetary motions, three circumstances of resemblance, which are now known by the name of *Kepler's laws*. 50 Kepler's laws as instance.

1. All the planets describe ellipses, having the sun in one focus.

2. The elliptic areas described by a planet in the different parts of its orbit, are proportional to the times of description.

3. The squares of the periodic times are proportional to the cubes of the mean distances from the sun.

By

By this observation or discovery, the study of the planetary motions were greatly promoted, and the calculation of their appearances was now made with a facility and an accuracy which surpassed all hopes: for the calculation of the place of a planet at any proposed instant was reduced to the geometrical problem of cutting off an area from an ellipse of known dimensions, which should bear the same proportion to the whole area, as the time for whose duration the motion is required, has to the known time of a complete revolution.

51 Comprehended under one more general law,

Long after this discovery of Kepler, Sir Isaac Newton found that these laws of Kepler were only particular cases of a fact or law still more general. He found that the deflections of the planets from uniform rectilineal motion were all directed to the sun; and that the simultaneous deflections were inversely proportional to the squares of the distances from that body.

Thus was established a physical law of vast extent: but further observation showed him, that the motion of every body of the solar system was compounded of an original motion of projection, combined with a deflection towards every other body; and that the simultaneous deflections were proportional to the quantity of matter in the body towards which they were directed, and to the reciprocal of the square of the distance from it. Thus was the law made still more general. He did not stop here. He compared the deflection of the moon in her orbit with the simultaneous deflection of a stone thrown from the hand, and describing a parabola; and he found that they followed the same law, that is, that the deflection of the moon in a second, was to that of the stone in the same time, as the square of the stone's distance from the centre of the earth, to the square of the moon's distance from it. Hence he concluded, that the deflection of a stone from a straight line was just a particular instance of the deflections which took place through the whole solar system.

52 *called gravitation.*

The deflection of a stone is one of the indications it gives of its being *gravis* or heavy; whence he calls it *gravitation*. He therefore expresses the physical law which obtains through the whole solar system, by saying that "every body *gravitates* to every other body; and the gravitations are proportional to the quantity of matter in that other body, and inversely proportional to the square of the distance from it."

Thus we see how the arrangement of the celestial phenomena terminated in the discovery of physical laws; and that the expression of this arrangement is the law itself.

Since the fall of a heavy body is one instance of the physical law, and since this fall is considered by all as the effect of its *weight*, and this weight is considered as the cause of the fall, the same cause is assigned for all the deflections observed in the solar system; and all the matter in it is found to be under the influence of this cause, or to be heavy: and thus his doctrine has been denominated the *system of universal gravitation*.

Philosophers have gone farther, and have supposed that gravity is a power, property, or quality, residing in all the bodies of the solar system. Sir Isaac Newton does not expressly say so, at least in that work where he gives an account of these discoveries. He contents himself with the immediate consequence of the first axiom in natural philosophy, viz. that every body remains in a state of rest, or of uniform rectilineal motion, unless affected by some moving force. Since the bodies of the solar system are neither in a state of rest, nor of uniform rectilineal motion, they must be considered as so affected; that is, that there operates on every one of them a moving force, directed towards all the others, and having the proportions observed in the deflection.

53 Attempts to include this law under impulse,

Other philosophers have endeavoured to show, that this general fact, detected by Sir Isaac Newton, is included in another still more general, viz. that every body moves which is impelled by another body in motion. They assert, that all the bodies of the solar system are continually impelled by a fluid which they call *ether*, which is moving in all places, and in all directions, or in circular vortices, and hurries along with it the planets and all heavy bodies. It would seem that the familiarity of motion produced by impulse, at least in those instances in which our own exertions are most employed, has induced philosophers to adopt such notions; perhaps, too, they are influenced by an obscure and indistinct notion affixed to the term action, as applied to changes in the material world, and which has given rise to an axiom, "that a body cannot act at a distance, or where it is not;" and thus have thought themselves obliged to look out for an immediate and contiguous agent in all those phenomena.

But the philosophers who profess to be most scrupulous in their adherence to the rules of philosophic discussion, deny the legitimacy of this pretended investigation of causes, saying that this doctrine is in direct opposition to the procedure of the mind in acquiring the knowledge of causes. Since the *fact* of impulse is not really *observed* in the celestial deflections, nor in the motions of heavy bodies, the law cannot be *inferred*. They say that it is not even necessary to show that the phenomena of the celestial motions are unlike the phenomena of impulse, although this can be done in the completest manner. It is enough that neither the fluid nor the impulse are observed; and therefore they are in the right when they assert, that there is inherent in, or accompanies all the bodies of the system, a power by which they deflect to one another. See Optics.

54 whilst impulse itself is never observed.

The debate is foreign to our present purpose, which is only to show how the observation and arrangement of phenomena terminates in the discovery of their causes, or the discovery of the powers or properties of natural substances.

This is a task of great difficulty, as it is of great importance. There are two chief causes of this difficulty.

55 Causes of the difficulty of philosophical investigation.

1. In most of the spontaneous phenomena of nature there is a complication of many events, and some of them escape our observation. Attending only to the most obvious or remarkable, we conjoin these only in our imagination, and are apt to think these the concomitant events in nature, the proper indication of the cause, and the subjects of this philosophical relation, and to suppose that they are always conjoined by nature. Thus it was thought that there resided in a vibrating chord a power by which the sensation of sound was excited, or that a chord had a sounding quality. But it appears clearly from observation that there is an inconceivable number of events interposed between the vibration of the chord and the sensitive affection of our ear; and therefore, that sound is not the effect of the vibration of the chord, but of the very last event of this series: and this is completely

View of Bacon's Philosophy.

pletely demonstrated by showing that the vibration and the sound are *not necessarily* connected, because they are not *always* connected, but require the interposition of air or of some other elastic body.

These observations show the necessity of the most accurate and minute observation of the phenomena, that none of those intermediate events may escape us, and we be thus exposed to the chance of imaginary connections between events which are really far asunder in the procedure of nature. As the study has improved, mistakes of this kind have been corrected; and philosophers are careful to make their trains of events under one name as short as possible. Thus, in medicine, a drug is no longer considered as a *specific* remedy for the disease which is sometimes cured when it has been used, but is denominated by its most immediate operation on the animal frame: it is no longer called a *febrifuge*, but a *sudorific*.

56 Means of insuring success.

2. When many natural powers combine their influence in a spontaneous phenomenon of nature, it is frequently very difficult to discover what part of the complicated effect is the effect of each; and to state those circumstances of similarity which are the foundation of a physical law, or entitle us to infer the agency of any natural power. The most likely method for insuring success in such cases is to get rid of this complication of event, by putting the subject into such a situation that the operation of all the known powers of nature shall be suspended, or so modified as we may perfectly understand *their* effects. We can thus appreciate the effects of such as we could neither modify nor suspend, or we can discover the existence of a new law, the operation of a new power.

This is called *making an experiment;* and is, of all, the most effectual way of advancing in the knowledge of nature, and has been called EXPERIMENTAL PHILOSOPHY.

It seems, however, at first sight, in direct opposition to the procedure of nature in forming general laws. These are formed by induction from multitudes of individual facts, and must be affirmed to no greater extent than the induction on which they are founded. Yet it is a matter of fact, a physical law of human thought, that one simple, clear, and unequivocal experiment, gives us the most complete confidence in the truth of a general conclusion from it to every similar case. Whence this anomaly? It is not an anomaly or contradiction of the general maxim of philosophical investigation, but the most refined application of it. There is no law more general than this, that "Nature is constant in all her operations." The judicious and simple form of our experiment insures se (we imagine) in the complete knowledge of all the circumstances of the event. Upon this supposition, and this alone, we consider the experiment as the faithful representative of every possible case of the conjunction. This will be more minutely considered afterwards.

57 A seeming anomaly explained.

58 Theory or explanation of subordinate phenomena.

The last branch of philosophic occupation is the explanation of subordinate phenomena. This is nothing more than the referring any particular phenomenon to that class in which it is included; or, in the language of philosophy, it is the pointing out the general law, or that general fact of which the phenomenon is a particular instance. Thus the feeling of the obligations of virtue is thought to be explained, when it is shown to be a particular case of that regard which every person has for his dearest interests. The rise of water in pumps is explained, when we show it to be a particular case of the pressure of fluids, or of the air. The general law under which we show it to be properly arranged is called the PRINCIPLE of the explanation, and the explanation itself is called the THEORY of the phenomenon. Thus Euler's explanation of the lunar irregularities is called a theory of the lunar motions on the principle of gravitation.

This may be done either in order to advance our own knowledge of nature, or to communicate it to others. If done with the first view, we must examine the phenomenon minutely, and endeavour to detect every circumstance in it, and thus discover all the known laws of nature which concur in its production; we then appreciate the operation of each according to the circumstances of its exertion; we then combine all these, and compare the result with the phenomenon. If they are similar, we have explained the phenomenon. We cannot give a better example than Franklin's explanation of the phenomena of thunder and lightning. See LIGHTNING, and ELECTRICITY *Index*.

If we explain a phenomenon from known principles, we proceed synthetically from the general law already established and *known* to exert its influence in the present instance. We state this influence both in kind and degree according to the circumstances of the case; and having combined them, we compare the result with the phenomenon, and show their agreement, and thus it is explained. Thus, because all the bodies of the solar system mutually gravitate, the moon gravitates to the sun as well as to the earth, and is continually, and in a certain determinate manner, deflected from that part which she would describe did she gravitate only to the earth. Her motion round the earth will be retarded during the first and third quarters of her orbit, and accelerated during the second and fourth. Her orbit and her period will be increased during our winter, and diminished during our summer. Her apogee will advance, and her nodes will recede; and the inclination of her orbit will be greatest when the nodes are in syzigee, and least when they are in quadrature. And all these variations will be in certain precise degrees. Then we show that all these things actually obtain the lunar motions, and they are considered as explained.

This summary account of the object and employment in all philosophical discussion is sufficient for pointing out its place in the circle of the sciences, and will serve to direct us to the proper methods of prosecuting it with success. Events are its object; and they are considered as connected with each other by causation, which may therefore be called the philosophical relation of things. The following may be adopted as the fundamental proposition on which all philosophical discussion proceeds, and under which every philosophical discussion or discovery may be arranged:

"*Every change that we observe in the state or condition of things* IS CONSIDERED BY US *as an effect, indicating the agency, characterising the kind, and determining the degree of its* INFERRED *cause.*" 59 Fundamental proposition of philosophical discussion.

As thus enounced, this proposition is evidently a physical law of human thought. It may be enounced as a necessary and independent truth, by saying, *every change in the state and condition of things* IS AN EFFECT, &c. And

View of Bacon's Philosophy.

And accordingly it has been so enounced by Dr Reid*; and its title to this denomination has been abundantly supported by him. But we have no occasion to consider it as possessing this quality. We are speaking of philosophy, which is something contingent, depending on the existence and constitution of an intellectual being such as man; and, in conformity to the view which we have endeavoured to give of human knowledge in the subjects of philosophical relation, it is quite sufficient for our purpose that we maintain its title to the rank of an universal law of human thought. This will make it a first principle, even although it may not be a necessary truth.

* Essays on the Intellectual Powers of Man.

All the proof necessary for this purpose is universality of fact; and we believe this to be without exception. We are not to expect that all mankind have made, or will ever make, a formal declaration of their opinion; but we may venture to say that all have made it, and continually do make it, virtually. What have the philosophers of all ages been employed about but the discovery of the causes of those changes that are incessantly going on? *Nil turpius physico* (says Cicero) *quam fieri sine causâ quidquam dicere.* Human curiosity has been directed to nothing so powerfully and so constantly as to this. Many absurd causes have been assigned for the phenomena of the universe; but no set of men have ever said that they happened without a cause. This is so repugnant to all our propensities and instincts, that even the atheistical sect, who, of all others, would have profited most by the doctrine, have never thought of advancing it. To avoid so shocking an absurdity, they have rather allowed that chance, that the concourse of atoms, are the causes of the beautiful arrangements of nature. The thoughtless vulgar are no less solicitous than the philosophers to discover the cause of things; and the poet expresses the natural and instinctive passion of all men, when he says,

Felix qui potuit rerum cognoscere causas.

And this anxiety is not to nourish, but to get rid of superstitious fears: for thus

—— metus omnes, et inexorabile fatum
Subjecit pedibus, strepitumque Acherontis avari.

Had men never speculated, their conduct alone gives sufficient evidence of the universality of the opinion. The whole conduct of man is regulated by it, nay, almost wholly proceeds upon it, in the most important matters, and where experience seems to leave us in doubt: and to act otherwise, as if any thing whatever happened without a cause, would be a declaration of insanity. Dr Reid has beautifully illustrated this truth, by observing, that even a child will laugh at you if you try to persuade him that the top, which he misses from the place where he left it, was taken away by nobody. You may persuade him that it was taken away by a fairy or a spirit; but he believes no more about this nobody, than the master of the house when *he* is told that nobody was the author of any piece of theft or mischief. What opinion would be formed, says Dr Reid, of the intellects of the juryman, on a trial for murder by persons unknown, who should say that the fractured skull, the watch and money gone, and other like circumstances, might possibly have no cause? he would be pronounced insane or corrupted.

60 Controverted by Mr Hume

We believe that Mr Hume is the first author who has ventured to call the truth of this opinion in question; and even *he* does it only in the way of mere possibility. He acknowledges the *generality* of the opinion; and he only objects to the foundation of this generality: and he objects to it merely because it does not quadrate with his theory of belief; and therefore it *may* happen that some men may have no such opinion. But it must be observed on this occasion, that the opinion of a philosopher is of no greater weight in a case like this than that of a ploughboy. If it be a first principle, directing the opinions and actions of all, it must operate on the minds of all. The philosopher is the only person who may chance to be without it: for it requires much labour, and long habits resolutely maintained, to warp our natural sentiments; and experience shows us that they may be warped if we are at sufficient pains. It is also worthy of remark, that this philosopher seems as much under the influence of this law as ordinary mortals. It is only when he is aware of its not tallying with his other doctrines that his scruples appear. Observe how he speaks when off his guard: "As to those impressions which arise from the senses, their ultimate cause is, in my opinion, perfectly inexplicable by human reason; and it will always be impossible to decide with certainty whether they arise immediately from the object, are produced by the creative power of the mind, or are derived from the Author of our being."

61 with great inconsistency.

Among these alternatives he never thought of their not being derived from any cause.

But it is not enough to show that this is a physical law of the human mind: we have assumed it as a first principle, the foundation of a whole science; therefore not included in or derived from any thing more general. Mr Hume's endeavours to prove that it is not a necessary truth, show with sufficient evidence that most attempts to derive it in the way of argument are *petitiones principii*; a thing very commonly met with in all attempts to prove first principles. It cannot be proved by induction of facts that every event has a cause, because induction always supposes an *observed fact* or event. Now in by far the greatest number of events the causes are unknown. Perhaps in no event whatever do we know the real cause, or that power or energy which, without any intervention, produces the effect. No man can say, that in the simplest event which he ever observed, he was fully apprised of every circumstance which concurred to its production. We suppose that no event in nature can be adduced more simple than the motion of a suspended glass ball when gently struck by another glass ball; and we imagine that most of our readers will say that he perfectly sees every thing which happens in this phenomenon. We believe, too, that most of our readers are of opinion that a body is never put in motion but by the impulse of another, except in the cases of animal motion; and that they are disposed to imagine that magnets put iron in motion, and that an electrified body moves another, by means of an interposed though invisible fluid somehow circulating round them. Now we must inform such readers, that unless the stroke has been very smart, so smart indeed as to shatter the glass balls, the motion of the suspended ball was produced without impulse: that is, the two balls were not in contact during the stroke; and the distance between them was not less than the

62 This proposition a first principle incapable of proof.

View of Bacon's Philosophy

9000th part of an inch, and probably much greater. We must say farther, that it is not certain that even the most violent stroke, such as would shatter them to pieces, is enough to bring them into real contact. The proofs of this singular position are too long for this place; but the evidence will be sufficiently seen by consulting the article OPTICS.

Unless, therefore, our readers are willing to allow that the suspended ball was put in motion by a repulsive force inherent in one or both balls, they must acknowledge that they *do not* fully know all the circumstances of this so simple phenomenon, or all the train of events which happen in it; and therefore they are reduced to the necessity of *supposing*, although they do not see it, an intervening fluid or matter, by the immediate action of whose *adjoining* particles the motion is produced.

This being the case in the simplest phenomenon that we can pitch upon, what shall we say of the numberless multitudes which are incomparably more complex: Must we not acknowledge that the efficient causes, even in the vulgar sense of the word, the immediately preceding events, are unknown, because the conjunctions are not observed? and therefore it cannot be said that it is from experimental induction that this truth gains universal belief. Experience, so far from supporting it as a direct proof, seems rather the strongest argument against it; for we have no experiment of unquestionable authority but the narrow circle of our own power exerted on our thoughts and actions. And even here there are perhaps cases of change where we cannot say with certainty that we perceive the efficient cause.

Nothing seems to remain, therefore, but to allow that this physical law of human judgment is instinctive, a constituent of the human soul, a first principle; and incapable of any other proof than the appeal to the feelings of every man.

63 Causes not observed, but inferred from the phenomena which are the language of nature.

Simply to say, that every change is considered as an effect, is not giving the whole characters of this physical law. The cause is not always, perhaps never, *observed*, but is *inferred* from the phenomena. The inference is therefore in every instance dependant on the phenomenon. The phenomenon is to us the language of nature: It is therefore the sole indication of the cause and of its agency: it is therefore the indication of the very cause, and of no other. The observed change therefore characterises the cause and marks its kind. This is confirmed by every word of philosophical language, where, as has already been observed, the names of the inferred powers of nature are nothing but either abbreviated descriptions of the phenomena, or terms which are defined solely by such descriptions. In like manner, the phenomenon determines the cause in a *particular degree*, and in no other; and we have no immediate measure of the degree of the cause but the phenomenon itself. We take many measures of the cause, it is true; but on examination they will be found not to be immediate measures of the cause, but of the effect. Assuming gravitation as the cause of the planetary deviations from uniform rectilineal motion, we say that the gravitation of the moon is but $\frac{1}{3600}$th part of the gravitation of a stone thrown from the hand: but we say this only from observing that the deflection of the stone is 3600 times greater than the simultaneous deflection of the moon. In short, our whole knowledge of the cause is not only *founded* on our knowledge of the phenomenon, but *it is the same*. This will be found a remark of immense consequence in the prosecution of philosophical researches; and a strict attention to it will not only guard us against a thousand mistakes into which the reasoning pride of man would continually lead us, but will also enable us fully to detect many egregious and fatal blunders made in consequence of this philosophical vanity. Nothing can be more evident than that whenever we are puzzled, it would be folly to continue groping among those obscure beings called *causes*, when we have their prototypes, the phenomena themselves, in our hands.

Such is the account which may be given of philosophy, the study of the works of God, as related by causation. It is of vast extent, reaching from an atom to the glorious Author of the Universe, and contemplating the whole connected chain of intelligent, sensitive, and inanimate beings. The philosopher makes use of the descriptions and arrangements of the natural historian as of mighty use to himself in the beginning of his career, confiding in the uniformity of nature, and expecting that similarity in the quiescent properties of things will be accompanied by some resemblances in those more important properties which constitute their mutual dependencies, linking them together in a great and endlessly ramified chain of events.

We have endeavoured to ascertain with precision the peculiar province of philosophy, both by means of its object and its mode of procedure. After this it will not require many words to point out the methods for prosecuting the study with expedition and with success. The rules of philosophizing, which Newton premises to his account of the planetary motions, which he so scrupulously followed, and with a success which gives them great authority, are all in strict conformity to the view we have now given of the subject.

64 The chief rule of philosophising explained.

The chief rule is, that similar causes are to be assigned to similar phenomena. This is indeed the source of all our knowledge of connected nature; and without it the universe would only present to us an incomprehensible chaos. It is by no means, however, necessary to enjoin this as a maxim for our procedure: it is an instinctive propensity of the human mind. It is absolutely necessary, on the contrary, to caution us in the application of this propensity. We must be extremely confident in the certainty of the resemblance before we venture to make any inference. We are prone to reason from analogy: the very employment is agreeable; and we are ever disposed to embrace opportunities of engaging in it. For this reason we are satisfied with very slight resemblances, and eagerly run over the consequences, as if the resemblance were complete; and our researches frequently terminate in falsehood.

This propensity to analogical reasoning is aided by another equally strong, and equally useful, when properly directed; we mean the propensity to form general laws: it is in fact a propensity to discover *causes*, which is equivalent to the establishing of general laws. It appears in another form, and is called a love of or taste for simplicity; and this is encouraged or justified as agreeable to the uniformity and simplicity of nature. "Natura semper sibi similis et consona," says Newton; "Frustra fit per plura, quo fieri potest per pauciora," says another. The beautiful, the wise economy of nature, are phrases in every body's mouth; and Newton enjoins us to adopt no more causes than are sufficient to explain

explain the phenomena. All this is very well, and is true in its own degree; but it is too frequently the subterfuge of human vanity and self-love. This inordinate admiration of the economy and simplicity of nature is generally conjoined with a manifest love of system, and with the actual production of some new system, where from one general principle some extensive theory or explanation is deduced and offered to the world. The author sees *a sort* of resemblance between a certain series of phenomena and the consequences of some principle, and thinks the principle adequate to their explanation. Then, on the authority of the acknowledged simplicity of nature, he roundly excludes all other principles of explanation; because, says he, this principle is sufficient, "et frustra fit per plura," &c. We could point out many instances of this kind in the writings of perhaps the first mathematician and the poorest philosopher of this century; where extensive theories are thus cavalierly exhibited, which a few years examination have shown to be nothing but analogies, indistinctly observed, and, what is worse, inaccurately applied.

To regulate these hazardous propensities, and keep philosophers in the right path, Newton inculcates another rule, or rather gives a modification of this injunction of simplicity. He enjoins that no cause shall be admitted but what is real. His words are, that *no causes*

65 A true cause explained.

shall be admitted but such as are true, and sufficient to account for the phenomena. We apprehend that the meaning of this rule has been mistaken by many philosophers, who imagine that by *true* he means causes which really exist in nature, and are not mere creatures of the imagination. We have met with some who would boggle at the doctrines of Aristotle respecting the planetary motions, viz. that they are carried along by conducting intelligent minds, because we know of *none such* in the universe; and who would nevertheless think the doctrine of the Cartesian vortices deserving of at least an examination, because we see such vortices exist, and produce effects which have some resemblance to the planetary motions, and have justly rejected them, *solely* because this resemblance has been very imperfect. We apprehend Newton's meaning by these words is, that no cause of any event shall be admitted, or even considered, which we *do not know* to be actually concurring or exerting some influence *in that very event*. If this be his meaning, he would reject the Cartesian vortices, and the conducting spirits of Aristotle, for one and the same reason; not because they were not adequate to the explanation, nor because such causes do not exist in nature, but because we did not *see them* anyhow concerned in the phenomenon under consideration. We neither see a spirit nor a vortex, and therefore need not trouble ourselves with enquiring what effects they would produce. Now we know that this was his very conduct, and what has distinguished him from all philosophers who preceded him, though many, by following his example, have also been rewarded by similar success. This has procured to Newton the character of the *modest* philosopher; and modest his procedure may, for distinction's sake, be called, because the contrary procedure of others did not originate so much from ignorance as from vanity. Newton's conductor in this was not modesty, but sagacity, prudence, caution, and to say it purely, it was sound judgment.

For the bonds of nature, the supposed philosophical causes are not *observed;* they are *inferred* from the phenomena. When two substances are observed, and only when they are observed, to be connected in any series of events, we *infer* that they are connected by a natural power: but when one of the substances is not seen, but fancied, no law of human thought produces any inference whatever. For this reason alone Newton stopped short at the last FACT which he could discover in the solar system, that all bodies were deflected to all other bodies, according to certain regulations of distance and quantity of matter. When told that he had done nothing in philosophy, that he had discovered no cause, and that to merit any praise he must show how this deflection was produced;—he said that he knew no more than he had told them; that he saw nothing causing this deflection; and was contented with having discovered it so exactly, that a good mathematician could now make tables of the planetary motions as accurate as he pleased, and with hoping in a few years to have every purpose of navigation and of philosophical curiosity completely answered; and he was not disappointed. And when philosophers on all sides were contriving hypothetical fluids and vortices which would produce these deflections, he contented himself with showing the total inconsistency of these explanations with the mechanical principles acknowledged by their authors; showing that they had transgressed both parts of his rule, their causes neither being real nor sufficient for explaining the phenomena. A cause is sufficient for explaining a phenomenon only when its legitimate consequences are perfectly agreeable to these phenomena.

Newton's discoveries remain without any diminution or change: no philosopher has yet advanced a step further.

But let not the authority, or even the success, of Newton be our guide. Is his rule founded in reason? It surely is. For if philosophy be the only interpretation of nature's language, the inference of causes from the phenomena, a fancied or hypothetical phenomenon can produce nothing but a fanciful cause, and can make no addition to our knowledge of real nature. 66 This doctrine founded in reason.

All hypotheses therefore must be banished from philosophical discussion as frivolous and useless, administering to vanity alone. As the explanation of any appearance is nothing but the pointing out the general fact, of which this is a particular instance, a hypothesis can give no explanation: knowing nothing of cause and effect but the conjunction of two events, we see nothing of causation where one of the events is hypothetical. Although all the legitimate consequences of a hypothetical principle should be perfectly similar to the phenomenon, it is extremely dangerous to assume this principle as the real cause. It is illogical to make use of the economy of nature as an argument for the truth of any hypothesis: for if true, it is a physical truth, a matter of fact, and true only to the extent in which it is observed, and we are not entitled to say that it is so one step farther; therefore not in *this* case *till it be observed.* But the proposition that nature is so economical is false; and it is astonishing that it has been so lazily acquiesced in by the *readers* of hypotheses: for it is not the *authors* who are deceived by it, they are generally led by their own vanity. Nothing is more observable than the prodigious variety of nature. That the same phenomena may be produced by different means is well known to the astronomers, 67 Danger of hypotheses.

nomers, who must all grant, that the appearances of motion will be precisely the same whether the earth moves round the sun like the other planets, or whether the sun with his attendant planets moves round the earth; and that the demonstration of the first opinion is had from a fact totally unconnected with all the deflections or even with their causes: for it may be asserted, that Dr Bradley's discovery of the aberration of the fixed stars, in consequence of the progressive motion of light, was the first thing which put the Copernican system beyond question; and even this is still capable of being explained in another way. The Author of Nature seems to delight in variety; and there cannot be named a single purpose on which the most inconceivable fertility in resource is not observed. It is the most delightful occupation of the curious mind and the sensible heart to contemplate the various contrivances of nature in accomplishing similar ends.

As a principle therefore on which to found any maxim of philosophical procedure, this is not only injudicious, because imprudent and *apt* to mislead, but as false, and almost sure to mislead. In conformity to this observation, it must be added, that nothing has done so much harm in philosophy as the introduction of hypotheses.

Authors have commonly been satisfied with very slight resemblances, and readers are easily misled by the appearances of reasoning which these resemblances have countenanced. The ancients, and above all Aristotle, were much given to this mode of explanation, and have filled philosophy with absurdities. The slightest resemblances were with them sufficient foundations of theories. It has been by very slow degrees that men have learned caution in this respect; and we are sorry to say that we are not yet cured of the disease of hypothetical systematizing, and to see attempts made by ingenious men to bring the frivolous theories of antiquity again into credit. Nay, modern philosophers even of the greatest name are by no means exempted from the reproach of hypothetical theories. Their writings abound in ethers, nervous fluids, animal spirits, vortices, vibrations, and other invisible agents. We may affirm that all these attempts may be shown to be either unintelligible, fruitless, or false. Either the hypothesis has been such that no consequence can be distinctly drawn from it, on account of its obscurity and total want of resemblance to any thing we know; or the just and legitimate consequences of the hypothesis are inconsistent with the phenomena (N). This is remarkably the case in the hypotheses which have been introduced for the explanation of the mechanical phenomena of the universe. These can be examined by accurate science, and the consequences compared without any mistake; and nothing else but a perfect agreement should induce us even to listen to any hypothesis watever.

It may here be asked, Whether, in the case of the most perfect agreement, after the most extensive comparison, the hypothesis should be admitted? We believe that this must be left to the feelings of the mind. When the belief is irresistible, we can reason no more. But as there is no impossibility of as perfect an agreement with some other hypothesis, it is evident that it does not convey an irrefragable title to our hypothesis. It is said, that such an agreement authorises the reception of the hypothetical theory in the same manner as we *must* admit that to be the *true* cypher of a letter which will make perfect sense of it. But this is not true: in decyphering a letter we know the sounds which *must* be represented by the characters, and that they are really the constituents of speech: but in hypothetical explanations the first principle is not known to exist; nay, it is possible to make two cyphers, each of which shall give a meaning to the letter. Instances of this are to be seen in treatises on the art of decyphering; and there has been lately discovered a national character (the *ogam* discovered in Ireland) which has this property.

We conclude our criticism on hypothetical explanations with this observation, that it is *impossible* that they can give any addition of knowledge. In every hypothesis we thrust in an intermediate event between the phenomenon and some general law; and this event is not seen, but supposed. Therefore, according to the true maxims of philosophical investigation, we give no explanation; for we are not by this means enabled to assign the general law in which this particular phenomenon is included: nay, the hypothesis makes no addition to our list of general laws; for our hypotheses must be *selected*, in order to tally with all the phenomena. The hypothesis therefore is understood only *by* and *in* the phenomena; and it must not be made more general than the phenomena themselves. The hypothesis gives no generalisation of facts. Its very application is founded on a great coincidence of facts; and the hypothetical fact is thrust in between two which we really observe to be united by nature. The applicability therefore of the hypothesis

(N) It has often been matter of amusement to us to examine the hypothetical theories of ingenious men, and to observe the power of nature even when we are transgressing her commands, *Naturam expellat furca, tamen usque revertitur*. The hypothesis of an ingenious man is framed in perfect conformity to nature's dictates? for you will find that the hypothetical cause is touched and retouched, like the first sitting of a picture, till it is made to resemble the phenomena, and the cause is still inferred, nay explained, in spite of all his ingenuity, from the phenomenon; and then, instead of desiring the spectators to pay him his due praise, by saying that the picture is like the man, he insists that they shall say, what gives him no credit, that the man is like the picture. But alas! this is seldom the case: The picture is generally an anamorphosis, unlike any thing extant in nature, and having parts totally incongruous. We have seen such pictures, where a wood is standing on the sea, and an eye is on the end of an elephant's trunk; and yet when this was viewed through a proper glass, the wood became an eyebrow to the eye, and the proboscis was a very pretty ringlet of hair. We beg indulgence for this piece of levity, because it is a most apposite illustration of a hypothetical theory. The resemblance between the principle and phenomenon is true only in detached unconnected scraps, and the principle itself is an incongruous patchwork. But by a perversion of the rules of logic, all these inconsistencies are put out of view, and the explanation is something like the phenomenon.

hypothesis is not more extensive than the similarity of facts which we observe, and the hypothetical law is not more general than the observed law. Let us then throw away entirely the hypothetical law, and insert the observed one in our list of general laws: it will be in different language from the hypothetical law, but it will express the same facts in nature.

68 On what occasions they may be useful.

It is in experimental philosophy alone that hypotheses can have any just claim to admission; and here they are not admitted as explanations, but as conjectures serving to direct our line of experiments.

Effects only appear; and by their appearance, and the previous information of experience, causes are immediately ascertained by the perfect similarity of the whole train of events to other trains formerly observed: Or they are suggested by more imperfect resemblances of the phenomena; and these suggestions are made with stronger or fainter evidence, according as the resemblance is more or less perfect. These suggestions do not amount to a confidential inference, and only raise a conjecture. Wishing to verify or overturn this conjecture, we have recourse to experiment; and we put the subject under consideration in such a situation, that we can say what will be the effect of the conjectural cause if real. If this tallies with the appearance, our conjecture has more probability of truth, and we vary the situation, which will produce a new set of effects of the conjectured cause, and so on. It is evident that the probability of our conjecture will increase with the increase of the conformity of the legitimate effects of the supposed cause with the phenomena, and that it will be entirely destroyed by *one* disagreement. In this way conjectures have their great use, and are the ordinary means by which experimental philosophy is improved. But conjectural systems are worse than nonsense, filling the mind with false notions of nature, and generally leading us into a course of improper conduct when they become principles of action. This is acknowledged even by the abbettors of hypothetical systems themselves when employed in overturning those of their predecessors, and establishing their own: witness the successive maintainers of the many hypothetical systems in medicine, which have had their short-lived course within these two last centuries.

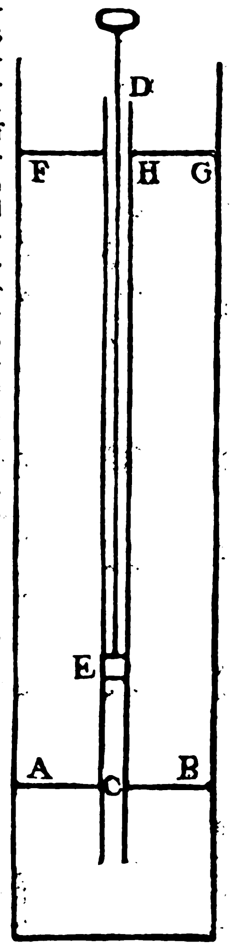
Let every person therefore who calls himself a philosopher resolutely determine to reject all temptations to this kind of system-making, and let him never consider any composition of this kind as any thing better than the amusement of an idle hour.

69 True mode of philosophical procedure.

After these observations, it cannot require much discussion to mark the mode of procedure which will insure progress in all philosophical investigations.

The sphere of our intuitive knowledge is very limited; and we must be indebted for the greatest part of our intellectual attainments to our rational powers, and it must be deductive. In the spontaneous phenomena of nature, whether of mind or body, it seldom happens that the energy of that natural power, which is the principle of explanation, is so immediately connected with the phenomenon that we see the connection at once. Its exertions are frequently concealed, and in all cases modified, by the joint exertions of other natural powers: the particular exertion of each must be considered apart, and their mutual connection traced out. It is only in this way that we can discover the perhaps long train of intermediate operations, and also see in what manner and degree the real principle of explanation concurs in the ostensible process of nature.

In all such cases it is evident that our investigation (and investigation it most strictly is) must proceed by steps, conducted by the sure hand of logical method. To take an instance from the material world, let us listen to Galileo while he is teaching his friends the cause of the rise of water in a pump. He says that it is owing to the pressure of the air. This is his principle; and he announces it in all its extent. All matter, says he, is heavy, and in particular air is heavy. He then points out the connection of this general principle with the phenomenon. Air being heavy, it must be supported; it must lie and press on what supports it; it must press on the surface AB of the water in the cistern surrounding the pipe CD of the pump; and also on the water C within this pipe. He then takes notice of another general principle which exerts its subordinate influence in this process. Water is a fluid; a fluid is a body whose parts yield to the smallest impression; and, by yielding, are easily moved among themselves; and no little parcel of the fluid can remain at rest unless it be equally pressed in every direction, but will recede from that side where it sustains the greatest pressure. In consequence of this fluidity, *known* to be a property of water, if any part of it is pressed, the pressure is propagated through the whole; and if not resisted on every side, the water will move to that side where the propagated pressure is not resisted. All these subordinate or collateral propositions are supposed to be previously demonstrated or allowed. Water therefore must yield to the pressure of the air unless pressed by it on every side, and must move to that side where it is not withheld by some opposite pressure. He then proceeds to show, from the structure of the pump, that there is no opposing pressure on the water in the inside of the pump. "For (says he) suppose the piston thrust down till it touches the surface of the water in the pipe; suppose the piston now drawn up by a power sufficient to lift it, and all the air incumbent on it; and suppose it drawn up a foot or fathom—there remains nothing now (says he) that I know of, to press on the surface of the water. In short (says he), gentlemen, it appears to me, that the water in the pump is in the same situation that it would be in were there no air at all, but water poured into the cistern to a height AF: such, that the column of water FABG presses on the surface AB as much as the air does. Now in this case we know that the water at C is pressed upwards



View of Bacon's Philosophy.

wards with a force equal to the weight of a column of water, having the section of the pipe for its base and CH for its height. The water below C therefore will be pressed up into the pipe CD, and will rise to G, so that it is on a level with the external water FG; that is, it will rise to H. This is a necessary consequence of the weight and pressure of the incumbent column FABG, and the fluidity of the water in the cistern. Consequences perfectly similar must necessarily follow from the weight and pressure of the air; and therefore on drawing up the piston from the surface C of the water, with which it was in contact, the water must follow it till it attain that height which will make its own weight a balance for the pressure of the circumambient air. Accordingly, gentlemen, the Italian plumbers inform me, that a pump will not raise water quite fifty palms; and from their information I conclude, that a pillar of water fifty palms high is somewhat heavier than a pillar of air of the same base, and reaching to the top of the atmosphere."

70 The synthetic method.

Thus is the phenomenon explained. The rise of the water in the pump is shown to be a particular case of the general fact in hydrostatics, that fluids in communicating vessels will stand at heights which are inversely as their densities, or that columns of equal weights are in equilibrio.

This way of proceeding is called arguing *à priori*, the synthetic method. It is founded on just principles; and the great progress which we have made in the mathematical sciences by this mode of reasoning shows to what length it may be carried with irresistible evidence. It has long been considered as the only inlet to true knowledge; and nothing was allowed to be known with certainty which could not be demonstrated in this way to be true. Accordingly logic, or the art of reasoning, which was also called the art of discovering truth, was nothing but a set of rules for successfully conducting this mode of argument.

Under the direction of this infallible guide, it is not surely unreasonable to expect that philosophy has made sure progress towards perfection; and as we know that the brightest geniuses of Athens and of Rome were for ages solely occupied in philosophical researches in every path of human knowledge, it is equally reasonable to suppose that the progress has not only been sure but great. We have seen that the explanation of an appearance in nature is nothing but the arrangement of it into that general class in which it is comprehended. The class has its distinguishing mark, which, when it is found in the phenomenon under consideration, fixes it in its class, there to remain for ever an addition to our stock of knowledge. Nothing can be lost any other way but by forgetting it; and the doctrines of philosophers must be stable like the laws of nature.

We have seen, however, that the very reverse of all this is the case; that philosophy has but very lately emerged from worse than total darkness and ignorance; that what passed under the name of philosophy was nothing but systems of errors (if systems they could be called), which were termed doctrines, delivered with the most imposing apparatus of logical demonstration, but belied in almost every instance by experience, and affording us no assistance in the application of the powers of nature to the purposes of life. Nor will this excite much wonder in the mind of the enlightened reader of the present day, who reflects on the use that in this dialectic process was made of the *categories*, and the method in which those categories were formed. From first principles so vague in themselves, and so gratuitously assumed, ingenious men might deduce many different conclusions all equally erroneous: and that this was actually done, no surer evidence can be given, than that hardly a lifetime elapsed in which the whole system of doctrines which had captivated the minds of the most penetrating, have been oftener than once exploded and overturned by another system, which flourished for a while, and then was supplanted by a third which shared the same fate. Here was an infallible proof of their error, for instability is incompatible with truth.

It is allowed by all that this has been the case in those branches of study at least which contemplate the philosophical relations of the material world, in astronomy, in mechanical philosophy, in chemistry, in physiology, in medicine, in agriculture. It is also acknowledged, that in the course of less than two centuries back we have acquired much knowledge on these very subjects, call it philosophy, or by what name you will, so much more conformable to the natural course of things, that the deductions made from it by the same rules of the synthetic method are more conformable to fact, and therefore better fitted to direct our conduct and improve our powers. It is also certain that these bodies of doctrine which go by the name of philosophical systems, have much more stability than in ancient times; and though sometimes in part superseded, are seldom or never wholly exploded.

This cannot perhaps be affirmed with equal confidence with respect to these speculations which have our intellect or propensities for their object: and we have not perhaps attained such a representation of human nature as will bear comparison with the original; nor will the legitimate deductions from such doctrines be of much more service to us for directing our conduct than those of ancient times: and while we observe this difference between these two general classes of speculations, we may remark, that it is conjoined with a difference in the manner of conducting the study. We have proceeded in the old Aristotelian method when investigating the nature of mind; but we see the material philosophers running about, passing much of their time away from books in the shop of the artizan, or in the open fields engaged in observation, labouring with their hands, and busy with experiments. But the speculatist on the intellect and the active powers of the human soul seems unwilling to be indebted to any thing but his own ingenuity, and his labours are confined to the closet. In the first class, we have met with something like success, and we have improved many arts: in the other, it is to be feared that we are not much wiser, or better, or happier, for all our philosophic attainments. 71 No inlet to truth.

Here, therefore, must surely have been some great, some fatal mistake. There has indeed been a material defect in our mode of procedure, in the employment of this method of reasoning as an inlet to truth. The fact is, that philosophers have totally mistaken the road of discovery, and have pretended to set out in their investigation from the very point where this journey should have terminated.

The Aristotelian logic, the syllogistic art, that art so much boasted of as the only inlet to true knowledge, the

View of Bacon's Philosophy.

the only means of discovery, is in direct opposition to the ordinary procedure of nature, by which we every day, and in every action of our lives, acquire knowledge and discover truth. It is not the art of discovering truth, it is the art of communicating knowledge, and of detecting error: it is nothing more than the application of this maxim, 'whatever is true of a whole class of objects, is true of each individual of that class.' This is not a just account of the art of discovering truth, nor is it a complete account of the art of reasoning. Reasoning is the producing belief; and whatever mode of argumentation invariably and irresistibly produces belief, is reasoning. The ancient logic supposes that all the first principles are already known, and that nothing is wanted but the application of them to particular facts. But were this true, the application of them, as we have already observed, can hardly be called a discovery; but it is not true; and the fact is, that the first principles are generally the chief objects of our research, and that they have come into view only now and then as it were by accident, and never by the labour of the logician. He indeed can tell us whether we have been mistaken; for if our general principle be true, it must influence *every* particular case. If, therefore, it be false in any one of these, it is not a true principle. And it is here that we discover the source of that fluctuation which is so much complained of in philosophy. The authors of systems give a set of consecutive propositions logically deduced from a first principle, which has been hastily adopted, and has no foundation in nature. This does not hinder the amusement of framing a system from it, nor this system from pleasing by its symmetry; and it takes a run: but when some officious follower thinks of making some use of it, which requires the comparison with experience and observation, they are found totally unlike, and the whole fabric must be abandoned as unsound: and thus the successive systems were continually pushing out their predecessors, and presently met with the same treatment.

72 But the art of communicating knowledge.

How was this to be remedied? The ratiocination was seldom egregiously wrong; the syllogistic art had ere now attained a degree of perfection which left little room for improvement, and was so familiarly understood by the philosophical practitioners, that they seldom committed any great blunders. Must we examine the first principles? This was a task quite new in science; and there were hardly any rules in the received systems of logic to direct us to the successful performance of it. Aristotle, the sagacious inventor of those rules, had not totally omitted it; but in the fervour of philosophic speculation he had made little use of them. His fertile genius never was at a loss for first principles, which answered the purpose of verbal disquisition without much risk of being belied on account of its dissimilitude to nature; for there was frequently no prototype with which his systematic doctrine could be compared. His enthusiastic followers found abundant amusement in following his example; and philosophy, no longer in the hands of men acquainted with the world, conversant in the great book of nature, was now confined almost entirely to recluse monks, equally ignorant of men and of things. But curiosity was awakened, and the men of genius were fretted as well as disgusted with the disquisitions of the schools, which one moment raised expectations by the symmetry of composition, and the next moment blasted them by their inconsistency with experience.

They saw that the best way was to begin *de novo*, to throw away the first principles altogether, without exception or examination, and endeavour to find out new ones, which should stand the test of logic; that is, should in every case be agreeable to fact.

73 The method of induction pointed out by nature.

Philosophers began to reflect, that under the unnoticed tuition of kind nature we have acquired much useful knowledge. It is therefore highly probable, that her method is the most proper for acquiring knowledge, and that by imitating her manner we shall have the like success. We are too apt to slight the occupations of children, whom we may observe continually busy turning every thing over and over, putting them into every situation, and at every distance. We excuse it, saying that it is an innocent amusement; but we should say with an ingenious philosopher (Dr Reid), that they are most seriously and rationally employed: they are acquiring the habits of observation; and by merely indulging an undetermined curiosity, they are making themselves acquainted with surrounding objects: they are struck by similitudes, and amused with mere classification. If some new effect occurs from any of their little plays, they are eager to repeat it. When a child has for the first time tumbled a spoon from the table, and is pleased with its jingling noise on the floor, if another lie within its reach, it is sure to share the same fate. If the child be indulged in this diversion, it will repeat it with greediness that deserves our attention. The very first eager repetition shows a confidence in the constancy of natural operations, which we can hardly ascribe wholly to experience; and its keenness to repeat the experiment, shows the interest which it takes in the exercise of this most useful propensity. It is beginning the study of nature; and its occupation is the same with that of a Newton computing the motions of the moon by his sublime theory, and comparing his calculus with observation. The child and the philosopher are equally employed in the contemplation of a similarity of event, and are anxious that this similarity shall return. The child, it is true, thinks not of this abstract object of contemplation, but throws down the spoon again to have the pleasure of hearing it jingle. The philosopher suspects that the conjunction of events is the consequence of a general law of nature, and tries an experiment where this conjunction recurs. The child is happy, and eager to enjoy a pleasure which to us appears highly frivolous; but it has the same foundation with the pleasure of the philosopher, who rejoices in the success of his experiment: and the fact, formerly a trifle to both, now acquires importance. Both go on repeating the experiment, till the fact ceases to be a novelty to either: the child is satisfied, and the philosopher has now established a new law of nature.

Such (says this amiable philosopher) is the education of kind nature, who from the beginning to the end of our lives makes the play of her scholars their most instructive lessons, and has implanted in our mind the curiosity and the inductive propensity by which we are enabled and disposed to learn them. The exercise of this inductive principle, by which nature prompts us to infer general laws from the observation of particular facts, gives us a species of logic new in the schools, but old as

View of Bacon's Philosophy.

as human nature. It is certainly a method of discovery; for by these means general principles, formerly unknown, have come into view.

74 Is a just logic.

It is a just and rational logic; for it is founded on, and indeed is only the habitual application of, this maxim, "That whatever is true with respect to every individual of a class of events, is true of the whole class." This is just the inverse of the maxim on which the Aristotelian logic wholly proceeds, and is of equal authority in the court of reason. Indeed the expression of the general law is only the abbreviated expression of every particular instance.

This new logic, therefore, or the logic of induction, must not be considered as subordinate to the old, or founded on it. See Logic, Part III. chap. 5. In fact, the use and legitimacy of the Aristotelian logic is founded on the inductive,

All animals are mortal;
All men are animals; therefore
All men are mortal.

This is no argument to any person who chooses to deny the mortality of man; even although he acknowledges his animal nature, he will deny the major proposition.

It is beside our purpose to show, how a point so general, so congenial to man, and so familiar, remained so long unnoticed, although the disquisition is curious and satisfactory. It was not till within these two centuries that the increasing demand for practical knowledge, particularly in the arts, made inquisitive men see how useless and insufficient was the learning of the schools in any road of investigation which was connected with life and business; and observe that society had received useful information chiefly from persons actually engaged in the arts which the speculists were endeavouring to illustrate; and that this knowledge consisted chiefly of experiments and observations, the only contributions which their authors could make to science.

The *Novum Organum* of Bacon, which points out the true method of forming a body of real and useful knowledge, namely, the study of nature in the way of description, observation, and experiment, is undoubtedly the noblest present that science ever received. It may be considered as the grammar of nature's language, and is a counter-part to the logic of Aristotle; not exploding it, but making it effectual.

75 Its chief rule

As the logic of Aristotle had its rules, so has the Baconian or inductive; and this work, the *Novum Organum Scientiarum*, contains them all. The chief rule, and indeed the rule from which all the rest are but derivations, is, that "the induction of particulars must be carried as far as the general affirmation which is deduced from them." If this be not attended to, the mind of man, which from his earliest years shows great eagerness in searching for first principles, will frequently ascribe to the operation of a general principle events which are merely accidental. Hence the popular belief in omens, palmistry, and all kinds of fortune-telling.

76 for discovering general principles.

This rule must evidently give a new turn to the whole track of philosophical investigation. In order to discover first principles, we must make extensive and accurate observations, so as to have copious inductions of facts, that we may not be deceived as to the extent of the principle inferred from them. We must extend our acquaintance with the phenomena, paying a minute attention to what is going on all around us; and we must study nature, not shut up in our closet drawing the picture from our own fancy, but in the world, copying our lines from her own features.

To delineate human nature, we must see how men act. To give the philosophy of the material world, we must notice its phenomena.

This method of studying nature has been prosecuted during these two last centuries with great eagerness and success. Philosophers have been busy in making accurate observations of facts, and copious collections of them. Men of genius have discovered points of resemblance, from which they have been able to infer many general powers both of mind and body; and resemblances among these have suggested powers still more general.

By these efforts investigation became familiar; philosophers studied the rules of the art, and became more expert; hypotheses were banished, and nothing was admitted as a principle which was not inferred from the most copious induction. Conclusions from such principles became every day more conformable to experience. Mistakes sometimes happened; but recourse being had to more accurate observation or more copious induction, the mistakes were corrected. In the 77
present study of nature, our steps are more slow, and hesitating and painful; our conclusions are more limited and modest, but our discoveries are more certain and progressive, and the results are more applicable to the purposes of life. This pre-eminence of modern philosophy over the ancient is seen in every path of inquiry. It was first remarkable in the study of the material world; and there it still continues to be most conspicuous. But it is no less to be seen in the later performances of philosophers in metaphysics, pneumatology, and ethics, where the mode of investigation by analysis and experiment has been greatly adopted; and we may add, that it is this juster view of the employment which has restored philosophers to the world, to society. They are no longer to be found only in the academies of the sophists and the cloisters of a convent, but in the discharge of public and private duty. A philosophic genius is a genius for observation as well as reflection, and he says, *Homo sum, humani à me nihil alienum puto.*

and rectifying mistakes.

78 Estimate of the philosophic character.

After saying so much on the nature of the employment, and the mode of procedure, it requires no deep penetration to perceive the value of the philosophical character. If there is a propensity in the human mind which distinguishes us from the inferior orders of sentient beings, without the least circumstance of interference, a propensity which alone may be taken for the characteristic of the species, and of which no trace is to be found in any other, it is disinterested intellectual curiosity, a love of discovery for its own sake, independent of all its advantages.

We think highly (and with great justice do we think so) of our rational powers; but we may carry this too far, as we do every ground of self-estimation. To every man who enjoys the cheering thought of living under the care of a wise Creator, this boasted prerogative will be viewed with more modesty and diffidence; and He has given us evident marks of the rank in which He esteems the rational powers of man. In no case that is of essential importance, of indispensable necessity, not only

View of Bacon's Philosophy.

ly to our wellbeing but to our very existence, has He left man to the care of his reason alone; for in the first instance, He has given us reason

To guide the helm, while passion blows the gale.

79 We should think modestly of our rational powers.

God has not trusted either the preservation of the individual or the continuance of the race to man's notions of the importance of the task, but has committed them to the surer guards of hunger and of sexual desire. In like manner, He has not left the improvement of his noblest work, the intellectual powers of the soul of man, to his own notions how important it is to his comfort that he be thoroughly acquainted with the objects around him. No: He has committed this also to the sure hand of curiosity: and He has made this so strong in a few superior souls, whom He has appointed to give light and knowledge to the whole species, as to abstract them from all other pursuits, and to engage them in intellectual research with an ardour which no attainment can ever quench, but, on the contrary, inflames it the more by every draught of knowledge.

80 Importance of our instinctive principles.

——————— But what need words
To paint its power? For this the daring youth
Breaks from his weeping mother's folding arms
In foreign climes to rove. The pensive sage,
Heedless of sleep, or midnight's hurtful vapour,
Hangs o'er the sickly taper.—Hence the scorn
Of all familiar prospects, though beheld
With transport once. Hence the attentive gaze
Of young astonishment.
Such is the bounteous providence of Heaven,
In every breast implanting the desire
Of objects new and strange, to urge us on
With unremitting labour to attain
The sacred stores that wait the rip'ning soul
In Truth's exhaustless bosom. *Aikenside.*

But human life is not a situation of continual necessity; this would ill suit the plans of its beneficent Author: and it is from induction of phenomena totally opposite to this, and from such induction alone, that we have ever thought of a wise Creator. His wisdom appears only in His beneficence. Human life is a scene filled with enjoyment; and the soul of man is stored with propensities and powers which have *pleasure, in direct terms*, for their object. Another striking distinction of our nature is a continual disposition to refinement, of which few traces are to be found in the actions of other animals. There is hardly a gift of nature so grateful in itself as to please the freakish mind of man, till he has moulded it to his fancy. Not contented with food, with raiment, and with shelter, he must have nice cookery, ornamental dress, and elegant houses. He hunts when he is not hungry, and he refines sexual appetite into a most elegant passion. In like manner he has improved this anxious desire of the knowledge of the objects around him, so as to derive from them the means of subsistence and comfort, into the most elegant and pleasing of all gratifications, the accumulation of intellectual knowledge, independent of all consideration of its advantages. And as every man has a title to the enjoyment of such pleasures as he can attain without injuring his neighbour; so it is allowable to such as have got the means of intellectual improvement, without relinquishing the indispensable social duties, to push this advantage as far as it will go: and, in all ages and countries, it has been considered as forming the greatest distinction between men of easy fortune and the poor, who must earn their subsistence by the sweat of their brow. The plebeian must learn to work, the gentleman must learn to think; and nothing can be a surer mark of groveling soul than for a man of fortune to have an uncultivated mind.

81 Our disposition to refinement.

82 Ought to be cherished as far as it is subservient to the duties of life.

Let us then cherish to the utmost this distinguishing propensity of the human soul: but let us do even this like philosophers. Let us cultivate it as it is: as the handmaid to the arts and duties of life; as the guide to something yet more excellent. A character is not to be estimated from what the person knows, but from what he can perform. The accumulation of intellectual knowledge is too apt to create an inordinate appetite for it: and the man habituated to speculation is, like the miser, too apt to place that pleasure in the mere *possession*, which he ought to look for only or chiefly in the *judicious use* of his favourite object. Like the miser, too, his habits of hoarding up generally unfit him for the very enjoyment which at setting out he proposed to himself. Seldom do we find the man, who has devoted his life to scientific pursuits for their own sake, possessed of that superiority of mind which the active employ to good purpose in times of perplexity; and much seldomer do we find him possessed of that promptitude of apprehension, and that decision of purpose, which are necessary for passing through the difficult scenes of human life.

But we may use the good things of this life without abusing them; and by moderation here, as in all other pursuits, derive those solid advantages which philosophy is able to bestow. And these advantages are great. To enumerate and describe them would be to write a great volume. We may just take notice of one, which is an obvious consequence of that strict and simple view which we have given of the subject; and this is a modest opinion of our attainments. Appearances are all that we know; causes are for ever hid from our view; the powers of our nature do not lead us so far. Let us therefore, without hesitation, relinquish all pursuits which have such things as ultimate principles for *objects of examination*. Let us attend to the subordinations of things which it is our great business to explore. Among these there is such a subordination as that of means to ends, and of instruments to an operation. All will acknowledge the absurdity of the project of viewing light with a microscope. It is equally absurd for us to examine the nature of knowledge, of truth, of infinite wisdom, by our intellectual powers. We have a wide field of accessible knowledge in the works of God; and one of the greatest advantages, and of the most sublime pleasures, which we can derive from the contemplation, is the view which a judicious philosophical research will most infallibly give us of a world, not consisting of a number of detached objects, connected only by the fleeting tie of coexistence, but an *universe*, a *system* of beings, all connected together by causation, with innumerable degrees of subordination and subserviency, and all cooperating in the production of one great and glorious purpose. The heart which has but a spark of sensibility must be warned by such a prospect, must be pleased to find itself an important part of this stupendous machine; and cannot but adore the incomprehensible Artist

83 Limits of our knowledge.

tist who contrived, created, and directs the whole. Let us not listen, then, to the timid admonitions of theological ignorance, which shrinks with superstitious horror from the thoughts of accounting for every thing by the powers of nature, and considers these attempts as an approach to atheism. Philosophical disquisition will, on the contrary, exhibit these general laws of the universe, that wonderful concatenation and adjustment of every thing both material and intellectual, as the most striking instance of incomprehensible wisdom; which, by means so few and so simple, can produce effects which by their grandeur dazzle our imagination, and by their multiplicity elude all possibility of enumeration. Of all the obstacles which the weakness, the folly, or the sinful vanity of men, has thrown in the way of the theologian, there is none so fatal, so hostile to all his endeavours, as a cold and comfortless system of materialism, which the reasoning pride of man first engendered, which made a figure among a few speculatists in the last century, but was soon forgotten by the philosophers really busy with the observation of nature and of nature's God. It has of late reared up its head, being now cherished by all who wish to get rid of the stings of remorse, as the only opinion compatible with the peace of the licentious and the sensual; for we may say to them as Henry IV. said to the prince of Wales, "Thy wish was father, Harry, to that thought." In vain will the divine attempt to lay this devil with the metaphysical exorcisms of the schools; it is philosophy alone that can detect the cheat. Philosophy singles out the characteristic phenomena which distinguish every substance; and philosophy never will hesitate in saying that there is a set of phenomena which characterise mind and another which characterise body, and that these are *toto cœlo* different. Continually appealing to fact, to the phenomena, for our knowledge of every cause, we shall have no difficulty in deciding that thought, memory, volition, joy, hope, are not compatible attributes with bulk, weight, elasticity, fluidity. *Tuta sub ægide Pallas;* philosophy will maintain the dignity of human nature, will detect the sophisms of the materialists, confute their arguments; and she alone will restore to the countenance of nature that ineffable beauty, of which those would deprive her, who would take away the supreme Mind which shines from within, and gives life and expression to every feature.

84 Philosophical disquisition gives just notions of God and of our own souls.

For a view of the progress of modern philosophy, see the Dissertations prefixed to the volumes of the SUPPLEMENT.

Natural PHILOSOPHY. See *NATURAL Philosophy*, PHILOSOPHY, and PHYSICS.

Experimental PHILOSOPHY. See *EXPERIMENTAL Philosophy.*

Moral PHILOSOPHY. See *MORAL Philosophy.*

PHILOSTORGIUS, an ecclesiastical historian of the 4th century, was born in Cappadocia, and wrote an abridgement of ecclesiastical history, in which he treats Athanasius with some severity. This work contains many curious and interesting particulars. The best edition is that of Henry de Valois in Greek and Latin. There is also attributed to him a book against Porphyry.

PHILOSTRATUS, FLAVIUS, was an ancient Greek author. He wrote the Life of Apollonius Tyanensis, and some other things which have come down to our time. Eusebius against Hierocles calls him an Athenian, because he taught at Athens; but Eunapius and Suidas always speak of him as a Lemnian: and he hints, in his Life of Apollonius, that he used to be at Lemnos when he was young. He frequented the schools of the sophists; and he mentions his having heard Damianus of Ephesus, Proclus Naucratitas, and Hippodromus of Larissa. This seems to prove that he lived in the reign of the emperor Severus, from 193 to 212, when those sophists flourished. He became known afterwards to Severus's wife Julia Augusta, and was one of those learned men whom this philosophic empress had continually about her. It was by her command that he wrote the Life of Apollonius Tyanensis, as he relates himself in the same place where he informs us of his connections with that learned lady. Suidas and Hesychius say that he was a teacher of rhetoric, first at Athens and then at Rome, from the reign of Severus to that of Philippus, who obtained the empire in 244.

Philostratus's celebrated work is his Life of Apollonius; which has erroneously been attributed to Lucian, because it has been printed with some of that author's pieces. Philostratus endeavours, as Cyril observes, to represent Apollonius as a wonderful and extraordinary person; rather to be admired and adored as a god than to be considered as a mere man. Hence Eunapius, in the preface to his Lives of the Sophists, says that the proper title of that work would have been, *The Coming of a God to Men;* and Hierocles, in his book against the Christians which was called *Philalethes*, and which was refuted by Eusebius in a work still extant, among other things drew a comparison between Apollonius and Jesus Christ. It has always been supposed that Philostratus composed his work with a view to discredit the miracles and doctrines of our Lord, by setting up other miracles and other doctrines against them, and this supposition may be true; but that Apollonius was really an impostor and magician may not be so certain. He may, for what we know, have been a wise and excellent person; and it is remarkable, that Eusebius, though he had the worst opinion of Philostratus's history, says nothing ill of Apollonius. He concluded that that history was written to oppose the history of Jesus; and the use which the ancient infidels made of it justifies his opinion; but he draws no information from it with regard to Apollonius. It would have been improper to have done so; since the sophistical and affected style of Philostratus, the sources from whence he owns his materials to have been drawn, and, above all, the absurdities and contradictions with which he abounds, plainly show his history to be nothing but a collection of fables, either invented or at least embellished by himself.

The works of Philostratus, however, have engaged the

the attention of critics of the first class. Grævius had intended to have given a correct edition of them, as appears from the preface of Meric Casaubon to a dissertation upon an intended edition of Homer, printed at London in 1658, 8vo. So had Bentley, who designed to add a new Latin version of his notes; and Fabricius says that he saw the first sheet of Bentley's edition printed at Leipsic in 1691. Both these designs were dropped. A very exact and beautiful edition was published at length at Leipsic, 1709, in folio, by Olearius, professor of the Greek and Latin tongues in that university; who has proved himself perfectly qualified for the work he undertook, and shown all the judgement, learning, and industry, that are required in an excellent editor.

See APOLLONIUS, and BLOUNT (Charles).

At the end of Apollonius's Life there are 95 letters which go under his name. They are not, however, believed to be his; the style of them being very affected, and like that of a sophist, while they bear in other respects all the marks of a forgery. Philostratus says that he saw a collection of Apollonius's Letters in Hadrian's library at Antium, but had not inserted them all among these. They are short, and have in them little else than moral sentences. The Lives of the Sophists contain many things which are to be met with nowhere else. The Heroics of Philostratus are only a dialogue between a vintner of Thracian Chersonesus and a Phœnician, in which the former draws characters of Homer's heroes, and represents several things differently from that poet; and this upon the faith of Protesilaus's ghost, who had lately visited his farm, which was not far from the tomb of this hero. Olearius conjectures, with much probability, that Philostratus's design in this dialogue was secretly to criticise some things in Homer, which he durst not do openly on account of the great veneration then paid to him, and for fear of the odium which Zoilus and others had incurred by censuring him too freely. The images are elegant descriptions and illustrations of some ancient paintings and other particulars relating to the fine arts; to which Olearius has subjoined the description of some statues by Callistratus; for the same reason that he subjoined Eusebius's book against Hierocles to the Life and Letters of Apollonius, namely, because the subjects of these respective works are related to each other. The last piece is a collection of Philostratus's Letters; but some of these, though it is not easy to determine which, were written by a nephew to our Philostratus, of the same name, as were also the last eighteen in the book of images. This is the reason why the title runs not *Philostrati*, but *Philostratorum quæ supersunt omnia*.

There were many persons of the name of Philostratus among the ancients; and there were many other works of the Philostratus here recorded, but no others are extant besides those we have mentioned.

PHILOTIS, a servant maid at Rome, saved her countrymen from destruction. After the siege of Rome by the Gauls, the Fidenates assembled an army, and marched against the capital, demanding all the wives and daughters in the city as the only conditions of peace. This demand astonished the senators; and when they refused to comply, Philotis advised them to send all the female slaves disguised in matrons clothes, and she offered to march herself at the head. Her advice was followed; and when the Fidenates had feasted late in the evening, and were quite intoxicated and fallen asleep, Philotis lighted a torch as a signal for her countrymen to attack the enemy. The whole was successful; the Fidenates were conquered; and the senate, to reward the fidelity of the female slaves, permitted them to appear in the dress of the Roman matrons.

PHILOXENUS, an officer of Alexander, who received Cilicia at the general division of the provinces. ——A son of Ptolemy, who was given to Pelopidas as an hostage.——A dithyrambic poet of Cythera. He enjoyed the favour of Dionysius tyrant of Sicily for some time, till he offended him by seducing one of his female singers. During his confinement Philoxenus composed an allegorical poem called *Cyclops*; in which he had delineated the character of the tyrant under the name of Polyphemus, and represented his mistress under the name of Galatæa, and himself under that of Ulysses. The tyrant, who was fond of writing poetry, and of being applauded, removed Philoxenus from his dungeon; but the poet refused to purchase his liberty by saying things unworthy of himself, and applauding the wretched verses of Dionysius, and therefore he was sent to the quarries. Being set at liberty, he some time after was asked his opinion at a feast about some verses which Dionysius had just repeated, and which the courtiers had received with the greatest applause. Philoxenus gave no answer, but he ordered the guards that surrounded the tyrant's table to take him back to the quarries. Dionysius was pleased with his pleasantry and with his firmness, and immediately forgave him. Philoxenus died at Ephesus about 380 years before Christ.

PHILTER, or PHILTER, (*Philtrum*), in *Pharmacy*, &c. a strainer.

PHILTER, is also used for a drug or preparation, which it is pretended will excite love.—The word is formed from the Greek φιλεω, "I love," or φιλος, "lover."

Philters are distinguished into *true* and *spurious*, and were given by the Greeks and Romans to excite love. The spurious are spells or charms, supposed to have an effect beyond the ordinary laws of nature by some magic virtue; such are those said to be given by old women, witches, &c.—The true philters are those supposed to work their effect by some natural and magnetical power. There are many grave authors who believe the reality of these philters, and allege matter of fact in confirmation of their sentiments: among the rest, Van Helmont, who says, that upon holding a certain herb in his hand for some time, and taking afterwards a little dog by the foot with the same hand, the dog followed him wherever he went, and quite deserted his former master; which he pretends to account for thus: The heat communicated to the herb, not coming alone, but animated by the emanations of the natural spirits, determines the herb towards the man, and identifies it to him: having then received this ferment, it attracts the spirit of the other object magnetically, and gives it an amorous motion. But this is mere cant; and all philters, whatever facts may be alleged, are mere chimeras.

PHILYCA. See PHYLICA, BOTANY *Index*.

PHILYRA, in fabulous history, was one of the Oceanides, whom Saturn met in Thrace. The god, to escape from the vigilance of Rhea, changed himself into a horse, to enjoy the company of Philyra, by whom he had a son half a man and half a horse, called *Chiron*.

Philyra was so ashamed of giving birth to such a monster, that she entreated the gods to change her nature. She was accordingly metamorphosed into a tree, called by her name among the Greeks.

PHIMOSIS, in *Medicine*, a disorder of the penis, in which the prepuce is so strict or tense, that it cannot be drawn back over the glans. See SURGERY.

PHINEHAS, or, as the Jews pronounce it PINEHAS, was the son of Eleazar, and grandson of Aaron. He was the third high-priest of the Jews, and discharged this office from the year of the world 2571, till towards the year 2590. He is particularly commended in Scripture for the zeal he showed in vindicating the glory of God, when the Midianites had sent their daughters into the camp of Israel, to tempt the Hebrews to fornication and idolatry. For Zimri having publicly entered into the tent of a Midianitish woman named *Cozbi*, Phinehas arose up from among the people (Numb. xxv. 7, &c.), took a javelin in his hand, entered after Zimri into that infamous place, and stabbed both man and woman at one blow, in those parts that were chiefly concerned in this criminal commerce. Upon which the plague or distemper ceased with which the Lord had already begun to punish the Israelites. This happened in the year of the world 2553.

Then the Lord said to Moses, Phinehas the son of Eleazar the high-priest has turned away my wrath from the children of Israel, because he has been zealous in my cause, and has hindered me from destroying them: wherefore acquaint him, that I give him my covenant of peace, and the priesthood shall be given to his posterity by a perpetual covenant, because he has been zealous for his God, and has made atonement for the crime of the children of Israel. This promise that the Lord made to Phinehas, to give him the priesthood by a perpetual covenant, interpreters observe, evidently included this tacit condition, that his children should continue faithful and obedient; since we know that the priesthood passed out of the family of Eleazar and Phinehas to that of Ithamar, and that it returned not to the posterity of Eleazar till after about 150 years.

This is what we find concerning the translation of the high-priesthood from one family to the other. This dignity continued in the race of Phinehas, from Aaron down to the high-priest Eli, for about 353 years. See AARON.

The manner and causes of this change are unknown. It re-entered again into the family of Eleazar, under the reign of Saul, when this prince having put to death Abimelech, and the other priests of Nob, he gave the high-priesthood to Zadok, who was of the race of Phinehas. At the same time, David had Abiathar with him of the race of Eli, who performed the functions of high-priest. So that after the death of Saul, David continued the priesthood to Zadok and Abiathar conjointly. But towards the end of David's reign, Abiathar having espoused the interest of Adonijah, to the prejudice of Solomon, he was in disgrace, and Zadok only was acknowledged as high-priest. The priesthood continued in his family till after the captivity of Babylon, and even to the destruction of the temple. But from the beginning of Zadok's priesthood alone, and the exclusion of Abiathar, to the ruin of the temple, is 1084 years.

We read of another memorable action of Phinehas, in which he still showed his zeal for the Lord. This was when the Israelites that were beyond Jordan had raised upon the banks of this river a vast heap of earth (Josh. xxii. 30, 31.). Those on the other side fearing they were going to forsake the Lord, and set up another religion, deputed Phinehas and other chief men among them, to go and inform themselves of the reason of erecting this monument. But when they had found that it was in commemoration of their union and common original, Phinehas took occasion from thence to praise the Lord, saying, "We know that the Lord is with us, since you are not guilty of that prevarication we suspected you were."

We do not exactly know the time of the death of Phinehas. But as he lived after the death of Joshua, and before the first servitude under Chushan-rishathaim, during the time that there were neither kings nor judges in the land, and every one did what was right in his own eyes (Judges xvii. 6. xviii. 1. xxi. 24.); his death is put about the year of the world 2590. It was under his pontificate that the story of Micah happened, as also that of the tribe of Dan, when they made a conquest of Laish; and the enormity that was committed upon the wife of the Levite of the mountain of Ephraim (Judges xx. 28.). Phinehas's successor in the high-priesthood was Abiezar, or Abishuah.

The Rabbins allow a very long life to Phinehas. There are some who believe he lived to the time of the high-priest Eli, or even to the time of Samson. Others will have it, that he was the same as Eli, or rather as the prophet Elias, which would still prolong his life for several ages.

PHINEUS, in fabulous history, was a son of Agenor, king of Phœnicia, or according to some of Neptune. He became king of Thrace, or, according to the greater part of mythologists, of Bithynia. He married Cleopatra the daughter of Boreas, called by some *Cleobula*, by whom he had Plexippus and Pandion. After her death, he married Idæa the daughter of Dardanus. Idæa, jealous of his former wife's children, accused them of attempts upon their father's life and crown, or, as others assert, of attempts upon her virtue; on which they were condemned by Phineus to be deprived of their eyes. This cruelty was soon after punished by the gods; for Phineus suddenly became blind, and the Harpies were sent by Jupiter to keep him in continual alarm, and to spoil the meats which were placed on his table. He was afterwards delivered from these dangerous monsters by his brothers in-law Zetes and Calais, who pursued them as far as the Strophades. He likewise recovered his sight by means of the Argonauts, whom he had received with great hospitality, and whom he instructed in the easiest and speediest way of arriving in Colchis. The causes of the blindness of Phineus are a matter of dispute among the ancients; some supposing that this was inflicted by Boreas for his cruelty to his grandsons; while others attribute it to the anger of Neptune, because he had directed the sons of Phryxus how to escape from Colchis to Greece. Many, however, imagine that it proceeded from his having rashly attempted to develope futurity; while others assert that Zetes and Calais put out his eyes on account of his cruelty to their nephews. The second wife of Phineus is called by some *Dia*, *Eurytia*, *Danae*, and *Idothea*.—He was killed by Hercules.

PHLEBOTOMY, the opening of a vein with a proper sharp-edged and pointed instrument, in order to let out a certain quantity of blood either for the preservation or recovery of a person's health. See SURGERY.

PHLEGM, in the animal economy, one of the four humours whereof the ancients supposed the blood to be composed. The chemists make phlegm or water an elementary body; the characters of which are fluidity, insipidity, and volatility.

PHLEGMAGOGUES, in *Medicine*, a term anciently made use of for such medicines as were supposed to be endowed with the property of purging off phlegm; such as hermodactyls, agaric, turbith, jalap, &c.

PHLEGMATIC, among physicians, an appellation given to that habit or temperament of body wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c.

PHLEGMON, denotes an external inflammation and tumour, attended with a burning heat.

PHLEGON, who was surnamed *Trallianus*, was born in Trallis a city of Lydia. He was the emperor Hadrian's freed man, and lived to the 18th year of Antoninus Pius; as is evident from his mentioning the consuls of that year. He wrote several works of great erudition, of which we have nothing left but fragments. Among these was a History of the Olympiads, A Treatise of Long-lived Persons, and another of Wonderful Things; the short and broken remains of which Xylander translated into Latin, and published at Basil in 1568, with the Greek and with notes. Meursius published a new edition of them with his notes at Leyden, in 1622. The titles of part of the rest of Phlegon's writings are preserved by Suidas. It is supposed that the History of Hadrian, published under Phlegon's name, was written by Hadrian himself, from this passage of Spartianus: "Hadrian thirsted so much after fame (says he), that he gave the books of his own life, drawn up by himself, to his freedmen, commanding them to publish those books under their own names; for we are told that Hadrian wrote Phlegon's books."

Phlegon's name has been more familiar among the moderns, and his fragments have had a greater degree of regard paid to them than perhaps they deserve, merely because he has been supposed to speak of the darkness which prevailed during our Lord's passion. The book in which the words are contained is lost; but Eusebius has preserved them in his *Chronicon*. They are these: "In the 4th year of the 202d Olympiad, there was a greater and more remarkable eclipse of the sun than any that had ever happened before: for at the sixth hour the day was so turned into the darkness of night, that the very stars in the firmament were visible; and there was an earthquake in Bithynia which threw down many houses in the city of Nicæa." Eusebius thinks that these words of Phlegon related to the prodigies which accompanied Christ's crucifixion; and many other fathers of the church have thought the same: but this opinion is liable to many difficulties; for no man had ever a stronger desire than Phlegon to compile marvellous events, and to observe the supernatural circumstances in them. How was it then possible that a man of this turn of mind should not have taken notice of the most surprising circumstance in the eclipse which it is imagined he hints at, viz. its happening on the day when the moon was at the full? But had Phlegon done this, Eusebius would not have omitted it; and Origen would not have said that Phlegon had omitted this particular.

It was a matter of controversy some time ago, whether Phlegon really spoke of the darkness at the time of our Lord's passion; and many dissertations were written on both sides of the question. This dispute was occasioned by the above passage from Phlegon being left out in an edition of Clarke's Boyle's Lectures, published after his death, at the instance of Sykes, who had suggested to Clarke, that an undue stress had been laid upon it. Whiston, who informs us of this affair, expresses great displeasure against Sykes, and calls "the suggestion groundless." Upon this, Sykes published "A Dissertation on the Eclipse mentioned by Phlegon: or, "An Inquiry whether that Eclipse had any relation to the darkness which happened at our Saviour's Passion; 1732," 8vo. Sykes concludes it to be most probable that Phlegon had in view a natural eclipse which happened November 24, in the first year of the 202d Olympiad, and not in the 4th year of the Olympiad in which Christ was crucified. Many pieces were written against him, and to some of them he replied; but perhaps it is a controversy which concerns the learned world merely, since the cause of religion is but little affected by it.

Photius blames Phlegon for expatiating too much on trifles, and for collecting too great a number of answers pronounced by the oracles. "His style (he tells us) is not altogether flat and mean, nor does it everywhere imitate the attic manner of writing. But otherwise, the over nice accuracy and care with which he computes the Olympiads, and relates the names of the contests, the transactions, and even oracles, is not only very tiresome to the reader, whereby a cloud is thrown over all other particulars in that book, but the diction is thereby rendered unpleasant and ungrateful; and indeed he is every moment bringing in the answers pronounced by all kinds of deities."

PHLOGISTON, a term used by chemists to denote a principle which was supposed to enter into the composition of various bodies.

The bodies which were thought to contain it in the largest quantity are such as are inflammable; and the property which these substances possess of being susceptible of inflammation was thought to depend on this principle; and hence it was sometimes called the *Principle of Inflammability*. Inflammation, according to this doctrine, was the separation of *this principle* or *phlogiston* from the other matter which composed the combustible body. As its separation was always attended with the emission of light and heat, some chemists concluded that it was light and heat combined with other matter in a peculiar manner, or that it was some highly elastic and very subtile matter, on certain modifications of which heat and light depended.

Another class of bodies which were supposed to contain phlogiston are the metals; and the chemists supposed that the peculiar lustre of the metals depended on this principle. Of this they thought themselves convinced by the evidence of their senses in two ways; viz. first, because

Phlogiston. because by exposing a metal to the action of a long continued heat, it lost its metallic lustre, and was converted into an earthy-like substance called *calx metallicus*, or *oxide;* and secondly, because by mixing this oxide with any inflammable substance whatever, and subjecting the mixture to certain operations, the inflammable matter disappeared, and the metal was restored to its former state and lustre, without suffering much diminution in quantity, especially if the processes had been conducted with care and attention.

This fact relative to the metals was thought to be a full demonstration of itself, independent of other proofs which were brought to support the doctrine. These were, that a combustible body, by the act of inflammation (i. e. by the dissipation of its phlogiston in the form of heat and light), was converted into a body that was no longer combustible, but which might have its property of combustibility restored to it again by mixing the incombustible remains with any kind of inflammable matter, and submitting the mixture to certain processes. In this way the body was restored to its former state of inflammability.

They were also at some pains to prove that the *phlogiston* or the *principle of inflammability* was the same in all inflammable bodies and in the metals. This identity of phlogiston they thought to be evident from the fact, that the calx of a metal might be restored to its metallic state, or that the remains after the combustion of a combustible body might be restored to its original state of combustibility by the addition of any inflammable body whatever, taken either from the animal, vegetable, or mineral kingdoms.

These and several other facts were brought to prove, not only the existence of phlogistion, but its effects in mixture with other substances; and the objections which were made against the doctrine were removed with wonderful ingenuity. The chief objection against it was, that if the inflammation of a combustible body, or the conversion of a metal into calx, depends on the dissipation or extrication of phlogiston; then it must follow, that the remains of a combustible body after inflammation, and the calx of the metal, must be less than the matter from which they were produced: but this is contrary to fact; for when we collect with care all the vapour into which the purest inflammable bodies are converted by combustion, these incombustible remains are much heavier than the inflammable body was from which they were produced, and the calx into which a metal is converted by long exposure to the action of heat is heavier than the metal from which it was produced. This consideration made several people doubt of the truth of the doctrine; but the objection was removed by saying, that phlogiston was so subtle, as not only to have no weight, but to possess an absolute levity; and that when it was taken from an absolutely heavy body, that body must, by losing so much absolute levity, become heavier, in the same manner as the algebraists say, that a positive quantity is augmented by the substraction of a negative quantity. This sophism satisfied the minds of most of the chemists, especially those who were algebraists.

The opinion that phlogiston was heat and light somehow combined with other matter, was proved, not only by the fact, that heat and light were emitted from a combustible body during its combustion, but from the reduction of certain metallic calces to the original metallic state again, at least in some degree, by simple exposure to heat and light. The white calx of silver, for instance, when exposed in close sealed glass vessels to the light and heat of the sun, resumes a black tinge, and is in part restored to its metallic lustre without any addition whatever; but then this restoration, like the others above mentioned, is attended with a loss of weight.

Besides constituting the principal part of inflammable bodies and metals, phlogiston was thought to be the cause of colour in all vegetable and animal substances. This was concluded from the fact of plants growing white when defended from the action of the sun's rays, and in having their green colour restored by exposure to his rays again; and so far did the chemists suffer themselves to be deceived, that they actually thought the green colouring matter, which they extracted from fresh plants by certain chemical processes, to be an inflammable substance. A very material objection was made to this argument, viz. if plants owe their colour to phlogiston imparted by the sun's rays, why do the sun's rays destroy vegetable colours that are exposed to them? for we know that the sun's rays are very effectual in diminishing the lustre of the cloth dyed with vegetable colours, and in bleaching or taking out various stains from linen and other substances. All this was removed by saying, that the sun's rays possessed different powers on living and on dead vegetable matter, and that the living vegetables had the power of absorbing phlogiston from the sun's rays, which dead vegetable matter had not.

Since the existence of phlogiston, as a chemical principle in the composition of certain bodies, is now fully proved to be false, we shall not trouble our readers with any farther observations on it, except adding, that although the chemists were satisfied with the proofs they gave of its reality, they were never able to exhibit it in a separate state, or show it in a pure form, unmixed with other matter.

Phlogiston seems to have been admitted as a principle in the composition of certain bodies, and to have been supposed the cause of certain modifications of matter, merely with a view to explain some of those natural phenomena which the authors of it were unable to explain on other principles. Subsequent discoveries in natural philosophy and in chemistry have represented things in a very different light from that in which the old chemists viewed them. The old chemists knew nothing but chemistry; they seldom extended their views to the observation of objects beyond their laboratories, and it was not till philosophers became chemists, and chemists philosophers, that chemistry began to wear the garb of science. The epoch in which this change began was in the time of Lord Verulam, who first removed the dimness from the chemist's eyes, and to him succeeded the honourable Mr Boyle. Sir Isaac Newton, with the little assistance which his predecessors in this branch of science afforded him, is in reality the first who established chemistry on scientific ground. It must, however, be acknowledged, that although he made a great progress, he left much undone; and subsequent chemists, who were less accurate observers of nature, admitted principles unwarrantably. From the time of Sir Isaac Newton till the middle of the 18th century, no real improvement was made in scientific chemistry; and the progress this science has made since that period is owing

owing to the important discovery of the existence of heat in a state of composition with other matter. Heat thus combined loses its activity or becomes insensible, just in the same way as any other active substance loses its apparent qualities in composition. Acids, for example, when combined in a certain proportion with substances for which they have strong attraction, as alkalies or absorbent earths, lose all their obvious acid qualities, and the compound turns out mild, and totally conceals the acid which it contains. In a similar manner, heat, when combined in certain proportions with other matter, loses its sensible qualities, and the compound conceals the heat which it contains. Heat, in this combined state, was called by its ingenious discoverer, Dr Black, *latent heat*, and it was found to be very abundant in the atmosphere, which owes its existence as an elastic fluid to the quantity of latent heat that it contains. After this discovery was made, Dr Crawford, considering that air was absorbed by a burning body, concluded that the heat which appears in the combustion of a combustible body, is the heat that had before existed in the air which was consumed by the burning body. M. Lavoisier and others, prosecuting this inquiry, found that the combustible body, while it is burning, unites with the basis of the air, and that the heat which the air contained, and which was the cause of the air existing in the state of air, is expelled. This absorption of the basis of the air by the burning body, and the reduction of this basis to a solid form, accounts for the increase of weight which a body acquires by burning; or, in other words, gives a reason why the matter into which a combustible body is converted by combustion, is heavier than the body from which it was produced. The same absorption of air is observable, when a metal is converted into a calx, and the additional weight of the calx is found to be precisely equal to the weight of the air absorbed during the calcination. On these principles, therefore, we now explain the phenomena in a much more satisfactory manner than by the supposition of phlogiston, or a principle of inflammability. See Chemistry.

PHLOMIS, the Sage-tree, or *Jerusalem Sage*; a genus of plants belonging to the didynamia class. See Botany *Index*.

PHLOX, Lychnidea, or *Bastard Lychnis*; a genus of plants belonging to the pentandria class. See Botany *Index*.

PHLYCTENÆ, in *Medicine*, small eruptions on the skin.

PHOCA, a genus of quadrupeds of the order of feræ. See Mammalia *Index*.

PHOCÆA, the last town of Ionia, (Mela, Pliny); of Æolis, (Ptolemy), because situated on the right or north side of the river Hermus, which he makes the boundary of Æolis to the south. It stood far in the land, on a bay or arm of the sea; had two very safe harbours, the one called *Lampter*, the other *Naustathmos*, (Livy.) It was a colony of Ionians, situated in the territory of Æolis, (Herodotus). Massilia in Gaul was again a colony from it. *Phocæenses*, the people, (Livy); *Phocaicus*, the epithet, (Lucan); applied to *Marseilles*. It was one of the 12 cities which assembled in the Panionium or general council of Ionia.

Ancient Univ. Hist. vol. vi.

Some writers tell us, that while the foundations of this city were laying, there appeared near the shore a great shoal of sea-calves; whence it was called *Phocæa*, the word *phoca* signifying in Greek a *sea-calf*. Ptolemy, who makes the river Hermus the boundary between Æolia and Ionia, places Phocæa in Æolis; but all other geographers reckon it among the cities of Ionia. It stood on the sea-coast, between Cuma to the north, and Smyrna to the south, not far from the Hermus; and was, in former times, one of the most wealthy and powerful cities of all Asia; but is now a poor beggarly village, though the see of a bishop. The Phocæans were expert mariners, and the first among the Greeks that undertook long voyages; which they performed in galleys of fifty oars. As they applied themselves to trade and navigation, they became acquainted pretty early with the coasts and islands of Europe, where they are said to have founded several cities, namely, Velia in Italy; Alalia, or rather Aleria, in Corsica; and Marseilles in Gaul. Neither were they unacquainted with Spain; for Herodotus tells us, that in the time of Cyrus the Great, the Phocæans arriving at Sartessus, a city in the bay of Cadiz, were treated with extraordinary kindness by Arganthonius king of that country; who, hearing that they were under no small apprehension of the growing power of Cyrus, invited them to leave Ionia, and settle in what part of his kingdom they pleased. The Phocæans could not be prevailed upon to forsake their country; but accepted a large sum of money, which that prince generously presented them with, to defray the expence of building a strong wall round their city. The wall they built on their return; but it was unable to resist the mighty power of Cyrus, whose general Harpagus, investing the city with a numerous army, soon reduced it to the utmost extremities. The Phocæans, having no hopes of any succour, offered to capitulate; but the conditions offered by Harpagus seeming severe, they begged he would allow them three days to deliberate; and in the mean time, withdraw his forces. Harpagus, though not ignorant of their design, complied with their request. The Phocæans, taking advantage of this condescension, put their wives, children, and all their most valuable effects, on board several vessels which they had ready equipped, and conveyed them safe to the island of Chios, leaving the Persians in possession of empty houses. Their design was to purchase the Oenessian islands, which belonged to the Chians, and settle there. But the Chians not caring to have them so near, lest they should engross all the trade to themselves, as they were a seafaring people, they put to sea again; and, having taken Phocæa, their native country, by surprise, put all the Persians they found in it to the sword. They went to Corsica; great part of them however returned very soon, as did the rest also in a few years. They then lived in subjection either to the Persians, or tyrants of their own. Among the latter we find mention made of Laodamus, who attended Darius Hystaspis in his expedition against the Scythians; and of Dionysius, who, joining Aristagoras, tyrant of Miletus, and chief author of the Ionian rebellion, retired, after the defeat of his countrymen, to Phœnicia, where he made an immense booty, seizing on all the ships he met with trading to that country. From Phœnicia he sailed to Sicily, where he committed great depredations on the Carthaginians and Tuscans; but is said never to have molested the Greeks.

In the Roman times the city of Phocæa sided with Antiochus

Antiochus the Great; whereupon it was besieged, taken, and plundered by the Roman general; but allowed to be governed by its own laws. In the war which Aristonicus brother to Attalus, king of Pergamus, raised against the Romans, they assisted the former to the utmost of their power; a circumstance which so displeased the senate, that they commanded the town to be demolished, and the whole race of the Phocæans to be utterly rooted out. This severe sentence would have been put in execution, had not the Massilienses, a Phocæan colony, interposed, and, with much difficulty, assuaged the anger of the senate. Pompey declared Phocæa a free city, and restored the inhabitants to all the privileges they had ever enjoyed; whence, under the first emperors, it was reckoned one of the most flourishing cities of all Asia Minor. This is all we have been able to collect from the ancients touching the particular history of Phocæa.

PHOCAS, a Roman centurion, was raised to the dignity of emperor by the army, and was crowned at Constantinople about the year 603. The emperor Mauritius, who was thus deserted both by the army and the people, fled to Chalcedon with his five children, whom Phocas caused to be inhumanly murdered before his eyes, and then he murdered Mauritius himself, his brother, and several other persons who were attached to that family.

Ancient Univ. Hist. vol. xv.

Phocas, thus proclaimed and acknowledged at Constantinople, sent, according to custom, his own image and that of his wife Leontia to Rome, where they were received with loud acclamations, the people there being incensed against Mauritius on account of the cruel exactions of the exarchs, and his other ministers in Italy. Gregory, surnamed the Great, then bishop of Rome, caused the images to be lodged in the oratory of the martyr Cæsarius, and wrote letters to the new emperor, congratulating him upon his advancement to the throne, which he said was effected by a particular providence, to deliver the people from the innumerable calamities and heavy oppressions under which they had long groaned. Had we no other character of Phocas and Leontia but that which has been conveyed to us in Gregory's letters, we should rank him amongst the best princes mentioned in history; but all other writers paint him in quite different colours; and his actions, transmitted to us by several historians, evidently speak him a most cruel and blood-thirsty tyrant. He was of middling stature, says Cedrenus, deformed, and of a terrible aspect: his hair was red, his eye-brows met, and one of his cheeks was marked with a scar, which, when he was in a passion, grew black and frightful: he was greatly addicted to wine and women, blood-thirsty, inexorable, bold in speech, a stranger to compassion, in his principles a heretic. He endeavoured, in the beginning of his reign, to gain the affections of the people by celebrating the Circensian games with extraordinary pomp, and distributing on that occasion large sums among the people; but finding that instead of applauding they reviled him as a drunkard, he ordered his guards to fall upon them. Some were killed, many wounded, and great numbers were dragged to prison: but the populace rising, set them at liberty, and thenceforth conceived an irreconcileable aversion to the tyrant.

As soon as the death of Mauritius was known, Narses, who then commanded the troops quartered on the frontiers of Persia, revolted. Phocas, however, managed matters so as to gain him over to his interest, and then treacherously and cruelly burnt him alive. He endeavoured to strengthen his cause by respectable alliances; but his cruelty was such as to render him generally hated, for he spared neither sex nor age, and amongst others he murdered Constantina the widow of Mauritius, and her daughters. These cruelties were at length the cause of his downfall. He became universally hateful; and persons in great authority near his person conspired against him. This conspiracy, however, was discovered, and the persons concerned in it were all put to death. The following year, however, 610, he was overtaken by the fate he had so long deserved.

Heraclius, the son of the governor of Africa, who bore the same name, taking upon him the title of emperor, and being acknowledged as such by the people of Africa, sailed from thence with a formidable fleet, and a powerful army on board, for Constantinople, while Nicetas marched thither by way of Alexandria and the Pentapolis. Heraclius steered his course to Abydus, where he was received with great demonstrations of joy by several persons of rank, who had been banished by Phocas. From Abydus he sailed to Constantinople, where he engaged and utterly defeated the tyrant's fleet. Phocas took refuge in the palace; but one Photinus, whose wife he had formerly debauched, pursuing him with a party of soldiers, forced the gates, dragged the cowardly emperor from the throne, and having stripped him of the imperial robes, and clothed him with a black vest, carried him in chains to Heraclius, who commanded first his hands and feet, then his arms, and at last his head, to be cut off: the remaining part of his body was delivered up to the soldiers, who burnt it in the forum. We are told, that Heraclius having reproached him with his evil administration, he answered, with great calmness, "It is incumbent upon you to govern better." Such was the end of this cruel tyrant, after he had reigned seven years and some months.

PHOCILIDES, a Greek poet and philosopher of Miletus, flourished about 540 years before the Christian era. The poetical piece now extant, attributed to him, is not of his composition, but of another poet who lived in the reign of Adrian.

PHOCION was a distinguished Athenian general and orator in the time of Philip II. of Macedon. His character is thus described in the Ancient Universal History. "He was too modest to solicit command, nor did he promote wars that he might raise his authority by them; though, taken either as a soldier, orator, statesman, or general, he was by far the most eminent Athenian of his time. As he was a most disinterested patriot, he could entertain no great affection for Philip: but as he perfectly well knew the disposition of his countrymen, and how unlikely they were long to support such measures as were necessary to humble the Macedonian power, he did not express himself vehemently, but chose rather to cultivate the esteem which on all occasions Philip showed for the state of Athens, as a mean of preserving her, when she should be reduced to that situation which he conceived they wanted virtue to prevent. From this character the reader will easily discern that

Ancient Univ. Hist. vol. v.

Demosthenes

Phocion.

Demosthenes and he could not well agree. The former was always warm, his language copious, and his designs extensive; and Phocion, on the other hand, was of a mild temper, delivered his opinion in very few words, and proposed schemes at once necessary and easy to be effected. Yet he seldom or never concurred with the people, but spoke as poignantly against their vices as Demosthenes himself; insomuch, that this orator once told him, 'The Athenians, Phocion, in some of their mad fits, will murder thee.' 'The same (answered he) may fall to thee, Demosthenes, if ever they come to be sober.'

He was afterwards appointed to command the army which was sent to assist the Byzantines against Philip, whom he obliged to return to his own dominions. This truly great man, whom (though extremely poor) no sum could bribe to betray his country, and who at every risk on all occasions gave them sound advice, was at length accused by his ungrateful countrymen. This event happened in the year before Christ 318. He was sent to Athens by Polysperchon head of a faction in Macedonia, together with his friends, chained in carts, with this message, "That though he was convinced they were traitors, yet he left them to be judged by the Athenians as a free people." Phocion demanded whether they intended to proceed against him by form of law; and some crying out that they would, Phocion demanded how that could be if they were not allowed a fair hearing: but perceiving, by the clamour of the people, that no such thing was to be expected, he exclaimed, "As for myself, I confess the crime objected to me, and submit to the judgment of the law; but consider, O ye Athenians, what have these poor innocent men done that they should be involved in the same calamity with me?" The people replied with great vociferation, "They are your accomplices, and that is enough." Then the decree was read, adjudging them all to death, viz. Phocion, Nicocles, Aheudippus, Agamon, and Pythocles; these were present: Demetrius Phalereus, Callimedon, Charicles, and others, were condemned in their absence. Some moved that Phocion might be tortured before he was put to death; nay, they were for bringing the rack into the assembly, and torturing him there. The majority, however, thought it enough if he was put to death, for which the decree was carried unanimously; some putting on garlands of flowers when they gave their votes. As he was going to execution, a person who was his intimate friend asked him if he had any message for his son? "Yes," replied Phocion; "tell him it is my last command that he forget how ill the Athenians treated his father."

The spleen of his enemies was not extinguished with his life: they passed a decree whereby his corpse was banished the Athenian territories; they likewise forbade any Athenians to furnish fire for his funeral pile. One Conopian took up the corpse, and carried it beyond Eleusina, where he borrowed some fire of a Megarian woman and burned it. A Megarian matron, who attended with her maid, raised on the place an honorary monument; and having gathered up the bones, carried them home, and buried them under her own hearth; praying at the same time thus to the Penates: "To you, O ye gods, guardians of this place, I commit the precious remains of the most excellent Phocion. Protect them, I beseech you, from all insults; and deliver them one day to be reposited in the sepulchre of his ancestors, when the Athenians shall become wiser." It was not long before this opportunity occurred. When the Athenians began to cool a little, and remember the many services they had received from Phocion, they decreed him a statue of brass; ordered his bones to be brought back at the public expence; and decreed that his accusers should be put to death. Agnonides, who was principally concerned in that tragedy, suffered; but Epicurus and Demophilus, who were also accomplices in it, fled. However, Phocion's son met with them, and executed his revenge upon them; which was almost the only good action he ever performed, as he had a very small share of his father's abilities, and not any of his virtues. Such is the fickleness and such the injustice of popular governments; failings which, if we are to judge from universal experience, are absolutely inseparable from them.

Phocion, Phocis.

PHOCIS, (Demosthenes, Strabo, Pausanias); a country of Greece, contained between Bœotia to the east and Locris to the west, but extending formerly from the Sinus Corinthiacus on the south to the sea of Eubœa on the north, and, according to Dionysius, as far as Thermopylæ; but reduced afterwards to narrower bounds. *Phocenses*, the people; *Phocicus*, the epithet, (Justin); *Bellum Phocicum*, the sacred war which the Thebans and Philip of Macedon carried on against them for plundering the temple at Delphi; and by which Philip paved the way to the sovereignty of all Greece, (Justin). It greatest length was from north to south, that is, from 38° 45′ to 39° 20′, or about 35 miles; but very narrow from east to west, not extending to 30 miles, that is, from 23° 10′ to 23° 40′ at the widest, but about 23 miles towards the Corinthian bay and much narrower still towards the north. This country is generally allowed to have taken its name from Phocus the son of Ornytion, a native of Corinth; but having been soon after invaded by the Eginetæ, under the conduct of another Phocus, who was the son of Eacus king of Enopia, the memory of the first insensibly gave way to that of the second.

Ancient Univ. Hist. vol. v.

In Phocis there were many celebrated mountains, such as Cythæron, HELICON, and PARNASSUS. The last two we have already noticed in the order of the alphabet. Cythæron was consecrated to the muses as well as the other two, and was consequently much celebrated by the poets. Both it and Helicon contend with Mount Parnassus for height and magnitude. There were no remarkable rivers in Phocis except Cephisus, which runs from the foot of Parnassus northward, and empties itself into the Pindus, which was near the boundary of that kingdom. It had several very considerable cities; such as Cyrra, Crissa, and Antecyra, which, according to Ptolemy, were on the sea coasts; and Pythia, Delphi, Daulis, Elatia, Ergosthenia, and Baulia, which were inland towns. Elatia was the largest and richest after Delphi.

Deucalion was king of that part of Phocis which lies about Parnassus, at the time that Cecrops flourished in Attica; but the Phocians afterwards formed themselves into a commonwealth, to be governed by their general assemblies, the members of which were chosen from among themselves, and were changed as often as occasion required. Of the history of the Phocians but little is known till the time of the holy war, of which we have the following account in the Ancient Universal History.

"The Phocians having presumed to plough the territories of the city of Cyrra, consecrated to the Delphic god, were summoned by the other Grecians states before the court of the Amphictyons, where a considerable fine was imposed upon them for their sacrilege. They refused to pay it, on pretence that it was too large; and at the next assembly their dominions were adjudged confiscated to the use of the temple. This second sentence exasperated the Phocians still more; who, at the instigation of one Philomelus, or, as he is called by Plutarch, Philomedes, seized upon the temple, plundered it of its treasure, and held the sacred depositum for a considerable time. This second crime occasioned another assembly of the Amphictyons, the result of which was a formal declaration of war against the Phocians. The quarrel being become more general, the several states took part in it according to their inclinations or interest. Athens, Sparta, and some others of the Peloponnesians, declared for the Phocians; and the Thebans, Thessalians, Locrians, and other neighbouring states, against them. A war was commenced with great fury on both sides, and styled *the holy war*, which lasted ten years; during which the Phocians, having hired a number of foreign troops, made an obstinate defence, and would in all probability have held out much longer had not Philip of Macedon given the finishing stroke to their total defeat and punishment. The war being ended, the grand council assembled again, and imposed an annual fine of 60 talents upon the Phocians, to be paid to the temple, and continued till they had fully repaired the damage it had sustained from them; and, till this reparation should be made, they were excluded from dwelling in walled towns, and from having any vote in the grand assembly. They did not, however, continue long under this heavy sentence: their known bravery made their assistance so necessary to the rest, that they were glad to remit it; after which remission they continued to behave with their usual courage and resolution, and soon obliterated their former guilt."

We cannot finish this article without mentioning more particularly Daulis, rendered famous, not so much for its extent or richness, as for the stature and prowess of its inhabitants; but still more for the inhuman repast which was served up to Tereus king of Thrace by the women of this city, by whom he was soon after murdered for the double injury he had done to his sister-in law Philomela, daughter of Pandion king of Athens. See PHILOMELA.

PHOEBUS, one of the names given by ancient mythologists to the Sun, Sol, or Apollo. See APOLLO.

PHOENICIA, or more properly PHOENICE, the ancient name of a country lying between the 34th and 36th degrees of north latitude; bounded by Syria on the north and east, by Judæa on the south, and by the Mediterranean on the west. Whence it borrowed its name is not absolutely certain. Some derive it from one Phœnix; others from the Greek word *phœnix*, signifying a *palm* or *date*, as that tree remarkably abounded in this country. Some again suppose that Phœnice is originally a translation of the Hebrew word *Edom*, from the Edomites who fled thither in the days of David. By the contraction of Canaan it was also called *Chna*, and anciently *Rhabbothin* and *Colpitis* (A). The Jews commonly named it *Canaan*; though some part of it, at least, they knew by the name of *Syrophœnice* (B). Bochart tells us that the most probable etymology is *Phene Anak*, i. e. "the descendants of Anak." Such were the names peculiar to this small country; though Phœnice was sometimes extended to all the maritime countries of Syria and Judea, and Canaan to the Philistines, and even to the Amalekites. On the contrary, these two names, and the rest, were most generally swallowed up by those of Palestine and Syria (C).

Ancient Univ. Hist. vol. ii.

There is some disagreement among authors with respect to the northern limits of this country. Ptolemy makes the river Eleutherus the boundary of Phoenice to the north; but Pliny, Mela, and Stephanus, place it in the island of Aradus, lying north of that river. Strabo observes, that some will have the river Eleutherus to be the boundary of Seleucis, on the side of Phœnice and Cœlesyria. On the coast of Phœnice, and south of the river Eleutherus, stood the following cities: SIMYRA, Orthosia, TRIPOLIS, Botrys, Byblus, Palæbyblus, Berytus, SIDON, SAREPTA, TYRUS, Palætyrus.

Phœnice extended, according to Ptolemy, even beyond Mount Carmel; for that geographer places in Phœnice not only Ecdippa and Ptolemais, but Sycaminum and Dæra, which stand south of that mountain. These, however, properly speaking, belonged to Palestine. We will not take upon us to mark out the bounds of the midland Phœnice. Ptolemy reckons in it the following towns; Arca, Palæbyblus (Old Byblus), Gabala, and Cæsaria Paniæ. This province was considerably extended in the times of Christianity; when, being considered as a province of Syria, it included not only Damascus but Palmyra also.

The soil of this country is good, and productive of many necessaries for food and clothing. The air is wholesome, and the climate agreeable. It is plentifully watered by small rivers; which, running down from Mount Libanus, sometimes swell to an immoderate degree, either increased by the melting of the snows on that mountain, or by heavy rains. Upon these occasions they overflow, to the great danger and hinderance of the traveller and damage of the country. Among these rivers is that of ADONIS.

It

(A) This last name is a translation of the first. *Rabhotsen* is in Hebrew a *great gulf* or *bay*. From *rabhotsen*, by changing the Hebrew *ts* into the Greek *t*, comes *rabboten*; and, with a little variation, *rhabbothin*. Κολπος, *colpos*, is Greek also for a *bay* or *gulf*; whence it appears that *colpitis* or *colpites* is a translation of *rabbothin*.

(B) Bochart supposes that the borderers, both upon the Phœnician and Syrian side, were called by the common name of Syrophœnicians, as partaking equally of both nations.

(C) Or rather Phœnice, Palestine, and Syria, were promiscuously used for each other, and particularly the two former. Phœnice and Palestine, says Stephanus Byzantinus, were the same. As for Syria, we have already observed, that in its largest extent it sometimes comprehended Phœnice and Cœlesyria. Herodotus plainly confounds these three names; we mean, uses one for the other indifferently.

It is universally allowed that the Phœnicians were Canaanites (D) by descent: nothing is plainer or less contested, and therefore it were time lost to prove it. We shall only add, that their blood must have been mixed with that of foreigners in process of time, as it happens in all trading places; and that many strange families must have settled among them, who could consequently lay no claim to this remote origin, how much soever they may have been called Phœnicians, and reckoned of the same descent with the ancient proprietors.

The Phœnicians were governed by kings; and their territory, as small a slip as it was, included several kingdoms; namely, those of Sidon, Tyre, Aradus, Berytus, and Byblus. In this particular they imitated and adhered to the primitive government of their forefathers; who, like the other Canaanites, were under many petty princes, to whom they allowed the sovereign dignity, reserving to themselves the natural rights and liberties of mankind. Of their civil laws we have no particular system.

With regard to religion, the Phœnicians were the most gross and abominable idolaters. The Baal-berith, Baalzebub, Baalsamen, &c. mentioned in Scripture, were some of the Phœnician gods; as were also the Moloch, Ashtaroth, and Thammuz, mentioned in the sacred writings.—The word *Baal*, in itself an appellative, was no doubt applied to the true God, until he rejected it on account of its being so much profaned by the idolaters. The name was not appropriated to any particular deity among the idolatrous nations, but was common to many; however, it was generally imagined that one great God presided over all the rest. Among the Phœnicians this deity was named *Baal-samen;* whom the Hebrews would have called *Baal-shemim*, or the God of heaven. In all probability this was also the principal Carthaginian deity, though his Punic name is unknown. We have many religious rites of the Carthaginians handed down to us by the Greek and Roman writers; but they all bestowed names of their own gods upon those of the Carthaginians, which leads us to a knowledge of the correspondence between the characters of the Phœnician and European deities. The principal deity of Carthage, according to Diodorus Siculus, was Chronus or Saturn. The sacrifices offered up to him were children of the best families. Our author also tells us, that the Carthaginians had a brazen statue or colossus of this god, the hands of which were extended in act to receive, and bent downwards in such a manner, that the child laid thereon immediately fell down into a hollow where there was a fiery furnace. He adds also, that this inhuman practice seemed to confirm a tradition handed down to the Greeks from very early antiquity, viz. that Saturn devoured his own children.

The goddess Cœlestis, or Urania, was held in the highest veneration by the Carthaginians. She is thought to have been the same with the queen of heaven mentioned in Jeremiah, the Juno Olympia of the Greeks. According to Hesychius, the same word applied in the Punic language both to Juno and Venus: Nay, the ancient Greeks frequently confound Juno, Venus, and Diana or the moon, all together; which is to be attributed to the Egyptians and Phœnicians, from whom they received their system of religion; who seem in the most ancient times to have had but one name for them all. Besides these there were several other deities of later date, who were worshipped among the Phœnicians, particularly those of Tyre, and consequently among the Carthaginians also. These were Jupiter, Apollo, Mars, and Bacchus. Jupiter was worshipped under the name of *Belus* or *Baal.* To him they addressed their oaths; and placed him for the most part, as there is reason to believe, at the head of their treaties. The same name was also given to the other two, whence they were frequently mistaken for one another. Apollo or the sun, went either by this name simply, or by others of which this made a part.

The Carthaginian superstition, however, was not confined to these deities alone. They worshipped also the fire, air, and other elements; and had gods of rivers, meads, &c. Nay, they paid divine honours to the spirits of their heroes, and even to men and women themselves while yet in life; and in this adoration Hannibal the Great had for some time a share, notwithstanding the infamous conduct of his countrymen towards him at last. In order to worship those gods with more conveniency on all occasions, the Carthaginians had a kind of portable temples. These were only covered chariots, in which were some small images representing their favourite deities; and which were drawn by oxen. They were also a kind of oracle; and their responses were understood by the motion impressed upon the vehicle. This was likewise an Egyptian or Libyan custom; and Tacitus informs us that the ancient Germans had something of the same kind. The tabernacle of Moloch is thought to have been a machine of this kind; and it is not improbable that the whole was derived from the tabernacle of the Jews in the wilderness.

Besides all the deities above mentioned, we still find another, named the *Dæmon* or *Genius* of Carthage, mentioned in the treaty made by Philip of Macedon and Hannibal. What this deity might be, we know not; however, it may be observed, that the pagan world in general believed in the existence of dæmons, or intelligences who had a kind of middle nature between gods and men, and to whom the administration of the world was in a great measure committed. Hence it is no wonder that they should have received religious honours. For when once mankind were possessed with the opinion that they were the ministers of the gods, and trusted with the dispensation of their favours, as well as the infliction

(D) Bochart insinuates that the Canaanites were ashamed of their name, on account of the curse denounced on their progenitor, and terrified by the wars so vigorously and successfully waged on them by the Israelites, purely because they were Canaanites; and that therefore, to avoid the ignominy of the one and the danger of the other, they abjured their old name, and changed it for Phœnicians, Syrians, Syrophœnicians, and Assyrians. Heidegger conjectures also that they were ashamed of their ancestor Canaan.

fliction of their punishments, it is natural to suppose that they would be desirous of making their addresses to them. See ASTARTE and POLYTHEISM.

Herodotus supposes the Phœnicians to have been circumcised; but Josephus asserts, that none of the nations included under the vague name of Palestine and Syria used that rite, the Jews excepted; so that if the Phœnicians had anciently that custom, they came in time to neglect it, and at length wholly laid it aside. They abstained however from the flesh of swine.

Much is said of their arts, sciences, and manufactures; but as what we find concerning them is couched in general terms only, we cannot descant on particulars. The Sidonians, under which denomination we comprehend the Phœnicians in general, were of a most happy genius. They were from the beginning addicted to philosophical exercises of the mind; insomuch that a Sidonian, by name Moschus, taught the doctrine of atoms before the Trojan war: and Abomenus of Tyre puzzled Solomon by the subtility of his questions. Phœnice continued to be one of the seats of learning, and both Tyre and Sidon produced their philosophers of later ages; namely, Boethus and Diodatus of Sidon, Antipater of Tyre, and Apollonius of the same place; who gave an account of the writings and disciples of Zeno. For their language, see PHILOLOGY, N° 61. As to their manufactures, the glass of Sidon, the purple of Tyre, and the exceeding fine linen they wove, were the product of their own country, and their own invention: and for their extraordinary skill in working metals, in hewing timber and stone; in a word, for their perfect knowledge of what was solid, great, and ornamental in architecture—we need only put the reader in mind of the large share they had in erecting and decorating the temple at Jerusalem under their king Hiram. Their fame for taste, design, and ingenious invention, was such, that whatever was elegant, great, or pleasing, whether in apparel, vessels, or toys, was distinguished by way of excellence with the epithet of Sidonian.

The Phœnicians were likewise celebrated merchants, navigators, and planters of colonies in foreign parts. As merchants, they may be said to have engrossed all the commerce of the western world: as navigators, they were the boldest, the most experienced, and greatest discoverers, of the ancient times: they had for many ages no rivals. In planting colonies they exerted themselves so much, that considering their habitation was little more than the slip of ground between Mount Libanus and the sea, it is surprising how they could furnish such supplies of people, and not wholly depopulate their native country.

It is generally supposed that the Phœnicians were induced to deal in foreign commodities by their neighbourhood with the Syrians, who were perhaps the most ancient of those who carried on a considerable and regular trade with the more eastern regions: and this conjecture appears probable at least; for their own territory was but small, and little able to afford any considerable exports, if we except manufactures: but that their manufactures were anyways considerable till they began to turn all the channels of trade into their own country, it is hard to believe. In Syria, which was a large country, they found store of productions of the natural growth of that soil, and many choice and useful commodities brought from the east. Thus, having a safe coast, with convenient harbours, on one side, and excellent materials for ship-building on the other; perceiving how acceptable many commodities that Syria furnished would be in foreign parts, and being at the same time, perhaps, shown the way by the Syrians themselves, who may have navigated the Mediterranean—they turned all their thoughts to trade and navigation, and by an uncommon application soon eclipsed their masters in that art.

It were in vain to talk of the Edomites, who fled hither in David's time; or to inquire why Herodotus supposes the Phœnicians came from the Red sea: their origin we have already seen. That some of the Edomites fled into this country in the days of David, and that they were a trading people, is very evident: what improvements they brought with them into Phœnice, it is hard to say; and by the way, it is as difficult to ascertain their numbers. In all probability they brought with them a knowledge of the Red sea, and of the south parts of Arabia, Egypt, and Ethiopia; and by their information made the Phœnicians acquainted with those coasts; by which means they were enabled to undertake voyages to those parts, for Solomon, and Pharaoh Necho, king of Egypt.

Their whole thoughts were employed on schemes to advance their commerce. They affected no empire but that of the sea; and seemed to aim at nothing but the peaceable enjoyment of their trade. This they extended to all the known parts they could reach; to the British isles, commonly understood by the Cassiterides; to Spain, and other places in the ocean, both within and without the straits of Gibraltar; and, in general, to all the ports of the Mediterranean, the Black sea, and the lake Mæotis. In all these parts they had settlements and correspondents, from which they drew what was useful to themselves, or might be so to others; and thus they exercised the three great branches of trade, as it is commonly divided into importation, exportation, and transportation, in full latitude. Such was their sea-trade; and for that which they carried on by land in Syria, Mesopotamia, Assyria, Babylonia, Persia, Arabia, and even in India, it was of no less extent, and may give us an idea of what this people once was, how rich and how deservedly their merchants are mentioned in Scripture as equal to princes. Their country was, at that time, the great warehouse, where every thing that might either administer to the necessities or luxury of mankind was to be found; which they distributed as they judged would be the best for their own interest. The purple of Tyre, the glass of Sidon, and the exceeding fine linen made in this country, together with other curious pieces of art in metals and wood, already mentioned, appear to have been the chief and almost only commodities of Phœnice itself. Indeed their territory was so small, that it is not to be imagined they could afford to export any of their own growth; it is more likely that they rather wanted than abounded with the fruits of the earth.

Having thus spoken in general terms of their trade, we shall now touch upon their shipping and some things remarkable in their navigation. Their larger embarkations were of two sorts; they divided them into round ships or gauli; and long ships, galleys, or triremes. When they drew up in line of battle, the gauli were disposed

posed at a small distance from each other in the wings, or in the van and the rear: their triremes were contracted together in the centre. If, at any time, they observed that a stranger kept them company in their voyage, or followed in their track, they were sure to get rid of him if they could, or deceive him if possible; in which policy they went so far, as to venture the loss of their ships, and even their lives; so jealous were they of foreigners, and so tenaciously bent on keeping the whole trade to themselves. In order to discourage other nations from engaging in commerce, they practised piracy, or pretended to be at war with such as they met when they thought themselves strongest. This was but a natural stroke of policy in people who grasped at the whole commerce of the then known world. We must not forget here the famous fishery of Tyre, which so remarkably enriched that city. See ASTRONOMY, N° 7. OPHIR, and TYRE.

PHOENICOPTERUS, or FLAMINGO, a genus of birds belonging to the order of grallæ. See ORNITHOLOGY *Index*.

PHOENIX, in *Astronomy*. See ASTRONOMY *Index*.

PHOENIX, the *Great Palm*, or *Date tree*, a genus of plants belonging to the order of palmæ. See BOTANY *Index*. As the account of this valuable plant already given in its proper place, under BOTANY, is rather short to be satisfactory, we shall here enter a little more into the detail of its natural history. There is only one species, viz. the dactylifera, or common date-tree, a native of Africa and eastern countries, where it grows to 50, 60, and 100 feet high. The trunk is round, upright, and studded with protuberances, which are the vestiges of the decayed leaves. From the top issues forth a cluster of leaves or branches eight or nine feet long, extending all around like an umbrella, and bending a little towards the earth. The bottom part produces a number of stalks like those of the middle, but seldom shooting so high as four or five feet. These stalks, says Adanson, diffuse the tree very considerably; so that, wherever it naturally grows in forests, it is extremely difficult to open a passage through its prickly leaves. The date-tree was introduced into Jamaica soon after the conquest of the island by the Spaniards. There are, however, but few of them in Jamaica at this time. The fruit is somewhat in the shape of an acorn. It is composed of a thin, light, and glossy membrane, somewhat pellucid and yellowish; which contains a fine, soft, and pulpy fruit, which is firm, sweet, and somewhat vinous to the taste, esculent, and wholesome; and within this is inclosed a solid, tough, and hard kernel, of a pale gray colour on the outside, and finely marbled within like the nutmeg. For medicinal use dates are to be chosen large, full, fresh, yellow on the surface, soft and tender, not too much wrinkled; such as have a vinous taste, and do not rattle when shaken. They are produced in many parts of Europe, but never ripen perfectly there. The best are brought from Tunis; they are also very fine and good in Egypt and in many parts of the east. Those of Spain and France look well; but are never perfectly ripe, and very subject to decay. They are preserved three different ways; some pressed and dry; others pressed more moderately, and again moistened with their own juice; and others not pressed at all, but moistened with the juice of other dates, as they are packed up, which is done in baskets or skins. Those preserved in this last way are much the best. Dates have always been esteemed moderately strengthening and astringent.

Though the date tree grows everywhere indiscriminately on the northern coasts of Africa, it is not cultivated with care, except beyond Mount Atlas; because the heat is not sufficiently powerful along the coasts to bring the fruits to proper maturity. We shall here extract some observations from Mr Des Fontaines respecting the manner of cultivating it in Barbary, and on the different uses to which it is applied. All that part of the Zaara which is near Mount Atlas, and the only part of this vast desert which is inhabited, produces very little corn; the soil being sandy, and burnt up by the sun, is almost entirely unfit for the cultivation of grain, its only productions of that kind being a little barley, maize, and sorgo. The date-tree, however, supplies the deficiency of corn to the inhabitants of these countries, and furnishes them with almost the whole of their subsistence. They have flocks of sheep; but as they are not numerous, they preserve them for the sake of their wool; besides, the flesh of these animals is very unwholesome food in countries that are excessively warm; and these people, though ignorant, have probably been enabled by experience to know that it was salutary for them to abstain from it. The date trees are planted without any order, at the distance of 12 feet one from the other, in the neighbourhood of rivulets and streams which issue from the sand. Forests of them may be seen here and there, some of which are several leagues in circumference. The extent of these plantations depends upon the quantity of water which can be procured to water them: for they require much moisture. All these forests are intermixed with orange, almond, and pomegranate trees, and with vines which twist round the trunks of the date trees; and the heat is strong enough to ripen the fruit, though they are never exposed to the sun.

Along the rivulets and streams, dykes are erected to stop the course of their waters, in order that they may be distributed amongst the date trees by means of small canals. The number of canals is fixed for each individual; and in several cantons, to have a right to them, the proprietors are obliged to pay an annual sum proportionable to the number and extent of their plantations. Care is taken to till the earth well, and to raise a circular border around the root of each tree, that the water may remain longer and in larger quantity. The date trees are watered in every season, but more particularly during the great heats of summer.

It is generally in winter that new plantations of this tree are formed. For this purpose those who cultivate them take shoots of those which produce the best dates, and plant them at a small distance one from the other. At the end of three or four years these shoots, if they have been properly taken care of, begin to bear fruit; but this fruit is as yet dry, without sweetness, and even without kernels; they never reach the highest degree of perfection of which they are susceptible till they are about 15 or 20 years old.

These plants are however produced from the seeds taken out of the fruit, provided they are fresh. They should be sown in pots filled with light rich earth, and plunged into a moderate hotbed of tanners bark, which should

should be kept in a moderate temperature of heat, and the earth frequently refreshed with water. When the plants are come up to a proper size, they should be each planted in a separate small pot, filled with the same light earth, and plunged into a hotbed again, observing to refresh them with water, as also to let them have air in proportion to the warmth of the season and the bed in which they are placed. During the summer time they should remain in the same hotbed; but in the beginning of August, they should have a great share of air to harden them against the approach of winter; for if they are too much forced, they will be so tender as not to be preserved through the winter without much difficulty, especially if you have not the conveniency of a bark stove to keep them in. The soil in which these plants should be placed, must be composed in the following manner, viz. half of light fresh earth taken from a pasture-ground, the other half sea sand and rotten dung or tanners bark in equal proportion; these should be carefully mixed, and laid in a heap three or four months at least before it is used, but should be often turned over to prevent the growth of weeds, and to sweeten the earth.

The trees, however, which spring from seed never produce so good dates as those that are raised from shoots; they being always poor and ill tasted. It is undoubtedly by force of cultivation, and after several generations, that they acquire a good quality.

The date trees which have been originally sown, grow rapidly, and we have been assured that they bear fruit in the fourth or fifth year. Care is taken to cut the inferior branches of the date tree in proportion as they rise; and a piece of the root is always left of some inches in length, which affords the easy means of climbing to the summit. These trees live a long time, according to the account of the Arabs; and in order to prove it, they say that when they have attained to their full growth, no change is observed in them for the space of three generations.

The number of females which are cultivated is much superior to that of the males, because they are much more profitable. The sexual organs of the date tree grow, as is well known, upon different stalks, and these trees flower in the months of April and May, at which time the Arabs cut the male branches to impregnate the female. For this purpose, they make an incision in the trunk of each branch which they wish to produce fruit, and place in it a stalk of male flowers; without this precaution the date tree would produce only abortive fruit (A). In some cantons the male branches are only shaken over the female. The practice of impregnating the date tree in this manner is very ancient. Pliny describes it very accurately in that part of his work where he treats of the palm tree.

There is scarcely any part of the date tree which is not useful. The wood, though of a spongy texture, lasts such a number of years, that the inhabitants of the country say it is incorruptible. They employ it for making beams and instruments of husbandry; it burns slowly, but the coals which result from its combustion are very strong, and produce a great heat.

The Arabs strip the bark and fibrous parts from the young date trees, and eat the substance which is in the centre; it is very nourishing, and has a sweet taste: it is known by the name of the marrow of the date tree. They eat also the leaves, when they are young and tender, with lemon juice; the old ones are laid out to dry, and are employed for making mats and other works of the same kind, which are much used, and with which they carry on a considerable trade in the interior parts of the country. From the sides of the stumps of the branches which have been left, arise a great number of delicate filaments, of which they make ropes, and which might serve to fabricate cloth.

Of the fresh dates and sugar, says Hasselquist, the Egyptians make a conserve, which has a very pleasant taste. In Egypt they use the leaves as fly-flaps, for driving away the numerous insects which prove so troublesome in hot countries. The hard boughs are used for fences and other purposes of husbandry; the principal stem for building. The fruit, before it is ripe, is somewhat astringent; but when thoroughly mature, is of the nature of the fig. The Senegal dates are shorter than those of Egypt, but much thicker in the pulp, which is said to have a sugary agreeable taste, superior to that of the best dates of the Levant.

A white liquor, known by the name of *milk*, is drawn also from the date tree. To obtain it, all the branches are cut from the summit of one of these trees, and after several incisions have been made in it, they are covered with leaves, in order that the heat of the sun may not dry it.

The sap drops down into a vessel placed to receive it, at the bottom of a circular groove, made below the incisions. The milk of the date tree has a sweet and agreeable taste when it is new; it is very refreshing, and it is even given to sick people to drink, but it generally turns sour at the end of 24 hours. Old trees are chosen for this operation, because the cutting of the branches, and the large quantity of sap which flows from them, greatly exhaust them, and often cause them to decay.

The male flowers of the date tree are also useful. They

(A) The celebrated Linnæus, in his Dissertation on the Sexes of Plants, speaking of the date tree, says, " A female date-bearing palm flowered many years at Berlin without producing any seeds; but the Berlin people taking care to have some of the blossoms of the male tree, which was then flowering at Leipsic, sent to them by the post, they obtained fruit by these means; and some dates, the offspring of this impregnation, being planted in my garden, sprung up, and to this day continue to grow vigorously. Kœmpfer formerly told us, how necessary it was found by the oriental people, who live upon the produce of palm-trees, and are the true *Lotophagi*, to plant some male trees among the females, if they hoped for any fruit; hence it is the practice of those who make war in that part of the world to cut down all the male palms, that a famine may afflict their proprietors; sometimes even the inhabitants themselves destroy the male trees when they dread an invasion, that their enemies may find no sustenance in the country."

They are eaten when still tender, mixed up with a little lemon juice. They are reckoned to be very provocative: the odour which they exhale is probably the cause of this property being ascribed to them.

These date trees are very lucrative to the inhabitants of the desert. Some of them produce 20 bunches of dates; but care is always taken to lop off a part of them, that those which remain may become larger; 10 or 12 bunches only are left on the most vigorous trees.

It is reckoned that a good tree produces, one year with another, about the value of 10 or 12 shillings to the proprietor. A pretty considerable trade is carried on with dates in the interior part of the country, and large quantities of them are exported to France and Italy. The crop is gathered towards the end of November. When the bunches are taken from the tree, they are hung up in some very dry place where they may be sheltered and secure from insects.

Dates afford wholesome nourishment, and have a very agreeable taste when they are fresh. The Arabs eat them without seasoning. They dry and harden them in the sun, to reduce them to a kind of meal, which they lay up in store to supply themselves with food during the long journeys which they often undertake across their deserts. This simple food is sufficient to nourish them for a long time.—The inhabitants of the Zaara procure also from their dates a kind of honey which is exceedingly sweet. For this purpose they choose those which have the softest pulp; and having put them into a large jar with a hole in the bottom, they squeeze them by placing over them a weight of eight or ten pounds. —The most fluid part of the substance, which drops through the hole, is what they call the *honey* of the date.

Even the stones, though very hard, are not thrown away. They give them to their camels and sheep as food, after they have bruised them or laid them to soften in water.

The date, as well as other trees which are cultivated, exhibits great variety in its fruit, with respect to shape, size, quality, and even colour. There are reckoned to be at least twenty different kinds. Dates are very liable to be pierced by worms, and they soon corrupt in moist or rainy weather.

From what has been said, it may easily be perceived, that there is, perhaps, no tree whatever used for so many and so valuable purposes as the date tree.

PHOENIX, in antiquity, a famous bird, which is generally looked upon by the moderns as fabulous. The ancients speak of this bird as single, or the only one of its kind; they describe it as of the size of an eagle; its head finely crested with a beautiful plumage, its neck covered with feathers of a gold colour, and the rest of its body purple, only the tail white, and the eyes sparkling like stars: they hold, that it lives 500 or 600 years in the wilderness; that when thus advanced in age, it builds itself a pile of sweet wood and aromatic gums, and fires it with the wafting of its wings, and thus burns itself; and that from its ashes arises a worm, which in time grows up to be a phoenix. Hence the Phœnicians gave the name of *phœnix* to the palm-tree; because when burnt down to the root it rises again fairer than ever.

In the sixth book of the Annals of Tacitus, sect. 28. it is observed that, in the year of Rome 787, the phœnix revisited Egypt; which occasioned among the learned much speculation. This being is sacred to the sun. Of its longevity the accounts are various. The common persuasion is, as we have mentioned above, that it lives 500 years; though by some the date is extended to 1461. The several eras when the phœnix has been seen are fixed by tradition. The first, we are told, was in the reign of Sesostris; the second is that of Amasis; and, in the period when Ptolemy the third of the Macedonian race was seated on the throne of Egypt, another phœnix directed its flight towards Heliopolis. When to these circumstances are added the brilliant appearance of the phœnix, and the tale that it makes frequent excursions with a load on its back, and that when, by having made the experiment through a long tract of air, it gains sufficient confidence in its own vigour, it takes up the body of its father and flies with it to the altar of the sun to be there consumed; it cannot but appear probable, that the learned of Egypt had enveloped under this allegory the philosophy of comets.

PHOENIX, son of Amyntor king of Argos by Cleobule or Hippodamia, was preceptor to young Achilles. His father having proved faithless to his wife, through fondness for a concubine called *Clytia*, Cleobule, who was jealous of him, persuaded her son Phœnix to ingratiate himself with his father's mistress. Phœnix easily succeeded; but Amyntor discovering his intrigues, he drew a curse upon him, and the son was soon after deprived of his sight by divine vengeance. Some say that Amyntor himself put out his son's eyes, which so cruelly provoked him that he meditated the death of his father. Reason and piety, however, prevailed over passion; and that he might not become a parricide, Phœnix fled from Argos to the court of Peleus king of Phthia. Here he was treated with tenderness; Peleus carried him to Chiron, who restored his eyesight; soon after which he was made preceptor to Achilles, his benefactor's son. He was also presented with the government of many cities, and made king of the Dolopes. He went with his pupil to the Trojan war; and Achilles was ever grateful for the instructions and precepts which he had received from him. After the death of Achilles, Phœnix, with others, was commissioned by the Greeks to return into Greece, to bring to the war young Pyrrhus. This commission he successfully performed; and after the fall of Troy, he returned with Pyrrhus, and died in Thrace. He was buried, according to Strabo, near Trachinia, where a small river in the neighbourhood received the name of *Phœnix*. There was another Phœnix, son of Agenor, by a nymph who was called *Telephassa*, according to Apollodorus and Moschus, or, according to others, *Epimedusa*, *Perimeda*, or *Agriope*. He was, like his brother Cadmus, and Cilix, sent by his father in pursuit of his sister Europa, whom Jupiter had carried away under the form of a bull; and when his inquiries proved unsuccessful, he settled in a country, which, according to some, was from him called *Phœnicia*. From him, as some suppose, the Carthaginians were called *Pœni*.

PHOLAS, a genus of shell-fish belonging to the order of vermes testacea. See CONCHOLOGY *Index*.

The word *pholas* is derived from the Greek, and signifies something which lies hid. This name they derive from

from their property of making themselves holes in the earth, sand, wood, or stone, and living in them. The means of their getting there, however, are as yet entirely unknown. All that we can know with certainty is, that they must have penetrated these substances when very small; because the entrance of the hole in which the pholas lodges is always much less than the inner part of it, and indeed than the shell of the pholas itself. Hence some have supposed that they were hatched in holes accidentally formed in stones, and that they naturally grew of such a shape as was necessary to fill the cavity.

The holes in which the pholades lodge are usually twice as deep, at least, as the shells themselves are long; the figure of the holes is that of a truncated cone, excepting that they are terminated at the bottom by a rounded cavity, and their position is usually somewhat oblique to the horizon. The openings of these holes are what betray the pholas being in the stone; but they are always very small in proportion to the size of the fish. There seems to be no progressive motion of any animal in nature so slow as that of the pholas; it is immersed in the hole, and has no movement except a small one towards the centre of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion; but it has great time to perform it in, as it only moves downward, sinking itself deeper in the stone as it increases itself in bulk. That part by means of which it performs this, is a fleshy substance placed near the lower extremity of the shell; it is of the shape of a lozenge, and is considerably large in proportion to the size of the animal; and though it be of a soft substance, it is not to be wondered at that in so long a time it is able, by constant work, to burrow into a hard stone. The manner of their performing this may be seen by taking one of them out of the stone, and placing it upon some soft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themselves in the mud in as large a hole as they had taken many years to make in the stone. They find little resistance in so soft a substance; and the necessity of their hiding themselves evidently makes them hasten their work. The animal is lodged in the lower half of the hole in the stone, and the upper half is filled up by a pipe of a fleshy substance and conic figure, truncated at the end: this they usually extend to the orifice of the hole, and place on a level with the surface of the stone; but they seldom extend it any farther than this. The pipe, though it appears single, is in reality composed of two pipes, or at least it is composed of two parts separated by a membrane. The use of this pipe or proboscis is the same with that of the proboscis of other shell fish, to take in sea-water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a small green vessel, the use of which has not yet been discovered. This, when plunged in spirit-of-wine, becomes of a purple colour; but its colour on linen does not become purple in the sun like that of the murex.

The pholas is remarkable for its luminous quality, which was noticed by Pliny, who observes that it shines in the mouth of the person who eats it: and if it touch his hands or clothes, it makes them luminous. He also says that the light depends upon its moisture. The light of this fish has furnished matter for various observations and experiments to M. Reaumur and the Bolognian academicians, especially Beccarius, who took so much pains with the subject of phosphoreal light.

M. Reaumur observes, that whereas other fishes give light when they tend to putrescence, this is more luminous in proportion to its being fresh; that when they are dried, their light will revive if they be moistened either with fresh or salt water, but that brandy immediately extinguishes it. He endeavoured to make this light permanent, but none of his schemes succeeded.

The attention of the Bolognian academicians was engaged to this subject by M. F. Marsilius in 1744, who brought a number of these fishes, and the stones in which they were inclosed, to Bologna, on purpose for their examination.

Beccarius observed, that though this fish ceased to shine when it became putrid, yet that in its most putrid state it would shine, and make the water in which it was immersed luminous when it was agitated. Galeatius and Montius found that wine or vinegar extinguished this light; that in common oil it continued some days, but in rectified spirit of wine or urine hardly a minute.

In order to observe in what manner this light was affected by different degrees of heat, they made use of a Reaumur's thermometer, and found that water rendered luminous by those fishes increased in light till the heat arrived to 45°, but that it then became suddenly extinct, and could not be revived again.

In the experiments of Beccarius, a solution of sea-salt increased the light of the luminous water; a solution of nitre did not increase it quite so much. Sal ammoniac diminished it a little, oil of tartar *per deliquium* nearly extinguished it, and the acids entirely. This water, poured upon fresh calcined gypsum, rock-crystal, ceruse, or sugar, became more luminous. He also tried the effects of it when poured upon various other substances, but there was nothing very remarkable in them. Afterwards, using luminous milk, he found that oil of vitriol extinguished the light, but that of tartar increased it.

This gentleman had the curiosity to try how differently coloured substances were affected by this kind of light; and having, for this purpose, dipped several ribbons in it, the white came out the brightest, next to this was the yellow, and then the green: the other colours could hardly be perceived. It was not, however, any particular colour, but only light, that was perceived in this case. He then dipped boards painted with the different colours, and also glass tubes filled with substances of different colours, in water rendered luminous by the fishes. In both these cases, the red was hardly visible, the yellow was the brightest, and the violet the dullest. But on the boards, the blue was nearly equal to the yellow, and the green more languid; whereas in the glasses, the blue was inferior to the green.

Of all the liquors to which he put the pholades, milk was rendered the most luminous. A single pholas made seven ounces of milk so luminous, that the faces of persons might be distinguished by it, and it looked as if it were transparent.

Air appeared to be necessary to this light: for when Beccarius put the luminous milk into glass tubes, no agitation would make it shine unless bubbles of air were mixed ed with it. Also Montius and Galeatius found, that, in an exhausted receiver, the pholas lost its light, but the water was sometimes made more luminous: which they ascribed to the rising of bubbles of air through it.

Beccarius, as well as Reaumur, had many schemes to render the light of these pholades permanent. For this purpose he kneaded the juice into a kind of paste with flour, and found that it would give light when it was immersed in warm water; but it answered best to preserve the fish in honey. In any other method of preservation, the property of becoming luminous would not continue longer than six months, but in honey it had lasted above a year; and then it would, when plunged in warm water, give as much light as ever it had done. See Barbut's *Genera Vermium*, p. 14. &c.

PHOLEYS, or FOULIES, are a people of Africa, of very peculiar manners. Some authors tell us, that the kingdom of Pholey, from whence they derive their name, is divided from that of Jaloff by a lake called in the language of the Mundingoes *Cayor;* and that it stretches from east to west about 180 miles; but that, though it extends a great way south, its limits in that direction are not exactly ascertained.

Mr Moore, however, gives a very different account, and says, that the Pholeys live in clans, build towns, and are in every kingdom and country on each side of the river; yet are not subject to any of the kings of the country, though they live in their territories; for if they are used ill in one nation, they break up their towns, and remove to another. They have chiefs of their own, who rule with such moderation, that every act of government seems rather an act of the people than of one man. This form of government is easily administered, because the people are of a good and quiet disposition, and so well instructed in what is just and right, that a man who does ill exposes himself to universal contempt.

The natives of all these countries, not being avaricious of land, desire no more than they can use; and as they do not plough with horses or other cattle, they can use but very little; and hence the kings willingly allow the Pholeys to live in their dominions, and cultivate the earth.

The Pholeys have in general a tawney complexion, though many of them are of as deep a black as the Mundingoes; and it is supposed that their alliances with the Moors have given them the mixed colour between the true olive and the black. They are rather of a low stature, but have a genteel and easy shape, with an air peculiarly delicate and agreeable.

Though they are strangers in the country, they are the greatest planters in it. They are extremely industrious and frugal, and raise much more corn and cotton than they consume, which they sell at reasonable rates; and are so remarkable for their hospitality, that the natives esteem it a blessing to have a Pholey town in their neighbourhood; and their behaviour has gained them such reputation, that it is esteemed infamous for any one to treat them in an unhospitable manner. Their humanity extends to all, but they are doubly kind to people of their race; and if they know of any one of their body being made a slave, they will readily redeem him. As they have plenty of food, they never suffer any of their own people to want; but support the old, the blind, and the lame, equally with the others.

These people are seldom angry; and Mr Moore observes that he never heard them abuse each other; yet this mildness is far from proceeding from want of courage, they being as brave as any people of Africa, and very expert in the use of their arms, which are javelins, cutlasses, bows and arrows, and upon occasion guns. They usually settle near some Mundingo town, there being scarce any of note up the river that has not a Pholey town near it. Most of them speak Arabic, which is taught in their schools; and they are able to read the Koran in that language, though they have a vulgar tongue called *Pholey*. They are strict Mahometans, and scarce any of them will drink brandy, or any thing stronger than sugar and water.

They are so skilful in the management of cattle, that the Mundingoes leave theirs to their care. The whole herd belonging to a town feed all day in the savannahs, and after the crop is off, in the rice-grounds. They have a place without each town for their cattle, surrounded by a circular hedge, and within this enclosure they raise a stage about eight feet high, and eight or ten feet wide, covered with a thatched roof; all the sides are open, and they ascend to it by a ladder. Round this stage they fix a number of stakes, and when the cattle are brought up at night, each beast is tied to a separate stake with a strong rope made of the bark of trees. The cows are then milked, and four or five men stay upon the stage all night with their arms to guard them from the lions, tygers, and other wild beasts. Their houses are built in a very regular manner, they being round structures, placed in rows at a distance from each other to avoid fire, and each of them has a thatched roof somewhat resembling a high-crowned hat.

They are also great huntsmen, and not only kill lions, tygers, and other wild beasts, but frequently go 20 or 30 in a company to hunt elephants; whose teeth they sell, and whose flesh they smoke-dry and eat, keeping it for several months together As the elephants here generally go in droves of 100 or 200, they do great mischief by pulling up the trees by the roots, and trampling down the corn; to prevent which, when the natives have any suspicion of their coming, they make fires round their corn to keep them out.

They are almost the only people who make butter, and sell cattle at some distance up the river. They are very particular in their dress, and never wear any other clothes but long robes of white cotton, which they make themselves. They are always very clean, especially the women, who keep their houses exceedingly neat. They are, however, in some particulars very superstitious: for if they chance to know that any person who buys milk of them boils it, they will from thenceforth on no consideration sell that person any more, from their imagining that boiling the milk makes the cows dry.

PHOLIS, in *Natural History*, is an old name for gypsums or plaster-stones. The name is derived from φολις, a *scale* or *small flake*, because they are composed of particles of that form.

PHOLIS, in *Ichthyology*, is the name of a small anguilliform fish. The back is brown, the belly is white, the whole back and sides are spotted, and the skin is soft, free of scales, but with a tough mucilaginous matter

ter like the eel. This species most of all approaches to the *alauda*; and though usually larger, yet Mr Ray doubts whether it really differs from it in any thing essential; the distinction is its colour, which though a very obvious is certainly a very precarious one.

PHONICS, the doctrine or science of sound, otherwise called ACOUSTICS, which see.

PHORMIUM, FLAX-PLANT, (*Phormium tenax*, Forst.) is a name which we may give to a plant that serves the inhabitants of New Zealand instead of hemp and flax. Of this plant there are two sorts; the leaves of both resemble those of flags, but the flowers are smaller, and their clusters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of these plants, with very little preparation, they make all their common apparel, and also their strings, lines, and cordage, for every purpose; which are so much stronger than any thing we can make with hemp, that they will not bear a comparison.—From the same plant, by another preparation, they draw long slender fibres, which shine like silk, and are as white as snow: of these, which are very strong, they make their finest clothes; and of the leaves, without any other preparation than splitting them into proper breadths, and tying the strips together, they make their fishing-nets, some of which are of an enormous size.

The seeds of this valuable plant were brought over into England; but, upon the first trial, appeared to have lost their vegetating power. We understand however that it has since succeeded with the aid of artificial heat.

The filamentous parts of different vegetables have been employed in different countries for the same mechanic uses as hemp and flax among us. Putrefaction, and in some degree alkaline lixivia, destroy the pulpy or fleshy matter, and leave the tough filaments entire. By curiously putrefying the leaf of a plant in water, we obtain the fine flexible fibres, which constituted the basis of the ribs and minute veins, and which form as it were a skeleton of the leaf. In Madagascar, different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in strong ley; and some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton: others are coarser and stronger, and last thrice as long as cotton; and of these filaments they make sails and cordage to their vessels. The stalks of nettles are sometimes used for like purposes, even in France; and Sir Hans Sloane relates, in one of his letters to Mr Ray, that he has been informed by several, that muslin and callico, and most of the Indian linens, are made of nettles. A strong kind of cloth is said to be prepared in some of the provinces of Sweden of hop-stalks; and in the Transactions of the Swedish Academy for 1750, we have an account of an experiment relating to this subject: A quantity of stalks was gathered in autumn, which was equal in bulk to a quantity of flax sufficient to yield a pound after preparation. The stalks were put into water, and kept covered with it during the winter. In March, they were taken out, dried in a stove, and dressed as flax. The prepared filaments weighed nearly a pound, and proved fine, soft, and white; they were spun and wove into six ells of fine strong cloth. Unless the stalks are fully rotted, which will take much longer time than flax, the woody part will not separate, and the cloth will prove neither white nor fine.

PHOSPHATE is a saline body composed of phosphoric acid united to some base, as for instance, lime, which is called phosphate of lime. For an account of the different phosphates, see CHEMISTRY and MINERALOGY *Index*.

PHOSPHORUS, a name given to certain substances which shine in the dark without emitting heat. By this circumstance they are distinguished from the *pyrophori*, which though they take fire on being exposed to the air, are yet entirely destitute of light before this exposure.

Phosphori are divided into several kinds, known by the names of *Bolognian phosphorus*, *Mr Canton's phosphorus*, *Baldwin's phosphorus*, *phosphorus of urine*, &c. of which the last is by far the most remarkable both with respect to the quantity of light which it emits, and its property of taking fire and burning very fiercely upon being slightly heated or rubbed. For the method of preparing these, and for an account of their properties and combinations, see CHEMISTRY *Index*.

PHOTINIANS, in ecclesiastical history, were a sect of heretics in the fourth century who denied the divinity of our Lord. They derive their name from *Photinus* their founder, who was bishop of Sirmium, and a disciple of Marcellus. Photinus published in the year 343 his notions respecting the Deity, which were repugnant both to the orthodox and Arian systems. He asserted, that Jesus Christ was born of the Holy Ghost and the Virgin Mary: that a certain divine emanation, which he called the *Word*, descended upon him; and that because of the union of the divine word with his human nature, He was called the son of God and even God himself; and that the Holy Ghost was not a person, but merely a celestial virtue proceeding from the Deity. Both parties condemned the bishop in the councils of Antioch and Milan, held in the years 345 and 347. He was condemned also by the council at Sirmium in 351, and was afterwards degraded from the episcopal dignity, and at last died in exile in the year 372 or 375. His opinions were afterwards revived by Socinus.

PHOTIUS, patriarch of Constantinople, was one of the finest geniuses of his time, and his merit raised him to the patriarchate; for Bardas having driven Ignatius from the see, Photius was consecrated by Asbestus in 859. He condemned Ignatius in a synod, whereupon the pope excommunicated him, and he, to balance the account, anathematized the pope. Basilius of Macedon, the emperor whom Photius had reproved for the murder of Michael the late emperor, expelled him, and restored Ignatius; but afterwards re-established Photius, upon Ignatius's death, in 878. At last, being wrongfully accused of a conspiracy against the person of Leo the philosopher, son and successor to Basilius, he was expelled by him in 886, and is supposed to have died soon after. He wrote a *Bibliotheca*, which contains an examen of 280 authors: we have also 253 epistles of his; the *Nomacanon* under 14 titles; an abridgement of the acts of several councils, &c. This great man was born in Constantinople, and was descended from a very illustrious and noble family. His natural abilities were very great, and he cultivated them with the greatest assiduity.

siduity. There was no branch of literature, whether sacred and profane, and scarcely any art or science, in which he was not deeply versed. Indeed he appears to have been by far the greatest man of the age in which he lived; and was so intimately concerned in the chief transactions of it, that ecclesiastical writers have on that account called it *Seculum Photianum*. He was first raised to the chief dignities of the empire, being made principal secretary of state, captain of the guards, and a senator. In all these stations he acquitted himself with a distinction suitable to his great abilities, for he was a refined statesmen, as well as a profound scholar. His rise to the patriarchate was very quick; for when he was chosen to that office he was only a layman; but that he might be as it were gradually raised to that dignity, he was made monk the first day, reader the next, and the following days sub-deacon, deacon, and priest. So that in the space of six days he attained to the highest office in the church. On the whole, however, his ardent love of glory and unbounded ambition made him commit excesses which rendered him a scourge to those about him.

Fabricius calls his *Bibliotheca* or library, *non liber, sed insignis thesaurus*, "not a book, but an illustrious treasure," in which are contained many curious things, relating to authors, and many fragments of works which are no where else to be found. It was brought to light by Andreas Scottus, and communicated by him to David Hoeschelius, who caused it to be printed in 1601. Scottus, considering the great utility of this work, translated it into Latin, and printed his translation alone in 1606. The Greek text, together with the translation, was afterwards printed at Geneva in 1611.

PHOTOMETER, an instrument for ascertaining the intensity of light. See OPTICS *Index*.

PHRAATES, or PHRAHATES. There were four kings of this name in Parthia. See PARTHIA.

PHRASE, in *Grammar*, an elegant turn or manner of speech, peculiarly belonging to this or that occasion, this or that art, or this or that language. Thus we say, an Italian *phrase*, an eastern *phrase*, a poetical *phrase*, a rhetorical *phrase*.

PHRASE is sometimes also used for a short sentence or small set or circuit of words constructed together. In this sense, Father Buffier divides phrases into complete and incomplete.

Phrases are *complete* where there is a noun and a verb, each in its proper function; i. e. where the noun expresses a subject, and the verb the thing affirmed of it.

Incomplete phrases are those where the noun and the verb together only do the office of a noun; consisting of several words without affirming any thing, and which might be expressed in a single word. Thus, *that which is true*, is an incomplete phrase, which might be expressed in one word, *truth*; as, *that which is true satisfies the mind*, i. e. *truth satisfies the mind*.

PHRASEOLOGY, a collection of the phrases or elegant expressions in any language. See PHRASE.

PHREATIS, or PHREATTIUM, in Grecian antiquity, was a court belonging to the civil government of Athens, situated upon the sea-shore, in the Piræus. The name is derived from ἀπὸ τοῦ φρέατος, because it stood in a *pit*, or, as others suppose, from the hero *Phreatus*. This court heard such causes as concerned persons who had fled out of their own country for murder, or those that fled for involuntary murder, and who had afterwards committed a deliberate and wilful murder. The first who was tried in this place was Teucer, on a groundless suspicion that he had been accessory to the death of Ajax. The accused was not allowed to come to land, or so much as to cast anchor, but pleaded his cause in his bark; and if found guilty, was committed to the mercy of the winds and waves, or, as some say, suffered there condign punishment; if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelvemonth's banishment for the former. See Potter's *Gr. Antiq.* vol. i. p. 111.

PHRENITIC, a term used to denote those who, without being absolutely mad, are subject to such strong sallies of imagination as in some measure pervert their judgment, and cause them to act in a way different from the more rational part of mankind.

PHRENITIS, the same with PHRENSY; an inflammation of the meninges of the brain, attended with an acute fever and delirium. See MEDICINE, N° 176; also an account of a strange degree of phrensy which attacked Charles VI. of France, in the article FRANCE, N° 88, 90.

PHRYGANEA, a genus of insects, belonging to the order neuroptera. See ENTOMOLOGY *Index*.

PHRYGIA, a country in Asia. From whence it derived its name is not certain: some say it was from the river Phryx (now Sarabat), which divides Phrygia from Caria, and empties itself into the Hermus; others from Phrygia, the daughter of Asopus and Europa. The Greek writers tell us, that the country took its name from the inhabitants, and these from the town of Brygium in Macedonia, from whence they first passed into Asia, and gave the name of *Phrygia* or *Brygia* to the country where they settled. Bochart is of opinion that this tract was called Phrygia from the Greek verb φϱυγειν, "to burn or parch;" which, according to him, is a translation of its Hebrew name, derived from a verb of the same signification.

Ancient Universal History, vol. iii. p. 441, &c.

No less various are the opinions of authors as to the exact boundaries of this country; an uncertainty which gave rise to an observation made by Strabo, viz. that the Phrygians and Mysians had distinct boundaries; but that it was scarce possible to ascertain them. The same writer adds, that the Trojans, Mysians, and Lydians, are, by the poets, all blended under the common name of Phrygians, which Claudian extends to the Pisidians, Bithynians, and Ionians. Phrygia Proper, according to Ptolemy, whom we choose to follow, was bounded on the north by Pontus and Bithynia; on the west by Mysia, Troas, the Ægean sea, Lydia, Mæonia, and Caria; on the south by Lycia; on the east by Pamphylia and Galatia. It lies between the 37th and 41st degrees of north latitude, extending in longitude from 56 to 62 degrees. The inhabitants of this country, mentioned by Ptolemy, are the Lycaones and Anthemisenii, towards Lycia; and Moccadelis or Moccadine, the Cyddeses or Cydisses towards Bithynia; and between these the Peltini or Speltini, the Moxiani, Phylacenses, and Hierapolitæ. To these we may add the Berecyntes mentioned by Strabo.

Phrygia is commonly divided into the Greater and Lesser Phrygia, called also Troas. But this division did not take place till Troas was subdued by the Phrygians; and hence it is more considered by some Roman writers as a part of Phrygia, than Bithynia, Cappadocia, Phrygia. cia, or any other of the adjacent provinces. In after ages, the Great Phrygia was divided into two districts or governments; one called Phrygia Pacatiana, from Pacatianus, who, under Constantine, bore the great office of the præfectus prætorio of the East; the other Phrygia Salutaris, from some miraculous cures supposed to have been performed there by the archangel Michael.

This country, and indeed all Asia Minor, as lying in the fifth and sixth northern climates, was in ancient times greatly celebrated for its fertility. It abounded in all sorts of grain; being, for the most part, a plain country covered with a deep rich soil, and plentifully watered by small rivers. It was in some parts productive of bitumen and other combustible substances. It was well stocked with cattle, having large plains and pasture grounds. The air was anciently deemed most pure and wholesome, though it is now in some parts thought extremely gross, great part of the country lying uncultivated.

In Phrygia Major were anciently several cities of great celebrity; such as APANEA, LAODICEA, HIERAPOLIS, Gordium, &c.—There were also some famous rivers; such as Marsyas, Mæander, &c. The Mæander is now called *Madre* or *Mindre*, and was much celebrated by the ancients for its windings and turnings; from whence all such windings and turnings have been denominated *mæanders*.

The Phrygians accounted themselves the most ancient people in the world. Their origin, however, is extremely dark and uncertain. Josephus and St Jerome say, they were descended from Togarmah, one of Gomer's sons: and that they were known to the Hebrews under the name of Tigrammanes. The Heathen authors derive them from the Brygians, a people of Macedonia. But this is but mere conjecture; and it is a conjecture totally unsupported, except by the similarity of names. Bochart thinks that the Phrygians were the offspring of Gomer the eldest son of Japhet: the word Phrygia being the Greek translation of his name. Josephus makes Gomer the father of the Galatians; but he, by the Galatians, must necessarily mean the Phrygians inhabiting that part of Phrygia which the Galatians had made themselves masters of; the descendants of Gomer being placed by Ezekiel northward of Judæa, near Togarmah (which Bochart takes to be Cappadocia), long before the Gauls passed over into Asia. We are willing to let Gomer enjoy the fine country which Bochart is pleased to give him, and allow him the honour of being the progenitor of the Phrygians, since we know no other person on whom it can be conferred with any degree of probability.

The ancient Phrygians are described as superstitious, voluptuous, and effeminate, without any prudence or foresight, and of such a servile temper, that nothing but stripes and ill usage could make them comply with their duty; which gave rise to several trite and well known proverbs (A). They are said to have been the first inventors of divination by the singing, flying, and feeding of birds. Their music, commonly called the *Phrygian mood*, is alleged by some as an argument of their effeminacy. Phrygia.

This government was certainly monarchical; for all Phrygia was, during the reigns of some kings, subject to one prince. Ninnacus, Midas, Manis, Gordius, and his descendants, were undoubtedly sovereigns of all Phrygia. But some time before the Trojan war, we find this country divided into several petty kingdoms, and read of divers princes reigning at the same time. Apollodorus mentions a king of Phrygia contemporary with Ilus king of Troy. Cedrenus and others speak of one Teuthrans, king of a small country in Phrygia, whose territories were ravaged by Ajax, himself slain in single combat, his royal seat laid in ashes, and his daughter, by name Tecmessa, carried away captive by the conqueror. Homer makes mention of Phorcys and Ascanius, both princes and leaders of the Phrygian auxiliaries that came to the relief of Troy. Tantalus was king of Sipylus only, and its district; a prince no less famous for his great wealth, than infamous for his covetousness and other detestable vices. That Phrygia was subdued either by Ninus, as Diodorus Siculus informs us, or by the Amazons, as we read in Suidas, is not sufficiently warranted. Most authors that speak of Gordius tell us, that the Phrygians having sent to consult an oracle in order to know how they might put an end to the intestine broils which rent their country into many factions and parties, received for answer, that the most effectual means to deliver themselves and their country from the calamities they groaned under, was to commit the government to a king. This advice they followed accordingly, and placed Gordius on the throne.

Apamea was the chief emporium of all Asia Minor. —Thither resorted merchants and traders from all parts of Greece, Italy, and the neighbouring islands. Besides, we know from Syncellus, that the Phrygians were for some time masters of the sea; and none but trading nations ever prevailed on that element. The country produced many choice and useful commodities, which afforded considerable exports. They had a safe coast, convenient harbours, and whatever may incline us to think that they carried on a considerable trade. But as most of the Phrygian records are lost, we will not dwell on conjectures so difficult to be ascertained.

We have no set form of their laws; and as to their learning, since we are told that for some time they enjoyed the sovereignty of the sea, we may at least allow them a competent skill in geography, geometry, and astronomy; and add to these, from what we have said above, a more than ordinary knowledge of music.

Some have been of opinion that the Phrygian language bore a great resemblance to the Greek; but the

(A) "Phryges sero sapiunt, Phryx verberatus melior, Phryx non minus quam Spyntharus, &c.:" which proverbs intimate their servile temper; and show that they were more fit to bewail misfortunes in an unmanly manner, than to prevent them by proper measures. Their music, too, was suited to their effeminate temper. The Doric mood was a kind of grave and solid music; the Lydian a doleful and lamentable harmony; but the Phrygian chiefly calculated to effeminate and enervate the mind. But this character is contradicted by others.

the contrary is manifest from the few Phrygian words which have been transmitted to us, and carefully collected by Bochart and Rudbechius. To these we may add the authority of Strabo, who, after attempting to derive the name of a Phrygian city from the Greek, concludes, that it is a difficult matter to discover any similitude between the barbarous words of the Phrygian language and the Greek. The Phrygian tongue, after the experiment made by Psammetichus king of Egypt, was looked upon by the Egyptians as the most ancient language of the world. But other nations, particularly the Scythians, refused to submit to their opinion, as founded on an argument of no real weight. "As the two children (say they) had never heard the voice of any human creature, the word *bec*, or *bekkos*, the first they uttered, was only an imitation of the goats that had suckled them, and happened to be a Phrygian word signifying *bread* (B).

We have already said, that the Phrygians were superstitious; their idols were consequently very numerous. The chief of these was Cybele, who went by a variety of names. (See CYBELE). They also worshipped Bacchus under the name of *Sabazios;* and his priests they called *Saboi.*

The history of their kings is dark and uncertain, and the dates of their several reigns and actions cannot now be fixed; we shall refer such of our readers, therefore, as wish to know what is certain respecting them, to the Ancient Universal History, already quoted more than once in the present article. See also GORDIUS, MIDAS, &c. For Phrygia Minor, see TROY.

PHRYGIAN STONE, in *Natural History*, is the name of a stone described by the ancients, and used by them in dyeing; perhaps from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers. It was light and spungy, resembling a pumice; and the whitest and lightest were reckoned the best. Pliny gives an account of the method of preparing it for the purpose of dyeing, which was by moistening it with urine, and then heating it red hot, and suffering it to cool.—This calcination was repeated three times, and the stone was then fit for use. Dioscorides recommended it in medicine after burning; he says it was drying and astringent.

PHRYGIANS, a Christian sect. See CATAPHRYGIANS and MONTANISTS.

PHRYNE, was a famous prostitute, who flourished at Athens about 328 years before the Christian era. She was mistress of Praxiteles, who drew her picture, which was one of his best pieces, and was placed in the temple of Apollo at Delphi. We are told that Apelles painted his Venus Anadyomene after he had seen Phryne on the sea-shore naked, and with dishevelled hair. Phryne became so very rich by the liberality of her lovers, that she offered to rebuild Thebes at her own expence, which Alexander had destroyed, provided this inscription was placed on the walls: *Alexander diruit, sed meretrix Phryne refecit;* which was refused. See *Plin.* 34. c. 8.——There was another of the same name who was accused of impiety. When she found that she was going to be condemned, she unveiled her bosom, which so influenced her judges, that she was immediately acquitted.

PHRYNICUS, a general of Samos, who endeavoured to betray his country, &c.——A flatterer at Athens. ——A tragic poet of Athens, disciple to Thespis. He was the first who introduced a female character on the stage.

PHRYNIS was a musician of Mitylene. He was the first who obtained a musical prize at the Panathenæa at Athens. He added two strings to the lyre, which had always been used with seven by all his predecessors. He flourished about 438 years before the Christian era. We are told that he was originally a cook at the house of Hiero king of Sicily.——There was another of the same name, a writer in the reign of Commodus, who made a collection, in 36 books, of phrases and sentences from the best Greek authors, &c.

PHRYXUS, in fabulous history, was a son of Athamas king of Thebes, by Nephele. When his mother was repudiated, he was persecuted with the most inveterate fury by his step-mother Ino, because he was to sit on the throne of Athamas, in preference to the children of a second wife. His mother apprized him of Ino's intentions upon his life; or, according to others, his preceptor; and the better to make his escape, he secured part of his father's treasures, and privately left Bœotia with his sister Helle, to go to their friend and relation Æetes king of Colchis. They embarked on board a ship, or, as we are informed by the fabulous account of the poets and mythologists, they mounted on the back of a ram, whose fleece was of gold; and proceeded on their journey through the air. The height to which they were carried made Helle giddy, and she fell into the sea. Phryxus gave his sister a decent burial on the sea-shore, and after he had called the place *Hellespont* from her name, he continued his flight, and arrived safe in the kingdom of Æetes, where he offered the ram on the altar of Mars. The king received him with great tenderness, and gave him Chalciope his daughter in marriage. She had by him Phrontis Melas, Argos Cylindrus, whom some call *Cytorus.* He was afterwards murdered by his father-in-law, who envied him the possession of the golden fleece; and Chalciope, to prevent her children from sharing their father's fate, sent them privately from Colchis to Bœotia, as nothing was to be dreaded there from the jealousy or resentment of Ino, who was then dead. The fable of the flight of Phryxus to Colchis on a ram has been explained by some, who observe, that the ship on which he embarked was either called by that name, or carried on her prow a figure of that animal. The fleece of gold is accounted for, by observing that Phryxus carried away immense treasures from Thebes. Phryxus was placed among the constellations of heaven after death. The ram which carried him to Asia is said to have been the fruit of Neptune's amour with Theophane the daughter of Altis. This ram the gods had given to Athamas in order to reward his piety and religious life; and Nephele procured it for her

(B) Goropius Becanus makes use of the same argument, to prove that the High Dutch is the original or mother-tongue of the world, because the word *beker* in that language signifies "a baker."

her children, just as they were going to be sacrificed to the jealousy of Ino. Phryxus's murder was some time after amply revenged by the Greeks; it having occasioned the famous expedition achieved under Jason and many of the princes of Greece, which had for its object the recovery of the golden fleece, and the punishment of the king of Colchis for his cruelty to the son of Athamas.

PHTHIRIASIS, the Lousy Evil, from φθιρ, "a louse." Children are frequently its subjects, but adults are sometimes troubled with it. The increase of lice, when in a warm moist situation, is very great; but a cold and dry one soon destroys them. On the human body four kinds of lice are distinguished: 1. The *pediculi*, so called because they are more troublesome with their feet than by their bite. These are in the heads of children, especially if sore or scabby; and often in those of adults, if they are slothful and nasty. 2. Crab-lice. 3. Body lice; these infest the body, and breed in the clothes of the nasty and slothful. 4. A sort which breed under the cuticle, and are found in the hands and feet: they are of a round form, and so minute as often to escape the sight: by creeping under the scarf-skin they cause an intolerable itching; and when the skin bursts where they lodge, clusters of them are found there. See Acarus.

A good diet and cleanliness conduce much to the destruction of lice. When they are in the head, comb it every day; and, after each combing, sprinkle the pulv. sem. staph. agr. or coccul. Ind. among the hairs every night, and confine it with a tight cap.

Codrochius, in his treatise on lice, says, that the powdered coc. Ind. exceeds all other means; and that it may be mixed in the pulp of apple, or in lard, and applied every night to the hair. Some writers assert, that if the pulv. cort. rad. sassafr. be sprinkled on the head, and confined with a handkerchief, it destroys the lice in one night.

The body-lice are destroyed by any bitter, sour, salt, or mercurial medicine, it applied to the skin.

Black soap, and the flowers called *cardamine* or *lady's smock*, are said to be specifics in all cases of lice on the human body.

PHTHISIS, a species of consumption, occasioned by an ulcer in the lungs. See Medicine *Index*.

PHUL, or Pul, king of Assyria, is by some historians said to be Ninus under another name, and the first founder of that monarchy: A renowned warrior. He invaded Israel in the reign of Menahem, who became tributary to him, and paid him 1000 talents of silver for a peace. Flourished 771 B. C.

PHUT, or Phuth, the third son of Ham (Gen. x. 6.). Calmet is of opinion, that Phut peopled either the canton of Phtemphu, Phtemphuti, or Phtembuti, set down in Pliny and Ptolemy, whose capital was Thara in Lower Egypt, inclining towards Libya; or the canton called Phtenotes, of which Buthus was the capital. The prophets often spoke of Phut. In the time of Jeremiah, Phut was under the obedience of Necho king of Egypt. Nahum (iii. 9.) reckons up his people in the number of those who ought to have come to the assistance of No-ammon or Diospolis.

PHYLACETRY, in the general, was a name given by the ancients to all kinds of charms, spells, or characters, which they wore about them, as amulets, to preserve them from danger or diseases.

Phylactery particularly denoted a slip of parchment, wherein was written some text of Holy Scripture, particularly of the decalogue, which the more devout people among the Jews wore on the forehead, the breast, or the neck, as a mark of their religion.

The primitive Christians also gave the name *phylacteries* to the cases wherein they inclosed the relicks of their dead.

Phylacteries are often mentioned in the New Testament, and appear to have been very common among the Pharisees in our Lord's time.

PHYLICA, Bastard Alaternus; a genus of plants belonging to the pentandria class. See Botany *Index*.

PHYLLANTHUS, Sea-side Laurel; a genus of plants belonging to the monœcia class. See Botany *Index*.

PHYLLIS, in fabulous history, was a daughter of Sithon, or, according to others, of Lycurgus king of Thrace, who received Demophoon the son of Theseus; who, at his return from the Trojan war, had stopped on her coasts. She became enamoured of him, and did not find him insensible to her passion. After some months of mutual tenderness and affection, Demophoon set sail for Athens, where his domestic affairs recalled him. He promised faithfully to return as soon as a month was expired; but either his dislike for Phyllis, or the irreparable situation of his affairs, obliged him to violate his engagement: and the queen grown desperate on account of his absence, hanged herself, or, according to others, threw herself down a precipice into the sea and perished. Her friends raised a tomb over her body, where there grew up certain trees, whose leaves, at a particular season of the year, suddenly became wet as if shedding tears for the death of Phyllis. According to an old tradition mentioned by Servius, Virgil's commentator, Phyllis was changed by the gods into an almond tree, which is called *phylla* by the Greeks. Some days after this metamorphosis, Demophoon revisited Thrace; and when he heard of the fate of Phyllis, he ran and clasped the tree, which, though at that time stripped of its leaves, suddenly shot forth, and blossomed as if still sensible of tenderness and love. The absence of Demophoon from the house of Phyllis has given rise to a beautiful epistle of Ovid, supposed to have been written by the Thracian queen about the fourth month after her lover's departure.—A country woman introduced in Virgil's eclogues.—The nurse of the emperor Domitian.—A country of Thrace near Mount Pangæus.

PHYSALIS, the Winter Cherry; a genus of plants belonging the pentandria class. See Botany *Index*.

PHYSETER, or Spermaceti Whale, a genus belonging to the order of cete. See Cetology *Index*.

PHYSIC, or Physick, the art of healing; properly called Medicine. The word is formed from the Greek φυσις, "nature;" in regard medicine consists principally in the observation of nature. See Physics and Medicine.

PHYSICAL, something belonging to, or really existing

Physical, Physician. existing in, nature. In this sense we say a physical point, in opposition to a mathematical one, which only exists in the imagination; a physical substance or body, in opposition to spirit, or metaphysical substance, &c.

PHYSICIAN, a person who professes medicine, or the art of healing diseases. See MEDICINE.

Physicians, Physico-mathematics. PHYSICIANS, *College of, in London, Edinburgh, and Dublin.* See COLLEGE *of Physicians.*

PHYSICO MATHEMATICS, includes those branches of physics which, uniting observation and experiment to mathematical calculation, undertake to explain the phenomena of nature.

PHYSICS,

1 General definition of physics. TAKEN in its most enlarged sense, comprehends the whole study of nature; and NATURAL PHILOSOPHY is a term of the same extent: but ordinary language, and especially in this country, employs both of these terms in a much narrower sense, which it is proper in this place to determine with some precision.

2 A more particular explanation of the term. Under the article PHILOSOPHY, we gave a particular account of that view of nature in which the objects of our attention are considered as connected by causation; and we were at some pains to point out the manner in which this study may be successfully cultivated. By a judicious employment of the means pointed out in that article, we discover that the objects of our contemplation compose an UNIVERSE, which consists, not of a number of independent existences solitary and detached from each other, but of a number of substances connected by a variety of relations and dependencies, so as to form a whole which may with great propriety be called the SYSTEM OF NATURE.

This assembling of the individual objects which compose the universe into one system is by no means the work of a hasty and warm fancy, but is the result of sober contemplation. The natural historian attempts in vain to describe objects, by only informing us of their shape, colour, and other sensible qualities. He finds himself obliged, in describing a piece of marble, for instance, to tell us that it takes a fine polish; that it strikes fire with steel; that it burns to quicklime; that it dissolves in aquafortis, and is precipitated by alkalies; that with vitriolic acid it makes gypsum, &c. &c. &c. and thus it appears that even the *description* of any thing, with the view of ascertaining its specific nature, and with the sole purpose of discrimination, cannot be accomplished without taking notice of its various relations to other things. But what do we mean by the *nature* of any thing? We are ignorant of its essence, or what makes it that thing and no other thing. We must content ourselves with the discovery of its *qualities* or *properties*; and it is the assemblage of these which we call its *nature*. But this is very inaccurate. These do not constitute its essence, but are the consequences of it. Yet this is all we shall ever know of its nature. Now the term *property* is nothing but a name expressing some relation which the substance under consideration has to other things. This is true of all such terms. Gravity, elasticity, sensibility, gratitude, and the like, express nothing but certain *matters of fact*, which may be observed respecting the object of our contemplation in different circumstances of situation with regard to other things. Our distinct notions of individuals, therefore, imply their relations to other things.

The slightest observation of the universe shows an evident connection between all its parts in their various properties. All things on this earth are connected with each other by the laws of motion and of mind. We are connected with the whole of the solar system by gravitation. If we extend our observations to the fixed stars, the connection seems to fail; but even here it may be observed. Their inconceivable distance, it is true, renders it impossible for us to obtain any *extensive* information as to their nature. But these bodies are connected with the solar system by the sameness of the light which they emit with that emitted by our sun or any shining body. It moves with the same velocity, it consists (in most of them at least) of the same colours, and it is reflected, refracted, and inflected, according to the same laws. 3 All parts of the universe evidently connected in their various properties.

4 Our attention naturally directed in the first instance to our fellow men. In this unbounded scene of contemplation, our attention will be directed to the different classes of objects nearly in proportion to the interest we take in them. There is nothing in which we are so much interested as our fellow men; and one of the first steps that we make in our knowledge of nature, is an acquaintance with them. We learn their *distinctive* nature by attending to their *characteristic* appearances; that is, by observing their actions. We observe them continually producing, like ourselves, certain changes in the situation or condition of surrounding objects; and these changes are evidently directed to certain ends *which respect themselves*. Observing this subserviency of the effects which they produce to their own accommodation, we consider this adjustment of means to ends as the effect of an INTENTION, as we experience it to be in our own case, where we are conscious of this intention, and of these its effects. We therefore interpret those actions of other men, where we observe this adjustment of means to ends, as marks or signs of intention in them similar to our own. And thus a quality, or power, or faculty, is *supposed* in them *by means of its sign*, although the quality itself is not *immediately* cognisable by our senses. And as this intention in ourselves is accompanied by perception of external objects, knowledge of their properties, desire of good, aversion from evil, volition and exertion, without all of which we could not or would not perform the actions which we daily perform, we *suppose* the same perception, knowledge, desire, aversion, volition, and exertion in them. 5 Nature of intention.

Thus, by the constitution of our mind, we consider the employment of means, by which ends terminating in the agent are gained, as the natural signs of design or intention. ART, therefore, or the employment of means, is the natural sign of intention; and wherever we observe this adjustment of means to ends, we infer the agency of design.

A small acquaintance with the objects around us, obliges us to extend this inference to a great number of beings besides our fellow men, namely, to the whole animal

Introduction.

animal creation: for in all we observe the same subserviency to the ends of the agent in the changes which we find them continually producing in the objects around them. These changes are all adjusted to their own well-being. In all such cases, therefore, we are forced, by the constitution of our own minds, to infer the existence of design or intention in these beings also.

But in numberless changes produced by external objects on each other, we observe no such fitness in the effects, no such subserviency to the well-being of the agent. In such cases, therefore, we make no such inference of thought or design.

6. All objects divided into thinking and unthinking beings.

Thus, then, there is presented to our observation an important distinction, by which we arrange all external objects into two classes. The first resembles ourselves, in giving external marks of that thought or intention of which we are conscious; and we *suppose* in them the other properties which we discover in ourselves, but cannot *immediately* observe in them, viz. thought, perception, memory, foresight, and all that collection of faculties which we feel in ourselves, and which constitute the animal. The other class of objects exhibits no such appearances, and we make no such inference. And thus we divide the whole of external nature into the classes of THINKING and UNTHINKING beings.

7. How we come to the knowledge of mind.

Our first judgments about these classes will be very inaccurate; and we will naturally ascribe the differences, which we do not very well understand, to the differences in organical structure, which we clearly observe. But when we have knocked down or perhaps smothered an animal, we find that it no longer gives the former mark of thought and intention, and that it now resembles the class of unthinking beings: And yet it still retains all that fitness of organical structure which it had before; it seems only to want the intention and the will. This obliges us to conclude that the distinction does not arise from a difference in organical structure, but from a distinct substance common to all thinking beings, but separable from their organical frame. To this substance we ascribe thought, intention, contrivance, and all that collection of faculties which we feel in ourselves. To this substance in ourselves we refer all sensations, pleasures, pains, remembrances, desires, purposes; and to this aggregate, however imperfectly understood, we give the name MIND. Our organical frame, which seems to be only the instrument of information and operation to the mind, we call *our* body.

8. The nature of mind as understood by mankind in rude ages.

As the animating principle is not, like our body, the immediate object of the senses, we naturally conceive it to be a substance essentially different from those which are the objects of our senses. The rudest people have shown a disposition to form this conclusion. Observing that animal life was connected with breathing, it was natural to imagine that breathing was living, and that breath was life. It is a remarkable fact, that in most languages the term for expressing *breath* is at least one of the terms for expressing the soul; רוח, *πνευμα*, *spiritus*, in the Hebrew, Greek and Latin, express both; *gheist*, or *ghost*, in the Teutonic, comes from *gheisen*, to "breath or sigh;" *dūcha* or *dūha*, "the soul," in Sclavonic, comes from *duichat*, "to breathe;" so in the Gaelic does *anal* come from *anam;* and the same relation is found between the two words in the Malay and other eastern languages. We believe that most persons can recollect some traces of this notion in their early conceptions of things; and many who do not consider themselves as uncultivated, believe that the soul quits the body *along with the last breath*. Among the Tartar nations hanging is considered with particular horror, on account of the ungraceful and filthy exit which the soul is obliged to make from the body.

9. Their opinion not just.

But the observation of the same appearances of thought and intention in fishes and other animals which do not breathe, would soon show that this was but a rude conception. Very little refinement indeed is necessary to convince us that air or breath cannot be the substance which thinks, wishes, and designs; and that the properties of this substance, whatever it is, must be totally different from, and incompatible with, any thing that we know of the immediate objects of our senses.

10. Of the two kinds of substances in nature, one is the object of reflection alone, the other of the senses.

Hence we are led to conclude that there are two kinds of substances in nature: One, which is the principle of sensation; and therefore *cannot* be the object of our senses, any more than light can be the object of the microscope. This substance alone can feel, think, desire, and propose, and is the object of *reflection alone*. The objects of our senses compose the other class, and therefore can have none of the other properties which are not cognoscible by the senses. These have all the properties which our senses can discover; and we can have no evidence of their having any other, nor indeed any conception of their having them. This class is not confined to the unorganized masses of matter; for we see that the bodies of animals lose after death that organical form, and are assimilated to all the rest of unthinking beings. It has arisen from such views as this, that while all nations have agreed to call this class of objects by the name BODY, which originally expresses our organical frame, some nations, farther advanced in cultivation or refinement, have contrived an abstract term to express this general substance of which all inanimate beings are composed. Such a term we have in the words *materies*, *ὑλη*.

11. The distinction between material and immaterial substances is very important.

Matter, then, is that substance which is immediately cognoscible by our senses. Whatever, therefore, is not thus immediately cognoscible by our senses is not material, and is expressed by a negative term, and called *immaterial:* hence it is that mind is said to be immaterial. It is of importance to keep in mind this distinction, merely grammatical. Little more is necessary for detecting the sophisms of Helvetius, Mirabeau, and other sages of the Gallic school, who have been anxious to remove the ties of moral and religious obligation by lowering our conceptions of our intellectual nature. It will also serve to show how hastily *they* have formed their opinions who have ascribed to the immediate agency of mind all those relations which are observed in the actions of bodies on each other at a distance. The connecting principles of such relations *à distante* (if there be any such), are not the immediate objects of our senses: they are therefore immaterial. But it does not follow that they are minds. There may be many immaterial substances which are not minds. We know nothing of any object whatever but by the observation of certain appearances, which suggest to our minds the existence and agency of its qualities or powers. Such phenomena are the natural signs of these qualities, and it is to those signs that we must always have recourse when we wish to conceive

conceive without ambiguity concerning them. What is the characteristic phenomenon of mind, or what is the *distinguishing* quality which brings it into view? It is INTENTION: and it may be asserted with the utmost confidence, that we have no other mark by which mind is immediately suggested to us, or that would ever have made us suppose that there existed another mind besides our own. The *phenomenon* by which this quality is suggested to us is *art*, or the employment of means to gain ends; and the mark of art is the supposed conduciveness of these ends to the well-being of the agent. Where this train is not observed, design or intention is never thought of; and therefore where intention is not perceived in any immaterial substance, if any such has ever been observed, it is an abuse of language to call it mind. We do not think that even perception and intelligence entitle us to give the name mind to the substance in which they are inherent, because it is from marks of intention alone that we infer the existence of mind; and although these must be accompanied with perception and intelligence, it does not follow that the substance which can perceive and understand must also desire and propose. However difficult we may find it to separate them, they are evidently separable in imagination. And let not this assertion be too hastily objected to; for the separation *has been made* by persons most eminent for their knowledge and discernment. When Leibnitz ascribed to his MONADES, or what we call the ultimate ATOMS of matter, a perception of their situation in the universe, and a motion precisely suited to this perception, he was the farthest in the world from supposing them animated or endowed with minds. It is true indeed, that others, who think and call themselves philosophers, are much more liberal in their application of this term. A modern author of great metaphysical eminence says, "I call that *mind* which moves, and that *body* which is moved." This class of philosophers assert that no motion whatever is begun except by the agency of an animating principle, which (after Aristotle) they call *Nature*, and which has in these days been exalted to the rank of a god. All this jargon (for it is nothing else) has arisen from the puzzle in which naturalists think themselves involved in attempting to explain the production of motion in a body at a distance from that body which is conceived as the cause of this motion. After having been reluctantly obliged, by the reasonings of Newton, to abandon their methods of explaining such phenomena by the impulses of an intervening fluid, nothing seemed left but the assertion that these motions were produced by minds, as in the case of our own exertions. These explanations (if they deserve the name) cannot be objected to in any other way than as an abuse of language, and as the introduction of an unmeaning jargon. We have, and can have, no notion of mind different from those of our own minds; and we discover the existence of other minds as we discover the existence of bodies, by means of phenomena which are characteristic of minds, that is, which resemble those phenomena that follow the exertion of our own mental faculties, that is, by the employment of means to attain selfish ends; and where such appearances are not observed, no existence of a mind is inferred. When we see a man fall from the top of a house, and dash out his brains on the pavement, we never ascribe this motion to his mind. Although the fitness of many of the celestial motions for most important purposes make us suppose design and contrivance somewhere, and therefore a *Supreme Mind*, we no more think of inferring a mind in the earth from the fitness of its motions for purposes most beneficial to its inhabitants, than of inferring a mind in a bit of bread from its fitness for nourishing our bodies. It is not from the mere motions of animals that their minds are inferred, but from the conduciveness of these motions to the well-being of the animal.

12 The mind is not that which produces motion, but that which desires and wills.

The term mind therefore, in the *ordinary language* of all men, is applied to what desires and wills at the same time that it perceives and understands. If we call that mind which *produces motion*, we must derive our notions of its qualities or attributes from observing their effects. We must therefore discover the general laws by which they act, that is, the general laws observed in those motions which we consider as their effects. Now these are the general laws of motion; and in none of these can we find the least coincidence with what we are accustomed to call the laws of mind. Nay, it has been the total want of similarity which has given rise to the distinction which all men, in all ages and countries, have made between mind and matter. This distinction is found in all languages; and it is an unpardonable liberty which men take with language when they use a *term of distinction*, a *specific term*, to express things of a different species. What these authors have been pleased to call *mind*, the whole world besides have called by another name, FORCE; which, though borrowed from our own exertions, is yet sufficiently distinctive, and never leads us to confound things that are different, except in the language of some modern philosophers, who apply it to the laws of the agency of mind; and, when speaking of the force of motives, &c. commit the same mistakes which the followers of Aristotle commit in the use of the term mind, *Force*, in the language of these philosophers, means what connects the operations of mind; as mind, in the language of Lord Monboddo, is that which connects the operations of body.

13 The principle of motion not distinct from matter and mind.

These are not less to blame who consider this *Nature* of Aristotle, this principle of motion, as an existence or substance different both from matter and from the minds of intelligent creatures. Aristotle calls it in some places ὡσπερ ψυχη. He might with equal propriety, and equal consistency with his other doctrines, have called mind, ὡσπερ τελος, or an ὡσπερ δυναμις. Besides, we have no evidence for the separability of this ὡσπερ ψυχη from body as we have for the separability of such minds as our own, the genuine ψυχαι. Nay, his whole doctrines, when maturely considered, assume their absolute inseparability.

14 Elemental minds are an abuse of language.

This doctrine of elemental minds, therefore, as the immediate causes of the phenomena of the material world, is an abuse of language. It is a jargon; and it is a frivolous abuse, for it offers no explanation whatever. The phenomena are totally unlike the phenomena of ordinary minds, and therefore receive no explanation from them; and since our knowledge of these *quasi* minds must be derived entirely from the phenomena, it will be precisely the same, although we express it in common language. We shall not indeed raise the wonder of our hearers, as those do who fill the world with minds which they never suspected to exist; but we shall not

not bewilder their imaginations, confound their ideas, and mislead their judgments.

15 The dreadful consequences of materialism.

We flatter ourselves that our readers will not think these observations unseasonable or misplaced. Of all mistakes that the naturalist can fall into, there is none more fatal to his progress in knowledge than the confounding things which are essentially different; and of all the distinctions which can be made among the objects of our contemplation, there is none of equal philosophical importance with this between mind and matter: And when we consider the consequences which naturally follow from this confusion of ideas, and particularly those which follow from sinking the mental faculties of man to a level with the operations of mechanics or chemistry, consequences which the experience of the present eventful day shows to be destructive of all that is noble or desirable in human nature, and of all that is comfortable in this life, and which blasts every hope of future excellence—we cannot be too anxious to have this capital distinction put in the plainest point of view, and expressed in the most familiar characters, "so that he who runneth may read." When we see the frenzy which the reasoning pride of man has raised in our neighbourhood, and hear the dictates of philosophy incessantly appealed to in defence of whatever our hearts shudder at as shocking and abominable; and when we see a man (A), of great reputation as a naturalist, and of professed humanity and political moderation, congratulating his countrymen on the rapid improvement and almost perfection of philosophy; and after giving a short sketch of the constitution of the visible universe, summing up all with a table of elective attractions, and that particular combination and mode of crystallization which constitutes God (*horresco referens!*)—is it not full time for us to stop short, and to ask our own hearts "whither are you wandering?"—But sound philosophy, reasoning from effects to their causes, will here listen to the words of our sacred oracles: "By their fruits ye shall know them. Do men gather grapes of thorns, or figs of thistles?" The absurd consequences of the sceptical philosophy of Berkeley and Hume have been thought, by men of undoubted discernment, sufficient reasons for rejecting it without examination. The no less absurd and the shocking consequences of the mechanical philosophy now in vogue should give us the same abhorrence; and should make us abandon its blood-stained road, and return to the delightful paths of nature, to survey the works of God, and feast our eyes with the displays of mind, which offer themselves on every hand in designs of the most extensive influence and the most beautiful contrivance. Following the guidance of heavenly wisdom, we shall indeed find, that "all her ways are ways of pleasantness, and all her paths are peace."

16 The extent of philosophical study.

Such is the scene of our observation, the subject of philosophical study. Its extent is almost unbounded, reaching from an atom to God himself. It is absolutely necessary for the successful cultivation of this immense field of knowledge, that it be committed to the care of different cultivators, and that its various portions be treated in different ways: and, accordingly, the various tastes of men have given this curiosity different directions; and the study, like all other tasks, has been promoted by this division of labour.

Some philosophers have attended only to the appearances of fitness which are exhibited in every quarter of the universe; and by arranging these into different classes, and interpreting them as indications of thought and intention, have acquired the knowledge of many classes of sentient and intelligent beings, actuated by propensities, and directed by reason.

17 The nature and uses of animal instincts.

While the contemplation of these appearances indicates thought and design in any individual of one of these classes, and brings its propensities and purposes of action, and the ends gained by these actions, into view, the contemplation of these propensities, purposes, and ends, occasions an inference of a much more general kind. All these intelligent beings give indications of knowledge and of power; but their knowledge bears, in general, no proportion to their power of producing changes in nature, and of attaining important ends; and their power is neither always, nor in the most important cases, the consequence of their knowledge. Where the effect of their actions is most eminently conducive to their important interests, the power of attaining these valuable ends is generally independent on any attention to the fitness of the means, and the exertion is frequently made without even thinking of the important end. The well-being of the individual is secured against any danger from its ignorance, indolence, or inattention, by an instinctive propensity, which leads it to the performance of the necessary action, which is thus made immediately and ultimately desirable, without any regard to its ultimate and important end. Thus, in our own nature, the support of animal life, and the improvement of the means of subsistence by a knowledge of the objects which surround us, are not entrusted to our apprehensions of the importance of these ends, but are committed to the surer guides of hunger and curiosity.

18 There is a connection between the individuals of a class of animals different from that of resemblance.

The same observers discover a connection between the individuals of a class, different from that which arises from the mere resemblance of their external appearance, or even of their propensities and pursuits; the very circumstances which produced the classification. They observe, that these propensities are such, that while each individual seeks only its own enjoyment, these enjoyments are in general such as contribute to the support of the species and the enjoyment of other individuals. Thus, in the classes of animals, and in human nature, the continuance of the race, and the enjoyment of the whole, are not entrusted to the apprehension we entertain of the importance of these ends, but are produced by the operation of sexual love and the love of society.

19 There is also a link of connection between sentient beings of different classes.

The same observers find that even the *different* classes of sentient beings are connected together: and while the whole of each class aim only at their own enjoyment, they contribute, in some way or other, to the well-being of the other classes. Even man, the selfish lord

(A) M. de la Metherie, editor of the *Journal de Physique*. See his prefaces to the volumes for 1792 and 1793, January and July.

Introduction.

lord of this sublunary world, is not the unconnected inhabitant of it. He cannot, in every instance, reap all the fruits of his situation, without contributing to the enjoyment of thousands of the brute creation. Nay, it may be proved to the satisfaction of every intelligent man, that while one race of animals, in consequence of its peculiar propensities, subsists by the destruction of another, the sum total of animal life and enjoyment is prodigiously increased. See a very judicious dissertation on this curious and puzzling subject, entitled *A Philosophical Survey of the Animal Creation;* where it appears that the increase of animal life and enjoyment which is produced by this means, beyond what could possibly obtain without it, is beyond all conception. See likewise the last edition of *King's Origin of Evil*, by Dr Law, late bishop of Carlisle.

20 The end of this connection is the accumulation of happiness.

Thus the whole assemblage seems connected, and jointly employed in increasing the sum total of possible happiness. This fitness of the various propensities of sentient and intelligent beings, this subserviency to a general purpose, strikes these observers as a mark of intention, evidently distinct from, and independent of, all the particular intentions, and superior to them all; and thus it irresistibly leads them to infer the existence of a SUPREME MIND, directing the whole of this INTELLECTUAL SYSTEM, while the individuals of which it consists appear the unconscious instruments in the hand of a great Artist, with which he executes his grand and beneficent purposes.

21 All nature, animate and inanimate, and unthinking, is connected.

But the observation goes yet further. The bodies of the inanimate creation are not only connected with each other by a mutual dependence of properties, and the relation of causation, but they are also connected with the sentient beings by a subserviency to their purposes of enjoyment. The philosopher observes that this connection is admirably kept up by the constancy of natural operations and the expectations of intelligent beings. Had either of these circumstances been wanting, had either the operations of nature been without rule, or had sentient beings no perception or expectation of their uniformity; the subserviency would be totally at an end. This adjustment, this fitness, of which the effect is the enjoyment of the sentient inhabitants of the universe, appear to be the effect of an intention of which this enjoyment is the final cause. This constancy, therefore, in the operations of nature, both in the intellectual and material world, and the concomitant expectation of sentient beings, appear the effects of *laws* imposed on the different parts of the universe by the Supreme Mind, who has formed both these classes of beings so admirably suited to each other.

22 The origin of natural theology.

To such observers the world appears a WORK OF ART, a system of means employed for gaining certain proposed ends, and it carries the thoughts forward to an ARTIST; and we infer a degree of skill, power, and good intention in this Artist, proportioned to the ingenuity, extent and happy effect which *we are able to discern* in his works. Such a contemplation of nature therefore, terminates in NATURAL THEOLOGY, or the discovery of the existence and attributes of GOD.

23 Our mode of reasoning on the operations of God.

Our notions of this *Supreme Mind* are formed from the indications of design which we observe, and which we interpret in the same way as in the actions of men. These notions, therefore, will differ from our notions of other minds only in the *degrees* which *we are able* to observe, and which we assign to these faculties; for the phenomenon or the effect is not only the mark, but also the measure of its supposed cause. These degrees must be ascertained by our own capacity of appreciating the extent, the multiplicity, and the variety of the contrivance. Accordingly, the attributes of the Supreme Mind, in the theological creed of a rude Indian, are much more limited than in that of a European philosopher. In proportion as our understandings are enlarged, and as our acquaintance with the operations of nature around us is extended, we shall perceive higher degrees of power, of skill, and of kind intention: and since we find that the scene of observation is unbounded, we cannot affix any boundaries to these attributes in our own imagination, and we are ready to suppose that they are infinite or unbounded *in their own nature*. When our attentive survey of *this* universe, and a careful comparison of all its parts, as far as we can understand or appreciate them, have made us conclude that it is *one* design, the work of *one Artist;* we are under the necessity of inferring, that, with respect to *this universe*, his power, wisdom, and benevolence, are indeed infinite.

24 The system of nature is governed by general laws.

When men have been led to draw this conclusion from the appearances of fitness which are observed everywhere around them, they consider that constancy which they observe in natural operations, whether in the material or the intellectual system, and that expectation of, and confidence in, this constancy, which renders the universe a source of enjoyment to its sentient inhabitants, as the consequences of laws imposed by the Almighty Artist on his works, in the same manner as they would consider the constancy in the conduct of any people as the consequences of laws promulgated and enforced by the supreme magistrate.

25 The nature and progress of the study of mind.

There can be no doubt of this view of nature being extremely captivating, and likely to engage the curiosity of speculative men; and it is not surprising that the phenomena of mind have been keenly studied in all ages. This part of the study of nature, like all others, was first cultivated in subserviency to the wants of social life; and the general laws of moral sentiment were the first phenomena which were considered with attention. This gradually ripened into a regular system of moral duty, accompanied by its congenial study, the investigation or determination of the *summum bonum*, or the constituents of human felicity; and these two branches of intellectual science were always kept in a state of association by the philosophers of antiquity.

26 The rise of moral sentiments and of moral duty.

Jurisprudence, the science of government, legislation, and police, were also first cultivated as arts, or at least in immediate subserviency to the demands of cultivated society; and all these so nearly related parts of the study of human nature, had made a very considerable progress, in the form of maxims or precepts for directing the conduct, before speculative men, out of mere curiosity, treated them as subjects of philosophical study. Our moral sentiments, always involving a feeling of obligation, are expressed in a language considerably different from the usual language of pure philosophy, speaking of things which *ought to be*, rather than of things which *are;* and this distinction of language was increased by the very aim of the writers, which

Introduction.

which was generally to influence the conduct as well as the opinions of their scholars. It was reserved for modern times to bring this study into the pure form of philosophy, by a careful attention to the phenomena of moral sentiment, and classing these according to their generality, and ascertaining their respective ranks by an appeal to experiment, that is, to the general conduct of mankind: and thus it happens that in the modern treatises on ethics, jurisprudence, &c. there is less frequent reference made to the *officia* or duties, or to the constituents of the *summum bonum*, than among the ancients, and a more accurate description of the human mind, and discrimination of its various moral feelings.

27
The origin of logic and other intellectual sciences.

It was hardly possible to proceed far in these disquisitions without attending to the powers of the understanding. Differences of opinion were supported by reasonings, or attempts to reasoning. Both sides could not be in the right, and there must be some court of appeals. Rules of argumentation behoved to be acquiesced in by both parties: and it could hardly escape the notice of some curious minds, that there were rules of truth and falsehood as well as of right and wrong. Thus the human *understanding* became an object of study, first in subserviency to the demands of the moralists, but afterwards for its own sake; and it gradually grew up into the science of logic. Still further refinement produced the science of metaphysics, or the philosophy of universals. But all these were *in fact* posterior to the doctrines of morals; and disquisitions on beauty, the principles of taste, the precepts of rhetoric and criticism, were the last additions to the study of the phenomena of mind. And now, since the world seems to have acquiesced in the mode of investigation of general laws by experiment and observation, and to agree that this is all the knowledge that we can acquire of any subject whatever, it is to be expected that this branch of philosophical discussion will attain the same degree of improvement (estimated by the coincidence of the doctrines with fact and experience) that has been attained by some others.

28
The partial practice of natural philosophy preceded its study as a science.

The occupations, however, of ordinary life have oftener directed our efforts towards material objects, and engaged our attention on their properties and relations; and as all sciences have arisen from arts, and were originally implied in the maxims and precepts of those arts, till separated from them by the curious speculatist, the knowledge of the material system of nature was possessed in detached scraps by the practitioners in the various arts of life long before the *natural philosopher* thought of collecting them into a body of scientific doctrines. But there have not been wanting in all ages men of curiosity who have been struck by the uniformity of the operations of nature in the material world, and were eager to discover their causes.

Accordingly, while the moralists and metaphysicians turned their whole attention to the phenomena of mind, and have produced the sciences of pneumatology, logic, ethics, jurisprudence, and natural theology, these observers of nature have found sufficient employment in considering the phenomena of the material world.

The bodies of which it consists are evidently connected by means of those properties by which we observe that they produce changes in each other's situation. This assemblage of objects may therefore be justly called a system. We may call it the MATERIAL SYSTEM. It is frequently termed NATURE; and the terms NATURAL APPEARANCES, NATURAL CAUSES, NATURAL LAWS, have been generally restricted to those which take place in the material system. This restriction, however, is improper, because there is no difference in the manner in which we form our notions of those laws, and reason from them, both with respect to mind and body. Or if there is to be any restriction, and if any part of the study of the universe is to be excluded in the application of these terms, it is that part only which considers moral obligation, and rather treats of what *ought to be* than of what *is*. As has been already observed, there is a considerable difference in the language which must be employed; but still there is none in the principles of investigation. We have no proof for the extent of any moral law but an appeal to the feelings of the hearts of men, indicated by the general laws or facts which are observed in their actions.

29
The nature of the material system, with the definition of that and other terms.

30
The unrestricted sense in which some of these terms are used, and its bad consequences.

But this is only a question of the propriety of language. And no great inconvenience would arise from the restriction now mentioned if it were scrupulously adhered to; but unfortunately this is not always the case. Some authors use the term *natural law* to express *every* coincidence of fact; and this is certainly the proper use of the term. The French writers generally use the term *loy physique* in this enlarged sense. But many authors, misled by, or taking advantage of, the ambiguity of language, after having established a law founded on a copious and perhaps unexcepted induction of the phenomena of the material system (in which case it must be considered in its restricted sense), have, in their explanation of phenomena, extended their principle much farther than the induction on which they had founded the existence of the physical law. They have extended it to the phenomena of mind, and have led their followers into great and dangerous mistakes. Languages, like every other production of human skill, are imperfect. They are deficient in terms, and are therefore figurative. The most obvious, the most frequent, and the most interesting uses of language, have always produced the appropriated terms, and the progress of cultivation has never completely supplied new ones. There are certain analogies or resemblances, or certain associations of ideas, so plain, that a term appropriated to one very familiar object will serve to suggest another analogous to it, when aided by the concomitant circumstances of the discourse; and this with sufficient precision for the ordinary purposes of social communication, and without leading us into any considerable mistakes: and it is only the rare and refined disquisitions of the curious speculatist that bring the poverty and imperfection of language into view, and make us wish for words as numerous as our thoughts. There is hardly a sentence, even of common discourse, in which there are not several figures either of single words or of phrases; and when very accurate discrimination is required, it is almost impossible to find words or phrases to express distinctions which we clearly feel. We believe it impossible to express, by the scanty vocabulary

cabulary of the Hebrews, the nice distinctions of thought which are now familiar to the European philosopher. In nothing does this imperfection of language appear so remarkably as in what relates to mind. Being a late subject of separate discussion, and interesting only to a few speculatists, we have no appropriated vocabulary for it; and all our disquisitions concerning its operations are in continual metaphor or figure, depending on very slight analogies or resemblances to the phenomena of the material world. This makes the utmost caution necessary; and it justifies the British philosophers, who have been the most successful in prosecuting the study of the intellectual system, for having, almost without exception, restricted the terms, natural laws, natural causes, natural philosophy, and such like, to the material system. With us pneumatology makes no part of physics. And we may venture to affirm, that the sciences have fared better by the restriction of the terms. In no country has the spirit of liberal discussion been more encouraged and indulged than in Britain; and her philosophers have been equally eminent in both branches of science. Their performances in ethics, jurisprudence, and natural theology, are considered by all our neighbours as the fountains of knowledge on these subjects; and Locke and Clarke are names no less familiar on the continent than Newton. The licentious and degrading doctrines of the Gallican school have as yet made little impression here; and man is still considered among us as a glorious creature, born to, and fitted for, the noblest prospects.

31 **The term *physics* defined as it is generally understood in Britain.**

Physics, then, is with us the study of the material system, including both natural history and philosophy. The term is not indeed very familiar in our language; and in place of *physicus* and *disciplina physica*, we more generally use the terms *naturalist* and *natural knowledge*. The term *natural philosophy*, in its common acceptation, is of less extent. The field of physical investigation is still of prodigious extent; and its different quarters require very different treatments, make very different returns, and accordingly have engaged in their particular cultivation persons of very different talents and tastes. It is of some importance to perceive the distinctions, and to see how the wants and propensities of men have led them into the different paths of investigation; for, as has been more than once observed, all sciences have sprung from the humble arts of life, and both go on improving by means of a close and constant correspondence.

32 **The phenomena of the material system arranged into two classes.**

All the phenomena of the material system may be arranged into two classes, distinguished both by their objects and by the proper manner of treating them.

The first class comprehends all the appearances which are exhibited in the *sensible motions* of bodies, and their actions on each other producing *sensible motion*.

The second class comprehends the appearances which are exhibited in the *insensible* motions and actions of the invisible particles of matter.

33 **Examples of those of the first class,**

Of the phenomena of the first class we have examples in the planetary motions, the motions of heavy bodies, the phenomena of impulse, the motions and actions of machines, the pressure and motions of fluids, the sensible actions of magnetical and electrical bodies, and the motions of light.

34 **and of those of the second.**

We have examples of the second class in the phenomena of heat and mixture, and those exhibited in the growth of animals and vegetables, and many phenomena of solid, fluid, magnetical, electrical, and luminous bodies, in which no change of place can be observed.

35 **This arrangement is apparently natural.**

Thus it appears that there is a distinction in the phenomena sufficiently great to warrant a division of the study, and to make us expect a more rapid improvement by this division. Nay, the division has been made by nature itself, in the acquaintance which men have attained with her operations without study, before science appeared, and while art constituted all our knowledge.

36 **Of the progress of knowledge in rude ages.**

Before man had recourse to agriculture as the most certain means of procuring subsistence, our acquaintance with external substances was principally that of the natural historian; consisting of a knowledge of their fitness for food, medicine, or accommodation, their places of growth or habitation, and the means of procuring them, depending on their manner of life or existence.

37 **The origin of agriculture, physic, surgery, and chemistry,**

It required a studied attention to these circumstances to give rise to agriculture, which therefore generally made its appearance after men had been in the practice of keeping flocks; by which means they were more at their ease, and had some leisure to attend to the objects around them, and in particular to those circumstances of soil and weather which affected the growth of their pasture.

When agriculture and a rude medicine were thus established, they were the first *arts* which had their foundation in a *system of laws*, by which the operations of nature were observed to be regulated; and with these arts we may begin the *general study of nature*, which was thus divided into two different branches.

The rude physician would be at first a collector of *specifics*; but by degrees he would observe resemblances among the *operations* of his drugs, and would class them according to these resemblances. He would thus come to attend less to the drug than to its mode of operation; and would naturally speculate concerning the connection between the operation and the economy of animal life. His art now becomes a scientific system, connected by principle and theory, all proceeding on the observation of changes produced by one kind of matter on another, but all out of sight. The frequent recourse to the vegetable kingdom for medicines would cause him to attend much more minutely to the few plants which he has occasion to study than the husbandman can do to the multitude he is obliged to rear. The physician must learn to think, the husbandman to work. An analogy between the economy of animal and vegetable life could hardly fail to engage the attention of the physician, and would make him a botanist, both as a classifier of plants and as a philosopher.

He would naturally expect to unite the services of his drugs by combining them in his recipes, and would be surprised at his disappointments. Curious and unexpected changes would frequently occur in his manipulations: the sensible qualities, and even the external appearances of his simples, would be often changed, and even inverted by their mixture; and their medicinal properties would frequently vanish from the compound, and new ones be induced. These are curious, and to him interesting facts; and he would naturally be inquisitive after

ter the principles which regulate these changes. His skill in this would by degrees extend beyond the immediate use for the knowledge; and the more curious speculatist would lay the foundations of a most extensive and important science, comprehending all the phenomena of heat and mixture.

Along with this, and springing from the same source, another science must arise, contemplating the appearances of animal and vegetable life, and founded on a careful observation and accurate description of the wonderful machine. The most incurious of men have in all ages been affected by the displays of wisdom and contrivance in the bodies of animals, and immediately engaged in investigation into the uses and functions of their various parts and organs. The phenomena have been gradually discriminated and arranged under the various heads of nutrition, concoction, secretion, absorption, assimilation, rejection, growth, life, decay, disease, and death; and, in conformity to the doctrines which have with greater or less evidence been established on these subjects, the action of medicines, and the whole practice of physic and surgery, has been established in the form of a liberal or scientific art.

38 The origin of the knowledge of the mechanical powers.

The husbandman in the mean time must labour the ground which lies before him. He, too, is greatly interested in the knowledge of the vegetable economy, and forms some systems on the subject by which he regulates his labours: but he sees, that whatever is the nature of vegetable life, he must work hard, and he searches about for every thing which can tend to diminish his labour. The properties of the lever, the wedge, and the inclined plane, soon become familiar to him; and without being able to tell on what their efficacy depends, he uses them with a certain sagacity and effect. The strength of timber, the pressure and force of water, are daily seen and employed by him and other artisans who labour for their mutual accommodation; and some rude principles on these subjects are committed to memory. Many tools and simple machines are by this time familiar; and thus the *general* properties of matter, and the general laws of the actions of bodies on each other, become gradually matter of observation and reflection; and the practical mechanic will be frequently improving his tools and machines. The general aim is to produce a greater quantity of work by the same exertion. The attempts to improvement will be awkward, and frequently unsuccessful. When a man finds, that by increasing the length of his lever he increases his power of overcoming a resistance, a small degree of curiosity is sufficient to make him inquire in what proportion his advantage increases. When he finds that a double length gives him a double energy, he will be suprised and mortified to find, that at the end of the day he has not performed twice the quantity of work: but, after much experience, he will learn that every increase of energy, by means of a machine, is nearly compensated by an increase of time in the performance of his task; and thus one of the great and leading principles of practical mechanics was inculcated in a manner not to be forgotten, and the practical mechanic was brought to speculate about motion and force, and by gradual and easy steps the general laws of simple motions were established.

39 The origin of mathematics.

It is evident that these speculations cannot be carried on, nor any considerable knowledge acquired, without some acquaintance with the art of measurement: and the very questions which the mechanic wishes to solve, presuppose some advances in this art, which in process of time refined itself into mathematics, the most perfect of all the sciences. All the phenomena of sensible motion afford employment to the mathematician It is performed in a double or triple time, through a double or triple space, by a double or triple body, by the exertion of a double or triple force, produces a double or triple effect, is more to the right or to the left, upwards or downwards, &c. In short, every affection of motion is an object of mathematical discussion. Such a science must have appeared ere now in the form of an art, in consequence of the mutual transactions of men. These among an uncultivated people are chiefly in the way of barter. If I want corn from a peasant, and have nothing to give for it but the cloth which I have made, we must fall on some way of adjusting our terms in respect of the quantity. We should soon discover that the length, and breadth, and depth, of the box or bag, were equally important; and it was not difficult to see that if any of them were doubled or tripled, the quantity of grain would be so too; if two of them were doubled, the grain would be quadrupled; and if all the three were doubled the quantity of grain would be increased eight times: the same thing would be observed with respect to my cloth. By such transactions as these, a few of the properties of plane and solid numbers and figures would become known, and the operations of multiplication and division, where arithmetic is combined with geometry: and daily observation shows us, that the more abstruse properties of number and figure, which to the generality of mankind are so insignificant, lay hold on the fancy of some individuals with such force, as to abstract them from every other intellectual entertainment, and are studied with a keenness and perseverance almost unequalled in any other walk of science. To most men the performance of a machine is a more attractive object than the properties of a figure, and the property of a figure more entertaining than that of a number; but the fact seems to have been otherwise. Before Pythagoras had invented the theorem that bears his name (see PHILOSOPHY, N° 15. and note H), and which is among the first elements of geometry, he had reformed the Grecian music by the addition of a note to their scale, and this addition proceeds on a very refined speculation on the properties of numbers; so that among the Greeks arithmetic must have made considerable progress, while geometry was yet in its cradle; and we know to what astonishing length they prosecuted the science of pure geometry, while their knowledge of mechanical principles was almost nothing. Also the Arabs hardly made any addition to the geometry of the Greeks, if they did not rather almost completely forget it; whilst they improved their arithmetic into algebra, the most refined and abstracted branch of human knowledge. There is such a distance, in point of simplicity, between pure mathematics and the most elementary mechanics, that the former continued to make rapid steps to improvement in more modern times, while the latter languished in its infancy, and hardly deserved the name of science till very lately, when the great demand for it, by the increase and improvement in manufactures, both interested many in the study, and facilitated its progress, by the multitude of machines which were contriving on all hands by the manufacturers and artisans: and even at present it must be be acknowledged, that it is to them that we are indebted for almost every new invention in mechanics, and that the speculatist seldom has done more than improve the invention, by exhibiting its principles, and thus enabling the artist to correct its imperfections; and now science and art go hand in hand, mutually giving and receiving assistance. The demands of the navigator for mathematical and astronomical knowledge have dignified these sciences; and they are no longer the means of elegant amusement alone, but merit the munificence of princes, who have erected observatories, and furnished voyages of discovery, where the mathematical sciences are at the same time cherished and applied to the most important purposes.

This short sketch of what may be called *the natural history of physical sciences* will not, we hope, be thought improper or unprofitable. It tends to confirm an assertion often alluded to, that the prosecution of the study of nature will be more successful, if we imitate her mode of proceeding, and divide the labour. It will be still further confirmed by attending to the scientific difference of the phenomena, which marks out a different mode of proceeding, and a difference in the knowledge which we shall ultimately acquire, after our most successful researches.

40 The connecting principle of concomitant events is totally unknown.

In both classes of phenomena already distinguished (N° 6.) we must grant, that the principle which connects the pairs of concomitant events, rendering the one the inseparable companion of the other, is totally unknown to us, because it is not the immediate object of our perception.

41 In the first class, however, the exertion of this principle may be accurately observed,

But in the phenomena of the first class, we see the *immediate* exertion of this principle, whatever it may be; we can observe the exertion with accuracy; we can determine its kind and degree, which are the signs and measures of the kind and degree of the unperceived cause. This exertion, being always some modification of motion, allows us to call in the aid of mathematical knowledge, and thus to ascertain with the precision peculiar to that science the energy of the cause, judging of the tendency and quantity by the tendency and the quantity of the observed effect.

42 but not in the second:

But in the second class of phenomena the case is very different. In the operations of chemistry, for instance, the *immediate* exertion of the cause is not perceived: all that we observe is the assemblage of particles which obtains before mixture, and that which takes place when it is completed, and which we consider as its result. The procedure of nature in producing the change is unseen and unknown. The steps are hid from our observation. We are not only ignorant of the cause which determines one particle of our food to become a part of our body while others are rejected, but we do not see the operation. We are not only ignorant of the cause which determines a particle of vitriolic acid to quit the fossil alkali with which it is united in Glauber salt, and to attach itself to a particle of magnesia already united with the muriatic acid, which also quits it to unite with the alkali, but we do not see the operation. The particles and their motions are not the objects of our senses; and all that we see is the Epsom salt and common salt separated from the water in which we had formerly dissolved the sal mirabile and the muriated magnesia. The motions, which are the *immediate* effects of the changing causes, and therefore their *only indications, characteristics and measures*, fitted to show their nature, are hid from our view.

43 And therefore the phenomena of the second class are less understood.

Our knowledge therefore of these phenomena must be less perfect than that of the phenomena of the former class; and we must here content ourselves with the discovery of more remote relations and remote causes, and with our ignorance of the very powers of nature by which these changes are brought about, and which are cognoscible only by their immediate effects, viz. the motions which they produce unseen. The knowledge which we do really acquire is somewhat similar to what the mechanical philosopher has acquired when he has discovered, by many experiments and investigations, that magnets attract each other by their dissimilar poles, and repel each other by their similar poles, and do not act at all on any bodies but loadstones and iron. Here we leave undiscovered all that is most curious in the phenomenon, viz. how these attractions and repulsions are produced; and even here the magnetical philosopher has the advantage of seeing the agents and the operation.

44 Though some philosophers have attempted to explain them by the doctrine of motion;

But philosophers attending to this circumstance, that, even in these cases, the changes are produced by motions, or consist in motions, however unperceived these may be, have concluded, that the laws according to which nature operates in producing these changes are similar to the laws which regulate her operations in the sensible actions of bodies, or are included in them; and that the motions, though unseen, and the moving forces, are perfectly similar. They have therefore employed similar modes of investigation, applying the laws of impulse, and calling in the aid of mathematical knowledge.

Of this we have many examples in the writings of Dr Freind, Keil, Bernouilli, Helsham, Boerhaave, Hartley, and others, who have delivered theories of fermentation, solution, precipitation, crystallization, nutrition, secretion, muscular action, nay even of sensation and intelligence, founded, as they think, on the laws of motion, and illustrated and supported by mathematical reasoning. Lord Bacon himself, that careful and sagacious distinguisher of intellectual operations, has gone into the same track in his explanation of the phenomena of fire and combustion: and Sir Isaac Newton has made several attempts of the same kind, although with peculiarities which always characterize his discussions, and make them very different from those of an inferior class.

45 but their attempts have been unsuccessful.

But the success of these philosophers has hitherto been very discouraging: indeed they had no title to expect any; for their whole trains of reasoning have proceeded on analogies which were not observed, but assumed or *supposed* without any authority. There is not that similarity in the phenomenon, or in the visible effect, which is absolutely necessary for a successful reasoning by analogy. We do not observe any local motion, any change of place, which alone enables us to reason mathematically on the subject. And to make the case desperate, this ill-founded analogy has been mixed with hypotheses completely gratuitous. Certain forms have been assigned to the particles, and certain modes of action have been laid down for them, for whose reality we have not the least argument or indication: and to complete the matter, these fancied forms and laws of action have been such as are either self-contradictory and inconsistent, or they

Introduction.

they have been such as, if allowed to act in a way analogous to what we observe in the sensible motions of bodies, would produce effects totally different from those which are observed. These atomical theories, as they are called, transgress every rule of philosophical discussion, and even the best of them are little better than trifling amusements. By far the greatest part of them only serve to raise a smile of pity and contempt in every person at all acquainted with mechanical philosophy. Whenever we see an author attempting to explain these hidden operations of nature by invisible fluids, by æthers, by collisions, and vibrations, and particularly if we see him introducing mathematical reasonings into such explanations—the best thing we can do is to shut the book, and take to some other subject. That we may not be thought to speak presumptuously on this occasion, we only beg leave to remind our readers, that the united knowledge of the most eminent mathematicians of Europe has not yet been able to give any thing more than an approximation to the solution of the problem of three bodies; that is, to determine with accuracy the motions of three particles of matter acting on each other in the simplest of all possible manners, viz. by forces varying as the squares of the distances inversely: and the vibrations of elastic bodies, of any but the very simplest possible forms, are to this day beyond the reach of investigation. What then should be our expectations in cases where millions of particles are acting at once, of forms unobserved, and with forces unknown, and where the object is not a determination of an average result of many, where the precise state of an individual article need not be known, but where it is this very precise state of each single particle that we want to know? What can it be but uncertainty and mistake?

46 The advantage derived in these speculations from mathematical philosophy.

Notwithstanding these discouraging circumstances, we must observe that this kind of inquiry has greatly improved of late years, along with the improvement and extension of mathematical philosophy, and since philosophers have given over their incessant attempts to explain every thing by impulse; and we need not despair of making still farther advances, if we will content ourselves with going no farther than Newton has done in his explanation of the planetary motions. He has immortalized his own name, and has added immensely to our stock of useful knowledge: yet he has stopped short at the discovery of the fact of universal gravitation; and all who have endeavoured to explain or account for this fact have only exposed themselves to pity. We may perhaps be one day able to demonstrate from the phenomena that the particles of matter have certain mutual tendencies to or from each other, exerted according to fixed or invaried rules; and from these tendencies we may be able to explain many other phenomena, and predict the consequences, with as much certainty and evidence as an astronomer calculates a future eclipse. This would be a great acquisition, and perhaps more is impossible: and the road to this has been hinted by Sir Isaac Newton, who has expressed his suspicion, that as the great movements of the solar system are regulated by universal gravitation, so the mutual actions of the particles of matter are produced and regulated by tendencies of a similar kind, *equally* but not *more* inexplicable, and of which the laws of action are to be discovered by as careful an attention to the phenomena, and by the same patient thinking, which he has employed on the planetary motions. And a beautiful introduction to this new and almost unbounded field of inquiry has been given us by the celebrated Abbé Boscovich, in his Theory of Natural Philosophy, where he has shown how such mutual tendencies, similar in every ultimate particle of matter, and modified by conditions that are highly probable, nay almost demonstrable, will not only produce the sensible forms of solidity, hardness, elasticity, ductility, fluidity, and vapour, under an inconceivable variety of subordinate appearances, and the observed laws of sensible motion, but will go far to explain the phenomena of fusion, congelation, solution, crystallization, &c. &c. &c. both in chemistry and physiology. We earnestly recommend this work to the perusal of all who wish to obtain a distinct notion of the internal constitution of natural bodies, and of the way in which the uniting forces produce their ultimate and sensible effects. Any person, possessed of a moderate share of mathematical knowledge, will be convinced that the process of nature is not very different from what he describes; and that much of what we observe must happen as he says, even although the ultimate atoms of matter are not inextended mathematical points, accompanied with attracting and repelling forces.

47 Our ignorance still great, and the probable increase of knowledge among posterity.

But we have many steps to make before we begin this study: Nature opens to us an immense volume; and we doubt not that our posterity will long find employment in the perusal, even though advancing with the eagerness and success of the last century. We have not yet arrived at the threshold in many parts of this research: In many parts of chemistry, for instance, we are as yet uncertain with respect to the phenomena themselves, which are to be the subjects of this discussion. The composition of bodies must be fully understood before we begin to speak of the forces which unite their particles, or speculate about their modes of action. As long as water was considered as an element, we were ignorant of the forces inherent in its particles; we are, perhaps, still ignorant of this; but we now know that they are extremely different from what we formerly supposed them to be. It is but in a very few, if in any, cases of chemical combination, that we even know what are the ingredients: till we know this, it is too soon to speculate about their mode of union. Our ignorance in the real events in the animal and vegetable economy is still greater. Our first task therefore is to proceed, as we are now doing, in the accurate examination and classification of the phenomena themselves; and, without attempting to bring them within the pale of mathematical philosophy, by attempting what are called mechanical explanations, let us give up the consideration of these hidden operations, and augment to the utmost our list of secondary laws of visible but remote connections. All the mechanical speculations of the honourable Robert Boyle about the sensible qualities of things are now forgotten; but his chemical experiments preserve all their value, and are frequently referred to. The same may be said of the sagacious Dr Hales, whose fanciful notions of internal conflicts, and collisons, and vibrations, derogate nothing from the value of the curious facts which he has established both in the animal and vegetable economy.

48 The particular divisions of physical science in Britain.

This distinction in the nature of the phenomena, and this difference in the nature of the knowledge which is to be acquired, and the means which are to be employed

ployed for the successful prosecution of these two branches of general physics, has occasioned a still farther restriction (at least in Britain) of the term NATURAL PHILOSOPHY. It is particularly applied to the study of the phenomena of the first class, while those of the second have produced the sciences of CHEMISTRY and PHYSIOLOGY.

Natural philosophy and chemistry have generally been made particular institutions in our seminaries of learning, but physiology has more commonly been taught in conjunction with anatomy, medicine, and botany.

The phenomena of the first class have been usually called MECHANICAL, in order to distinguish them from those observed in the operations of chemistry, and in the animal and vegetable economy; and the explanations which have been attempted of some of the last, by applying the laws observed in the phenomena of the first class, have been called *mechanical explanations*.

As this first class is evidently but a part of general physics, there is some impropriety in giving the name *natural philosophy* to a course of doctrines which is confined to these alone. Indeed at the first institution of universities, the lectures given in the *Schola Physica* were much more extensive, comprehending almost all the phenomena of the material world: but as all arts and sciences have improved most where the labour has been most divided, it was found more conducive to the advancement of knowledge that separate institutions should be founded for the studies of natural history, chemistry, physiology, &c.; and thus the phenomena, purely mechanical, and a few others in magnetism, electricity, and optics, which either were susceptible of mathematical treatment, or had little connection with the studies of chemistry and physiology, were left to the care of the professor of natural philosophy.

As the terms *chemistry* and *physiology* have been applied to two very important branches of general physics, we think that a more specific or characteristic name might be appropriated to the other, and that it might very properly be termed MECHANICAL PHILOSOPHY.

It only remains to make a few observations on the distinctive means of prosecuting the studies with success, and to point out some of the advantages which may reasonably be expected from a careful prosecution of them: and as the second branch has been fully treated under the several articles of CHEMISTRY, PHYSIOLOGY, &c. we shall confine ourselves to what is usually called NATURAL PHILOSOPHY.

49 Mechanical philosophy defined, and its principles explained.

MECHANICAL PHILOSOPHY may, in conformity with the foregoing observations, be defined, "the study of the sensible motions of the bodies of the universe, and of their actions producing sensible motions, with the view to discover their causes, to explain subordinate phenomena, and to improve art."

The principle upon which all philosophical discussion proceeds is, that *every change which we observe in the condition of things is considered by us as an effect, indicating the agency, characterising the kind, and measuring the degree, of its cause.*

In the language of mechanical philosophy, the cause of any change of motion is called a moving or changing FORCE.

The disquisitions of natural philosophy must therefore begin with the consideration of motion, carefully noticing every affection or quality of it, so as to establish marks and measures of every change of which it is susceptible; for these are the only marks and measures of the changing forces. This being done, it only remains to apply them to the motions which we observe in the universe.

50 The laws of motion and their application.

From the general principle of philosophical discussion already mentioned, there flow directly two axioms.

1. *Every body perseveres in a state of rest, or of uniform rectilineal motion, unless affected by some moving force.*

2. *Every change of motion is in the direction and in the degree of the force impressed.*

These are usually called the LAWS OF MOTION. They are more properly laws of human judgment, with respect to motion. Perhaps they are necessary truths, unless it be alleged that the general principle, of which they are necessary consequences, is itself a contingent though universal truth.

By these two axioms, applied *in abstracto* to every variety of motion, we establish a system of general doctrines concerning motions, according as they are simple or compounded, accelerated, retarded, rectilineal, curvilineal, in single bodies, or in systems of connected bodies; and we obtain corresponding characteristics and measures of accelerating or retarding forces, centripetal or centrifugal, simple or compound.

We have an illustrious example of this abstract system of motion and moving forces in the first book of Sir Isaac Newton's Mathematical Principles of Natural Philosophy. Euler's *Mechanica sive Scientia Motus*, Herman's *Phoronomia sive de Viribus Corporum*, and D'Alembert's *Traité de Dynamique*, are also excellent works of the same kind. In this abstract system no regard is paid to the casual differences of moving forces, or the sources from which they arise. It is enough to characterise a double accelerating force, for instance, that it produces a double acceleration. It may be a weight, a stream of water, the pressure of a man; and the force, of which it is said to be double, may be the attraction of a magnet, a current of air, or the action of a spring.

Having established these general doctrines, the philosopher now applies them to the *general* phenomena of the universe, in order to discover the nature of the forces which really exist, and the laws by which their operations are regulated, and to explain interesting but subordinate phenomena. This is the chief business of the mechanical philosopher; and it may with some propriety be called *the mechanical history of nature.*

51 Of the arrangement of the mechanical phenomena of the universe.

Some method must be followed in this history of mechanical nature. The phenomena must be classed by means of their resemblances, which infer a resemblance in their causes, and their classes must be arranged according to some principle. We have seen no method which appears to us less exceptionable than the following.

52 The generality of the phenomena is the principle of arrangement.

The principle of arrangement is the generality of the phenomena; and the propriety of adopting this principle, arises from the probability which it gives us of more readily discovering the most general actuating forces, whose agency is implicated in all other phenomena of less

less extent; and therefore should be previously discussed, that we may detect the discriminating circumstances which serve to characterise the subordinate phenomena, and are thus the marks of the distinguishing and inferior natural powers.

53 The laws of motion are first applied to astronomical phenomena. The most general of all phenomena is the curvilinear motion of bodies in free space; it is observed through the whole extent of the solar system.

The mechanical history of nature begins therefore with astronomy. Here, from the general phenomena of the planetary motions, is evinced the *fact* of the mutual deflection of every body towards every other body, and this in the inverse proportion of the squares of the distance, and the direct proportion of the quantity of matter. This is the fact of UNIVERSAL GRAVITATION, indicating the agency, and measuring the intensity, of the universal force of mutual gravity.

Having established this as an universal fact, the natural philosopher proceeds to point out all the particular facts which are comprehended under it, and whose peculiarities characterise the different movements of the solar system. That is, in the language of philosophy, he gives a theory or explanation of the subordinate phenomena; the elliptical motions of the planets and comets, their mutual disturbances; the lunar irregularities; the oblate figure of the planets; the nutation of the earth's axis; the precession of the equinoxes; and the phenomena of the tides and trade winds: and he concludes with the theory of the parabolic motion of bodies projected on the surface of this globe, and the motion of pendulums.

54 The application of this science to the arts of life. As he goes along, he takes notice of the applications which may be made to the arts of life of the various doctrines which are successively established; such as chronology, astronomical calculation, dialling, navigation, gunnery, and the measuring of time.

55 The nature of gravitation, If a square parcel of sand be lying on the table, and the finger be applied to any part of it to push it along the table, that part is removed where you will, but the rest remains in its place; but if it is a piece of sand-stone of the same materials and shape, and the finger is applied as before, the whole is moved; the other parts accompany the part impelled by the finger in all its motions.

56 and of cohesion. From the moon's accompanying the earth in all its motions round the sun, we infer a moving force which connects the moon and earth. In like manner, we must conclude that a moving force connects the particles of the stone; for we give the name *force* to every thing which produces motion: We call it the force of COHESION; a term which, like gravitation, expresses merely a fact.

This seems to be the next phenomenon of the universe in point of extent.

57 Mode of investigating the laws of cohesion. Having, from the general phenomenon, established the existence of this force, the philosopher proceeds to ascertain the laws by which its exertions are regulated; which is the ascertaining its distinctive nature and properties. This he does in the same way that he ascertained the nature of planetary gravitation, viz. by observing more particularly the various phenomena.

Here is opened a most extensive and varied field of observation, in which it must be acknowledged that very little regular and marked progress has been made. The variety of the phenomena, and the consequent variety in the nature of the connecting forces, appear as yet inconceivably great; and there seems little probability of our being able to detect in them all any sameness, combined with the other distinguishing circumstances, as we have done in the case of gravity. Yet we should not despair. Boscovich has shown, in the most unexceptionable manner, that although we shall suppose that every atom of matter is endued with a perfectly similar force, acting in a certain determined ratio of the small and imperceptible distances at which the particles of matter are arranged with respect to each other, the external or sensible appearances may, and must, have all that variety which we observe. He also shows very distinctly how, from the operation of this force, must arise some of the most general and important phenomena which characterise the different forms of tangible bodies.

We observe the chief varieties of the action of this CORPUSCULAR force on the bodies which we denominate *hard*, *soft*, *solid*, *fluid*, *vaporous*, *brittle*, *ductile*, *elastic*. We see instances where the parts of bodies avoid each other, and require external force to keep them together, or at certain small distances from each other. This is familiar in air, vapours, and all compressible and elastic bodies.

This is evidently a most curious and interesting subject of investigation. On the nature and action of these corpuscular forces depends the strength or firmness of solids, their elasticity, their power of communicating motion, the pressure, and motion, and impulse of fluids; nay, on the same actions depend all the chemical and physiological phenomena of expansion, fusion, congelation, vaporisation, condensation, solution, precipitation, absorption, secretion, fermentation, and animal and vegetable concoction and assimilation.

Out of this immense store of phenomena, this inexhaustible fund of employment for our powers of investigation, the natural philosopher selects those which lead directly to the production or modification of sensible motion.

He will therefore consider,

1. The communication of motion among detached and free bodies, establishing the laws of impulse or collision. This has always been considered as the elementary doctrine of mechanical philosophy, and as the most familiar fact observed in the material world; and in all ages philosophers have been anxious to reduce all actions of bodies on each other to impulse, and have never thought a phenomenon completely explained or accounted for till it has been shown to be a case of impulse. This it is which has given rise to the hypotheses of vortices, ethers, magnetic and electric fluids, animal spirits, and a multitude of fancied intermediums between the sensible masses of matter, which are said in common language to act on each other. A heavy body is supposed to fall, because it is impelled by a stream of an invisible fluid moving according to certain conditions suited to the case. The filings of iron are supposed to be arranged round a magnet, by means of a stream of magnetic fluid issuing from one pole, circulating perpetually round the magnet, and entering at the other pole, in the same manner as we observe the flote-grass arranged by the current of a brook. 58 The production of motion by impulse has been thought the most familiar fact in nature.

But the philosopher who has begun the mechanical study of nature by the abstract doctrines of dynamics, and made its first application to the celestial phenomena, and who has attended carefully to the many analogics 59 But this opinion is very questionable.

logies between the phenomena of gravitation and cohesion, will be at least ready to entertain very different notions of this matter. He will be so far from thinking that the production of motion by impulse is the most familiar fact in nature, that he will acknowledge it to be comparatively very rare; nay, there are some appearances in the facts, which are usually considered as instances of impulsion, which will lead him to doubt, and almost to deny, that there has *ever been observed* an instance of one body putting another in motion by coming into absolute contact with it, and striking it; and he will be disposed to think that the production of motion in this case is precisely similar to what we observe

60 Motion seems to be produced from the equality of action and reaction.

when we gently push one floating magnet towards another, with their similar poles fronting each other. There will be the same production of motion in the one and diminution of it in the other, and the same uniform motion of the common centre of gravity: and, in this case of the magnets, he sees completely the necessity of a law of motion, which is not an axiom, but is observed through the whole of nature, and which receives no explanation from any hypothesis of an intervening fluid, but is even totally inconsistent with them. We mean, "that every action of one body on another is accompanied by an equal and opposite action of that other on the first." This is usually called the *equality of action and reaction*: it is not intuitive, but it is universal; and it is a necessary consequence of the perfect similarity of the corpuscular forces of the same kinds of matter. This general fact, unaccountable on the hypothesis of impelling fluids, is considered in the planetary motions as the unequivocal indication of the sameness of that gravity which regulates them all. The rules of good reasoning should make us draw the same conclusion here, that the particles of tangible matter are connected by equal and mutual forces, which are the *immediate causes* of all their sensible actions, and that these forces, like gravitation, vary with every change of distance and situation.

The laws of collision and impulsion being now established, either as original facts or as consequences of the agency of equal and mutual forces which connect the particles of matter, the philosopher considers,

61 Of motion as it respects the theory of machines, &c.

2. The production of motion by the intervention of solid bodies, where, by reason of the cohesion of matter, some of the motions are necessarily confined to certain determinate paths or directions. This is the case in all motions round fixed points or axes, or along planes or curves which are oblique to the action of the forces.

62 MECHANICS.

This part of the study contains the theory of machines, pointing out the principles on which their energy depends, and consequently furnishing maxims for their construction and improvement. But these observations do not complete the discussion of the mechanism of solid bodies: they are not only solid and inert, but they are also heavy; therefore the action of gravity must be combined with the consequences of solidity. This will lead to discussions about the centre of gravity, the theory and construction of arches and roofs, the principles of stability and equilibrium, the attitudes of animals, and many particulars of this kind.

63 The nature and definition of fluidity.

3. The philosopher will now turn his attention to another form, in which tangible matter exhibits many interesting phenomena, viz. FLUIDITY. The first thing to be attended to here is, *What is that particular form of existence?* What is the precise phenomenon which characterises fluidity? What is the definition of a fluid? This is by no means an easy question, and considerable objections may be stated against any definition that has been given of it. Sir Isaac Newton says, that *a fluid is a body whose particles yield to the smallest impression, and by so yielding are easily moved among themselves.* It may be doubted whether this be sufficiently precise; what is meant by the *smallest impression?* and what is *easily* moving? Is there any precise degree of impression to which they do not yield; and do they oppose any resistance to motion? And a stronger objection may be made: It is not clear that a body so constituted will exhibit all the appearances which a body acknowledged to be fluid does really exhibit. Euler offers some very plausible reasons for doubting whether it will account for the horizontal surface, and the complete propagation of pressure through the fluid in every direction; and therefore prefers selecting *this last phenomenon*, the propagation of pressure *quâqua versum*, as the characteristic of fluidity, because a body having this constitution (on whatever circumstance it may depend) will have every other observed property of a fluid. But this definition is hardly simple or perspicuous enough; and we think that the objections against Newton's more simple and intelligible definition are not unanswerable. Boscovich defines a fluid to be, *a body whose particles exert the same mutual forces in all directions;* and shows, that such particles must be indifferent, as to any position, with respect to each other. If no external force act on them, they will remain in every position, and will have no tendency to arrange themselves in one position rather than another; differing in this respect from the particles of solid, or soft, or viscid bodies; which require some force to change their respective positions, and which recover these positions again when but gently disturbed. He illustrates this distinction very beautifully, by comparing a parcel of balls thrown on quicksilver, and attracting each other, with a parcel of magnets in the same situation. The balls will stick together, but in *any position;* whereas the magnets will always affect a particular arrangement.

When the characteristic phenomenon of fluidity has been selected, the philosopher proceeds to combine this property with gravity, and establishes the doctrines of HYDROSTATICS, or of the pressure and equilibrium of heavy fluids, the propagation of this pressure in every direction; and demonstrates the horizontality of surface assumed by all perfect fluids. 64 Of the pressure and equilibrium of fluids, or hydrostatics.

These doctrines and principles enable us to determine several very interesting circumstances respecting the mutual pressure of solids and fluids on each other; the pressures exerted on the bottoms and sides of vessels; the support and whole mechanism of floating bodies, &c.

He then considers how fluids will move when their equilibrium of pressure is destroyed; and establishes the doctrines of HYDRAULICS, containing all the modifications of this motion, arising from the form of the vessels, or from the intensity or direction of the pressure which occasions it. And this subject is completed by the consideration of the resistance which fluids oppose to the motion of solid bodies through them, and their impulse on bodies opposed to their action. 65 Of the motion of fluids, or hydraulics.

These are very important matters, being the foundations of many mechanical arts, and furnishing us with some of our most convenient and efficacious powers for impelling

Mechanical Philosophy.

impelling machines. They are also of very difficult discussion, and are by no means completely investigated or established. Much remains yet to be done both for perfecting the theories and for improving the arts which depend upon them.

66
The importance and difficulty of these branches of science.

It is evident, that on these doctrines depend the knowledge of the motions of rivers and of waves; the buoyancy, equilibrium, and stability of ships; the motion of ships through the waters; the action of the winds on the sails; and the whole arts of marine construction and seamanship.

67
The nature and definition of vapour.

There is another general form of tangible matter which exhibits very different phenomena, which are also extremely interesting; we mean that of VAPOUR. A vapour is a fluid; and all the vapours that we know are heavy fluids: they are therefore subject to all the laws of pressure and impulse, which have been considered under the article HYDRODYNAMICS. But they are susceptible of great compression by the action of external forces, and expand again when these forces are removed. In consequence of this compression and expansion, the general phenomena of fluidity receive great and important modifications; and this class of fluids requires a particular consideration. As air is a familiar instance, this branch of mechanical philosophy has been called PNEUMATICS.

68
The doctrine of air or pneumatics.

Under this head we consider the pressure of the atmosphere, and its effects, both on solid and fluid bodies. It produces the rise of waters or other fluids in pumps and syphons, and gives us the theory of their construction: it explains many curious phenomena of nature, such as the motions in the atmosphere, and their connection with the pressure of the air, and its effect on the barometer or weather-glass. Air, when in motion, is called *wind;* and it may be employed to impel bodies. The theory of its action, and of its resistance to moving bodies, are therefore to be considered in this place.

But besides their motions of progression, &c. such as we observe in winds, compressible or elastic fluids are susceptible of what may be termed *internal motion;* a kind of undulation, where the contiguous parts are thrown into tremulous vibrations, in which they are alternately condensed and rarefied; and these undulations are propagated along the mass of elastic fluid, much in the same way in which we observe waves to spread on the surface of water. What makes this an interesting subject of consideration is, that these undulations are the more ordinary causes of sound. A trembling chord, or spring, or bell, agitates the air adjoining to it: these agitations are propagated along the air, and by its intervention agitate the organ of hearing. The mechanism of these undulations has been much studied, and furnishes a very beautiful theory of musical harmony.

69
Of the compressibility of elastic fluids, and its consequence.

The philosopher examines the *law of compressibility* of air and other elastic fluids; and thus gets the knowledge of the constitution of the atmosphere, and of the action of those fluids when employed to impel solid bodies. Gunpowder contains an immense quantity of permanently elastic air, which may be set at liberty by inflammation. When this is done at the bottom of a piece of ordnance, it will impel a ball along the barrel, and discharge it from the muzzle, in the same way that an arrow is impelled by a bow. And thus having discovered in what degree this air presses in proportion to its expansion, we discover its action on the ball through the whole length of the piece, and the velocity which it will finally communicate to it. Here then is contained a theory of artillery and of mines.

Chemistry teaches us, that most bodies can be converted by fire into elastic fluids, which can be employed to act on other bodies in the way of pressure or impulse. Thus they come under the review of the mechanical philosopher; and they have become interesting by being employed as moving forces in some very powerful machines. 70

70
Of the conversion of bodies into elastic fluids by fire.

These discussions will nearly exhaust all the general mechanical phenomena. There remain some which are much more limited, but furnish very curious and important subjects of investigation.

71
Of the phenomena of loadstone, or magnetism.

The phenomena exhibited between loadstones or magnets and iron have long attracted attention; and the use to which the polarity of the loadstone has been applied, namely, the directing the course of a ship through the pathless ocean, has rendered these phenomena extremely interesting. They are specified by the term MAGNETISM. Considerable progress has been made in the arrangement and generalization of them; but we have by no means been able hitherto to bring them all under one simple fact. The attention has been too much turned to the discovery of the ultimate cause of magnetism; whereas we should have rather employed our ingenuity in discovering all the general laws, in the same manner as Kepler and Newton did with respect to the celestial phenomena, without troubling themselves with the cause of gravitation. Dr Gilbert of Colchester was the first who considered the magnetical phenomena in the truly philosophical manner; and his treatise *De Magnete* may be considered as the first and one of the most perfect specimens of the Baconian or inductive logic. It is indeed an excellent performance; and when we consider its date, 1580, it is a wonder. Æpinus's *Tentamen Theoriæ Magnetismi* is a most valuable work, and contains all the knowledge which we have as yet of the subject.

72
Of electrical phenomena.

There is another class of mechanical phenomena which have a considerable affinity with the magnetical; we mean the phenomena called ELECTRICAL. Certain bodies, when rubbed or otherwise treated, attract and repel other bodies, and occasion a great variety of sensible motions in the neighbouring bodies. Philosophers have paid much attention to these appearances of late years, and established many general laws concerning them. But we have not been more successful in bringing them all under one fact, and thus establishing a complete theory of them, than in the case of magnetism. Franklin and Æpinus are the authors who have been most successful in this respect. Dr Franklin in particular has acquired great celebrity by his most sagacious comparison of the phenomena; which has enabled him to establish a few general laws, almost as precise as those of Kepler, and of equally extensive influence. His discovery too of the identity of thunder and electricity has given an importance and dignity to the whole subject.

73
These are not all mechanical.

There are many phenomena of electricity which cannot be called mechanical, and are of the most curious and interesting kind. As these have little connection with any of the other great branches of physical science, they have generally been considered in treatises of natural philosophy; and, along with inquiries into the original cause of electricity in general, continue to engage much of our attention.

The appearances which are presented to us by our sense

sense of seeing form another class, which have always been considered as making a branch of natural philosophy in all seminaries of learning. It does not, however, obviously appear, that they are mechanical phe-

74 Of the phenomena of vision.

nomena. The intimate nature of light is still a secret. Fortunately it is not necessary to be known to give us a very perfect theory of the chief phenomena. The general laws of optics are so few, so simple, and so precise, that our theories are perhaps more perfect here than in any other branch of physics; but these theories are as yet far removed from the rank of primary facts. Many unknown events happen before the phenomenon comes under the hands of the ordinary optician, so as to become the subjects of the simple laws of reflection and

75 It has been doubted whether light is corporeal.

refraction. It may even be doubted, and has been doubted, whether the phenomena of optics are cases of body in motion; whether all the lines which the optician draws are any thing but the directions along which certain *qualities* are exerted. The side of a ball which is next the candle may be bright and the other side dark, just as the side of a ball which is next the electrical globe is *minus* and the other side *plus;* and all this without any intervening medium. Apparition or visibility may be a quality of a body, depending on the proximity and position of another body, without any thing between them, just as weight is; and this quality may be cognizable by our faculty of seeing alone, just as the pressure of a heavy body is by our feeling alone.

76 How optics came to be considered as a part of mechanical philosophy.

The first thing which made it probable that mechanical philosophy had any thing to do with the phenomena of optics, was the discovery of Mr Roemer, "that apparition was not instantaneous;" that some time elapsed between the illumination of a body and its being seen at a distance. He discovered, that it was not till 40 minutes after the sun illuminated one of Jupiter's satellites that it was seen by the inhabitants of this globe. If therefore a sun were just created, it would be 40 minutes before Jupiter would be illuminated by him, and 200 be-

77 The nature of light is still undetermined.

fore the Georgian planet would be illuminated. Here then is motion. It is therefore highly probable that there is something moved; but it is still doubted whether this something, which we call LIGHT, is a matter emitted from the shining body, and moving with great velocity, and acting on and affected by other bodies, in the various phenomena of optics, or whether it is a *certain state* of a medium which is thus propagated, as we see that waves are propagated along the surface of water, or sonorous undulations through the mass of air, while the water or air itself is hardly moved out of its place. Either of these suppositions makes optics a legitimate branch of mechanical philosophy; and it is the philosopher's business to examine both by the received laws of motion, and see which of them gives consequences which tally with the phenomena. This has been done; and we imagine that a complete incompatibility has been demonstrated between the consequences of the undulations of an elastic medium, and the phenomena of optics; while the consequences of the other or vulgar notion on this subject are perfectly consistent with mechanical laws. There are some things in this hypothesis very far beyond our power to conceive distinctly; but they are all similar in this respect to many facts acknowledged by all; and there is no phenomenon that is inconsistent with the legitimate consequences of the hypothesis. This gives it great probability; and this probability is confirmed by many chemical facts, and by facts in the vegetable economy, which give strong and almost undeniable indications of light being a body capable of a chemical union with the other ingredients of sublunary bodies, and of being afterwards set at liberty under its own form, as the cause or medium of vision.

78 But this does not affect the science of optics.

But these are questions similar to those about the cause of gravity, and totally unnecessary for establishing a complete theory of the optical phenomena, for explaining the nature of vision, the effects of optical instruments, the cause of colours, the phenomena of the rainbow, halos and parhelia, &c. &c. &c. Only all this theory is unconnected with the principles called mechanical.

79 The probable increase of the above extensive field of observation.

Such is the field of observation to the mechanical philosopher of the present day. We may hope to extend it, and by degrees apply its doctrines even to the unseen motions which take place in chemistry and phisiology. But we must, in the first place, perfect our knowledge and description of the sensible motions and actions of bodies. Those of fluids still demand much investigation; and till these are thoroughly understood, it is not time to attempt penetrating further into the recesses of nature.

80 Investigation of the law that action is always equal and opposite to reaction.

In the prosecution of this study, it is found that every change which can be observed in the state of a body, with respect to motion by the action of another body, is accompanied by an equal and opposite change in the state of that other body. Thus, in the phenomena of gravitation, it is observed that the deflections of the sun and planets are mutual. The same thing is observed in the actions of magnets on each other and on iron; it is also observed in the attractions and repulsions of electrical bodies; and it also obtains in all the phenomena of impulse and of corporeal pressure. It is therefore an universal law of motion, that *action is always equal and opposite to reaction:* but this must be considered merely as a matter of fact, a contingent law of nature, like that of gravitation. The contrary is perfectly conceivable, and involves no contradiction. That this is so, is evident from the proceedings of philosophers, who in every new case make it their business to discover by experiment whether this law was observed or not. It was among the last discoveries made by Sir Isaac Newton in his examination of the celestial motions. This being the case, it should never be assumed as a principle of reasoning till its operation has been ascertained by observation.

81 The term *inertia* has occasioned much wrangling and misconception on this subject.

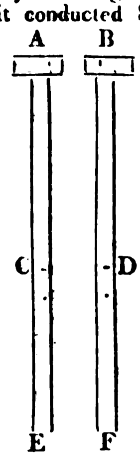
It has been owing to this improper procedure that much false reasoning has been introduced into mechanical philosophy, and particularly into the theory of impulsion or the communication of motion by impulse. In considering this subject, a term has been introduced which has occasioned much wrangling and misconception; we mean the term INERTIA. It serves indeed to abbreviate language, but it has often misled the judgment. When used with cautious attention to every circumstance, it expresses nothing but the necessity of a cause to the production of any effect: but it is generally used as expressing a quality inherent in matter, by which it *resists* any change of state, or by which it maintains its present state. Matter is said to be inert; and as every thing which changes the motion of a body is called a *force*, and as this inertia of A is supposed to change the motion of B, it is called *vis inertiæ*; and yet matter is said to be indifferent as to motion or rest, and to be inactive. These are

are surely very incongruous expressions. This obscure discourse has arisen from the poverty of all languages, which are deficient in original terms, and therefore employ figurative ones. Force, action, resistance, are all appropriated terms related to our own exertions; and some resemblance between the external effects of these exertions and the effects of the connecting qualities of natural bodies, has made us use them in our disquisitions on these subjects. And as we are conscious that, in order to prevent our being pushed by another from our place, we must resist, exerting force; and that our resistance is the reason why this other man has not accomplished his purpose, we say, that the quiescent body resists being put in motion, and that its inertia is discovered by the diminution made in the motion of the impelling body: and upon the authority of this *vis inertiæ* as a first principle, the phenomena of impulsion are explained, and the law of equal action and reaction is established.

But all this procedure is in contradiction to the rules of inductive logic; and the obscurity and confusion which has arisen from this original misconception, the consequent incongruity of language, and the awkward attempts that have been made to botch and accommodate it to the real state of things, have occasioned a dispute, and the only dispute, in natural philosophy which has not yet been settled, and never can be settled, while such misconceptions are allowed to remain.

82
Its proper meaning, with an example.

If the word *inertiæ* be taken as expressing not a quality of matter, but a law of human judgment respecting matter, as expressing our necessity of inferring the agency of a moving force whenever we observe a change of motion, all difficulties will vanish, and the equality of action and reaction will be inferred, as it should be, from the phenomena of collision. There will be inferred a *vis insita corpori impellenti*, not *quâ moventi*, but *quâ corpori*; and this inference will carry us through all the mysteries of corporeal action, as it conducted Sir Isaac Newton in his grand researches.



Let us just consider how we reason in a new case. Let A and B be two magnets fastened on the ends of two long wooden laths AE, BF, which turn horizontally on pivots C, D, like compass needles, with their north poles fronting each other, 12 inches apart; and let A be pushed towards B, so that it would move uniformly with the velocity of two inches in a second. The phenomena *which have been observed* are as follow: A will gradually diminish its velocity; and when it has advanced about nine inches, will stop completely. B, in the mean time will gradually acquire motion; and when it has advanced about nine inches, will have a velocity of about two inches per second, with which it will continue to move uniformly. Now what is inferred from these phenomena? Because the motion of A is gradually retarded, we infer that a retarding force, that is, a force in the direction BA, has acted on it. And since this would not have happened if B had not been there, and always happens when B is there, we infer that B is either its cause or the occasion of its action. The vulgar say that B repels A; so say the dynamists. The abettors of invisible fluids say, that a stream of fluid issuing from B impels A in the opposite direction. All naturalists agree in saying, that an active force connected with B has destroyed the motion of A, and consider this curious phenomenon as the indication and characteristic of a discovery. The same inference is made from the motion produced in B: it is considered by all as effected by a force exerted or occasioned by the presence of A; and the dynamists and the vulgar say that A *repels* B. And both parties conclude, from the equal changes made on both bodies, that the changing forces are equal; here acknowledging, that they *observe* an equality of action and reaction; and they add this to the other instances of the extent of this law of motion.

All this while no one thinks of the inertia or inactivity of B, but, on the contrary, conclude this to be a curious instance of its activity; and most people conclude that both bodies carry about with them a *vis insita* both when at rest and when in motion.

83
It is doubtful whether actual contact has ever been observed.

If other phenomena give unquestionable evidence that in ordinary collisions, there is the same changes of motion, produced without mathematical contact, the same inferences must be drawn; and a scrupulous naturalist will doubt whether contact should make any change in our reasonings on the subject, and whether actual contact ever has been or can be observed. He will also be convinced, that while this is the general, or perhaps universal, process of nature in producing motion by impulse, all explanations of the action of bodies *è distanti*, by the intervention of ethers and other invisible fluids, are nothing but multiplying the difficulties; for in place of one fact, the approach of one magnet (for instance) to another, they substitute millions of unseen impulses, each of which equally needs an explanation. And if this fluid be supposed to produce its effects by any *peculiarity* in its constitution, as in the case of Newton's elastic ether proposed by him to explain gravitation, the hypothesis substitutes, in the most unqualified manner, millions of similar phenomena for the one to be explained; for there is the same want of a second fluid in order to produce that mutual recess of the particles of the ether which constitutes its elasticity.

84
The folly of supposing intervening ethers, &c.

85
The quality of bodies whereby they affect other bodies is inscrutable by us.

And this seems to be the limit to our inquiries into all the classes of natural phenomena. We find the masses or the particles of matter endued in fact with qualities which affect the state of other particles or masses, at smaller or at greater distances from each other according to certain general rules or laws. This ultimate step in the constitution of things is inscrutable by us. It is arrogance in the highest degree for us to say, that because we do not comprehend how there is inherent in a body any quality by which another body may be affected at any distance from it, therefore no such quality *is possible*. It is no less so to say, that matter has no active property but that of moving other matter by impulse; and that because it may be so moved, and also by the agency of our own minds, therefore, when it is not moved by impulse, it is moved by minds. The same almighty FIAT which brought a particle of matter into existence could bring those qualities equally into existence; and the *how* in both is equally beyond our comprehension.

86
This should not, however, stop further inquiries.

But, on the other hand, we must guard against the incurious resting on this consideration as a stop to further inquiry. There may be species of matter possessed

sed of the mechanical powers, and which notwithstanding is not cognisable by our senses. All the properties of matter are not known to a person who is both deaf and blind; and beings possessed of more senses may perceive matter where we do not; and many phenomena may really be produced by the action of intervening matter, which we, from indolence or from haste, ascribe to the agency of inherent forces. The industry of philosophers has already discovered intermedia in some cases. It is now certain that air is the conveyor of sound, and it is almost certain that there is such a thing as light. Let us therefore indulge conjectures of this kind, and examine the conjectures by the received laws of motion, and reject them when we find the smallest inconsistency; and always keep in mind that even the most coincident with the phenomena is still but a possibility.

87
These observations are not physical, but metaphysical.

We may conclude the whole of these observations with the remark, that these questions about the activity or inactivity of matter are not physical, but metaphysical. Natural philosophy, it is true, commonly takes it for granted that matter is wholly inactive; but it is not of any moment in physics whether this opinion be true or false; whether matter be acted on according to certain laws, or whether it act of itself according to the same laws, makes no difference to the natural philosopher. It is his business to discover the laws which really obtain, and to apply these to the solution of subordinate phenomena: but whether these laws arise from the nature of some agent external to matter, or whether matter itself is the agent, are questions which may be above his comprehension, and do not immediately concern his proper business.

88
The above account points out the best method of study.

The account we have now given of natural philosophy points out to us in the plainest manner the way in which the study must be prosecuted, and the helps which must be taken from other branches of human knowledge.

89
This method further explained and exemplified.

The causes, powers, forces, or by whatever name we choose to express them, which produce the mechanical phenomena of the universe, are not observed, and are known to us only in the phenomena themselves. Our knowledge of the mechanical powers of nature must therefore keep pace with our knowledge of the motions, and indeed is nothing different from it. In order to discover and determine the forces by which the moon is retained in her orbit round the earth, we must know her motions. To a terrestrial spectator she appears to describe an ellipse, having the earth in one focus; but, in the mean time, the earth is carried round the sun, and the moon's real path, in absolute space, is a much more complicated figure. Till we know this figure, and the variations in the velocity with which it is described, we know nothing of the forces which actuate the moon in her orbit.

90
The meaning of some terms used in speaking of the celestial motions.

When Newton says that the forces by which she is retained in this elliptical orbit are directed to the earth, what does he mean? Only this, that the deflections from that uniform rectilineal motion which she would otherwise have performed are always in this direction. In like manner, when he says that these forces are inversely proportionate to the squares of her distances from the earth, he only means that the deflections made in equal times in different parts of her motion are in this proportion. These deflections are considered as the characteristics and measures of the forces. We imagine that we have made all plain when we call this indicated cause a *tendency* to the earth; but we have no notion of this tendency to the earth different from the approach itself. This word tendency, so fashionable among the followers of Sir Isaac Newton, is perverted from its pure and original sense. *Tendere versus solem*, is, in the language of Rome and also of Newton, *to go* towards the sun; but we now use the words *tend, tendency*, to signify, not the *approach*, but the *cause* of this approach. And when called upon to speak still plainer, we desert the safe paths of plain language, and we express ourselves by metaphor; speaking of *nisus*, *conatus sese mutua accedende*, *vis centripeta*, &c. When these expressions have become familiar, the original sense of the word is forgotten, and we take it for granted that the words never had another meaning; and this metaphor, sprung from the poverty of language, becomes a fruitful source of misconception and mistake. The only way to secure ourselves against such mystical notions as are introduced by these means into philosophy, is to have recourse to the way in which we acquire the knowledge of these fancied powers; and then we see that their names are only names for phenomena, and that universal gravitation is only an universal mutual approach among the parts of the solar system.

91
The absurdity of reasoning *à priori*.

There is one case in which we fondly imagine that we know the cause independent of the effect, and that we could have predicted the phenomenon *à priori*; we mean the case of impulse: and hence it is that we are so prone to reduce every thing to cases of impulsion, and that we have fallen upon all these subterfuges of ethers and other subtile fluids. But we might have saved ourselves all this trouble; for after having, by much false reasoning and gratuitous assumptions, shown that the phenomenon in question *might have been produced* by impulse, we are no nearer our purpose, because that property by which matter in motion puts other matter in motion, is known to us only *by* and *in* the effect.

92
We know nothing of the immediate causes of motions except by a knowledge of the motions themselves.

The fair and logical deduction from all this is, that we must not expect any knowledge of the powers of nature, the immediate causes of the motions of bodies, but by means of a knowledge of the motions themselves; and that every mistake in the motions is accompanied by a similar mistake in the causes. It is impossible to demonstrate or explain the gravitation of the planets to him who is ignorant of the properties of the ellipse, or the theory of gunnery to him who does not know the parabola.

93
A man cannot be a good natural philosopher without being a mathematician.

A notion has of late gained ground, that a man may become a natural philosopher without mathematical knowledge; but this is entertained by none who have any mathematics themselves; and surely those who are ignorant of mathematics should not be sustained as judges in this matter. We need only appeal to fact. It is only in those parts of natural philosophy which have been mathematically treated, that the investigations have been carried on with certainty, success, and utility. Without this guide, we must expect nothing but a school-boy's knowledge, resembling that of the man who takes up his religious creed on the authority of his priest, and can neither give a reason for what he imagines that he believes,

lieves, nor apply it with confidence to any valuable purpose in life. We may read and be amused with the trifling or vague writings of a Nollet, a Ferguson, or a Priestley; but we shall not understand, or profit by the truths communicated by a Newton, a D'Alembert, or De la Grange.

These observations, on the other hand, show us the nature of the knowledge which may be acquired, and the rank which natural philosophy holds among the sciences.

94
The motions of bodies the only objects of observation, are subjects of pure mathematical disquisition.

Motions are the real and only objects of our observation, the only subjects of our discussion. In motion are included no ideas but those of space and time, the subjects of pure mathematical disquisition. As soon, therefore, as we have discovered the fact, the motion, all our future reasonings about this motion are purely mathematical, depending only on the affections of figure, number, and proportion, and must carry along with them that demonstration and irresistible evidence which is the boast of that science. To this are we indebted for that accuracy which is attained, and the progress which has been made, in some branches of mechanical philosophy; for when the motions are distinctly and minutely understood, and then considered only as mathematical quantities, independent of all physical considerations, and we proceed according to the just rules of mathematical reasoning, we need not fear any intricacy of combination or multiplicity of steps; we are certain that truth will accompany us, even though we do not always attend to it, and will emerge in our final proposition, in the same manner as we see happen in a long intricate algebraic analysis.

95
Mechanical philosophy thus cultivated is a demonstrative science.

Mechanical philosophy, therefore, which is cultivated in this way, is not a system of probable opinions, but a *disciplina accurata*, a demonstrative science. To possess it, however, in this form, requires considerable preparation. The mere elements of geometry and algebra are by no means sufficient. Newton could not have proceeded *sine* "*sua mathesi facem preferente;*" and, in creating a new science of physics, he was obliged to search for and discover a new source of mathematical knowledge.

96
The lamentable decay of mathematics in Britain,

It is to be lamented that the taste for the mathematical sciences has so prodigiously declined in this country of late years; and that Britain, which formerly took the lead in natural philosophy, should now be the country where they are least cultivated. Few among us know more than a few elementary doctrines of equilibrium: while, on the continent, we find many authors who cultivate the Newtonian philosophy with great assiduity and success, and whose writings are consulted as the fountains of knowledge by all our countrymen who have occasion to employ the discoveries in natural philosophy in the arts of life. It is to the foreign writers that we have recourse in our seminaries, even for elementary treatises; and while the continent has supplied us with most elaborate and useful treatises on various articles, in physical astronomy, practical mechanics, hydraulics, and optics, there has not appeared in Britain half a dozen treatises worth consulting for these last forty years; and this notwithstanding the unparalleled munificence of our present sovereign, who has given more liberal patronage to the cultivators of mathematical philosophy, and indeed of science in general, than any prince in Europe. The magnificent establishments of Louis XIV. originated from his insatiable ambition and desire of universal influence, directed by the sagacious Colbert. And his patronage being exerted according to a regular plan in the establishment of pensioned academics, and in procuring the combined efforts of the *most eminent* of all countries, his exertions made a conspicuous figure, and filled all Europe with his eulogists. But all this was done without the smallest self-denial, or retrenchment of his own pleasures, the expences being furnished out of the public revenues of a great and oppressed nation; whereas the voyages of discovery, the expensive observations and geodetical operations in Britain, and the numberless unheard-of pensions and encouragements given to men of science and activity, were all furnished out of the private estate of our excellent sovereign, who seems to delight in repaying, by every service in his power, the attachment of a loyal and happy nation. It is therefore devoutly to be wished that his patriotic efforts were properly seconded by those whom they are intended to serve, and that the taste for the mathematical sciences may again turn the eyes of Europe to this country for instruction and improvement. The present seems a most favourable era, while the amazing advances in manufactures of every kind seem to call aloud for the assistance of the philosopher. What pleasure would it have given to Newton or Halley to have seconded the ingenious efforts of a Watt, a Boulton, a Smeaton, an Arkwright, a Dollond? and how mortifying is it to see them indebted to the services of a Belidor, a Bossut, a Clairaut, a Boscovich?

97
notwithstanding the amplest encouragement from the crown.

We hope to be pardoned for this digression, and return to our subject.

98
Mechanical philosophy is almost wholly a mathematical study.

It appears from what has been said, that mechanical philosophy is almost wholly a mathematical study, and that it is to be successfully prosecuted only under this form: but in our endeavours to initiate the young beginner, it will be often found to require more steadiness of thought than can generally be expected for keeping the mind engaged in such abstract speculations. The object presented to the mind is not readily apprehended with that vivacity which is necessary for enabling us to reason upon it with clearness and steadiness, and it would be very desirable to have some means of rendering the conception more easy, and the attention more lively.

99
Experiments are, however, necessary to insure the attention of young minds.

This may be done by exhibiting to the eye an experiment, which, though but a single fact, gives us a sensible object of perception, which we can contemplate and remember with much more steadiness than any mere creature of the imagination. We could, by an accurate description, give such a conception of a room that the hearer should perfectly comprehend our narration of any occurrence in it: but one moment's glance at the room would be infinitely better. It is usual therefore to employ experiments to assist the imagination of the beginner; and most courses of natural philosophy are accompanied by a series of such experiments. Such experiments, connected by a slight train of argumentative discourse, may even serve to give a notion of the general doctrines, sufficient for an elegant amusement, and even tending to excite curiosity and engage in a serious prosecution of the study. Such are the usual courses which go by the name of experimental philosophy: but this is

Experimental Philosophy.

is a great misapplication of the term; such courses are little more than *illustrations* of known doctrines by experiments.

100 Experimental philosophy defined and explained.

EXPERIMENTAL PHILOSOPHY is the investigation of general laws, as yet unknown, by experiment; and it has been observed, under the article PHILOSOPHY, that this is the most infallible (and indeed the sole) way of arriving at the knowledge of them. This is the *Novum Organum Scientiarum* strongly recommended by Lord Bacon. It was new in his time, though not altogether without example; for it is the procedure of nature, and is followed whenever curiosity is excited. There was even extant in his time a very beautiful example of this method, viz. the Treatise of the Loadstone, by Dr Gilbert of Colchester; a work which has hardly been excelled by any, and which, when we consider its date, about the year 1580, is really a wonderful performance.

The most perfect model of this method is the Optics of Sir Isaac Newton. Dr Black's Essay on Magnesia is another very perfect example. Dr Franklin's Theory of Electricity is another example of great merit. That the investigation is not complete, nor the conclusions certain, is not an objection. The method is without fault; and a proper direction is given to the mind for the experiments which are still necessary for establishing the general laws.

101 A good treatise on the method of inquiry by experiment very necessary.

It were much to be wished that some person of talents and of extensive knowledge would give a treatise on the method of inquiry by experiment. Although many beautiful and successful examples have been given as particular branches of inquiry, we have but too many instances of very inaccurate and inconclusive investigations. Experiments made at random, almost without a view, serve but little to advance our knowledge. They are like shapeless lumps of stone merely detached from the rock, but still wanting the skill of the builder to select them for the different purposes which they may chance to serve; while well contrived experiments are blocks cut out by a skilful workman, according as the quarry could furnish them, and of forms suited to certain determined uses in the future edifice. Every little series of experiments by Margraaf terminates in a general law, while hardly any general conclusion can be drawn from the numberless experiments of Pott. Lord Bacon has written much on this subject, and with great judgment and acuteness of distinction; but he has exceeded in this, and has fatigued his readers by his numerous rules; and there is in all his philosophical works, and particularly in this, a quaintness and affectation that greatly obscure his meaning, so that this most valuable part of his writings is very little read.

102 An objection to experimental inquiry.

A formidable objection has been made to this method of inquiry. Since a physical law is only the expression of a general fact, and is established only in consequence of our having observed a similarity in a great number of particular facts; and since the great rule of inductive logic is to give the law no greater extent than the induction on which it is founded—how comes it that a few experiments must be received as the foundation of a general inference? This has been answered in very general terms in the article PHILOSOPHY. But it will be of use to consider the subject a little more particularly. Our observations on this subject are taken from the dissertation on evidence by Dr Campbell in his Philosophy of Rhetoric.

103 The objection answered, with examples showing the nature and certainty of this mode of inquiry.

An attentive consideration of the objects around us, will inform us that they are generally of a complicated nature, not only as consisting of a complication of those qualities of things called accidents, such as gravity, mobility, colour, figure, solidity, which are common to all bodies: but also as consisting of a mixture of a variety of substances, very different in their nature and properties; and each of these is perhaps compounded of ingredients more simple.

Moreover, the farther we advance in the knowledge of nature, we find the more reason to be convinced of her constancy in all her operations. Like causes have always produced like effects, and like effects have always been preceded by like causes. Inconstancy sometimes appears in Nature's works at *first sight*; but a more refined experience shows us that this is but an appearance, and that there is no inconstancy: and we explain it to our satisfaction in this way.

Most of the objects being of a complicated nature, we find, on an accurate scrutiny, that the effects ascribed to them ought often to be solely ascribed to one or more of these component parts, while the others either do not contribute to them, or hinder their production; and the variety of nature is so great, that hardly any two individuals of the same species are in every respect like any other. On all these accounts we expect dissimilitudes in the phenomena accompanying perfectly similar treatment of different subjects of the same kind; but we find, that whenever we can be assured that the two substances are perfectly alike, the phenomena arising from similar treatment are the same: and long and extensive observation teaches us, that there are certain circumstances which insure us in the perfect similarity of constitution of some things. Whenever we observe the effect of any natural agent on one, and but one, of these, we invariably expect that the same will be produced on any other.

Should a botanist meet with a plant new to him, and observe that it has seven monopetalous flowers, he will conclude with the utmost confidence that every plant of this species will have monopetalous flowers; but he will not suppose that it will have seven, and no more than seven, flowers. Now these two facts seem to have no difference to warrant such a difference in the conclusion; which may therefore seem capricious, since there is but one example of both.

But it is not from this example only that he draws the conclusion. Had he never before taken notice of any plant, he would not have reasoned at all from these remarks. But his mind runs immediately from this unknown species to all the known species of this genus, and to all the genera of the same order; and having experienced in the *figure* of the flower an uniformity in every species, genus, and order, which admits of no exception, but, in the *number* of flowers, a variety as boundless as are the circumstances of soil, climate, age, and culture, he learns to mark the difference, and draws the above-mentioned conclusions. Thus we learn, that *perfect* uniformity is not to be expected in any instance whatever, because in no instance is the simplicity of constitution sufficiently great to give us assurance of perfect uniformity in the circumstances of the case; and the utmost

most that our experience can teach us is a quick discrimination of those circumstances which produce the occasional varieties.

The nearer that our investigations carry us to the knowledge of *elementary* natures, the more are we convinced by general experience of the uniformity of the operations of real elements; and although it may perhaps be impossible for us ever to arrive at the knowledge of the simplest elements of any body, yet when any thing *appears* simple, or rather so exactly uniform, as that we have invariably observed it to produce similar effects, on discovering any *new* effect of this substance, we conclude, from a general experience of the efficient, a like constancy in the energy as to the rest. Fire consumes wood, melts lead, and hardens clay. In these instances it acts uniformly, but not in these only. We have always found, that whatever of any species is consumed by it in one instance, has been consumed by it on trial at any time. If therefore a trial be made for the first time of its influence on any particular substance, he who makes it is warranted to conclude that the effect, whatever it may be, is a faithful representative of its effects on this substance in all past and future ages. This conclusion is not founded on this single instance, but upon this instance combined with the general experience of the regularity of this element in its operations.

This general conclusion, therefore, drawn from one experiment, is by no means in opposition to the great rule of inductive logic, but, on the contrary, it is the most general and refined application of it. General laws are here the real subject of consideration; and a law still more general, viz. *that nature is constant in all its operations*, is the inference which is here applied as a principle of explanation of a phenomenon which is itself a general law, viz. *that nature is constant in this operation.*

The foundation of this general inference from one experiment being so firmly established, it is evident that experiments must be an infallible method of attaining to the knowledge of nature; and we need only be solicitous that we proceed in a way agreeable to the great rule of inductive logic; that is, the subject must be cleared of every accidental and *unknown* circumstance, and put into a situation that will reduce the interesting circumstance to a state of the greatest possible simplicity. Thus we may be certain that the event will be a faithful representative of every similar case: and unless this be done in the preparation, nothing can result from the most numerous experiments but uncertainty and mistakes.

104 Mathematics do not supersede the use of experiment.

The account which has been given of mechanical philosophy would seem to indicate that experiment was not of much use in the farther prosecution of it. The two laws of motion, with the assistance of mathematics, seem fully adequate to the explanation of every phenomenon; and so they are to a *certain degree.* But this degree is as yet very limited. Our mathematical knowledge, great as it is in comparison with that of former times, is still insufficient for giving accurate solutions even of very simple (comparatively speaking) questions. We can tell, with the utmost precision, what will be the motions of two particles of matter, or two bodies, which act on each other with forces proportioned to the squares of the distances inversely; but if we add a third particle, or a third body, acting by the same law, the united science of all Europe can only give an approximation to the solution.

105 Experiment is often the only resource.

What is to be done then in the cases which come continually before us, where millions of particles are acting at once on each other in every variety of situation and distance? How shall we determine, for instance, the motion of water through a pipe or sluice when urged by a piston or by its own weight? what will be its velocity and direction? It is impossible, in the present state of mathematical knowledge, to tell with any precision or certainty. And here we must have recourse to experiment. But if this be the case, must the experiment be made in every possible variety of situation, depth, figure, pressure? or is it possible to find out any general rules, founded on the general laws of motion, and rationally deduced from them? Or, if this cannot be accomplished, will experiment itself furnish any general coincidences which show such mutual dependences, that we may consider them as indications of general principles, though subordinate, complicated, and perhaps inscrutable? This can be discovered by experiment alone.

106 Accurate experiments cannot always be made.

The attention of philosophers has been directed to each of these three chances, and considerable progress has been made in them all. Numerous experiments have been made, almost sufficient to direct the practice in many important cases, without the help of any rule or principle whatever. But there are many cases, and these of by far the greatest importance, such as the motion of a ship impelled by the winds, resisted by the water, and tossed by the waves, where distinct experiments cannot be made.

107 Example of the necessity of experiment.

Newton, Bernouilli, d'Alembert, and others, have laboured hard to deduce from the laws of motion rules for determining what may be called the *average* motion of water in these circumstances, without attempting to define the path or motion of any individual particle; and they have actually deduced many rules which have a great degree of probability. It may here be asked, why do you say *probability?* the rules, as far as they go, should be *certain.* So they are: they are strict deductions from their premisses. But the premisses are only *suppositions*, of various degrees of probability, assumed in order to simplify the circumstances of the case, and to give room for mathematical reasoning; therefore these deductions, these rules, must be examined by experiment. Some of the suppositions are such as can hardly be refused, and the rules deduced from them are found to tally precisely with the phenomena. Such is this, "that the velocities of issuing water in similar circumstances are in the sub-duplicate ratio of the pressures." And this rule gives a most important and extensive information to the engineer. Other suppositions are more gratuitous, and the rules deduced from them are less coincident with the phenomena. The patient and sagacious Newton has repeatedly failed in his attempts to determine what is the *absolute velocity* of water issuing from a hole in the bottom of the vessel when urged by its weight alone, and the attempts of the others have hardly succeeded better. Experiment is therefore absolutely necessary on this head.

Those who have aimed at the discovery of *rules* purely experimental on this subject, have also been pretty successful; and the Chevalier Buat has, from a compari-

son.

son of an immense variety of experiments made by himself and various authors deduced an empirical rule, which will not be found to deviate from truth above one part in ten in any case which has yet come to our knowledge.

This instance may serve to show the use of experiments in mechanical philosophy. It is proper in all cases by way of illustration; and it is absolutely necessary in most, either as the foundation of a characteristic of a particular class of phenomena, or as argument in support of a particular doctrine. Hydrostatics, hydraulics, pneumatics, magnetism, electricity, and optics, can hardly be studied in any other way; and they are at present in an imperfect state, and receiving continual improvement by the labours of experimental philosophers in all quarters of the world.

108 The advantages derived from the study of philosophy

Having in the preceding paragraphs given a pretty full enumeration of the different subjects which are to be considered in the study of natural philosophy, it will not be necessary to spend much time in a detail of the advantages which may reasonably be expected from a successful prosecution of this study. It stands in no need of panegyric: its intimate connection with the arts gives it a sufficient recommendation to the attention of every person. It is the foundation of many arts, and it gives liberal assistance to all. Indebted to them for its origin and birth, it has ever retained its filial attachment, and repaid all their favours with the most partial affection.

109 in navigation,

To this science the navigator must have recourse for that astronomical knowledge which enables him to find his place in the trackless ocean; and although very small scraps of this knowledge are sufficient for the mere pilot, it is necessary that the study be prosecuted to the utmost by some persons, that the unlearned pilot may get that scanty pittance which must direct his routine. The few pages of tables of the sun's declination, which he uses every day to find his latitude, required the successive and united labours of all the astronomers of Europe to make them tolerably exact: and in order to ascertain his longitude with precision, it required all the genius of a Newton to detect the lunar irregularities, and bring them within the power of the calculator; and, till this was done, the respective position of the different parts of the earth could not be ascertained. Vain would have been the attempt to do this by geodætical surveys independent of astronomical observation. It is only from the most refined mechanics that we can hope for sure principles to direct us in the construction and management of a ship, the boast of human art, and the great means of union and communication between the different quarters of the globe.

110 in architecture,

A knowledge of mechanics not much inferior to this is necessary for enabling the architect to execute some of his greatest works, such as the erection of domes and arches, which depend on the nicest adjustment of equilibrium. Without this he cannot unite economy with strength; and his works must either be clumsy masses or flimsy shells.

111 in gunnery and other engines, &c.

The effects of artillery cannot be understood or secured without the same knowledge.

The whole employment of the engineer, civil or military, is a continual application of almost every branch of mechanical knowledge; and while the promises of a Smeaton, a Watt, a Belidor, may be confided in as if already performed, the numberless failures and disappointments in the most important and costly projects show us daily the ignorance of the pretending crowd of engineers.

The microscope, the steam engine, the thunder-rod, are presents which the world has received from the natural philosopher; and although the compass and telescope were the productions of chance, they would have been of little service had they not been studied and improved by Gilbert, Halley, and Dollond.

But it is not in the arts alone that the influence of natural philosophy is perceived: it lends its aid to every science, and in every study.

112 in law,

It is often necessary to have recourse to the philosopher in disputes concerning property; and many examples might be given where great injustice has been the consequence of the ignorance of the judges. Knowledge of nature might have prevented many disgraceful condemnations for sorcery.

113 in history,

The historian who is ignorant of natural philosophy easily admits the miraculous into his narrations, accompanies these with his reflections, draws consequences from them, and fills his pages with prodigies, fables, and absurdity.

114 in medicine,

It is almost needless to speak of the advantages which will accrue to the physician from this study. So close is the connection between it and medicine, that our language has given but one name to the naturalist and to the medical philosopher. Indeed, the whole of his study is a close observation of the laws of material nature, in order to draw from them precepts to direct his practice in the noble art of healing. During the immaturity of general knowledge, while natural philosophy was the only study which had acquired any just pretension to certitude either in its principles or method of investigation, the physicians endeavoured to bring the objects of their study within its province, hoping by this means to get a more distinct view of it; and they endeavoured to explain the abstruse phenomena of the animal functions by reducing them all to motions, vibrations, collisions, impulses, hydrostatic and hydraulic pressures and actions, with which the mechanical philosophers were so ardently occupied at that time. But unfortunately their acquaintance with nature was then very limited, and they were but little habituated to the rules of just reasoning; and their attempts to explain the economy of animal life by the laws of mechanics did them but little service either for the knowledge of diseases or of the methods of cure. The mechanical theories of medicine, which had considerable reputation about the end of the 17th century, were many of them very ingenious, and had an imposing appearance of symmetry and connection; but are now forgotten, having all been formed on the narrow supposition that matter was subject only to mechanical laws.

But the discovery of error diminishes the chance of again going wrong, especially when the cause of error has been discovered, and the means pointed out of detecting the mistakes; and the vital principle must combine its influence with, or operate on, the properties of rude matter. It appears therefore evident that a knowledge of the mechanical laws of the material world is not only a convenient, but a necessary, accomplishment

to

to the physician. We are fully justified in this opinion, by observing medical authors of the present day introducing into medicine theories borrowed from mechanical philosophy, which they do not understand, and which they continually misapply. Appearance of reasoning frequently conceals the errors in principle, and seldom fails to mislead.

115
in religion,

But there is no class of men to whom this science is of more service than to those who hold the honourable office of the teachers of religion. Their knowledge in their own science, and their public utility, are prodigiously hurt by ignorance of the general frame and constitution of nature; and it is much to be lamented that this science is so generally neglected by them, or considered only as an elegant accomplishment: nay, it is too frequently shunned as a dangerous attainment, as likely to unhinge their own faith, and taint the minds of their hearers. We hope, however, that few are either so feebly rooted in the belief of the great doctrines of religion as to fear this, or of minds so base and corrupted as to adopt and inculcate a belief which they have any suspicion of being ill-founded. But many have a sort of horror at all attempts to account for the events of nature by the intervention of general causes, and think this procedure derogatory to the Divine nature, and inconsistent with the doctrine of his particular providence; believing, that "a sparrow does not fall to the ground without the knowledge of our heavenly Father." Their limited conceptions cannot perceive, that, in forming the general law, the Great Artist did at one glance see it in its remotest and most minute consequence, and adjust the vast assemblage so as completely to answer every purpose of His providence. There never was a more eager enquirer into the laws of nature, or more ardent admirer of its glorious Author, than the Hon. Robert Boyle. This gentleman says, that he will always think more highly of the skill and power of that artist who should construct a machine, which, being once set a going, would of itself continue its motion for ages, and from its inherent principles continue to answer all the purposes for which it was first contrived, than of him whose machine required the continual aid of the hand which first constructed it. It is owing to great inattention that this aversion to the operation of secondary causes has any influence on our mind. What do we mean by the introduction of secondary causes? How do we infer the agency of any cause whatever? Would we ever have supposed any cause of the operations of nature, had they gone on without any order or regularity? Or would such a chaos of events, any more than a chaos of existences, have given us any notion of a forming and directing hand? No surely. We see the hand of God in the regular and unvaried course of nature, only because it is regular and unvaried. The philosopher expresses this by saying, that the phenomena proceed by unalterable laws. Greatly mistaken therefore are they who think that we supersede the existence of mind and of providence when we trace things to their causes. A physical law being an unvaried fact, is an indication, and the strongest possible indication, of an unerring mind, who is incapable of change, and must do to day what He always did: for to change is to deviate from what is best *. The operations of unerring mind will therefore be regular and invariable. Physical laws, therefore, or secondary causes, are the best proofs of unerring wisdom. Such regularity of conduct is universally considered as an indication of wisdom among men. The wise man is known by the constancy of his conduct, while no man can depend on the future conduct of a fool.

And what astonishing evidences of wisdom do we not observe in the general laws of the material world? They will ever be considered by the intelligent philosopher as the most glorious display of inconceivable wisdom, which has been able, by means so few and so simple, to produce effects which by their grandeur astonish our feeble understandings, and by their inexhaustible variety elude all possibility of enumeration.

While the teachers of religion remain ignorant of the beautiful laws of nature, the great characteristics of the wisdom and goodness of the Almighty Creator, their hearers are deprived of much sublime pleasure; God is robbed of that praise which he would have received from an enlightened people; and the only worship he receives is tainted with mean notions of his attributes, and groundless fears of his power.

But besides these advantages which accrue to different classes of men from this study, there are some effects which are general, and are too important to be passed over unnoticed. 116

and in other sciences.

That spirit of dispassionate experimental enquiry which has so greatly promoted this study, will carry with it, into every subject of enquiry, that precision and that constant appeal to fact and experience which characterize it. And we may venture to assert, that the superior good order and method which distinguish some of the later productions in other sciences, have been in a great measure owing to this mathematical spirit, the success of which in natural philosophy has gained it credit, and thus given it an unperceived influence even over those who have not made it their study. 117

More general advantages of philosophy.

The truths also which the naturalist discovers are such as do not in general affect the passions of men, and have therefore a good chance of meeting with a candid reception. Those whose interest it is to keep men in political or religious ignorance, cannot easily suspect bad consequences from improvements in this science; and if they did, have hardly any pretext for checking its progress. And discoveries accustom the mind to novelty; and it will no longer be startled by any consequences, however contrary to common opinion. Thus the way is paved for a rational and discreet scepticism, and a free enquiry on other subjects. Experiment, not authority, will be considered as the test of truth; and under the guidance of fair experience we need fear no ill as long as the laws of nature remain as they are.

Lastly, since it is the business of philosophy to describe the phenomena of nature, to discover their causes, to trace the connection and subordination of these causes, and thus obtain a view of the whole constitution of nature; it is plain that it affords the surest path for arriving at the knowledge of the great cause of all, of God himself, and for forming proper conceptions of him and of our relations to him: notions infinitely more just than can ever be entertained by the careless spectator of his works. Things which to this man appear solitary and detached, having no other connection

* *Ferguson's Lectures on Ethics.*

tion with the rest of the universe but the shadowy and fleeting relation of co-existence, will, to the diligent philosopher, declare themselves to be parts of a great and harmonious whole, connected by the general laws of nature, and tending to one grand and beneficent purpose. Such a contemplation is in the highest degree pleasant and cheering, and cannot fail of impressing us with the wish to co-operate in this glorious plan, by acting worthy of the place we hold among the works of God, and with the hopes of one day enjoying all the satisfaction that can arise from conscious worth and consummate knowledge; and this is the worship which God will approve. "This universe (says Boyle) is the magnificent temple of its great Author; and man is ordained, by his powers and qualifications, the high priest of nature, to celebrate divine service in this temple of the universe."

PHYSIOGNOMONICS, among physicians, denote such signs as, being taken from the countenance, serve to indicate the state, disposition, &c. both of the body and mind: and hence the art of reducing these signs to practice is termed *physiognomy*.

PHYSIOGNOMY

1 Various definitions of physiognomy ancient and modern.

IS a word formed from the Greek φυσις, *nature*, and γινωσκω, *I know*. It is the name of a science which occupied much of the attention of ancient philosophers, and which, since the revival of learning, has in a great degree been disregarded. Till of late it has seldom in modern times been mentioned, except in conjunction with the exploded arts of magic, alchemy, and judicial astrology. Within the last two centuries, no doubt, the bounds of human knowledge have been greatly extended by means of the patient pursuit of fact and experiment, instead of the hasty adoption of conjecture and hypothesis. We have certainly discovered many of the ancient systems to be merely creatures of imagination. Perhaps, however, in some instances, we have decided too rapidly, and rejected real knowledge, which we would have found it tedious and troublesome to acquire. Such has been the fate of the science of physiognomy; which certainly merits to be considered in a light very different from alchemy and those other fanciful studies with which it had accidentally been coupled. The work lately published by M. Lavater on the subject has indeed excited attention, and may perhaps tend to replace physiognomy in that rank in the circle of the sciences to which it seems to be intitled.

It does not appear that the ancients extended the compass of physiognomy beyond *man*, or at least animated nature: But the study of that art was revived in the middle ages, when, misled probably by the comprehensiveness of the etymological meaning of the word, or incited by the prevalent taste for the marvellous, those who treated of the subject stretched the range of their speculation far beyond the ancient limits. The extension of the signification of the term was adopted universally by those naturalists who admitted the theory of signatures (see SIGNATURE); and physiognomy came thus to mean, the knowledge of the *internal* properties of *any* corporeal existence from the *external* appearances. Joannes Baptista Porta, for instance, who was a physiognomist and philosopher of considerable eminence, wrote a treatise on the physiognomy of *plants (philognomonica)*, in which he employs physiognomy as the generic term. There is a treatise likewise *De Physiognomia Avium*, written, we believe, by the same person. In the *Magia Physiognomica* of Gaspar Schottus, *physiognomia humana* is made a *subdivision* of the science.

Boyle too adopts the extensive signification mentioned, which indeed seems to have been at one time the usual acceptation of the word (A). At present physiognomy seems to mean no more than "a knowledge of the moral character and extent of intellectual powers of human beings, from their external appearance and manners." In the Berlin Transactions for the years 1769 and 1770 there appears a long controversial discussion on the subject of the *definition* of physiognomy between M. Pernetty and M. Le Cat, two modern authors of some note. Pernetty contends that *all knowledge whatever* is physiognomy; Le Cat confines the subject to the *human face*. Neither seems to have hit the medium of truth. Soon after the celebrated book of Lavater appeared. He indeed defines physiognomy to be "the art of discovering the *interior* of *man* by means of his *exterior*; but in different passages of his work he evidently favours the extended signification of Pernetty. This work gave occasion to M. Formey's attack upon the science itself in the same Berlin Transactions for 1775. Formey strenuously controverts the extent assigned by Lavater to his favourite science.

2 Pythagoras probably brought this science to Greece.

Before the era of Pythagoras the Greeks had little or no science, and of course could not be scientifical physiognomists. Physiognomy, however, was much cultivated in Egypt and India; and from these countries the sage

---

(A) They'll find i' the physiognomies
O' th' planets all men's destinies. HUDIBRAS.

sage of Samos probably introduced the rudiments of this science, as he did those of many others, generally deemed more important into Greece.

3 It was a profession in the time of Socrates.

In the time of Socrates it appears even to have been adopted as a profession. Of this the well-known anecdote of the decision of Zopyrus, on the real character of Socrates himself, judging from his countenance, is sufficient evidence. Plato mentions the subject; and by Aristotle it is formally treated of in a book allotted to the purpose.

It may be worth while to give a brief outline of Aristotles sentiments on the subject.

4 General outline of Aristotle's opinion on this subject.

Physiognomy, he in substance observes, had been treated of in three ways. Some philosophers classed animals into genera, and ascribed to each genus a certain mental disposition corresponding to their corporeal appearance. Others made a farther distinction of dividing the genera into species. Among men, for instance, they distinguished the Thracians, the Scythians, the Egyptians, and whatever nations were strikingly different in manners and habits, to whom accordingly they assigned the distinctive physiognomical characteristics. A third set of physiognomists judged of the actions and manners of *the individual*, and presumed that certain manners proceeded from certain dispositions. But the method of treating the subject adopted by Aristotle himself was this: A peculiar form of body is invariably accompanied by a peculiar disposition of mind; a human intellect is never found in the corporeal form of a beast. The mind and body reciprocally affect each other; thus in intoxication and mania the mind exhibits the affections of the body; and in fear, joy, &c. the body displays the affections of the mind.

From such facts he argues, that when in man a particular bodily character appears, which by prior experience and observation has been found uniformly accompanied by a certain mental disposition, with which therefore it must have been necessarily connected; we are intitled in all such cases to infer the disposition from the appearance. Our observations, he conceives, may be drawn from other animals as well as from men: for as a lion possesses one bodily form and mental character, a hare another, the corporeal characteristics of the lion, such as strong hair, deep voice, large extremities, discernible in a human creature, denote the strength and courage of that noble animal; while the slender extremities, soft down, and other features of the hare, visible in a man, betray the mental character of that pusillanimous creature.

Upon this principle Aristotle treats of the corporeal features of man, and the correspondent dispositions, so far as observed: he illustrates them by the analogy just mentioned, and in some instances attempts to account for them by physiological reasoning.

At the early period in which Aristotle wrote, his theory, plausible certainly, and even probable, displays his usual penetration, and a considerable degree of knowledge. He distinctly notices individual physiognomy, national physiognomy, and comparative physiognomy. The state of knowledge in his time did not admit of a complete elucidation of his general principles; on that account his enumeration of particular observations and precepts is by no means so well founded or so accurate as his method of study. Even his style, concise and energetic, was inimical to the subject; which, to be made clearly comprehensible, must require frequent paraphrases. Aristotle's performance, however, such as it is, has been taken as the groundwork and model of every physiognomical treatise that has since appeared.

The imitators of this great man in the 16th and 17th centuries, have even copied his language and manner, which are sententious, indiscriminate, and obscure. His comparative physiognomy of men with beasts has been frequently though not universally adopted. Besides his treatise expressly on the subject, many incidental observations on physiognomy will be found interspersed through his other works, particularly in his history of animals.

5 Theophrastus's ethic characters form an important branch of physiognomy.

Next after Aristotle, his disciple and successor Theophrastus would deserve to be particularly mentioned as a writer on the subject in question. His ethic characters, a singular and entertaining performance, composed at the age of 99, form a distinct treatise on a most important branch of physiognomy, *the physiognomy of manners*; but the translations and imitations of La Bruyere are so excellent, that by referring to them we do greater justice than would otherwise be in our power, both to Theophrastus and to our readers. We cannot, however, omit observing, that the accuracy of observation and liveliness of description displayed in the work of Theophrastus will preserve it high in classical rank, while the science of man and the prominent characteristics of human society continue to be objects of attention.

6 Other Greek authors on this subject.

Polemon of Athens, Adamantius the sophist, and several others, wrote on the subject about the same period. Lately there was published a collection of all the Greek authors on physiognomy: the book is entitled, *Physiognomiæ veteris scriptores Græci, Gr. et Lat. à Franzio Altenb.* 1780, 8vo. From the number of these authors, it appears that the science was much cultivated in Greece; but the professors seem soon to have connected with it something of the marvellous. This we have cause to suspect from the story told by Apion of Apelles: *Imaginem adeo similitudinis indiscretæ pinxit, ut (incredibile dictu) Apion Grammaticus Scriptum reliquerit quemdam ex facie hominum ad divinantem (quos melaposcopos vocant) ex iis dixisse aut futuræ mortis annos, aut præteritæ* *. The noviciates of the Pythagorean school were subjected to the physiognomic observation of their teachers, and it is probable the first physiognomists by profession among the Greeks were of this sect. They, too, to whom, from the nature of their doctrines and discipline, mystery was familiar, were the first, it is likely, who exposed the science of physiognomy in Greece to disgrace, by blending with it the art of divination.

7 The science was then coupled with something of the marvellous.

* Pliny Nat. Hist. lib. 35. § 35. par. 39.

8 The observations of Roman and other writers.

From the period of which we have been treating to the close of the Roman republic, nothing worthy of remark occurs in the literary history of physiognomy. About the last-mentioned era, however, and from thence to the decline of the empire under the later emperors, the science appears to have been cultivated as an important branch of erudition, and assumed as a profession by persons who had acquired a superior knowledge in it.

In the works of Hippocrates and Galen, many physiognomical observations occur. Cicero appears to have been peculiarly attached to the science. In his oration

tion against Piso, and in that in favour of Roscius, the reader will at the same time perceive in what manner the orator employs physiognomy to his purposes, and find a curious instance of the *ancient* manner of oratorical *abuse*.

Many physiognomical remarks are to be found likewise in the writings of Sallust, Suetonius, Seneca, Pliny, Aulus Gellius, Petronius, Plutarch, and others.

That in the Roman empire the science was practised as a profession, ample evidence appears in the writings of several of the authors just mentioned. Suetonius, for instance, in his *Life of Titus*, mentions that Narcissus employed a *physiognomist* to examine the features of Britannicus, who predicted that Britannicus would not succeed, but that the empire would devolve on Titus.

9 This science fell with the Roman empire.

The science of physiognomy shared the same fate with all others, when the Roman empire was overthrown by the northern barbarians. About the beginning of the 16th century it began again to be noticed.—From that time till the close of the 17th, it was one of the most fashionable studies. Within that space have appeared almost all the approved modern authors on the subject (B).

It has been unfortunate for physiognomy, that by many of these writers it was held to be connected with doctrines of which the philosophy of the present day would be ashamed. With these doctrines it had almost sunk into oblivion.

10 Particular studies have peculiarly prevailed at particular times.

In every period of the history of literature there may easily be marked a prevalence of particular studies. In the early period, for instance, of Grecian literature, *mythological morality* claimed the chief attention of the philosophers. In the more advanced state of learning in Greece and in Rome, *poetry*, *history*, and *oratory*, held the pre-eminence. Under the latter emperors, and for some time afterwards, the history of *theological controversies* occupied the greatest part of works of the learned. Next succeeded *metaphysics*, and *metaphysical theology*. These gave place to *alchemy*, *magic*, *judicial astrology*, the doctrine of signatures and sympathies, the *mystic*, *theosophic*, *and Rosicrucian theology*, with physiognomy. Such were the pursuits contemporary with the science which is the object of our present inquiry. It is no matter of surprise, that, so associated, it should have fallen into contempt. It is not unusual for mankind hastily to reject valuable opinions, when accidentally or artificially connected with others which are absurd and untenable. Of the truth of this remark, the history of theology, and the present tone of theological opinions in Europe, furnish a pregnant example.

To physiognomy, and the exploded sciences last mentioned, succeeded *classic philology*; which gave place to *modern poetry* and *natural philosophy*; to which recently have been added the studies of *rational theology*, *chemistry*, the *philosophy of history*, the *history of man*, and the *science of politics*.

11 The observations of the writers of the present century on this subject.

About the commencement of the 18th century, and thenceforward, the occult sciences, as they are termed, had declined very considerably in the estimation of the learned; and those who treated of physiognomy forbore to disgrace it by a connection with those branches of ideal learning with which formerly it had been invariably conjoined. In Britain, Dr Gwither noticed it with approbation.—His remarks are published in the Philosophical Transactions, vol. xviii.; and Dr Parsons chose it for the subject of the Croonean lectures, published at first in the second supplement to the 44th volume of the Philosophical Transactions, and afterwards (1747) in a separate treatise, entitled *Human Physiognomy explained*.

The observations, however, of these writers, as well as of Lancisius, Haller, and Buffon, relate rather to the transient expression of the passions than to the permanent features of the face and body. The well-known characters of Le Brun likewise are illustrative of the transient physiognomy, or (as it is termed) pathognomy.—See *Passions in Painting*.

12 We find nothing very important till the controversy between Pernetty and Le Cat.

During the present century, although physiognomy has been now and then attended to, nothing of importance appeared on the subject till the discussion already mentioned between Pernetty and Le Cat, in the Berlin Transactions. The sentiments of these authors, in so far as relates to the *definition* of physiognomy, have been above noticed. Their essays are, besides, employed in discussing the following questions: 1st, Whether it would or would not be advantageous to society, were the character, disposition, and abilities, of each individual so marked in his appearance as to be discovered with certainty?

2dly, Whether, on the supposition that by the highest possible proficiency in physiognomy, we could attain a knowledge in part only of the internal character, it would be advantageous to society to cultivate the study, mankind being in general imperfect physiognomists?

No reasoning *à priori* can possibly determine these questions. Time and experience alone must ascertain the degree of influence which any particular acquisition of knowledge would have on the manners and characters of mankind; but it is difficult to conceive how the *result* of any portion of knowledge, formerly unknown, and which mankind would be *permitted* to discover, could be any thing but beneficial.

13 Lavater's celebrated Work.

Soon after this controversy in the Berlin Transactions, appeared the great work of M. Lavater, dean of Zurich, which has excited no inconsiderable portion of attention in the literary world. The work itself is magnificent: That circumstance, as well as the nature of the subject, which was supposed to be fanciful, have contributed to extend

(B) They are, Bartholem. Cocles, Baptista Porta, Honoratus Nuquetius, Jacobus de Indagine, Alstedius, Michael Schottus, Gaspar Schottus, Cardan, Taisnierus, Fludd, Behmen, Barclay, Claromontius, Conringius, the commentaries of Augustin Niphus, and Camillus Balbus, on the Physiognomica of Aristotle,—Spontanus, Andreas Henricus, Joannes Digander, Rud. Goclenius, Alex. Achillinus, Joh. Prætorius, Jo. Belot, Guliel. Gratalorus, &c. They are noticed in the Polyhistor of Morhoff, vol. i. lib. i. cap. 15. § 4. and vol. ii. lib. iii. cap. i. § 4.

extend its fame; and certainly, if we may judge, the book, though many faults may be detected in it, is the most important of any that has appeared on the subject since the days of Aristotle. Lavater professes not to give a complete synthetical treatise on physiognomy, but, aware that the science is yet in its infancy, he exhibits fragments only, illustrative of its different parts. His performance is no doubt desultory and unconnected. It contains, however, many particulars much superior to any thing that had ever before appeared on the subject.

With the scholastic and systematic method adopted by the physiognomists of the last and preceding centuries, Lavater has rejected their manner of writing, which was dry, concise, indeterminate, and general: His remarks, on the contrary, are, for the most part, precise and particular, frequently founded on distinctions extremely acute. He has omitted entirely (as was to be expected from a writer of the present day) the astrological reveries, and such like, which deform the writings of former physiognomists; and he has with much propriety deduced his physiognomical observations but seldom from anatomical or physiological reasoning. Such reasoning may perhaps at some future period become important; but at present our knowledge of facts, although extensive, is not so universal, as to become the stable foundation of particular deductions. Lavater has illustrated his remarks by engravings; a method first adopted by Baptista Porta.—Lavater's engravings are very numerous, often expressive, and tolerably executed.

14 His opinions the result of observation.

The opinions of this celebrated physiognomist are evidently the result of actual observation. He appears indeed to have made the science his peculiar study, and the grand pursuit of his life. His performance exhibits an extended comprehension of the subject, by a particular attention to *osseal* physiognomy, and the effect of *profiles* and *contours*. His style in general is forcible and lively, although somewhat declamatory and digressive. His expressions are frequently precise, and strikingly characteristic; and the spirit of piety and benevolence which pervades the whole performance renders it highly interesting.

15 His imagination has, however, often outstript his judgement.

The defects of the work, however, detract much from the weight which Lavater's opinions might otherwise challenge. His imagination has frequently so far outstript his judgment, that an ordinary reader would often be apt to reject the whole system as the extravagant reverie of an ingenious theorist. He has clothed his favourite science in that affected mysterious air of importance, which was so usual with his predecessors, and describes the whole material world to be objects of the universal dominion of physiognomy *. He whimsically conceives it necessary for a physiognomist to be a well-shaped handsome man †. He employs a language which is often much too peremptory and decisive, disproportioned to the real substance of his remarks, or to the occasion of making them. The remarks themselves are frequently opposite in appearance to common observation, and yet unsupported by any illustrations of his.

* Vol. i. p. 33—38. vol. ii. p. 89. French translation.

† Vol i p. 126.

16 Other weaknesses of this great physiognomist.

Lavater certainly errs in placing too great a reliance on single features, as the foundation of decision on character. His opinions on the physiognomy of the ears, hands, nails, and feet of the human species, on hand-writing, on the physiognomy of birds, insects, reptiles, and fishes, are obviously premature, as hitherto no sufficient number of accurate observations has been made, in regard to either of these particulars, to authorise any conclusion. He has erred in the opposite extreme, when treating of the important topic of national physiognomy, where he has by no means prosecuted the subject so far as facts might have warranted. We must farther take the liberty to object to the frequent introduction of the author's own physiognomy throughout the course of his work. His singular remarks on his own face do not serve to prejudice the reader in favour of his judgment, however much his character may justify the truth of them. We must regret likewise, for the credit of the science, that the author's singularly fanciful theory of apparitions should so nearly resemble a revival of the antiquated opinions of the sympathists.

To these blemishes, which we have reluctantly enumerated, perhaps may be added that high impassioned tone of enthusiasm in favour of his science everywhere displayed throughout the work of this author, which is certainly very opposite to the cool patient investigation befitting philosophy. To that enthusiasm, however, it is probable that in this instance (as is, indeed, no unfrequent effect of enthusiasm) we are indebted for the excellency which the author has attained in his pursuit; and it possesses the salutary tendency of putting us on our guard against a too implicit acquiescense in his physiognomical decisions.

In the Berlin Transactions for 1775, there appears a formal attack upon Lavater's work by M. Formey. This essay we have already mentioned. After disputing the propriety of the extensive signification applied by Lavater and Pernetty to the term physiognomy, M. Formey adopts nearly the same definition which we conceive to be the most proper, and which we have put down as such near the beginning of this article. He allows that the mental character is intimately connected with, and sensibly influenced by, every fibre of the body; but his principal argument against physiognomy is, that the human frame is liable to innumerable accidents, by which it may be changed in its external appearance, without any correspondent change of the disposition; so that it surpasses the extent of the skill of mortals to distinguish the modifications of feature that are natural, from those which may be accidental. Although, therefore, the science of physiognomy may be founded in truth, he infers that the Deity only can exercise it. 17 His work was attacked in the Berlin Transactions by M. Formey.

M. Formey further contends, that education, diet, climate, and sudden emotions, nay even the temperaments of ancestors, affect the cast of human features; so that the influence of mental character on these features may be so involved with, or hidden by, accidental circumstances, that the study of physiognomy must ever be attended by hopeless uncertainty. These objections are worthy of notice, but they are by no means conclusive.

We shall give a specimen of M. Lavater's manner of treating the subject on the opposite side of the question: A specimen, not in Lavater's precise words, but conveying more shortly an idea at once of his sentiments, and of his manner of expressing them. 18 Lavater's mode of treating his subject.

No study, says he, excepting mathematics, more justly deserves to be termed *a science* than physiognomy. It is a department of physics, including theology and belles lettres, and in the same manner with these sciences may 19 Physiognomy is justly called a science.

may be reduced to rule. It may acquire a fixed and appropriate character: It may be communicated and taught.

Truth or knowledge, explained by fixed principles, becomes science. Words, lines, rules, definitions, are the medium of communication. The question, then, with respect to physiognomy, will thus be fairly stated. Can the striking and marked differences which are visible between one human face, one human form, and another, be explained, not by obscure and confused conceptions, but by certain characters, signs, and expressions? Are these signs capable of communicating the vigour or imbecility, the sickness or health, of the body; the wisdom, the folly, the magnanimity, the meanness, the virtue, or the vice, of the mind?

20 Experiment is limited in extent.

It is only to a certain extent that even the experimental philosopher can pursue his researches. The active and vigorous mind, employed in such studies, will often form conceptions which he shall be incapable of expressing in words, so as to communicate his ideas to the feebler mind, which was itself unable to make the discovery: But the lofty, the exalted mind, which soars beyond all written rule, which possesses feelings and energies reducible to no law, must be pronounced unscientific.

21 Physiognomical truth may be defined and communicated to a certain length.

It will be admitted, then, that to a certain degree physiognomical truth may as a science be defined and communicated. Of the truth of the science, there cannot exist a doubt. Every countenance, every form, every created existence, is individually distinct, as well as different, in respect of class, race, and kind. No one being in nature is precisely similar to another. This proposition, in so far as regards man, is the foundation-stone of physiognomy. There may exist an intimate analogy, a striking similarity, between two men, who yet being brought together, and accurately compared, will appear to be remarkably different. No two minds perfectly resemble each other. Now, is it possible to doubt that there must be a certain native analogy between the external varieties of countenance and form and the internal varieties of the mind? By anger the muscles are rendered protuberant: Are not, then, the angry mind, and the protuberant muscles, as cause and effect? The man of acute wit has frequently a quick and lively eye. Is it possible to resist the conclusion, that between such a mind and such a countenance there is a determinate relation?

Every thing in nature is estimated by its physiognomy; that is, its external appearance. The trader judges by the colour, the fineness, the exterior, the *physiognomy* of every article of traffic; and he at once decides that the buyer "has an honest look," or "a pleasing or forbidding countenance.

22 This knowledge, however improved would not be detrimental to man.

That knowledge and science are detrimental to man, that a state of rudeness and ignorance are preferable and productive of more happiness, are tenets now deservedly exploded. They do not merit serious opposition. The extension and increase of knowledge, then, is an object of importance to man: And what object can be so important as the knowledge of man himself? If knowledge can influence his happiness, the knowledge of himself must influence it the most. This useful knowledge is the peculiar province of the science of physiognomy. To conceive a just idea of the advantages of physiognomy, let us for a moment suppose that all physiognomical knowledge were totally forgotten among men; what confusion, what uncertainty, what numberless mistakes, would be the consequence? Men destined to live in society must hold mutual intercourse. The knowledge of man imparts to this intercourse its spirit, its pleasures, its advantages.

23 It affords great mental gratification.

Physiognomy is a source of pure and exalted mental gratification. It affords a new view of the perfection of Deity; it displays a new scene of harmony and beauty in his works; it reveals internal motives, which without it would only have been discovered in the world to come. The physiognomist distinguishes accurately the permanent from the habitual, the habitual from the accidental, in character. Difficulties, no doubt, attend the study of this science.

24 Difficulties in the study.

The most minute shades, scarcely discernible to the unexperienced eye, denote often total opposition of character. A small inflexion, diminution, lengthening or sharpening, even though but of a hair's-breadth, may alter in an astonishing degree the expression of countenance and character. How difficult then, how impossible indeed, must this variety of the same countenance render precision? The seat of character is often so hidden, so masked, that it can only be detected in certain, perhaps uncommon, positions of countenance. These positions may be so quickly changed, the signs may so instantaneously disappear, and their impression on the mind of the observer may be so slight, or these distinguishing traits themselves so difficult to seize, that it shall be impossible to paint them or describe them in language. Innumerable great and small accidents, whether physical or moral, various incidents and passions, the diversity of dress, of position, of light or shade, tend to display the countenance often in so disadvantageous a point of view, that the physiognomist is betrayed into an erroneous judgment of the true qualities of the countenance and character. Such causes often occasion him to overlook the essential traits of character, and to form a decision on what is purely accidental.—How surprisingly, for instance, may the smallpox disfigure the countenance, and destroy or confound, or render imperceptible, traits otherwise the most decisive?

25 May one day be obviated.

We shall, then, continues Lavater, grant to the opposer of phiosognomy all he can ask; and yet we do not live without hopes that many of the difficulties shall be resolved which at first appeared inexplicable.

26 The nature of Lavater's work.

He then proceeds to a specific illustration of his subject under a great variety of titles, in which he treats of human nature in general, and of each particular feature separately.

To enumerate the different divisions of his book would not be more satisfactory to our readers than the perusal of the *contents* of the book itself; and an attempt to epitomize even the essential substance of the vast multiplicity of matter contained in his essays, (which are yet only *fragments*, and to which indeed he himself does not pretend to give any higher appellation), would extend this article to a disproportionate length. Such an abridgement, after all, would convey no solid information on a subject which merits all the time and study that an attentive perusal of Lavater's works at large would require.

27 Probable causes of the disrepute into which this science has fallen.

From the historical deduction of the literary progress of physiognomy which we have thus attempted to lay before our readers, it appears, that although the science has fallen into disrepute, there can scarcely be mentioned a period in which any cultivation of science took place when physiognomy was not likewise the study, nay sometimes even the profession, of men of the most eminent abilities and the greatest learning.

The reasons why at present so little attention is paid to the subject probably are,

1st, That it has been treated in conjunction with subjects now with propriety exploded: And,

2dly, That it has been injured by the injudicious assertions and arguments of those who have undertaken its defence.

Sometimes, however, the wise and the learned may err. The use of any thing must not be rejected for no better reason than that it is capable of abuse. Perhaps the era is not distant when physiognomy shall be reinstated in the rank which she merits among the valuable branches of human knowledge, and be studied with that degree of attention and perseverance which a subject deserves so essentially connected with the science of man.

28
There is a relation between the dispositions of the mind and the features of the face.

That there is an intimate relation between the dispositions of the mind and the features of the countenance is a fact which cannot be questioned. He who is sinking under a load of grief for the death of an affectionate wife or a dutiful child, has a very different cast of features from the man who is happy in the prospect of meeting his mistress. A person boiling with anger has a threatening air in his countenance, which the most heedless observer never mistakes; and if any particular disposition be indulged till it become habitual, there cannot be a doubt but that the corresponding traces will be so fixed in the face as to be discernible by the skilful physiognomist, under every effort made to disguise them. But when we attempt to decide on a man's intellectual powers by the rules of this science, we are often deceived; and in this respect we have reason to believe that Lavater himself has fallen into the grossest mistakes.

29
Craniognomic system of Dr Gall.

Connected with physiognomy, we may consider the *craniognomic* system of Dr Gall of Vienna, which is so called, because, from the exterior form of the cranium, he infers the powers and dispositions of the mind. The brain, he observes, is the material organ of the action of the mind; and as it increases in direct proportion to the faculties of animals, he has endeavoured to prove, that the faculties are distinct and independent on each other; that each has its proper material organ, and that the expansion of the organ is in proportion to the strength of the faculty. This system is attempted to be established by the following reasoning.

"The internal faculties, (says Dr Bojanus, the author of a view of this system), do not always exist in the same proportion to each other. There are some men who have a great deal of genius without having a memory, who have courage without circumspection, and who possess a metaphysical spirit without being good observers.

"Besides, the phenomena of dreaming, of somnambulism, of delirium, &c. prove to us that the internal faculties do not always act together; that there is often a very great activity of one, while the rest are not sensible.

"Thus, in old age, and sometimes in disease, such, for example as madness, several faculties are lost, while others subsist; besides a continued employment of the same faculty sensibly diminishes its energy: If we employ another, we find it has all the force of which it is susceptible; and if we return to the former faculty, it is observed that it has resumed its usual vigour. It is thus that, when fatigued with reading an abstract philosophical work, we proceed with pleasure to a poetical one, and then resume with the same attention our former occupation."

"All these phenomena prove that the faculties are distinct and independent of each other, and we are inclined to believe that the case is the same with their material organs."

"[We do not entirely agree with this idea of Dr Gall, and we believe, on the contrary, that the separation of the material organs ought to be considered as the cause of the distinction of the internal faculties. It appears, to us at least, that by supposing the faculties themselves as originally separated, we cannot save ourselves from falling into materialism, which exists when the mind is no longer considered as unity.]

"*The expansion of the organs contained in the cranium is in the direct ratio of the force of their corresponding faculties.*"

"This principle, dictated by analogy, rests on this axiom, that throughout all nature the faculties are always found to be proportioned to their relative organs; and the truth of it is proved in a special manner by the particular observations of Dr Gall.

"It is however to be remarked, that exercise has a great influence on the force of the faculties, and that an organ moderately expanded, but often exercised, can give a faculty superior to that which accompanies a very extensive organ never put in action; as we see that a man of a weak conformation acquires, by continued exercise, strength superior to another of a more athletic structure.

"[We must here mention an opinion which seems to result immediately from this principle, and which, however, is false: It is, that the volume of the brain, in general, is in the direct ratio of the energy of its faculties. Observation has proved to Dr Gall, that we cannot judge of the strength of the faculties but by the developement of the separate organs which form distinct eminences in the cranium? and that a cranium perfectly round, of whatever size it may be, is never a proof of many or of great faculties.]

"We do not recollect to have heard the reason assigned by Dr Gall; but in our opinion, these brains may be considered as in a state analogous to obesity; and as we do not judge of the muscular force of a man or an animal by the volume of their members, but by the developement of the muscles in particular, one would think we ought, in like manner, to judge of the strength of the faculties by the developement of the relative organs.

"In the last place, the 4th principle, the most important for practice in regard to the system of Dr Gall, is:

"*We may judge of these different organs, and of their faculties by the exterior form of the cranium.*

"The truth of this principle is founded upon another, viz. that the conformation of the cranium depends on that of the brain; a truth generally acknowledged, and proved by the anterior part of the brain, by the impressions in the anterior part of the cranium, and by other facts.

[There are skulls, it is true, in which an external protuberance

protuberance of the bone corresponds to an interior one; and this irregularity, which is found sometimes as a disease, and most commonly at an advanced age, when the cerebral organs do not oppose the same resistance to the cranium, renders the practice of Dr Gall's system, in some measure, uncertain.]

"Guided by these principles, Dr Gall examines the nature of the skull, compares the crania of animals and those of men analogous and different in faculties. His researches have proved to him, in a manner almost incontestable, not only the above truths, but that the faculties of animals are analogous to those of man; that what we call instinct in animals is found also in the latter, such as attachment, cunning, circumspection, courage, &c.; that the quantity of the organs fixes the difference of the genus of animals, their reciprocal proportion that of individuals; that the disposition originally given to each faculty by nature may be called forth by exercise and favourable circumstances, and sometimes by disease, but that it never can be created in the case where it has not been given by nature (c); that the accumulation of the organs takes place in a constant manner from the hind part forwards, from the bottom to the top, in such a manner, that animals in proportion as they approach man in the quantity of their faculties have the superior and anterior part of the brain more expanded; and, in the last place, that in the most perfect animal, man, there are organs in the anterior and superior parts of the frontal bone, and of the parietals, destined for faculties which belong to them exclusively. It is under the latter point of view that the discoveries of Dr Gall agree perfectly with the theory of the facial angle, which seems still further to establish the truth of them."

Most of our readers will probably be satisfied with the short view which we have now given of this fanciful and visionary system; but such as wish for a fuller exposition of it, may consult the Philosophical Magazine, vol. xiv. p. 77. from which the above is extracted. We shall only add the names of a few of the organs, which the author of the system thinks he has discovered. *Organ of the tenacity of life. Organ of music. Organ of fighting. Organ of murder. Organ of cunning. Organ of arithmetic. Organ of thieving*, &c.

PHYSIOLOGY.

INTRODUCTION.

1 Definition and objects of physiology.

1. PHYSIOLOGY is that part of physical science which treats of the nature, properties, and functions of living bodies; comprehending under this term, animals and vegetables. The word is derived from φυσις, "nature," and λογος, "a discourse; and signified originally what we may call *natural knowledge*.

The object of this science is to examine and compare the phenomena of life; to discover the properties, powers, and operations of the bodies that are actuated by this principle, and to pursue the developement, progress, and decay of vital energy, from brute matter, which possesses no portion of vitality, to the most perfect animal, which seems to have it in the greatest perfection.

2 Divisions.

2. Physiology may be considered under three heads; *historical*, *philosophical* or *rational*, and *practical* physiology.

3 Historical physiology.

3. *Historical physiology* is occupied in giving a simple relation of the facts and phenomena that take place in living bodies; in bringing them together, and comparing those which succeed each other without interruption during the existence of vitality.

4 Philosophical physiology.

4. It is the business of *philosophical physiology* to consider the nature of these phenomena, and endeavour to deduce from them some general conclusions, by which they may be explained or elucidated; to draw from them natural consequences, and unfold successively their analogies and relations; to arrange, distribute, and classify them, and thus acquire sufficient *data* by which to discover the causes which produce them.

5 Practical physiology.

The *practical* part of physiology is intended to point out the application of the principles of the science to the useful purposes of life, especially to medicine and agriculture. Of these divisions the first is the most important, as, until we have acquired a pretty complete knowledge of the facts relating to living beings, and arranged these in a natural manner, it cannot be expected that we should make any great progress in explaining them, or investigating their causes. From the multitude, variety, and complex nature of these phenomena, a complete view of them is extremely difficult, and requires the united efforts of genius, dexterity, patience, and discernment.

6 Relations to anatomy.

Physiology is intimately related to several other departments of natural knowledge. Its relation to anatomy is the most strict and natural; and indeed the knowledge of the structure of living bodies is a necessary introduction to that of their properties and functions. So close is the union between these two sciences, that it is generally thought that the study of them should go hand in hand. Certain it is, that, without physiology, anatomy is a dry and uninteresting study; while, on the other hand, physiology, unaided by anatomy, is obscure and uncertain. It is by means of anatomy that we learn the structure and organization of the animal machine; the disposition and form of its several members; the parts that concur in the composition of them; the arrangement and the connection of these: it is by means of anatomy that we know how to estimate the advantages

(c) The germ of every organ must exist in embryo, if the expansion of that organ is to be afterwards called forth.

ges of any particular conformation; that we estimate the proportion between the solid and fluid parts of the body, and the adaptation of the organs to the various uses for which they are destined. But we must remember, that the aid of anatomy in physiological researches, extends no farther than to the mechanical arrangement and relation of the several parts of the body; it teaches us nothing of its intimate composition, and much less does it inform us respecting the vital powers and mental energies displayed by the living body. The most accurate inspection of the brain will afford us no light respecting the obscure function of sensation, and the hidden operation of thought and judgment; nor will the nicest dissection of the eye, or of the tongue shew us how the former is unable to convey to us the ideas of external objects, or how the latter imparts to us the thousand varied flavours of sapid bodies. In short, we may conclude, that the more the exercise of any function depends on the structure and organization of the organs that perform it, the more capable is it of illustration from anatomy.

7 chemistry,

The science of chemistry has proved of eminent use in explaining several functions of the animal economy, which, without its assistance, would have been very imperfectly understood. The action of the air on the blood during respiration, and the digestion of food in the stomach, are found to depend chiefly on chemical operations; while this science has explained to us, in a most satisfactory manner, the nature, composition, and reciprocal action of the component principles of organized beings, and the nature of several changes which they undergo, both in the living and the dead state. But if we extend the application of chemistry too far, and imagine, as some of our modern chemical physiologists have done, that it is capable of explaining *life, motion*, and even *sensation*, we shall only betray our own presumption and our ignorance of vital phenomena. When the performance of any function depends on the intimate composition of its organs, or the combinations and decompositions that take place among their component principles; then, and then only, is it susceptible of chemical illustration.

8 mechanical philosophy,

Mechanical philosophy is employed with advantage in explaining some of the phenomena that take place in living beings. The strength and solidity of the bony compages; the force and direction of the muscular motions; the propagation, direction, and mechanical effect of light, sound, odours; the effects of the gravity and elasticity of atmospheric air, and a few other circumstances, may be submitted to calculation, and illustrated on physical principles: but the laws of mechanical and of vital action are, in general, so different, and even the most mechanical phenomena of living beings are often so modified and counteracted by the agency of the vital powers, that, on the whole, we must consider general physics as one of the least useful auxiliaries of physiological researches.

9 metaphysics,

Of all the branches of physical science, physiology certainly makes the nearest approach to the region of metaphysics; but yet there is a difference between these, though it may not be very easy to point out the precise line of termination. Physiology, as already defined, being that science which has for its object the organical economy of living bodies, the word organical, we think, here should mark the distinction.

Whenever the economy of living bodies indicates design, and cannot result from any combination or structure of organs, it must be supposed the effect of something different from matter, and whose explanation belongs to that science which is called *metaphysics*, or which we might term the *philosophy of the mind*. By ascribing, indeed, to the glandular contents within the cranium, and to that fiction animal spirits, the motives of action, the superficial and ill-informed may have been led to an opinion that perception, memory, and imagination, are the functions of the *cerebrum*, the *medulla oblongata*, and *cerebellum*; that the soul is a consequence of organization; and the science which treats of it only a particular branch of physiology. But mind and its faculties are now so well understood and investigated, that this opinion can seldom prevail but where penetration is not remarkable for its acuteness, or where reflection, reading, and research, have long been confined within the limits of a narrow circle.

Some metaphysical physiologists contend, that every living system of organs supposes mind, and indeed in the study of such systems the physiologist must often meet with many phenomena that are less singular than simple perception, and yet for which he cannot account by any knowledge he possesses of organic powers. This truth we partly acknowledge, when, like ancient Athens erecting her altars to unknown gods, we retreat to those asylums of ignorance, the *vis insita*, the *vis nervea*, the *vis vitalis*, the *vis medicatrix*, and a number of others of the same kind. 10

and natural history.

Physiology, in the general sense in which we have defined it, is a science that investigates the nature and the functions of all living beings. It is, therefore, reasonable to suppose that it must have an intimate connection with natural history, and in fact, it is to this branch of physics that it has been perhaps more indebted than to any other. A comparative view of the various gradations among organized beings has taught us to appreciate the value of the several functions that characterise vitality, and has shewn us, that in proportion as the structure is more complex, the functions are more numerous, and more complete. Repeated observations, and multiplied experiments on various tribes of animated nature have cleared up many doubtful and obscure phenomena in the economy of man, and a continuation of this truly philosophical method of research promises to place physiology on the solid basis of experience, and enable us to reason, where only we can reason with safety, by a deduction from facts. The more numerous these facts, and the more complete their arrangement, the more extensive and the more secure will be the foundation which they afford for physiological conclusions. In short, (to use the language of Dumas, who has illustrated this relation at great length), "the physiologist who is conversant with natural history, is so much the better fortified against uncertain opinions, inasmuch as he has more fully observed the operations of nature in connection and in detail. An hypothesis which to others appears perfectly adequate to the object in view, is not convincing to him. He rises above the particular object to which it is accommodated, in order to appreciate its value; and it is often among circumstances which are foreign to the original subject, that he seeks for exceptions or contradictions that overturn the hypothesis. Every thing that may serve to complete the knowledge

knowledge of the animal economy enters into his plan; and as the nature of man is so much the less incomprehensible as we employ a greater number of comparative ideas in its exposition, it is doubtless in the power of natural history to elucidate that subject, by revealing a multitude of unknown relations between man and those beings which resemble or which differ from him *."

* Dumas Principes de Physiologie, tom. i. p. 231.

11 Importance and utility of physiology.

The importance and utility of physiology will scarcely be questioned, and need therefore but little illustration. To all who desire to become acquainted with the operations that take place in the animal economy, or to trace the progress of vegetation, and examine the various changes produced on the seed or bud from the action of air, heat, and moisture, (and what studies can be more deserving of a rational and an enlightened mind?) physiology must afford the most interesting subjects of contemplation. To the anatomist and the botanist, it relieves the tedium of dry description and severe classification; to the physician it holds out the surest lights to direct his researches into the circumstances that are favourable to life and health, into the nature and phenomena of death, and of course, the means of avoiding or delaying its attack; to the agriculturist it furnishes some of the most certain principles to direct him (with the aid of chemistry) in the choice of soils and the application of manures; while to the genuine naturalist, no subject presents such a field of amusement and instruction. When it shall have been rendered as complete as the state of contemporary science will allow, it will exhibit the general result of all those experiments and observations that have purposely been made to illustrate the phenomena of animated matter, or have accidentally contributed to that illustration; and when it shall reach that summit of perfection to which the efforts of genius may carry it, it may diffuse a light, of which at the present day we can form no just or adequate conception. On many occasions it may introduce order for confusion, certainty for doubt; and may establish science, in various departments that are now occupied by fancy and conjecture.

After having pointed out the *nature*, *divisions*, *relations*, and *utility* of physiology, it may not be improper to make a few remarks on the best methods of pursuing the study of it, and the works that are most worthy of a perusal.

12 Methods of studying physiology.

From what has been said of the relations between physiology and other sciences, it will be inferred that the student of our present subject should come prepared with a moderate share of knowledge in anatomy, both human and comparative, of chemistry, of mechanical philosophy, especially dynamics, optics, pneumatics, and acoustics; and natural history, especially zoology and botany. At least the *rudiments* of these branches should be well understood, and the student will then have laid a foundation on which to raise a firm and durable superstructure.

He has now to make himself acquainted with what is already known; and in this inquiry it is of much consequence that he should select those works that embrace the whole subject, without being too diffuse on the one hand or too brief and general on the other. The *Elementa Physiologiæ* of Haller contains a mass of information that will ever render it valuable as a book of reference, though it will scarcely at the present day be studied as a system of physiology. His *Primæ Lineæ Physiologiæ*, though first written, is chiefly a compendium of the larger work, and is better adapted to the general student, though, from its not containing the later discoveries in the science, it is far from complete. The *Institutiones Physiologiæ* of Blumenbach is a useful work, though it has now given place to the later and more accurate publications of Cuvier and Dumas. The *Anatomie Comparée* of the former writer contains an excellent digest of comparative physiology, and the preliminary observations prefixed to the anatomical details contained in this work, may be read with considerable advantage. Probably, however, the *Principes de Physiologie* of Dumas is the most perfect and scientific modern production that has appeared on the subject. We cannot say so much of the *Elements of Physiology* lately published by Richerand, and translated into English by Mr Kerrison; for although it contains considerable information, and a great display of reading, and even of original observation and experiment, it is neither scientific nor always very accurate. The works of Bichat, especially his *Anatomie Generale*, *Anatomie Descriptive*, and his *Recherches Physiologiques sur la Vie et la Mort*, abound with excellent physiological remarks, and, allowing for the great extent to which he has carried some peculiar doctrines, are among the best that have appeared on the animal economy.

In our own country, we have many valuable treatises and papers on different parts of physiology, and the names of Hunter, Monro, Home, Cooper, Abernethy, Carlisle, Sanders, Barclay, Jones, and many others, will ever reflect honour on the country and on the age in which they lived. We can scarcely, however, point out a complete work in our language on the general subject of physiology, though we doubt not that many will be disposed to consider the *Zoonomia* of Dr Darwin as entitled to that appellation. We allow that this is a stupendous monument of the genius and industry of its author, and it contains an ample store of valuable facts, which, if they could be divested of the hypothesis with which they are so much blended, would be extremely useful to the cause of physiological science. At present many of them tend to mislead, by a shew of metaphysical acuteness, and by the new sense in which several terms are employed. Another of Dr Darwin's works, not less valuable, in a physiological point of view, is his *Phytologia*, in which he treats of the economy of vegetation with ability and success.

13 Means of advancing and improving physiology.

He who is desirous of advancing and improving the science of physiology, must, in the first place, have recourse to a patient, and, as far as may be, an accurate observation of the phenomena that take place in organized beings; but the multitude, the variety, and complicated nature of these phenomena, place in his way obstacles that it is difficult to surmount. It is only through time, and patience, and assiduity, that he can attain his object; and it requires considerable dexterity and acuteness to detect the appearances under which these phenomena sometimes present themselves, to pierce through the obscurity in which they are often involved, and to avoid, in a route so uncertain, both the illusions of sense and the errors of genius. The living body has properties peculiar to itself, while it also possesses others that are common to it with brute matter. The phenomena by which it manifests these two orders of properties, are therefore of two kinds, as they relate particu-

larly

Introduction.

larly to the state of vitality, and as they are found in every object that exists. These latter are subject to the general laws of matter, are confounded with the phenomena of universal nature, and may be denominated *physical phenomena*. Among the former, some are confined to the arrangement or disposition of the parts in organs, and depend on the structure or form of these organs. These may be called *organic phenomena*. Others depend on the particular laws that govern vital beings, and are not the result of any peculiar organization; these are *vital phenomena*.

14 Observation.

Observation alone is sufficient to indicate the presence or the existence of these phenomena; but to unveil them fully there is required an unceasing attention, that is resolved to pursue them through the changes produced by age, sex, climate, situation, and all those circumstances that can affect the living system.

15 Experiment.

To observation, he must add, wherever this can be done with a chance of accuracy, a patient investigation of nature by experiment. From the experiments of Spallanzani and Stevens on digestion; of Goodwin, Menzies, Spallanzani, and Davy on respiration; of Monro, Galvani, Volta, and a hundred others on animal irritability, with many other experiments made both at home and abroad, more light has been thrown on the economy of living bodies, than by all the hypotheses and theories that the most ingenious speculatists have contrived since the first dawn of infant science.

16 Cautions.

In following out Bacon's great plan of observation and experiment, we must, however, take care in physiological, as in all other physical inquiries, not to be too hasty in our conclusions, and not to suppose that we have reached the bottom of the well of truth, when we have barely got within its verge. Further observations on this subject are unnecessary here, as we have already treated it at some length in the articles PHILOSOPHY and PHYSICS.

17 Modern arrangements.

We shall conclude these introductory remarks with a brief sketch of the principal arrangements of modern physiologists, and a tabular outline of the subject as we propose to treat it in the following pages.

18 Two modes of arrangement.

There are two modes of arrangement that have usually been adopted in treating physiology; one according to the order of the functions, and another according to that of the organs by which these are performed. The latter of these was adopted by Haller; the former is that of Dumas, Cuvier, and most of our later physiologists.

19 Arrangement of Dumas.

Dumas, after a long introductory discourse, in which he treats of the best method of pursuing the study of anatomy and physiology, divides his subject into six parts. In the first of these he offers some general views respecting anatomy, physiology, and all the branches of physics which are employed in illustrating the nature and properties of organized and living beings. In this part he gives a compendious history of the progressive improvements in anatomy and physiology, points out the relations that take place between these sciences, and the auxiliary branches of mathematics, mechanical philosophy, chemistry, and natural history; he considers the principal differences that distinguish organized from inorganic matter; the nature, effects, and duration of life, and of the general and particular powers or faculties of nature, both in living and brute matter.

In the second part he lays down the fundamental principles on which the physical constitution and particular economy of man depend; treats of man considered individually; of his formation, structure, and varieties; of the modifications produced in the nature of man by age, sex, habit, and temperament; of the relations between man and external objects; of the action and reaction of the organic systems on each other; of the organic structure of man, and of its several varieties in the different parts and organs; of the natural composition of the different fluids and solids of the human body: and gives a methodical division of the functions, with a critical examination of the modes of classification commonly received.

In the third part he treats of the phenomena of the animal economy, in the relation which they bear to the perpetual commerce established between man and the organs that surround him, or of *sensation* and *motion*. Here he considers the action of external objects upon man, whence result the phenomena of sensation, and the action of man on external objects, from which arise the phenomena of motion.

In the fourth part he treats of the phenomena of the animal economy, in the relation which they bear to the consistence of the fluids, the cohesion of its solids, and the temperature of the whole system. Here he considers the mutual action between the vessels and the blood, from which result, both in the solids and fluids, that degree of cohesion and pliability that favours the necessary expansibility of the living body, or the function of circulation; the action of the air, and of caloric, on the solids and fluids, from which results the degree of expansion necessary to life, or the function of respiration.

In the fifth part he treats of the phenomena of the animal economy in the relation which they bear to the healthy and entire state of the material substance and composition of the body. Here he considers the action of alimentary substances on the human body, in repairing its loss, and preserving its substance, from which result the phenomena of digestion, absorption, and nutrition; and of the action of certain organs on the fluids of the body, in separating those which do not serve the purposes of nutrition, from which result the phenomena of secretion and excretion.

In the sixth and last part, he treats of the phenomena of the animal economy in the relation which they bear to the commerce established between the individual and the species. Here he considers the mutual physical action of the two sexes, from which arise the phenomena of generation; and the mutual moral action of several individuals, from which result the phenomena of speech, and mutual intelligence.

From this sketch of the arrangement of Dumas it will be seen, that although he takes a very extensive view of the subject, his observations are chiefly confined to the human body.

20 Arrangement of Cuvier.

Though the lectures of Cuvier do not contain a complete system of physiology, the anatomical matter in them is, however, so much blended with observations on the animal economy, that it will be of importance for the physiological student to be acquainted with his arrangement.

The whole work is divided into 30 lectures: the first of which is occupied with preliminary observations on the animal economy, comprehending a general view of the functions of animal bodies; a general idea of the organs of which the animal body is composed; a view of

Introduction.

of the principal differences exhibited by these organs, and of the relations which exist among those variations, together with a division of animals founded on their organization. The second lecture treats of the organs of motion in general; the third, fourth, fifth, and sixth lectures are merely anatomical, exhibiting a comparative view of these organs in the several classes of animals. The seventh lecture is strictly physiological, and treats of the organs of motion considered in the several actions of standing, walking, seizing and climbing, leaping, swimming, and flying.

The eighth, ninth, tenth, eleventh, twelfth, thirteenth, fourteenth, and fifteenth lectures, are occupied in considering the anatomy and physiology of the function of sensation. Of these, part of the ninth treats of the nervous system in general, and of its action; part of the twelfth gives the physiology of vision; part of the thirteenth, that of hearing; part of the fourteenth, that of touch; and part of the fifteenth, that of smell and taste.

The sixteenth, seventeenth, eighteenth, nineteenth, twentieth, and twenty-first lectures treat of the organs and phenomena of digestion, mastication, insalivation, and deglutition. The twenty-second lecture treats of what have been called the assistant chylopoietic viscera, namely, the liver, the pancreas, the spleen, and their offices. The twenty-fourth treats of the organs and phenomena of circulation in general; the twenty-sixth of those of respiration in general; the twenty-eighth of the organs of voice.

The twenty-ninth treats of the organs and phenomena of generation, and the thirtieth, of those of excretion, comprehending a general view, both of secretion and excretion.

21 Of Bichat.

Subjoined to Bichat's introduction to his *Anatomie Generale*, there is a tabular view of physiology, in which, after some preliminary outline of the general structure of the organs and of the phenomena of vitality, he divides the functions into classes, orders, and genera.

The first class consists of the functions that relate to the individual; the first order of which, comprising the functions of *animal life*, comprehends five genera, viz. *sensations*, *cerebral functions*, *locomotion*, *voice*, and *nervous transmission*, besides *sleep*. The second order of this class contains the functions of *organic life*, and comprehends eight genera, viz. *digestion*, *respiration*, *circulation*, *exhalation*, *absorption*, *secretion*, *nutrition*, and *calorification*.

The second class contains the functions that relate to the species in general, and is divided into three orders. The first of these, comprising the functions peculiar to the male, comprehends only one genus, viz. the *production of the seminal fluid*. The second comprises the functions peculiar to the female, and contains three genera, viz. *menstruation*, *the production of milk*, and of *the female generative fluids*. The third order comprises the functions that relate to the union of the two sexes, and the product of that union; and it comprehends also three genera, viz. *generation*, *gestation*, and *delivery*.

Respecting the peculiar doctrines of this writer we shall speak hereafter.

22 Zoological arrangement.

There is still another mode of arranging the phenomena of living bodies, that deserves to be noticed, namely, that in which they are arranged according to the artificial systems of natural history. This mode of arrangement, though of infinite advantage to the zoologist, by showing him at once the extent of his subject, and giving to his memory a power of recollection which it could not otherwise possess, is yet not such as the physiologist would wish to be observed. Zoological arrangements are useful chiefly as they facilitate the study of the manners, dispositions, and habits of different animals; and all that part of the outward economy which indicates something of the wisdom and design displayed by the Creator, in their structure and adaptation to the modes of life which they are intended to pursue; but they do not sufficiently illustrate the internal structure on which this outward economy depends, nor do they sufficiently explain the more secret functions, which being independent of the will of the creature, only display the power and omniscience of him who made it. This will be readily conceived from considering the difference between zoology and physiology, as we have defined it. Zoology is chiefly led to examine the animal kingdom as it usually presents itself to the eye, including a great variety of objects; physiology examines only that part of the animal economy which is principally made known by anatomy and chemistry. Zoology has been accustomed to divide its kingdom into so many classes or orders of animals; physiology would naturally divide its economy into so many functions. Zoology has usually subdivided its classes by certain obvious external marks, as the teeth and claws; physiology would naturally subdivide its functions by the varieties of those organs which are destined to perform them, as the several kinds of lungs and stomachs. Zoology mentions the functions only in a cursory manner, as forming a part of the history of animals; physiology takes notice of animals, only when they are of use to illustrate the functions. To these differences we may add another; that physiology, in the extended sense which we have given it, goes beyond zoology in comprehending the economy of the vegetable creation. From this comparison it will be admitted, that things which are primary in a zoological method, will often be secondary in a physiological arrangement, and *vice versa*. This is very conspicuously the case in one of the grand divisions of Linnæus, viz. mammalia, where the important secretory organs of the milky fluid are noticed only like the colour of the hair, or the length of the tail, as a good outward mark of distinction, and likewise in the excellent table by D'Aubenton in his introductory view of natural history, in the *Encyclopédie Methodique*, in which the function of digestion is not even mentioned.

23 Utility of the application of physiological to zoological arrangement.

It is, however, extremely useful, both to the naturalist and physiologist, that the arrangements of both sciences should be, as far as possible, adapted to each other, by marking the relative importance of the several functions in the various classes of living beings. This has been very ably performed by Vicq d'Azyr, a modification of whose table has been given in the comparative part of our Anatomy. See Vol. II. p. 280.

24

With respect to all physiological arrangements we may observe, that as the phenomena of living beings are so intimately dependent on each other, as to form the links of one continued chain, it is of little consequence which of the functions or phenomena we make the point from which we set out in our examination. But as the organs of sensation in most animals, and those of diges-

Introduction.

tion in almost all living creatures, are among the first that are evolved, it appears most convenient to begin with one of these. The following is the arrangement that we shall adopt in the present article.

25 Arrangement of the present article.

After giving a sketch of the progress of physiological discoveries and opinions, we shall divide the remaining part of the article into 16 chapters. In the first of these we shall treat of the characteristic marks, general phenomena, duration, and principle of life. In the second we shall consider the phenomena of sensation, the action of the nervous system, and the external senses of feeling, tasting, smelling, hearing, and sight. In the third and fourth chapters we shall treat of irritability, and the phenomena of motion. In the fifth we shall treat of digestion; in the sixth of absorption; in the seventh of circulation; in the eighth of respiration and voice; and in the ninth of nutrition, as completed by the successive performance of the four preceding functions. In the tenth chapter we shall treat of the phenomena of secretion; and in the eleventh, of those of excretion. In the twelfth we shall consider the various means by which living beings defend themselves from external injury, or the phenomena that attend the evolution and change of the integuments, to which function we shall give the name of *integumation*. In the thirteenth chapter we shall consider the transformations that take place in some tribes of living beings, especially insects and reptiles. In the fourteenth we shall briefly examine the phenomena of reproduction, and the hypotheses to which they have given birth. In the fifteenth we shall consider the nature of sleep, and the phenomena of dreams; and in the sixteenth we shall terminate our inquiries by a few observations on the nature and phenomena of death.

The following table is intended to exhibit an outline of the principal circumstances attending the phenomena of life, in the order in which we have enumerated them.

26 Tabular outline.

1. LIFE—is either	Universally diffused through the body. *Polypi*, &c.
	Most concentrated in certain organs.
	Continued for only a few hours. *Ephemeræ, and some other insects.*
	———— about a year. *Annual plants.*
	———— two years. *Biennial plants.*
	———— several years. *Perennial plants, and most animals.*
	———— about a century. *Elephants, pikes*, &c.
	———— several centuries. *Oaks, chesnuts*, &c.
2. SENSIBILITY—Appears to	Exist in a very low degree in plants. *Sensitivity.*
	Exists in a greater or less degree in all animals.
	Confined to the senses of feeling and taste. *Most zoophytes.*
	Extended besides these to the senses of smelling, sight, and hearing.
	Appears farther extended by an additional sense. *Bats.*
3. IRRITABILITY—Affected by	Stimulants invisible.
	———— unknown.
	———— unthought of.
	The nervous influence.
	Light.
	Heat.
	Moisture.
	Electricity.
	Salts.
	Gases.
	Bodies that act mechanically.
4. MOTION—Performed by	Legs.
	Wings.
	Fins.
	The tail.
	Organs which fall not properly under these descriptions, *bats, flying opossums*, &c.
	The springiness of the body or of some part of it, *maggots, fleas*, &c.
	Contrivances which fit living bodies for being moved by foreign agents.

5. DIGESTION— Performed by an alimentary canal.
- Without teeth.
- With teeth in the mouth.
- ——— in the stomach.
- ——— stones or artificial teeth in the stomach.
- ——— glands in the mouth for secreting a liquor to be mixed with the food.
- ——— pouches in the mouth where the food is kept and moistened.
- ——— a sac or bag where the food is kept and moistened.
- ——— a membranous stomach.
- ——— a muscular stomach.
- ——— an intermediate stomach.
- Without a cœcum or blind gut.
- With a cœcum.
- ——— two cœca.
- ——— three cœca.
- ——— four cœca.
  - (With a cœcum; two, three, four cœca:) These parts, as well as ruminating stomachs and their œsophagus, have antiperistaltic motions.
- ——— one entrance or mouth.
- ——— many entrances by absorbents.
- Plants have many alimentary canals.
- Some polypes have alimentary canals that branch through the body.
- The alimentary canals of plants and worms distribute the fluids without the aid of a circulating system.

6. ABSORPTION— Performed by
- Vessels beginning from the alimentary canal.
- ——— the cavities.
- ——— the surface.
- Veins in the penis and placenta.
- Re-absorbents originating from all the parts of the system.

7. CIRCULATION— Performed by a system with
- One heart.
- A heart for distributing the blood through the respiratory organs, and an artery for distributing it through the system.
- One heart for the respiratory organs, and one for the system, both in one capsule.
- Two hearts for the respiratory organs, and one for the system.
- A pulmonary heart, or a heart for the respiratory organs in the course of circulation.
- A pulmonary heart within or without the course of circulation at pleasure.
- A heart situated in the breast.
- ——— near to the head.
- ——— in the opposite extremity.
- Some animals and all plants have no circulating system.

8. RESPIRATION— Performed by organs
- Diffused through the system.
- Confined to one place.
- Situated externally.
- ——— internally.
- In the course of the circulation.
- Not in the course of the circulation.
- Within or without the course of circulation at pleasure.
- Without tracheæ.
- With tracheæ ramified through the system where the respiratory organs are generally diffused.
- ——— not ramified through the system where the respiratory organs are confined.
- ——— formed by rings.
- ——— by segments of rings on one side, and a membrane on the other.
- ——— by contiguous rings running spirally like a screw.
- ——— admitting air by one entrance.
- ——— by several entrances.
- ——— wholly concealed in the body.
- ——— partly projecting from the body.
- ——— opening at the head.
- ——— at the opposite extremity.
- ——— upon one side.
- ——— both sides.

9. Nutrition—Food prepared by
- The alimentary canal.
- The lacteals.
- The respiratory organs.
- The circulating system.
- The cellular membrane.
- The glands.
- And by the several parts in which it becomes finally assimilated.

10. Secretion—Performed by
- Vessels.
- Exhaling vessels.
- Excretory organs.
- Organic pores.
- Glands.
- And by all the parts of which the system is composed.

11. Excretion—Excrementitious matters thrown out by
- The integuments chiefly.
- The common opening of the alimentary canal.
- Two openings of this tube.
- By the lungs and other emunctories.

12. Integumation—Some living bodies have integuments which are
- Scaly.
- Shelly.
- Membranous.
- Corneous.
- Cretaceous.
- Ligneous.
- Covered with down.
- ——— hair.
- ——— prickles.
- ——— feathers.
- ——— a viscid matter.
- Change their colour.
- ——— their covering.
- Changed themselves.

13. Transformation—Takes place
- By a change of proportion among the parts.
- ——— of their form.
- — throwing off old parts.
- — an addition of new ones of a different use, structure, and form.
- — a change of the whole form together.
- ——— of qualities, propensities, manners.

14. Generation—Performed by
- The temporary union of two sexes.
- The spontaneous separation of parts.
- Organs situated in the breast.
- ——— in the side.
- ——— near to the head.
- ——— in the opposite extremity.
- An intrant organ of the male, and a recipient organ of the female.
- An intrant organ of the female, and a recipient organ of the male.
- The stamina and pistils of flowers.
- The seminal secretion of the male thrown into the organs of the female.
- ——— sprinkled at the entrance of the female organs.
- ——— thrown upon them from a distance.
- ——— transported to them by the winds.
- ——— sprinkled on the embryo after emission.
- ——— dissolved in a fluid secreted by the female before it can rightly perform its office.
- ——— dissolved perhaps sometimes in air, as in the case of dioicous plants, where it probably acts like an aroma.

15. Sleep—Natural sleep is occasioned by
- Quietness.
- The absence of stimuli.
- The sameness of stimuli when long continued.
- Deficient assimilation.
- Deficient irritability, which is owing sometimes to the weakness, inattention, or confined powers of the mental principle.

16. Death. See Life.

HISTORY.

HISTORY.

27 Utility of the history of physiology.

The early history of physiology can be little more than an account of the opinions of the ancient philosophers respecting the nature and functions of the human body; but as their opinions reflect considerable light on the progressive improvement of the philosophy of man, the history of physiology, even in its early stages, is curious and interesting.

28 Opinions of Pythagoras respecting man.

Of the origin of physiology as a science we know nothing. On examining the writings of the earliest philosophers, we meet with little more than a collection of abstract principles and hypothetical reasonings, especially previous to Pythagoras. He considered man as a microcosm, or an epitome of the universe, in which were produced the same phenomena as in the larger world, only to a less extent. He admitted more than one intelligent principle, conducting all the operations of the human body. He supposed that the human soul, nourished by the blood, fixed by the veins, the arteries, and the nerves, as so many visible situations, became obedient to the general laws of universal harmony. He did not pretend that the eternal power of numbers had prescribed all the phenomena of nature, and that the force of numerical harmonies regulated the motions of the bodies which filled the universe, though he has been made so to express himself by his disciples. He was contented with asserting, that every thing in nature was brought about according to the qualities and proportions of numbers, without attributing to them an intrinsic virtue and a positive existence. He perceived that the phenomena of the animal economy succeeded each other with a strict regularity, by which they concurred in maintaining order; and in this order he found the principle of the existence and preservation of all beings; a principle without which they could not exist. He considered the souls of men as emanations from the general soul of the universe, or *anima mundi*.

29 Of Alcmæon.

Alcmæon considered the brain as the seat of the soul. He supposed sound to be produced by the reverberation of the air within the cavity of the ear; and he thought that taste was owing to the moisture of the tongue. He compared the body of a fœtus to a sponge, which obtained its nourishment by the suction established over every part of its substance. According to him, the motion of the blood was the essential principle of life; and he supposed that the stagnation of this fluid in the veins produced sleep, and its active expansion brought back the waking state of the body. Health consisted in the equilibrium and well proportioned mixture of certain primary qualities; and that whenever any of these became too predominant, disease was the consequence.

30 Of Empedocles and Anaxagoras.

Empedocles involved himself in a multitude of absurd hypotheses, in order to explain the formation of man, and the combination of the elements from which he was produced. He too, like the disciples of Pythagoras, sought among the properties of numbers, for the general principles both of physical and moral science. In uniformity with this system it was, that he reckoned the four elements, and admitted among the particles of these material principles a kind of affection and aversion, of desire and antipathy, capable of separating and reuniting them, as occasion might require. He believed that respiration commenced within the *uterus*, where the infant was provided from each parent with certain organic particles, which tended to unite into one uniform whole. Anaxagoras, convinced that we must attribute the arrangement of matter to the intelligence of a superintending being, imagined that the body of every animal was formed of homogeneous particles, which were brought together by a sort of affinity. It appeared to him, that bodies which were endowed with thought, were composed of sensible elements; that these elements remained unalterable, and that no power in nature could exert any action on them.

31 Democritus.

Democritus dedicated his life to repeated experiments on plants and animals. He explained the principal phenomena of organized bodies by the action and reaction of atoms, which he supposed to be endowed with powers essentially active, and susceptible of repelling and attracting each other. According to him, generation consisted in the cohesion of homogeneous atoms. He conceived the heat inherent in the elements of the body to be the sole active principle with which man was animated; and that by increase of this he became capable of life and motion. He compared the organs of the senses to mirrors, on which were painted the images of things, and he reduced all sensations to the sense of feeling, which he supposed to be more or less delicate according to circumstances.

28 Hippocratus.

These philosophers, who lived before the time of Hippocrates, had, as we see, but very rude and indistinct notions of the animal economy; nor were those of the great father of physic much superior. Excellent as was his practice, and acute his knowledge of the symptoms and progress of diseases, the physiology of Hippocrates was very lame and defective. He seems, indeed, to have understood the functions of nutrition better than most others; he traces the aliment into the stomach, seems aware of the processes it has to undergo there, and hazards a conjecture that part of the chyle is taken up immediately by the pores of the cellular texture; and that the juices admitted into this membrane, served for the production of milk, the matter of which is afterterwards transported, and laid up within the breasts. He attributes to each vital part an attractive force, which it exerts on the nutritious particles, in order to incorporate and appropriate to itself those which bear to it a certain analogy. He thought that the heat generated in a living body was kept up entirely by powers of vitality; and that the external air introduced by respiration, served rather to check it, by exerting a cooling effect on the pulmonary organs. He represents the human body as agitated in all its parts by an alternate flux and reflux, which carried the matters from within outwards, or brought them from without inwards. From this some have supposed that he understood the circulation of the blood, a supposition made two hundred years ago, and lately again brought forward by the French physiologists. We shall not at present stay to canvass this opinion, which, however, we conceive to be founded on very unsatisfactory arguments.

33 Plato.

After Hippocrates, the science of man was again left to the schools of philosophy, from which he had first separated it. Plato is the first philosopher whose opinions merit peculiar notice. He wrote on the physiology of man with his accustomed elegance and splendour of diction; and he assumed the tone of an inspired prophet in decribing, with the force of enthusiasm, the grand images that suggested themselves to his mind. According

History. cording to him, the human body does not contain within itself the cause of the phenomena which are the consequence or the attendants of life. It is only a passive subject, on which the soul expresses the series of its functions, like the canvas on which the painter traces the conceptions of his inventions. He distinguishes two principles of action in man, a rational soul, on which depend reflection and intelligence, and an irrational soul, on which depend life and motion. The latter is diffused through every part of the body; and it is by means of these parts that it feels, suffers pain, or enjoys pleasure. Thus it is by means of the heart it is susceptible of courage and of passion; by the liver of desire. The head is the seat of reason; the chest, and especially the heart, the seat of strength and anger; the lungs, the general coolers of the body. One division of the irrational soul, which possesses an appetite for food, and all the necessary refreshments of the body, resides in the epigastric region; which, in the language of Plato, is a sort of stable, in which resides a voracious animal. During nutrition, the vital parts assimilate to their substance the aliments which are presented to them; and this assimilation is the consequence of an affinity that takes place between these parts and the nutritious juices. He thus seems to regard nutrition as the effect of a combat between the aliments and the parts of the animal. A young animal will receive more nourishment than one which is old, because the force of its body has more effect in overcoming the force of the nutritious substances.

As the reciprocal action of the soul and the body on each other did not appear to him capable of being explained on the supposition of immateriality, he proposed the idea of a *plastic nature*, which he supposed to be an intermediate principle connecting the soul and the body.

The human body, which is entirely spongy, is exposed through every part to opposite currents of air and fire, which traverse and penetrate it, being introduced alternately by the lungs and by the skin. Hot, cold, dense, rare, and the other sensible properties of bodies, are only the causes of the phenomena which we perceive, and are, as it were, the occasions or accidents that are required to keep in play the intelligent force disseminated through nature.

34 Aristotle.

Aristotle, the disciple of Plato, for a long time disputed with him the palm of genius and celebrity; but, as his physiological doctrines differed very little from those of his master, it is unnecessary to detail them, except to remark, that he attributed to the soul three faculties, a *nutritive*, a *sensitive*, and a *rational* faculty; in the first of which life is the only principle; in the second, feeling is produced; and the third is peculiar to man, and is that part of him which knows or judges. This part is either an active or a passive intellect, of which the first may be separated from the body, and is immortal; whereas the second perishes together with the body. Life, according to this philosopher, is a permanence of the soul, retained by the natural heat, the principle of which resides in the heart.

About the period which we are now considering, philosophy was divided into two sects; the materialists, who attributed the formation of all beings to the fortuitous concourse of atoms; and the spiritualists, who held that the soul enjoyed an existence anterior to that of the body, which was no other than a passive organ, in which the phenomena that previously existed in the soul, in an abstract, latent manner, became evident and sensible. To the former sect belonged Democritus and Epicurus; to the latter, Zeno and Plato.

35 Herophilus.

The professors of the Alexandrian school, though they did much for the improvement of anatomy, added little to physiology. Of these Herophilus brought to some degree of perfection the doctrine of the pulse, and seems to have understood the action of the pulmonary organs more correctly than his predecessors, attributing to them a sort of natural appetite, by which they attracted and rejected the matter of respiration. He considered the nerves, the muscles, and the arteries, as the moving powers of the body.

36 Galen.

In Galen, also a disciple of this school, we find the most scientific physiologist that has yet come under our notice. He seems first to have ascertained by experiment, that the arteries contain blood, and not air, as had been the opinion of Herophilus and his predecessors: and that they possessed a moving force, independent of that which the heart exercises on the mass of blood, and he found that the contraction of the heart always alternated with a proportional dilatation. He even tried some delicate experiments, in order to ascertain the influence of the nervous system upon the sensitive and motive powers of the body, by which he found, that when a nerve was intercepted with a ligature, the part to which it led became deprived of sense and motion. He believed that the stomach, in a state of contraction, applied itself to the aliment that had been taken in; that the mesenteric veins absorbed a portion of the chyle prepared in the intestines; that the *ductus choledochus* carried the bile from the gall bladder into the duodenum; that the kidneys separated a part of the urine: and he supposed, that another part of this fluid passed immediately from the stomach to the bladder, through some unknown passage. He believed that the lungs transmitted to the blood contained within them, an aerial principle, destined to free them from fuliginous vapours, and to temper the excess of heat generated within the body. The obscure function of generation did not entirely escape his researches; and he made some curious attempts to find out how the sexual organs prepared the seminal fluid, and how this acted in reproduction.

For more respecting the doctrines of Galen, see the History of MEDICINE.

37 The chemists.

The commencement of the 13th century is the epoch of a material revolution in physiology. Chemistry having penetrated into Europe, soon exerted its influence on most of the sciences, and especially on those connected with medicine, the doctrines of which were totally changed from their ancient simplicity, and became a farrago of the most wild and fanciful opinions. The Peripatetics and the Galenists sunk into oblivion; and the primitive qualities and occult faculties of the ancient school gave way to the fermentations and effervescences of the chemists. Albertus Magnus and Roger Bacon, when they introduced the science of chemistry, scarcely dreamed of applying it to medicine; but Arnoldus de Villa Nova undertook this application, and sought for the foundation of medical theory amid the processes of his laboratory. Paracelsus followed, and surpassed him in this chemical delirium. An enlightened chemist and a credulous

credulous astrologer, his head burning with the fire of his furnaces, and his imagination filled with magical reveries, he believed himself capable of constructing a new system of philosophy, from examining the course of the stars, and the products of his alembics. With the daring assurance of inspiration, he declared man to be composed of sulphur, mercury, and salt; and, having traced the origin of all diseases to certain chemical operations, he flattered himself, that by means of his arcana he could preserve health, and prolong, to an indefinite extent, the natural duration of human existence.

38 Van Helmont.

Van Helmont, the disciple of Paracelsus, not less fanciful, but more scientific than his master, saw the necessity of something more than chemical principles to explain the functions of the animal machine. He therefore introduced his *archæus*, an intelligent being who established his throne in the epigastric region, having several subaltern ministers under him, who presided over the several functions of the body, and whose chief seats were, the head, the chest, and the belly.

39 Des Cartes.

In the philosophy of Des Cartes, the separate existence of the vital principle is entirely rejected. He availed himself of the progress that had been made by Willis, and some other anatomists, in the investigation of the nervous system, to form an hypothesis of the vital functions, founded on the supposition of the nervous fluid, or what was then called the *animal spirits;* and this nervous fluid was assumed independently of the sensitive soul, to explain the appearances of sensation and voluntary motion.

The discovery of the valves in the veins by Fabricius; of the lymphatics by Rudbeck and Bartholin; of the lacteals by Asellius, and of the circulation of the blood by Harvey, all of which took place during the 17th century, gave to physiology an interest and a clearness which it never possessed before that period. Some account of the discoveries in the circulating and absorbing systems, hath been already given under ANATOMY; but as these discoveries have been productive of great advantages, both in general physiology, and in medicine, it will be worth while briefly to trace their origin and progress.

40 Discovery of the circulation.

To begin with the circulation of the blood. Hippocrates speaks of the usual and constant motion of the blood, of the veins and arteries as the fountains of human nature, as the rivers that water the whole body, and which if they be dried up man dies. He says, that the blood-vessels are, for this reason, everywhere dispersed through the whole body; that they give spirits, moisture, and motion; that they all spring from one; and that this one has no beginning and no end, for where there is a circle there is no beginning. In such language was the prince of physicians accustomed to express his vague ideas of a circulation; for so far was he from having acquired accurate conceptions on this subject, that when he saw the motions of the heart, he believed that the auricles were two bellows to draw in air, and to ventilate the blood.

When after his time anatomy came to be more studied, the notions of the ancients respecting the blood were better defined; and, however chimerical they may seem to us, they were partly derived from dissection and experiment. On opening dead bodies, they found that the arteries were almost empty, and that very nearly the whole of the blood was collected in the veins, and in the right auricle and ventricle of the heart. They therefore concluded that the right ventricle was a sort of laboratory; that it attracted the blood from the cavæ; by some operation rendered it fit for the purpose of nutrition, and then returned it by the way that it came. From the almost empty state of the arteries, they were led to suppose that the right ventricle prepared air, and that this air was conveyed by the arteries to temper the heat of the several parts to which the branches of the veins were distributed.

To this last notion, entertained by Erasistratus, Galen added an important discovery. By certain experiments, he proved, that the arteries contained blood as well as the veins. But this discovery was the occasion of some embarrassment. How was the blood to get from the right to the left ventricle? To solve the difficulty in which this new discovery had involved him, he supposed that the branches of the veins and arteries anastomosed; that when the blood was carried to the lungs by the pulmonary vein, it was partly prevented by the valves from returning; that therefore during the contraction of the thorax it passed through the small inosculating branches to the pulmonary vein, and was thence conveyed along with the air to the left ventricle to flow in the aorta. This opinion, so agreeable to fact, unfortunately afterwards gave place to another that was the result of mere speculation. This notion was that the left ventricle received air by the pulmonary vein; and that all its blood was derived through pores in the septum of the heart.

The passage through the septum being once suggested, and happening to be more easily conceived than one through the lungs, it was generally supposed the only one for a number of centuries; and supported likewise, as it was thought, by Galen's authority, it was deemed blasphemy in the schools of medicine to talk of another. In 1543, however, Vesalius having published his immortal work upon the structure of the human body, and given his reasons in the sixth book why he ventured to dissent from Galen, he particularly shewed how it was impossible that the blood could pass through the septum of the heart. His reasoning roused the attention of anatomists; and every one grew eager to discover the real passage which the blood must take in going from the right to the left ventricle. The discovery of this was first made by Michael Servede, a Spanish physician, who published his opinion in 1553. He expressly says, that the blood does not pass through the septum of the heart, as is commonly believed, but is conveyed by an admirable contrivance from the right ventricle of the heart, by a long passage through the lungs. This opinion was deemed heretic, and Servede's book was suppressed by public authority. Soon after, however, the same discovery was made by Realdus Columbus, an Italian professor, who published his account in 1559. It farther appears, that Andreas Cæsalpinus, who published in 1571, and again in 1593, was acquainted, not only with the lesser circulation, but observed, that the blood sometimes flowed from the branches of the veins towards their trunks; and that when a vein was tied with a ligature, it swelled between the ligature and the distant extremity of the vein, and not between the ligature and the heart. He thence inferred, that the veins and arteries opened into each other, and ventured to assert

History. sert that the blood could not return by the arteries to the left ventricle of the heart. He did not, however, discover the true circulation, but most unaccountably maintained with Aristotle, of whom he was a zealous disciple, that the blood flowed like the tides of Euripus, backward and forward in the same channel, and supposed that it flowed from the arteries into the veins during sleep, and back again from the veins into the arteries till the waking state.

In 1574, Hieronymus Fabricius ab Aquapendente, while he was seeking for a cause by which to explain the various swellings of some veins, which had arisen from friction and ligature, he, to his great joy and astonishment, discovered their valves in one of his dissections; and here again the true theory of circulation seemed almost unavoidable. Yet whoever reads the small treatise De Venarum Ostiolis, first printed by Fabricius in 1603, will soon perceive that he was as far from entertaining a just notion of the circulation as his predecessors. Notwithstanding all that he saw, he still was of opinion that the blood flowed from the heart to the extremities even in the veins. He thought that the valves were intended by nature only to check and moderate its force. He calls them an instance of admirable wisdom, and mistakes his own awkward conjecture for one of the designs of infinite intelligence. In another respect, it must be confessed that he bore no inconsiderable share in promoting the discovery of the circulation. By writing on the valves, the formation of the fœtus, and chick in ovo, he directed the attention of his pupil Harvey to those subjects where it was likely that the motion of the blood would frequently occur.

Harvey, who was born in 1578, and graduated at Padua in 1602, examined the valves with more accuracy than Fabricius, and explained their use in a treatise which he published soon after his graduation. In 1616, he taught the true doctrine of the circulation in his lectures, and published on the subject in 1628. He was the first author who spoke consistently of the motion of the blood, and who, unbiassed by the doctrine of the ancients, drew rational conclusions from his experiments and observations. His books present us with many indications of a great mind, acute discernment, unwearied application, original remark, bold inquiry, and a clear, forcible, and manly reasoning; and every one who considers the surprise which his doctrine occasioned among the anatomists of those days, the strong opposition that it met with from some, and the numerous and powerful prejudices which it had to encounter from the sanction of time and of great names, must allow it was new; and that the author has from its importance, a title to rank in the first class of eminent discoverers, ancient or modern.

We have been the more particular in tracing the progressive discovery of the circulation, and in attempting to shew that the real merit of the discovery is due to Harvey, because both the abilities and the originality of this eminent man have been called in question by his countryman Dr William Hunter; and many hints are given in the writings of some foreign physiologists, that the circulation was at least guessed at by Hippocrates and other ancient writers.

We shall be less minute in tracing the discovery of the lymphatic system, because this has been related more at large in the article ANATOMY.

We learn from Galen, that certain vessels had been seen in kids by Erasistratus, which appear to have been lacteals, though he called them arteries. These lacteals were, however, first accurately distinguished in 1622, by Asellius, who printed his account in 1627. In 1651, Pecquet published his account of the thoracic duct, which appears, however, to have been seen before by Eustachius. In 1653, Bartholin published on the lymphatics, which had been some time before discovered by Rudbeck. In 1654, Glisson ascribed to these vessels the office of carrying back the lubricating lymph from the arteries into the blood, or considered them as absorbents. In 1664, the valves of these vessels were discovered by Swammerdam, and a year after, an account of them was given by Ruysch. The farther discoveries of Nuck, Nouges, Warton, Steno, Hunter, Monro, Hewson, Cruikshank, Sheldon, Mascagni, &c. have nearly completed our knowledge of the absorbent system, and its uses.

41 Discovery of the absorbent system.

In the latter end of the 17th century, some important discoveries were made on the subject of respiration, by our countryman Mayow; and these were supported by the observations of Lower, Verheyen, and Borelli. These discoveries, however, lay dormant till they were brought into recollection a hundred years after in consequence of the experiments of Priestley and Lavoisier.

During the 17th century, considerable progress was made in completing the knowledge of the internal organs of generation. Much was done in this way by De Graaff and Malpighi, and Leuwenhoeck, the two latter of whom made several discoveries with the assistance of their microscopes, though Leuwenhoeck founded on his observations a theory of generation which at this day appears not a little ridiculous.

42 System of Boerhaave.

The beginning of the 18th century is remarkable for the promulgation of a new physiological doctrine, founded on a mistaken application of the circulation of the blood. We allude to the system of Boerhaave. This great physician supposed that all the functions of the living body, excepting the will, are carried on by mechanical movements, susceptible of rigid calculation, which necessarily succeed each other in the organs, from the time that life commences. These movements are brought into action as soon as the animal begins to respire, and are the consequence of an impulsive power in the heart, renewed by means of the influence of the nervous fluid brought from the brain. He conceived the living body to be merely a hydraulic machine, in which the heart performs the office of a piston, and that the alternate contractions and dilatations that take place without intermission in that organ, are owing to the alternately increased and diminished compression of the nerves that are distributed to the heart. When a contraction takes place, the blood fills the large arteries, and thus distends and compresses them; when the principal nerves of the heart, which pass between these arteries, must of course become compressed, and thus their influence being diminished, a relaxation takes place. But in proportion as the heart is relaxed, the large arteries become empty, and consequently cease to compress the nerves, which thus recovering their influence, reanimate the heart to a new contraction. Thus succeed each other without interruption the movements which form the mechanical principle of all the sensible motions that we observe in the animal machine.

Proceeding

History.

Proceeding on these principles, Boerhaave conceived some very strange notions respecting the constituent properties of the living fluids, in which he saw no other mark of vitality than the globular form of their particles. He confined all the functions of the several organs to the operation of rounding into spheres the particles of the fluids which are presented to them, or of preserving that form in those which they already contained. He thought that the lungs were chiefly of advantage, because they contained within them a complete series of vessels, in which the particles of the blood can receive all those dimensions which may fit them to circulate through the rest of the body. The greater or less velocity with which the fluids circulate through the secretory organs, constitutes the principal difference in the nature of the secretions. Various orders of vessels receive the blood and other fluids which pass through these divisions, subject to the laws of hydraulics; and when a fluid got by chance into an order of vessels that was not fitted to receive it, some disease was the consequence. Every thing in the animal machine was reduced to an assemblage of conduits, canals, cords, levers, pulleys, and other mechanical contrivances, put into action by mechanical means.

43 Mechanists.

Thus was completed the system of mechanical physiology, which was begun some time before by Bellini and Borelli; and this system maintained its ground in defiance of observation and common sense, till about the middle of the 18th century. In the mean time, however, there arose two men, whose enlarged ideas and acute genius induced them to dissent from the received opinions of the day, and to think for themselves. These were Hoffman and Stahl, who, though they did not, any more than Boerhaave, form complete or unobjectionable theories, contributed much to improve our ideas of the animal economy.

44 System of Hoffman.

Hoffman saw, that in the living body we ought not to separate the principle of vitality from the general properties of matter. He believed that that principle, susceptible in itself of activity and motion, was sufficient for all the occasions and all the functions of the body which it animated. The animal body was not, in his eyes, an hydraulical elastic machine, formed of solids and canals, differing only in size, form, elasticity and force. He saw, that if the solids act upon the fluids, these must, in their turn, react upon the solids; and that life could subsist only by these mutual actions and reactions. The essential cause of life, according to Hoffman, is the progressive motion of the blood, occasioned by the impulse of the heart. and kept up by the alternate contractions and dilatations of the vessels. These contractions and dilatations are the consequence of the force of an elasticity inherent in the vascular fibres, and this force is still farther promoted by the different structure of these elastic fibres, which is such that they can be penetrated by the blood and the nervous fluid. This last fluid he imagined to be composed of aerial and etherial particles enveloped in a certain portion of a very pure subtile lymph, that served them as a vehicle. By this fluid the cavities of the nerves are filled, and it constitutes the sensitive soul, in which resides the seat of the passions. Now, all the functions. even those which we attribute to the sentient principle, are the effect of physical powers, whose mechanism has, however, something more sublime and more exalted with respect to the animal operations than to others. If all the nervous, vascular, and membranous parts, preserve a moderate degree of action, and a moderate state of tension and relaxation, the solids are subjected to oscillatory motions which balance each other, and produce a proper equilibrium in the system. In this state, all the operations of the body and the mind take place with proper regularity; and this happy harmony, by assuring to the animal the entire plenitude of its existence, becomes the foundation of health. This degree of moderate tension is always more or less altered in a state of disease.

45 Of Stahl.

Little satisfied with all the theories founded on a gross mechanism, and convinced of their insufficiency to explain he phenomena of vitality, Stahl admitted forces that were something more than mechanical, and that were directed by an intelligent principle which applies them to their destined uses, and which, by distributing them with a wise economy, poportions or accommodates them to the different occasions of the individual. His disciples consider Stahl as the first modern writer who has treated the science of man on a general plan, and according to a philosophical arrangement; and as his doctrine has still numerous advocates in the medical schools of France, we shall be somewhat more particular on it than on that of Hoffman.

In determining the limits between medicine and the other physical sciences, Stahl commences with separating from the former all those principles which, though true in themselves, have no relation to the nature of that science, which he considers as originating in observation alone. The knowledge of the physical state of the animal body cannot, he thinks, throw any light, either on the injuries to which it is exposed, or on the means of preventing or removing them. Consequently it is of little use in medicine, and has no right to govern an art, the object of which is, to remedy those injuries that threaten the human body. He proves that living bodies are freed from the necessary laws of mechanics, because all their actions tend to one common end;—an end which embraces the whole chain of the movements essential to life, and the means established for its preservation. The human body, by means of this mixture of mechanical and vital powers, tends naturally to self-destruction; but, on the other hand, the organic structure to which is attached the exercise of the actions peculiar to the human species, is founded on this mixture. It is therefore necessary that the body should be in a state of resisting this tendency, in order that it may be sustained; and as the corruptibility inherent in its nature, pursues it through every period of its existence, the opposing action necessary to prevent the corruption from taking place, must also be exercised without intermission. It is this preserving action that constitutes the essence of life.

The preservation of the body is indeed effected by a sort of mechanical action; it requires the corporeal organs as its instruments, and it depends on different coexistent and successive actions. Health is the result of that just conformation of the organs which enables them to perform their functions with ease.

The exact conformity which subsists between the structure of each organ, and the functions it is destined to perform, demonstrates to the philosophical eye an intelligent and wise principle, that in the formation of organized bodies directs and prescribes every thing in the

History.

the manner most favourable to the end which it proposes. A speculative metaphysician, accustomed to wander over the field of abstraction, to enlarge the sphere of his intellectual notions, to transform sensible objects into ideas, this author could never persuade himself that a being could not proportion and adapt its organs to the operations they are to perform, without possessing a knowledge of these operations, and having already exercised a judgment with respect to them. It is from this that he confounds the principle of life with the thinking soul, which being incessantly present in every part of the body, directs and disposes them according to its own views, and to the end that it proposes in the continual developement of the actions it is to conduct.

The formation, the structure, duration and movements of the body, do not belong peculiarly to it, as it is only a passive subject on which the soul impresses and realises the idea of the phenomena that she has conceived. Every thing is derived from the union of the body with the active foreseeing principle, which governs, according to special laws, those phenomena which are more particularly vital, and which are most independent of the will. The immediate action of this latter faculty does not require the assistance of any other substance. The intervention of an intermediate principle would be there superfluous; and Stahl rejects that of the animal spirits, which had been introduced to explain the mechanism of vitality, and which, by overcharging the science, embarrasses it with a useless hypothesis.

Two faculties are sufficient for the soul to act upon the body, and to preserve it in a living state, viz. those of sense and motion. By the former the animal learns to know the properties of the objects by which he is surrounded, or in which he is interested, and to estimate the relations that subsist between these objects and himself; the latter produces the motion of the whole machine, and determines all the changes of situation which it has to undergo in its whole, and in its parts.

The faculty of sensation has two modifications, relative to the two kinds of knowledge which the soul may receive by means of that function. The first of these resides in the organs of sense, and is adapted to external objects; the second establishes its seat in the interior organs, and refers to objects that are within, or ideas. Sometimes the moving power enveloped in the muscular system is displayed by the sensible actions that regulate the position of the body with respect to the objects of the universe, of which it makes a part; sometimes concentrated within these organs, it excites intestinal motions, which maintain among their constituent parts, those relations, and that equilibrium, which are necessary to preserve the healthy state, consistence, and tone of each organ. The muscular apparatus is subservient to the exercise of the senses; and the different motions which it impresses on the body, for the purpose of transporting it towards, or to a distance from, certain objects, are always determined by the convenience or inconvenience which the body, by means of the senses, experiences from those objects. The tonic motion, determined by the confused ideas of the principle of life, is displayed in the most hidden organic parts, in the most perfect repose and profound silence of the voluntary movements.

The soul gives to its organs the disposition that is favourable to the sensations it wishes to receive, by virtue of the judgment that it exerts respecting these sensations, before it has experienced them. This judgment is exerted on the relations between the objects that excite these impressions, and the actual state of the body; and it is the intuitive knowledge of these relations that determines, in all their infinitely diversified shades, the pleasure or the pain which the animal experiences from the objects that surround it.

Stahl regards the excretions as the means employed by nature to counteract the natural tendency of the body towards putrefaction. He believes that the animal humours are exceedingly disposed to thicken, and that the circulation of the blood is the means made use of by nature to keep up their original fluidity. One of the causes that most favour the tendency of the humours to putrefaction, is *plethora*, to which nature opposes, sometimes the motion of the solids that distribute the blood; sometimes the hemorrhagic fluxes which unload the vascular system. These latter opinions are the principal foundations of what has been called the *humoral pathology*, which prevailed so long in most of our medical schools, and which, with certain modifications, is still maintained in many parts of the continent.

46 Of Haller.

The favourable impulse given to physical science in general, by the philosophical writings of Bacon and Newton, extended itself at length to physiology; and physiological writers became convinced that it was better to collect and arrange the facts that related to the economy of living beings, than to frame hypothetical systems concerning them. The honour of forming a rational digest of the phenomena of the animal economy was reserved for Haller, who perceived the importance of assembling under one view, the experiments, facts, and observations of preceding writers, and of substituting them in the place of hypothetical reasonings. He traced the plan of the immense edifice that he designed to construct in his *First Lines of Physiology*, and executed it on a grand and extensive scale, in his *Elements*, in which he has brought together into a body of doctrine, as complete as could be expected in his time, all the materials of the science. He perceived the inconvenience of a too strict application of the laws of mechanical philosophy to the living system. He admitted an active force, which he considered as peculiar to the animal body, viz. irritability, which contains the reason or the experimental cause of muscular motion. He maintained that irritability should never be confounded with sensibility, and that the irritable fibre differs as much from the sensible fibre, as the function of motion from that of sensation. Lastly, in his *Opera Minora*, he lays down many new and important points of doctrine respecting the structure of our organs, and the mechanism of our functions; and he relates a number of experiments made on living animals, for the purpose of drawing from nature the secret of those phenomena which she appears most desirous to conceal. We owe to Haller some curious researches respecting the formation of bone, and the production of callus, as well as some important elucidations of the manner in which the embryo contained in the egg is developed, and passes through the successive stages of its organization. He has left us many experiments and details respecting the structure of the heart, the circulation of the blood, and the pulsation of the arteries; on the mechanism of the ribs, and the action of the intercostal muscles during respiration; on the differences between the sensible and irritable organs; on the action of the brain and nerves, &c.

The

History.

The latter half of the 18th century is remarkable for many able physiologists, who will be admired by posterity, either for the acuteness of their genius, or the important improvements that they have made in the science. We may mention the names of Bordeu, La Caze, Bonnet, Vicq d'Azyr, Bichat, Dumas, and Cuvier in France; of Fontana and Spallanzani in Italy, and of Whytt, Cullen, Brown, and Darwin in Britain. We cannot pretend to enumerate all the opinions and discoveries of these celebrated men, but must content ourselves with giving a sketch of the three rival systems of Cullen, Brown, and Darwin, and a brief outline of the opinions of Bichat.

47
Of Cullen.

The physiological system of Cullen was founded chiefly on that of Hoffman. He placed the principle of the whole animal economy in the movement of the vital solids, regulated by the fundamental laws of the nervous system. This notion of the vital solids, according to him, originates in the nerves, and being almost always united in the *sensorium*, is easily transmitted from one nervous part to another, as long as the medullary substance of the nerves continues in its natural state of life and continuity. The contraction of the moving fibres connected with the sensible organs through the medium of the brain, is the direct effect of a movement that commences with those objects. It is on the contractility inherent in the moving fibres, excited by their own extension, by the application of various stimuli, and often by the immediate influence of the animal or nervous powers, that all the physical actions of a living being depend. He regards this contractile force as distinct from all those which are possessed by the simple solid, and the inorganic elastic parts of the body.

Of the theory of Brown, we have given a sufficient detail under his life, and need not repeat it here.

48
Of Darwin.

It is not easy to give a compendious view of the system of Dr Darwin, that shall be intelligible to those who have not examined his celebrated work, the Zoonomia; but we shall endeavour to give as brief and perspicuous an account of it as possible. It is necessary first to notice the descriptions given of the terms to be employed, which are as follows.

The immediate organs of sense are, by Dr Darwin, asserted to consist, like the muscles, of moving fibres. The contractions of the muscles and of the organs of sense, are comprehended under what are called *fibrous motions*, in contradistinction to the *sensorial motions*, or the changes which occasionally take place in the *sensorium*. By this latter term is understood, not only the *medulla* of the brain and nerves, but also at the same time that living principle or *spirit of animation*, which resides throughout the body, and which we perceive only in its effects. An idea is defined to be a motion of the fibres of some immediate organ of sense; and hence is frequently termed also a *sensual motion*. Perception comprehends both the fibrous motion or idea, and the attention to it. When the pain or pleasure arising from this motion and this attention produces other fibrous motion, it is termed *sensation*; thus limiting this term to an active sense. Ideas, not immediately excited by external objects, but which recur without them, are termed either, 1. Ideas of *recollection*, as when we will to repeat the alphabet backwards; or 2. Ideas of *suggestion*, as when we repeat it forwards, A suggesting B, B suggesting C, &c. from habit.

History.

After mentioning a number of experiments to prove the fibrous motions of the organs of sense, Dr Darwin proceeds to lay down the following laws of animal causation.

1. The fibres which constitute the muscles, and organs of sense, possess a power of contraction. The circumstances attending the exertion of this power of *contraction* constitute the laws of *animal* motion, as the circumstances attending the exertion of the power of attraction constitute the laws of *inanimate* matter.

2. The *spirit of animation* is the *immediate* cause of the contraction of animal fibres. It resides in the brain and nerves, and is liable to general or *partial* diminution or accumulation.

3. The stimulus of bodies external to the moving organ is the *remote* cause of the original contractions of animal fibres.

4. A certain quantity of stimulus produces *irritation*, which is an exertion of the spirit of animation exciting the fibres to contraction.

5. A certain quantity of contraction of animal fibres, if it be perceived at all, produces *pleasure*; a greater or less quantity of contraction, if it be perceived at all, produces *pain*. These constitute *sensation*.

6. A certain quantity of sensation produces *desire* or *aversion*. These constitute *volition*.

7. All animal motions which have occurred at the same time or in immediate succession, become so connected, that when one of them is reproduced, others have a tendency to accompany or succeed it. When fibrous contractions succeed or accompany other fibrous contractions, the connection is termed *association*; when fibrous contractions succeed sensorial motions, the connection is termed *causation*; when fibrous and sensorial motions reciprocally introduce each other, it is termed *catenation of animal motions*. All these connections are said to be produced by habit; that is, by frequent repetition. These laws of animal causation are, according to our author, evinced by numerous facts, which occur in our daily exertions, and are employed by him to explain the diseases and decay of the animal system.

The four *sensorial powers*, upon which all the actions or motions depend, are thus characterized:

Irritation is an exertion or change of some extreme part of the sensorium, presiding in the muscles or organs of sense, in consequence of the appulses of external bodies.

Sensation, is an exertion or change of the central parts of the sensorium, or the whole of it, beginning in some of those extreme parts of it which reside in the muscles or organs of sense.

Volition is an exertion or change of the central parts of the sensorium, or of the whole of it, terminating in some of those extreme parts of it which reside in the muscles or organs of sense.

Association is an exertion or change of some extreme part of the sensorium, residing in the muscles or organs of sense, in consequence of some antecedent or attendant fibrous contractions.

To these four faculties correspond so many classes of fibrous contractions, named *irritative*, *sensitive*, *voluntary*, and *associate*. But all muscular motions, and all ideas, are originally irritative, and become causable by sensation and volition from habit, i. e. because *pleasure* or *pain*, or *desire* or *aversion*, have accompanied them;

those ideas or muscular motions which have been frequently excited together, ever afterwards have a tendency to accompany each other.

Of these motions the *associate* seem most to have excited Dr Darwin's attention. He divides them into three kinds; *irritative associations*, as when any part of the extracted heart of a frog is irritated by puncture, the whole heart contracts regularly: *sensitive associations*, or the trains or tribes of motions established by pain or pleasure; and the *voluntary associations*, or those produced by volition.

The activity of this power of volition is supposed to form the great difference between man and the brute creation; the means of producing pleasure and avoiding pain given to man by this power being denied to brutes.

Corresponding to these four classes of motions, there are four classes of ideas; *irritative*, preceded by irritation; *sensitive*, preceded by the sensation of pleasure or pain; *voluntary*, preceded by voluntary exertion; and *associate*, preceded by other ideas or muscular motions.

It has been observed in Hudibras, that

> " ——— A rhetorician's rules
> Serve nothing but to name his tools."

So we find that a considerable part of Darwin's works is taken up in establishing the new meaning which he attaches to terms well understood and long adopted.

We cannot enter more fully at present into the opinions of the Zoonomia, but we shall have occasion to notice some of them in the succeeding part of this article.

49 Opinions and arrangement of Bichat.

Bichat's system, which has made so much noise on the continent, is chiefly founded on the division of life into two kinds, *organic* and *animal;* the former of which is common to all organized beings, while the latter, as its name imports, is peculiar to animals. Each of these two kinds of life may be considered as composed of two orders of functions, which succeed each other in an inverse order. The first of these series in *animal life* commences with external objects, and proceeds towards the brain; the second begins in the brain, and is thence propagated to the organs of motion and voice. In the first order of functions, the animal is passive; in the second he is active. External objects act on the body through the medium of the first; by the second, the body reacts on the external objects.

Two kinds of motion take place in *organic life.* In the first the formation of the body is constantly going on; in the second there is a constant decomposition: hence the elements of the body are continually changing, while the organization continues the same. Organic life is accommodated to the continual circulation of matter. The one order of functions assimilates to the nature of the animal, the nutritious particles received into the system; the other rejects what is useless, or is so much altered as to become noxious. The assimilating order of functions consists of digestion, circulation, respiration, and nutrition; all of which processes the matter received into the body must undergo, before it can become a part of the animal substance. When it has for some time constituted a part of the body, it is taken up by absorption, conveyed into the circulation, and thrown out thence, by cutaneous or pulmonary exhalation, or by some other emunctories. Hence, the second order of organic functions, or disassimilating functions, consist of absorption, circulation, exhalation, secretion, and excretion. The *brain* is the centre of *animal life;* the *heart* of *organic life.*

Bichat considers the proper balance of life to be preserved by the proportion which exists between the action of surrounding bodies, and the reaction of the system. This reaction is greatest in youth, hence the principle of life is at that time in excess. It is least in old age, and then the vital principle is defective. The measure of life is therefore the difference which exists between the efforts of external powers to overturn life, and the internal resistance to support it. The excess of the former shows the weakness of life; that of the latter indicates its strength.

The following table exhibits Bichat's distribution of the organs, or, as he calls them, *appareils*, belonging to *animal* and *organic life*, and to *generation*, which is common to both.

I. Organs of Animal Life.

Organs	1. *Locomotive,*	including	1. The bones and their dependances. 2. The muscles and their dependances.
	2. *Vocal,* including the larynx and its dependances.		
	3. *External sensitive,*	including	1. The eye. 2. The ear. 3. The nostrils. 4. The tongue. 5. The skin and its dependances.
	4. *Internal sensitive,*	including	1. The brain and its membranes. 2. The spinal marrow and its membranes.
	5. *Conducting sensation and motion,*	including	1. The cerebral nerves. 2. The nerves of the *ganglia.*

II. Organs.

II. Organs of Organic Life.

Organs	1. *Digestive.*	including	1. The mouth. 2. The pharynx and *œsophagus.* 3. The stomach. 4. The small intestines. 5. The large intestines. 6. The *peritonæum* and *epiploon.*
	2. *Respiratory.*	including	1. The *trachea.* 2. The lungs and their membranes.
	3. *Circulatory.*	including	1. The heart and its membranes. 2. The arteries. 3. The veins of the general system. 4. The veins of the abdominal system.
	4. *Absorbent,*	including	1. The absorbent glands. 2. The absorbent vessels.
	5. *Secretory,*	including	1. The lachrymal ducts. 2. The salivary and pancreatic ducts. 3. The biliary and splenic ducts. 4. The urinary passages.

III. Organs of Generation.

Organs	1. *Male.*		
	2. *Female.*		
	3. *Produced by this union.*	including	1. The membranes and placenta. 2. The fœtus.

50 Recapitulation. We have now taken such a view of the progressive state of physiological science, as we deemed consistent with the nature and extent of this article. It has taught us that the prevailing spirit of every age has had a marked influence on the productions both of art and science that have appeared during that period; and that physiology has always been impressed with the character of the science that was most prevalent at any particular period. While the doctrines of Aristotle prevailed in the schools, physiology never extended beyond the bounds that had been set to it by Galen; and the belief in occult qualities universally prevailed. When a taste for metaphysical speculations began to gain ground, this science was given over to the most abstract subtilities and absurd fictions. When Des Cartes had reformed the principles of the ancient philosophy, the study of the animal economy, like all the other branches of physics, was fettered by the trammels of the Cartesian doctrines. After the genius of philosophers was directed to chemistry, physiology also took a chemical turn, which it quitted only to take a new direction pointed out to it by the taste for mathematics and mechanical philosophy, which prevailed among all the literary at the end of the 17th and beginning of the 18th century; and now that the study of chemistry is become so general, we see that physiologists are for reducing the functions of the animal economy to the analytical and synthetical operations of the laboratory, and converting the living body into a furnace where a constant combustion is going on while life remains.

We are now to enter on the phenomena of life, and the functions of organized beings; and here we must premise, that in our illustration of these phenomena and functions we shall occasionally refer to every class of living creatures; it being our object rather to give a comparative view of physiology in general, than to confine our remarks to the human economy in particular. Indeed much of the physiology of man has already been given under Anatomy and Medicine; and of that of the inferior animals, we have treated of the physiology of the order *Cete* under Cetology; of that of *Reptiles* under Erpetology; of that of *Fishes* under Ichthyology; of that of *Serpents* under Ophiology.

Chap. I. *Of the General Phenomena of Life.*

51 General idea of life. When we take a general view of the objects of nature, we see that they differ from each other in many important particulars, and we soon find that they may be conveniently divided into two great classes; one capable of growth, nourishment, and reproduction; the other not susceptible of these changes. We perceive that all those substances which are found in the bowels of the earth, and many of those which appear upon its surface, continue for an indefinite time in the same circumstances, until they are acted on by each other, when they undergo certain changes which entirely alter their nature and former properties.

Sulphur, in its natural state, is a solid substance insoluble in water, and possessing little activity when applied to the human skin; but if it be subjected to the action of heat, in contact with atmospheric air, or any other gas containing oxygen, it becomes a fluid, very miscible with water, and of a most corrosive quality, namely sulphuric acid. The hydrogenous gas found in the upper part of mines, would remain for ever uncombined with the oxygenous gas which forms part of the atmosphere in which it floats, were it not subjected to the action of caloric, or electricity in a very concentrat-

General Phenomena of Life.

ed state; but as soon as either of these agents comes in contact with the mechanical mixture of gases, a combination takes place, attended with a tremendous explosion, and the hydrogenous gas disappears.

52 Distinction between organized and inorganic matter.

We find that all the bodies to which we give the name of minerals, possess no power in themselves which can enable them to resist the operation of external agents; each individual of them is composed of a small number of principles, and their texture appears to be made up of independent particles. Every other body in nature, comprehending the almost infinite variety of plants and animals, though under certain circumstances subject to the same changes which take place among minerals, have, when these circumstances do not exist, an innate property by which they are enabled to resist the production of these changes. They do indeed undergo certain alterations, but by these their original habit and essential properties are not changed. From the time that a plant springs from the seed, till it ceases to vegetate, it is perpetually receiving an accession of new matter, and giving out a part of its former composition: but the new matter is assimilated to it, and becomes a part of the plant; the identity of the plant is preserved, though its component parts are perpetually changing. The same in a still higher degree takes place in animals. The individuals of this latter class, comprehending plants and animals, possess peculiar structure, very different from that of the former. Their texture is fibrous, and the fibres arranged and interwoven, so as to form parts called organs, by means of which they carry on certain operations or *functions* necessary for their preservation, or for the reproduction of the species. Hence these have been called *organized* bodies, while the others have been denominated *brute* or *inorganic* matter. See *Natural History*, N° 7.

The component principles of organized beings are much more numerous in each individual than those of inorganic matter, though their absolute number in the former class is smaller than in the latter. In order to present, under a compendious point of view, the distinguishing characteristics of these two classes of beings, we shall give the following table.

The phenomena of inorganic matter are,	Mobility, Repose, Aggregation, Cohesion, Gravitation, Condensation, Dilatation, Combination, Dissolution.	Resolvable into	Inertia, Impulsion, Attraction, Affinity.
The phenomena of organized matter, besides those of inorganic matter are,	Impression, Sensation, Perception, Affection, Sympathy, Action, Locomotion, Digestion, Circulation, Respiration, Assimilation, Accretion, Reproduction.	Resolvable into four general forces,	Sensitive, Motive, Assimilative, and Vital resistance.

The properties of inorganic matter are,	Extension, Gravity, Hardness, Elasticity, Fluidity, Impenetrability, Divisibility, Expansibility, Permeability, Figurability.	The variations or degrees of which distinguish	Crystals, Salts, Metals, Stones, Fossils.
The properties of organized matter, besides those of inorganic matter, are,	Regularity, Individuality, Spontaneity, Sensibility, Contractility, Irritability, Expansibility, Corruptibility.	The variations or degrees of which distinguish	Man, Mammalia, Birds, Reptiles, Serpents, Fishes, Mollusca, Crustacea, Insects, Worms, Zoophytes, Plants.

53 Effects of life.

The differences that are found to prevail between organized beings and inorganic matter, have always been attributed to something of a superior nature, called vitality or life. This term life forms one of those simple ideas which it is difficult to define, and as all understand the meaning of the expression, a definition is the less necessary; but if it be required, it cannot be expressed more accurately than in the language of Bichat, who calls life *the sum of those functions which resist death*. In short, life is best described by the effects produced on a body while it resides in it, contrasted with those appearances which take place in the same body when life is no longer present.

54 Resistance to chemical change.

One of the most general effects of the presence of life is, as we have said, the resistance which living beings are by it enabled to oppose to the operation of external agents; and this is most remarkably seen with respect to temperature. Every living being possesses, in a greater or less degree, the power of preserving nearly an uniform temperature, which is always a few degrees greater than that of the medium in which it lives. In plants, this power seems to exist but in a low degree. Some of the lower animals which inhabit the air, particularly insects, possess it much more completely. The great heat generated in a hive of bees is a familiar illustration of this. In birds this property is very remarkable, the heat of their bodies being greater than that of any other species of animals. The heat of fishes, worms, and of most reptiles, very little exceeds the temperature of the medium in which they reside; but when the water in which fishes live is frozen, they are capable of resisting, for a long time, the consequences of the diminished temperature. The power which many animals possess of resisting high degrees of heat without any considerable increase of their own temperature, seems still more remarkable, and probably led to the fable of the salamander, which was supposed able to endure the heat of fire, and even extinguish it, when thrown in for that purpose.

55 Degrees of vitality.

Life seems to pervade almost every part of a living being. In animals, every part, except the cuticle, hair, and nails, exhibits marks of vitality; but it seems to be distributed

tributed through those parts in a different manner in the various tribes of organized beings. In plants, and in a few of the inferior animals, as the zoophyta, it seems to exist independently in almost every part. A bud, slip, or sucker, torn from the parent plant, and inserted within the bark of another plant, or placed within the earth, in favourable circumstances, vegetates, increases, and in due time becomes a perfect plant, in all respects similar to the parent stock. If a polypus be cut in pieces, each piece lives and grows, till it becomes itself a complete polypus. If a worm be cut in two, so as to leave one part with the head, and the other with the tail, each part becomes a perfect worm, possessing both head and tail. As we ascend, however, in the scale of beings, we find life less equally and independently diffused. A part cut or torn from the body of most animals quickly loses its vitality; but this is lost sooner in some animals than in others. The head of a turtle or a snake is able to bite many hours or even days, after it is severed from the body; and in the former instance, the animal seems for a long time to experience little inconvenience from its loss. The heart of a frog is seen to move many hours after it is cut out.

56
Functions of living beings.

The principal effects of the presence of life appear in the exercise of those functions or actions by which living beings preserve their existence, or reproduce their like.

57
Motion.

One of the most general properties of organized beings is that susceptibility to motion, which is called irritability, which appears essential to life, and is possessed, in a greater or less degree, by every class of organized beings. The motions of plants are sometimes very remarkable, and approach very nearly to those which take place in animals. The stamina of the *cistus helianthemum* are seen to move in various directions when the sun shines on them; the leaves of the *mimosa pudica* (sensitive plant), when touched by the hand, or when irritated by the alighting of an insect on them, immediately contract; the *dionæa muscipula* (Venus's fly-trap), when a fly touches its leaves, closes the thorny fringes with which they are beset, on the presumptuous insect, and crushes it to death; but the motions of the *hedysarum gyrans* are the most remarkable of all those that take place in plants. The leaves of this extraordinary vegetable are seen in constant motion through the greatest part of the day, without the intervention of any apparent external impulse; and even when a branch is cut off and kept in water, the motion of the leaves continues for many hours together. All the plants which grow above the earth, expose their leaves and flowers to the warm sunshine, and when situated in a place which is supplied by light only from one quarter, they gradually direct their branches towards that part by which the light enters. In stormy weather they retract their leaves, and fold up their flowers, and when confined in the dark, their branches retain the position which they had when last exposed to the light.

The motions of many of the lower animals, though sufficiently apparent, are more obscure than those of plants. A muscle or an oyster seems to possess little more motion than is necessary to open and close the valves of its shell, and, no more than plants, has the faculty of conveying itself from place to place. This faculty of locomotion, which in all the higher classes of animals is dependent on the will, will be fully considered in the second chapter.

58
Digestion.

The function which appears to be most universally diffused in living beings, is digestion, (including nutrition) or that by which the substances intended for their nourishment are assimilated to the nature of the body which they enter. This function varies considerably in the different classes. Plants merely attract water from the earth in which they grow, by means of the fibrous parts of their roots, whence it is conveyed by innumerable capillary vessels throughout the whole plant, in which it appears partly to be decomposed, and partly to remain in the state of water, diluting some of the vegetable principles, and thus forming the juices of the plant. In some of the inferior animals, digestion seems to be almost the only function which they are capable of performing. Thus, many of the zoophytes, as the polypi, appear to be almost entirely composed of a stomach, resembling the finger of a glove, into which the aliment is received, the nutritive part extracted, and the excrementitious part thrown out by the same opening. In most other animals, the alimentary canal has two distinct openings, one for the reception of the food, and the other for the ejection of the excrement.

By some animals the food is swallowed entire, and digestion is performed by a simple solution or trituration in the stomach; while in others the mouth is furnished with teeth, or other hard parts, capable of reducing the aliment to a pulpy state, in order to render its further digestion more easy and expeditious. In most animals, the food having undergone some change in the digestive organs, is taken up from them by certain very minute vessels, and carried to every part of the body; but in some it appears rather to exude through pores in the sides of the alimentary canal.

59
Circulation.

The function of circulation, by which the fluids are constantly moved through every part of the body, is not so general as either of the former functions. In plants there is no proper circulation; for although there are numerous vessels by which water enters into the substance of the plant, and in which the peculiar juices of the vegetable move, the motions of these fluids are not uniform, and do not tend towards one centre. The same defective circulation appears in many of the inferior animals, as in zoophytes and insects. As we rise, however, to the higher classes, we find a perfect circulation. In these there is always a peculiar organ from which the fluids are conveyed to the rest of the body, and to which they again return in a perpetual round. In some animals this central organ is single, while in others it consists of two similar organs joined together, from one of which the whole of the fluids proceed through one particular organ in a lesser circulation, and thence return to the other part, before they are distributed to the general system.

60
Respiration.

All organized beings require more or less the presence of atmospheric air for their subsistence, or at least for the due performance of the vital functions. In some, the agency of this fluid is conveyed merely by pores upon the surface; as in plants, in which the leaves absorb the air; and in several of the inferior animals, as insects and worms, over the surface of whose bodies are distributed numerous openings, by which the air enters. In animals of the higher orders there are peculiar organs called

General Phenomena of Life.

called lungs or gills, through which air, or water containing air, enters, and from which its beneficial influence is imparted to the fluids which are circulating through them. In general, these beings exist for a very short time, when deprived of atmospheric air, or when the element in which they live is deprived of oxygen; but in some of the lower classes of animals the absence of oxygen is much less injurious; and there are instances of reptiles in particular having been preserved in a state susceptible of life and motion, while buried for many years in the heart of a tree, or in the middle of a block of stone. Respiration, then, though in general necessary to the continuance of vitality, may, in many tribes of organized beings, be suspended for a considerable time, without the principle of life being entirely destroyed.

61 Reproduction.

A function equally general, and equally indispensible with that of digestion, and one which forms another characteristic of living beings, is the function of regeneration, a function more peculiarly necessary, as all organized beings, though capaple of resisting for a considerable time the operation of external agents, tend ultimately to corruption and decay; and as they cannot, like inorganic matter, be regenerated by a reunion of their component principles, it was necessary that they should possess the capacity of producing, while in existence, a creature similar to themselves, to supply their place in the scale of being.

It has been a very general opinion among naturalists, that all living beings, both plants and animals, originate from seeds or eggs produced by the parent. This, although very generally true, is not a universal fact. Most plants, indeed, with which we are acquainted, appear capable, in their natural state, of producing seeds, which form the embryo of a future plant. But in a great many of them new plants are obtained from buds, slips, or suckers, furnished by the parent. In some animals too, as the polypi, reproduction may be effected by dividing the parent into several pieces; and even the natural generation of these animals is performed by protuberances which grow from the body of the parent, and seem to drop off spontaneously, when capable of an independent existence.

There are two striking differences in the manner by which living beings are generated. In some, two distinct sets of organs are necessary, and by the mutual action of these generation is effected; while in others, as in the instances we have mentioned of the polypus, this act of copulation appears to be unnecessary. Almost all plants possess distinct sexual organs, and in most both male and female organs are situated in the same individual. In these plants the female ovum is impregnated by a very fine powder, which is contained in part of the male organs, and is applied to those of the female. We are fully convinced of the necessity of the vegetable copulation, by observing that the females of those plants which have the sexual organs situated in distinct individuals are not capable of producing fruit, or a least do not produce this in perfection, if they are excluded from the influence of the male; and that an artificial impregnation may be brought about by bringing the male and female organs in contact. Many animals are hermaphrodite; and among these the individuals of some species generate without the assistance of another individual of the same species. This appears to be the case with the bivalve shell-fish. Others again, as snails, and most of the mollusca, which crawl upon the earth, copulate reciprocally, or each individual performs the double office of male and female. In most animals, however, the sexes are distinct, and probably a real hermaphrodite in the superior classes never existed. Another striking difference with respect to generation in animals is the more or less perfect state in which they bring forth their young. A large proportion of animals, among which are the insect tribe, fishes and birds, produce eggs, which are afterwards hatched by the heat of the parent, or by that of the sun. Other classes again, as some of the amphibia, and the whole of the mammalia, carry their young for a certain time within an organ destined for that purpose, from which they are excluded in the state of perfect animals.

62 Sensation.

The last function which we shall here notice, is sensation. This appears to be less general than any which we have hitherto mentioned. It has indeed been supposed by many philosophers and naturalists, that plants possess a degree of sensibility; and this opinion has been lately avowed and strenuously supported by the elegant but enthusiastic author of the Botanic Garden, and the Loves of the Plants. That plants possess a suceptibility of receiving impressions, and in consequence of that of being roused into action by external stimuli, we shall readily admit, and shall hereafter assign to this susceptibility its due importance; but as there is no reason to believe that it ever produces sensation, we must not confound it with the sensibility of animals; nor is the difficulty of explaining some of the functions of vegetables, without resorting to the hypothesis of a vegetable sensorium, a sufficient reason for investing them with this faculty. It has even been doubted whether some of the inferior animals, as the zoophytes, possess this function, as nervous fibres have not yet been detected in their organization. It is probable, that there is a regular gradation in the tribes of organized beings with respect to sensation, as well as the other functions; and though we have not been able to discover all the links of this chain, these will probably, as our knowledge of nature increases, come more into view, and we shall then be able to reconcile many circumstances which we cannot at present comprehend.

With respect to the varieties that take place in the number and degree of the external senses, as possessed by the various classes of animals, we may refer the reader to what has been said on that subject in the first chapter of the comparative part of the article ANATOMY.

63 Duration of life.

The duration of life is exceedingly various. We know that there are animals which live but a few hours, as the insects called *ephemeræ;* and that others, as the *elephant*, the *raven*, and the *pike*, may exist for a century. The term of life allotted to plants is also various; some live only for a year, and are hence called *annual* plants; others exist for two years, and are called *biennial* plants; while a few surpass in longevity any thing with which we are acquainted in animated nature. Thus, the *oak* is said to require 100 years, in order to acquire its full maturity; to retain its perfect vigour for the like term, and to complete at least a third century before it entirely decays. The *chesnut* is a still more remarkable instance of vegetable longevity. The account of the gigantic chesnut on Mount Ætna, given by

General Phenomena of Life.

by Brydone and other travellers, which has existed for many centuries, must be familiar to most of our readers.

We have hitherto considered life as displayed in the exercise of functions; but it may exist independently of this exercise, or it may lie dormant for a considerable time, till called into action by particular circumstances. Every one knows how long a seed or an egg, when excluded from heat, air, and moisture, will retain the faculty of producing a plant or an animal. The only proof we have, that this faculty still exists, is, that when we place the seed or the egg in circumstances favourable to the developement of the embryo which it contains, the process of generation goes on, till the plant or the animal is excluded. We know also, that after an organized being has commenced the exercise of its functions, this exercise may cease for a time, or at least become almost imperceptible, while yet the vital power shall remain susceptible of reviving its activity at a future period. We then say that the animal or vegetable is in a torpid state. On this part of the history of life we shall not enter at present, but shall defer the consideration of it till we come to treat of sleep and death.

The above is a hasty comparative sketch of the functions, exercised by the various tribes of organized beings. It is sufficient to show, that there is in these beings a vital power which completely distinguishes them from brute or inorganic matter.

64 Cause of life.

A question which naturally arises in every thinking mind is, What is the essence of life, or on what does it depend? Though we profess ourselves unable to answer this question in a satisfactory manner, and believe that all who have hitherto attempted to do so, have failed in their attempts, it may be acceptable to most of our readers to know the opinions of the most respectable writers on this abstruse subject. These, therefore, we shall briefly state.

65 Opinions respecting the vital principle.

These opinions have chiefly rested on the question, whether life be an independent, immaterial principle, or merely a physical or chemical modification of matter. We have already, in the historical view which we have given of the progress of physiology, mentioned some of the more remarkable doctrines respecting the principle of life that have been delivered prior to the 18th century; we shall here, therefore, only mention those which have been maintained since that time.

66 John Hunter.

Mr John Hunter, in his valuable treatise on the blood, supposes the principle of vitality to exist in that fluid, or that the blood has life; and has founded this doctrine chiefly on the following proofs. First, It unites living parts, when it is effused between them. Secondly, It becomes vascular like other living parts; its temperature as it flows from the vessel, is always equal in the most opposite temperature in which the body can bear exposure. Thirdly, It is capable of being acted upon by a stimulus, as is the case when it coagulates. Fourth, Paralytic limbs, though deprived of motion and sensation, are yet nourished and preserved alive by the blood circulating through them.

Mr Hunter's idea of the vitality of the blood is merely the revival of one of the oldest physiological doctrines on record; namely, that delivered to the Israelites by Moses, that in the blood is the life of an animal.

67 Goodwin.

Dr Goodwin, in his work on the connection of life with respiration, is of opinion, that the heart is the great seat of the principle of life in all the more perfect animals; and that the contractions of the heart with the ordinary stimulus is the only mark of the presence of this principle; that when the heart contracts under such circumstances, the body is alive; when not, it is dead. Life he therefore defines to be the faculty of propelling the fluids through the circulatory system. According to him, the external concomitant circumstances which operate upon the body in health are heat and respiration, which excite the vital principle to action; and whenever the functions of an animal are suddenly suspended, and the body puts on the appearance of death, it is always in our power to determine whether it be really dead, by restoring the temperature, and by inflating the lungs with proper air. He is of opinion, with some others, that there are no means of determining the absolute deprivation of the vital principle but by the presence of putrefaction.

It has lately become fashionable to consider life as the consequence of certain chemical changes, which are going on in the body; an opinion which is chiefly supported by Hufeland, Girtanner, and Humboldt.

According to Hufeland, life is a chemico-animal flame, to the production of which oxygen is absolutely necessary, and the vital power is the most general and powerful of all the powers of nature. He considers it as the cause of organization, and as possessing the following properties. 68 Hufeland.

1. It has a greater affinity to some organized bodies than to others; thus, the polypus may be cut in pieces without being divested of it, and a decapitated tortoise or a frog deprived of its heart will live a long time after; whilst to the human body, or a quadruped, it would be instant death. According to this physiologist, it is a general rule, that the stronger the affinity between life and an organized being, the more imperfect is the animal; hence the zoophytes, whose whole organization consists in a mouth, a stomach, and a gut, have a life exceedingly tenacious, and difficult to be destroyed. 2. It is in greater quantity in some organized bodies than in others. In general, cold-blooded animals live longer than those with warm blood. 3. It frees bodies from the chemical laws of inanimate matter, and transfers the component parts of a body from the physical or chemical to the organic or living world. 4. It prevents putrefaction, for no organized body can putrefy unless deprived of life.

Humboldt is of opinion, that the degree of vitality depends upon the reciprocal balance of the chemical affinities of all the elementary parts of which the animal body is composed. 69 Humboldt.

Some physiologists of the present day deny the existence of the vital principle altogether, "The idea of life (says Cuvier), is one of those general and obscure ideas produced in us by observing a certain series of phenomena, possessing mutual relations, and succeeding each other in a constant order. We know not indeed the nature of the link that unites these phenomena, but we are sensible that a connection must exist; and this conviction is sufficient to induce us to give it a name, which the vulgar are apt to regard as the sign of a particular principle, though in fact that name can only indicate the totality of the phenomena which have occasioned its formation." 70 Cuvier.

Dr Ferriar, in his observations concerning the vital principle, thinks, that some direct arguments may be brought 71 Ferriar.

General Phenomena of Life.

brought against the general supposition of an independent living principle. These arguments he divides into two kinds, viz. refutations of the general proofs offered in support of the vital principle; and instances of the direct influence of the mind and brain over what is termed the independent living principle. The great proofs for the support of a vital principle, are the contraction of muscles separated from the body on the application of stimulants; the performance of the vital and involuntary motions without any exertion or even consciousness of the mind, and the birth of full grown fœtuses destitute of a brain. In all these cases, something is alleged to operate, independently of the mind, in producing muscular motion.

Dr Ferriar, in answer to the first argument drawn from the contraction of separated muscles, affirms, it may be said, 1st, That the power of contraction, in a separate muscle, is lost before putrefaction takes place, i. e. before the destruction of its texture; but if its vitality depended on its texture, this ought not to happen. 2dly, The power of contraction, in a separated muscle, is strongest upon its first separation, and becomes weaker by degrees; therefore, the contracting power seems to have been derived from some source from which it is detached by the excision of the part. 3dly, Irritation of the *medulla oblongata*, or of the nerves supplying particular muscles, occasions stronger contractions than irritation of the muscles themselves; and Dr Whytt furnishes an experiment on a frog, directly proving, that the action of separated muscles depends upon the nervous energy. 4thly, Dr Haller himself is obliged to make on this subject a concession sufficient to destroy his favourite hypothesis of the *vis insita*. 5thly, When a paralytic limb is convulsed by the electric shock, the motion never takes place without the patient's consciousness. In this case there is no distinction between the vital principle, and that exertion which in voluntary motion is always attributed to the mind. See Chap. iii.

In answer to the second argument, in favour of a vital principle, drawn from the performances of the vital and other involuntary motions, Dr Ferriar contents himself with only observing, that, allowing the organs of those motions to be supplied with nervous energy, their motions may be very well accounted for by the stimulus of their contained fluids.

The force of the third argument, drawn from the want of a brain in full-grown fœtuses, is taken off by Dr Whytt, who remarks, that as the heart is sometimes wanting in full-grown fœtuses, the argument would equally prove, that the heart is not necessary for the continuance of circulation, as that the brain is not necessary to the support of the system. Accordingly, fœtuses born without a brain do not, in general, survive birth.

Besides the general supposition of an independent living principle, an inference has been drawn from facts, of a nervous energy independent of the brain. By this term is meant, that condition derived from the brain to different parts of the body, by means of which they become capable of motion. To show, by direct proof, that there is no independent vital principle, Dr Ferriar observes, 1. That it is justly urged by Dr Monro against the doctrine of the *vis insita*, that there is too much design in the actions of different muscles, affected by different *stimuli*, to be the effect of mere mechanism. Thus, when the hand or foot is burnt, or otherwise suddenly injured, the muscles on the part immediately stimulated are not thrown into action, nor the muscles on the side irritated, but their antagonists contract immediately and strongly. Now, if the instantaneous action be in this case chiefly produced by an effort of the mind, the supposition of a distinct vital principle is superfluous: if it be said to be produced by a living power independent of the mind, then there must be a rational power in the body independent of the mind, which is absurd. 2. The state of the vital and involuntary motions is considerably affected by the state of the mind, which equally disproves the existence of a separate vital principle, and proves the dependence of the nervous energy upon the brain. 3. Madness, it is well known, is frequently produced by causes purely mental, and in persons apparently in good health; and, as the patient's sensibility to very powerful stimuli is much diminished in maniacal cases, they afford another proof of the subordination of the nervous energy. 4. It has been observed, that in paralytic cases, motion is frequently destroyed, while sense remains. As the cause of palsy almost always resides in the brain, this fact appears equally inexplicable on the opinion of a distinct living principle, or of a nervous energy, independent of the brain. 5. When nerves are regenerated, after being cut through, sensation and voluntary motion are not always restored to the parts beneath the division: the restoration was never made in Dr Monro's experiments. But, on the supposition of a distinct nervous power, the nerve, after its reunion ought to resume all its offices. 6. Dr Whytt asserts, that when the spinal marrow of a frog is destroyed, after decollation, no contraction can be excited in the limbs, by cutting or tearing the muscles. Such are the facts and arguments which Dr Ferriar brings against the opinion of a distinct living principle; and he thinks, that their investigation appears to lead us back to the brain as the source of sensibility and irritability.

72 Rush.

In the life of Dr John Brown, we have given an account of the doctrine, of life being a forced state. This doctrine appears to have been first delivered by Dr Cullen, though he afterwards retracted it. Of late Dr Rush of Philadelphia, in his *Lectures on Animal Life*, has advanced many arguments in favour of this doctrine. He includes, in animal life, three properties as applied to the human body, viz. *motion*, *sensation*, and *thought*; and these, when united, compose perfect life. It may exist without thought or sensation; but neither sensation nor thought can exist without motion. He affirms, that the lowest degree of life exists even in the absence of motion. He first considers animal life as it appears in the waking and sleeping state, in a healthy adult; and afterwards inquires into the modification of its causes in the fœtal, infant, youthful and middle states of life, in certain diseases, in different states of society, and in different animals, and lays down the following propositions:

1. Every part of the human body, the nails and hair excepted, is endued with sensibility or excitability, or with both.

2. The whole body is so formed and connected, that impressions made in the healthy state upon one part excite

General Phenomena of Life.

excite motion, or sensation, or both, in every other part of the body,

3. Life is the effect of certain stimuli acting upon the sensibility and excitability, which are extended in different degrees to every external and internal part of the body; and these stimuli are as necessary to its existence as air is to flame.

He continues to observe, that the action of the brain, the diastole and systole of the heart, the pulsation of the arteries, the contraction of the muscles, the peristaltic motion of the bowels, the absorbing power of the lymphatics, secretion, excretion, hearing, seeing, smelling, taste, and the sense of touch, even *thought* itself, are all the effects of stimuli acting upon the organs of sense and motion.

These have been divided into external and internal.

1. The external are light, sound, colours, air, heat, exercise, and the pleasures of the senses.

2. The internal stimuli are food, drinks, chyle, blood, tension of the glands which contain secreted liquors, and the exercise of the faculties of the mind.

Life, therefore (according to the hypothesis of Rush), even thought itself, is merely a quality residing in the component parts of a material system, dependent upon a peculiar organization, by which it is enabled to act, or in some ways to move on being stimulated or excited. Hence life can never be inherent in a simple uncompounded substance, nor in a particle of animal matter; and if the stimulus be withheld from a living system beyond a given time, all motion, sensation, and thought, must necessarily be extinguished.

73
Vital principle supposed by some to be divisible.

Instead of one vital principle, some physiologists have supposed the existence of several in the same body; and from the phenomena that take place in some organized beings, as the reunion of parts that had been separated, the reproduction of others that have been lost, and the separate existence of the divided parts of some worms and zoophytes, it was formerly the opinion of a celebrated lecturer on anatomy, that the vital principle was really divided. From more considerate and extensive inquiry, however, he is now of opinion, that the irritability on which these phenomena depend, is never the direct or immediate operation of the vital principle, but only the consequence of its operation; and in no case exclusively the consequence, but the consequence likewise of other operations proceeding from a number of different causes: and hence it is that a vital principle may often exist where it cannot operate in a sensible manner, from the want of auxiliaries; and hence it is, likewise, that its effects may often be continued, at least for a while after its departure.

With regard to the portions of plants and polypi that continue to live in a separate state, assume the form of their respective species, and propagate their kind, they will be found, on a close examination, to have been originally complete systems; many of the plants and many of the polypi that were usually considered as simple individuals, not constituting one animated system, but rather a congeries of animated systems,—a congeries, too, which after all is nothing more than a species of society, where animated beings are associated together for mutual protection; such as we see among men in a city; among bees in their cells, which, in point of form, are similar to plants †.

† *Barclay on Muscular Motions*, p. 265.

Chap. II. *Of Sensation.*

Of Sensation.

74
Necessity of sensibility to organized beings.

As all living beings are so related to each other, and to the inanimate objects of nature, as to be capable of deriving benefit, or receiving injuries, from the one or from the other; it seems necessary that they should possess the faculty of perceiving the proximity of the beneficial or injurious object, that they may avail themselves of the benefit which it holds out, or avoid the danger which it threatens. Accordingly, we find that all organized beings enjoy in some degree the capacity of *receiving impressions*, which we think is proved by the motions which take place in them when affected by external agents. When a plant expands its flowers to the sun, or turns, as it were, its back to the blast; when it stretches out the fibres of its roots to imbibe the distant moisture, or directs its branches to the only chink by which it can receive the light of day; we think these motions are the consequence of that capacity of *receiving impressions*, or of being roused to action by *stimuli*; we think that this may be conceded, without having recourse to the influence of mind, or even the medium of a nervous system; we do not believe that the grass we crush beneath our feet is sensible of pain, nor do we suppose with the poet, that

—— " E'en the poor beetle that we tread on
In mortal sufferance feels a pang as great
As when a giant dies."——

but we are of opinion, that even in the lowest tribes there is a degree of that faculty, which in the higher orders of animals we call *sensibility*, and which we shall here, after a lecturer on the animal economy in London, denominate *sensitivity*. This inferior degree of the sensitive faculty we shall suppose to be possessed by plants, zoophytes, and animalcules, or those organized beings in which we can perceive no marks of a nervous system; while we shall confine the term *sensibility* to all other classes of animals. 75 Sensitivity.

These faculties we consider as qualities of living *bodies*, while we regard sensation, like perception, as a quality of *mind*. We leave it to the metaphysician to mark the line of distinction between sensibility and sensation, and to show how the one arises from the other. See METAPHYSICS, Part I. chap. 1.

The organs of sensation consist of the brain properly so called, the cerebellum, the medulla oblongata, the spinal marrow, the nerves, and ganglia; together forming what is called the *nervous system*. These parts in the human body have been described under ANATOMY. For an account of these organs in the inferior animals, we must refer to the lectures of Cuvier, vol. ii. or the Comparative Anatomy of Blumenbach. 76 Nervous system.

In respect of *sensibility* the animal is only passive; but when *sensation* is produced, he becomes active, in as much as the organs of the external senses are then brought into action. It is by means of these senses that the animal receives intelligence from without. We shall therefore examine these before we mention the phenomena of sensation in general.

1. *Of Feeling.*

The most general of all the senses, and the most wide- 77 Feeling.

ly

ly diffused over the body of an animal is that of touch or feeling. Animals that possess scarcely any other sense seem always to have that of *touch*. It is doubtless by this that *polypi*, *actiniæ*, and other water animals, perceive the approach of their prey, or are warned of impending danger, from the agitation of the water that is communicated to their bodies. Indeed so general is this sense, that some physiologists think we may reduce all others to it as a genus; and suppose that *smelling*, *tasting*, *hearing*, and *seeing*, are only species of *feeling*. This reference is not uncommon in ordinary speech, as it is not unusual to talk of *feeling* a *smell*.

78 Use. By *touch*, taken in its ordinary limited sense, we perceive the more striking external qualities of bodies, as *figure*, *hardness*, *softness*, *roughness*, *smoothness*, *moisture*, *dryness*, *heat*, *cold*; of all which, except figure, we could scarcely form any idea by the other senses. There is probably no sense that can so well supply the place of others as that of *touch*; and it is particularly acute in those who have lost their sight or hearing. See the article BLIND, especially the Appendix.

79 Organs. The organs of touch are the skin and its productions, or rather the nervous papillæ (see ANATOMY, N° 76.) that form so large a part of the true skin. As many animals, however, have the body so enveloped in a scaly, shelly, or hairy covering, as to prevent the actual contact of the body by external objects, there are other organs that seem destined to fulfil this office. In man, the points of the fingers and the lips are the most delicate feeling organs; in many quadrupeds too, the lips seem to possess an exquisite sensibility, and in some, as the *rhinoceros*, the upper lip is lengthened out as if to serve the purpose of a hand. The prolonged snouts of the *tapir*, the *shrew*, the *mole*, and the *hog*, seem to answer the same purpose; and the exquisite sensibility and flexibility of the trunk of the elephant is well known to fit that organ for almost all the purposes to which the human hand can be applied. The tail, in some species of *monkey*, *opposum*, and *ant-eater*, and in some reptiles, seems to possess a high degree of sensibility. In some animals, as the *cat*, the whiskers are employed as organs of *feeling*, as we know that these are erected when the animal is passing through a narrow hole. Several species of fishes have *cirri* and *tentacula*, which they seem to use as fingers in ascertaining the approach of their prey; and in insects, the *antennæ* and the *palpi* are evidently organs of feeling, as are the arms, the tufts, and tentacula of *sea-stars*, *sea-urchins*, *actiniæ*, *medusæ*, and many zoophytes.

80 Nature of touch. Most of the actions of external bodies on the surface of the animal body, are merely mechanical, though the sensations which they communicate may often be the effects of a chemical change in some of the feeling organs, and this change can be produced only in consequence of the power of simple pressure, to form or destroy some of the combinations that take place in the animal system. The sensations which appear most evidently to arise from a chemical change in the organs, are those that give notice of a change of temperature. When a body that has a temperature below that of the animal, comes in contact with the surface of this latter, we know that it abstracts from that surface a part of its caloric, as by the contact it gradually acquires the temperature of the animal; unless, indeed, it be so large and so cold as altogether to destroy life. As, however, the resistance which the animal body gives to a too great change of temperature, generally confines this change to the surface of the body; there must be something more than a mechanical or a chemical action, or the sense of feeling must depend chiefly on the vital principle.

As the sense of feeling, from its general diffusion, may be considered as the most essential of all the senses; its degrees of perfection have considerable influence on the nature of different animals. 81 Universality of feeling.

Of all *vertebral* animals, man seems to possess this sense in the most perfect degree; but among the *invertebral* animals, the touch seems to improve as the other senses degenerate; and those animals which appear to have no other sense, possess this in so exquisite a degree that they seem to feel even the light.

Dr Darwin thinks it probable, that the animal body is furnished with a distinct set of nerves for the sensation of *heat* and *cold*. We do not see the necessity of this, as we think that this sensation is very naturally reducible to that of *feeling*.

To this head naturally belongs the consideration of what parts of the human body possess sensibility, and what are insensible. This discussion is curious, and some time ago exercised the ingenuity of two very able physiologists, Haller and Whytt; between whom it gave rise to a long and warm dispute. We cannot pretend to enter into the merits of this controversy, for an account of which we refer our readers to Dr Whytt's *Physiological Essays*, and to the *Principes de Physiologie* of Dumas, tom. ii. part iii. sect. 1. chap. 1. 82 Sensibility of the animal body.

The general result seems to be, that many parts will appear sensible or insensible, according to the nature of the stimuli applied to them, and that many of those parts which in their natural and healthy state appear insusceptible of pain, are when inflamed or otherwise altered by diseases, highly sensible; and that the brain, which is considered as the centre of all sensation, and the puncture or laceration of which is attended with most distressing symptoms in other parts, is to ordinary stimuli as insensible as the cuticle or the nails. See also on this subject, Bichat "Anatomie Generale," tom. i. p. 161—167.

The principal morbid affections of this sense, are *pain*, *itching*, and *want of feeling*; for an account of which see MEDICINE, N° 77. The functions of the skin, independently of its use as an organ of touch, will be considered in two of our succeeding chapters.

2. *Of Tasting*.

This sense is the most nearly allied to feeling of any of the other senses, and therefore very properly comes under our consideration after that sense. 83 Tasting.

The principal organ of taste is the tongue, especially at its upper surface, point, and edges; but it also extends to the lips, the palate, and the *velum pendulum palati*. The tongue is not absolutely necessary to taste, as appears from a case mentioned by Jussieu, of a person, who had only a fleshy tubercle in place of a tongue, and yet possessed the sense sufficiently perfect. 84 Organs.

The several parts of the organs of taste are not equally sensible to every sapid body; the tongue seems to be more particularly affected by saline and saccharine substances, chiefly, however, at its upper surface; the lips are said to be 85 Different organs variously affected.

be most susceptible of the taste of *hellebore*, the palate of *belladonna*, and the gullet of *wormwood*. The *momordica elaterium* is said chiefly to affect the back of the tongue, and *colocynth* its middle.

86 On what the perfection of taste depends.

The greater or less perfection of this sense depends much on the softness, flexibility, and moistness of these parts. As man seems to possess these qualifications in a more eminent degree than most other animals, so, in the natural unsophisticated state of the tongue, he probably enjoys the benefit of taste much more highly than they. Such is the case with all young children, and with the peasant, whose simple fare appears to be eaten with a much greater relish than all the delicacies of the voluptuary, who must have recourse to various stimuli to enable him to derive gratification from even the daintiest viands (A).

Taste seems to be more exquisite when the sapid body is strongly pressed between the tongue and the palate. Taste is also rendered more acute when the tongue is stimulated by various condiments, as *pepper*, *mustard*, which even, when not taken in such quantity as to be very perceptible themselves, evidently increase the relish of the dishes which they season. Much also depends on the nature and state of the bodies that are applied to the organs of taste. These must, in the first place, be either fluid, or capable of solution in the saliva. They must also possess some saline or acrid quality, to render them capable of acting on the nervous *papillæ*. It was formerly supposed, that saline bodies alone possessed the power of affecting the organs of taste; and it was conceived by Bellini, that the different flavours of saline bodies depended on the figure of their crystalline particles. M. Dumas has taken considerable pains, and has advanced several arguments, to show the absurdity of this hypothesis; and we think has treated it with more seriousness than it deserves. That the different sensations which sapid bodies excite in our organs of taste, depend chiefly on a difference in their chemical nature, must, we think, be allowed, and some have gone so far as to suppose, that the sensation depends on some chemical affinity between the sapid body and the nervous fluid.

87 Modifications of taste.

The impression which sapid bodies make on the organs of taste is modified by age, sex, temperament, and habit. We know that children are particularly pleased with sweet things, while high seasoned dishes and vinous liquors are more palatable to people of a more advanced age. Women, from various causes, especially during pregnancy, and when labouring under hysteric affections, have often very singular tastes. People of a warm and a mobile constitution are often affected by flavours that are almost insensible to others; and custom will render palatable many substances, which, when first tasted, are rejected with disgust.

88 Uses of taste.

Besides the gratification afforded to animals by the sense of taste, this is supposed to afford one of the principal means of distinguishing between wholesome and deleterious substances. Indeed, with respect to the inferior animals, this discriminating sense is seldom known to fail, and in this instance, they are superior to man, who is often deceived. There are many poisonous herbs, the fruits or roots of which have a taste not unpleasant, but which cannot be eaten with impunity.

On the morbid affections of taste, see MEDICINE, N° 48.

3. *Of Smelling.*

The sense of smelling, like that of taste, is nearly allied to feeling, and is one of those by which we become acquainted with the mechanical and chemical properties of external bodies. It is caused by volatile particles flying off from odorous bodies, and diffused or dissolved in the atmosphere, in union with which they enter the nostrils and affect the nerves of the smelling organs. 89 Smelling.

It is difficult to ascertain what are the essential organs of smelling. We know that in most animals which breathe through lungs or gills, there is either a nose, or there are certain holes that serve the purpose of nostrils; but in many animals there is nothing similar to these, and yet there is every reason to believe that they possess the sense of smelling in an exquisite degree. 90 Organs.

Insects discover their food at a distance. Butterflies seek their females, even when inclosed in boxes; and as they are liable to be deceived by resemblance of colour, it is evident that these insects are guided in many circumstances by the sense of smell. Thus the flesh-fly (*musca vomitoria*) lays its eggs on plants that have a fœtid smell, imagining that it places them on corrupted flesh, and the larvæ which are thus produced perish for want of their necessary food.

As the organ of smell, in all animals which respire air, is situated at the entrance of the organs of respiration, the most probable conjecture that has been proposed respecting its seat in insects, is that of Baster, since revived by several naturalists, who placed it in the mouths of the tracheæ or air tubes. Besides many other reasons that might be stated in support of this opinion, we may observe, that the internal membrane of the tracheæ appears very well calculated to perform this office, being soft and moistened, and that the insects in which the tracheæ enlarge, and form numerous or considerable vesicles, are those which seem to possess the most perfect sense of smelling. Such are all the *scarabæi*, the *bees*, *flies*, &c.

The antennæ, which other anatomists have supposed to be the seat of smelling in insects, do not appear to Cuvier to possess any of the requisites for that organ.

The *mollusca*, which respire air, may also possess this sensation at the entrance of their pulmonary vessels; but it is not necessary to search for a particular organ of this sense in them, as their whole skin appears to resemble a pituitary membrane. It is everywhere soft, fungous, and is always moistened by a great quantity of muscous matter. Finally, it is supplied with numerous nerves, which animate every point of its surface.

The

(A) It is generally supposed, that the sense of tasting is more acute in some of the inferior animals than in man; an opinion which is founded chiefly on the greater size and number of the *papillæ* of the tongue in those animals. It is scarcely possible to decide this point; but we should conceive, from the infinite variety of substances that are occasionally subjected to the human palate, and from the extreme delicacy of taste displayed by some individuals, that man has the advantage of his brute neighbours in this sense.

Of Sensation.

The worms and soft zoophytes, and all the polypes, are probably in the same situation. It cannot be doubted but that these animals enjoy the sense of smell. It is chiefly by it that they discover their food, particularly the species that have no eyes. Aristotle remarked, that certain herbs, which have a strong odour, were avoided by *cuttle-fishes* and the *octopus*.

91 Nature of odours little understood.

Of all the substances which affect our organs of sensation, odours are the least understood, though the impressions which they make on the animal body appear to be most powerful and extensive. Some bodies are always odorous, because the whole or a part of their substance, being volatile, it is constantly flying off: others become odorous, only under certain circumstances; as when a body containing a volatile principle in its composition is decomposed by another that has a less affinity for that principle, e. gr. when *muriate of ammonia* is decomposed by quicklime.

Odours seem to be propagated in the air, much in the same manner as one fluid is diffused through another. Their motion is not direct like that of light, nor is it rapid or susceptible of reflection and refraction like light and caloric. The odorous particles of volatile bodies may enter into combination with different substances, by chemical affinity, and thus lose their original properties. In this way the effluvia of putrid meat are destroyed by fresh burnt charcoal, and the noxious exhalations from pestilential apartments are removed by the vapours of nitric or muriatic acid.

These circumstances seem to prove that each smell is occasioned by a particular substance floating in the atmosphere. There are others, however, which appear to indicate that odour is not always produced in this manner.

Several bodies yield a strong smell for a great length of time, without sustaining any sensible loss of substance; such, for example, is musk. Some odours are perceived when no evaporation can be observed, as the smell which arises from the friction of copper, that produced by the fusion of a great number of bodies, and even by the melting of common ice. In other cases, real evaporations produce no sensible odour; this may be remarked on the disengagement of several gases, and even on the ordinary evaporation of water. Perhaps these phenomena prove only that the force of sensation is not proportional to the quantity of the substance by which it is excited, but that it depends on the nature and degree of the affinity of that substance with the nervous fluid *. The action of the greater part of odorous substances on the nervous system, is rendered manifest by a number of other effects besides the sensation of smell; some produce faintings, others giddiness, or even convulsions. Some, on the contrary, serve to remove these disorders: indeed the greater part of medicines act in general rather by their volatile and odorous parts, than by their other principles; and afford new proofs of the influence exercised in the animal economy by the gaseous and impalpable substances, the greater part of which are doubtless still unknown to us.

* *Cuvier.*

We know not whether odours have a peculiar vehicle, besides the matter of heat, which is common to them all in their quality of vapours or elastic fluids. We cannot explain why odours are agreeable or disagreeable to us, nor why those that are disgusting to us appear pleasing to other animals, and *vice versa*. Though man and other animals are generally pleased with the odour of those substances which serve them as food; yet when their appetite is satisfied, this odour often becomes displeasing to them. On the contrary, some animals appear to have a passionate fondness for strong smelling substances which seem altogether useless to them. Thus cats are extremely fond of *cat-mint*, and the fresh roots of valerian. In general, those odours which are most disagreeable indicate that the substances from which they proceed are injurious. Thus venomous plants, putrid flesh, and poisonous minerals, have commonly an unpleasant odour. This rule, however, is not universal; and the sense of smell, like that of taste, is not an unerring guide to man, whatever it may be to other animals.

It appears that the effluvia of odorous bodies are capable of diffusing themselves through water as well as air; for when these substances are thrown into water as bait for fish, we find that these animals are attracted by the smell from a considerable distance.

92 Comparative physiology of smelling.

The comparative physiology of this sense is very curious, though we cannot explain the reason of the differences that we find to take place in the various tribes of animals. Man in a state of civilized society, where he may have recourse to a great variety of means by which to distinguish the properties of bodies, has less occasion for acuteness of smell; but we know that savages are in that respect greatly his superiors. Their smell is so acute, that like a blood-hound, they can scent their enemy to a great distance, and pursue his track with almost certain success. Among birds and beasts of prey we also find that acuteness of smell is a very general property. Hyænas, wolves, vultures, and ravens, can distinguish the putrid carcases on which they feed many miles off; and it is asserted by naturalists, that jackalls hunt in packs, and follow their game like hounds by the scent. There is a curious diversity in this respect among birds, some having this sense very acute, others very blunt. We are told by Gattoni *, that the cock is scarcely affected with the smell of ammonia or hartshorn, while the duck is said to avoid all powerful odours whether agreeable or otherwise. We are not sufficiently acquainted with the nature of the olfactory membrane, nor with that of the nerves distributed to it, to enable us to form an opinion respecting the degree and the kind of sensations they procure to different animals. It may, however, be at first sight presumed, that all things in other respects being equal, the animals in which the olfactory membrane is most extensive, enjoy the sensation of smell most exquisitely; and experience confirms this conjecture. It would be curious to learn why the animals which possess the sense of smell in the highest degree, are precisely those which feed on the most fetid substances, as we observe in *dogs* which eat carrion.

* *Scarpa de Auditu et Olfactu.*

Of Hearing.

93 Hearing.

The sense of *hearing* is more important than any which we have yet noticed, but it appears to be less generally diffused.

By means of it we become acquainted with those properties of bodies which fit them for making sensible impressions on the air, as hardness, elasticity, &c.; and these impressions on the air, when communicated to the organs of hearing, convey to our mind the ideas of sound.

By

By this sense we derive two of the highest gratifications that we are capable of enjoying, viz. the pleasures of conversation and of music; and in this way most animals hold intercourse with each other.

94 Organs. The organs of hearing differ exceedingly in the various classes of animals. The *human* ear and its appendages have been described in ANATOMY, Part I. chap. vi. sect. 4.; and for an account of these organs in other animals, we must refer to *Cuvier's Lectures*, vol. ii. or the *Comparative Anatomy* of Blumenbach, chap. xx. Red-blooded animals without exception have evident auditory organs; and analogous parts are found in many of the white-blooded. In a great number of the inferior classes, however, no such parts have been ascertained, though it is certain that many of them do really hear. In all those in which these organs have been detected, there is always found a *gelatinous pulp*, covered with a fine, elastic membrane, and in this *pulp* the ramifications of the auditory nerve are lost. It is therefore, highly probable that the *seat* of hearing resides in the minute nervous fibres that are distributed through the pulp, and that this latter is the medium by which sounds are communicated from the percussed air. We may form a tolerably just idea of the manner in which this pulpy substance is connected with the external movements that are the cause of sound; for this quivering jelly will readily receive the concussions of the air or water that are transmitted to it from the vibrations of sonorous bodies, and communicate them to the nervous filaments. Thus far only can we trace the motion of sound; but the steps by which this motion is carried on till the perception of sound is produced in the mind, are equally unknown to the anatomist and the metaphysician.

95 Varieties of sound. The philosophy of sound has already been treated of under ACOUSTICS. It is necessary here to remark only, that the qualities of sound may be distinguished into *force*, depending on the extent of the vibrations of the body from which the sound proceeds; *tone*, depending on the velocity of the vibrations; *resonance*, arising from the intimate composition of the sonorous body; *simple modulation of voice*, and *articulations*.

96 Comparative physiology of hearing. The human ear can distinguish all these different qualities with relation to one sound; this distinction is made with wonderful accuracy, by persons who frequently exercise that faculty, and particularly by professional musicians. The other mammalia exhibit proofs that they are capable of distinguishing the qualities of sound which relate to speech, that is to say, *simple vocal modulations* and *articulations*: for we may observe daily, that they remember the sound and signification of several words. Some are strongly affected by certain sounds. Acute tones produce a painful sensation in *dogs*, and we also observe that these animals are terrified by violent noises; they therefore distinguish these two properties. Birds have a feeling, no less exquisite, of *voice*, *tone*, *articulation*, and even *resonance*, since they learn to sing with great correctness; and when their vocal organs permit them, can completely counterfeit the human speech, with all the modifications practised by the individuals they imitate.

As to cold-blooded animals, it is well known that several of them call each other by certain sounds, and that others, which are incapable of producing sounds, can at least understand them, as *carps*, which appear when the noise of a bell indicates to them that they are to be fed, &c.; but we know not what qualities of sound they distinguish, and how far, in this respect, the delicacy of their sense of hearing extends *.

* Cuvier Comp. Anat. vol. ii. sect. 13.

For the morbid affections of hearing, see MEDICINE N° 80.

5. *Of Seeing.*

97 Seeing. As we ascend from the simpler to the more complex senses, we find a greater scope for description and observation; but we also find our physiological difficulties increased. The sense of touch, being the most simple of all the senses, requires but a simple organization, and is the most widely diffused; that of vision, on the other hand, is the most complex, and requires for its mechanism, a more elaborate set of organs. There is not, in the whole animal structure, a more curious and admirable organ than the eye, whether we contemplate it in its most perfect state in the human body, or in its most simple conformation, as it appears in the horn of a snail.

98 Organs. The anatomy of the human eye has been sufficiently described in the article ANATOMY, Part I. chap. vi. sect. 5.; and if our readers desire a fuller account of this organ, we may refer them to the elegant work of Professor Soemmering. The structure of the eye in the inferior animals is well described in Cuvier's twelfth lecture, and in Blumenbach's Comparative Anatomy, chap. xvi. We shall extract from the former a description of the eyes of insects and crustaceous animals, as being among the most curious and least known subjects of comparative anatomy.

"The structure of the eye of insects is so very different from that of other animals, even the mollusca, that it would be difficult to believe it an organ of sight, had not experiments, purposely made, demonstrated its use. If we cut out, or cover with opaque matter, the eye of the *dragon fly*, it will strike against walls in its flight. If we cover the compound eyes of the *wasp*, it ascends perpendicularly in the air, until it completely disappears; if we cover its simple eyes only, it will not attempt to fly, but will remain perfectly immoveable.

"The surface of a compound eye, when viewed by the microscope, exhibits an innumerable multitude of hexagonal facets, slightly convex, and separated from one another by small furrows, which frequently contain fine hairs, more or less long.

"These facets form altogether a hard and elastic membrane, which, when freed of the substances that adhere to it posteriorly, is very transparent.

"Each of these small surfaces may be considered either as a cornea, or a crystalline; for it is convex externally, and concave internally, but thicker in the middle than at the edges, it is also the only transparent part in this singular eye.

"Immediately behind this transparent membrane there is an opaque substance, which varies greatly as to colour in different species, and which sometimes forms, even in the same eye, spots or bands of different colours. Its consistence is the same as that of the pigment of the *choroides*; it entirely covers the posterior part of the transparent facets, without leaving any aperture for the passage of the light.

"Behind this pigment we find some very short white filaments, in the form of hexagonal prisms, situated close to each other, like the stones of a pavement, and precisely

Of Sensation.

precisely equal in number to the facets of the cornea; each penetrates into the hollow part of one of these facets, and is separated from it only by the pigment mentioned above. If these filaments are nervous, as in my opinion they appear to be, we may consider each as the retina of the surface behind which it is placed: but it will always remain to be explained, how the light can act on this retina, through a coat of opaque pigment.

"This multitude of filaments, perpendicular to the cornea, have behind them a membrane which serves them all as a base, and which is consequently nearly parallel to the cornea; this membrane is very fine, and of a blackish colour, which is not caused by a pigment, but extends to its most intimate texture; we observe in it very fine whitish lines, which are tracheæ, and will produce still finer branches, that penetrate between the hexagonal filaments, as far as the cornea. By analogy, we may name this membrane the *choroides*.

"A thin expansion of the optic nerve is applied to the posterior part of the choroides. This is a real nervous membrane, perfectly similar to the retina of red-blooded animals; it appears that the white filaments, which form the particular retinæ of the different ocular surfaces, are productions of this general retina, which perforates the membrane I have named choroides, by a multitude of small and almost imperceptible holes.

"To obtain a distinct view of all these parts, it is necessary to cut off the head of an insect that has the eyes large, and dissect it posteriorly; each part will then be removed in an order the reverse of that in which I have described them.

"In the cray fishes, in general, the eye is situated on a moveable tubercle. The extremity, which is rounded on every side, and sometimes elongated into a cone, when viewed by a glass, presents the same surfaces as the eyes of insects. When we cut this tubercle longitudinally, we observe that the optic nerve passes through it in a cylindrical canal, which occupies the place of its axis. Arrived at the centre of the concavity of the eye, it forms a small button, which detaches very fine filaments in every direction; at a certain distance these filaments meet the choroides, which is nearly concentrical with the cornea, and covers the spherical brush of the extremity of the nerve, like a hood. All the distance between the choroides and the cornea is occupied, as in insects, by white filaments, closely arranged in a perpendicular direction to each other, and which have the extremity next the cornea also coated with a black pigment.

Cuvier's Lectures, vol. ii.

"These filaments perforate the choroides, and are continuations of those produced by the button, which terminates the optic nerve."

99 Immediate seat of vision probably the retina.

The immediate seat of vision is still in dispute; but it appears to be the expansion of the optic nerve upon the inner coat of the eye. The other parts of that organ serve to collect, refract, absorb, and sometimes even reflect, the rays of light, according as these operations are required for the distinct vision of any particular animal. Those animals that seek for their prey during night, have a pupil that is very dilatable, and have very little of that dark substance called *pigmentum nigrum*, that lies between the retina and the choroid coat in diurnal animals. Thus, the former have their eyes better adapted to receive and to retain the feeble rays of light, and thus possess a great advantage over the animals which they pursue, whose eyes are calculated for seeing best in a strong light.

The subject of vision has been so fully considered under OPTICS, Part I. sect. 5. that it is unnecessary for us to give any detailed account of it here. We shall therefore merely enumerate the principal phenomena. 100 Phenomena of vision.

1. The rays of light proceeding from luminous bodies, are collected by the cornea; variously refracted by the aqueous, crystalline, and vitreous humours, till they meet in a point (in perfect vision) in the retina, from which the sensation conveyed to the brain, excites there the ideas of light, colour, and other qualities of extreme objects, of which the eye is capable of judging.

2. The image of the object thus pictured on the retina, is inverted, though the mind is habituated to perceive it as if it were erect.

3. There is a certain point within the eye where the retina is deficient, and here the luminous rays make no impression.

4. The eye is calculated to see objects most distinctly at certain distances or foci, though these distances vary considerably in different species, and different individuals. A person of ordinary sight can read a middle-sized print most distinctly at the distance of about eight inches. Those who require a less distance are near-sighted, or *myopes*, and in them the point of divergence of rays is before the retina. Those who require a greater distance are long-sighted, or *presbyopes*; and in these the point of divergence is behind the retina.

5. In those animals that have two eyes, an image of a luminous object is formed in each, though the mind is accustomed to unite both images into one. In strabismus or squinting, the two eyes not being similarly directed, do not concur in producing a single object.

6. Though the images of many objects are impressed on the retina at the same time, the mind can attend distinctly to only one of them.

7. In perfect vision, the pupil contracts or dilates according to the greater or less quantity of light that is present.

8. When the eye has looked steadily for some time on a circumscribed space, of a particular colour, as a piece of red paper placed on a white ground, it perceives a border of a different colour surrounding the original spot. This surrounding colour is called the *accidental* colour of the former, and differs according to the colour of the original spot. In the present instance it is green, or bluish-green. The other natural colours are attended by the following accidental colours, viz. ORANGE, by *blue*, with nearly an equal proportion of *indigo*; YELLOW by *indigo*, with a mixture of *violet*; GREEN by *violet*, with a mixture of *red*; BLUE by *red*, with a mixture of *orange*; INDIGO by *yellow*, with a considerable mixture of *orange*; and VIOLET by *green*, with a considerable mixture of *blue* (B).

The

(B) Dr Darwin, in his *Zoonomia*, vol. i. sect. 2. employs the phenomena of accidental colours to prove that the fibres

Of Sensation.

The exercise of distinct vision depends chiefly on the following circumstances: 1. The perfect transparency of the cornea, and the several humours of the eye; 2. on the just proportional distance between the cornea and the crystalline lens, and on their degree of convexity; 3. on the sensibility of the retina; 4. on the degree of illumination of the visible object; 5. on the colour of the pigmentum between the choroid and the retina; and, 6. on the contraction and dilatation of the pupil.

101 Requisites for distinct vision.

102 Action of light on the system.

The action of light on living beings is not confined to its effects in producing vision. It seems to act on the system in general as a moderate but constant stimulus. When the light of day is vivid, as in bright sunshine, the body is more active, and the mind more vigorous, than under a cloudy sky. Those climates which are frequently obscured by clouds and vapours, are notoriously the birthplaces of seriousness and gloom; and Bœotian dulness and English melancholy have long become proverbial; while on the contrary, the serene brightness of an eastern sky has been considered as peculiarly favourable to the exertions of imagination, and the flights of fancy. Mr Stuart, a famous pedestrian traveller, told Dr Rush, that during a summer which he passed in a high northern latitude, where the sun is visible for several months together, he enjoyed an uncommon share of health and spirits, which he attributed to the long continuance of the light of the sun. In a state of nature most animals retire to rest when the light fails, and few people can sleep soundly, unless light be excluded.

The stimulating effects of light are peculiarly evident on persons whose nervous system is unusually sensible; they cannot bear strong light, which not only hurts their eyes, but produces considerable agitation on their whole frame. The same effects are produced on those who have been confined in a dark prison. The countenance of these unfortunates is pale and sallow. This latter effect of the absence of light is similar to what takes place in vegetables, as we know that the colour, taste, and smell of plants depend on their being exposed to a due degree of light.

103 Absence of light supposed to favour obesity.

It has been remarked, that those animals which have been long confined in a dark situation, are universally disposed to grow fat; and this has been found to take place even in condemned criminals, in whom we would least expect it. This obesity has been attributed chiefly to the absence of light. We are disposed to think that the absence of this stimulus can have no immediate effect, but that the disposition to obesity depends rather on the indolence of the confined animals, which is favoured by the absence of light.

For an account of the principal morbid affections of vision, see MEDICINE, No 81.

6. *Is there in some animals a sixth sense?*

104 Bats supposed to have a sixth sense.

From the experiments of Jurin and Spallanzani on the flight of bats that have been deprived of sight, (see MAMMALIA, N° 38.) it has been supposed by some that the accuracy with which these animals in their flight avoided the obstacles that were placed in their way, is owing to some additional sense which they possess. Others have conceived that the sense of hearing, which appears to be very acute in the species on which these experiments were made, is sufficient to supply their want of sight. It is scarcely possible to ascertain which of these two opinions is the more probable; but the writer of this article is rather inclined to adopt the latter, from having observed that when he was walking in an unfrequented street, when it was very dark, he was enabled to avoid running against the common stairs that projected into the street, from a certain sensation that he perceived, when he approached the wall of the stair, which he cannot better describe than by saying that the air at these points appeared to be unusually still.

With respect to sensation in general, we may lay down the following laws, which are considered by Dumas as fundamental principles of this function.

105 Laws of sensation.

1. As activity is an essential character of sensation, this cannot exist without a certain action of the organs, and must be proportioned to the degree of attention bestowed on the external objects, or ideas by which it is produced.

2. A repetition of the same sensations tends to render the sensibility less acute, and less capable of receiving new impressions. By repose its energy is restored.

3. As sensibility cannot be employed on two impressions at the same time, it must hold a certain balance throughout all the organs, and it cannot be acutely excited in one part, without being proportionably diminished in another.

4. Sensibility is a relative faculty, which is not equally obedient to all kinds of excitations, but only to those which have some relation to it in the different parts of the living body.

5. It is increased and accumulated in the direct proportion to the defect or weakness of stimulus.

6. It is not proportioned to the number, arrangement, or distribution of the nerves, and its changes of increase or diminution are not susceptible of calculation.

7. It is inconstant, variable in its progress, and unconfinable.*

* *Dumas, Principes de Physiologie*, tom. ii. p. 151.

To these we may add the following facts respecting this function and its organs.

1. The nerves which are principally distributed to the organs of the external senses, arise from that part of the sensorium that is within the head.

2. The sensations produced in any part by the contact of external bodies, are more perfect, according as the nerves which terminate in that part arise more immediately from the common sensorium.

3. When a ligature is fastened on a nerve, the parts on which the nerve is distributed are deprived of sensation as far as depends on that nerve.

4. Compression of the brain diminishes general sensation in proportion to its intensity. Slight compression produces numbness.

5. Though sensation probably takes place only in the central parts of the sensorium, it is commonly referred to the extremities of the nerves. Thus, a gouty person who has lost his leg, will suppose that he sometimes feels

fibres of the retina are thrown into contraction, like those of muscles, and that some of them act as antagonists to others; as he considers the accidental as the reverse of the natural colours.

feels the pain of the gout in the toe of the amputated limb.

6. A sympathy takes place between those parts which are supplied by branches of the same nerve. Thus, a violent scratching of the head often produces sneezing; powerful odours snuffed at the nose produce a flow of tears; the head sympathises with the stomach; the mammæ with the uterus, &c.

These are all the phenomena respecting sensation which we can at present notice; we shall mention others when we come to consider the relation between this function and those of motion, digestion, circulation, &c.

106 **Internal senses belong to metaphysics.**

What have been called the internal senses, as memory, imagination, and judgment, are rather qualities of the mind, than operations of the brain; and the consideration of them belongs rather to metaphysics than physiology. To that article, therefore, we refer the reader; and we shall conclude this account of the phenomena of sensation with the following comparative view of that function in the inferior animals.

107 **Comparative physiology of sensation.**

In all animals that have nerves, voluntary motions and direct sensations take place by the same means as in man. The differences in their motions depend partly on the intrinsic mobility of their fibres, and partly on the disposition of their muscles, and the parts to which they are attached.

The differences in their sensations depend on the number of their senses, and the perfection of the organs belonging to each sense. The animals that approach nearest to man have their senses equal in number to his. In certain species, some of these senses are even more perfect in the structure of their organs, and susceptible of more lively and delicate impressions than ours; on the contrary, in proportion as animals are removed from us, the number of their senses and the perfection of certain organs are diminished; but perhaps some animals, at the same time, possess senses of which we can form no idea.

We know not whether there are differences in the intrinsic sensibility of the nervous system of different animals, i. e. whether an equal impression made on an organ equally perfect, would affect every animal with the same force.

The animals next in order to man have, like him, spontaneous, or what we call internal, sensations. Images are excited in them at times, when they receive no immediate impression from external objects. Thus, dogs and parrots dream. We are not certain, indeed, that the more inferior animals experience similar sensations.

The passions produce effects in animals similar to those which they excite in man. Love is manifested in the same manner in all classes; fear occasions a discharge of excrements in quadrupeds and birds; it makes them tremble, and even renders insects immoveable; but the other animals afford fewer examples of these kind of phenomena than man, because they are not masters of their imagination, cannot direct it towards certain objects, and create for themselves factitious passions. We are even ignorant whether their imaginations can, like ours, be wrought up to such a pitch as to make them experience emotions of anger, desire, or fear, from simple ideas or simple recollections; and whether the real presence of the objects which cause these passions, is not always necessary to excite them in the inferior animals; we know, however, that those which approach nearest to us, the mammalia and the birds, have their sorrows. The affliction they feel on the absence or loss of a companion, friend, or benefactor, is manifested by evident signs, in the same manner as they testify their attachment without any temporary inducement.

The same animals exhibit frequent proofs of a very perfect memory; some even appear to possess a certain degree of judgment. But does any thing similar exist in the inferior classes, and particularly in the lowest? Of this we shall probably remain always ignorant.

With so much resemblance in the structure of the nervous system, in its mode of action, and in the number and structure of the principal external organs, why is there so vast a difference, as to the total result, between man and the most perfect animal?

Is this owing to a more accurate proportion in the relative perfection of the external organs, so that one does not so much surpass another? Or has the internal organ, in which are performed all the intermediate operations between the sensation received and the movement executed, that is to say, the organ of perception, memory and judgment, greater differences than we have yet observed? Or, finally, is the substance by which these processes are effected of a different nature? These, however, are not anatomical questions.

The sympathies or effects resulting from the connections of nerves with each other, and the influence of the nerves on vegetative functions, are subject to the same laws in man and the other animals *.

* Cuvier's Lectures, vol. ii.

108 **Theory of sensation.**

The theory of sensation is perhaps more imperfect than that of any other function. On this subject we can derive little light from the structure of the brain and nerves, accurately as this has been examined. Anatomy has taught us, that the principal part of these organs consists of very delicate fibres, intermixed with a medullary pulp, and incased in membranes; and that they are furnished with a great proportion of blood-vessels; but whether the seat of sensation resides in the fibrous or medullary part, we cannot ascertain.

109 **Vibration.**

It was formerly the opinion, that the nervous power was propagated between the brain and the external organs, by vibrations of the nerves; but as the structure of these chords, and their connection with surrounding parts, must wholly disqualify them for such vibrations, this theory has long been abandoned.

110 **Nervous fluid.**

Another hypothesis that has been very generally received is, that the nervous fibres are the conductors of a very subtile fluid, called the nervous fluid, the motions of which are the cause of sensation. This was the opinion of Dr Haller, (*First Lines*, chap. x.) and was strenuously maintained by Dr Cullen. We shall present our readers with the following modification of it, as given by an able disciple of Cullen.

"It is probable, (says this writer), that in each nervous fibril, an elastic fluid is inherent, forming, from the moment of animation, a part of it; differing, however, according to the state of the constitution, in power, mobility, and, perhaps, in other qualities. Of this fluid the the nerves are conductors, and are surrounded in their course by non-conducting membranes, while the same membrane lines every part of the brain, and is carried into the deepest cavities, guarding with particular attention the slightest aperture. In this view sanguiferous vessels are chiefly useful in nourishing this medullary substance, and they appear to be necessary also in adapting the

Of Sensation.

the nerves to their office; for, when the circulation is greatly increased, the sensibility is more acute; and when it languishes, or is destroyed, the nervous energy soon shares the same fate.

"This fluid must necessarily be an elastic one; and impressions are apparently conveyed through it by vibrations. It does not follow from hence, that the nerves vibrate like muscular cords; or that, in every the slightest motion, a portion is conveyed from the brain. The elasticity of the fluid is proved from the momentary continuance of the impression after the cause is removed; and vibration is a term employed in many branches of philosophy as a means of communicating motion, without any distinct application. If we touch an object with a stick, or with a metallic rod, we perceive through it the impression, and, in a general way, the nature of the substance. The impression must be conveyed by something; and whatever that something is, it may as well convey impressions through the nerves as through the rod. But through the nerves only can it affect the brain, and produce an *idea*, or some change in the brain, or its fluid connected with the nature of the object, and which conveys to the mind some peculiar and discriminated impression which it afterwards retains *."

* *New London Medical Dictionary*, vol. i. p. 398.

A third hypothesis, which is at present very fashionable, is, that sensation is produced by a change in the substance of the brain and nerves. M. Cuvier is an advocate for this doctrine, which he illustrates in the following manner.

The nervous system is susceptible of two kinds of action; one which is confined to our sensitive faculty, and another which affects our vital and vegetative functions only. External sensations are produced by the impressions of external bodies, on our senses; internal sensations, by changes which take place, in the state of the internal parts of the body, to which the nerves are distributed; and spontaneous sensations are caused by a change in the nerves, or in the brain itself, without any external excitement.

These circumstances, added to the phenomena arising from the cutting or tying of nerves, show, that sensation does not reside in the external organs, but nearly in the centre of the nervous system, and that the external organs serve only to receive the action of the external bodies, and to convey it to the nerves, by which it is propagated to a greater distance. They also demonstrate, that this propagation is not produced by any matter or concussion, but by a change in the state of the nervous substance. This change may arise from internal causes, or it may be produced by external causes, different from those which usually occasion it. The nerves are not merely passive agents, nor the conductors or reservoirs of any particular matter; but it appears that the substance which produces sensation, is liable to be consumed, or to lose its activity by exertion.

There are phenomena which shew that the general susceptibility of the nerves, for receiving sensations, may vary in consequence of causes external to the nerves themselves, and which can operate only by altering their substance. Certain medicines weaken or revive that susceptibility;—inflammation frequently increases it to an excessive degree. Does this take place in consequence of an increased secretion of the nervous matter? The most remarkable change that occurs in the susceptibility of nerves, is sleep. It is not unnatural to suppose that this change may be occasioned by the temporary loss of the substance which is essentially sensitive. But how does it happen that sleep depends, in a certain degree, on the will? Why do we awake suddenly, or from causes which do not appear calculated to restore that substance? Why does cold produce sleep? From these observations, may it not rather be supposed that this state is the effect of a change in the chemical nature of the nervous substance?

But whether the substance contained in the nerves is exhausted by sensations, or whether it merely undergoes an alteration in its chemical composition, and becomes, as it were, neutralized, it must remain in the nerve throughout the whole of its course, and leave it only at one of its extremities. It does not, however, resemble the blood in the vessels, either as to the manner in which it is retained, or in which it moves in the nerve. There is no evidence of the nerves being tubular. No phenomena indicate that any matter escapes from them when they are divided. Besides, what vessels could have parietes sufficiently compact to retain so subtile a fluid as that of the nerves must be. It is far more probable that it is retained in the nerves, in the same manner as the electric matter is in electric bodies, by communication and insulation; and that the nervous system is its only conductor, while all the other parts of the animal body are, with respect to it, cohibent substances *.

* *Cuvier's Lectures*, vol. ii.

The theory of *sensorial power*, brought forward by Dr Darwin, has already been noticed.

Chap. III. *Of Irritability*.

111 General phenomena of irritability.

1. When any part of a living animal body that contains muscular fibres, as a part of its composition, is touched with a sharp instrument, with a hot iron, or with a corrosive liquor, or when a shock of electricity or galvanism is made to pass through it, a contraction takes place in the part; and this contraction is discontinued when the stimulus is removed, but is renewed on repeating the application.

2. The same contractions take place in certain parts of a living animal body, from an exertion of the will.

3. Many parts in which the presence of muscular fibres has not been ascertained, possess the same capacity of being excited to motion by stimuli. Such are the ureters, the biliary ducts, the small blood-vessels, and probably the lymphatics; all of which, though not evidently muscular, have a fibrous structure.

4. Some parts of the living animal body which appear rather nervous than muscular, possess a contractile power, as the retina.

5. When the nerves which form a communication between a contractile part and the brain, in the higher orders of animals, are divided or compressed, those parts which before contracted in obedience to the will, lose this power; but,

6. These parts, as well as every muscular part, still contract on the application of stimuli, particularly electricity and galvanism.

7. Such parts of an animal body as have muscular fibres, are thrown into contraction on the application of stimuli, for some time after having been separated from the living body, provided that nervous filaments remain connected with the muscular fibres.

8. It has been found, that the fibrine of the blood is

Of Irritability.

susceptible of contraction on the application of the galvanic stimulus, after having been separated from the living body.

9. In some animals in which a nervous system has not been detected, as polypes, this contractile power seems to pervade every part of the animal.

10. Plants, in a greater or less degree, possess the power of moving on the application of stimuli; and in some species this motion is very remarkable. See N° 57.

The above are some of the principal phenomena which take place in organized beings with respect to irritability. They are so analogous, that we may attribute them to the same cause or the same vital power. This susceptibility of being thrown into contraction on the application of stimuli is called irritability; and it is possessed in a greater or less degree by every organized being with which we are acquainted.

112 Definition of irritability.

We have restricted the term *irritability* to denote the susceptibility of the fibrous structure to contraction on the application of stimuli; but it is proper to remark that this term has not always been used in the same sense.

113 Different applications of this term.

Irritability has long been employed in medicine, as in common language, in reference to the passions, especially that of anger; and this appears to have been the original meaning of the term.

Multo fero ut placem genus irritabile vatum. HOR.

It is perhaps still more common to apply it to a morbid sensibility of the system; and we speak of a person being of a very irritable habit, or possessing a great degree of irritability, when we mean to say that he possesses a more than ordinary share of sensibility, liable to a more keen sensation of the same impressions.

"Or are your nerves too irritably strung."
ARMSTRONG.

Even the accurate Dr Whytt, to whom the proper distinction between irritability and sensibility must have been familiar, and by whom it is in general strictly regarded, sometimes falls into this inaccuracy. He speaks, in his work on nervous diseases, of "a delicate or easily irritable nervous system." In fact, this confusion of irritability with sensibility, appears to be a stumbling block to most physiological writers. We shall presently inquire how far they are independent of each other.

The term irritability, in its most received acceptation, as a property of the muscular fibre, seems to have been first employed by Glisson, about the middle of the 17th century. He distinguishes two kinds of irritability, primary or direct, and secondary or sympathetic*. Haller was, however, the first, who treated of irritability, with any degree of accuracy. He confines it to the muscular fibre; though at the same time he will not allow it to many parts, the muscularity of which has never been questioned, and which, since his time, have, by decisive experiments, been proved to possess a considerable degree of contractile power. He completely distinguishes irritability from sensibility, with which he will have it to be totally unconnected; and he attempts to make a distinction between the irritability of the living, and that of the dead fibre †.

* *Glisson de Ventriculo et Intestinis.*

Dr Whytt, whose controversy with Haller respecting the nature of irritability and sensibility is famous in the annals of medical warfare, admits three kinds of irritability: 1. That power of alternate contraction and dilatation which is peculiar to those organs we call muscles; 2. That uniform contraction which takes place in the dartos (one of the coats of the scrotum) and the pores of the skin; and, 3. That redness and inflammation, which is excited in every sensible part of the body, as often as acrid things are applied to it; although this last is allowed by him to be only an effect of the first kind of irritability taking place in the small vessels of the part ‡. Thus he reduces the three kinds to two, and we may perhaps consider his second kind only as a modification of the first.

† *Haller's First Lines of Physiology*, chap. 11.

‡ *Whytt's Physiological Essays*, Essay ii. part 1.

Among those who seem to have a sufficiently just idea of the nature of irritability, the word itself is not unfrequently misapplied. Thus, Vicq d'Azyr ||, and Dumas §, in enumerating the functions of the animal body, called those of motion and sensation, irritability and sensibility. These latter are powers or capacities of living beings, and as such should be distinguished from the functions that depend on them.

|| *Encyclop. Method. Anatom. Comparée.*

§ *Principes de Physiologie*, tom. i.

In considering the phenomena of irritability, it is necessary to take notice of the several kinds of stimuli which excite it. These have been reduced by Cuvier to five orders, viz. *volition; external actions* operating on *nerves; external actions* operating on the *fibre* itself; *mixed actions* operating on both the *nerves* and *fibres*, and certain *diseases* or *violent emotions*.

114 Stimuli exciting irritability.

115 Volition.

When the animal body is in a state of health, and awake, the will exercises a prompt and constant influence over the greater part of the muscles, which, on that account, are denominated *voluntary* muscles. A small number of muscles, viz. those which produce the internal movements necessary to life, and which cannot be interrupted, such as the heart and the alimentary canal, are not subject to the will. It must be observed, however, that some of the muscles, that in man and most other animals are involuntary, are subject to the will in others. This is the case with the stomach in ruminating animals, the movements of which may be exerted at pleasure in two different directions. In some muscles, as in those of respiration, there seems to be a mixed action with respect to the will, as this faculty can interrupt their motion for a time, though, in general, this is continued from habit, without the will, or even consciousness of the animal. Those muscles that are absolutely involuntary, are continually excited by an extraneous irritating cause; for the blood which is brought to the heart on every dilatation, determines that organ to contraction, and the alimentary canal is affected in the same manner by its contents. It seems, therefore, that the will is not essential to the action of these muscles, and that it cannot interrupt their motion (c).

A

(c) There are facts which shew that the will has often considerable influence even on muscles that are universally styled involuntary. The abbé Fontana, when making experiments with *wheel polypes*, was led to believe that the heart, in these animalcules, is a *voluntary* muscle, and from this belief he learned, in some degree, to accelerate

Of Irritability.

A muscle laid bare, and exposed to an irritating cause, will contract itself, even in the living subject, without being influenced by the will. It should seem, therefore, that though the muscles which we call voluntary, are usually put in motion by the will, they may yet be excited to action in opposition to that faculty.

116 Nervous energy.

The will itself seems to act only through the medium of the nerves; and it is found that those nerves which supply the voluntary muscles, are generally the largest.

117 External stimuli.

The external stimuli that act on the muscular fibre through the medium of the nerves, and on the fibre itself, are chiefly of a mechanical and chemical nature, as concussions, punctures, lacerations, all of which are capable of producing convulsive motions in all the muscular parts to which the nerves extend.

118 Galvanism.

One of the most remarkable of these stimuli is the galvanic influence. It is well known that the experiments by which this influence is made to act on the muscular fibre, consist in establishing between a muscle and the trunk of the nerves which extend to it, an external communication with one, or a series of substances placed close to each other. Metals are not the only means that may be employed in this operation; and in general, the conductors are not the same as those of electricity. Experiments have sometimes been successfully performed, when an interval was left in the series of excitators: this circumstance, in the opinion of Cuvier, proves the existence of an atmosphere.

The moment the contact takes place, the muscle suffers violent convulsions. These experiments succeed on the living body, or animals recently dead, and even on parts separated from the body, precisely in the manner of those which Haller accounts for on the principle of irritability. Neither pointed instruments nor acrid liquors are necessary; and the galvanic experiments even succeed when these means have failed.

119 Distension.

Distension has been observed to have a powerful effect in exciting irritability.

120 Violent passions.

Violent passions may, to a certain degree, be considered as the acts of the will strongly excited. These, in some cases, have an influence even on the involuntary muscles; for it is no unusual thing for palpitation of the heart, and sometimes even a suspension of its motion, to be the consequence of strong passions. These actions, however, are to be prevented by moderating the excess of sensibility by which they are occasioned. Even in nervous diseases, which appear to be the least connected with those passions whose influence is more immediately felt, the will is often capable of preventing or retarding the approach of nervous symptoms, when the patient is determined to resist the paroxysm.

From what has been said, it appears that, in the superior classes of animals, all the orders of stimuli, either act through the medium of the nerves, or that they are capable of being modified or controuled by the will, the exertion of which depends on nervous influence.

121 Cause of irritability.

With respect to the immediate cause of irritability, there have been several opinions. One of those which has been most generally received is, that irritability is intimately connected with sensibility; or, that it is an immediate effect of the nervous power. This was the opinion of Whytt and Cullen, the former of whom endeavours to prove it by the following arguments.

122 Whytt's arguments in support of nervous influence.

1. We almost always observe the irritability of the muscular organs of the human body to bear a proportion to their sensibility. Thus, children, and people of delicate nerves and very quick feelings, are most subject to convulsive and spasmodic diseases, while on the other hand old people, and those of less delicate sensibility, have a muscular system that is not so irritable.

2. Whatever increases the sensibility of the muscles, also increases their irritability.

3. Whatever lessens or destroys the sensibility of the muscles, also lessens or destroys their irritability or power of motion.

4. That the motions of irritated muscles are owing to the sensation excited by the stimulus applied to them, Dr Whytt thinks highly probable, if it be considered that we are in fact conscious of many involuntary motions in our own bodies, proceeding from a particular sensation, either in the organs moved, or in the neighbouring parts*.

* *Physiological Essays*, Essay ii.

Dr Cullen was so fully convinced of the necessity of nervous influence to produce muscular contraction, that he considered the muscular fibre to be only a continuation of the nervous fibre. See MEDICINE, N° 73.

123 Haller's opinion of the *vis insita*.

Haller, as we have said, strenuously maintained, that irritability was quite independent of the nerves, and was an inherent power or *vis insita* of the muscular fibre. Indeed there are several circumstances which would induce us to believe that irritability is at least, in some cases, independent of nervous influence. We have seen (N° 111.) that it takes place in those animals in which there is no appearance of nerves; and that it is very remarkable in some species of vegetables, in which none but the most fanciful physiologists have dreamed of finding a nervous system. Nay, it appears that the fibrine of the blood, which we can scarcely suppose to be affected by the nervous power, when taken out of the body, is still susceptible of irritation.

124 General conclusion on this subject.

From a comparison of all these circumstances, we must either conclude, that the irritability of living muscles, and of the superior animals, is different from that of the fibrine, of polypes and plants; or, if we admit that nervous influenee is essential to irritability, we must also allow that this influence descends to the latter class of organized bodies.

125 Chemical doctrines of irritability

Before we quit the subject of irritability, we must notice the chemical hypotheses that have been lately proposed, to explain the immediate cause of this faculty.

126 Girtanner's opinions.

The first of these is that of Girtanner, who considered oxygen as the principle of irritability. The arguments

celerate and retard the motion of his own heart. We have even heard of a person who had such a command over both heart and lungs, that he could, at pleasure, arrest the motion of both, and assume all the appearance of a lifeless corpse. Many of those muscles, which, in ordinary subjects, are not obedient to the will, as those of the *nose* and *external* ear, may, however, become so by habit or patient assiduity in cultivating their action.

arguments on which he founded this opinion are the following.

1. The irritability of organized bodies is always in a direct ratio to the quantity of oxygen they contain.

2. Every thing that augments the quantity of oxygen in organized bodies augments at the same time their irritability.

3. Every thing that diminishes the quantity of oxygen diminishes likewise their irritability.

He distinguishes the organized fibre by three different states:

1. A state of health, or the *tone* of the fibre, in which the oxygen exists in its proper quantity.

2. A state of *accumulation*, in which the fibre is overcharged with the oxygen or irritable principle.

3. A state of *exhaustion*, in which the fibre is more or less deprived of it.

He likewise arranges the substances, that are capable of coming into contact with the irritable fibre, into three classes.

The first comprehends those substances that have the same degree of affinity for the irritable principle or oxygen, as the organized fibre itself; hence the substances produce no effect upon it.

The second comprehends those substances that have a less degree of affinity for oxygen than the organized fibre has: hence these, when they come into contact with it, surcharge it with oxygen, and produce a state of *accumulation*. They are called negative stimuli.

The third comprehends substances for which oxygen has a greater affinity than it has for the organized fibre. These, therefore, deprive the fibre of its oxygen, and produce a state of exhaustion. They are called positive stimuli.

By way of answer to this fanciful doctrine, we may observe, that if oxygen were so essential to irritability as is supposed in Girtanner's positions, those animals which respire most oxygen should possess most irritability, and those which are capable of living for a long time in deoxygenated air, should have their irritability very low. Now, the reverse of this is found to take place. The muscular fibres of birds which respire more oxygen than most other animals, possess but little irritability, while reptiles and worms, which can live for a long time without oxygen, are universally and strongly irritable *.

* *Johnson's Animal Chemistry*, vol. iii.

127 Hypothesis of Humboldt.

The other opinion is that of Humboldt, who considers the galvanic fluid as the source of nervous power, and the primary cause of irritability. He lays down three principles as necessary to excite irritability; viz. 1. Oxygen, which forms combinations with different acidifiable bases. 2. The acidifiable bases (carbone, hydrogen, azote, and phosphorus), of the fibre, with which the oxygen may combine. And, 3. The galvanic fluid.

The galvanic fluid produces, according to Humboldt, the same effect in the animal economy, as the electric fluid in the mixture of azote and oxygen. It is this galvanic fluid that, being conveyed by the nerves, brings about the combinations of the oxygen with the different acidifiable bases of the fibres; but when the nerve of a part is tied, it prevents the fluid from passing, which explains the reason of the irritability being destroyed.

The oxygen necessary for these unions is carried by the arterial blood in the course of circulation; and the acidifiable bases, which are to unite with it, are found to be already present in the fibre.

He found that every thing that augments too much the quantity of the acidifiable bases diminishes the irritability; and that every thing that increases too much the quantity of oxygen, likewise diminishes it; and he thinks it very probable, that the same takes place with respect to the proportion of the galvanic fluid.

It is therefore only in a just equilibrium of these principles that the necessary irritability of the parts consists.

Upon these principles this philosopher thus explains the production of muscular motion. "In a state of repose, the nerve being inserted in the muscles, the galvanic fluid is put into equilibrium in organs that touch each other. The spontaneous motion is made by a surcharge of galvanic fluid into the nerve. It appears that the instant we wish to make a motion, the galvanic fluid produced in the brain, is carried *en masse* towards the part that ought to move, and surcharges the nervous fibres. A discharge from the nerve is then made into the muscles. The particles of these last, animated by increased affinities, approach each other, and it is this that constitutes the phenomena of muscular motion *."

* *Johnson's Animal Chemistry*, vol. iii. p. 24.

128 Laws of irritability by Dumas.

Dumas lays down the following fundamental laws respecting animal irritability.

1. The essential characteristic of irritability consists in a series of contractions and dilatations, determined either by the impression of an external stimulus, or by the simple exertion of the will.

2. Irritability is independent of the action of the nerves; and though generally diffused throughout the animal organization, it belongs rather to the muscular fibre than to any other structure. Its action is in proportion to the number of fibres upon which the irritating causes can exert their influence.

3. Irritability is a relative faculty which is not indiscriminately obedient to every species of excitation, but only to those which have some relation to it in the different parts of the living body.

4. There belongs to each organ a specific irritability which requires a peculiar stimulus, accommodated to its nature, and to the kind of functions which it exercises.

5. Irritability has certain vicissitudes of diminution and increase, which vary in the different species of animals, in the different organs of the same animals, and under the different circumstances that successively occur in the life of an individual.

6. Irritability is developed with most energy at the moment of death, and immediately after this has taken place.

7. It is multiplied and revived in proportion as the organ which has lost it is divided into a greater number of pieces.

8. It diffuses itself in each part with a velocity proportioned to the activity, number, and duration, of the irritations by which it is excited.

9. There exist mutual relations with respect to influence between sensibility and irritability, though each of them is essentially distinct from the other.

10. The exercise of this faculty supposes in the organs a moderate degree of cohesion, above or below which the action of this force is enfeebled, obstructed, or opposed *."

* *Principes de Physiologie*, tom. iii. p. 53.

Of Animal Motion.

Chap. IV. *Of Animal Motion.*

129 Organs of motion.

The organs of motion vary considerably in their nature and connection in the different classes of animals. In some tribes, as in the animalcules and polypes, no distinct organs can be observed. In all above these, however, there are evident muscular fibres, and in many there are hard parts or strong membranes, which serve as points of attachment and fulcra of motion to these fibres. The muscular fibres are to be considered as the essential moving organs, while the parts to which they are attached are merely the passive functions of this organ. It would be out of place here to enter on a comparative account of the organs of motion; and there is the less occasion for it, as they have been more or less fully described in the former part of the work. The bones, ligaments, muscles, and tendons, with their appendages, as they appear in man, have been amply described in the first and second chapters of the First Part of ANATOMY; and those of other animals have been briefly noticed in the Second Part of that article. Such of our readers as wish for a more particular account, may consult Cuvier's Lectures, vol. i. or Blumenbach's Comparative Anatomy, chap. 1, 2, 3, 4, 5, and 22.

130 Principles of muscular action.

Many of the phenomena of muscular motion, as they take place in man, have also been related under ANATOMY, N° 85 and 86. We shall here therefore only enumerate and briefly illustrate these phenomena, and shall then proceed to consider a most interesting part of the physiology of motion, the progression of different animals.

Dr Barclay, in his late excellent work on the muscular motions of the human body, has considered the general subject of muscular action under the following heads, which may be considered as fundamental principles.

1. Fleshy fibres that are continued into tendon by a straight line, shorten the muscle which they compose, in the same degree in which they shorten themselves; those fibres which enter the tendon obliquely, shorten it more, and still more in proportion to their degree of contraction, as they deviate more from the line of the tendon, and approach nearer to the perpendicular, in which last direction they would shorten the muscle most with the least contraction.

This may be illustrated in the following manner. Let AB (fig. 1.) represent a tendon, and CD a fleshy fibre; and let us suppose that AB is the diameter, and CD the radius of the same circle ADB. It is evident that if the fibre CD should contract so as to bring the point C of the tendon to the point G in the straight line, the extremities of the tendon A, B, (which are supposed to be moveable) would come respectively to E and F; and the situation of the tendon itself would be represented by the angle EGF. If the fibre could be supposed to contract so as to bring the point C to D, the two parts of the tendon CA and CB, would come in contact. If, on the other hand, the fibre CH, which enters the tendon obliquely, were to contract to H, so as to bring the point C to H, the point A would be drawn but a little beyond the middle point C, so that although this latter fibre is contracted to as great an extent as the former, it has not brought the extremities of the tendon so near together.

Plate CCCCXVII. fig. 1.

2. When two fibres enter a tendon on opposite sides and contract at the same time, they will draw the tendon in the diagonal; and the more nearly the angles which they form with the tendon approach to right angles, the more will the length of the muscle be shortened in proportion to the degree of contraction of the fibres.

Let the fibres BC, BD, BE, BF, BG, (fig. 2.) be fleshy fibres, inserted into the tendon AB, at the point B, and let us suppose that all these fibres co-operate in bringing the point B to the point G, in the straight line BG. Now the straight fibre BG will be so much shortened when B comes to G, as to be obliterated, while the oblique fibres EB and FB will be shortened only to E *a* and F *b*, and the more oblique fibres CB and DB will remain of the length of C *c* and D *d*. Fig. 2.

3. All muscles that are inserted into bones, are thereby furnished with levers, and as in the action of all levers there are also a fulcrum, a power, and a resistance, these in different cases will be differently situated with respect to one another.

a. In the motions of the head backward and forward on the atlas, the fulcrum is situated between the power and the resistance; or the lever is of what is called in mechanics, the first kind. See MECHANICS, N° 33.

b. When the tibia rests upon the astragalus, and the heel is raised by the muscles of the calf of the leg acting on the tendo achillis, the resistance (which in this case is the pressure of the tibia) is situated between the power and the fulcrum, which are here respectively at the heel and at the toes; or the lever is of the second kind.

c. In raising a weight at the palm of the hand, and bending the arm at the joint of the elbow, the power of action in this joint is situated between the resistance and the fulcrum, which are here respectively at the palm of the hand and the *distal* extremity of the humerus (D), or the lever is of the third kind.

The shortness of the lever, and the consequently great force of the muscular power required to overcome the resistance in this last case, may be thus illustrated. Let AB (fig. 3.) represent the radius articulated at B with the *humerus* BC; let DFE represent the *biceps flexor* muscle running along the *humerus*, and attached to the *radius* at E; and suppose a weight W hung to the distal extremity A of the *radius*. Now, BH will represent the lever of resistance, and BG perpendicular to it the lever of the muscle, which is in this case extremely short. Fig. 3.

4. As, other things being equal, all muscles produce a greater extent of motion by a less proportional degree of contraction, and consequently a less proportional change in their fibres, than if they were shorter; those muscles which follow a direct course are seldom attached at the nearest points of the two bones with which

(D) In Dr Barclay's nomenclature, that extremity of a bone which is towards the trunk is called *proximal*, and that extremity which looks from the trunk is called *distal*.

Of Animal Motion.

which they are connected. Hence, beside the advantages already mentioned, relations are thus formed between parts at a distance, and the mutual dependence of the functions and their organs is extended and strengthened. On the contrary, those muscles that are not extended along the surface of the bones to which they are attached, are observed to follow an oblique direction, by which they acquire not only contractibility and length, but at the same time a shorter lever than if they had been inserted at the same place with a less obliquity.

5. Of muscles attached to ribs that are parallel, equally moveable, and at right angles to the vertebral column, those that follow a direct course from one to the other, will act on each by equal levers, and make them approach with the same velocity; while those that observe an oblique course will act on each by different levers, and make them approach with different velocities.

Fig. 4. Let AB and CD (fig. 4.) represent two parallel ribs, articulated with the vertebral column at A and C, where they are equally moveable; and let DB and DE be two muscles, the former observing a direct, and the latter an oblique course. The levers of DB will be AB and CD, which, as AC is parallel to BD, are evidently equal; but the levers of DE will be CF and AG, which being of different lengths, the muscle must act with different degrees of force on the different ribs, so that it will make CD, on which it acts with the longest lever, approach AB, faster than it will make this latter approach the former.

Corollary.—When bones are not parallel, the muscles that cross in the interval between them, must fall obliquely on both, as it is impossible for a straight line to be at the same time perpendicular to two other lines, unless these be parallel.

6. As all bones move on a centre or axis of motion, while the muscular attachments move in a circumference, the muscles, in changing the relative position of any two bones, must, at the same time, be changing the direction of their own action, and varying their lever.

Fig. 5. Let AB and CD (fig. 6.) represent parts of two parallel ribs, and let AB be moveable on the centre A, and let CF and GE be two muscles inserted obliquely into AB at F and E. Now suppose that by the action of these muscles, AB is brought into the position A *b*. The points of attachment of the two muscles to AB, will now be *f* and *e*, and the muscles will be C *f* and G *e*, having changed their length, situation, obliquity, and lever.

7. All muscles where the points of attachment move in a circle, draw either towards the centre, or towards the circumference.

8. If any two bones could, by the action of their muscles, be made to approach in a parallel direction, the oblique muscles attached to their parallel and approaching surfaces, would perform a greater extent of motion with a less shortening of their fibres, than any straight muscles attached to the same parallel surfaces.

Of Animal Motion.

Let AB and CD (fig. 6. and 7.) be parts of two ribs that are parallel, and that will continue parallel till they are brought in contact by the action of the straight muscles AC, EF, and BD, or by the action of the oblique muscles CE and DE (fig. 7.) and FA and FB (fig. 6.). It is evident, that when the point E comes in contact with F, the length of the straight muscles must be obliterated, while that of the oblique muscles will only be shortened by *c* E and *d* E in fig. 7. and *f* A and *g* B in fig. 6. Fig. 6. & 7.

9. As, however, no two bones can approach one another in a parallel direction, at least by the action of a single muscle, and as no muscle can continue to act in a direction perpendicular to their two approximating surfaces; a muscle entering them at right angles, when they are parallel, may be placed so near to the centre of motion as to carry the bones through a given space, with a less shortening of fibres than any oblique muscle that has the same origin, but is inserted at a distance, and acts through the medium of a longer lever. Further, a muscle with a less obliquity may be so situated as to carry the bones through a given space, with a less shortening of fibres than any other muscle of the same origin, but of a much greater obliquity.

Let AB and CD (fig. 8.) be two ribs, of which AB Fig. 8. is moveable about the centre A; and suppose that by the shortening of the straight muscle EF, and of the two oblique muscles, EG and EH, AB is brought into the position A*b*. The points of attachment, after moving in the segments F*f*, G*g*, and H*h*, will now be respectively at *f*, *g*, and *h*. Now, on the centre E, with the radii E*f*, E*g*, and E*h*, describe three different circular segments. The difference between the present and former lengths of the most oblique muscle EH, will be *e*H, while the differences between the present and former lengths of the muscles EG and EF, will be only ɩ G and η F respectively.

10. The shortenings which any muscle suffers in carrying round the point of its attachment through a given space, will partly depend on the length of its lever, partly upon its degree of obliquity, partly on its drawing *peripherad* or *centrad*, and partly on its acting without or with a pulley (E).

11. The lever of a muscle, which is varied with every degree of obliquity, is also varied by every change in the centre of motion. Where bones are connected by large surfaces, the centre of motion frequently shifts from one part to another; but in general it approaches towards that aspect whither the bone is moving at the time; and as it advances, the muscles recede, to increase their force.

a. The lever of resistance, as well as of the power, is varied by the several changes of position; is sometimes shortened at the time that the lever of the power is lengthened; and *vice versa*.

If

(E) The terms *peripheral* and *central* are employed, by Dr Barclay, to denote the aspects of any organ, according as they respect the *circumference* or the *centre* of the organ; and when the termination of these words is changed from *l* into *d*, they denote, like the other terms of his nomenclature, the direction in which the action of these parts is exerted. See Barclay's Anatomical Nomenclature.

Of Animal Motion.

If AB (fig. 9.) represent the radius, BC the humerus, DE the biceps flexor muscle, and R the resistance hung to the distal extremity of the radius, it will be evident that, when BA is, by the action of the flexor muscle, brought into the position B *a*, the lever of resistance will no longer be BA, but BH, equal to a perpendicular straight line drawn from B, the centre of motion, to the plane of resistance; and, as the lever of resistance has been shortened, the lever of the muscle has been proportionably lengthened. Were the radius to resume its former position, the reverse of these circumstances would take place.

b. Sometimes again, the lever of the power and of the resistance are lengthened or shortened at the same time.

Let AB (fig. 10.) represent the tibia, BC the femur, and DEF the crureus muscle; and that the femur, with the weight of the body, is to be raised to the situation B *c*; the centre of motion will, during extension, approach towards the muscle at the rotular aspect, while the plane of resistance, as is evident from the figure, will be approaching to the centre of motion.

c. In the changes of attitude, while a bone is turning on its centre of motion, the centre itself is often at the same time describing, either the segment of a circle, or a line composed of circular segments.

Let AB (fig. 11.) represent the foot, BC the *tibia*, CD the thigh bone, and DE the trunk; and let us suppose that it is required to bring the three last, by the action of their muscles, to the perpendicular BF, so that BC shall occupy the situation of BG, CD the situation of GI, and DE the situation of IF; the point C on the centre B will move in the segment CG, and as C is changing its position in CG, the point D, which moves round the point C as its centre, will, if the extensions be regularly performed in the same time, describe such a curve as DI; for as the point D must necessarily move atlantad and sternad, in order to preserve the centre of gravity, the general direction of its course must be known; and if CG be divided into equal parts, and at each of the divisions a circle described with the radius CD, the points in DI corresponding in number with the points in CG, and at equal distances in the sternal direction, will each be found in the circumference of one of the circles described successively round the point C as it passes along the segment CG.

In like manner, if the extensions of CD and DE be regularly performed in the same time, the point E will describe such a curve as EF, the points in EF being in the circumferences of the several circles successively described round the point D as it moves along the curve DI.

12. When we examine the structure of the animal system, we shall generally find that the motions of the bones, as produced by the muscles, are the combined effects of different forces, and hence that a small number of muscles is enabled to produce, with steadiness and accuracy, an almost infinite variety of changes *.

For more on the general subject of muscular action, and for an account of the principal motions of the human body, we must refer to Dr Barclay's publication.

* *Barclay on Muscular Motion.* Part ii. chap. 3.

One of the most interesting enquiries respecting animal motion, is that of the progression of different animals, or of the powers of loco-motion.

131 Progressive motions.

Those animals which possess the faculty of changing their place, exercise this faculty by very different organs. Some can only creep, as worms, and many mollusca; others can only swim, as all fishes, many of the mollusca, and some of the testacea. Most birds can both fly, walk, and run, while a few do not possess the power of exercising the first of these motions. All the mammalia, and most reptiles, properly so called, can walk, run, climb, leap, and perform a variety of other motions; and a few of the former class can imitate the flying of birds. We shall briefly examine the mechanism of these different actions, but by way of introduction, we shall first consider how the action of standing is performed.

132 Standing.

Standing, in most animals, is solely the effect of the continued action of the extensor muscles of all the joints, as is evident from the circumstance, that if an animal, while standing, suddenly dies, or in consequence of some powerful cause, as a strong electric shock, ceases to make the necessary efforts for preserving the upright position, all the articulations of the legs yield to the weight of the body, and bend under it. In some animals, however, the extension of the muscles is so much assisted by powerful ligaments attached to the articulations of the legs, that they are enabled to continue standing for a much longer time, and with much less fatigue than most others. This is the case with birds that perch, and it is particularly remarkable in the stork, which by means of this peculiar mechanism is able to stand on one foot for several days together.

The action of standing is somewhat different, according as the animal stands on two feet or on four.

133 Standing on two feet.

That a body may be supported in a vertical position, it is necessary that it be so disposed as to be in a state of equilibrium, or that it be so balanced that a perpendicular line from the centre of gravity shall fall within its base. See MECHANICS, N° 193, et seq. It is evident that the more extensive the base is on which the body stands, the less is the danger of its losing its balance. Man can very easily preserve himself in the vertical position, from the broad basis formed by his feet, and from the great power he possesses of separating these to a considerable distance. This latter depends chiefly on the greater weight of his pelvis, and the length and obliquity of the neck of the thigh bone, by which this bone is carried more outward, and removed farther in its articulation, than in any other animal. In man, too, the foot is peculiarly adapted to stand firmly on the ground, from the flatness of its inferior surface, and from having the heel bone so formed as to come in perfect contact with the ground. The muscles that move the foot are also very advantageously inserted, and the extensor muscles of the heel are proportionably thicker than in most of the mammalia.

The thigh of man, when in the erect posture, is in a straight line with the trunk and the leg, whereas in quadrupeds, it is situated close upon the flank, and forms an acute angle with the spine. On this account, the thigh bone of quadrupeds is flat, and proportionally weaker than that of man. The extensor muscles of the thigh are proportionally stronger in man than in the other animals; and as the thigh bone moves upon the pelvis in every direction, these extensors are in man so considerable, that he is the only animal that possesses what are properly called hips.

In consequence of this structure, the human sacral extremities are furnished with a sufficient base, and form very

very solid bodies for supporting the trunk. Man also possesses several advantages for maintaining the general equilibrium of the body, especially the facility with which he holds his head in the erect posture, owing to the position of the occipital bone, and the horizontal direction of the eyes and mouth. See the article MAN, N° 5. and 6.

The quadrupeds that sometimes try to stand on their hind feet only in order that they may either employ their fore feet in taking hold of some object, or avoid keeping their head too low, seem rather to sit than to stand. Their trunk rests at the same time on their hind feet, as far as the heel, and on the buttocks; it is still necessary, however, that their head and neck should be proportionally small, as in *monkeys*, *squirrels*, *oppossums*, *&c.* otherwise the weight of those parts would be too great for the force employed in their elevation; but even when seated, the animal is generally obliged to rest on the fore feet, as may be observed in *dogs*, *cats*, *&c.*

Some quadrupeds use their tail as a third foot, to enlarge the base of the body: and when it is strong, it is capable of contributing to their support for some time. We find examples of this in the *kangaroos* and *jerboas*.

We have already noticed the mechanism in the feet of birds, which enables these animals to support themselves on two legs, though they do not stand in a vertical position, and though the atlantal part of their bodies is advanced more beyond the centre of gravity than the sacral part. Other advantages possessed by birds in this respect are, the great flection of the thigh bone and tarsus; the length of the anterior toes, and the length and flexibility of the neck.

134 Standing on four feet.

An animal which stands on four feet is supported on a very considerable base; but from the great weight of the head and neck in these animals, their centre of gravity is nearer to the atlantal than to the sacral extremities (F). It is evident from this, that in quadrupeds, the former must sustain almost the whole weight of the body; and we find, accordingly, that they are furnished with very strong muscles. In short, all that the sacral extremities seem to want in muscular force, appears to be transferred to the atlantal.

As in most quadrupeds the head inclines towards the horizon, and the neck is often very long, very powerful means are required to sustain the former. These means are furnished by the great size, and extensive attachments of the muscles of the neck, and especially in many quadrupeds by the cervical ligament. In the *mole*, which employs its head to raise considerable burdens of earth, the cervical muscles are peculiarly strong, and the ligament is converted into bone.

The body of a quadruped hangs between the four legs, and by its weight tends to draw the spine downwards. This is counteracted by the abdominal muscles, especially by the straight muscles, which produce a curvature in the opposite direction. The abdominal muscles act with peculiar force in arching the spine upwards in those mammalia that are covered with scales or spines, and are accustomed to roll themselves up on the approach of danger, as the *hedgehog*, the *armadillos*, and the *pangolins*.

Oviparous quadrupeds or reptiles, have their thighs directed outward, and the inflections of the limbs take place in planes that are perpendicular to the spine. In these, therefore, the weight of the body must act with a much longer lever, in opposing the extension of the knee-joints; and accordingly they have the knees always bent, and the belly dragging on the ground between their legs, whence the name of *reptiles*.

135 Walking.

In walking on a fixed surface, the centre of gravity is alternately moved by one part of the extremities, and sustained by the other, the body never being at any time completely suspended over the ground.

136 Walking on two feet.

Animals which can stand erect on two legs, such as man and birds, walk also on two legs. But several quadrupeds that cannot stand on two feet but with great difficulty, may yet move in that posture for some time with sufficient ease. This arises from its being in general less painful to walk than to stand, the same muscles not being continued so long in action. And also it is less difficult to correct the unsteady motions by contrary and alternate vacillations (a thing easy in walking), than it is to prevent them altogether.

When man intends to walk on even ground, he first advances one foot; his body then rests equally on both legs, the advanced leg making an obtuse angle with the tarsus, and the other an acute one. The ground not yielding to the point of the foot, the heel and the rest of the leg must of necessity be raised, otherwise the heel could not be extended. The pelvis and trunk are consequently thrown upward, forward, and somewhat in a lateral direction. In this manner they move round the fixed foot as a centre, with a radius consisting of a leg belonging to that foot, which, during this operation, continually diminishes the angle formed with the tarsus. The leg which communicated this impulse is then thrown forward, and rests its foot upon the ground; while the other, which now forms an acute angle with its foot, has the heel extended in its turn, and in like manner makes the pelvis and trunk turn round upon the former leg.

As each leg supports the body in its turn, as in standing on one foot, the extensor muscles of the thigh and knee are brought into action, to prevent these articulations from yielding; and the flexors act immediately after, when the leg having thrown the weight of the body on its fellow must be raised before it can again be carried forward. As the undulatory motion that necessarily attends a man's walking, cannot be perfectly regulated on both sides, he cannot walk in a perfect straight line, nor can he walk in a direct course with his eyes shut.

In walking down an inclined plane, or descending a staircase, as the advanced leg is placed lower than that which remains behind, the extensors of the leg must act more powerfully to prevent the body from falling backwards. Again, on ascending such situations it is requisite at each step, not only to transport the body horizontally,

(F) These terms signify the same as *superior* and *inferior* in man, *anterior* and *posterior* in quadrupeds; but are more convenient, as applying indiscriminately to both. *Atlantal* denotes what is next the *atlas*; *sacral* what is next the *sacrum*. See *Barclay's Nomenclature*.

Of Animal Motion.

zontally, as on walking on level ground, but to bear it up against its own weight, by means of the extensors of the knee of the advanced leg, and those of the heel of that which is behind; this is the reason of the knee and calf of the leg being fatigued in ascending; and the fatigue is relieved by inclining the body forward, because then the lever by which its weight acts on the knee is shortened.

Running is only a succession of short leaps, and it will be understood from what we shall presently say of leaping.

137 Walking on four feet.

When a quadruped walks, he first slightly bends the articulations of the hind legs, and then extends them, in order to carry forward the body, which motion is considerably aided by the extensors of the knee and the heel. The breast being thus thrown forward, the fore legs incline backward, and the animal would fall, did it not instantly throw them forward in order to support itself. It then draws up the trunk upon the fore legs, and renews its former efforts.

In this walking, each step is performed by two legs, one belonging to the fore, and the other to the hind pair. Sometimes these are of the same side, and sometimes those of opposite sides. The motion of a horse who steps forward in the latter way, is termed a pace.

In the animals that have the fore feet longer than the hind, and have their strength chiefly in the anterior part of the body, the principal impulse is given by extending the fore foot. The hind foot then rises to follow it, and it is not until the moment that the latter extends itself in its turn, that the fore foot is raised. This is the manner in which the *giraffe* is said to move.

But when the fore legs are considerably disproportioned to the others, and particularly when the posterior extremities are feebly and badly articulated, as in the sloths, the animal is obliged to drag itself forward, by first extending the fore legs, and then bending them so as to draw the body after them. Hence the progression of the sloth is so laborious.

Those animals which have their fore legs very short in proportion to their hind legs, would be incapable of sufficiently supporting their bodies, and must fall forward on each impulse of the latter, had they not the precaution to make a prancing movement; that is, to raise the anterior extremities entirely off the ground, previously to their being impelled onward by means of the hind feet. Accordingly, such animals cannot in propriety of language be said to walk; they only move forward by leaps. This is the case with hares, rats, and particularly jerboas. Indeed, these animals cannot be said to walk at all, except in the action of ascending. When they attempt to walk slowly on level ground, they are obliged to move themselves by the fore feet, and merely to drag after them the hind pair. This may be observed in rabbits, and still more distinctly in frogs.

138 Leaping.

In leaping, the body rises completely from the earth, and remains without any support for a short period, the duration of which depends on the force with which the leap has been made. This action is performed by a sudden extension of all the muscles belonging to the sacral articulations, immediately after they have undergone an unusual degree of flection. By this general extension these articulations receive a violent motion, the impulse of which is communicated to the centre of gravity of the body, and it is thus projected with a determined velocity, which is more or less in opposition to its weight. The projectile force and extent of the leap depend on the proportional length of the bones, and strength of the muscles. Those animals, therefore, leap best that have the sacral extremities longer and thicker than the atlantal; as the *kangaroos*, *jerboas*, *frogs*, *alticæ*, *grylli*, *fleas*, &c.

Small animals leap proportionally much farther than the larger species; and we know of none whose muscular strength, in this way, can be put in competition with that of a flea, which in a moderate computation is known to leap to a distance of at least 200 times its own length. The direction of a leap depends on the situation of the centre of gravity with respect to the member by which the impulse is given. Hence, only man and birds can leap vertically, because they alone have the trunk situated above the members by which the leap is effected. Quadrupeds, and most insects, can only leap forward; but spiders, which have several long feet on each side of their body, can also leap sideways.

Running consists of a series of low leaps performed alternately by each leg. It differs from walking, in the body being projected forward at each step, and in the hind foot being raised before the anterior touches the ground. It is more rapid than the quickest walk, because the acquired velocity is preserved, and increased at each bound by a new velocity. Running, therefore, cannot be instantaneously suspended, though a stop may be put to walking at each step. 139 Running.

In running, the animal inclines its body forward, that the centre of gravity may be in a proper position for receiving an impulse in that direction from the hind leg; and it is obliged to move the fore leg rapidly forward, to guard against falling.

Man varies his manner of running, only by taking longer or shorter steps, or giving to this motion a greater or less degree of rapidity; but quadrupeds vary this motion by the different order in which they raise each foot, or bring it to the ground.

Trotting is a mode of running in which the feet diagonally opposite rise at once, and fall at once, each pair alternately, but in such a manner, that for a moment all the four feet are off the ground. This produces a regular motion, and the sound of the animal's steps are heard two and two in succession. 140 Trotting.

Galloping is a running motion in which the animal raises the anterior feet at each step, and throws the body forward by the extension of the posterior feet. When the two fore-feet descend at the same time, and are followed by the two hind feet also descending together, the motion is called a *full gallop*, which is the most rapid a *horse* can perform, and the only mode of running in *dogs*, *hares*, &c. In this kind of gallop the steps of the horse are likewise heard by two beats at a time. The *common gallop* is when the two fore-feet are lifted unequally, and fall one after another. This may be divided into *gallops* in which the horses footsteps are heard by a series of three or four beats, because the posterior feet may fall to the ground either both together, or one after the other. 141 Galloping.

There are several kinds of animals which leap by the means of organs different from feet, but always by a sudden extension of several articulations.

Serpents leap by folding their bodies into several undulations,

dulations, which they unbend all at once, according as they wish to give more or less velocity to their motion; some may be assisted by the scales of their belly, which they can elevate and depress, but only a few genera are capable of employing this means.

Some fishes also leap to the tops of cataracts by bending their bodies strongly, and afterwards unbending them with an elastic spring.

The long-tailed *cray-fishes*, particularly the *shrimps*, leap by extending the tail after it has been previously bent under the body.

The larva of the *fly*, vulgarly called the maggot, forms itself into a circle, contracts itself as much as possible, then suddenly unbending, darts forwards to a considerable distance.

142 Climbing.

The motion of climbing, so useful to many of the inferior animals, consists, in hanging from, and strongly grasping any object susceptible of being seized by the fingers, toes, or tail, and thus rising, by successive efforts, in a direction opposite to the animal's weight. From this explanation, it is evident that those animals which have the divisions of their extremities most distinct and flexible, will be the best climbers; and accordingly we find that the animals called *quadrumanous*, as the apes, lemurs, and a few others, perform this action in the most perfect manner. Man is but an indifferent climber, as he can only grasp with his hands. In *oppossums*, *ant-eaters* and *sloths*, one of the toes is distinct, like the thumb in man, apes, and lemurs; or else they have a considerable protuberance on the heel, which has the same effect. Many animals, as some of the *monkeys*, some species of *oppossum* and *ant-eater*, the *manis*, &c. have a very flexible prehensile tail, which assists them in climbing. The animals of the cat genus have very sharp talons, by which they are materially assisted in this kind of progression, as they enable them to adhere firmly to the bark of trees, &c. Creepers, nut-hatches, woodpeckers, and other climbing birds, support themselves in a similar manner.

143 Flying.

The motion of flying, by which an animal can support itself for some considerable time in the air, can properly be said to be performed only by birds: for though bats can imitate this motion with tolerable success, and the galiopithecus, flying squirrels, and flying oppossums, appear to fly from one tree to another, the motion of the former cannot be supported for so long a time as that of birds; and the motion of the latter animals can be considered only as a leap, assisted and prolonged by the opposition given to the air, by the membranous expansion between their limbs.

When a bird designs to fly, it first darts into the air, either by leaping from the ground, or by throwing itself from some height. In the mean time it raises the whole of the wings which had till then remained folded, and which it unfolds in a horizontal direction by extending the bones. When the wings have thus acquired all the superficial extent of which they are susceptible, they are suddenly depressed, till they form, with the vertical plane of the body, an angle that is obtuse upward, and acute downward. The resistance which the air gives to this motion suddenly performed in it, produces a reaction on the body of the bird, and thus moves it forward as in ordinary leaps. This impulse once given, the bird refolds the wings by bending the joints, and repeats its efforts by another stroke. As the velocity thus acquired in ascending is gradually diminished by the effect of gravitation, a moment occurs in which it ceases, and in which the bird tends neither to ascend nor descend. If at this moment it gives a new stroke with the wings, it acquires a new ascending velocity, by which it will be carried as far as before, and by repeating these efforts, it will ascend in a uniform manner. If this second stroke be made before the velocity first acquired is lost, an additional impulse will be received; and by a continuance of this action the bird will ascend with an accelerated motion. If the wings do not vibrate when the ascending velocity is lost, the bird will begin to descend; and if it allow itself to fall down to the point from which it set out, it cannot ascend as high as at first, but by a much stronger exertion of the wings; but if it seizes in the fall a point so situated that the acquired descending velocity, and the small space which it has to fall down reciprocally balance each other, it may, by a series of equal vibrations, keep itself at the same height.

When a bird wishes to descend rapidly, as when it darts upon its prey, it altogether suppresses the vibration of its wings, and thus falls by its own gravity. While descending, however, it may suddenly break its fall by extending its wings, and this suspension is called a *recover*.

We have as yet considered only the vertical flight of a bird. To fly horizontally, it must rise in an oblique direction, and make a new movement of its wings, when it is ready to descend below the point from which it departed; but in this way it will not fly in a straight line, but will describe a series of curves so very much depressed, that the horizontal will overcome the vertical motion. In order to ascend obliquely, the bird must make quicker vibrations of its wings, and to ascend in a similar direction, the vibrations must be slower.

The deviations of flight to the right or left are chiefly produced by the unequal vibrations of the opposite wing; those of the left wing carrying the bird to the right, and *vice versa*. The more rapid the flight is forward, the greater is the difficulty of one wing surpassing the other in the velocity of its vibrations, and of course the deviation sideways is the more difficult. Hence birds which fly with the greatest velocity make large circles in turning.

The tail, when spread out, contributes to sustain the posterior part of the body. If it is depressed when the bird has acquired a progressive velocity, it presents an obstacle which elevates the posterior part of the body, and depresses the anterior. If it is turned up, the contrary effect is produced. Some birds incline to one side, to assist them like a rudder, when they wish to change their horizontal direction.

The structure of most birds peculiarly adapts them for rapid motion through the air, and for sustaining themselves in this element with the greatest facility. See ORNITHOLOGY, N° 37.

The action of swimming, like that of flying, nearly resembles leaping, except that, like flying, the leap does not take place on a fixed surface. A great variety of animals, besides fish, and most of the other inhabitants of the waters, are capable of swimming. This action is performed with considerable ease by several of the mammalia, 144 Swimming.

Of Animal Motion. malia, even by the bulky elephant, and the unwieldy hippopotamus; by many tribes of birds; by several reptiles and serpents, and by some insects.

The organs employed by fishes, in making their way through the water, are their fins, tail, and air-bladder; the two former exerting the necessary motions like the wings of birds, while the latter, by being compressed or expanded, causes the necessary changes in the specific gravity of the body, and thereby renders the animal more or less buoyant. The swimming of fishes has been treated of with sufficient minuteness under ICHTHYOLOGY, chap. iii. sect. 3. to which we refer the reader.

The cetacea employ much the same means as fishes; but in them the principal efforts of the tail are made in a vertical direction, and the use of the air-bag is supplied by lungs, which they can compress and dilate at pleasure, by the action of the diaphragm, or the intercostal muscles. See CETOLOGY.

The swimming of mammalia, and of water birds, is performed by means of the legs and feet, which are used like oars, to propel the body forward by the resistance which they make to the water in the contrary direction. Hence those quadrupeds and birds that have flat or webbed feet, swim most easily, as the resisting surface is the greatest. Of all the mammalia, man has the most occasion to use his hands in swimming, on account of the greater proportional weight of his head.

Serpents, and the larvæ of such insects as sometimes inhabit the waters, perform the action of swimming by rapid inflections of the body like an eel or a leech. The larvæ that are most commonly found in the waters are those of the water *beetles*, the *hydrophilus*, the *day flies*, the *aquatic tipulæ*, and *gnats*.

145. No animal walks without legs, or flies without wings (if we except the flying fish, whose fins enable it rather to spring than fly); but there are many that swim without fins, and that leap or creep without any legs. The rapidity of movement is not proportioned to the number of instruments that are employed: if the spout-fish be observed to move slowly with one leg, the sea-urchin moves still more slowly with many thousands; the oyster moves by squirting out water; the scallop by the jerk of its shell, and when in the water it rises to the surface and sails before the wind.

Many animals are formed by nature to fly, walk, leap, and swim: the fate of those are rather uncommon whose muscles or feet are by nature attached to their teguments; the lobster is obliged to throw off its shell, and the caterpillar all its feet, with the skins, and in that situation to remain stationary till it receive new instruments of motion.

146 Whoever has read the celebrated work *De Motu Animalium*, needs not to be told that, besides the organs which are here mentioned, the form, the structure, and even the specific gravity of the body, as depending on the nature of the bones and muscles, or as varied by air-vesicles and bubbles, with a great variety of other circumstances, are necessary to explain the different phenomena of locomotion.

147 Vegetable motions. As to vegetable motions, they evidently depend on external agents: the wings of seeds only fit them to be carried by the wind, their specific gravity to float in the water, and their legs or tentacula to adhere to bodies that are in motion; the singular motions which have been ascribed to sleeping, to waking, to sensation, and volition, in the vegetable kingdom, seem only the consequence of light, heat, moisture, and such stimulants, acting invisibly or with secret influence: the opening and closing of the meteoric flowers are always correspondent to the states of the atmosphere; and the opening and closing of the equinoctial and tropic flowers, to the light, the length or shortness of the day.

The principal intentions of locomotion are to get food, to shun danger, to promote intercourse and disperse the species. 148 Uses of locomotion.

There is perhaps no part of physiology which is more important than the relations which subsist between the different functions of the living body; but it is a part of the subject which is as yet but little understood. We regret that our limits will not permit us to pay all the attention to it which we could wish. We shall, however, briefly notice under each function, the principal relations that are found to take place between it and those which have been previously considered.

Besides the dependence which animal motion has, in most instances, on the nervous system, (see N° 111.) we find an evident sympathy between these two functions in a variety of phenomena. A violent emotion or impression on the nerves often throws the limbs into convulsive agitations; spasmodic affections are relieved, or sometimes removed, by the coming on of delirium; and these symptions will alternate with each other: a compression of the brain, or of some large nervous trunk, produces general or partial want of motion, and when this compression is removed, the muscles for the most part recover their usual action; an attack of epilepsy is often preceded by the sensation of a stream of vapour commencing in some external part, and rising to the brain. These, and many other phenomena that might be mentioned, fully prove the sympathy between the nervous and muscular systems; and with this enumeration we must dismiss the subject. 149 Mutual relations between sensation and motion.

CHAP. V. *Of Digestion.*

THE necessity of repairing the waste of the body is announced in all animals by the feelings of hunger and thirst; the former of which intimates the occasion for solid, the latter for liquid food. This imperious necessity overrules all the other affections of the vital principle, and every other appetite often remains suspended till that necessity be satisfied. It is difficult to assign the final cause of these singular sensations, but probably our researches on that subject are rather curious than useful. Whatever be the ultimate end of these appetites, we readily perceive how much they are influenced by habit. We find that when we are accustomed to take food at particular times, the appetite, under ordinary circumstances, always reminds us at these times, of the occasion, whether real or apparent, for receiving a new supply. By this influence of habit some animals, especially man, are accustomed to take several meals in a day, while others can fast for days, or even weeks, together. The appetite for food also varies considerably at different ages. It is more lively and more imperious in infancy and early childhood, and in general in those animals who have not yet acquired their full growth; it is on the contrary weaker in advanced age, and when the body ceases to increase 150 Appetite for food.

Of Digestion.

increase in size. It is more frequently renewed in the strong and healthy, and those who are accustomed to laborious occupations or active exercises.

151 We know that in the natural state of the animal body, the appetite for food is influenced by the nature of the aliment on which the animal is accustomed to subsist. Many animals live entirely on vegetable food, and these have no appetite for animal substances, and even reject these when offered to them. On the other hand, many tribes live entirely on animal food, and either refuse vegetable, or, if obliged by necessity to employ it as food, do not appear to derive nourishment from it. We find, however, that it is in the power of habit to remove these appetites; that a horse or a sheep may be taught to live on animal food, while a dog or a cat may be supported entirely on vegetable substances. A few animals are capable of subsisting on almost every kind of animal or vegetable substances, or are omnivorous.

152 Plants and some animals live on water and air alone.

Many animals are capable of being supported by water and air alone. We know that several fishes, as the minow, the gold and silver fish, &c. will live for a long time in a vessel containing pure water, and freely exposed to the air. Rondelet a celebrated writer on fishes in the 16th century) relates a remarkable instance of this. He kept a fish during three years in a vessel that was constantly full of very pure water. It grew to such a size, that at the end of that time the vessel could no longer contain it. Leeches are often kept for several years with no other nutriment but water, and that not very often changed. There is good reason to believe that the sole food of plants consists of water and air, and that the soil in which they grow answers scarcely any other purpose than that of preserving and conducting those necessary aliments.

153 It has been supposed that some animals are capable of subsisting on matters that appear to contain no nutritious principles, such as sand, hair, and wool. Borelli long ago conceived this opinion, from observing that in many testaceous animals which he dissected, the alimentary tube contained nothing but sand. It has often been remarked, that horses, cows, and sheep, when deprived of their usual nourishment, will lick their bodies, and swallow down the hair, or, in the case of sheep, will tear off and swallow each others wool. If we consider the nature of these substances, we think there is no reason to suppose that they answer any other purpose than distending the alimentary canal or stomach, and thus in some measure counteracting the effect of hunger.

The subject of food in general has been already treated of, under ALIMENT, and in MATERIA MEDICA, Part I. N° 17; and the function of digestion, as far as it relates to man, has been considered under ANATOMY, N° 106, 107, and under CHEMISTRY, N° 2548. It remains for us here only to make a few observations on the comparative physiology of this function.

154 Differences of digestion

Digestion differs considerably in the various classes of animals, both as to the organs by which it is performed, and as to the simplicity or complex nature of the operation itself. The general variations that take place in the organs of digestion, have been mentioned under the comparative part of ANATOMY, N° 152, and are fully treated of by Cuvier, in his *Leçons d'Anatomie Comparée*, tom. iii. and Blumenbach, in his *Comparative Anatomy*, chap. 6. and 7.

In the more perfect animals, digestion supposes a series of operations, from the time that the food enters the mouth, till the nutritious parts of it are taken into the circulating system. These operations are, *mastication*, *insalivation*, *deglutition*, *chymification*, and *chylification*.

155 Mastication.

Mastication is performed by means of teeth, and therefore can scarcely be said to take place in those animals that are not furnished with these organs. We know that all mammalia, except those which Cuvier calls *edentata*, as the ant-eaters, pangolins, and platypus, have teeth, fitted both for dividing and chewing their food; but here an important difference takes place. Those animals which live chiefly on animal food, have most of their teeth sharp and pointed, for the purpose of seizing and tearing their prey, while the graminivorous and granivorous animals have very large and strong grinders, in which the hard substance commonly called enamel (or what Blake calls *corpus striatum*,*) forms alternate layers with the bony part. Such are also found in most reptiles and serpents, and in many fishes; but in some of these they seem less to serve the purpose of dividing the food, than to seize and retain it till swallowed. Birds have no teeth, though some of them have the mandibles of the bill so formed as to divide and cut in pieces their food.

* *Blake on the Structure and Formation of the Teeth.*

156 Insalivation.

During mastication the food is mixed with the saliva, and is thus better fitted for easy solution in the stomach. This insalivation of the food may, however, take place, without previous mastication. It is common for serpents to swallow their food whole; but in order to facilitate its passage down the throat, they first besmear it all over with their muscous saliva. In many animals, a process similar to insalivation takes place, while the food remains in the mouth. In several species of the ape tribe there is a pouch situated on each side of the jaw, and in these pouches the greater part of the food is retained, not merely as some suppose, to serve as a future meal, but to undergo a dilution by the fluids that are there secreted. In granivorous birds, the food is first received into a membranous bag, formed by a dilatation of the gullet, and commonly called the *crop*, where it is macerated by the fluids that are there separated by means of glands or exhaling vessels, and passes down, as the animal requires, to be further prepared by the stomach. The bustard, indeed, though a granivorous bird, has no proper crop, but the gullet is furnished with numerous and large glands.

For an account of the chemical nature and properties of saliva, see CHEMISTRY, N° 2723.

157 Deglutition.

The operation of deglutition depends chiefly on the action of the tongue, and on that of the muscles which surround the pharynx and gullet. It is more or less speedy in proportion as these are more or less active and vigorous. Most animals, after having once swallowed their food, do not receive it again into the mouth; but this takes place in several tribes, and is called *rumination*, or chewing the *cud*.

158 Rumination.

Rumination takes place chiefly in those animals that feed on herbage, and have not a muscular stomach; such as all the tribes that Linnæus has ranked under the order *pecora*. In these the food, after being slightly chewed, is received into the first stomach, and after remaining there for a short time, it is gradually brought by a retrograde action of the gullet into the mouth, where it undergoes a complete trituration and insalivation,

Of Digestion.

tion, and is then conveyed into the 2d, 3d, and 4th stomachs, to be mixed with the gastric juice.

Some of those birds which have a diluting sac or ingluvies, seem likewise to ruminate. This in the parrot was observed by the gentlemen of the French academy. It has since been observed in rooks, macaws, cockatoos, and others: and Mr Hunter, to whom physiology is so much indebted, discovered that the male and the female pigeon secrete in their ingluvies a certain liquor for feeding their young; and that most kinds of what have been thought ruminating birds do very often in expressing their fondness regurgitate their food. Yet both this and another species of regurgitation which is very common with those animals that swallow indigestible substances with their food, should be carefully distinguished from rumination. For a farther account of rumination, and of the digestive organs of ruminating animals, see *Comparative* ANATOMY, N° 228—234. and *Phil. Trans.* 1807, Part ii.

159 Chymification.

The food having entered the stomach, undergoes in that organ processes that are partly mechanical, or rather organic, and partly chemical, depending on the structure of the stomach, and the nature of the juices secreted into its cavity. By these actions it is reduced into a pulpy substance commonly called *chyme*.

160 Organic action of the stomach.

The organic action of the stomach is greater or less, according as this organ is more or less muscular. There are many animals, chiefly birds of the granivorous tribes, that have a very muscular stomach, commonly called *gizzard*, capable of grinding, not only the grains received into it, but even of reducing to powder small pieces of glass, and of blunting the points of needles and lancets. These facts were first proved by Borelli, who introduced into the gizzards of fowls, nuts, filberts, hollow spheres of glass, hollow cubes of lead, small pyramids of wood, and several other substances, which he found were either crushed together, or broken to pieces. He computes the power exerted by the stomach of the Indian cock as equal to the pressure of 1350 pounds weight. These experiments were repeated and verified by Spallanzani.

Some animals that are not possessed of a muscular stomach have, within that organ, teeth, or other hard bodies, for the purpose of breaking or grinding their food. This is the case with many of the crustacea, as crabs and lobsters.

A great many animals have what Spallanzani calls *intermediate* stomachs, i. e. not so muscular as the gizzard of fowls, nor so membranous as the stomachs of ruminating animals; this is the case with many birds, as ravens, crows, herons, &c. The stomachs of these animals are possessed of considerable force, though this is not nearly equal to that exerted by the gizzard. These animals possess the power of rejecting by the mouth the substances that are incapable of digestion in the stomach, every nine, or sometimes every three hours.

The animals with membranous stomachs are very numerous, comprehending man, most beasts and birds of prey; many reptiles, snakes, fish, &c. The stomachs of these animals are susceptible of but little muscular action, though in many species they both contract upon the food, and reject it through the gullet, on various occasions. Birds of prey, like the ravens, crows, &c. possess the power of rejecting, in the form of pellets, the indigestible parts of their food, which usually takes place every 24 hours.

161 Discoveries of Mr Home.

A most interesting paper by Mr Everard Home is published in the Philosophical Transactions for 1807, part ii. on the structure and functions of the stomachs of various animals. We regret that we can here give little more than the results of his inquiries.

From previous investigations respecting the stomachs of ruminating animals, Mr Home was led to believe that the fourth stomach in these tribes was either always, or during digestion, divided into two portions, each performing a different office in the digestive process; and he even conjectured, that a similar division might take place in other animals.

Mr Home has examined the stomachs of a great variety of animals, and investigated the progress of digestion in *ruminants*, the *hare* tribe, which occasionally ruminate, the *beaver*, *dormouse*, *water-rat*, *common rat*, *mouse*, *horse*, and *ass*, *kangaroo*, *pecaré*, *hippopotamus*, *elephant*, the *cetacea*, *fowls*, and lastly in *man*.

162 Human stomach the link between carnivorous and phitivorous stomachs.

The human stomach appears to be the uniting link between those that are fitted only to digest vegetable substances, and those of animals that are entirely carnivorous; and yet we find, that in its internal structure it is in every material respect similar both to those of the monkey and squirrel, which usually digest only vegetable food, and to those of carnivorous animals.

163 Into a *cardiac* and *pyloric* portion.

The human stomach is occasionally divided into a *cardiac* and a *pyloric* portion, by a muscular contraction similar to those of other animals; and as this circumstance has not before been noticed, it is proper to be more particular in describing it.

The first instance in which Mr Home observed this muscular contraction in the human stomach, was in a woman who died in consequence of being burnt, and who had been unable to take much nourishment for several days before her death. The stomach was found empty, and was taken out of the body at a very early period after death. It was carefully inverted to expose its internal surface, and gently distended with air. The contraction was so permanent, that after the stomach had been kept in water, in an inverted state, for several days, and at different times distended with air, the appearance was not altogether destroyed.

Since that time, Mr Home has taken every opportunity of examining the human stomach shortly after death; and he finds that this contraction, in a greater or less degree, is very generally met with. He is of opinion that this effect is not produced by a peculiar band of muscular fibres, but that it arises from the muscular coat, in the middle part of the stomach, being thrown into action to a greater or less extent according to circumstances. When this part of the stomach is examined by dissection, its muscular fibres are not to be distinguished from the rest. If the body be examined so late as 24 hours after death, this appearance is rarely met with; a circumstance which accounts for its not having before been particularly noticed.

164 Food first dissolved in the cardiac portion;

That the food is dissolved in the *cardiac* portion of the human stomach, is proved by this part only being found digested after death; the instances of which are sufficiently numerous to require no addition being made to them. This could not take place unless the solvent liquor was deposited there. Mr Hunter goes so far as

to

Of Digestion.

to say in his paper on this subject, "there are few dead bodies in which the stomach at its great end is not in some degree digested."

165 but the chyle formed in the pyloric portion.

That the chyle is not formed there, and that it is commonly formed before the food passes through the *pylorus*, is proved by the result of some experiments made by Mr Hunter upon dogs, in the year 1760. The dogs were killed while digestion was going on; and in all, the food was least dissolved, or even mixed, towards the great end of the stomach, but became more and more so towards the *pylorus*, just within which it was mixed with a whitish fluid like cream.

166 Solvent liquor secreted by glands near the gullet.

From the result of these experiments, as well as from the analogy of other animals, it is reasonable to believe, that the glands situated at the termination of the cuticular lining of the œsophagus, which are described by Mr Home, secrete the solvent liquor, which is occasionally poured on the food, so as to be intimately mixed with it before it is removed from the cardiac portion; and the muscular contraction retains it there, till this takes place.

167 Curvature of the stomach accounted for.

Such contraction being occasionally required in the stomach, accounts for its being more or less bent upon itself, as by this structure it is more readily divided into two portions, by the action of the muscular fibres at that part where the angle is formed.

This contraction also explains why the contents of the stomach are not completely discharged from the first effect of an emetic; and by it Mr Home thinks we may explain the cramp of the stomach, and some kinds of indigestion.

168 Ornithorinchus the real link between quadrupeds and birds.

After comparing the stomachs of several carnivorous animals with that of man; in tracing the gradation from carnivorous beasts through the bat tribe to birds of prey, Mr Home remarks, that "the only real link between the stomachs of quadrupeds and birds is that of the ornithorinchus (or platypus), which, however, is more an approach to the gizzard, being lined with a cuticle containing sand, and having the same relative situation to the œsophagus and duodenum. The food of this animal is not known; it is probably of both kinds; the papillæ at the pylorus, which appear to be the secretory ducts of glands, are peculiar to it.

169 General conclusions.

From the facts and observations brought forward in this valuable paper, Mr Home deduces the following general conclusions. "That the solvent liquor is secreted from glands of a somewhat similar structure in all animals, but much larger and more conspicuous in some than in others.

"That these glands are always situated near the orifice of the cavity, the contents of which are exposed to their secretion.

"That the viscid substance found on the internal membrane of all the stomachs that were examined recently after death, is reduced to this state by a secretion from the whole surface of the stomach, which coagulates albumen. This appears to be proved, by every part of the fourth cavity of the calf's stomach having the property of coagulating milk.

"This property in the general secretion of the stomach leads to an opinion, that the coagulation of fluid substances is necessary for their being acted on by the solvent liquor; and a practical observation of the late Mr Hunter, that weak stomachs can digest only solid food, is in confirmation of it.

"That in converting animal and vegetable substances into chyle, the food is first intimately mixed with the general secretions of the stomach, and after it has been acted on by them, the solvent liquor is poured upon it, by which the nutritious part is dissolved. This solution is afterwards conveyed into the pyloric portion, where it is mixed with the secretions peculiar to that cavity, and converted into chyle.

"The great strength of the muscles of the pyloric portion of some stomachs will, by their action, compress the contents, and separate the chyle from the indigestible part of the food.

"In animals whose food is easy of digestion, the stomach consists of a cardiac and pyloric portion only; but in those whose food is difficult of digestion, other parts are superadded, in which it undergoes a preparation before it is submitted to that process."

170 Action of the gastric juice.

The action of the juices of the stomach, or of what we call the *gastric juice*, appears to have much more effect in the process of chymification, than the muscular action of the stomach, though the dissolving power of this fluid seems to be proportionally less in those animals that have the most muscular stomachs. The gastric juice of granivorous birds is capable of dissolving flesh; but when this is entire, it requires four or five days for solution; whereas when bruised, half that time is sufficient. Even grain is not dissolved in it except when bruised. The gastric juice of animals with intermediate stomachs dissolves flesh and cartilage, but not bone. It is incapable of dissolving entire seeds. In animals with membranous stomachs, the gastric juice is extremely active, and seems to be almost the only agent in the digestive process. In some of these animals, however, as the ruminating tribes, this fluid has no effect on the food, unless it be bruised, or thoroughly masticated. Spallanzani found, that owls digest flesh and bones, but not grain;—that the gastric juice of the eagle dissolves bread and bone, and even animal and vegetable matters, when it is taken out of the body;—that a wood pigeon may be gradually brought to live on flesh;—that the owl and falcon do not digest bread;—that the gastric juice of the dog dissolves even the enamel of the teeth.

Hence, in every order of animals, the gastric juice is the principal cause of digestion, and it agrees in all in many properties, and differs in others. In the frog, the newt, scaly fishes, and other cold-blooded animals, it produces digestion in a temperature nearly equal to that of the atmosphere. In warm-blooded animals it is capable of dissolving the aliment in a degree of heat lower than that of these animals. In them too the food is digested in a few hours, whereas in the opposite kind it requires several days, and even weeks, particularly in serpents; likewise, the gastric juice of the gallinaceous class can dissolve only bodies of a soft and yielding texture, and previously triturated: whilst in others, as serpents, the heron, birds of prey, and the dog, it decomposes substances of great tenacity, as ligaments and tendons; and even of considerable hardness, as the most compact bone. Man belongs to this class, but his gastric juice seems to have no action on the hardest kinds of bones. Some species, likewise, are incapable of digesting vegetables, as birds of prey; but man, the dog, cat, crows, &c. dissolve the individuals of both kingdoms alike, and are omnivorous, and in general their gastric juices produce these effects out of the body.

For

Of Digestion.

For an account of the chemical nature and properties of the gastric juice, see CHEMISTRY, N° 2551.

171 Solubility of foods. The process of chymification depends also, in a great measure, on the nature of the substances employed as food, as some of these are much more soluble than others. On this subject much information may be derived by consulting the experiments of Dr Stark *, and those of M. Gosse of Geneva, an abstract of which is given in Johnson's Animal Chemistry, vol. i. p. 207. From the latter experiments it appears, 1*st*, That the following substances are either insoluble, or are not digested in the usual time in the stomach.

* *Stark's Works.*

Animal substances. 1. Tendinous parts. 2. Bones. 3. Oily or fatty parts. 4. Indurated white of egg.

Vegetable substances. 1. Oily or emulsive seeds. 2. Expressed oils of different nuts and kernels. 3. Dried grapes. 4. Rind of farinaceous substances. 5. Pods of beans and pease. 6. Skins of stone fruits. 7. Husks of fruit, with grains or seeds. 8. Capsules of fruit, with grains. 9. Ligneous stones of fruits. 10. The gastric juice does not destroy the life of some seeds; hence bitter-sweet, hemp, misletoe, and other plants which sometimes grow upon trees, are produced by the means of the excrements of birds, the kernels of seeds being defended from the menstruum by their exterior covering.

2*d*, That the following are partly soluble, viz.

Animal substances. 1. Pork dressed various ways. 2. Black puddings. 3. Fritters of eggs, fried eggs and bacon.

Vegetable Substances.—1. Salads of different kinds, rendered more so when dressed. 2. White of cabbage less soluble than red. 3. Beet, cardoons, onions, and leeks. 4. Root of scurvy-grass, red and yellow carrots, succory, are more insoluble in the form of salad than any other way. 5. Pulp of fruit with acids, when not fluid. 6. Warm bread and sweet pastry, from their producing acidity. 7. Fresh and dry figs. By frying all these substances in butter or oil they become still less soluble. If they are not dissolved in the stomach, they are, however, in the course of their passage through the intestines.

3*d*, That the following are soluble, or easy of digestion, being generally reduced to chyme in an hour, or an hour and a half.

Animal Substances.—1. Veal, lamb, and in general the flesh of young animals, are sooner dissolved than that of old. 2. Fresh eggs. 3. Cows milk. 4. Perch boiled with a little salt and parsley. When fried or seasoned with oil, wine, and white sauce, it is not so soluble.

Vegetable Substances.—1. Herbs, as spinach, mixed with sorrel, are less soluble. Celery. Tops of asparagus, hops, and the ornithogalus of the Pyrenees. 2. Bottom of artichokes. 3. Boiled pulp of fruits, seasoned with sugar. 4. Pulp or meal of farinaceous seeds. 5. Different sorts of wheaten bread, without butter, the second day after baking; the crust more so than the crumb. Salted bread of Geneva more so than that of Paris without salt; brown bread in proportion as it contains more bran is less soluble. 6. Rapes, turnips, potatoes, parsnips, not too old. 7. Gum arabic, but its acid is soon felt. The Arabians use it as food.

The solvent power of the gastric juice is increased by various stimulants, especially by those called *condiments*, as sea salt, spices, mustard, vinegar, as well as by vinous and spirituous liquors and old cheese in small quantities, and by various bitters. It is retarded by large quantities of diluting liquors, especially when taken hot; by acids and astringents taken a short time after eating; by unctuous substances; by mental employment, or severe bodily exercise, too soon after a meal; and by leaning with the breast against a table.

172 Various theories of digestion. It may be proper here to notice the various opinions that have been entertained respecting the immediate cause of digestion. The principal of these opinions are, that it is produced by coction or heat; by trituration in the stomach; by fermentation, or by putrefaction.

173 Heat. That it is not brought about by heat alone, will appear from the circumstance, that many cold-blooded animals digest their food as completely, though not so expeditiously, as warm-blooded animals.

174 Trituration. That it is not effected by trituration in the stomach alone, is evident from the experiments that have been made by Spallanzani, Stevens, and others, of giving to animals food enclosed in hollow perforated balls, sufficiently strong to resist the muscular power of the stomach; as the balls have been found empty, and not compressed.

175 Fermentation. That it is not owing to fermentation is proved by the circumstance, that the more perfectly digestion proceeds, the less is the evolution of gases in the stomach; the contrary of which would be the case, if digestion consisted in a fermentation of the aliment.

176 Putridity. That it does not depend on putridity, is evidenced by the observations that have been made on putrid food given to dogs, and examined some time after, when it was found perfectly sweet.

On the whole it appears, that in most animals the digestion of food in the stomach depends partly on a due degree of heat, partly on the vital action of the stomach, but chiefly on the action of the gastric juice.

177 Chylification. When the aliments have been converted in the stomach to the crude pulp called *chyme*, they are gradually propelled through the *pylorus* into the duodenum, where they are mixed with the bile, the pancreatic juice, and the fluids that are separated by the mucous coat of that intestine, and are thus reduced to a still finer pulp, containing, as one of its principal ingredients, the nutritious fluid called *chyle*, the nature and properties of which, as they have been but slightly mentioned in the former parts of this work, fall to be noticed here.

178 Properties of chyle. The properties of chyle have not been minutely investigated; but according to Fordyce, as far as experiment has been carried, the chyle of quadrupeds is so similar to that of man, and of each other, as hardly to be distinguished, even in tribes the most opposite to each other in their structure, food, and habits of life. As far as we can perceive, the chyle of a dog or a wolf differs in nothing from that of a sheep or an ox.

The chyle consists of three parts; one part which is fluid, and contained in the lacteals, but coagulates on extravasation.

The second part consists of a fluid, which is coagulable by heat, and in all its properties hitherto observed, it is similar to the serum of the blood.

The third part consists of globules, which render the whole white and opake. These globules have been supposed by many to be an expressed oil; but this has not been proved. Neither has it been perfectly demonstrated that sugar is contained in the chyle, although it has been

Of Digestion

been made very probable. The difficulty of determining these points arises from the small quantity that can be collected, the largest animals not supplying more than one ounce or two, at the most. However, the part coagulating on extravasation; the part agreeing with serum in its qualities; the globular part, which in some animals, but not in quadrupeds, exists without giving whiteness to the chyle—alone, or along with sugar, form the essential parts of the chyle *.

* Fordyce on Digestion.

179 Progress of the chyle.

The compound pulpy matter containing the chyle is carried forward from the duodenum through the whole course of the intestines, where it is subjected to the continual action of the internal wrinkled membrane of the bowels, and its nutritious particles, or chyle, selected and absorbed by the lacteals that are abundantly distributed there, and open their mouths directly within the cavity.

180 Passage of food through the intestines.

As to the movements of the alimentary canal, the direction of hairs found in the stomach, and the balls of hairs which are thrown up, would appear to indicate a circular motion. The intestinal part has a motion similar to that of a worm, and is called the *vermicular* or *peristaltic*. Here every portion retains its own motion, although it be separated from the rest by ligatures. The stomach of the polype, the gullets of the ruminating kinds, and the cæca, have the motion in different directions at different times; and that observed in the alimentary canal of a louse is, when viewed through a microscope in the time of action, amazingly rapid; the stimulating causes employed are the food, the different liquors with which it is mixed, the air, the nerves where they exist, and a portion of heat. Some degree of heat is necessary to every process of digestion, both in the animal and vegetable kingdom; what that degree is depends on the nature of the living body; and is various according to its age, its health, its employments and habits.

With respect to the function of digestion in the lower classes of animals, we can say but little. We know that their food is dissolved in the stomachs of the crustacea, of mollusca, and of polypes; but whether this process in most insects and worms is any thing more than imbibition, or taking in aliment, which is to undergo little change, we are uncertain. We know, indeed, that many insects live on substances which must be dissolved before they enter into the pores of their bodies, and that many of them abound in acrid juices, which are well fitted for this solution. It does not appear that plants possess what may be called the faculty of digestion.

181 Relations between digestion and sensation.

The relations between digestion and the functions we have already considered, especially sensation, are various and important. The sympathies that exist between the head and the stomach, have been long acknowledged. Several affections of the brain are accompanied with sickness at the stomach, loss of appetite, and indigestion; while on the other hand, the deranged state of the digestive organs seldom fails to produce giddiness, headach, ringing in the ears, confusion or depravation of sight, &c.; and if the former symptoms arise to a great height, as in the case of overloaded stomach or surfeit, coma, or even apoplexy, is frequently produced. In many nervous affections, particularly hysteria and hypochondriasis, in which there frequently takes place astonishing accumulations of air in the stomach and bowels, the affections of the head, such as stupor, confusion of thought, partial blindness, &c. sometimes proceed to such a height, as to threaten, or even sometimes to produce, an apoplectic paroxysm. In many cases these affections are referred immediately to the head; but are proved, in most instances, to depend on the disordered state of the alimentary canal, from the immediate relief procured by those remedies which promote the discharge of air, or produce copious evacuation from the bowels. On the other hand, in some diseases, where the head is primarily affected, as in phrenitis hydrocephalica (water in the head), the complaint is referred to the bowels, from the costiveness or other disordered state of these. The daily experience of literary men shows how much intense thought diminishes the digestive powers, and how imperfectly studious occupations can be carried on after a full meal. The action of the digestive organs is also considerably influenced by the mind, or the passions. We know how readily the appetite may be diminished or destroyed by sudden anger or affliction.

The action of the stomach may even be influenced by the will. We have known a person who could vomit whenever he pleased; and Dr Darwin speaks of another who had acquired this voluntary command over the inverted motions of the stomach and throat, to such a degree, as to gain a subsistence by exhibiting these unnatural powers to the public. At these exhibitions he was accustomed to swallow a pint of red rough gooseberries, and a pint of white smooth ones; to bring them up in small parcels into his mouth, and restore them separately to the spectators, who called for red or white, as they pleased, till the whole were redelivered *.

* Zoonomia, vol i. p. 276.

The sympathies that take place between the brain and the digestive organs, are easily explained, from considering the distribution of the great sympathetic nerve, to illustrate which we have given a figure (fig. 1.) showing its course and distribution from the head through the chest, as far as the stomach.

Plate CCCCXVIII.

182 Relations between digestion and motion.

The relations between the digestive and the locomotive functions, are not less obvious. Experience shews how much digestion depends on regular exercise, and how imperfectly it is carried on in the stomach of the indolent and sedentary; while on the other hand, when the stomach is overloaded, voluntary motion becomes difficult and fatiguing. Spasmodic contractions of the muscles, twitchings of the limbs, and similar affections, are the common attendants of indigestion, though these may perhaps be referred equally to the nervous as to the muscular system.

183 Morbid affections of digestion.

The principal morbid affections of digestion are, nausea, flatulence, eructation, rumination (G), vomiting, heartburn,

(G) That ruminating power which is natural to the quadrupeds of the order *Pecora*, is sometimes met with in man. We have heard of persons who regularly brought up their food into the mouth soon after eating, chewed it over again, swallowed the juices with the saliva, and spat out the more solid parts. In these cases, the rumination is heartburn, water-brash or *pyrosis*, loss of appetite, and inordinate appetite; for an account of which, see the article MEDICINE.

CHAP VI. *Of Absorption.*

184 Absorption. WE have said that the chyle is taken up from the compound pulpy matter composed of the food and the animal juices, as it passes through the intestines, by the lacteals. This, however, is not the only absorption that takes place in the animal body. The fluids poured out into cavities by the exhalant arteries, as well as all the secreted or exuding fluids, and even the solid materials of the system, are taken up by the lymphatics, and carried into the circulation; the blood poured out into cells in some parts, is evidently absorbed by veins; and, as we shall endeavour to prove, an absorption takes place over the external surface of the body.

185 Organs. What is called the absorbent system, is composed, in the superior animals, of the *lacteals*, the *mesenteric glands*, the *thoracic duct*, the *lymphatics*, and the *lymphatic glands*. For an account of these in man, see ANATOMY, Part I. Sect. 14. This system, in a greater or less degree, is found in all animals, except some mollusca, insects, worms, and zoophytes. See Cuvier's *Leçons*, tom. iv. leç. xxiii. and Blumenbach's *Comparative Anatomy*, chap. xiii.

186 By lacteals and lymphatics. The action of the lacteals and lymphatics is probably much the same, and is exerted in a similar manner. That of the lacteals is to convey the nourishing parts of the food into the circulating system; that of the lymphatics to carry to the same system watery fluids, for the purpose of diluting the blood, and such fluid or solid materials as are useless, or may prove noxious to the system. The action of the lacteals may be readily seen on opening an animal killed two or three hours after eating; and in this way they were first seen by Asellius. They are then found filled with a milky fluid, while, at other times, they are invisible. That the lymphatics are the principal organs of absorption, is now the general opinion of all physiologists, though their action in this way can seldom be demonstrated. As, however, it has been satisfactorily proved, that the veins do not generally absorb, and as the lymphatics that proceed from parts that contain irritating matters, are often seen inflamed, proving that they have imbibed a part of the irritating matter, there is little doubt that the office of absorption belongs almost exclusively to the action of the lymphatics.

Mr John Hunter made several experiments to shew that the veins do not absorb. He conveyed milk, coloured with various dyeing substances, or perfumed with musk, into the small intestines of an ass, which was soon after killed. On opening the veins of the intestines, and allowing the blood to separate into serum and crassamentum, the serum was found neither to be tinged with the colouring matters, nor scented by the perfume, while the coloured milk was evident in the lacteals. That the veins, however, do in some cases perform the office of absorbents, is evident from the speedy depletion of the *corpora cavernosa penis*, after having been distended with arterious blood; and from a similar depletion that takes place in the nipple of the female breast. 187 By the veins.

The principal object in dispute respecting the function of absorption in man and the higher classes of animals, is, whether the skin possesses the power of absorption. This question, as it is both curious and important, we shall examine pretty much at large; and for this purpose we shall avail ourselves of an able paper on the subject, by Dr George Kellie. 188 By the skin.

It had long been received as an established truth, that the skin was an inhaling or an absorbing organ, and that sometimes the inhalation balanced, or even surpassed, the exhalation of the cutaneous surface; but of late this doctrine of inhalation has been called in question, and, in the opinion of many, entirely overthrown. It has been said, that this absorption neither does nor can take place on the outside of the cuticle; that in every case of apparent absorption, the *epidermis* had been injured, or that the matter absorbed had been mechanically forced through it, and brought into immediate contact with the skin.

Haller had asserted *, on the authority of Dessault, that the body acquired an increase of weight in the warm bath; and this augmentation of weight was esteemed an *experimentum crucis* in favour of cutaneous absorption.

Experiments, however, have since been made with every necessary care, which seem to contradict the position, and to prove, that the body acquires no additional weight in the warm bath.

Seguin, from a great many experiments of this description, concludes, that there is no inhalation, because the body, so far from gaining, always lost some part of its weight during immersion, although much less than in the air in equal times †.

In other experiments again, as in those of Gerard and Currie, there was no increase of weight; but the body was

* *Elementa Physiologiæ*, tom. v. p. 88.

† *La Med. Eclairée.*

is to be considered as a disease, depending on the inability of the stomach to propel the solid food into the duodenum.

Mr Home, in the paper we have already quoted, (N° 161—169), relates a curious instance of habitual rumination in a man 19 years of age, who is blind, and has been an idiot from his birth. He has a very ravenous appetite, and it is necessary to restrict him in the quantity of his food, since, if he eats too much, it disorders his bowels. Fluid food does not remain on his stomach, but comes up again. He swallows his dinner, which consists of a pound and a half of meat and vegetables in two minutes, and in about 15 minutes he begins to chew the cud. Mr Home was once present on this occasion. The morsel is brought up from the stomach with apparently a very slight effort, and the muscles of the throat are seen in action when it comes into the mouth; he chews it three or four times, and swallows it; there is then a pause, and another morsel is brought up. This process is continued for about half an hour, and he appears to be more quiet at that time than at any other. Whether the regurgitation of the food is voluntary or involuntary, cannot be ascertained, the man being too deficient in understanding, to give any information on the subject.

Of Absorption.

was not observed to have lost any thing during immersion in the warm bath.

Now, during these experiments, the body was doubtless wasting, by the pulmonary and cutaneous discharges, and yet the weight of the body either continued unchanged; or where a loss of weight was observed, this was constantly less, greatly less, than is experienced during the same interval in air. And we might be inclined to infer, from a truth so general, and so well ascertained, an argument in favour of absorption.

It might be argued, that the loss of weight amounts to little or nothing, because, during immersion, the body acquires more by inhalation than it does or can do in the air; that the loss by the pulmonary and cutaneous discharges are counterbalanced, or nearly counterbalanced, by the increased absorption.

Those, however, who deny absorption, will not allow us the advantage of this argument. They tell us, that the exhalation by the skin and lungs is diminished, which sufficiently explains why the body loses less in the warm bath than in air. But that the accustomed discharges are suppressed or diminished in the warm or tepid bath, is, we apprehend, far from being proved; and, till this proposition is made good, the argument against cutaneous inhalation cannot be securely maintained.

One of Dr Currie's cases deserves farther consideration. We allude to the case of dysphagia, published by this gentleman *, in which Mr M. the subject of the case, was several times immersed in a warm bath of milk and water, and was weighed when taken out. Mr M. it is true, gained no weight while in the warm bath: but the loss continually going on in the air was, as in other trials, suspended during the immersions. Besides, he also expressed great comfort from the bath, with abatement of thirst; and, subsequent to the daily use of it, the urine flowed more plentifully, and became less pungent. An observation, precisely similar, is made by Mr Cruickshank. "A patient of mine (says Mr Cruickshank), with a stricture of the œsophagus, received nothing, either solid or liquid, into the stomach for two months; he was exceedingly thirsty, and complained of making no water. I ordered him the warm bath for an hour, evening and morning, for a month; his thirst vanished, and he made water in the same manner as when he used to drink by the mouth. (H) †.

* *Medical Report*, first edit. p. 227.

† *Cruickshank on the Absorbents.*

But to return to the case of Mr M——. Dr Currie himself remarks, that the discharge by urine alone exceeded much in weight the waste of his whole body; and it cannot be doubted that the discharge by stool and perspiration exceeded the weight of the clysters.—Thus it appears, that the *egesta* exceeded the *ingesta* in a proportion much greater than the waste of his body will explain. How is this accounted for, Dr Currie asks, unless by cutaneous absorption?

That the excess of these discharges above the *ingesta* and total waste, can be accounted for by absorption only, was indeed an irresistible conclusion. Still, however, cutaneous absorption is denied; and, when forced to confess that there are cases where the *egesta* exceed the *ingesta* in a much greater proportion than the waste of the body will explain, and which can only be accounted for by absorption, they refuse this function to the skin, and bestow it most liberally, and, in so far as we know, most gratuitously, on the lungs. We are not entitled, in return, to deny the reality of pulmonary absorption, but we may surely be allowed to urge, that there is no proof that the only inhaling organ is in the lungs; and there is none against the possibility of cutaneous absorption.

Is it not, on the other hand, proved, by the experiments of Seguin and Lavoisier, that the exhalation greatly exceeds the absorption by the pulmonary system? And if this is always the case, we cannot explain by pulmonary inhalation alone, why the *egesta* should, in some cases, exceed the *ingesta* in a much greater proportion than the waste of body will account for.

We now proceed to examine another class of experiments, much insisted on by those who deny cutaneous absorption; we mean those experiments performed by immersing a part of the body in solutions of active drugs, the absorption of which should be indicated by their usual effect on the system.

Seguin made numerous experiments of this kind with solutions of muriate of mercury (corrosive sublimate), on syphilitic patients. And we are informed, that in cases where the epidermis was perfectly sound, neither the known effects of mercury on the body, nor any amelioration of the venereal symptoms, was ever observed.

He also immersed his own arm in a solution of two drams of the mercurial muriate in ten pounds of water. At the temperature of 10° and 28° Reaumur, no part of the salt was missing at the end of the experiment; but when the bath was at 18° of the same scale there was a loss of one or two grains of the muriate in the hour, though the quantity of fluid was not diminished.

The explanation given by Seguin of this unexpected result is curiously ingenious, but embarrassed, and inconsistent.

At the temperature of 12°, he observes, the exhalants are in a state of contraction, and their orifices nearly closed. When the heat again is raised to 26°, the exhalation is so rapid, that nothing can enter the vessels from without; but at 18° of temperature, the orifices of the exhalants are sufficiently relaxed, and the exhalation at the same time so conveniently languid, that the solution rests quietly in contact with the matter of perspiration in the mouths of the exhalants, where it is somehow or other decomposed; a part of the salt leaving the water of solution, and combining with the perspirative matter, with which it is carried into the system *. Carried into the circulation by the exhalants! Is not this a plain acknowledgment of the reality of inhalation? But if in one case substances may thus be carried into the circulation, why not in many others?

* *La Med. Eclairée*, tom. iii. p. 238.

Surely if the weight continues undiminished, in circumstances

(H) That thirst may be allayed by immersion in water, is fully proved by the experience of shipwrecked mariners, who, when obliged to take to their boats with very little fresh water, frequently have recourse to bathing in the sea, or covering themselves with a shirt wetted in salt water, and thus quench their thirst, nearly as well as if they had drunk fresh water.

Of Absorption.

cumstances where the body is continually losing, we may infer, that something has been gained by absorption. And where the egesta exceed the ingesta in a proportion much greater than the waste of the body will explain, there absorption must have been going on.

The case of Mr M——, published by Dr Currie, is not singular. The writings of physicians abound in similar examples. They had often occurred to that excellent clinical practitioner De Haen, who was therefore persuaded that water was imbibed *. Haller too, with his usual industry, has collected a great many observations of the same kind †.

* *Ratio Medendi*, part iv. chap. 3.

† *Elem. Physiol.* tom. v. p. 90.

Again, when physicians were engaged in their extensive statical experiments, weighing themselves, their *ingesta* and *egesta*, for many months, nay for years together; they sometimes observed, that so far from losing, they had gained weight, especially during cold and moist weather. Thus, Rye, under a cold and humid atmosphere, gained 13 ounces. Linnings, during two hours exposed to cold, acquired 8½ ounces. The abbé Fontana, after two hours exposure to a moist atmosphere, returned home some ounces heavier than he went out. De Gorter gained 6 ounces in one night; and on other occasions, two ounces and four ounces. These observations are confirmed also by the experience of Dr Francis Home, professor of Materia Medica in the university of Edinburgh. 'Having fatigued myself pretty much (says he) in the afternoon, I went to bed without supper, and was so hungry that I could not fall asleep for some time. Betwixt eleven at night and seven next morning I had gained two ounces ‡.'

‡ *Medical Tracts and Exper.* p. 250.

Here then are examples of the body gaining considerably more than the *ingesta* will account for, acquiring weight when neither food nor drink had been swallowed. And we have the concurring testimony of the most respectable writers supporting the same truth.

How can this increase of weight be accounted for, unless by absorption? In such experiments, the *loss of weight*, which cannot be accounted for by the sensible *egesta*, is attributed to the exhalation; the increased weight sometimes observed, and which cannot be explained by the sensible *ingesta*, must in like manner be referred to the *inhalation*.

That the system may be affected by active medicines introduced and absorbed by the skin, cannot be denied. And were proofs still wanting to establish the doctrine of cutaneous absorption, this argument might be insisted on. It is true, that friction is commonly employed when we wish to introduce medicines by the skin, by which, it is said, the substance is mechanically forced through the cuticle, and brought into contact with the absorbents of the true skin. The system, however, may be affected without friction, for example, by wearing a mercurial plaster, and more certainly by mercurial fumigation, as practised by Lalonette and others ‖.

‖ *Edin. Med. and Surg. Jour.* vol i. p. 181.

It might even be concluded from an examination of the structure of the skin, that absorption must take place at its surface. We know that the cuticle is porous, and is penetrated by exhaling vessels; we know that lymphatics commence immediately below it; and we know that when certain substances are applied to the cuticle, especially when this application is aided by moderate friction, as in the case of applying garlic poultices to the feet, and the more familiar instances of mercurial inunction, that these substances are taken up by the absorbents, and conveyed into the circulation.

From a consideration of all these circumstances, we think it fully proved, that the skin is an absorbing or inhaling organ. For further proofs we may refer our readers to Bichat's *Anat. Gener.* tom. iv. p. 691.

189 Supposed retrograde action of the lymphatics.

Mr Charles Darwin, son of the late Dr Darwin, published in 1780, a Latin thesis, which is translated in the 29th sect. of his father's Zoonomia, vol. i. in which he attempts to prove, that the valves of the lymphatics are so formed as in particular cases to admit of the regurgitation of the absorbed fluids. The arguments on which he founds this opinion (beside the difficulty of accounting for the phenomena of several diseases on any other principle), are chiefly the following:

First, The mouths of the lymphatics seem to allow water to pass through them after death, the inverted way, more easily than in the natural direction.

Secondly, In some diseases, as diabetes and scrofula, it is probable the valves themselves are diseased, and are thence incapable of preventing the return of the fluids they should support.

Thirdly, There are valves in other parts of the body, analogous to those of the absorbent system, which are liable, when diseased, to regurgitate their contents.

Fourthly, The capillary vessels, which must be considered as analogous to absorbents, may be seen, in animals submitted to the microscope, to regurgitate their contents into the arteries, during the struggles of the dying animal.

By means of this hypothesis (for notwithstanding the arguments adduced in its favour, we can call it no better) Mr Darwin explained the speedy passage of watery fluids from the stomach to the urinary bladder; the phenomena of diabetes; diarrhœa, dropsy, cold sweats; translations of matter, chyle, milk, and urine; the operation of external remedies, &c.

190 Absorption in the lowest classes of animals.

In all those classes of animals that possess a complete absorbent system, the phenomena of absorption seem to proceed much in the same manner as in man; but in some of the inferior animals, especially in mollusca and worms, this function seems to be performed by the veins *. In the *echinodermata*, however, especially in the sea-urchin (*echinus esculentus*), lymphatics have been demonstrated by the second Monro. In insects and polypes there is no proper absorption.

* *Cuvier Leçons*, tom. iv. p. 161.

191 Absorption of plants.

The absorbing vessels of plants are chiefly the fibrils of the roots, which evidently imbibe moisture, and perhaps gaseous fluids, from the earth; but there have also been demonstrated vessels opening beneath the outer bark, which botanical physiologists consider as lymphatics. "Lymphatic vessels (says Wildenow), are found in the epidermis of plants, and are of great minuteness, anastomosing in various ways through small intermediate branches." They surround the apertures of the cuticle, by which the inhalation and exhalation of vegetables are carried on; but they are so minute as not to have yet been filled with coloured liquids. Round each opening, which is commonly shut by a moveable valve, they form a circle, rarely a rhombus, as in the *zea mays*. In the *lilium calcedonicum*, those vessels run obliquely, and somewhat in an irregular undulating manner, fig. 2. In the common onion (*allium cepa*), they run in a straight, though oblique and regular form, fig. 3. In the pink, (*dianthus*

Plate CCCCXVIII.

Of Absorption.

(*dianthus caryophyllus*), they are very straight, with straight and horizontally transverse branches, fig. 4. In almost every plant they have their certain and peculiar direction, which in each remains constantly the same *.

* *Wildenow's Princ. of Bot.* sect. 236.

192 Theory of absorption.

The theory of absorption is still but imperfectly understood. We shall briefly notice the principal hypotheses that have been brought forward to account for the entrance of substances into the mouths of the absorbing vessels; for this part of the process alone seems to be disputed.

It was long the opinion of physiologists, that fluids enter the mouths of the absorbents on the principle of capillary attraction; but as the absorbing vessels are not circumstanced like rigid capillary tubes, immersed in a fluid; and as, were this hypothesis just, absorption should go on with regularity, and all fluids should be absorbed indiscriminately, neither of which circumstances is true; this hypothesis is now generally abandoned.

Mr John Hunter accounted for the entrance of substances into the mouths of the absorbents, by attributing to the mouths of these vessels a power of nibbling, similar to that exerted by a caterpillar when feeding on a leaf. This opinion may be called ingenious, but is certainly very wild and fanciful.

Dr Fullarton, in a thesis on absorption, published at Glasgow in 1800, attributes to the absorbing orifices, a power of suction similar to that of the proboscis of butterflies, and the tentacula of some marine animals.

The first and third of these hypotheses suppose the absorbents incapable of taking up any but fluid substances; but we well know that even the hardest bones are somehow absorbed, and conveyed to the circulation. We must therefore add another hypothesis, which supposes that there is secreted in the animal body, a fluid capable of dissolving flesh and bones †. The hypothesis, however, is without foundation. It is contrary to the simplicity of the animal economy, that there should take place, first, a secretion of solid matters to compose the structure of the body, and then a second secretion to dissolve them. We must therefore consider this part of physiology as a subject of future investigation.

† *Duncan's Med. Com.* vol. x. p. 354.

When the absorbed substances have once passed the barrier of the first valve, it is not difficult to account for their further progress through the lymphatics. A continual succession of fresh absorbed matter must drive forward what is already in the vessels, while the valves must in general prevent its reflux. The impelling force from behind is also probably assisted by the irritability of the vessels. It is not easy to decide how the absorbed matters pass through the glands: if, as is generally believed, they do not in these form continuous tubes, there must be a fresh absorption by the mouths of the vessels that pass out of the gland, which is as difficult to account for as the first reception at the origin of the vessels.

193 Relations of absorption with the preceding functions.

The relations that take place between absorption and the preceding functions, are perhaps the least understood of any that occur in the animal economy. We know that the action of the absorbents is greatly assisted by muscular motion, and that it is in general most defective in indolent and sedentary persons. An evident sympathy is also observed between the stomach and the absorbents. Nausea, and especially vomiting, are powerful promoters of absorption, and some remarkable instances are related of the speedy absorption of a large quantity of purulent matter from an abscess, in consequence of violent vomiting.

Of Circulation.

Chap. VII. *Of Circulation.*

194 Circulation.

We have traced the nutritious particles of the food from the intestines through the *lacteals*, the *mesenteric glands*, and the *thoracic duct*, into the left *subclavian vein*, where we find the chyle is mixed with the venous blood, and carried to the right auricle of the heart. We must now consider how the fluids are conveyed to every part of the body, or we must examine the function of *circulation*.

195 Organs.

This function takes place in all the vertebral animals, and in mollusca, worms, and crustacea; but there appears to be no real circulation in insects, zoophytes, and plants.

The organs by which circulation is performed differ essentially in the several classes of animals. Those of the human system have been described in the first part of ANATOMY, sect. x. and xi. and a brief comparative view of these organs in the inferior animals, has been given in the second part of that article, N° 154, 201—204, 300, &c. and in the articles CETOLOGY, ERPETOLOGY, ICHTHYOLOGY, and ORNITHOLOGY. For a fuller account of these latter, we may refer to Cuvier's *Leçons*, leç. xxiv. and xxv. and to the Comparative Anatomy of Blumenbach, chap. xii.

196 Pulmonic and systemic parts.

It is well known that, in the red-blooded animals, the blood is not of the same shade of red in every part of the body; but that what has passed through the lungs, and is circulating through the arteries that proceed from the aorta, is of a florid red colour, while that which is sent to the lungs by the pulmonary artery, as well as that which is returning from the extremities of the arteries through the veins, is of a purple or crimson colour. As one set of organs always contains florid, and another set always crimson blood, it is convenient to distinguish each set by an appropriate name. Dr Barclay has done this, and he calls that set of organs which are employed to convey the blood from the arteries, and distribute it to the lungs, *pulmonic*, comprising the *pulmonic veins*, viz. the vena cava and its branches, *pulmonic auricle*, *pulmonic ventricle*, and *pulmonic arteries*: while he denominates that set of organs which return the blood from the lungs, and distribute it to the system, *systemic*, comprehending the systemic veins (pulmonary veins), systemic auricle, systemic ventricle, and systemic arteries, (the aorta and its ramifications). One great advantage of this nomenclature, is that it prevents the ambiguity of the expressions *right* and *left*, *anterior* and *posterior*, applied to the auricles and ventricles of the heart. We shall therefore employ them in the subsequent part of this chapter *.

* See *Barclay on Muscular Motions*, p. 231.

For an account of the nature and properties of the blood, see ANATOMY, Part I. sect. 14. and CHEMISTRY, N° 2642.

197 Proofs of the circulation of the blood.

It may not be improper, in this chapter, to notice the principal arguments that have been used to prove the circulation of the blood. They are as follow:

1. When the artery is tied, the part of the artery that is betwixt the ligament and the heart, swells; but that part of it which is betwixt the ligature and the remote branches, becomes more flaccid than before. On the other hand, when a vein is tied, the part between the ligature

Of Circulation. gature and the remote branches, swells, while the part between the ligature and the heart becomes flaccid.

2. The valves placed at the mouths of the aorta and pulmonary artery, must prevent the blood from regurgitating into the ventricles, while they permit it to flow forward through the arteries, into the capillary branches of the veins. Again, the valves situated in the course of the veins prevent the blood from flowing back into the arteries, while they permit it to proceed forward through the venous trunks into the heart.

3. By the assistance of a microscope, the blood may be seen in the pellucid parts of animals, as the feet of frogs, flowing from the arteries into the veins.

4. When an artery of moderate size is wounded, and not secured by ligature or compression in proper time, the blood flows out till the animal be dead.

5. Any thin liquid, when injected into an artery, does not pass backwards into the heart, but flows forward into the inosculating veins. On the other hand, such a liquid thrown into a vein, flows towards the heart, and not into the smaller branches of the vein.

The phenomena of circulation in the human body have been already mentioned under ANATOMY, sect. xii. and xiii. and under MEDICINE, N° 95. We shall here only offer a compendious view of the course of the blood in the adult and in the fœtal state.

198 Circulation in the adult man.

I. After birth, the blood coming from every part of the body through the numerous ramifications of the vena cava, is poured into the right or pulmonic auricle of the heart, by the contraction of which it is thrown into the right or pulmonic ventricle, which contracting, throws it into the pulmonary artery, being prevented from regurgitating into the auricle by the action of the tricuspid valves. It is now, by means of the ramifications of the pulmonary artery, distributed through the lungs, from which it is brought back by four principal pulmonary veins, and poured into the left or systemic ventricle, which contracting with great force, propels it into the aorta, it being prevented from regurgitating into the auricle by the action of the mitral valves. The blood being propelled into the aorta, is by its trunks and branches, distributed to every part of the body, and brought back as before by the ramifications and trunks of the *vena cava*.

199 Circulation in the human fœtus.

II. In the fœtal state, the blood being brought back from every part of the body by the ramifications and trunks of the vena cava, is poured into the pulmonic auricle of the heart, where it is mixed with the blood brought from the placenta. A part of this blood is conveyed from the sinus of the auricle while in a state of dilatation, through the oval hole, into the systemic auricle; while another part, by the contraction of the auricle, is thrown into the pulmonic ventricle, which contracting, propels it into the root of the pulmonary artery. From this the greater part of the blood passes through the arterious canal, that in the fœtus joins the pulmonary artery to the aorta, in this latter; while the remainder is distributed by the ramifications of the pulmonary artery to the lungs, and brought back by the pulmonary veins to the systemic auricle of the heart. By the contraction of this auricle, the blood is thrown into the systemic ventricle, which contracting, propels it into the aorta. Now, while one part of the blood is distributed by the numerous ramifications of the aorta to every part of the body of the fœtus, another part is carried from the internal iliac arteries, through the two umbilical arteries, into the placenta, from which it is conveyed through the umbilical vein to the sinus of the liver. Hence, one part of the blood, without entering the liver, is transmitted by a branch of the umbilical vein, called *venous duct*, into the left branch of the *vena cava hepatica*; thence into the inferior great vena cava; while another part, by another branch of the umbilical vein, flows into the left branch of the *vena porta*, by the numerous ramifications of which it is distributed to the liver. From the liver it is carried by the *venæ cavæ hepaticæ* into the inferior great *vena cava*, whence it is conveyed, with the rest of the blood, to the pulmonic auricle of the heart, to be distributed as before.

200 Powers carrying on the circulation.

We must now briefly consider the powers by which the blood is made to circulate through such a multitude of vessels, so infinitely ramified, and differing so much in their diameter. It seems generally allowed at the present day, that these powers are chiefly the immediate muscular action of the heart, the action of the arteries, the valves of the veins, and the pressure produced on some of the veins by the action of the muscles that lie contiguous to them.

201 Action of the heart.

1. That the heart must possess very considerable force in propelling the blood through the arteries, may be supposed from the great muscularity of its ventricles; and this force has been proved by experiment and observation. From experiments made by Hales, viz. that of inserting a glass tube into a large artery, and measuring the height to which the blood ascends at each pulsation, it has been calculated, that the human carotid artery is capable of projecting its blood to a perpendicular height of seven feet and a half; and if we estimate the surface of the systemic ventricle at 15 square inches, we shall find that it sustains a pressure of 1350 cubic inches, equal to 51 pounds weight, which it has to overcome by its contracting force *. This is a moderate computation of the force of the heart, for Borelli estimates it at 180,000 pounds, while Keill diminishes it to eight ounces. Senac again, from having observed, that if a weight of 50 pounds be attached to the foot, with the knee of that side placed over the opposite knee, the weight will be raised at each pulsation, and allowing for the distance at which the weight is placed from the centre of motion, computes the force of the heart at 400 pounds † Blumenbach has seen the blood projected from the carotid of an adult more than five feet ‡ On a medium calculation, estimating the quantity of blood contained in the body at 30 pounds, the number of pulsations in each minute at 75, and the quantity of blood ejected from the systemic ventricle at each contraction at two ounces and a half, we shall find that the whole 30 pounds of blood will be carried through the whole body no less than 23 times in an hour, or the circulation will be completed in less than three minutes. From these circumstances we must infer that the impelling power of the heart is very great, and fully adequate to the office which it has to perform.

* *Hales's Statical Essays*, vol. ii.

† *Traité du Cœur.*

‡ *Institutiones Physiolog.*

Various hypotheses have been formed to explain how the heart and arteries are excited to motion, but our limits will not permit us to detail them. Our readers will find them related at considerable length, and fully examined in the *Principes de Physiologie* of Dumas, tom. iii.

Of Circulation.

iii. p. 332—364. The general opinion at present entertained on this subject is, that the heart is excited to action by the stimulus of the blood.

202 Action of the arteries.

2. Although it is more than probable that the action of the heart is the principal instrument in carrying on the circulation, there can be no doubt that the arteries contribute essentially to this office. They are evidently muscular, and are possessed of considerable irritability; are supplied with numerous nervous filaments, and are nourished by small arterial branches, commonly called *vasa vasorum*. Nay, we know that they are susceptible of contraction; for when we divide an artery in the living body, the divided extremities gradually contract, till, if the animal is not killed by the experiment, the aperture is at length obliterated *. Lastly, there have been instances of fœtuses without a heart; and as we must suppose that, during the life of the fœtus, the circulation was going on, it is a natural inference that this was chiefly effected by the contraction of the arteries, and not entirely by the impelling power of the circulating system of the mother.

* *Hunter on the Blood*, p. 114.

203 Valvular structure of the veins.

3. It cannot be supposed that the veins have any immediate action on the blood, as they exhibit no circular fibres like the arteries, except in the immediate vicinity of the heart; but their valvular structure must contribute to the carrying on of the circulation, from the opposition it gives to the return of the blood, so that what is called the *vis à tergo*, or impelling power from behind, aided by the conical form of the veins, may have its full effect.

204 Action of the muscles.

4. That the action of the muscles has considerable influence in propelling the blood towards the heart, in those veins that lie in their neighbourhood, is evident from the effect that bodily exercise produces in accelerating the circulation, and from the efficacy of friction in removing congestions of blood in the veins of the extremities, and in the more familiar instance of promoting the swelling of the veins of the arm by the same means in the operation of bleeding.

205 Circulation of the inferior animals.

The circulation in those animals whose structure approaches to that of man, differs little from what is above described. There are indeed some peculiarities, a few of which we shall presently notice. An account of the circulation in the cetacea will be found in the article Cetology, N° 140—145; that of the reptiles is described under Erpetology, p. 309.

206 Circulation of the mollusca;

The mollusca possess an evident and powerful circulation. Most of them have a simple heart, consisting of one auricle and one ventricle; and in these the vena cava performs the office of an artery, carrying the returning blood to the gills, whence it passes to the auricle, and is afterwards thrown into the aorta. There is a peculiarity in the cuttle fish, which has a heart consisting of three ventricles, without any part that can properly be called an auricle. Two of the ventricles are placed at the roots of the two bronchiæ, and have each a branch of the vena cava, by which they receive the blood from the body, and propel it into the bronchiæ. The returning veins open into the middle ventricle, and from this the aorta proceeds.

207 in the vermes;

Some of the vermes, as the leech, and the tribes of the *naias*, *nereis*, and *aphroditæ*, and some species of *lumbricus*, have no heart, but they have circulating vessels with evident contraction and dilatation.

208 in crustacea.

In the *crustacea*, the circulation is performed by a single ventricle, expelling the blood into the arteries of the body, and receiving it again after it has passed through the gills, in a manner very similar to the circulation of fishes.

209 Contracting and dilating tube in insects.

There is no circulation in insects; but these animals have running along the back a membranous tube, in which alternate contractions and dilatations are perceptible. This tube, however, is closed at both ends, and has no vessels proceeding from it.

210 No circulation in plants.

From the researches which evince circulation to be a function so general among animals, some are disposed to think it takes place in all living bodies. But notwithstanding the fashionable language of circulating fluids, of veins, arteries, and even of valves, in the vegetable structure; yet nothing performing the office of a heart, and nothing that seems to conduct fluids in a circular course, has been found in plants. In the vegetable kingdom, the chyle is distributed to all the parts, from the numerous vessels which convey the sap; and these vessels, being fitted by their structure to carry the sap either downwards or upwards, from the branches to the roots, or from the roots to the branches, is the reason why plants inverted in the ground will send forth roots from the place of their branches, and send forth branches from the place of their roots. Even a similar distribution of the chyle takes place in some animals. In the human tænia, in the *fasciola hepatica* (fluke) of sheep, and in most polypes, the chyle, without a circulating system, is conveyed directly to the different parts from the alimentary canal.

211 nor in some animals.

For an account of the motion of sap in plants, see Darwin's *Phytologia*, a paper by Mr Knight in the *Philosophical Transactions* for 1801, Wildenow's *Principles of Botany*, sect. 276, and the article Plant in this Encyclopædia.

212 Relations between circulation and sensation.

The relations that subsist between the function of circulation, and those which we have already considered, are very important. We shall begin with those of circulation and sensation. That the functions of the nervous system must be considerably influenced by the circulation of the blood, may be supposed *à priori*, from the large quantity of blood sent to the head, this being, on a moderate calculation, about one-tenth of the whole. A certain quantity of blood in the vessels of the brain seems essential to the due performance of the functions of that organ; and those animals, which, like man, have the blood sent in greatest quantity, and with greatest impulse, seem to possess the faculties of the brain in the greatest perfection, while those in whom the motions of the blood towards the head is much retarded, as in the sheep and cow, are remarkable for mildness and stupidity. When, however, the quantity of blood becomes too great, or its impetus too violent, the faculties of the brain are impaired, or altogether destroyed. No man, and very few other animals, can remain suspended with the head downwards for any long time, without dangerous, and commonly fatal consequences. The bat, indeed, is a remarkable exception to this rule, for this animal can hang by its hinder feet for days or weeks together, with perfect safety, a circumstance that may be accounted for from the very small quantity of blood contained in its circulating vessels. Again, the brain exerts an evident influence on the circulation. It is well known how much the action of the heart and arteries is quickened, impeded, or rendered irregular, by the

Of Circulation. the passions of the mind. Cases are recorded in which these passions, carried to excess, have altogether stopped the circulation, and produced instant death. Fainting is often brought on by the sight of a disgusting or terrifying object, or by the odour of perfumes, or of substances to which the person has a particular antipathy. The sympathy between the heart and the nervous system is farther shown by the violent pain below the *sternum*, and sometimes in the arm, in cases of organic disease of the heart.

The circulation is even affected by intense thought; and we have heard of a bleeding from the nose being brought on by long and deep study, while the body was in a reclining posture, namely in bed.

213 Relations between circulation and motion. The functions of circulation and motion are intimately related. It is scarcely necessary to notice the acceleration of the pulse, in consequence of exercise and labour, or to remark that in indolent and sedentary people the circulation is generally slow and languid. In general, too, the blood circulates with most rapidity in those animals who are formed for quick motion, though the instance above quoted, of the bat, shows that the quickness of motion does not depend on the quantity of blood. Several curious anatomical facts have rendered it probable, that the production of quick or slow motion depends in a great measure on the mode in which the arterial branches are distributed to the moving organs. The arterial branches that supply the organs of voluntary motion, are divided in such a manner as to impede the motion of the blood towards these organs as little as possible: their ramifications are therefore few, and they go off from the trunk at very acute angles; whereas those that supply the viscera are at nearly right angles, are often tortuous, and are otherwise so constructed as frequently to impede the flow of blood. Physiologists have even explained the greater power that is generally found in the right arm, and the greater readiness with which most people use that arm, by the manner in which the right subclavian artery comes off from the aorta. This indeed we are disposed to consider as fanciful, and to attribute the more ready use of the right arm solely to habit and early instruction not to employ the left.

214 Distribution of the arteries in the limbs of slow moving animals. In some animals that are remarkable for slowness of motion, as the *lemur tardigradus*, or slow lemur, and the *bradypus tridactylus*, or common sloth, there is a curious construction of the arteries that are distributed to the limbs of these slow-moving animals, which must have the effect of breaking the force, and impeding the velocity of the blood towards these limbs. In the *lemur tardigradus*, a specimen of which was dissected by Mr Carlisle, it was found that the *subclavian artery* and the *external iliac* were, soon after rising from the general trunk, divided into a great number of equal-sized cylinders surrounding the principal artery, now diminished to a very small size, and that each of these branches was sent to each of the principal muscles of the limbs, while the other arteries that supplied the other parts of the limbs were divided in the usual arborescent form. Struck with this appearance, Dr Shaw and Mr Carlisle afterwards examined several specimens of the sloth, and found a similar conformation, while in other species of bradypus, not remarkable for slow motion, no such appearance took place*. Fig. 5 & 6. Plate CCCCXVIII. represent the division of the arteries in the slow lemur above described.

* Shaw's General Zoology, vol. i.

The relations between the circulating and digestive organs are proved by the sudden acceleration of the pulse from stimuli received into the stomach; from the diminished circulation or sudden cessation of the heart's motion from powerful sedatives received into the same organ, especially the *prunus lauro-cerasus*; from the irregularity produced in the circulation in consequence of *dyspepsia*, and many other considerations. 215 Relations of circulation with digestion.

That there is an intimate relation between circulation and absorption, cannot be doubted, though the nature and effects of this relation are not yet well understood. We know that the vessels sympathize with the absorbents in their activity or languor; that when the absorbents are languid in their action, the blood-vessels, especially the exhalants, are in a feeble or relaxed state, and that the absorbents are often roused to greater action by remedies that first act on the circulation. 216 Relation of circulation and absorption.

Numerous experiments have shown how much the colour and consistence of the blood are altered by the mere action of the vessels; and this discovery has enabled us to conjecture with more probability than we did formerly, why in infants and phlegmatic persons the blood is paler, in the choleric more yellow, and in the sanguine of vermilion red. It explains likewise in some measure, why the blood varies in the same individual not only with regard to the state of health, but likewise at the same instant; and why the blood which circulates through the veins has not the same intensity of colour, nor the same consistence, as that of the arteries; and why the blood which flows through the organs of the breast differs from that which passes languidly through the viscera of the lower belly. This power of the vessels over the blood will bring us also to the true cause why the vessels vary in the density of their coats and in their diameters; why they are sometimes convoluted in a gland, and why they sometimes deposit their contents in a follicle; why they are sometimes of a spiral form; why the branches strike off at various angles; why they are variously anastomosed; why they sometimes carry the blood with dispatch, and sometimes slowly through a thousand windings. By these means their action is varied, and the blood prepared numerous ways to answer the ends of nutrition and secretion. 217 Action of the vessels on the blood.

On the varieties of the *pulse*, and the morbid affections of circulation, see MEDICINE, N° 96—104.

CHAP. VIII. *Of Respiration.*

WHILE the fluids are passing through the body, by what is called the *greater circulation*, they give out certain parts or principles, partly for the purpose of nutrition, and partly to free the system from noxious matters. In order to regain some of the principles which they have lost, it is necessary that they should be exposed to the influence of atmospheric air; for which purpose they are made to pass through appropriate organs, which, as we have already observed, are in general either lungs or gills. The action by which the fluids and the air are made to act on each other, is called *respiration*, and consists of two kinds, *inspiration*, by which the air is received into the body, and *expiration*, by which it is again thrown out. 218 Necessity of respiration.

So essential is respiration to the system, that snails, chameleons, and some other animals, can live for years, without any apparent nourishment, provided they be not excluded

excluded from air. We have seen a chameleon that lived, and was vigorous, for 22 months, without any food, and which might have continued to live much longer, but for an unfortunate bruise by a fall.

Other phenomena equally demonstrate the importance of air to the living body. The frog leaps away wanting its heart; it survives the loss of the greatest part of its spinal marrow; without its head, it lives for some days, and its heart continues to circulate its blood. Borelli found, that eels and serpents, though their bodies be opened, and the whole of their bowels be taken out, are able to move for a day after, and yet, in all these animals, the life is observed to be suddenly extinguished when the all-vivifying air is excluded. Even the smallest insect has died, and the plant lost its vegetative power, when retained, for any considerable time in a vacuum. Fishes themselves, when placed under an exhausted receiver, have started anxiously to the surface of the water in quest of fresh air; and finding none, have sunk to the bottom and expired in convulsions. It will presently appear that this necessity of air to life is general in all the classes of organized beings (K).

219 Organs.

The organs of respiration belonging to the human system, viz. the *larynx*, windpipe, lungs, diaphragm, ribs, and numerous muscles, have been sufficiently described in various parts of the article ANATOMY; and some account of these organs in the inferior animals has been given in the second part of that article, N° 155, 156, 206, 208, 271—274, and in the articles CETOLOGY, ERPETOLOGY, and ICHTHYOLOGY. For a more complete account of the respiratory organs in the inferior animals, the reader is referred to Cuvier's *Leçons d'Anatomie Comparée*, Leç. xxvi. et xxvii. and to Blumenbach's *Comparative Anatomy*, chap. xiv. and xv.

220 In examining the function of respiration in warm-blooded animals, two circumstances are principally to be considered; the mechanism of respiration, or the mechanical means by which the organs are enabled to receive and expel the air, and the effects produced by respiration on the circulating fluids, and on the system at large. Our principal object in this article is briefly to explain the mechanism of respiration; to notice the effects produced on the air by the respiration of different animals, with the effects produced on them, and the relations that take place between respiration and the preceding functions of sensation, motion, digestion, and circulation.

221 Mechanism of respiration in man.

In order to make an inspiration, the intercostal muscles, and the muscular fibres of the diaphragm, are thrown into contraction, while at the same time the abdominal muscles, and the muscular fibres of the windpipe, are relaxed. By these means the diaphragm being drawn towards the *sacrum*, and rendered less convex towards the chest, and the ribs being drawn upwards (or forwards in quadrupeds), the cavity of the chest is enlarged, and the air remaining in the lungs being rarefied, the external air rushes in through the windpipe by its own gravity, and distends the lungs. In making what is called a very deep inspiration, other muscles that are connected with the atlantal ribs, viz. those called *scaleni*, *trapezii*, *cervicales descendentes*, *serrati superiores*, and pectoral muscles, assist to elevate the ribs more than in an ordinary inspiration. By the action of the intercostal muscles the ribs are drawn *atlantad* (upwards in man, and forwards in quadrupeds), because the most atlantal rib on each side of the thorax is fixed, and therefore all the other ribs are drawn towards it; and they are also drawn peripherad (outwards), because their greater curvature is in the direction of the *sacrum*, and because they turn on their vertebral extremities as on a fulcrum.

In order to make an expiration, the abdominal muscles, and the muscular fibres of the windpipe, are contracted, while the intercostal muscles, and the muscular fibres of the diaphragm are at the same time relaxed. By these means, aided by the elasticity of the cartilages of the ribs, and perhaps of the mediastinum, the ribs are drawn sacred (towards the sacrum), while the diaphragm, partly by its own muscular action, and partly in consequence of the pressure of the bowels, is rendered convex towards the chest. Thus, this cavity is considerably diminished, the lungs are compressed, and part of the air is expelled through the windpipe. In making a strong expiration, little more is necessary than a more powerful contraction of the abdominal muscles. 222

In other animals.

The mechanism of respiration in mammalia is so similar to that of man, that we need not enter into it; that of *cetacea* has been sufficiently explained under CETOLOGY, N° 146—151; that of birds may be gathered from what has been said on their structure, in the comparative part of ANATOMY, N° 271, and in ORNITHOLOGY, N° 37; that of reptiles has been fully explained under ERPETOLOGY, page 311; and that of fishes under ICHTHYOLOGY, page 73. The mechanism of this function in the classes of animals below these is so simple, that a consideration of it is unnecessary. In insects the air enters the numerous ramifications of the *tracheæ*; is carried by them into every part of the body, and is then returned by the same passages. In some of the mollusca, respiration proceeds in a similar manner, by the ramifications of the pulmonary vessels that enter by the neck; but in most of these, and in all the lowest tribes, such as worms and zoophytes, respiration seems to be carried on entirely by the pores of the skin. 223

Quantity of air received and emitted.

Many attempts have been made to ascertain the quantity of air received and emitted in a single inspiration or expiration. See CHEMISTRY, N° 2535. This point is not yet fully ascertained, but we may probably estimate the quantity expelled by each ordinary expiration at one-seventh part of the whole contents of the lungs, and that of the most violent expiration at about four-sevenths

(K) It was long ago observed by Pliny, that if the bodies of insects are besmeared with oil, they soon perish: "*oleo illito insecta omnia exanimantur.*" The same observation was afterwards made by Ray, who explained it by showing that in this way the pores through which the animals breath are stopped. Mayow also found, that if the oil be applied only to some of these pores, the neighbouring parts become paralytic, while the rest of the body continued sound. See Ray's *Wisdom of God*, and Mayow's *Tractatus*.

Of Respiration.

sevenths of that quantity; or that the medium quantity of air consumed during a common inspiration or expiration is about 40 inches *.

224 Ordinary number of respirations in a minute. Another circumstance respecting the mechanism of respiration merits notice, viz. the ordinary number of respirations made in a minute by a healthy person. This varies considerably in different subjects, being in general greatest in children, and least in old persons. Dr Hales estimated the number of 20 in a minute; the subject of Dr Menzies' experiments respired only 14 times in the same period, while Mr Davy reckons his respirations at between 26 and 27; the subject of the experiments made by Messrs Allen and Pepys, breathed about 19 times in a minute, and with this Dr Thomson's experience agrees. The average of all these is about 20, which we may probably consider as a tolerably just estimate. Much, however, will depend on the circumstances in which the person is placed; on his habits of activity or indolence, of temperance or intemperance; on the state of the atmosphere, &c.

* Bostock on Respiration, p. 35.

225 Experimental writers on respiration. The chemical changes produced on the air by the respiration of animals have been described, so far as they were then known, under CHEMISTRY, N° 2536. Since that article was written, however, several valuable observations have been published, and the most important of these must be here noticed; but as we cannot, in this place, give any thing more than a summary sketch of these observations, we shall here enumerate the principal works that have appeared on this experimental part of our subject. The chemical physiologists who have been most conspicuous in these researches are, Mayow (in his *Tractatus de Respiratione*, or the *Analysis* of his works by Beddoes); Priestley (*Experiments and Observations on Air*); Lavoisier (*Traité Elementaire de Chimie*, *Physical and Chemical Essays*, and a work on *Atmospheric Air*); Goodwyn (*On the Connection of Life with Respiration*); Coleman (*On Suspended Respiration*); Menzies (*On Respiration*); Spallanzani (*Memoires sur la Respiration*), translated into French by Senebier, and since into English, and *Rapports de l'Air avec les Etres Organisés*, &c. also collected by Senebier); Davy (*Researches Philosophical and Chemical, into the Nature of Nitrous Oxide*); Ellis (*Inquiry into the Effects produced on Atmospheric Air by Respiration*), and Allen and Pepys (*Philosophical Transactions*, 1808, Part II. or *Phil. Mag.* vol. xxxii.). Most of the facts observed by these experimentalists, except those of the three last mentioned, have been collected by Dr Bostock, in his *Essay on Respiration*, by Dr Thomson in his *System of Chemistry*, vol. v. third edition, and by Mr Johnson in his *Animal Chemistry*, vol. iii.

226 Ascertained changes on respired air. The following changes produced on air that has been respired by warm-blooded animals, seem to have been fully ascertained; viz. 1. That the respired air generally suffers a sensible diminution of bulk; 2. That it loses a part of its oxygenous portion; 3. that it acquires an additional quantity of carbonic acid gas; 4. That it is charged with watery vapour. We shall resume these facts, and consider the additional information which has been acquired respecting them since the publication of our article CHEMISTRY.

227 Its volume sensibly diminished. 1. *Atmospheric air generally suffers, by the respiration of warm-blooded animals, a sensible diminution in its bulk.*—The results of the experiments made by different chemists on the diminished volume of respired air, are exceedingly various. Mr Davy makes the diminution amount to one-eighteenth † of the whole air inspired; Lavoisier and Goodwyn estimate it at no more than one-sixtieth ‡, and Dr Bostock so low as one-eightieth ||, while Crawford and some later experimentalists could perceive no diminution. Dr Thomson states the results of his experiments upon this subject to be, that in some cases he could perceive no diminution at all, while in others it was perceptible. It was greatest when the animal was taken out repeatedly during the experiment, or when he employed air purer than that of the atmosphere. He is disposed to consider the diminution as accidental, and as owing to some absorption of air, altogether independent of respiration, and exceedingly various in different circumstances §. In the experiments of Messieurs Allen and Pepys, the general average of the deficiency in the total amount of common air inspired, appeared to be very small, amounting to about six parts in 1000, and they are inclined to attribute it, in a great measure, to the difficulty of exhausting the lungs so completely after an experiment as before it *.

† Researches, p. 435.

‡ Bostock on Respiration, p. 87.

|| Ib. p. 99.

§ System of Chem. third edit. vol. v. p. 735.

* Philos. Mag. vol. xxxii.

228 Part of its oxygen abstracted. 2. *Atmospheric air, by the respiration of warm-blooded animals, loses a part of its oxygen.*—From a comparison of the experiments of Mr Davy, with those made by Lavoisier just before his death, Dr Thomson estimates the quantity of oxygen consumed in a minute, by respiration, at 31.6 cubic inches, making in 24 hours 45,504 cubic inches; and he concludes that in a day a man consumes rather more than 25 cubic feet of oxygen, and that he renders unfit in the same time for supporting combustion and respiration, no less than 125 cubic feet of air †.

† System of Chemistry, vol. v. p. 736.

229 Carbonic acid gas acquired. 3. *Atmospheric air acquires, by respiration, an additional quantity of carbonic acid gas.*—The opinion of Dr Menzies, that the bulk of carbonic acid gas produced by respiration, is precisely equal to that of the oxygen lost, appears now to be fully confirmed. In Mr Davy's experiments they corresponded very nearly ‡, and in those of Mr Dalton and Dr Thomson, they corresponded exactly. The latter chemist found, on the whole, that the bulk of oxygen which disappeared was somewhat greater than that of the carbonic acid generated; but the difference varied considerably, and kept pace with the diminution of the bulk of air respired. Hence he considers it as owing to the abstraction of part of the air by some other way than respiration, and allowing for this abstraction, he has no doubt that the bulk of the carbonic acid formed is precisely equal to that of the oxygen that has disappeared. He is disposed to consider the absolute quantity of carbonic acid generated in 24 hours, as something less than 40,000 cubic inches on an average §. The following results of the experiments made by Messieurs Allen and Pepys, as these were made on a large scale, may be considered as quite satisfactory on this head. 1. It appears that the quantity of carbonic acid gas emitted is exactly equal, bulk for bulk, to the oxygen consumed. 2. Atmospheric air once entering the lungs, returns charged with from 8 to 8.5 per cent. carbonic acid gas, and when the contacts are repeated almost as frequently as possible, only 10 per cent is emitted. When the inspirations and expirations are more rapid than usual, a larger quantity of carbonic acid is emitted in a given time; but the proportion is nearly the same, or about eight

‡ Researches, p. 431.

§ System Chem. vol. v. p. 737.

Of Respiration.

eight per cent. The proportions of carbonic acid gas, in the first and last portions of a deep inspiration, differ as widely as from 3.5 to 9.5 per cent. 3. It appears that a middle-sized man, aged about 38 years, and whose pulse is 70 on an average, gives off 302 cubic inches of carbonic acid gas from his lungs in 11 minutes; and supposing the production uniform for 24 hours, the total quantity in that period would be 39534 cubic inches (*agreeing almost exactly with Dr Thomson's estimate*), weighing 18,683 grains, the carbone in which is 5363 grains, or rather more than 11 ounces troy; the oxygen consumed in the same time will be equal in volume to the carbonic acid gas; but it is evident, that the quantity of carbonic acid gas emitted in a given time, must depend very much upon the circumstances under which respiration is performed; and here it may be proper to notice, that all these experiments were made between breakfast and dinner. 4. A larger proportion of carbonic acid gas is formed by the human subject, from oxygen than from atmospheric air *.

230 Watery vapour required.

4. *Atmospheric air returns from the lungs charged with aqueous vapour.*—Of this circumstance there is no doubt, but the quantity of water contained in the expired air, and the sources from which it is derived, are still in dispute. Dr Thomson estimates the former at about 19 ounces per day; but he does not lay much stress on the results of his own experiments, as they were not sufficietly varied to give a fair average. As to the sources of this watery vapour, it has been generally supposed, that the water is formed in the lungs by a combination of part of the oxygen consumed with hydrogen evolved from the venous blood. This, however, is mere hypothesis. It has not been proved that hydrogen is evolved from the blood; and as the quantity of oxygen consumed appears to be taken up in forming the carbonic acid gas that is expired, there is none left to form water. No hydrogen, or any other gas, except carbonic acid and azotic gas, appear to be evolved during the process of respiration †.

231 Is azote lost?

There is another change supposed by most chemical physiologists, to be produced on the air by respiration, namely the loss of part of its azote; but this is still disputed. Dr Bostock concludes it to be probable, that a small portion of azote is lost, which he estimates on an average at $\frac{1}{180}$ of the air respired, making in 24 hours, about 4.5 ounces, or four cubic feet ‡. Mr Davy found the consumption of azote to amount to about one seventh of that of oxygen ‖; and some late experiments of Dr Henderson afford a similar result, though in these the proportion is rather less §. Dr Thomson also found a loss of azote, but it was extremely inconstant, sometimes being scarcely perceptible, at others considerable. It kept pace with the diminution of the bulk of the air respired, and with the difference between the bulk of the oxygen consumed, and the carbonic acid formed. He conceives that a portion of the air respired disappears without undergoing any change, and that this portion occasions the diminution of the azote, and the difference between the bulk of the carbonic acid formed, and that of the oxygen consumed. He thinks it conceivable, that the disappearing of such a portion may be confined to the unnatural circumstances occasioned by the experiment; that the difficulty of throwing out the air from the lungs in these circumstances, may be such as to induce absorbents to act, and remove a portion which in the ordinary state of the lungs would have been thrown out by expiration *.

232 Changes on the air by the respiration of the inferior animals.

Experiments on the changes produced on atmospheric air and oxygenous gas, by the respiration of the inferior animals, have been made chiefly by Vauquelin, Spallanzani, and Mr Davy, and some of them have been repeated and varied by Mr D. Ellis. From all these experiments we find, that by the respiration of amphibia, of fishes, of insects, of mollusca, and of worms, the air in which they have been confined suffers changes analogous to those produced in it by the respiration of the warm-blooded animals; that the oxygenous part is diminished, and that this diminution is most complete when insects and worms have been confined in it; that carbonic acid gas is in all cases produced, but that the quantity produced varies in different animals; that fishes live for the shortest time, and amphibia and worms for the longest, when confined in a certain quantity.

From the latest experiments made by Spallanzani, on the effects both of living and dead animals, on atmospheric air, as collected by Senebier, that experimentalist has drawn the following conclusions. 1. In beginning with worms, and rising up to man, there is no species of animal which does not destroy the oxygen of the atmosphere after death, and destroy it entirely if it be kept inclosed in it, provided the quantity be not too great in proportion to the size of the animal; because a considerable time is required when the volume of air is large, and a less time when the quantity is small.

2. This destruction of oxygen by dead animals, is under similar circumstances slower than that effected by living animals; if we regard merely the effects produced by the cutaneous organ, independent of the action of the lungs.

3. He thought he had legitimately proved, that the destruction of oxygen by the cutaneous organ, is not occasioned by the combination of this gas with the carbone of the animal; but that it is a true absorption of that element, by the body of the animal deprived of life. It does not give out carbone, but carbonic acid, as he believed he had proved by unanswerable experiments.

4. The absorption of oxygen by animals cut into small pieces, is greater than that occasioned by animals entire in similar circumstances.

5. A cold-blooded animal of the same bulk, and in the same circumstances as a warm blooded animal, absorbs more oxygen than the latter after death.

6. The skin is not the only part of an animal which absorbs oxygen; all the parts, solid, fluid, and soft, not excepting the driest horny parts, as the nails of quadrupeds, the bill and feet of birds, produce the same effect †.

233 Effects of vegetation on the air.

It has long been known that plants would not vegetate, if excluded from atmospheric air. Papin confined an entire plant in the exhausted receiver of an air-pump, and it soon perished; but on keeping a similar plant in this vacuum, with only its leaves exposed to the air, it continued to live for a long time ‡. When the leaves of a plant are stript off, or blighted by insects; when they have the upper surface smeared with oil, with varnish, or laid upon water §, the plant dies in a few days. Hence it is evident that the leaves of a plant are necessary organs, and that there is produced on the air in which

* Syst. Chem. vol. v. p. 738.

‡ Darwin's Phytologia, p. 51.

§ Ellis's Inquiry, p. 18.

Of Respiration.

which the plant vegetates, some change essential to the healthy action of the plant. What this change is, has not been fully ascertained. It is the general opinion, that the leaves absorb a portion of the atmosphere, and give out certain gaseous products; and it is generally believed, that most plants have the property of giving out oxygenous gas during their exposure to the light, and azotic gas or some other irrespirable air in the dark. That oxygenous gas is necessary to vegetation, is fully proved; and it seems certain, especially from the experiments of Mr Ellis, that under the ordinary circumstances, carbonic acid gas is generated during their vegetation *. Mr Ellis, who is not satisfied with the accuracy of the experiments of Scheele and Priestley, seems to doubt whether plants at any time give out oxygenous gas; and thinks that the principal use of oxygen to them, is to combine with the superfluous carbone produced by vegetation, and thus form the carbonic acid evolved.

* Ellis's Inquiry, p. 39. et seq.

234 Effects of respiration on the animal system.

Having considered the effects produced on the air by the respiration of animals, and the vegetation of plants, we must now notice the effects produced by the exercise of the same function on the animal body, as the comparison of these effects with the changes produced on the air itself, affords us the only clue to a rational theory of respiration.

235 Changes on the blood.

We have already stated (CHEMISTRY, 2540), that during respiration, the blood changes from the dark colour which it has in the veins, to the bright scarlet of arterial blood. It has been found, that a clot of venous blood, when out of the body, assumes the bright tinge, when exposed to the action of oxygenous gas; and that venous blood confined within a bladder, undergoes a similar change, when the bladder is immersed in oxygenous gas. It has been also found, that when arterial blood out of the body is exposed to the action of irrespirable gases, it loses its bright colour, and assumes the purple hue of venous blood.

236 Increase of temperature.

It is fully ascertained, that the heat of the body is chiefly kept up by respiration. See CHEMISTRY, N° 2545.

237 Theory of respiration.

Let us now consider the most probable theories of respiration, chiefly as they are applicable to the human system. Without staying to notice the older hypotheses that have been advanced to explain this function, we shall only state the present most received doctrine, and mention the objections that have been lately made to it.

238 Theory of Allen and Bostock.

This doctrine is stated in the following manner by Dr Bostock, one of its most strenuous defenders. "The blood arises at the right side of the heart, in a venalized state, loaded with a quantity of the oxyde of carbone; as it passes through the pulmonary vessels, it becomes subjected to the action of the air contained in the bronchial cells; a portion of the oxygen is removed from the air, part of which, forming an intimate union with the oxyde of carbone, is expelled in the form of carbonic acid gas, while the remainder is dissolved in the blood." It is here necessary to remark, that it is not *oxygenous gas*, but *oxygen*, which is supposed to be mixed with the blood. The caloric thus set at liberty is employed, part of it in maintaining the temperature of the lungs, which would otherwise be cooled by the admission of the external air; part of it in carrying off the aqueous vapour, and another portion in converting the carbonic acid into carbonic acid gas; but the greatest part of it is united, in the form of specific heat, to the arterial blood, which, by becoming arterialized, has its capacity for heat increased. The arterial blood is poured into the left cavity of the heart, and propelled through the arteries into the extreme parts of the body The oxygen which was dissolved in the whole mass of blood, during the circulation, gradually unites itself more intimately to a portion of the carbone in it, which it converts into the oxide of carbone, and thus the blood acquires the venous state. By this change, its capacity for caloric is diminished; the specific heat which it obtained in the lungs, is given out in the capillary vessels, to keep up the temperature of the body, and the blood returns to the right side of the heart completely venalized. This hypothesis is nearly similar to the one which was proposed by M. M. La Grange and Hassenfratz; it received some modifications from Mr Allen of Edinburgh, and was delivered by him nearly in the form which I have stated above, in his admirable course of physiological lectures. It was, I believe, first published in my Essay on Respiration *."

* Edin. Med. Jour. vol. iv. p. 160.

This doctrine, if sufficiently established, would explain the manner in which the blood becomes arterialized in the course of the lesser circulation. It would also shew how, under particular circumstances, the arterial blood may be venalized without leaving the arteries, and the venous blood arterialized without leaving the veins. It accounts for the gradual evolution of caloric in the capillary vessels, during the course of the circulation, by the union which takes place between the oxygen and the carbone; whereas in the other hypothesis, (see N° 241.;) this union is entirely completed in the lungs. It would allow a considerable time in which this union might be accomplished, and would likewise suppose the constituent parts to remain in perfect contact for an indefinite period. This hypothesis would also explain how the oxygen is disposed of, which is supposed not to be concerned in the formation of carbonic acid, and would likewise possess the advantage of supposing the existence of a surplus quantity of oxygen, which being carried along the circulation, might be expended in a variety of useful purposes in the different parts of the animal economy. It would shew how the supply of matter which is poured into the blood by the absorbents, is gradually incorporated with the mass; and after the separation of that portion, which is necessary for repairing the waste of the different organs, the remainder is united to oxygen, and keeps up the temperature of the body; and, having afterwards no farther useful purpose to serve, it is discharged by the lungs †.

† Ib. p. 167.

239 Objections.

Several objections, however, may be made to this theory. It is not proved that there is in natural respiration any absorption of oxygen by the blood; for though much of the oxygenous portion of the atmosphere is lost, the quantity of carbonic acid generated is sufficient to account for it. Mr Ellis has lately made very strong objections to this supposed absorption of oxygen, drawn chiefly from the anatomical structure of the blood vessels, and of the bronchial cells. He contends that the coats of the former, and the membranes bounding the latter, can scarcely admit the passage of air through them, much less that of the solid basis of oxygenous gas, which basis Dr Bostock supposes to be the principle absorbed. It is still more improbable, according to Mr Ellis, that two solid bases, namely those of oxygenous gas, and of oxide of carbone, should be at the same time passing through these resisting membranes; a supposition that is necessary in the hypothesis just stated. Again, supposing that this absorption of oxygen should take place, from the affinity of the blood for this principle, it is not easy to conceive why this affinity should so soon cease, and why the blood should again part with the oxygen, to the base of carbonic oxide ‡. These objections are certainly very forcible; let us see how they have been answered.

‡ *Ellis's Inquiry*, p. 117—123.

240 answered.

Dr Bostock, in an ingenious reply to Mr Ellis's objections, in invalidation of the first objection, quotes the well known experiment of Dr Priestley, mentioned in N° 235. that venous blood becomes changed when exposed to oxygenous gas, even though a bladder be interposed between them; and in controverting of the rest, he seems chiefly to rely on the supposition that a greater quantity of oxygen is consumed than is taken up in the formation of the carbonic acid. He also does not consider it as *necessary* to suppose that either the oxygenous gas, or the oxygen itself, should enter the blood vessels, and should afterwards be expelled from them; but only that a *part of the oxygen* should be *attracted* by the blood, and after entering into a variety of new combinations, should be discharged as a constituent of some of these new compounds. Without inquiring in what way the action between the blood and oxygen takes place; whether it be in consequence of the mechanical structure of the membranes, which permits the oxygen to pass through their pores, or whether it be owing to the affinity of the blood for oxygen, which causes it as it were to become saturated with this substance before it transmits it; it appears to him sufficient to state, that oxygen and blood can act on each other, through a membrane which is very much thicker, and probably much denser, than that which separates the blood in the lungs from the air in the bronchial cells*.

* *Edin. Med. Jour.* vol. iv. p. 161. *et seq.*

241 Mr Ellis's opinion.

From a consideration of the principal experiments on respiration that have been made by the ablest chemical physiologists, and a comparison of these with what he has himself made, Mr Ellis contends that no part of the air enters into the blood, but all the oxygen which disappears is to be found in the carbonic acid produced; and that this carbonic acid is formed by the union of carbone emitted by the exhalant vessels of the lungs, uniting with part of the oxygenous portion of the inspired air †.

† *Edin. Med. Jour.* vol. iv. p. 327.

242 Objections.

To this opinion Dr Bostock, in the paper already referred to, makes the following objections; that this opinion does not explain how the regular supply of carbone is, at each successive circulation, brought to the lungs in a state proper to be discharged; and that it does not explain in what way the oxygen is employed, which is consumed in respiration ‡.

‡ *Edin. Jour.* vol. iv. p. 163.

243 answered.

To the first of these objections (which, if it be proved that the whole of the oxygen is taken up in forming carbonic acid, is the only objection that can properly lie against his opinion), Mr Ellis replies, that the supply of carbone is derived from the digestive organs; but he does not conceive, as Dr Bostock seems to imagine, that this is no sooner received into the blood than excreted, or that the first operation which takes place in the sanguiferous system after it has received the substance which is to afford nutriment to the body, is to discharge the greatest part of it. He regards carbone as a constituent part of the animal fluids, and he has endeavoured to shew, that it is emitted by the exhalants of the skin and intestines, as well as by those of the lungs, producing in all cases similar changes on the air. Digestion he holds to be in no other way the source of the carbone in these fluids, than as it is the source of all the other principles which they contain. We know that all the phenomena of respiration are often exhibited for long periods where no digestive process is carried on; but the functions of life must sooner or later come to an end, if the various means of exhaustion be not recruited by supplies through the digestive organs. It is only in this distant view that he considers digestion as the source of carbone; its immediate sources are the exhalant functions of the body, which will afford carbone as long as they are supported by the motion of the blood, and will no longer yield it when the motion of the blood has ceased. But whether the exhalant functions continue or cease, he considers that carbone exists abundantly, if not equally, in the serum and crassamentum, in arterial and venal blood *.

* *Edin. Jour.* vol. iv. p. 327.

244 Theory of respiration still incomplete.

On the whole, though the final causes of respiration, or the uses to which it is subservient in the animal economy, are now pretty well understood, we must acknowledge that the mode in which these beneficial effects are produced, has not yet been satisfactorily explained.

245 Uses of respiration.

The principal uses of respiration appear to be, 1. To bring about some beneficial change in the fluids of the body, and through them on the solids; 2. To preserve the equable temperature of the body; and, 3. In all those animals that breathe by lungs to produce those sounds which arise from what we call *voice*.

246 Animal heat.

That animal heat is kept up chiefly by respiration, requires we think, no particular proof. It is well known, that those animals which consume most air during respiration, have the highest temperature. Birds in particular have the most extensive breathing organs, and the temperature of these animals is higher than that of any other class. The respiration of reptiles, fishes, and most of the lower classes, is slow and languid, and the temperature of these animals is proportionally low. The heat of each species is, however, pretty uniform under ordinary circumstances. That of the human body is generally about 98° of Fahrenheit. This however depends on the circumstances in which it is placed. When much chilled by the action of cold, the temperature of the human body falls a degree or two below the ordinary height; and under the influence of violent fever, it rises several degrees above it. The temperature is generally highest in children; and instances are recorded of these having survived, while their mothers, to whose breasts they clung, have perished from the severity of cold.

247 Preservation of equable temperature.

One of the most interesting facts relating to the subject of animal heat, is the capacity of preserving the equable temperature of their bodies, possessed by most animals. Man himself can live with little inconvenience in the frozen regions of Spitzbergen, and under the equatorial heats of Africa. He can even support a greater degree of heat than is perhaps ever known to take place from the rays of the sun, as is proved by the experiment of Drs Blagden and Fordyce in heated rooms; these gentlemen having remained for 15 minutes together in a heat exceeding 130°. The heat supported by some of the inferior animals is still more extraordinary. A dog has been known to live for a considerable time in air heated to 260°, and still the heat of his body was not raised more than 2° above its natural standard. A frog has lived for more than 25 minutes when laid on flannel,

nel, heated from 95° to 106°. Fishes live very well at 72°; and Lucas, in his history of mineral waters, speaks of carp that were living in a hot bath, whose temperature was at least equal to that of the human body.

How this equable temperature is preserved, cannot be completely explained. We know that the heat of the human body is commonly moderated by perspiration; but in some cases, as in that of Dr Fordyce alluded to above, where the heated atmosphere was filled with watery vapour, this could have little effect. We can ascribe it only to the action of the living principle.

248
Voice.

It was long ago observed by Aristotle, that those animals only who possess lungs, have a true voice, and this opinion is confirmed by the experience of modern naturalists. We find, that only mammalia, cetacea, birds, reptiles and serpents, can utter vocal sounds. Several tribes below these do indeed emit certain sounds, especially insects; but these are owing to vibrations of the air in consequence of the agitation of their external organs. It is only in mammalia and birds that the voice becomes an interesting object of enquiry; for that of the cetacea is little more than blowing and grunting, and that of the other two classes is either hissing or croaking.

249
Amazing variety of the human voice.

Nothing can exceed, in variety and execution, the human voice; as will readily be allowed, if we consider the complicated structure of the human vocal organs, and the almost infinite variety of changes of which they are susceptible. Dr Barclay has calculated these with great accuracy, proceeding on the principle, that where a number of moveable parts constitutes an organ destined to some particular function, and where this function is varied and modified by every change in the relative situation of the moveable parts, the number of changes produceable on the organ must at least equal the number of muscles employed, together with all the combinations into which they can enter. Now, the muscles proper to the five cartilages of the larynx, are at least seven pairs; and fourteen muscles that can act separately or in pairs, in combination with the whole, or with any two or more of the rest, are capable of producing 16,383 different movements; not reckoning as changes the various degrees of force and velocity, nor the infinitely varied order of succession by which they may occasionally be brought into action. The number appears almost incredible; but to lessen the surprise, it must be recollected that we speak not here of the powers possessed by any individual, which will depend on habits and circumstances, but on the powers of the vocal organs, considered in the abstract, free from all the influence of custom, equally indifferent, and equally disposed to act in any order of succession, in any combination, and with any degree of force and velocity of which their original powers were susceptible.

If the powers we have mentioned appear astonishing, and able to account for many thousands of these varieties observed among the voices of the human species, we have further to add, that the muscles alluded to are only the proper muscles of the *larynx*, or the muscles restricted in their attachments to its five cartilages. These are but a few of the muscles of voice. In speaking we use a great many more. Fifteen pairs of different muscles, attached to the cartilages, or *os hyoides*, and acting as agents, antagonists, or directors, are constantly employed in preserving the cartilages of the larynx steady, in regulating the place of their situation, or moving them as occasion requires, upwards and downwards, backwards and forwards, and in every way, directly and obliquely, according to the course of the muscular fibres, or in the diagonal between different forces. These muscles, independent of the former, are susceptible of 1,073,741,823, different combinations; and co-operating with the seven pairs of the larynx, of 17,592,186,044,415, exclusive of the changes which must arise from the different degrees of force and velocity, and the infinitely varied order of succession in which they may be brought into action.

But these are not all that co-operate with the larynx, either in forming or changing the voice; the diaphragm, the abdominal muscles, the intercostals, and all that directly or indirectly act on the air, or on the parts to which the chondral and hyoidal muscles are attached, contribute their share. The *os hyoides* could not be raised unless the inferior jaw-bone were previously fixed by the *temporals*, *masseters*, and internal *pterygoids*; and a similar assistance is likewise furnished by several other auxiliary muscles that fix the head, *sternum*, and *scapula*; to these we must add some pairs belonging to the *pharynx* and *isthmus faucium*, and some also belonging to the tongue, which, combining with others, give to that organ an inconceivable variety of movement; and so quickly, that, in rapid utterance, they change its state 3000 times in a minute. Thus Haller could articulate 1500 letters in a minute, which required 1500 contractions, and as many relaxations of the lingual muscles †.

† *Barclay's Anat. Nomen.* p. 70.

250
Mechanism of voice and speech.

The principal organ of voice is the larynx, which is proved by the circumstance that, when this is injured, the voice is either lost, or rendered very indistinct. In ordinary respiration the chink of the glottis seems to be in a relaxed state, and when this chink is contracted, voice is produced, and the sound of the voice is more or less shrill, according as the *glottis* is more or less contracted. By this contraction of the glottis alone we can produce only inarticulate sounds, varied indeed almost infinitely with respect to intensity and tone, by the action of the muscles. The production of speech requires the action of the tongue, the lips, the palate, and the teeth; and the articulations are most complete, when all these parts are most perfect in their structure, and in the most healthy condition. Too great length or shortness of the tongue, swelling of this organ in consequence of inflammation, &c. imperfection of the palate, loss of the teeth, swelling of the lips, all serve to render speech imperfect and inarticulate. The strength of the voice depends on the quantity of air expired, and on the contraction of the glottis; and consequently those animals who have the most capacious and most dilatable lungs, together with an ample cartilaginous and elastic larynx, will, other things being equal, have the strongest voice.

251
Ventriloquism.

Among the various effects of the human voice, there is none more calculated to produce surprise in the hearers, than that extraordinary talent which some men possess of deceiving their hearers into a belief, that the sounds which they utter do not proceed from the real speaker, but from situations at a distance. This talent has been termed *ventriloquism*, from an idea that the voice of the speaker proceeded not from the mouth, but from the belly. The most remarkable instance of this rare talent of which we have heard, is that of M. Fitz-James, who was formerly at Paris, and exhibited in London in the year 1803. Mr Nicholson has given an amusing,

Of Respiration.

amusing account of the performance of this ventriloquist, and we shall present part of it to our readers.

After some remarks on the nature of ventriloquism, which we shall notice presently, and on the difficulty of ascertaining the direction of the sound, Mr Nicholson thus proceeds:—"We should scarcely be disposed to ascribe any definite direction to it; and consequently are readily led to suppose it to come from the place best adapted to what was said. So that when he went to the door, and asked in French (in which the whole performance was carried on), 'are you there?' to a person supposed to be in the passage, the answer in the unusual voice was immediately ascribed by the audience to a person actually in the passage; and upon shutting the door and withdrawing from it, when he turned round, directing his voice to the door, and said, 'stay there till I call you,' the answer which was lower, and well adapted to the supposed distance, and obstacle interposed, appeared still more strikingly to be out of the room. He then looked up to the ceiling, and called out in his own voice, 'what are you doing above?' 'do you intend to come down?' to which an immediate answer was given, which seemed to be in the room above, 'I am coming down directly.' The same deception was practised on the supposition of a person being under the floor, who answered in the unusual, but a very different voice from the other, that he was down in the cellar putting away some wine. An excellent deception of the watchman crying the hour in the street, and approaching nearer the house, till he came opposite the window, was practised. Our attention was directed to the street by the marked attention which Fitz-James himself appeared to pay to the sound. He threw up the sash and asked the hour, which was immediately answered in the same tone, but clearer and louder; but on his shutting the window down again, the watchman proceeded less audibly, and all at once the voice became very faint, and Fitz-James in his natural voice said, 'he has turned the corner.' In all these instances as well as others which were exhibited to the very great entertainment and surprise of the audience, the acute observer will perceive that the direction of the sound was imaginary, and arose entirely from the well-studied and skilful combinations of the performer. Other scenes which were to follow required the imagination to be too completely misled to admit of the actor being seen. He went behind a folding screen in one corner of the room, when he counterfeited the knocking at a door. One person called from within, and was answered by a different person from without, who was admitted, and we found from the conversation of the parties, that the latter was in pain, and desirous of having a tooth extracted. The dialogue, and all the particulars of the operation that followed, would require a long discourse if I were to attempt to describe them to the reader. The imitation of the natural and modulated voice of the operator, encouraging, soothing, and talking with the patient; the confusion, terror, and apprehension of the sufferer; the inarticulate noises produced by the chairs and apparatus, upon the whole, constituted a mass of sound which produced a strange but comic effect. Some observers would not have hesitated to assert, that they heard more than one voice at a time; and though this certainly could not be the case, and it did not appear so to me, yet the transitions were so instantaneous, without the least pause between them, that the notion might very easily be generated. The removal of the screen satisfied the audience that one performer had effected the whole.

"His principal performance, however, consisted in the debates at the meeting of *Nanterre*, in which there were twenty different speakers, and certainly the number of different voices was very great. Much entertainment was afforded by the subject, which was taken from the late times of anarchy and convulsion in France; when the lowest, the most ignorant part of society, was called upon to decide the fate of a whole people by the energies of folly and brute violence. The same remark may be applied to this debate, as to the other scene respecting tooth-drawing; namely, that the quick and sudden transitions, and the great differences in the voices, gave the audience various notions, as well with regard to the number of speakers, as to their positions and the direction of their voices *."

* Phil. Jour. 8vo. vol. iv. p. 203, 252

How explained.

Various explanations of this peculiar modification of voice have been given. From the report of Fitz-James himself, it appeared to Mr Nicholson, that by long practice he had acquired the faculty of speaking during the inspiration of the breath, with nearly the same articulation, though not so loud, nor so variously modulated, as the ordinary voice, formed by expiration of the air. M. Richerand, who heard Fitz-James at Paris, gives a different account of the matter. He says that every time the ventriloquist exerted this unusual peculiarity, he suffered distension in the epigastric region; that sometimes he perceived the wind rolling even lower, and that he could not long continue the exertion without fatigue. Richerand believes that the whole mechanism of this art consists in a slow, gradual expiration, drawn in such a way, that the artist either makes use of the influence exerted by volition over the muscles of the parietes of the thorax, or that he keeps the epiglottis down by the base of the tongue, the apex of which is not carried beyond the dental arches.

He always made a strong inspiration just before this long expiration, and thus conveyed into the lungs a considerable mass of air, the exit of which he afterwards managed with such address. Therefore repletion of the stomach greatly incommoded the talent of M. Fitz-James, by preventing the diaphragm from descending sufficiently to admit of a dilatation of the thorax, in proportion to the quantity of air that the lungs should receive. By accelerating or retarding the exit of the air, he can imitate different voices, and induce his auditors to a belief, that the interlocutors of a dialogue kept up by himself alone, are placed at different distances †.

† Richerand's Physiol. by Kerrison, p. 376.

Mr Gough in an ingenious paper, containing an investigation of the method whereby men judge, by the ear, of the position of sonorous bodies, relative to their own persons, explains the phenomena of *ventriloquism*, on the principles of reverberated sound, and considers it as consisting in the talent of making the voice issue only from the mouth; whereas he thinks that in ordinary cases the different vibrations which are excited by the joint functions of the several vocal organs in action, pass along the bones and cartilages from the parts in motion, to the external teguments of the head, face, neck, and chest, from which a succession of similar vibrations is imparted to the contiguous air, thereby converting the upper half of the speaker's body into an extensive seat of sound. He thinks that the sounds proceeding from the mouth

mouth of a ventriloquist are uttered in such a direction that the hearers may receive the impression of some echo with much more force than they can receive the original sounds *. It may be doubted whether such echoes can take place in an ordinary room filled with a large assembly; and on the whole we are inclined to consider this phenomenon as being effected partly by the gradual emission and a skilful management of a large quantity of air taken in by a full inspiration, and partly by the influence which the performer is capable of exerting over the imagination of his hearers.

* *Manchester Memoirs*, vol. i. part ii. p. 622.

253 Voice of brutes.

Several of the mammalia have a characteristic voice, which is formed by particular organs. These are in some animals tense membranes; in others peculiar cavities opening into the larynx, and sometimes appearing like continuations of the laryngeal ventricles. Thus the neighing of the horse is effected by a delicate, and nearly falciform, membrane, which is attached by its middle to the thyroid cartilage, and has its extremities running along the outer margins of the opening of the glottis. The braying of the ass is produced by means of a similar membrane, under which there is an excavation in the thyroid cartilage. In this animal there are also two large membranous sacs opening into the larynx. The purring of the cat seems to be owing to two delicate membranes that lie below the ligaments of the glottis. Some of the monkey tribe, especially the *simia seniculus* and beelzebul, have the middle and fore part of the *os hyoides* formed into a spherical bony cavity, by which these animals are enabled to produce those horrible and penetrating tones, which can be heard at vast distances, and have gained them the name of howling apes †. See MAMMALIA, N° 33.

† *Blumenbach's Comp. Anat.* chap. xv.

254 Voice of birds.

The simplest vocal organ seems to be that of birds. These animals have, on the sides of the windpipe next the lungs, and at the opening of the bronchiæ, two membranous folds which partly close the pulmonary aperture of the windpipe, and the aperture next the head is susceptible of great contraction and dilatation. In short, the vocal organ of birds may be considered as one of the most perfect wind instruments, very much resembling, both in its structure and effect, a clarinet or hautboy, the opening next the lungs being similar to the reed of these instruments. For some remarks on the song of birds, see ORNITHOLOGY, N° 42; and for farther observations on the voice, see ANATOMY, Part I. N° 122.

255 Relations of respiration with other functions.

In tracing the relations of respiration with the preceding functions, we must deviate a little from our usual order, and begin with those between respiration and *circulation*, as it seems to be through the medium of the circulating system that respiration principally acts on the other functions. The relations between respiration and circulation are the most immediate and the most obvious.

256 With circulation.

When the *breathing* is most free and rapid, the circulation is most vigorous and active; while in laborious or interrupted respiration, the action of the heart and arteries becomes slow, feeble, irregular; and where the lungs are deprived of oxygenous gas, the *arteries* gradually cease to pulsate, and soon after the motion of the *heart* ceases. If the stimulus of oxygen be not too long withheld, so that the lungs can again be excited to action, first the heart, and then the arteries, gradually renew the exercise of their functions, and the circulation proceeds as before. On the application of these principles depends the recovery of those apparently dead from *asphyxia* (suffocation, drowning, &c.) When the circulation becomes languid from indolence, from depressing passions or the want of accustomed stimuli, we feel about the breast a peculiar sensation, which physicians call *anxiety*, and which is relieved by a deep inspiration; by sighing, yawning, &c. Violent exertions of the respiratory organs, such as laughing, coughing, singing, talking unusually long or loudly, quicken the circulation, sometimes to an alarming degree, so as to occasion hæmorrhage in such as are predisposed to that affection. Breathing in an atmosphere that is much rarefied, as on the top of a high mountain, has often the effect of producing plethora and hæmorrhage; though this, perhaps, is imputable rather to a want of the ordinary pressure on the surface of the body.

257 With sensation.

When the circulation through the lungs is impeded or obstructed, a determination of blood takes place to other parts, especially to the head. The effects produced on the brain and other organs of sensation, by the breathing of impure air, are dreadful. When the same quantity of air is repeatedly respired, there is experienced, first, great anxiety about the breast, and this soon becomes intolerable; the face swells, becomes livid, or even black, and feels excessively hot; sparks of fire seem to dance before the eyes; the sight becomes depraved; giddiness, ringing in the ears, and confusion of thought succeed; and if fresh air be not soon supplied, the subject of the experiment loses both sensation and motion, and falls into a state resembling apoplexy †. When rarefied air is breathed, the nervous system experiences a kind of excitement; agreeable sensations are produced with a disposition to mirth and cheerfulness; but if the person continue for some time in such a situation, an unusual languor, heaviness, and disposition to sleep, come on ‡. We need not here describe the pleasurable sensations excited by the respiration of nitrous oxide, as these have been already related under CHEMISTRY, N° 366. The exhilarating effects which a pure and serene atmosphere produce on the general system, and the uneasy sensations experienced under a thick and clouded sky, are partly referable to this head. The nervous system also acts on the organs of respiration. In some affections of the brain, respiration is much quickened, while in others, especially the comatose affections, it is slow, laborious, and often attended with that peculiar noise called *stertor*. It is well known what effect anxiety, eagerness, hope, or desire, have on the respiration. According as one or other of these passions is predominant, the breathing becomes hurried, irregular, or suspended.

† *Kite's Essay on Apparent Death*, p. 25.

‡ *Saussure Voyage dans les Alpes*, p. 559.

258 With motion;

An evident relation takes place between respiration and motion. The breathing is quickened by exercise; and when there is a considerable debility of the muscular system, the slightest exertion produces hurried respiration, panting, &c. In those animals that possess the greatest powers of motion, respiration is most free, and the air most extensively diffused over the body. In birds, not only the lungs are very extensive, but the air is conveyed into the bones of the skull, and into the hollows of the larger cylindrical bones; and in insects which have the most rapid motions, the air penetrates to every part of the body. Motion, as well as sensation, becomes unusually free and vigorous in rarefied air, and during the respiration of nitrous oxide; while in cases of

Of Respiration. of impeded or obstructed respiration, the action of the muscles is languid and feeble. Indeed, if we may implicitly rely on the experiments that have been made on the respiration of de-oxygenated gases, the muscular fibres are among the first organs that are injured. We are told that by the admission of black blood, or blood that has not undergone the necessary changes by healthy respiration, the muscles lose their power of contraction, and even their irritability.

259 With digestion.

The organs and functions of respiration sympathise with those of digestion. When the former function is most free, the latter is generally most healthy; the respiration of pure or rarefied air, or of the nitrous oxide, is attended with an increase of appetite, and of the digestive powers, as was experienced by M. Saussure while wandering among the Alps, and by Davy while respiring the *gas of Paradise*. Again, when digestion is impaired, or when the stomach is overloaded, the breathing is rendered difficult, laborious or irregular, and in many cases of affection of the stomach, cough is a very common symptom. These effects produced on the respiratory organs in consequence of impaired digestion, are ascribable chiefly to the pressure on the diaphragm by the distended stomach.

Many other relations might be pointed out between respiration and the other functions of the animal economy, but our limits do not permit us to enlarge further on the subject *.

* See Bichat Recherches Physiol. sur la Vie et la Mort.

For an account of the morbid affections of respiration, such as *sneezing*, *hiccup*, *coughing*, *anxiety*, *dyspnœa*, or *difficulty of breathing*, see the article MEDICINE.

CHAP. IX. *Of Nutrition and Assimilation.*

260 Nature of nutrition.

THE function by which the nutritious particles received by a living being are assimilated to the nature of that being, or become part of its substance, is properly called *nutrition*. This is the completion of the process which, in most animals, is the combined result of several other operations. Thus, in the superior animals, from man to the mollusca, the whole process of nutrition consists of *digestion*, *absorption*, *circulation*, and *respiration*; by the two last of which the nourishment received is changed into perfect blood, and fitted for the support and renewal of the several parts of the system. From the account of the constituent parts of the blood given under CHEMISTRY, N° 2660, it will appear, that this fluid contains within itself the principles of which every part of the body is composed. Thus it contains *fibrine*, which is the chief principle of the muscular parts; *phosphate of lime*, which forms the basis of the bones; *albumen* and *gelatine*, the chief constituents of cartilages, ligaments and tendons, &c. These principles are conveyed by the arterial blood, during its circulation, to those parts of the system where they are required, for renewing waste, or supplying deficiencies, and thus they are assimilated to the nature of the body.

261 Each assimilating organ produces peculiar changes.

The power of assimilation, so remarkable in living bodies, is not the same in every assimilating organ; but each has the property of converting the materials it receives (provided they be susceptible of this conversion) into a peculiar substance. Thus the stomach always converts the food into *chyme;* the intestines change it into *chyle;* but if chyle, or what is very similar to it, fresh milk, be received into the stomach, this organ exerts on it the usual change, and does not pass it forward into the intestines unaltered, though we know by experiment, that fresh milk is capable of being taken up unchanged by the absorbents of the bowels *. Again, blood is always perfected within the circulating vessels; and if chyle or fresh milk be injected into the arteries, it produces dangerous effects, while the fresh blood of another living animal may be transfused into these vessels without injury. In like manner, if a piece of fresh muscular flesh be cut from a living animal, and applied to the muscles of another living animal, also newly divided, the two parts unite, and are immediately assimilated; and even fresh bone may, in the same manner be ingrafted on the living bones of the same, or of a different species of animal †; while substances that are foreign to the nature of the animal body, when introduced into the blood-vessels, prove fatal, and when inserted into a wounded muscular or bony part, prevent the wound from healing.

* Fordyce on Digestion, p. 159.

† Phil. Mag. vi. 308.

262 Assimilation a chemical process.

These circumstances show that assimilation is a chemical process, though modified and regulated by the action of the living principle. The chemical nature of assimilation is most distinctly proved by the well-known experiment of colouring the bones of an animal, by feeding it on madder. The particles of the madder, which we know to have a strong affinity for phosphate of lime, are carried unchanged from the stomach into the blood-vessels, and are thence conveyed, probably in combination with the phosphate of lime there contained, into the substance of the bones, where they are deposited, and remain for a considerable time.

263 Nutrition not performed by nerves.

We have considered nutrition as performed by the circulating vessels. It has been supposed that the nerves are the organs of nutrition; but this strange hypothesis is completely overturned by an experiment of the second Monro, which proves that the limb of a frog may be preserved alive and nourished by the blood-vessels, after its communication with the brain has been cut off by dividing the nerves.

264 Nutrition in insects and zoophytes.

In insects and zoophytes, where there are no circulating vessels, nutrition must be a very simple operation. According to Cuvier, it is performed by *imbibition;* the pores of the animal's body receiving immediately the nutritious fluids on which it feeds.

265 Assimilating power limited.

In plants and animals, the assimilating power has always certain limits prescribed to it; its influence is very generally confined to the sort of food congenial to the species, and its strength is varied according to circumstances, as the age, the habits, and the state of health. Those which are young assimilate faster than those which are old; and one species, which may partly be owing to the nature of their food, will assimilate much faster than another. Certain worms that feed on animal and vegetable substances will, in twenty-four hours after their escape from the egg, become not only double their former size, but will weigh, according to Redi, from 155 to 210 times more than before. Most oils are of very difficult assimilation; and those which are *volatile* will often resist the long-continued and the varied action of the living organs; will mingle with the parts, and, undecomposed, communicate their flavour.

Other circumstances respecting nutrition have been noticed

Of Secretion. noticed in the first part of ANATOMY, N° 130; and the chemical doctrine of assimilation is more fully considered under CHEMISTRY, N° 2567—2571.

CHAP. X. *Of Secretion.*

266 Secretion. THAT function by which any organ, or set of organs, separates from the general mass of blood certain principles intended to perform some important office in the animal economy is called *secretion;* and the substances so separated, are called *secretions.*

267 Organs. The secretory organs in the more perfect animals are very numerous, and some of them very complex. The most simple of them seem to be the *cellular texture*, and the *mucous membranes*. The next in simplicity are the *conglobate glands*, and perhaps the *spleen*, while the more complex organs are the *liver*, the *testicles*, the *atrabiliary capsules*, &c. An account of all these organs, as they occur in the human body, has been given in the first part of the article ANATOMY; and the corresponding organs of the inferior animals, with others not found in man, are described by writers on comparative anatomy, especially Cuvier and Blumenbach.

268 Kinds of secretion. Secretion appears to be of three kinds: 1. *Transudation*, in which the secreted matters merely ooze through the pores of the secreting organ. This takes place in the lowest classes of animals, as in zoophytes, insects, and some worms, but rarely in the human subject. 2. *Exhalation*, in which the secreted fluids are poured out into cavities by certain branches of the arteries with open mouths, called *exhalants*. This appears to take place in many organs of the most perfect animals, especially from the mucous membranes, the synovial glands, &c. 3. *Secretion*, properly so called, in which the blood passes through glandular bodies, where a part of it is decomposed, and carried out in another form by particular tubes called *excretory ducts*. This is the case with most of the secreting organs, as the salivary glands, the lachrymal glands, the liver, the pancreas, the testicles, and a few others.

269 Secreted matters. The secreted fluids are chiefly the following: *lymph, serum, tears, mucus, saliva, pancreatic juice, gastric juice, enteric juice, bile, semen, synovia, fat, marrow, cerumen* or *ear-wax*, and in the female, *milk*. The other matters secreted, which may rather be termed solid than fluid, are *albumen, gelatine, fibrine*, and *phosphate of lime*. On the nature and properties of all these substances, see the article CHEMISTRY, Chap. xix. sect. 3.

270 General modifications of secretion. With respect to the secretions in general, we may remark, that they are considerably influenced by age, sex, various affections of the mind, and various bodily diseases. They are formed by organs which are sometimes capable of supplying the deficiencies of each other; they are subjected to the influence of the atmosphere, and to the temperaments of the body; they are sometimes mixed together, and by this combination their nature is changed.

We shall now briefly examine the action of three of the secreting organs, viz. the *cellular membrane*, the *liver*, and the *spleen*.

271 Action of the cellular membrane. From the extensive distribution of the cellular membrane it is reasonable to conclude, that it is intended to perform several important offices in the animal economy. One of its most obvious uses is to form a general connecting medium between every part of the structure, while it at the same time separates and distinguishes every organ. From its elasticity, and the lubricating fluid which it holds within its cells, it facilitates motion, and thus assists the action of all the muscular parts and organs. That it is susceptible of great dilatation is proved by the phenomena of anasarcous dropsy; and the gradual evacuation of the water when anasarcous limbs are punctured, as well as the passage of extraneous bodies below the skin from one part to another, seem to show that it possesses considerable contractile powers. It is chiefly, however, as a *secreting* organ that we are here to consider the *cellular membrane;* and in this way its function is of the utmost importance. The *fatty matter*, that is so copious in most of the superior animals, is contained within particular cells or *bags* of the cellular membrane, and is found in greatest quantities below the skin, especially on the *sternal* part of the belly, and about the kidneys. In some animals, as the *hog*, the *seal*, the *walrus* and the *cetaceous* tribes, it forms a layer several inches in thickness, and in all the water animals above mentioned it is nearly fluid. To these animals it not only serves the purposes of a warm covering by the slowness with which it conducts heat; but, by diminishing their specific gravity, renders their motions on the surface of the water much more easy and expeditious. One of the most important uses of the fat seems to be to supply nourishment to the body, when the ordinary channel is obstructed, or the system rendered incapable, from torpor or disease, of receiving food. When fat persons are attacked by fever, or similar acute diseases, they become emaciated, sometimes to so great a degree, as to appear a mere skeleton; and those animals who sleep during winter, though very fat when they retire to their dormitories, are extremely lank and lean when they quit these on the return of spring. In all these cases the fat alone is absorbed, and supplies the waste that takes place in the body, and would otherwise prove fatal.

On the actions of the cellular membrane, see Bichat, *Anatomie Generale*, tom. i.

272 Action of the liver. Some physiologists have supposed that the bile secreted by the liver is not formed entirely from the blood of the *vena portarum*, but partly from the hepatic artery. Dr Saunders who has examined the arguments in favour of this supposition, decides against it, and considers the usual opinion of the bile being solely secreted from the blood of the *vena portarum*, as quite satisfactory. It has also been supposed, that the whole of the bile is not secreted by the liver, but that the gall bladder has a share in this office, and is not merely a reservoir, like the urinary bladder. This supposition is highly improbable, although we think there can be little doubt that the bile undergoes, within the gall bladder, some peculiar changes, which render it better fitted for the functions it has to perform. We know that the gall bladder is very muscular, and that there is an appearance of follicles within it. It is therefore probable that some matter is secreted from its internal surface, which produces a necessary change in the bile.

273 Uses of the bile. The principal use of the bile seems to be to stimulate the intestines, and thus keep up their energy and peristaltic motion, though it is probable that, besides this office, it performs several others of importance in the animal economy, such as assisting in the decomposition of the food, and thus forming chyle; and acting as a general

general stimulus to the system. That it has this last effect is probable from the torpor, inactivity, and dejection that attend hypochondriacal and chlorotic affections, in which this secretion is defective. Too great a secretion, or rather excretion of bile, is attended with violent purging *.

* *See Saunders on the Liver.*

On the nature of the bile, and biliary concretions, see CHEMISTRY, N° 2664.

274 Uses of the spleen.

Few subjects in physiology have given rise to more discussion, and few have been considered with so little success, as the use of the spleen in the animal economy. That an organ so large, and so well supplied with blood, should be intended for some important function, is scarcely to be doubted; and yet the instances of animals that have lived, seemingly with little inconvenience, after the spleen had been cut out, seem to prove that this organ is not of such great importance as it appears to be. The conjectures respecting its uses are various, and some of them not a little ludicrous. Some have supposed that it acted by its weight and pressure on the stomach, and thus promoted digestion at one time, and counteracted hunger at another; some, that it was intended to dilute and attenuate the blood; others, to deprive that fluid of its superabundant oil; another party, that it contributed to form the red globules of the blood; and some of

275 Opinion of Dumas.

the older physiologists supposed that it secreted that fluid to which they gave the name of *black bile*. Dumas is of opinion that it is a sort of supplementary organ, both to the liver and the kidneys, separating from the blood part of its serosity, and then delivering it over to the liver in a proper state for the formation of bile; and furnishing to the kidneys another portion of serosity to form the watery part of the urine *. That at least a part of these opinions of Dumas has some foundation, will appear from the following summary of the late experiments of Mr Everard Home.

* *Principes de Physiol.* tom. iii. p. 592.

276 Experiments of Mr Home.

Prosecuting the inquiry respecting the state of the stomach during digestion, which we have formerly alluded to (see N° 161), Mr Home found that during digestion, the fluids taken into the stomach are principally contained in the cardiac portion; and he inferred, from the uniform consistence of the chyme in the pyloric portion, that a great part of the fluids are carried out of the stomach without ever reaching the *pylorus*. As he conceived very naturally, that the lymphatics of the stomach were inadequate to this office, he conjectured that the fluids might pass off by the spleen. He proved, by a decisive experiment, that liquors might pass through the stomach without going through the pylorus, and he also found at the same time, that the spleen was turgid, unusually large, and its external surface very irregular; and when cut into, small cells were every where met with, containing a watery fluid, and occupying a considerable portion of its substance. Rudiments of these cells had been seen before by Malpighi, who considered them to be glands, and by Cuvier, who calls them corpuscles; but the cells in a distended state seem not to have been examined till Mr Home was led to look for them, in consequence of the above experiment. Mr Home varied this experiment, by giving animals a decoction of madder, and an infusion of rhubarb, and obtained similar results. Part of the fluid swallowed was again rejected by vomiting; but of that which remained it was always found that a part had escaped, without any possibility of passing by the *pylorus*, as this was secured by ligature. It did not probably escape by the absorbents, as these were not so much distended by fluid as to be visible; and it certainly did enter the spleen, as there was there found a quantity of liquor, which was proved, by an alkaline test, to contain rhubarb. A large quantity of urine was found in the bladder, also impregnated with rhubarb *.

* *Phil. Trans. for* 1805, p. 2.

277 Spleen carries off fluid from the stomach.

From these experiments it appears, that the spleen is capable of carrying off from the stomach, a part of its fluid contents, thus affording a much nearer passage to the bladder than through the absorbents. If this investigation, on further trials, shall prove equally satisfactory, it will explain why the bladder is often distended with urine in a short time after drinking; and will do away the necessity of having recourse to the disputed hypothesis of the retrograde action of the absorbents.

278 Peculiar animal secretions.

In the inferior classes of animals there are a number of peculiar secretions, which, from their utility in medicine or the arts, or from their noxious or unpleasant effects, are deserving the attention of physiologists. We can here only mention a few of the more important. The nature and properties of most of them are explained under CHEMISTRY.

Some of the mammalia secrete matters that have a very strong smell, as *musk*, *civet*, *castor*, and in particular the fluid emitted from the hide of several of the weazel tribe, beside the civet cat. *Ambergris* is secreted by some species of whales. Birds, especially water fowls, secrete a large quantity of oily matter, which they use in dressing their feathers. Some reptiles, especially the toad, secrete an acrimonious fluid, which seems to serve them as a weapon of defence. Many serpents, as is well known, produce a most virulent poison, which they insert into the wounds inflicted by their fangs. Some fishes secrete fluids of a similar tendency. Few animals, however, form secretions so various and so useful, as the insect tribes, from whom we procure *cochineal*, *kermes*, *lac*, *silk*, &c. Some of the mollusca, as the muscle, and the spinning slug, also secrete a matter similar to silk, by means of which they either secure themselves firmly in their situations, or facilitate their progressive motion. The *ink* of the *cuttle fish*, supposed with no small probability, to be the basis of Indian or Chinese ink, is also a remarkable animal secretion, which seems intended by nature to screen the animal, and assist it in eluding the vigilance of its pursuers.

279 Vegetable secretions.

There are also many important vegetable secretions, constituting what are called *gums*, *resins*, and *gum-resins*; as *gum-arabic*, *gum-dragant*; *guaiac*, *dragon's blood*; *assafoetida*, *gamboge*, *myrrh*, *aloes*, and many others; for an account of which see CHEMISTRY and MATERIA MEDICA.

CHAP. XI. *Of Excretion.*

280 Excretion.

THE function of excretion differs but little in its nature from that of secretion already considered. As the organs of secretion separate from the blood those substances which are useful in the animal economy, so the excretory organs separate from the blood, or from the food taken into the stomach, those substances which are to be conveyed out of the body as excrementitious, viz. the solid excrement, the urine, and perspiration.

281 Organs.

The organs of excretion, then, are chiefly the bowels, especially the larger intestines, the kidneys, with their appendages, Of Excretion.

appendages, the ureters and urinary bladder, and the skin. For an account of these in the human body, see ANATOMY, Part I.; and for the varieties of these organs in such of the inferior animals as possess them, and for the means by which their absence is supplied in others, see the works of Cuvier and Blumenbach already quoted.

282 Excretion by the intestines.

The physiology of intestinal excretion requires little explanation. The remains of the food, after the nutritious chyle has been extracted from it by the lacteals, are carried onward through the colon and rectum by the peristaltic motion of the intestinal canal, excited to action by the stimulus of their contents, and of the bile, and assisted by the pressure of the abdominal muscles, till they reach the extremity of the rectum, when becoming more stimulant, partly by their bulk, and partly by their increased acrimony, they rouse the muscular fibres of that intestine to greater action, so as, with the assistance of the abdominal muscles, to overcome the resistance of the *sphincter*, and are thus expelled.

283 Relations.

Intestinal excretion is influenced by most of the preceding functions. 1. By the nervous power; as we find that in cases of paralysis, the excrements are not passed without artificial means, or they are voided involuntarily. 2. By motion. Thus we find that the action of the bowels is increased by exercise, and lessened by indolence and a sedentary life; though the quantity of excrement passed is greater in the latter case than in the former, shewing that the stimulus of the excrementitious matter is not sufficient without muscular action, to produce the regular performance of this function. 3. By digestion. It is well known that the stronger the digestive powers of the stomach, the more active are the bowels, and again, when these latter are overloaded with excrement, the functions of the stomach are disordered. 4. By secretion. The action of the intestines is increased, when that of the secretory organs which pour their contents into the alimentary canal, becomes unusually great, viz. in unusual secretions of bile or mucus, as in *cholera* and *diarrhœa*; while, when those secretions are defective, as in cases of *jaundice*, the intestines become unusually torpid.

284 Excretion by the kidneys.

The morbid affections of intestinal secretion have been considered under MEDICINE, N° 109—112, and 114, 115.

The organs destined for the excretion of urine afford the most complete apparatus for this function of any that we shall have occasion to notice, consisting of an assemblage of glands, collected within one membrane; an excretory duct; a reservoir for collecting the excreted fluid, and a canal for conveying it out of the body. Indeed we may consider the kidneys rather as secreting than excreting organs, as the urine there formed differs so much in its nature and properties from the circulating fluids. We know, by a decisive experiment, that the kidneys perform the whole of this office, and that the other organs are intended for the excretion of the urine; for when the ureters are tied or obstructed next the bladder, we find that the secretion of urine still goes on, and that the ureters above the obstruction soon become filled and prodigiously distended.

The nature and properties of urine, in its natural state, and as altered in certain diseases, have been considered under CHEMISTRY, N° 2670.

As the urine contains two substances that are not found in the blood, viz. *urea* and *uric acid*, Dr Thomson concludes, on very probable grounds, that the office of the kidneys is not merely to separate from the blood, a quantity of water and salts, but that they exert on this fluid some peculiar action, decomposing some part of the blood, and forming some new substance or substances †.

† *Thomson's Chemistry*, vol. v. 3d edit. p. 748.

285 Relations.

The mutual relations between this excretion and the preceding functions, are not many, or very important. During certain affections of the nervous system there is a sudden and copious excretion of limpid urine, and some mental emotions produce an involuntary flow of it ‡. And in cases of palsy, an incontinence, or a total suppression of urine, is very common. This excretion is considerably influenced by motion, being less copious in those who use much exercise, or lead a laborious life.

‡ *Merchant of Venice*, act v. scene 1.

The morbid affections referable to this excretion, are noticed under MEDICINE, N° 118—122.

286 Excretion by the skin.

The excretion by the skin, or perspiration, has exercised the ingenuity of many physicians and physiologists, ever since the time of Sanctorius; and though it is not now considered as so essential to life and health as it was in the beginning of the 18th century, is certainly of great importance. The quantity of watery fluid occasionally thrown out by the skin in the form of sweat, proves that, by means of this organ, the blood is freed from a great deal of useless or perhaps injurious matter, which could not so conveniently, or so perfectly, be expelled by other outlets. The nature of the matter perspired, and the quantity of ordinary perspiration, have been investigated by many able experimentalists, the result of whose labours is given in the first volume of Johnson's *Animal Chemistry*; the fifth volume (third edition) of Dr Thomson's *System of Chemistry*; in a paper by Dr Kellie in the second number of the *Edinburgh Medical and Surgical Journal*, and in our article CHEMISTRY.

The principal facts that have been ascertained with respect to the perspirable matter thrown out by the skin, relate either to its quantity, or its chemical composition.

287 Quantity of the perspiration.

I. The experiments on the quantity perspired, on which we can the most rely, are those of Lavoisier, Seguin, and Mr Abernethy. From these experiments we may deduce the following conclusions: 1. The greatest quantity of matter perspired in a minute, amounts to about 26 grains troy, the least to about 9 grains; giving an average of about 17 grains in the minute, or about 52 ounces in 24 hours. Dr Kellie estimates the quantity at about 30 ounces, which seems too small. 2. The quantity of perspiration is increased by drink, but not perceptibly by solid food. 3. Perspiration is the least in quantity immediately after a meal, and reaches its highest proportion during digestion.

288 Its composition.

II. The perspirable matter is chiefly composed of a large quantity of water, some carbon or carbonic acid, a small quantity of another acid, supposed to be the phosphoric, and a peculiar oily matter of an odorous quality, differing in different animals, and, as it should seem, in different individuals. The perspiration of quadrupeds is frequently found to contain phosphate of lime, and sometimes urea. See CHEMISTRY, N° 2532.

289 Relations.

As to the relations of perspiration with the preceding functions, we may remark that this excretion is increased by various passions of the mind, by exercise, by healthy and rapid digestion; that it is generally in proportion to the vigour and quickness of the circulation and respiration, and that it is capable of supplying the defect of the two former excretions. On the contrary,

it

Of Integumation. it is lessened by inactivity; by the impaired state of the digestive organs; by languid circulation and respiration, and by violent purging, or evacuation of urine.

Chap. XII. *Of Integumation.*

290 Uses of integuments as defence. All living bodies are furnished with integuments, which are intended to afford them a defence against those injuries to which their situation is commonly exposed. Of the integuments, some are useful in preventing the dissipation of the fluids; some in resisting acrid and corrosive substances; some of them are indigestible in the stomach of animals, and some appear to be incorruptible in the earth. By these properties, seeds and the ova of insects are preserved for a considerable time, waiting the changes of soil or of season that are favourable to their evolution. They are protected from the action of weak membranous stomachs, and thus the animals who may swallow them contribute to their propagation. It is thus the seeds of the misletoe are dispersed, and deposited on the bark of the oak or the ash. There is a gelatinous substance frequently ejected by birds, and commonly called *tremella*, *nostoc*, or star-fall, which Dr Barclay has proved to be nothing else than the oviducts of frogs, which, as the embryo in form of an egg, moves along their winding canal, secrete that transparent and viscid matter which constitutes the albuminous part of the ovum, and feeds and protects the embryo while in water.

The most important circumstances with respect to integumation relate to the varieties of the integuments themselves, and to the changes or renovation of these in different animals.

291 Integuments useful by their hardness; I. Some integuments are useful, chiefly from their strength and hardness. The *elytra* or shelly coverings of the beetle tribes afford an excellent defence for their membranous wings, when folded up; the shell of the snail lodges the intestines, when the animal comes forth to search for food, and affords a safe retreat to the animal, when it is threatened with any danger from without. The shells of some animals can be opened and closed by a muscular power; and some of them, as in the tail of the lobster, are so disposed in plates or scales, as to be no hindrance to the animal's motion. Several insects which pass a part of their time in the water, always compose for themselves a shell, where it is needful.

292 by their external covering; Some integuments are covered with feathers, some with hair or thick down. Besides many other obvious uses of these coverings, they generally serve to repel insects; and being bad conductors of heat, tend to preserve an equal and necessary temperature. Some integuments are covered with prickles, which oppose the attacks of an enemy by the strength of their points, or by the venom which they infuse, as in the stings of nettles, and the down of some other plants, and some insects. Others again are moistened by a viscid secretion, which preserves the necessary softness of the parts, prevents evaporation, resists acrimony, enables some beings to destroy their enemies, and assists others in performing their progressive motions.

293 by their effluvia; Both plants and animals, but particularly the former, are often protected by odorous effluvia from their integuments. These effluvia are the finer parts of their volatile oil, always inflammable, and so subtle, that the continual emission of it from wood or flowers does not sensibly diminish their weight. To this fragrance it is owing that the deadly nightshade (*atropa belladonna*), the henbane, hounds-tongue, and many others, are seen on almost every high road untouched by animals. The manchinelle-tree of the West Indies emits so very dangerous vapours, that the natives poison their arrows with its juices, and those have died who have ventured to sleep under its shade. The *lobelia longiflora* of America produces a suffocating oppression in the breast of those who respire in its vicinity. The return of a periodical disorder has been attributed to the exhalation of the *rhus toxicodendron*. Of all the vegetable effluvia, however, that afford defence to the plant from which they proceed, or annoyance to the animals that approach it, none are equal to those of the celebrated *bohun-upas*, or poison-tree of Java, whose exhalations have been said to extend to the distance of several miles, preventing all access of animals, or punishing the intruders with certain death. It is rather unfortunate for the botanical poets, that the effects of this poison have been greatly exaggerated, if indeed such a marvellous tree really exists *.

294 by their colour. Various colours of the integuments afford a species of defence. Caterpillars which feed on leaves are generally green; and earth-worms the colour of the earth which they inhabit. Butterflies which frequent flowers are coloured like them. Small birds which frequent hedges have greenish backs like the leaves, and light-coloured bellies like the sky, and are hence less visible to the hawk who passes under them or over them. Those birds which are much amongst flowers, as the goldfinch, are furnished with vivid colours. The lark, partridge, and hare, are of the colour of dry vegetables or earth on which they rest; and frogs vary their colour with the mud of the streams which they frequent, and those which live on trees are green. Fish which are generally suspended in the water, and swallows which are generally suspended in the air, have their backs the colour of the distant ground, and their bellies of the sky. The *sphinx convolvuli*, or unicorn moth, resembles in colour the flower on which it rests; and and among plants, the nectary and petals of the *ophrys*, and of some kinds of the *delphinium*, resemble both in form and colour the insects which plunder them, and thus sometimes escape from their enemies by having the appearance of being pre-occupied. From colour being thus employed as a defence, many animals vary their colours with the seasons and circumstances; and those which are of different colours in summer according to the places which they inhabit, in winter assume in common the colour of the snow.

295 Changes of integuments. II. The changes that take place on the integuments consist either of a partial, or complete, renewal of them. As the more superficial integuments are commonly insensible to stimuli, and possess little or nothing of the vital principle; in all cases where they cannot be enlarged to admit of an additional increase of growth, or where they are not furnished with organs for repairing those injuries which they may suffer from accident or disease, the body is endowed by nature with a power of throwing them off, and of producing others in their stead. Thus, serpents and toads slough their skins; the crustacea cast their shells; the larvæ of insects change their cuticle; and several trees, especially the

* See Pinkerton's Geography, under Java.

Of Transformation.

the cork tree, throw off their outer bark. Even man himself generally changes the cuticle, which peels off in the form of scales. Most animals once a year change their hair, wool, or feathers, and have these renewed by a fresh covering; a process well known by the name of *moulting*. Some animals who do not usually cast their external covering, have the power of repairing this when injured. This is the case with most of the testacea, especially snails.

Chap. XIII. *Of Transformation.*

296 Transformation.

The alterations which organized beings undergo from *metamorphosis* or transformation, are more striking than those which we have described in the preceding chapter. It has indeed been asserted, that these alterations consist in throwing off certain temporary coverings; but this expression is inaccurate, and arises from a want of precision of ideas. Transformation and change of integuments are really different; the truth is, transformation often takes place without any change of integuments, and there is often a change of integuments without any change of form. This new form is sometimes occasioned by a change of shape, consistency, and colour, as when the lobes of a seed are converted into seminal leaves. It is at other times occasioned by a change of proportion among the parts, and at others by the addition of new organs, as when the emmet receives wings, and the plume of the seed is fed by new roots striking into the ground: or, lastly, it is occasioned by a change in the form and organs, and in their mode of operation, as happens in a remarkable degree to some insects. Indeed, though all living bodies, both plants and animals, undergo some degree of transformation in the course of their existence, these changes are most remarkable in insects.

297 Transformation of reptiles;

Many reptiles undergo very curious changes, but these are most remarkable in the frog tribe. The larva or tadpole, as it is called, of the frog, is an animal with a large head, a long tail, no limbs, and commonly possessed of gills, all obviously very different, both in form, proportion, and uses, from the parts of the perfect animal. The curious appearance of what has been considered as the tadpole of the *rana paradoxa*, has led some naturalists to describe it as an animal of a different genus, either a fish or a lizard; see Erpetolgy, p. 384.

298 of insects.

Many insects appear to consist of two distinct animal bodies, one within the other; the exterior, a creature of an ugly form, residing in the water, or under the earth, breathing by gills, or sometimes by tracheæ projecting from the tail, possessing a voracious and grovelling appetite, and having a system of sanguiferous vessels that circulates the blood towards the head. When all its parts decay and fall off, the creature inclosed succeeds in its stead: this often is an animal of a different form, generally lives in a different element, feeds on a different species of food, has different instruments of motion, different organs of sense, different organs of respiration and differently situated; and being endowed with the parts of generation, inclines to gratify the sensual propensity, and produces an embryo, which becomes like the first, and from which, in process of time, a creature is evolved similar to the former.

If the embryo or egg be deposited on a leaf, the leaf is frequently observed to bend, to wrap it in folds, intended for the purpose of protecting it from injuries and danger. If deposited in the body of an animal or plant, they accommodate themselves to its wants and necessities, and furnish a tumour which serves it for a nidus, and besides, like an uterus, supplies it with nourishment; and if deposited in the body of an insect, the creature provides for the future destination of its young charge with all the tender care of a parent, and then dies.

299 Parents of insects often not easily distinguished.

These circumstances, added to the great variety of forms which insects assume, renders it sometimes difficult to know who is the parent. We cannot, for instance, pronounce with certainty who is the true parent of the gordius, known by the name of the *seta equina*, or hair eel. A set of experiments which Dr Barclay once began with a view to throw some light on the subject, were unfortunately interrupted by an accident. He learned only, from a number of observations, that certain black beetles, at the end of summer, have the strongest propensity to run into the water, where they soon die; and that one or two, and sometimes three or four of those eels gradually drop from the beetle by the anus. Whether other insects provide for the gordius in this manner, we have not yet been able to determine.

300 Transformation accompanied by change of propensities.

In all living bodies possessed of a *sensorium*, the changes of form, as well as the changes of habit and of age, are usually accompanied with new propensities, appetites, and passions.

301 Consists in the evolution of parts.

Microscopic observations having demonstrated, that all the forms of the plant and animal existed previously in the seed or embryo; transformation must be owing entirely to the evolution of the different parts by means of nutrition.

302 Its uses.

What nature intends by transformation, we cannot determine; but by means of it different elements are peopled, the different seasons variously adorned, and animated nature wonderfully diversified without a multiplication of beings.

Chap. XIV. *Of Reproduction.*

303 Reproduction of parts.

In the present chapter we shall notice, first, the partial reproductions that take place in some classes of animals, and then take a general comparative view of the principal phenomena of generation, in the various classes of living beings.

304 In man and *mammalia*.

Experiments have proved, that even in the superior classes of animals, many parts of the body, when destroyed or removed, may be reproduced. A bone may be broken in such a manner, that part of it must be taken away, but in a few weeks the separated ends are brought together by the secretion of new bony matter, called *callus*. Little more than 24 hours have elapsed after a fracture, before nature begins her operations. The soft parts inflame; the periosteum becomes swelled; the vessels pour out coagulable lymph, and a pellucid, gelatinous substance appears about the broken extremities of the bone. Into this minute blood-vessels are gradually sent off from the arteries, and in no very long time phosphate of lime begins to be secreted, for rendering the whole firm and compact. In cases of *necrosis*, where the old bone entirely loses its vitality, new bony matter is secreted into the surrounding periosteum, which thickens and enlarges, and in time supplies the place of the old bone. When a muscular part is cut away, as in removing flesh that

Of Reproduction.

that has become gangrenous, if the healthy function of the surrounding parts can be restored, and the loss of flesh has not been too great, the wound gradually fills up, not indeed with fleshy fibres, but with granulations very much resembling the ordinary cellular substance. It is well known, that the hair, nails, and skin, are occasionally renewed; but it will appear extraordinary that blood-vessels, and even nerves, have been reproduced. In cases of aneurism, where the trunk of the diseased artery is divided, so as to cut off the usual channel for the blood, the anastomosing branches become gradually enlarged, and even new branches appear to be formed for carrying on the circulation. What has been said above respecting the formation of *callus*, also proves the formation of new blood-vessels; and the observations of Mr John Hunter put this beyond a doubt. Till within these few years, it was thought impossible that a divided nerve should re-unite; but some late experiments of Mr Cruickshank have proved that this reunion may take place *.

* *Phil. Trans.* 1795, p. 177.

Under this head we may mention some curious experiments that have been lately made by Dr Jones, on the means by which nature suppresses the hæmorrhage from divided arteries. These experiments were made on dogs, and the results of them lead us to conclude, that the following is nearly the process by which the hæmorrhage is suppressed. First, the divided artery contracts, and is drawn within the neighbouring parts; blood is gradually effused into the sheath of the artery and the adjoining cellular substance, where it is entangled, and affords a basis for the formation of a coagulum or clot, which surrounds the extremity of the divided artery, and prevents the farther effusion of blood, till another clot is formed within the mouth of the artery, plugging it completely up. Soon after there oozes out between the external and internal clot, a quantity of coagulable lymph, which cements all the parts together, and thus in time, if the artery divided be not very large, and the force of the circulation very great, the cavity of the vessel and the divided extremity, is obliterated, and all further loss of blood effectually prevented †.

† *Jones's Treatise on Hæmorrhages*, &c.

305 Reproduction of parts, in the inferior animals;

It is, however, in the lower classes that we are to look for the most remarkable instances of this provision of nature, particularly among the reptiles, crustacea, mollusca, worms, and polypes.

306 in reptiles;

In many reptiles, the legs and tail, when cut off, are soon renewed, and even the eyes have been re-produced. Some interesting experiments on this subject by Spallanzani have been related under Erpetology, p. 316, to which we refer the reader.

307 in crustacea;

In the crustacea, the legs and claws are very often torn away, either by accident, or by some voracious animal; but these never fail to be renewed in a short time, provided the animal is in good health. This is most remarkable in the craw-fish (cancer astacus, Lin.). It has been observed that when the claw of this animal is broken, the most distant part is gradually cast off, and about a day or two after, a red membrane, not unlike a bit of red cloth closes up the aperture. This is at first plain; but in the course of four or five days it assumes a convexity, which gradually augments till it takes the appearance of a small cone, which exceeds not a line in height. It continues, however, to stretch out, and in ten days it is sometimes more than three lines, or about one-fourth of an inch high. It is not hollow, but filled with flesh, and this flesh is the basis or rudiment of a new claw. The membrane that covers the flesh performs the same office to the young claw as the membranes do to the fœtus of the larger animals. It extends in proportion as the animal grows; and as it is pretty thick, we can perceive nothing but a lengthened cone. When 15 days are elapsed, this cone inclines towards the head of the animal. In a few days more its curvature increases, and it begins to assume the appearance of a dead claw. This claw, though at the end of a month or five weeks it has acquired the length of six or seven lines, which is more than half an inch, is still incapable of action. The membrane in which it is enclosed becoming gradually thinner, in proportion as it extends, gives an opportunity of observing the parts of the claw, and we now perceive that this conical substance is not a simple congeries of flesh. The moment is now arrived when the claw begins to be brought forth. The membrane at last bursts, and the new claw, though still soft, appears without encumbrance or investment. In a few days more it is covered with a shell; and though still delicate, and not the half of its former length, it is able to perform all the natural functions. It has likewise been discovered, that, whether the claw has been lopped off at the fourth articulation, or anywhere else, the animal in a short time recovers all that it had lost. The same reproduction takes place also in the horns; but, if the tail is cut off, the animal survives a few days only *.

* *Bingley's Animal Biog.* vol. iii.

308 in mollusca;

Many of the mollusca exhibit curious instances of reproduction, especially the actinia, the star fish, and snails. The abbé Dicquemaire made several experiments to ascertain the reproductive power of the *actinia rufa* (purple sea anemony). He first cut off all its tentacula, which grew again in less than a month; and on repeating this a second and third time, he had equal success. He cut off the upper part of one, and a few days after, the base of the animal was found to have fallen from its place; but it soon entirely recovered its limbs. But if the base of these animals is injured by the incision, the wound commonly proves mortal. The arms of the star-fish are often torn off, but appear always to be reproduced. The power of snails in this respect is very great; for Spallanzani has ascertained, that even if their heads are cut off, these are regenerated in no very long time. There can scarcely be a more surprising instance of animal reproduction than this, as we shall readily allow, if we consider the complicated structure of the head of a snail; that it contains a brain divided into two parts; that the horns attached to it are furnished with muscles, and that on the tops of the larger horns there are eyes, composed of two coats and three humours; that the head contains a mouth, lips, teeth, and a palate; and yet all these parts, when cut away, have been reproduced in the course of a few weeks.

309 in polypes.

On the reproductive power of polypes we have been sufficiently minute under Helminthology, N° 84.

310 Writers on the reproduction of parts.

As this subject of partial reproduction is extremely curious, and as we cannot here enter upon any particular detail on the experiments and observations that have been made on the subject, we shall conclude this part of the present chapter by enumerating the principal works to which the reader may refer for a more satisfactory account of the subject. These are chiefly Trembley, Of Reproduction bley, *Memoires sur les Polypes*; Bonnet, *Traité d'Insectologie*, *Palingenesie*, and *Considerations sur les Corps Organises*, vol. ii.; Reaumur, *sur les Insects*; Spallanzani, *Tracts on Animals and Vegetables*, and *Essay on Reproduction*; Hunter's *Treatise on the Blood*, &c.; Russel's *Practical Essay on Necrosis*. Moore *on the Healing Process*; Murray, *de Redintegratione Partium*; and the publications of Dr Jones and Mr Cruickshank already referred to. There is also a neat view of the principal facts relating to this subject in a thesis *De Vulnere Naturæ Sanándo*, published at Edinburgh in 1805, by Dr John Gordon.

311 Reproduction of the species by generation. We have already stated it as our opinion, that plants, as well as animals, reproduce their like by generation. We shall not now enter on a discussion of the controverted point of the sexual system; and as the parts that appear subservient to this function in plants, and their various modes of propagation, have been sufficiently explained under the articles BOTANY and PLANT, we shall in this chapter confine our attention to the generation of animals.

312 Organs. The human organs of generation are described in the article ANATOMY, sect. xv. those of the cetacea under CETOLOGY, N° 161.; those of birds under *Comparative* ANATOMY, 277: those of fishes have been noticed under ICHTHYOLOGY. For a more full comparative view of these organs, we refer to Cuvier and Blumenbach.

313 Nature of generation. The nature of generation which is the greatest mystery in the economy of living bodies, is still involved in impenetrable obscurity. The only circumstance common to all generation, and consequently the only essential part of the process, is, that every living body is attached at first to a larger body of the same species with itself. It constitutes a part of this larger body, and derives nourishment, for a certain time, from its juices. The subsequent separation constitutes *birth*, and may be the simple result of the life of the larger body, and of the consequent developement of the smaller, without the addition of any occasional action.

Thus the essence of generation consists in the appearance of a small organized body in or upon some part of a larger one; from which it is separated at a certain period, in order to assume an independent existence.

All the processes and organs, which co-operate in the business of generation in certain classes, are only accessory to this primary function.

314 Gemmiparous generation. When the function is thus reduced to the most simple state, it constitutes the gemmiparous, or generation by shoots. In this way the buds of trees are developed into branches, from which other trees may be formed. The polypes (hydra) see HELMINTHOLOGY, N° 84. and the sea anemones (actiniæ), multiply in this manner; some worms are propagated by a division of their body, and must, therefore, be arranged in the same division. This mode of generation requires no distinction of sex, no copulation, nor any particular organ.

315 Fecundation. Other modes of generation are accomplished in appropriate organs; the germs appear in a definite situation in the body, and the assistance of certain operations is required for their further developement. These operations constitute *fecundation*, and suppose the existence of *sexual parts*; which may either be separate, or united in the same individual.

In most animals the embryo of the future young is fecundated within the peculiar organs of one individual, while another of the same species is provided with the means of giving activity to the embryo by a fecundating fluid. In some animals, however, both these offices are performed by the same individual, which is then said to be androgynous, or hermaphrodite. 316

The office of the male sex is that of furnishing the *fecundating* or *seminal fluid*; but the manner in which that contributes to the developement of the germ is not yet settled by physiologists. In several instances, particularly in the frog, the germ may be clearly recognized in the ovum before fecundation; its pre-existence may be inferred in other cases from the manner in which it is connected to the ovum when it first becomes visible; for it is agreed on all hands, that the ovum exists in the female before fecundation, since virgin hens lay eggs, &c. 317 Distinction of sexes.

The combination of the sexes and the mode of fecundation are subject to great variety. In some instances they are united in the same individual, and the animal impregnates itself. The acephalous mollusca and the echini exemplify this structure. In others, although the sexes are united in each individual, an act of copulation is required, in which they both fecundate, and are fecundated; this is the case with the gasteropodous mollusca and several worms. In the remainder of the animal kingdom the sexes belong to different individuals. 318 Hermaphrodites.

The fecundating liquor is always applied upon or about the germs. In many cases the ova are extruded before they are touched by the semen, as in some bony fishes and the cephalopodous mollusca. Here, therefore, impregnation is effected out of the body, as it is also in the frog and toad. But in the latter instances the male embraces the female, and discharges his semen in proportion as she voids the eggs. In most animals the seminal liquor is introduced into the body of the female, and the ova are fecundated before they are discharged. This is the case in the mammalia, birds, most reptiles, and some fishes; in the hermaphrodite gasteropodous mollusca, in the crustacea, and insects. In all the last-mentioned orders ova may be discharged without previous copulation, as in the preceding. But they receive no further developement; nor can they be fecundated when voided *. We shall not gratify the prurient imagination of the philosophic sensualist, by any details of the mode in which these operations are carried on in the various classes of animals, except in one instance, which is so curious that we shall be excused for describing it. We allude to the copulation of the snail. Modes of impregnation.

* Cuvier Leçons d'Anat. Comp. tom. v. p. 12.

319 Copulation of snails. These animals meet in pairs, and stationing themselves an inch or two apart, launch several little darts, not quite half an inch long, at each other. These are of a horny substance, and sharply pointed at one end. The animals, during the breeding season, are provided with a little reservoir for them, situated within the neck, and opening on the right side. On the discharge of the first dart, the wounded snail immediately retaliates on its aggressor by ejecting at it a similar dart; the other again renews the battle, and in turn is again wounded. Thus are the darts of Cupid, metaphorical with all the rest of the creation, completely realised in snails. After the combat they come together. Each of them lays its eggs in some sheltered and moist situation,

tion, generally under a little clod of earth, or in some cool cavity †.

† *Shaw's Naturalist's Miscellany*, vol. i.

320 The effect of a single copulation varies in its degree: it usually fecundates one generation only; but sometimes, as in poultry, several eggs are fecundated; still, however, they only form one generation. In a very few instances one act of copulation fecundates several generations, which can propagate their species without the aid of the male. In the plant-louse (*aphis*) this has been repeated eight times; and in some *monoculi* 12 or 15 times.

321 Oviparous generation.

When the germ is detached from the ovary, its mode of existence may be more or less complete. In most animals it is connected, by means of vessels, to an organized mass, and the absorption of which nourishes and developes it until the period of its birth. It derives nothing, therefore, from the body of the mother, from which it is separated by coverings varying in number and solidity. The germ, together with its mass of nourishment, and the surrounding membranes, constitutes an egg, or *ovum;* and the animals which produce their young in this state, are denominated *oviparous.*

In most of these the germ contained in the egg is not developed until that part has quitted the body of the mother, or has been *laid;* whether it be necessary that it should be afterwards fecundated, as in many fishes; or require only the application of artificial heat for its incubation, as in birds; or that the natural heat of the climate is sufficient, as in reptiles, insects, &c. These are strictly oviparous animals.

322 Ovo-viviparous animals.

The ovum, after being fecundated and detached from the oviarum, remains in some animals within the body of the mother, until the contained germ be developed and hatched. These are *false viviparous* animals, or *ovo-viviparous.* The viper, and some fishes, afford instances of this process.

323 Viviparous generation.

Mammalia alone are truly viviparous animals. Their germ possesses no provision of nourishment, but grows by what it derives from the juices of the mother. For this purpose it is attached to the internal surface of the uterus, and sometimes, by accident, to other parts, by a kind of root, or infinite ramification of vessels, called *placenta.* It is not, therefore, completely separated from the mother by its coverings. It does not come into the world until it can enjoy an independent organic existence. The mammalia cannot, therefore, be said to possess an *ovum* in the sense which we have assigned to that term.

From this view of the subject, generation may be said to consist of four functions, differing in their importance, and in the number of animals to which they belong.

1. The *production of the germ,* which is a constant circumstance; 2. *Fecundation,* which belongs only to the sexual generation; 3. *Copulation,* which is confined to those sexual generations, in which fecundation is accomplished within the body; 4. *Uterogestation,* which belongs exclusively to viviparous generation *.

* *Cuvier,* lec. xxix.

There is a general rule observable among all quadrupeds, that those which are large and formidable produce but few at a time; while such as are mean and contemptible are extremely prolific. The lion, or tiger, have seldom above two cubs at a litter; while the cat,

314 Comparative fecundity of animals.

that is of a similar nature, is usually seen to have five or six. In this manner, the low tribes become extremely numerous; and, but for this surprising fecundity, from their natural weakness, they would quickly be extirpated. The breed of mice, for instance, would have long since been blotted from the earth, were the mouse as slow in production as the elephant. But it has been wisely provided, that such animals as can make but little resistance, should have at least a means of repairing the destruction which they must often suffer, by their quick reproduction; that they should increase even among enemies, and multiply under the hand of the destroyer. On the other hand, it has as wisely been ordered by Providence, that the larger kinds should produce but slowly; otherwise, as they require proportional supplies from nature, they would quickly consume their own store; and, of consequence, many of them would soon perish through want; so that life would thus be given without the necessary means of subsistence. In a word, Providence has most wisely balanced the strength of the great against the weakness of the little. Since it was necessary that some should be great and others mean, since it was expedient that some should live upon others, it has assisted the weakness of one by granting it fruitfulness, and diminished the number of the other by infecundity.

In consequence of this provision, the larger creatures, which bring forth few at a time, seldom begin to generate till they have nearly acquired their full growth. On the contrary, those which bring many reproduce before they have arrived at half their natural size. Thus the horse and the bull are at their best before they begin to breed: the hog and the rabbit scarce leave the teat before they become parents in turn. Almost all animals likewise continue the time of their pregnancy in proportion to their size (L).

For an account of the principal phenomena attending 315
the reproduction of the human species, viz. the requisites for conception and its signs; the effects of impregnation; the gradual evolution of the fœtus, and the successive changes that take place in the uterine system during uterogestation, see the article MIDWIFERY, chap. i. and ii. The phenomena of reproduction in other viviparous animals are so analogous to those in the human species, that we need not enter on an examination of them. We shall here only give a view of the successive changes that take place in the egg of birds during incubation, taken from the observations of the celebrated Blumenbach. 316

Progressive changes of the chick during incubation.

The following observations refer to the egg of the common hen, as affording the most familiar example of incubation.

A small shining spot, of an elongated form, with rounded extremities, but narrowest in the middle, is perceived at the end of the first day, not in nor upon the

(L) In the following table are noted the time of gestation, incubation, and the number of young produced in several species of quadrupeds and birds, as far as these have been ascertained; and the second column shews the period to which the life of each is usually extended.

Of Reproduction.

the cicatricula (M), but very near that part on the yolk-bag. This may be said to appear before-hand, as the abode of the chick which is to follow.

327 Second day.

No trace of the latter can be discovered before the beginning of the second day; and then it has an incurvated form, resembling a gelatinous filament with large extremities, very closely surrounded by the amnion, which at first can scarcely be distinguished from it.

About

	Species.	Period of Life.	Time of Gestation.	Number of Young.
Quadrupeds.	Apes.	- - -	- - -	About 2.
	Bats.	- - -	- - -	From 2 to 5.
	Sloth.	- - -	- - -	One.
	Rhinoceros.	70 or 80 years.	- - -	One.
	Elephant.	Above 100 years.	21 months.	One.
	Arctic walrus.	- - -	9 months.	One.
	Seal.	- - -	- - -	About 2.
	Bitch.	12 or 16 years.	9 weeks.	From 4 to 10.
	Wolf.	- - -	$3\frac{1}{2}$ months.	5 or 6.
	Fox.	About 14 years.	6 weeks.	From 3 to 6.
	Jackall.	- - -	- - -	From 6 to 8.
	Lioness.	Above 70 years.	- - -	4 or 5.
	Tigress.	- - -	- - -	Ditto.
	Cat.	From 10 to 18 years.	8 weeks.	From 4 to 6.
	Ferret.	- - -	6 weeks.	6 or 7.
	Otter.	- - -	9 weeks.	4 or 5.
	Virginian opossum.	- - -	- - -	Ditto.
	Kanguroo.	- - -	- - -	One.
	Mole.	- - -	- - -	4 or 5.
	Porcupine.	- - -	- - -	Two.
	Guinea pig.	6 or 7 years.	3 weeks.	From 5 to 12.
	Common rat.	- - -	5 or 6 weeks.	From 12 to 18.
	Mouse.	From 2 to 3 years.	- - -	From 6 to 10.
	Common squirrel.	- - -	6 weeks.	From 4 to 5.
	Hare.	- - -	A month.	3 or 4.
	Rabbit.	- - -	Ditto.	About 8.
	Camel.	40 or 50 years.	12 months.	One.
	Rein deer.	15 or 16 years.	8 months.	Two.
	Stag.	Near 50 years.	5 months.	One.
	Goat.	- - -	Ditto.	About 2 or 3.
	Ewe.	15 years.	Ditto.	From 1 to 3.
	Cow.	- - -	9 months.	1 to 3.
	Mare.	30 or 40 years.	11 months.	1 or 2.
	Sow.	Nearly 20 years.	4 ditto.	From 10 to 20.
			Time of Incubation.	
Birds.	Eagle.	Above 100 years.	30 days.	2 or 3.
	Raven.	Near 100 ditto.	20 ditto.	5 or 6.
	Cuckoo.	- - -	- - -	1 or 2.
	Humming bird.	- - -	12 days.	Two.
	Blackbird.	- - -	14 ditto.	4 or 5.
	Canary bird.	10 or 20 years.	Ditto.	Ditto.
	Wren.	- - -	Ditto.	From 10 to 18.
	Pigeon.	- - -	Ditto.	Two.
	Turkey.	- - -	A month.	18 or 20.
	Hen.	About 13 years.	3 weeks.	About 20.
	Ostrich.	- - -	6 weeks.	One or two each.
	Swan.	Above 100 years.	Ditto.	6 or 8.
	Goose.	Near 100 years.	A month.	9 to 12.
	Duck.	- - -	Ditto.	12 to 14.

(M) The structure of an egg has already been described under the article EGG; but for the better understanding of Blumenbach's observations, it may be necessary to enumerate the several parts, with the names given to them by that author. The membrane lining the shell is called *membrana albuminis*, and includes the two whites of the egg, the inner of which surrounds the yolk, which is contained within a peculiar, very delicate membrane, called the *yolk-bag*. From two opposite sides of this bag proceeds a white knotty body, terminating in the white of the egg, by a flocculent extremity. These bodies are called the *chalazæ* or *grandines*; the *cicatricula*, tread, or traddle, is surrounded by one or more whitish concentric circles called *halones*, or *circuli*, the use of which is not known.

Of Reproduction

About this time the halones enlarge their circles; but they soon after disappear entirely, as well as the cicatricula.

The first appearance of red blood is discerned on the surface of the yolk-bag, towards the end of the second day. A series of points is observed, which form grooves; and these closing, constitute vessels, the trunks of which become connected to the chick. The vascular surface itself is called *figura venosa*, or *area vasculosa;* and the vessel by which its margin is defined, *vena terminalis*. The trunk of all the veins joins the *vena portæ;* while the arteries, which ramify on the yolk-bag, arise from
328 Third day. the mesenteric artery of the chick.

On the commencement of the third day, the newly formed heart is discerned by means of its triple pulsation, and constitutes a threefold *punctum saliens*. Some parts of the incubated chicken are destined to undergo successive alterations in their form; and this holds good of the heart in particular. In its first formation it resembles a tortuous canal, and consists of three dilations lying close together, and arranged in a triangle. One of these, which is properly the right, is then the common auricle; the other is the only ventricle, but afterwards the left; and the third is the dilated part of the aorta.

About the same time, the spine, which was originally extended in a straight line, becomes incurvated; and the distinction of the vertebræ is very plain. The eyes may be distinguished by their black pigment, and comparatively immense size; and they are afterwards remarkable in consequence of a peculiar slit in the lower part of the iris.

329 Fourth day. From the fourth day, when the chicken has attained the length of four lines, and its most important abdominal viscera, as the stomach, intestines, and liver, are visible, (the gall-bladder, however, does not appear till the sixth day), a vascular membrane begins to form about the navel; and increases in the following days with such rapidity, that it covers nearly the whole inner surface of the shell, within the *membrana albuminis*, during the latter half of incubation. This seems to supply the place of the lungs, and to carry on the respiratory process instead of those organs. The lungs themselves begin indeed to be formed on the fifth day; but, as in the fœtus of the mammalia, they must be quite incapable of performing their functions while the chick is contained in the amnion.

330 Sixth day. Voluntary motion is first observed on the sixth day, when the chick is about seven lines in length.

331 Ninth day. Ossification commences on the ninth day, when the ossific juice is first secreted, and hardened into bony points. These form the rudiments of the bony ring of the sclerotica, which resembles at that time a circular row of the most delicate pearls.

At the same period, the marks of the elegant yellow vessels on the yolk-bag, begin to be visible.

332 Fourteenth day. On the fourteenth day the feathers appear; and the animal is able to open its mouth for air, if taken out of the egg.

333 Nineteenth day. On the nineteenth day it is able to utter sounds; and on the twenty-first to break through its prison, and commence a new life.

Blumenbach concludes his observations with a few remarks on those very singular membranes, the yolk-bag and the chorion, which are so essential to the life and preservation of the animal.

The chorion, that most simple yet most perfect temporary substitute for the lungs, if examined in the latter half of incubation in an egg very cautiously opened, presents, without any artificial injection, one of the most splendid spectacles that occurs in the whole organic creation. It exhibits a surface covered with numberless ramifications of arterial and venous vessels. The latter are of a bright scarlet colour, as they are carrying oxygenated blood to the chick; the arteries, on the contrary, are of a deep or livid red, and bring the carbonated blood from the body of the animal. Their trunks are connected with the iliac vessels; and, on account of the thinness of their coats, they afford the best microscopical object for demonstrating the circulation in a warm-blooded animal. 334 Remarks on the chorion.

The other membrane is also connected to the body of the chick; but by a two-fold union, and in a very different manner from the former. It is joined to the small intestine, by means of the *ductus vitello-intestinalis*, and also by the blood-vessels, with the mesenteric artery and vena portæ. 335 On the yolk-bag.

In the course of the incubation the yolk becomes constantly thinner and paler, by the admixture of the inner white. At the same time innumerable fringe-like vessels with flocculent extremities, of a most singular structure, form on the inner surface of the yolk-bag, opposite to the yellow ramified marks, and hang into the yolk. There can be no doubt that they have the office of absorbing the yolk, and conveying it into the veins of the yolk-bag, where it is assimilated to the blood, and applied to the nutrition of the chick. Thus in the chick which has just quitted the egg, there is only a remainder of the yolk and its bag to be discovered in the abdomen. These are completely removed in the following weeks, so that the only remaining trace is a kind of cicatrix on the surface of the intestine *.

Many of the causes which contribute to the formation of a living body have hitherto eluded human research; may in all probability never be discovered; and perhaps are beyond human comprehension.

Some philosophers, discovering the extreme divisibility of matter, and learning from the microscope that transformation is but the developement of certain parts that previously existed, have thence imagined that generation is somewhat analogous; that all organised bodies received their form at the beginning; that the first of every genus and species contained by involution the numberless millions of succeeding generations; and that the union of the two sexes gives only a stimulus, and brings into view forms that had existed since the world began. 336 Theories of generation. 337 Hypothesis of successive evolution.

By this hypothesis they have attempted to explain a thing that is unknown, by what must remain for ever incomprehensible to the human mind in its present state. They absurdly appeal from observation to conjecture; and suppose that bodies which are originally brought into view, which are daily augmented, frequently repaired, and sometimes renewed by organic action, do nevertheless in their first formation require an effort superior to what omnipotence is able to perform by secondary agents. Had the supporters of this hypothesis considered that many herbaceous plants produce new flowers when 338 Objection.

* Blumenbach's Comp. Anat. chap. xxvi.

Of Reproduction. when the first set are untimely cut off; that lobsters and many other animals renew their limbs, and that certain polypes can raise a structure so perfectly resembling a vegetable form as to puzzle the naturalist whether or not he should class them under plants, they would surely not have prescribed such bounds to omniscient wisdom and almighty power, or declared with such confidence what the Author of nature, to speak with the vulgar, must necessarily perform by his own hands, or what he may instrust to secondary causes regulated by his laws.

These philosophers will find it difficult to account in a very satisfactory manner for monstrous productions, and for those changes of structure and of form which for a while continue hereditary from the influence of habit. They object to others, that all the parts of a living body are mutually dependent on one another, and that they must necessarily have been coeval, or have existed at once. But though every attempt that has yet been made to ascertain which of the vital organs are prior and which posterior in a living body has proved unsuccessful, it has not been demonstrated that either themselves or their functions are coeval. It may, on the contrary, be plainly demonstrated from observation, that the lungs and the stomach do not begin to perform their functions so early as the heart and the vascular system; that even the heart and its system perform their functions with some considerable changes, immediately after birth; that the vegetable tribes are without nerves; and that the brain and nerves in the animal kingdom perform more and more of their functions, according as the system approaches towards maturity. It has even been shewn, that bones will unite; that the limbs of an animal continue to be nourished without the nerves; that there is a principle of life in the blood; that the heart will act under other stimuli beside that of nervous influence; and sound logic does by no means require us to suppose, that the first action of the fœtal heart, or the *punctum saliens*, is owing to the influence of stimuli from the brain, or that the brain must have existed when the heart first moved. Although the minuteness and transparency of the parts may prevent us from seeing the first gradual formation of the embryo, yet every observation corroborates the opinion, that it is formed by secondary causes, and through the medium of organic powers.

339 Hypothesis of Epigenesis. Most physiologists have believed that certain inorganic particles are contained in the system of one sex or of the other, and that by the union of the sexes these particles have become organized. It has, however, been asked whether or not is the embryo formed by the joint operation of the two sexes? or is it formed entirely by one, and brought into action by a stimulus from the other? The former of these questions supposes that each of the sexes has a seminal fluid; that some mixture takes place in the uterus, and produces an embryo, in the same manner that a neutral salt assumes a certain and determinate form. The notion implies some general and confused ideas of chemical combination: but does not bespeak a very clear understanding, profound reflection, or much acquaintance with the nature and properties of living bodies.

For a long time past the most rational physiologists have generally thought that the embryo is formed gradually and slowly in one or other of the two sexes, not by chemical combination, but a system of organs directed by laws and prompted by stimuli, with many of which we are yet unacquainted. From the great Hippocrates to Fabricius and Harvey, the credit of furnishing the fœtal embryo was almost universally given to the females of oviparous animals. Among the viviparous, the appearances were such, that the female was left to contest it with the male. At last the eclat of Leeuwenhoeck's discoveries seemed to put an end to all doubts entertained upon the subject. He very plainly saw through his microscope that very great profusion of particles that move to and fro with amazing rapidity in the male semen. Upon this he embraced the doctrine of Hamme, who had seen them before, and supposed from their motions that these particles were not only animalcules, but the principles or rudiments of that animal in whom they were formed, and that they were deposited in the uterus of the female only to be nourished and augmented in size.

340 Embryo supposed to be derived from the male.

341 Objections. What raised objections against this theory was, that numerous animalcules were discoverable by the microscope in other fluids, and that a vast profusion of young embryos appeared in cases where never more than one or two arrive at maturity. It was an objection to it, that some females had been impregnated, where the hymen remained unbroken, so that the impregnating fluid could have reached only the mouth of the uterus. Again, in frogs, fishes, and many other animals, the ova are not impregnated till after extrusion; and lastly, Haller had observed the chick completely formed in eggs that had not been fecundated.

It is now, we believe, pretty generally known, that the embryo does not commence its existence in the cavity of the uterus. De Graaf observed it on its passage down the fallopian tube; he saw the place where it first began in the ovarium of the female, and cases have occurred where it has missed the fallopian tube, where it has fallen into the abdomen, in which the placenta has been formed, and the fœtus has grown among the bowels.

342 More probable that the embryo exists in the female. From these facts it has been concluded, notwithstanding some feeble objections, that the female ovaria contain the embryos in the form of eggs; that these eggs are brought into action by the stimulating power of the male semen, which is sometimes thrown into the cavity of the uterus, sometimes applied only to its mouth, and sometimes sprinkled on the eggs after they are extruded. For more on this subject see the article MIDWIFERY.

343 Relations. A view of the relations between the present function and those which we have before examined, is a subject of so delicate a nature, that we must not enlarge on it. The sympathy between the reproductive and the nervous systems is well known. The effect which desire has occasionally produced on the brain is very great, madness being not unfrequently the consequence, either of too much indulgence, or of total continence. We are of opinion that the influence of the fancy or imagination on the uterine system has been overrated, though the accounts given of monsters or deformed births, in consequence of terror experienced by the mother, appear to be too well authenticated to warrant our total disbelief in this influence. Too much indulgence in this appetite produces a debilitated state, both of the

Of Sleep and Torpor. the mental and bodily functions, and deprives the system of that natural stimulus which seems essential to the activity and vigour of the body in the male.

Chap. XV. *Of Sleep and Torpor.*

344 Necessity of sleep. We have already considered the active means by which the waste of the body is repaired; but all these would have little effect, and could not indeed be carried on for any considerable time, without some general relaxation of the system. This relaxation is brought about by sleep, in which the active functions find a repose from the labours which they have undergone during the day; and in this way the system is recruited more completely than by any other means.

345 Sleep, an affection of mind. Sleep may be considered as an affection of mind, and therefore more properly a subject of metaphysical, than of physiological speculation. It is, however, generally treated of in systems of physiology; and it will be necessary to take notice of some circumstances respecting it. We shall chiefly consider the state of the body and mind during sleep, and some of the principal theories that have been contrived to account for it.

346 Phenomena of sleep. Natural sleep returns at certain intervals, which are, however, different in different animals. Most animals, and especially man, sleep only during the night, but most of the predacious species, as beasts and birds of prey, choose this time for their predatory excursions, and repose during the day. Sleep comes on with an unusual languor and lassitude; an aversion to motion; the mind becomes unfit for its usual exertions; and the desire of rest pervades the whole system. In particular, the extensor muscles lose their power of preserving the body in an erect posture; the eyelids involuntarily fall; the head bows forward; the joints bend, and the body sinks. During sleep, all the voluntary motions are in general suspended; but the involuntary actions of the heart and lungs proceed, though not so vigorously as in the waking state; the circulation and respiration being slower than usual. Most of the senses are also in a state of repose, especially those of feeling, smell, and probably of taste. Hearing is, in some animals, very acute during sleep, and they are thus enabled to escape any danger that threatens them. Some animals, as the hare, also sleep with their eyes open; and in most the impression of light, when the eyelids are raised, is very evident. The functions of digestion, absorption, and secretion, seem to proceed with greater ease and activity during sleep; and assimilation and nutrition are much promoted by this state of repose. Some of the faculties of the mind, especially the imagination, are, however, in full vigour, as appears from the dreams that take place during sleep. The duration of sleep is exceedingly various. Among the human species, young children, and very old persons, pass the greatest half of their time in sleep, while middle-aged and active people seldom sleep so much as one-third of the 24 hours.

Though the returns of sleeping and waking depend much on custom, they may, however, be changed by various circumstances; and though the commencement of one of these periods happen to be altered, that of the other may remain as before. If a person is accustomed to go to sleep exactly at nine in the evening, and to rise again at six in the morning, though the time of sleep may be occasionally protracted till twelve, he will yet awaken at his usual hour of six: or if his sleep be continued by darkness, quietness, or similar causes, till the day be farther advanced, the desire of sleep will return in the evening at nine.

347 Theory of sleep. Most of the causes that produce or prevent sleep, have been mentioned in the article Medicine, N° 94. As to the immediate cause, the opinions of physiologists are much at variance, and the theory of sleep is as little understood as that of any function of the animal economy.

348 Hypothesis of Haller. According to Haller, sleep arises, either from a simple absence, deficiency and immobility of the spirits, or from compression of the nerves, and always from the motion of the spirits through the brain being impeded *. That sleep is, some how or other, connected with a compression of the brain, appears very probable, from the heaviness and coma that take place in cases where such a compression has evidently been produced; but how this compression acts has never yet been satisfactorily explained; and the obstruction that Haller supposes in the motion of the animal spirits, or nervous fluid, is gratuitous.

349 Of Brown. One of the fashionable doctrines of the present day respecting the immediate cause of sleep is, that this state is produced by an exhaustion of irritability or excitability. According to Brown, sleep succeeds a diminution of excitement, during which the excitability is either only so far diminished that it can be accumulated again, or so abundant, that the excess can be wasted, and in each case the excitement restored †.

350 Of Darwin. Similar to this is the doctrine of Zoonomia, that sleep depends on an exhaustion of sensorial power. Dr Darwin thus characterizes perfect sleep: 1. The power of volition is totally suspended. 2. The trains of ideas caused by sensation proceed with greater facility and vivacity; but become inconsistent with the usual order of nature. The muscular motions caused by sensation continue; as those concerned in our evacuations during infancy, and afterwards in digestion, and in priapismus. 3. The irritative muscular motions continue, as those concerned in the circulation, in secretion, and respiration. But the irritative sensual motions, or ideas, are not excited; as the immediate organs of sense are not stimulated into action by external objects, which are excluded by the external organs of sense; which are not in sleep adapted to their reception by the power of volition, as in our waking hours. 4. The associate motions continue, but their first link is not excited into action by volition, or by external stimuli. In all respects, except those above mentioned, the three last sensorial powers are somewhat increased in energy during the suspension of volition, owing to the consequent accumulation of the spirit of animation ‡.

Thus, the immediate cause of sleep consists in the suspension of volition produced by the exhaustion of sensorial power; and hence, whatever diminishes the general quantity of sensorial power, acts as a remote cause of sleep.

Beside the insufficiency of these hypotheses to account for many circumstances that take place during sleep, we may remark, that this state is often produced when no exhaustion of irritability, excitability, or sensorial power, can be supposed to have taken place. Thus, the propensity to sleep often becomes irresistible from the effects of monotonous speaking, from stillness, darkness, or from

* First Lines of Physiology, § 585.

† Elem. Med. § 337.

‡ Darwin's Zoonomia, vol. i. § 18.

Of Sleep and Torpor.

from the sameness of the scenery around us; and when one stimulus, after long application, can arouse no more, another stimulus that in ordinary cases is less powerful, produces excitement, and keeps off sleep; an evident proof that excitability or sensorial power have not been very far exhausted.

351 Supposed sleep of plants. Plants have been said to sleep. At the approach of night, many of them are observed to change their appearances very considerably, and sometimes even to such a degree as scarcely to be known for what they are. These changes happen principally to the leaves and the flowers. During the night, many leaves, according to the nature and genus of the plant, are seen to rise up, to hang down, or to fold themselves in various ways, for the protection of the flowers, the buds, the fruits, the young stems; and many flowers, to escape a superabundance of moisture, to hang down their mouths towards the earth, or to wrap themselves up in their calices. These phenomena are owing to stimuli acting from without; we may add, that most of the motions are performed at the joints where the leaves and petals articulate with the stem. A period of rest is as necessary to plants as sleep is to animals. The irritable principle cannot act long under the influence of the same stimulus, except at intervals, and the rapid growth observable in plants during the night, is a strong proof that the organs employed in assimilation had been disturbed in discharging their functions during the day, when exposed to the action of heat and light and of other stimuli.

352 Dreaming. In our general outline, we had proposed introducing here an account of the phenomena of dreams, but we find that this subject has been so fully discussed under the article DREAM, that any additional remarks would be unnecessary. To this article therefore we refer the reader.

Rules for the management of the body with respect to sleep, scarcely come within our present province; but as we pass so much of our time in this state, during which we are sometimes occupied in a very agreeable manner, while at others we are subject to most uneasy sensations, it is a matter of considerable consequence to take those measures which may secure to us the former, and enable us to avoid the latter. We have seen few rules better adapted to those purposes than those of Dr Franklin; but as more important matter presses for insertion within the circumscribed limits to which we are restricted, we must refer our readers to the original paper, which is published in the late 8vo edition of *Franklin's Works*, vol. iii. p. 437.

353 Somnambulism. In a few cases, not only the imagination has a full range during sleep, but the voluntary motions of the body, and even the exercise of some of the external senses, are carried on with apparently as much perfection as when the person is awake. This state is called *somnambulism*, or sleep-walking, and is commonly considered as a variety of dreaming. Many surprising accounts have been given of sleep-walkers. They have been known to rise, dress themselves, go out of doors, and sometimes out of a window, from which they have climbed upon the roof of a house, dig in a garden, draw water from a well, saddle a horse and ride several miles; maintain a rational and interesting conversation, and even go through a laborious and difficult literary task; and after having performed these exploits, they have returned to their bed without being conscious of what they had been doing. This want of consciousness appears from their remembering nothing when they awake, of what passed during their sleep. It is disputed whether somnambulists incur as much danger in the actions which they perform, as those who are awake, in similar circumstances. We are inclined to think that the danger is much less in the former case, as sleep-walkers seem entirely free from the terror which commonly attends the attempting of any hazardous enterprise when awake; such as mounting to the roof of a house, climbing a steeple, &c. If suddenly awaked, however, while engaged in any of their hazardous actions, the danger is very great.

Dr Darwin considers somnambulism, not as a state of sleep or dreaming, but as a variety of reverie, carried to a morbid extent, so as to become a sort of epileptic or cataleptic paroxysm. In the state of reverie, according to Dr Darwin, the irritative motions occasioned by internal stimuli continue, those from the stimuli of external objects are either not produced at all, or are never succeeded by sensation or attention, unless they are at the same time excited by volition; the sensitive motions continue, and are kept consistent by the power of volition; the voluntary and associate motions continue undisturbed. He considers reverie as an effort of the mind to relieve some painful sensation, whence it is allied to convulsion and insanity *. 354 Reverie.

* *Zoonomia*, vol. i. § 19.

The torpor that takes place in many animals during winter, appears to be so nearly allied to sleep, that we shall consider it in this chapter. 355 Torpor of animals.

A great variety of animals of almost every class, retire during the cold of winter, to the recesses of caverns, holes in old walls, hollow trees, or below the earth, where they remain in apparently a lifeless state till the return of spring rouses them from their trance. We shall here enumerate the different animals that have been known to undergo this state of hibernation.

Bats, especially the *vespertilio murinus*, *auritus*, and *v. noctula* (see MAMMALIA, N° 39.); *bears*, especially the brown and the polar bear, and the badger; the *hedgehog*, (*erinaceus Europeus*); several species of the mouse and rat tribe, but more especially the *hamster* (*mus cricetus*), the *marmots*, especially the *arctomys marmota*, (see MAMMALIA, N° 124.); the *dormouse* (*myoxus muscardinus*). Sheep appear capable of living for a considerable time in a torpid state, as they have been known to remain alive for several weeks, buried under the snow. 356 Hibernating mammalia.

It does not appear that birds in general are capable of undergoing this state of existence; but the instances of swallows that have been found in this state in old walls and hollow trees, and even, as some affirm, below water, and have recovered life and activity on being exposed to gradual warmth, are too well authenticated to admit a doubt, that these at least sometimes hibernate. 357 Hibernation of birds;

Most reptiles and serpents pass the winter in a state of hibernation; but this is more particularly the case with the land tortoise (*testudo græca*) see ERPETOLOGY, p. 271.; frogs, and those lizards which inhabit cold climates. 358 of reptiles and serpents;

It is not certainly known whether many species of fish become torpid in winter; but there is no doubt that several of them are susceptible of this state *; and we are told that in North America, especially about Hudson's bay, 359 of fishes;

* *Reeve Dis. Inaug. de Animalibus Hiemopitis*, p. 10.

Of Sleep and Torpor. bay, fishes are not unfrequently found included within a body of ice, and when exposed to gentle heat, have recovered life and motion.

360 Of insects. Almost all insects remain, during the winter, in a torpid state. This happens principally to the crysalids, and such grubs as cannot, in that season, procure their food.

361 Of man. It will appear extraordinary that we should place man among the hibernating animals; and yet there seems little doubt, that even he is capable of having his life suspended for a considerable time, when exposed to those causes which bring about the torpidity of those animals that we have already mentioned. We are told of a woman, who, in February 1789, remained eight days buried in the snow, and still recovered; and the case of the three women who remained for 37 days in a stable at Bergamoletto, that had been overwhelmed by an *avalanche*, or snow heap, with no other sustenance than the milk of a half-starved she goat, is well known. These instances, added to others of persons who have passed several weeks in a state of almost uninterrupted sleep, tend to prove that man himself may, under certain circumstances, continue in a torpid state.

362 Principal phenomena of hibernation. During this state of torpidity, the animals scarcely appear to live; sensation seems altogether lost; their irritability is so much diminished, that they may be cut, torn, or even broken to pieces, without expressing any mark of feeling, or giving any sign of motion; digestion seems entirely suspended; the secretions and excretions are discontinued. Some of the functions, however, are carried on. Respiration and circulation, though very languid, and sometimes scarcely perceptible, appear to go on in a degree sufficient to preserve the existence of the animal; and the action of the absorbents seems to be very little diminished, as appears from the gradual absorption of the fat. If the animal is taken from its place of confinement, and exposed to a gentle heat, it gradually recovers all its faculties; but if carried back to its cell, it relapses into the state of torpidity.

363 Suspended animation of some animals. The long suspension of animation, of which several animals are susceptible, appears still more extraordinary than the torpidity above described. The common hair worm (*gordius aquaticus*) may, when dried, be preserved for an indefinite length of time, and when put into water, gradually recovers its usual activity of motion. See HELMINTHOLOGY, N° 32. One of the most remarkable cases of this suspended animation is that related of the garden snail, of which the following curious account has been given in the Philosophical Transactions for 1774. Mr Stuckey Simon, a merchant in Dublin, whose father, a fellow of the Royal Society, and a lover of natural history, left to him a small collection of fossils and other curiosities, had amongst them the shells of some snails. About 15 years after his father's death (in whose possession they were many years), he by chance gave to his son, a child about 10 years old, some of these shells to play with. The boy put them in a flower-pot, which he filled with water, and the next day into a bason. Having occasion to use this, Mr Simon observed that the animals had come out of their shells. He examined the child, who assured him that they were the same he had given him, and said he had also a few more, which he brought. Mr Simon put one of them into water, and in an hour and a half after observed that it had put out its horns and body, which it moved but slowly, probably from weakness. Major Vallancy and Dr Span were afterwards present, and saw one of these snails crawl out, the others being dead, most probably from their having remained some days in the water. Dr Quin and Dr Rutty also examined the living snail several times, and were greatly pleased to see him come out of his solitary habitation after so many years confinement. Dr Macbride, and a party of gentlemen at his house, were also witnesses of this surprising phenomenon. Dr Macbride has thus mentioned the circumstance: "After the shell had lain about ten minutes in a glass of water that had the cold barely taken off, the snail began to appear; and in five minutes more we perceived half the body pushed out from the cavity of the shell. We then removed it into a bason, that the snail might have more scope than it had in the glass; and here, in a very short time, we saw it get above the surface of the water, and crawl up towards the edge of the bason. While it was thus moving about, with its horns erect, a fly chanced to be hovering near, and, perceiving the snail, darted down upon it. The little animal instantly withdrew itself into the shell, but as quickly came forth again, when it found the enemy was gone off. We allowed it to wander about the bason for upwards of an hour, when we returned it into a wide-mouthed phial, wherein Mr Simon had lately been used to keep it. He was so obliging as to present me with this remarkable shell; and I observed, at twelve o'clock, as I was going to bed, that the snail was still in motion, but next morning I found it in a torpid state, sticking to the side of the glass."

The still more extraordinary instances that have been related, on what many have considered authentic testimony, of toads having been found inclosed in the trunk of a large tree, or within a solid block of stone, appear almost incredible; and yet if we consider that M. Herissant preserved toads in a state of suspended animation for 18 months, in boxes covered with a thick coating of mortar (see ERPETOLOGY, p. 286.); that the snails mentioned in the above quotation, must have lain for at least 20 years; and that flies have been recovered after being immersed for many months in Madeira wine, it is difficult to say how long this suspended animation may not be continued.

Similar phenomena take place in the vegetable creation. Most of those plants which survive one year, shed their leaves on the approach of winter; and, during this season, the motion of the sap ceases, and they have all the appearance of dead shrubs. The herbaceous tribes even die down to the roots, which, being mostly of the bulbous kind, afford shelter to the surviving germ; and are hence called, by botanists, the *hybernacula* of plants. On return of spring, the plant shoots anew from its winter's retreat, and flourishes with its former strength and beauty. 364 Hibernation of plants.

Some plants are even capable of having their vitality, or rather the exercise of all their functions, suspended, as in the *gordius* and the snail, for an indefinite length of time. *Mosses* have been kept in a dried state in a *hortus siccus* for many years, and have shown no sign of life, till they were moistened and exposed to air, light, and a moderate heat, when they have recovered all their powers, have erected their stems, shot forth new branches, and flourished as at first.

It

365 Theory of torpor.

It is almost impossible, in the present state of our physiological knowledge, to give any rational theory of these phenomena. The torpor of animals has been attributed to exhausted excitability, or exhausted sensorial power; to the effects of habit, and to the effect produced on the brain by suspended or diminished respiration. The last of these, though not quite satisfactory, appears to us the most probable hypothesis. It has been ably defended and illustrated by Dr George Kellie, in a paper in which he relates a remarkable case of torpor from cold.

"The powers of voluntary motion and of sensation (says Dr Kellie), are known to depend immediately upon the conditions of the brain and nerves; if, therefore, we could discover in what manner these organs are affected by any of the preceding events, we should advance considerably towards the solution of the questions above stated. (*Namely, What is the order of succession between the diminished irritability of the heart, in consequence of the abstraction of caloric, and the complete torpor of the voluntary muscles and of the organs of sense, and how are the intervening effects connected?*) Were the inactivity of these organs the direct effect of their diminished temperature; did the torpor in no case happen, till the heat of the brain and nerves was reduced beneath the natural standard, there could be hardly ground for any farther inquiry. But, as it is not so, some other change, less direct, must have occurred, in consequence of the connection of the brain with, and its dependence upon, some other of the functions antecedently and more immediately affected; and this function I apprehend to be respiration, between which and the energies of the nervous system a very intimate connection is maintained, through the changes produced on the blood during the pulmonary circulation. This dependence of the brain upon the properties of the blood, maintained by respiration, is evinced by a great variety of observations. Whatever impedes the respiratory changes of the circulating fluid debilitates or destroys the powers of muscular motion, as the respiration of noxious gases, of reduced or rarefied atmosphere; while greater exertions of muscular powers call for, and give occasion to more frequent respiration, more rapid consumption of air, and greater changes of the blood; and the breathing of more effective gases, as of the nitrous oxide, increases the motive and sensitive powers of animals. That these effects depend immediately upon the properties of the blood, as modified by respiration, acting on the brain, has, I think, been proved by the experiments of Bichat, who, in a masterly manner, has traced the mutual connection and dependencies of the vital functions in his admirable *Recherches Physiologiques sur la Vie et la Mort*. The transfusion or injection of venous blood into the carotids induced asphyxia or death, the instant it reached the brain; an effect which did not follow the similar transfusion of arterial blood from the carotid of another*. By these experiments, and by several other observations, he has shewn, that the asphyxia which so instantly follows impeded or suspended respiration is occasioned by the impression of dark, venous, unchanged blood upon the brain, and not, as has commonly been supposed, from this blood being incapable of stimulating the left side of the heart, which, on the contrary, continues to contract and to circulate the blood for some time after the voluntary functions are suspended; an observation confirmed also by Coleman and others.

* *Bichat, Recherches*, part ii. art. 7.

"Such then appears to be the connection between the functions of respiration and those of the brain. Now, in animals rendered torpid from cold, there are many observations which lead us to believe, that the immobility of the nervous system depends much, and very directly too, on the state of respiration.

"In the perfect torpor of the hibernating *amphibiæ*, respiration is completely suspended, and the consequent changes produced on the blood by that function totally prevented. This, which appeared from a variety of observations on the winter quarters of such animals found imbedded in mud, incased in ice, or closed up in opercula of their own construction, for the occasion of excluding the air, has been amply confirmed by the pointed experiments of Spallanzani, lately published by Senebier †.

"In every case of torpor from cold, where the respiration falls short of this complete suspension, it is at least more or less impaired. How much the torpid state depends on this condition of the respiratory functions, farther appears from observing, that hibernating animals, even those not of the amphibious order, warned by the approach of winter, instinctively or industriously seek situations unfavourable to perfect respiration, where this function may be either inadequately or not at all performed, as by premature and involuntary interment under ground, in old walls, in mud at the bottom of lakes, &c. The instinct of these animals, too, has been finely imitated by experiment, illustrating at once the object of this instinct, and confirming the opinion here advanced of its tendency. Thus the dormant hamster was found to regain and preserve its activity, when freely exposed to a pure atmosphere, the temperature, at the same time, not exceeding that at which it had formerly become torpid, or at which it returned to that state when again secluded under ground ‡. These observations seem conclusive on this point, and, with those already brought forward confirming the general connection established between the properties of the blood, as modified by respiration, and the functions of the brain, render it, I think, highly probable, that the torpor of the voluntary powers, in the cases now under consideration, is the consequence of a limited and imperfect respiration, antecedently induced by diminished temperature.

"Observation, indeed, is more deficient on this point with regard to the higher order of animals, and to men, who only occasionally become torpid from cold. Yet more than analogy, which is here very strong, leads me to believe that, even in these, the functions of respiration are much and necessarily affected. The examples of cattle and of men remaining long torpid, deeply buried under snow, are pretty direct and convincing proofs of this.

"If our induction from all these observations be admitted, we have the rudiments of a theory adequate to the explanation of the phenomena, in so far, at least, as the torpor of the voluntary powers is concerned.

"From the suspended or imperfect respiration, those changes, by which the blood is fitted for maintaining the activity of the sensorial system, are interrupted; this imperfect blood circulating slowly through the brain directly impedes its functions, and so debilitates the excitability of the motive and sensitive organs, that they become torpid. This enunciation may seem hypothetical; but let the proofs of the intimate connection between the respirable and sensorial functions be weighed;

† *Mem. on Respiration.*

‡ *Buffon's Nat. Hist.* by Smellie, vol. vii. p. 193.

consider also the interrupted respiration of hibernating and torpid animals, their instincts with regard to this, and the greater facility with which torpor is induced in a confined situation, which they naturally seek; and compare all these with the observations and experiments of Bichat on the effects of the immediate impression of venous blood upon the brain, and you will perceive a connected system, not entirely fanciful, a theory not without foundation and strength, and which appears to me at least to merit some attention *."

* *Edin. Med. and Surg. Jour.* vol. i p. 308.

For further particulars respecting the torpidity or hibernation of animals, we refer the reader to Spallanzani's *Tracts on Animals and Vegetables;* White's *Natural History of Selborne;* Barton's *Fragments of the Natural History of Pennsylvania;* Pennant's *Arctic Zoology;* La Cèpede *on Oviparous Quadrupeds, as translated by Kerr;* Townson's *Tracts on Natural History and Physiology*, and the *Inaugural Dissertation of* Dr Reeve *de Animalibus Hieme Sopitis*, published at Edinburgh in 1803.

Chap. XVI. *Of Death.*

366 In the article Man, (N° 33. *to the end*) we have traced the progress of human life, from the *cradle* to the *grave;* and have briefly considered the phenomena and the consequences of natural *death*. In that article, and Longevity, we have also stated the natural duration of human life, and the circumstances that tend to prolong our existence beyond the ordinary period. We shall not here enter again on any of these topics, except to give a more ample account of the gradual approaches of natural death, and shall then enumerate the causes which usually produce *violent* or *accidental* death, and mention the opinions of some of the best writers on the *nature* of death.

367 Gradual approach of natural death.

Natural death is, in the present state of civilized society, by no means a common occurrence. When it does take place, its approach is slow and gradual. He whose life terminates in consequence of advanced age, (to use the language of a celebrated French physiologist), dies in detail. His external functions successively cease to exert their action; all his senses are successively lost, or the ordinary causes of sensation pass over them without leaving their usual impressions. The *sight* becomes obscure, and at length the humours of the eye no longer transmit the rays of light; the *ear* receives only confused sounds, and frequently before death, is altogether insensible; the sense of *touch*, in consequence of the hardness and callousness of the cuticle, and the obliteration of many of the subcutaneous vessels, grows dull and uncertain; and all the parts depending on the skin show marks of weakness; the hair and the beard grow white, and a greater or less degree of baldness takes place; odours are no longer perceived, or they are perceived but faintly. The taste usually survives the rest of the senses; but that too, at last, grows equally obscure. The functions of the brain partake of the imbecility of the external senses. The imagination in particular becomes dull and often depraved; the memory no longer retains those occurrences which are every day taking place, though it recalls with increased relish and delight those of past times; the judgment becomes weak and wavering.

From the universal agency exerted by the nervous system on all the animal functions, we must expect that when the former is impaired, the latter will be proportionally enfeebled. The faculties of locomotion and of speech are commonly the first of these that fail; the body totters at every step, the voice grows weak, and the tongue faulters. The motion of the limbs is difficult and painful, and hence is but seldom willingly exerted. Not so with the vocal organs, though the impediments to utterance are evident and painful to his hearers, the old man himself seems scarcely to attend to them, but talks with proverbial garrulity, and especially delights in recounting the scenes and actions of his youth.

While the external functions, and those of the brain, are thus gradually impaired; the internal, or what are commonly called the vital and natural functions, as digestion, absorption, circulation, respiration, and secretion, proceed with but little derangement. The circulation and respiration are indeed slower than before, and the appetite is in general less keen and returns less frequently; but the digestive powers of the gastric fluids remain in full vigour, and even after death has taken place, are exerted on the coats of the stomach; absorption is also very active, and nutrition, at least in many parts of the body, is sufficiently evident. At length, however, all these functions lose their powers; digestion languishes; the secretions no longer take place; the circulation especially in the minute vessels, becomes obscure, and being deprived of the tonic powers by which it was carried on, gradually ceases altogether; the heart no longer propels the blood from its ventricles; and the circulation through the lungs being thus arrested, these organs cease to take in air, make their last expiration, and thus the natural life of man is terminated †.

† See *Bichat Recherches Physiol.* part i. art. 10.

368 Accidental or violent death.

Accidental death takes place in one of the two following ways; either suddenly, in consequence of some great disturbance produced in the animal economy, as when a man is cut off by a sudden stroke of apoplexy, violent hæmorrhage, *asphyxia*, &c. or by slow and gradual steps, in consequence of some less violent but still fatal disease. In the former case, it is *sudden* or *violent* death; in the latter *lingering* death.

Violent death may take place first, either in the *brain*, the *lungs*, or the *heart*; but when the action of one of these organs ceases, that of the others soon terminates. The entire cessation of life seems, however, to be more sudden in the two latter cases, and most of all in the last; when the *heart* is wounded or ruptured, the animal dies instantly; when the lungs are rendered inactive in consequence of suffocation, the animal may live for several minutes, or for an hour or two; but when the *brain* is overwhelmed, he may survive for hours or even days. Thus it sometimes happens, in cases of apoplexy, that the patient lies motionless, speechless, and quite insensible to external stimuli, while the circulation and respiration continue, impeded indeed, but not destroyed, for a considerable time, though life, as appears from the event, be in a state of irrecoverable declension. We shall presently show how these circumstances have been explained.

369 Signs of approaching death.

The usual signs of approaching death are, a very quick and small pulse, scarcely distinguishable, and commonly intermitting; coldness, and generally clammy sweats about the extremities; a "lack lustre" eye, sunk in features, want of expression about the countenance, and a prominence of the bones of the face, with a corresponding hollowness in the cheeks, orbits, and especially

Of Death. especially at the temples. These last appearances constitute the marks of what has been called *facies Hippocratica*. They are all signs of a loss of activity and power in the circulating and nervous systems. Under these bodily circumstances, the powers of the mind seem to decline, generally with an equal pace with those of the body; and when the medium through which the activity of the soul is manifested can no longer act, we cannot expect to find any further traces even of its existence. Yet at the period of its separation, we are told of brilliant mental exertions of powers of intellect, not equalled in the best portion of existence. It has not been our fortune to see such intellectual animation. At the moment of death, anxiety for those we have loved will sometimes occasion apparently disproportioned exertions; and as they were unexpected, they have been exaggerated. But in no instance could we ever detect the activity of mind independent of the body. To this temporary prison the soul is confined, till, by the destruction of the machine, its animating principle is emancipated, soaring probably in higher, and, we trust, in more blissful, regions *.

* New Lond. Med. Dict. vol. i. p. 534.

370 Signs or criterion of actual death.

A few cases have occurred, in which persons, who were thought dead, have recovered from what was really a state of *suspended animation;* and there is reason to believe, that some unhappy beings have been buried while in this seemingly lifeless state. It becomes, therefore, a matter of the highest importance to ascertain, with certainty, whether or not death has actually taken place. The ordinary signs of death, as enumerated by one of the latest writers on this subject, are as follows:

1. The *suspension of respiration*. 2. The *rigidity* of the limbs. 3. The *loss of sensation* and *motion*. 4. The *want of pulsation* in the heart and arteries. 5. The *spontaneous discharge of feces*. 6. The *collapse*, *opacity*, and *want of lustre* in the *eyes*. 7. The *coldness* of the body. 8. The *paleness* or *lividity* of the countenance. 9. The *relaxation* of the lower *jaw*. 10. The *regurgitation of liquids* to the mouth. 11. The *insensibility* of the *pituitary membrane* of the *nose*. 12. The *collapse*, *softness*, and *wrinkling* of the *lips*. 13. The *hollowness* of the *temples*, and *thinness* and *contraction* of the *nose*. 14. *Putrefaction* ‡.

‡ Davis Reglement concernant les décès, part ii.

Most of these signs singly have been shown to be fallacious; and none of them, except the last, are to be depended on with implicit confidence. Dr Davis recommends the following mode of procedure. "As soon as the evident signs of life cease, let us place the body in a warm or dry bed, give a proper temperature to the air of the apartment, and employ every means for restoring it to life. If we judge, from the nature of the disease which preceded the death, that these means are useless, we may content ourselves with keeping the body, until its decomposition become manifest; but let us never abandon an unfortunate person, who, perhaps by perseverance in the proper means, may be restored to life: should he recover, he will be a living monument of unexpected resurrection, and of the unceasing efforts of humanity. If a person die of malignant fever, scurvy, internal inflammation, or any other disease which corrupts the fluids, soon after death the belly becomes black and swelled; black or livid spots appear on the limbs and back, the eyes become hollow and soft, and discharge a puriform fluid; the eyelids grow yellow; the mouth opens, because the lower jaw is relaxed; the skin gets soft, the muscles flaccid; and, lastly, the whole body exhales a putrid odour. All these phenomena united, constitute an infallible proof of real death * (N)."

* Ibid.

The changes which the animal body undergoes in consequence of death, and during putrefaction, have been amply detailed and explained under CHEMISTRY, chap. xix. sect. 2.

371 Comparative pertinacity of life.

In treating of the general phenomena of life in the first chapter of this article, we made a few observations on the degree of vitality that appears in various tribes of organized beings. There is scarcely a more curious part of the physiology of death than the consideration of the greater or less difficulty with which it is produced in different animals. Some, as the herring and the whiting, die almost instantly on being removed from the situation in which they usually live. Some are killed by a slight blow on the nose or the neck; this is the case with the seal, the rat, the hare, and the rabbit. Others again retain life with great pertinacity. Among the mammalia, the cat is proverbial for being difficult to kill; the sloth has been known to live for above 40 days clinging to a pole, and entirely without food; and Dr Sparrman assures us, that the ratel, or honey weazel (*viverra mellivora*), is so hardy that it is almost impossible to kill it; the colonists and Hottentots both assert, says he, that it is almost impossible to kill this creature, without giving it a great number of violent blows on the nose; and it is remarkable that such a number of hounds as are able collectively to tear in pieces a lion of moderate size, are sometimes obliged to leave the ratel only apparently dead †. Some fishes live for a long time after being removed from the water, and even after being gutted and cut in pieces, as the *carp*, the *flounder* and the *eel*. It is among the reptiles, mollusca, and zoophytes, however, that we find the most remarkable instances of pertinacity of life. Referring the reader to the article ERPETOLOGY for these instances in reptiles, and to HELMINTHOLOGY for those in zoophytes, we shall here only mention two among mollusca. The sea marigold (*actinia calendula*) is destroyed with such difficulty, that after drilling the holes of the rock from which they appear, with an iron instrument, they have been known to rise again in the same places, and become as numerous as before in the course of a few weeks ‡. Snails whose remarkable suspended animation we have already recorded, may be crushed beneath the foot, and will yet survive, and repair the breaches in their shelly covering; nay, they are capable of passing the ordeal of boiling water, as we learn from the relation of a lady who, wanting some snail shells for a piece of grotto work, attempted to kill the animals by repeatedly pouring over them boiling water; but to her horror and astonishment, she observed them next day crawling about the edges of the vessel in

† Sparrman's Voyage.

‡ Hughes's Nat. Hist. of Barbadoes.

(N) The work of M. Brubier, *sur l'Incertitude des Signes de la Mort*, from which these remarks of Dr Davis appear chiefly to be taken, created so much alarm in France, that every body dreaded being buried alive. To combat these terrors, M. Louis, in 1752, published his *Lettres sur la Certitude des Signes de la Mort*; in which he has very happily, and we think successfully, refuted the arguments of Brubier, and has thereby relieved the minds of his readers from one of the most dreadful apprehensions that can appal us on this side the grave.

Of Death.

in which she had scalded them *. It is in vain for us to attempt any explanation of these extraordinary phenomena. We must refer them to some principle in the animal economy which is at present unknown.

* Annual Register, vol. xvii. p. 86.

372 Causes of death.

The remote causes of death have been, by Dr Ontyd, arranged under 12 general heads, to which he gives the name of *classes*. These we shall enumerate, with their principal subdivisions.

I. Death arising from the mechanism of the body.

II. Death from the passions of the mind.

1. *Exciting passions;* 2. *Depressing passions.*

III. Death from superabundance or deficiency of heat.

1. *From superabundant heat;* 2. *From deficient heat.*

IV. Death from electricity.

V. Death from noxious gases.

1. *From hyperoxygenized gases;* 2. *From deoxygenized gases;* 3. *From peculiarly stimulating gases.*

VI. Death from poisons.

1. *Animal poisons:* 2. *Vegetable Poisons;* 3. *Mineral poisons.*

VII. Death from universal disease.

1. *Fevers;* 2. *Febrile diseases* (exanthemata).

These seven classes are supposed to produce death by the immediate extinction of the *vital principle;* the five following are supposed to effect this by suppressing the action of some vital organ, or by disordering the chain of the vital powers by destroying the action of some of the intermediate links.

VIII. Death from inflammations.

1. *Inflammations of the head;* 2. *Of the breast;* 3. *Of the belly.*

IX. Death from fluxes.

1. *Alvine fluxes;* 2. *Hemorrhages.*

X. Death from cachexies.

1. *Ulcers;* 2. *Atrophies;* 3. *Debilities and Privations.*

XI. Death from diseases of the nervous system.

1. *Atony;* 2. *Spasm.*

XII. Death from diseases of the secretory organs.

1. *From altered action;* 2. *From altered structure* †.

† Ontyd on Mortal Diseases.

373 How these operate.

The manner in which these causes operate in terminating life, is thus stated by the same author.

The causes of the *first class* act by inducing too great a rigidity of the solids, and by rendering them insensible to *stimuli;* the necessary effects of the continued action of the powers of *life*. In death from causes of the *second class*, the person dies in consequence of *apoplexy*, *syncope*, or *suffocation;* the brain, the heart, or the lungs, being overwhelmed by accumulated blood. The causes of the *third class* act in a similar manner with those of the second; that of the *fourth* by suddenly extinguishing the *vital principle;* those of the *fifth* always act by inducing *suffocation*. The causes of the *sixth* class act in *four* ways: 1. By abolishing the vital principle by the violence of their stimulus; 2. By destroying the action of the brain, the heart, or the lungs; 3. By producing mortification of the intestinal canal; 4. By secretly and insensibly destroying life. Those of the *seventh* class act in *six* ways: 1. and 2. As in the last; 3. By local inflammation; 4. By *mortification* of some *vital organ;* 5. By a change in the organic structure of the intestinal canal inducing a colliquative *diarrhœa;* 6. By *colliquative sweats* wasting the body.

The causes of the *eighth* class act in *four* ways: 1. By inducing violent convulsions; 2. As in the two last; 3. By suppressing the action of some vital function from the violence of the inflammation; 4. By mortification. The *ninth* class may act in *five* modes: 1. By *spasm;* 2. By fatal *syncope;* 3. By impeded action of some vital organ; 4. By mortification or *sphacelus;* 5. By wasting the strength in *fruitless exertions*. The *tenth* class may act in no less than *nine* ways: 1. By the consumption of some vital organ, or destroying the tone of the whole body; 2. By the violence of the noxious stimulus; 3. By suffocation; 4. By apoplexy; 5. By *syncope;* 6. By hemorrhage; 7. By colliquative *diarrhœa;* 8. By mortification of some organ; 9. By malignant fever from absorbed ichorous matter. The causes of the *eleventh* class act only in two ways: 1. By violent spasm; 2. By apoplexy. Those of the *twelfth* class, produce death in three modes: 1. By the slow effect of the noxious stimulus; 2. By the continually stimulating noxious power alone, or by this and the continual wasting of the blood, to form some peculiar secretion; 3. By impeding or destroying the function of a vital organ *.

* Ontyd, p. 637.

Many of these modes of operation are very ill defined, and they may all be reduced to about eight or ten, or perhaps even fewer.

374 Nature of death.

Death has been defined *the separation of the soul from the body* †; the *extinction of the vital principle;* ‡ the *extinction of the faculty of answering a stimulus* ‡, &c. &c. Perhaps we cannot describe it better than by calling it *the irrecoverable cessation of all the bodily functions*. By this character we distinguish it from *suspended* animation and *lethargy*, in which *some* of the functions continue; while we acknowledge the survival of the *immaterial part* of our frame.

† Johnson. ‡ Ontyd.

It has been the general opinion among philosophers, both of ancient and modern times, that death produces only a change of the elements or principles of the organized body; and does not effect the *annihilation* of any part. Modern chemistry has fully confirmed this opinion, and has shown that by putrefaction the body is dissolved into a few *earthy*, *saline*, and *gaseous* products, all capable of entering into new combinations, and thus constituting a part of future bodies. See CHEMISTRY, N° 2572, and MAN, N° 44.

Of all the writers on the nature and phenomena of death, with whom we are acquainted, none has treated the subject with such accuracy and philosophic method, as Bichat. With a summary of some of the leading principles of this able physiologist we shall close the present chapter, and thus terminate our physiological enquiries.

375 Opinions of Bichat.

We have already mentioned Bichat's division of life into *animal* and *organic:* see N° 49. Proceeding on the principle of this division, he conceives that the two lives terminate in different ways, and that one often terminates while the other remains active. In the natural death that happens from old age, the *animal life* gradually ceases in the order we have described, N° 367, while the *organic* life remains. The same happens in those cases of violent death where life first ceases in the brain, this organ being the centre of animal life. In other cases of violent or accidental death, the *organic* life first ceases in its central organs, the *heart* or the *lungs;* but in these cases, the *animal* life also is speedily suppressed.

It

	VI. RESPIRATION.	VII. SECRETION.	VIII. REPRODUCTION.
1. ORGANS	Nostrils, *Larynx*, Windpipe, Lungs, and *Diaphragm*.	Salivary glands, Liver, *Pancreas*, Kidneys, *Testes*, Mucous glands, Membranes, &c. Miliary glands, Brain?	*Penis*, Testicles, *Vesiculæ Seminales*, Prostate gland, Spermatic vessels in Man; *Vulva*, *Vagina*, *Uterus*, and the *Mammæ*, in Woman.
2. FLUIDS.	Blood and *Mucus*.	Tears, *Mucus*, *Saliva*, Gastric juice, Pancreatic juice, Bile, Lymph, *Synovia*, Fat, Marrow, *Cerumen*, *Semen*, Urine, Milk, Nervous fluid?	*Semen*, Mucous fluid, Prostatic fluid, *Liquor amnii*, and Milk.
3. PHENOME	Purification of the fluids, Renewal of action, Animal heat, Mutual action between the air and the animal solids and fluids.	Separation of fluids useful in the economy, and Expulsion of noxious or useless parts.	Copulation, Conception, Parturition, Lactation.
4. POWER	As in CIRCULATION.	Various.	Generative power.
5. RELATIVE P MINANCE	Much as in CIRCULATION.	In middle age; various as to sex and temperament; in *warm* climates.	In *youth*; in those of a sanguine temperament, and lively imagination.
6. PRINCIPAL M AFFECTION	Yawning, Sighing, Sobbing, Hiccup, Sneezing, Coughing, Anxiety, *Dyspnœa*, *Stertor*, *Asphyxia*, Dumbness.	Increased secretion, Diminished secretion, Depraved secretion, Jaundice, *Calculus*, &c.	*Priapismus*, *Satyriasis*, *Nymphomania*, *Menorrhagia*, *Amenorrhœa*, Impotence, Sterility.

It is to violent or accidental death that Bichat principally confines his discussions, and in order to determine with precision the phenomena that take place in the three species, he examines at great length the relations that subsist among the three functions of circulation, respiration and sensation, as they are affected by the death of the *heart*, the *lungs*, or the *brain*. He first considers those cases of sudden death that commence with the death of the heart; then those originating in the lungs; and lastly those originating in the brain. He shows how, one of these functions ceasing, the others successively stop; he points out the mechanism, by which the death of all the parts follows that of the organ first affected; and he determines, according to his own principles, the nature of the several diseases by which the life of the heart, the lungs, or the brain, is extinguished *.

* *Recherches*, part ii. art. i.

We consider this as the most interesting part of his valuable work, and it well deserves the attentive perusal of every medical man. We regret that we cannot do more than extract from it the view given by the author of the successive phenomena produced by the influence which the death of each of the vital organs exerts on the general death of the body.

376 Progress of death commencing in the heart.

Whenever the heart ceases to act, says Bichat, general death comes on in the following manner. The action of the brain ceases for want of excitation; and from the same defect, the sensation, locomotion and speech, which immediately depend on the general sensorium, are interrupted. Besides, for want of the excitation of part of the blood, the organs of these functions would cease to act, even though the brain were supposed capable of exerting on them its usual influence. The whole of the animal life, then, is suddenly arrested. The man, from the moment that his heart dies, ceases to exist with respect to surrounding objects.

The interruption of *organic* life, which has commenced through the circulation, operates at the same time through the respiration. The mechanical actions of the lungs no longer proceed when the brain ceases to act, since on this organ depends the action of the diaphragm and intercostal muscles. The chemical changes can no longer take place, when the heart can neither receive nor convey the materials necessary for their developement. In short, general death continues to proceed in a gradual manner, by the interruption of *secretion*, *exhalation*, and *nutrition*. These are the effects produced when death is the consequence of a wound of the heart or large blood-vessels, a rupture of the heart, or similar accidents †.

† *Id.* art. 5.

377 Progress of death commencing in the lungs.

The series of phenomena that take place in death, as commencing in the lungs, is different according as the *mechanical* or the chemical action of these organs is first arrested. I. In the former case, as when death is produced by an extensive wound or laceration of the diaphragm, by the fracture of a great many ribs at the same time, &c. they proceed as follows: 1. Cessation of the mechanical action; 2. Cessation of the chemical phenomena, for want of the air which supported them; 3. Cessation of the brain's action for want of the red blood by which it was excited; 4. Interruption of animal life, of sensation, locomotion, and speech, from the loss of the exciting powers of the brain and the red blood on the organs of those functions; 5. Stoppage of the *general* circulation; 6. Stoppage of the circulation in the capillaries, of secretion, absorption, exhalation, for want of the excitation exerted on their organs by the red blood; 7. Cessation of digestion, for want of secretion, and of excitation of the digestive organs. II. When the chemical action of the lungs is interrupted, as when an animal is confined in a *vacuum;* in cases of *strangulation*, *suffocation*, *drowning*, &c. the phenomena of death proceed in the following order: 1. Interruption of the chemical phenomena; 2. Consequent suspension of action in the brain; 3. Cessation of sensation, voluntary motion, voice, and the mechanical functions of respiration; 4. Stoppage of the heart's action; and of the general circulation: 5. Termination of the capillary circulation, of secretion, exhalation, and absorption, and, by consequence, of digestion; 6. Cessation of animal heat, which, being the result of all the functions, must cease when all these are terminated ‡.

‡ *Id.* art. 9.

378 Progress of death commencing in the brain.

The phenomena of general death commencing in the brain come on in the following series: 1. Cessation of the brain's action; 2. Sudden interruption of sensation and voluntary motion; 3. Simultaneous paralysis of the diaphragm, and intercostal muscles; 4. Interruption of the mechanical phenomena of respiration, and, by consequence of voice; 5. Cessation of the chemical phenomena; 6. Passage of the *black* blood into the system of *red* blood; 7. Impeded circulation, from the action of the black blood on the heart and arteries, and from the immobility of all the parts, especially the organs of the chest; 8. Death of the heart, and stoppage of the general circulation; 9. Simultaneous interruption of organic life, especially in the parts that are usually penetrated by red blood; 10. Abolition of animal heat §.

§ *Id.* art. 13.

379 Conclusion.

We have now gone through the series of physiological enquiries, into which we proposed to enter in this article. In forming an estimate of the merit due to our labours, we request that our readers will consider the article in a great measure supplemental to many that have preceded it in the course of the present work. It has been our principal object to fill up blanks and supply deficiencies, especially with respect to *Comparative Physiology;* and to form, with those preceding articles which have a reference to the *animal economy*, particularly ANATOMY, MEDICINE, MIDWIFERY, CHEMISTRY, MAN, one *connected*, if not *uniform* whole. The difficulty of the task we had undertaken will probably be admitted as some apology for the imperfect execution of it; while the variety and interesting nature of the subjects which we have treated, with the numerous references to the most respectable sources of information, will, we trust, render this article acceptable both to the general and the scientific reader. See ANATOMY, ANIMAL, COMPARATIVE and VEGETABLE, SUPPLEMENT.

PHYTOLACCA, Pokeweed, or *American Nightshade*, a genus of plant belonging to the decandria class. See Botany *Index*.

PHYTOLOGY, a discourse concerning the growth, kind, and virtues of plants. See Botany, and Materia Medica.

PHYTON, a general of the people of Rhegium against Dionysius, the tyrant of Sicily. He was taken by the enemy, and tortured, and his son was thrown into the sea. See Syracuse.

PIA mater, a thin membrane which covers the brain, and is in immediate contact with it. See Anatomy *Index*.

PIABA, in *Ichthyology*, is a small fresh water fish caught in all the rivers and brooks in the Brasils, and in some other parts in America. It is about the size of the common minow.

PIABUCU, in *Ichthyology*, is an American fish, eaten in many places by the natives. It is said to be so ravenous, and greedy of blood, that if a person go into the water with a wound in any part of his body, the piabucu will make up to it to suck the blood. It seldom exceeds four inches in length.

PIACENZA is a city of Italy, in the duchy of Parma, in E. Long. 10. 25. N. Lat. 45. It is a large handsome city, whose name is derived by some from its pleasant situation, in a fruitful plain, on the Via Æmilia, about half a mile from the Po. It is the see of a bishop suffragan of Bologna, and has a university, but of no great fame. It is defended by a wall and a strong citadel, and is reckoned about three miles in circumference, so that it is somewhat bigger than Parma. The houses are low, but well built; the great street, called the *Stradone*, is in a direct line and of equal breadth, with a foot-way fenced with posts on each side like London, and is about 3000 feet long. The houses are generally built of brick, and some of them are prettily painted. The cathedral is an old structure, but well adorned within. The duke of Parma, who is sovereign of Piacenza, has a palace in the city built by Vignola. There are many excellent paintings in this place. There are two chapels painted, one with the history of St Catharine, and the other with a picture of Christ, as also the altar of the church of St Augustine, all by Pordenone. In the same church there is a fine picture of the blessed virgin, St Peter, and St Paul, by Paolo Veronese. At the Capuchins there is a Francis by Guercino. There is a fountain said to have been erected here by Julius Cæsar, and the equestrian statues of the famous general Alexander I. duke of Parma and Placentia, and of his son Ranuccio, both in the great square. In the palace of Scotti, there are a great many fine pictures by Lanfranco, who had been a page in their family, and among the rest the rape of Helen, the taking of Troy, the blessed virgin, and St Francis. The trade of this city consists chiefly in their cheese, as at Parma, these cities being surrounded with the richest pasture grounds in Italy; though the greatest part of what is called Parmesan cheese is made in the duchy of Milan, and particularly at Lodi. See *Parmesan Cheese*.—Without the walls, which are washed by the rivers Trebbia and Po, there is a large seminary or college, magnificently erected by Cardinal Alberoni, a native of this city, but considerably hurt by the modern Goths in the last war. Towards the north of the city is the mouth of the river Trebbia, famous for the victory which Hannibal obtained over the Romans.

PIANO Forte, or Forte Piano, is a musical instrument, which is too well known to require any detailed description. We shall here, however, notice some of its peculiarities. The voice, it has been observed, is the original musical instrument; of this all other instruments are to be considered but as imitations; and it is remarkable with what promptitude, as well as accuracy, the voice of man obeys the impulse of the heart. Even a coarse ear is hurt by an error in its tone, amounting to what is called a *comma;* and a limited voice can execute melodies which include 12 notes, or an octave and a fifth. Between these extremes the motion of the glottis does not amount to one twelfth of an inch, which must therefore be divided by the most ordinary singer into more than 1000 parts. All this too, without any seeming effort of thought, is done in an instant, and repeated with rapidity, without mistaking one of the divisions.

The great object in the construction of musical instruments is, to bring them as near as possible to express the sounds produced by the human voice: the violin, however, and a few of the simple wind instruments, are the only ones found fully to express these momentary gradations of sentiment, and those tender and delicate emotions with which the heart is agitated. For the purpose of removing this defect of harmonic instruments, the swell was added to the organ. Similar improvements were also attempted on other instruments of the same kind, and the same way. The harpsichord was shut up like the swell organ, and was opened by means of pedals, when the performer wished to enforce the sound. But as this was found not to succeed well, other methods were tried, and in particular unisons were added to each note, which were brought on, either by means of pedals, or by another set of keys; and in this way the power of the harpsichord was greatly improved. Among all the keyed instruments, the English piano forte seems to merit the preference, on account of the superior force of tone, adequate sweetness, and great variety of voice, of which, by the ingenuity of British artists, it has now become susceptible. It has been called a national instrument, because it is said to be an English contrivance, the invention of the celebrated poet, Mason. Mr Mason had seen some attempts that were made by the Germans to make keyed dulcimers, which were in some measure susceptible of the *forte* and *piano;* but as they were all constructed on one principle, and required a particular touch of the finger, which was of difficult acquisition, and which spoiled it for harpsichord practice; as they were also deficient in delicacy and justness; and as the performer was by no means certain of producing the very strength of sound intended, Mr Mason removed all those imperfections, by detaching the mallet entirely from the key, and giving them only a momentary connection. It is by this improvement that the English piano forte is distinguished from all others. Mr Mason's general principle may be fully understood by the following description. In the figure on Plate CCCCXVIII. the parts are represented in their state of inaction. The key ABK turns, as usual, on the round edge of the bar B, and a pin *b*, driven into the bar, keeps it in its place. The

The dot F represents a section of the string. ED is the mallet, having a hinge of vellum, by which it is attached to the upper surface of the bar E. At the other end is the head D, of wood, covered with some folds of prepared leather. The mallet lies in the position represented in the figure, its lower end resting on a cushion-bar K, which lies horizontally under the whole row of mallets. The key AR has a pin C, tipt with a bit of the softest cork or buckskin. This reaches to within $\frac{1}{10}$th of an inch of the shank of the mallet, but must not touch it. The distance E e is about $\frac{1}{3}$d or $\frac{1}{4}$th of the length of the shank. When the end A of the key is pressed down on the stuffing (two or three thicknesses of the most elastic woollen list) it raises the mallet, by means of the pin C, to the horizontal position E d, within $\frac{1}{8}$th or $\frac{1}{10}$th of an inch of the wire F; but it cannot be so much pressed down as to make the mallet touch the wire. At the same time that the key raises the mallet by means of the pin C, it also lifts off the damper G (a bit of spunge) from the wire. This damper is fixed on the end of a little wooden pin G g, connected with the lever g H, which has a vellum hinge at H. This motion of the damper is caused by the pin I, which is fixed into the key near to R. These pieces are so adjusted, that the first touch of the key lifts the damper, and, immediately after, the pin C acts on the shank of the mallet. As it acts so near to its centre of motion, it causes the head D to move briskly through a considerable arch D d. Being made extremely moveable, and very light, it is thus *tossed* beyond the horizontal position E d, and it strikes the wire F, which is now at liberty to vibrate up and down, by the previous removal of the damper G. Having made its stroke, the mallet falls down again, and rests on the soft substance on the pin C. It is of essential importance that this mallet be extremely light. Were it heavy, it would have so much force, after rebounding from the wire, that it would rebound from the pin C, and again strike the wire. For it will be recollected, that the key is, at this time, down, and the pin C raised as high as possible, so that there is very little room for this rebound. Lessening the momentum of the mallet by making it very light, making the cushion at the top of the pin C very soft, and great precision in the shape and figure of all the parts, are the only securities against the disagreeable rattling which these rebounds would occasion. In respect to the solidity and precision of workmanship, the British instruments are unrivalled, and vast numbers of them have been sent to all parts of the continent.

As the blow of so light a mallet cannot bring much sound from a wire, it has always been found necessary to have two strings for each note. Another circumstance contributes to enfeeble the sound. The mechanism necessary for producing it makes it almost impossible to give any considerable extent to the belly or sound board of the instrument. There is seldom any more of it than what occupies the space between the tuning pins and the bridge. This is the more to be regretted, because the basses are commonly covered strings, that they may be of a moderate length. The bass notes are also of brass, which has a considerably lower tone than a steel wire of the same diameter and tension. Yet even this substitution for steel in the brass strings is not enough. The highest of them are much too slack, and the lowest ones must be loaded, to compensate for want of length. This greatly diminishes the fulness, and still more the mellowness and distinctness of the tone, and frequently makes the very lowest notes hardly appreciable. This inequality of tone about the middle of the instrument is somewhat diminished by constructing the instrument with two bridges; one for the steel, and the other for the brass wires. But still the bass notes are very much inferior to the treble.

PIASTUS, a native of Poland, was originally a wheelwright, and the son of Cossisco, a citizen of Cruswitz. He flourished in the year 830, when on the extinction of the family of Popiel great disputes arose about his successor, and Cracow was afflicted with a severe famine. During this extremity, when the people were dropping down in the streets, two angels in human forms, as the story is told, took up their residence with Piastus, who was celebrated for his piety and extensive charity. He had nothing left but a small cask of the common liquor of the country, and this he presented to his new guests, who, charmed with his hospitality, promised him the crown of Poland. The faith of Piastus was equal to his other virtues: he implicitly believed the word of his guests, and piously followed their directions in every particular. He was ordered to distribute the liquor out of his little cask to the multitude: he did so, and found that it was inexhaustible. The people were astonished; all cried out, "A miracle!" and the electors determined to choose a person in whose favour Heaven had so visibly declared: Piastus was accordingly taken from his shop, and raised to the ducal dignity.

Mod. Univ. History, vol. xi. p. 336, &c.

Such is the relation of the canon of Cracow, which differs in many particulars from the account given by Guagnini, and several other historians. According to them, Piastus had prepared a small collation, to entertain some friends who were assembled at the birth of a child. Two pilgrims, Paul and John, afterwards murdered at Rome, came about this time to Cracow. They begged charity at the door of the election-hall, and were rudely repulsed; upon which they stumbled on the house of Piastus, and were kindly received. The miracle we have mentioned was wrought by them; and the two pilgrims, and not angels, were the instruments of the elevation of the hospitable wheelwright. Though we pay but little regard to the marvellous means by which Piastus ascended the ducal throne of Poland, it would be presumptuous entirely to omit a fact attested by all the writers upon this subject: it was proper, therefore, to take notice of it, and we leave the rest to the reader's judgment,

Being now raised to the supreme dignity, he was not intoxicated with his prosperity. His natural charity, benevolence, and sweetness of disposition, remained: nothing was altered but his power of doing good. He was truly called the father of his people: the injured never returned unredressed, nor merit unrewarded. Piastus wiped the tear from the eyes of the widow; and was himself the guardian of the orphan, and the general patron of the poor and distressed. His excellent inclinations served him in the room of great abilities; and the happiness that his people enjoyed made them forget that their prince was not born a statesman and a warrior. Several intestine commotions arose during his administration, all which he quelled by the mildness and clemency of his nature: his nobility were ashamed

ashamed of rebelling against a sovereign who devoted his whole life to render his people happy. He removed the court from Cruswitz, a city which he detested, because it was the scene of Popiel's crimes and tragical end, and fixed his residence at Gnesna, where he died beloved, esteemed, and even adored by his subjects.

It is in memory of this excellent prince, that all the natives of Poland, who have been since promoted to the ducal or regal dignity, were called Piastes, in contradistinction to the foreigners.

Piastus associated his son Ziemovitus with him in the government before his death; a circumstance of much benefit to the people.

PIAZZA, in building, popularly called *piache*, an Italian name for a portico, or covered walk, supported by arches.

The word literally signifies a broad open place or square; whence it also became applied to the walks or porticoes around them.

PIBROCH, says Dr Beattie *, is a species of tune peculiar, I think, to the Highlands and Western isles of Scotland. It is performed on a bagpipe, and differs totally from all other music. Its rythm is so irregular, and its notes, especially in the quick movement, so mixed and huddled together, that a stranger finds it almost impossible to reconcile his ear to it, so as to perceive its modulation. Some of these pibrochs, being intended to represent a battle, begin with a grave motion resembling a march, then gradually quicken into the onset; run off with noisy confusion and turbulent rapidity, to imitate the conflict and pursuit; then swell into a few flourishes of triumphant joy; and perhaps close with the wild and slow wailings of a funeral procession.

* Essay by Dr Beattie, 8vo edit. p. 422. note.

PICA. See CORVUS, ORNITHOLOGY *Index*.

PICA Marina. See HÆMATOPUS, and ALCA, ORNITHOLOGY *Index*.

PICA, in *Medicine*, a depravation of appetite, which makes the patient long for what is unfit for food, or incapable of nourishing; as chalk, ashes, coals, plaster-lime, &c. See MEDICINE *Index*.

PICA, or *Pye*, had formerly the same sense as *ordinal*, meaning a table or directory, pointing out the order in which the devotional services appointed for different occasions were to be performed. Accordingly we are told it is derived from *πι*, a contraction of *πιναξ*, *a table;* and by others from *litera picata*, a great black letter at the beginning of some new order in the prayer. The term was used in a similar sense by officers of civil courts, who called their kalendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts the *pyes*.

PICA, or *Picus*, *John*, prince of Mirandola and Concordia, was born in the year 1463, under the pontificate of Pius II. He was the youngest son of John Francis of Mirandola, and Julia, a lady of the noble family of Boiard. Some of the credulous historians of the time have related, that at his birth a globe of fire was seen to rest upon his mother's bed, portending, say they, by its shape the perfection of his genius, and by its element, the celestial turn of his mind. As soon as he was capable of receiving instruction, he was placed by his mother's care under the most able masters, and very early distinguished himself by the vigour of his application, and the strength of his memory; of which such prodigies are related as would be very difficult to credit, were we not assured by some modern instances, of the perfection to which that faculty may be carried. At the age of fourteen he was sent by his mother's direction, who was desirous that he should assume the clerical functions, to Bologna, at that time the principal resort of those who studied the pontifical law. After spending two years there, he became disgusted with this pursuit, although such was his industry, even at that early age, that he compiled an epitome of the pontifical epistles or decretals. His disposition, however, strongly led him to the pursuit of philosophy, with an eager curiosity to penetrate the secrets of nature and science: with this view he travelled over Italy and France, visited the most celebrated schools of each, and studied under the most famous teachers of both countries. After seven years spent in this course of instruction, and at the age of twenty-three, he went to Rome, and, after the fashion of the scholars of that time, brought himself into notice by publicly proposing literary questions for disputation. This sort of challenge was very common in that age, and, when printing was scarcely practised, and the name of a man of learning less rapidly extended than it is now, was almost the only method that a person of superior attainments had to make himself known. Mirandola proposed 900 questions, or as they were called *conclusiones*, in dialectics, mathematics, natural philosophy, and divinity, drawn not only from the stores of the Latin and Greek, but from the mysteries of the Hebrews and the arcana of the Chaldeans and Arabians. In addition to the endless topics of metaphysics, theology, and the ordinary subjects of disputation, into which he entered very profoundly, the *conclusiones* involved the ancient and obscure philosophy of Pythagoras, Trismegistus, and Orpheus; the doctrines of the Cabala, or mystic interpretation of the sacred writings, according to the Hebrews, taught by Origen and Hilarius; the extent, uses, and learning of natural magic, which was vindicated from the vulgar reproach of impiety and necromancy. Seventy-two new physical and metaphysical dogmata of the author's invention were likewise proposed and defended. These propositions, according to the ostentatious practice on these occasions, were fixed in the most public places in Rome, and the proposer engaged to defray the expences of any one who should come from a distance for the purpose of disputing with him. This challenge did not bring forward any disputants, but exposed Mirandola to much envy and jealousy, particularly from the professors of science at Rome, who felt the reflection that would be cast upon their credit by their declining a competition which they durst not encounter. Unable to injure his fame as a scholar, they made a much more dangerous attack upon the soundness of his faith; thirteen questions were selected, which were charged with the terrible suspicion of heresy and contempt of the ordinances of the church; a suspicion very readily listened to by the church when directed against great learning, which the increasing influence of philosophy and letters began to make her watch with extreme jealousy. Mirandola repelled this attack by publishing his Apologia, or Defence of the accused Propositions; which if he did not effectually clear away the suspicions he had incurred, tended to confirm his enemies in their dread of his learning and powers; and it must be owned that, overlooking

Pica.

ing the misapplication of talents to such subjects, the Apologia exhibits a command of profound and well digested learning and keen argument, truly astonishing at the age of twenty-three. This work, and the discussions it contained of certain delicate points, added to some hints of the limit of pontifical controul in matters of faith, were so disagreeable to Pope Innocent VIII. that he interdicted the reading both of the Apology and the disputed questions. The love of glory, however, was not Mirandola's only passion: his youth, splendid accomplishments, and the graces of his person, for which he is said to have been remarkable, attracted the admiration and caresses of many distinguished Roman ladies, who united the love of letters to that of pleasure, a taste very common amongst the Italian ladies of that age. The young philosopher yielded to the force of these allurements, or rather, according to the account of his nephew and biographer, Francisco of Mirandola, eagerly followed the bent of his disposition, naturally inclined to obey the attractions of beauty.

But this life of pleasure, however suitable to his condition and inclinations, was of a short continuance. Irritated by the restless persecutions of his enemies, and obliged perpetually to defend himself against the imputation of heresy, the most formidable calumny which in that age any man could have to contend with, he detached himself from vicious pleasures, and regulated his manner of life by rigidly observing the laws of abstinence imposed by Christianity; for being a firm adherent to the Christian doctrines, the charge of infidelity and the vigilance of his enemies made him the more solicitous to guard against the appearance of disobeying them. Becoming from this time wholly devoted to learning, he soon acquired such celebrity that the most eminent scholars from all parts of Italy came to visit him for conversation or instruction. As a proof of the sincerity of his reformation, he committed to the flames five books of elegiac poetry which he had composed on the subject of his amours, together with numerous pieces in Tuscan verse, which had been addressed to his various mistresses. There is perhaps reason to lament that the zeal of a new convert would not be satisfied without this sacrifice. It must, however, be considered that the spirit of religion at that period exacted many sacrifices from the professors of Christianity, which the lenient temper of these times does not call for. An example of this severity is to be met with amongst the works that still remain of Mirandola; at the end of which, in the folio edition published by his nephew, we find a learned and entertaining comment, in the Italian language, upon a composition of his friend Girolamo Benivieni, entitled *Una Canzona de Amore secundo la mente et openione de' Platonici*, "A poetical treatise upon love, explaining the doctrines of the Platonists." The author, Girolamo, informs the reader, in a short preface, that he had determined to suppress this poem and comment out of regard to his friend's character and his own; deeming it unbecoming a professor of Christianity, in treating of celestial and divine love, "to treat of it as a Platonist and not as a Christian;" but that having lent it to some of his friends for their perusal, an imperfect and erroneous copy was printed, which obliged him, but not till after the death of Mirandola, to publish it correctly; and he takes care to allege, in excuse for himself, that he has apprized the reader of his plan by the title of the poem, and warned him in all places where Plato's opinions depart from those of Christ, that the doctrines of a gentile and a heathen are not entitled to the least weight compared with the reasonings of the Christian theologists, "and particularly the irrefragable arguments of the angelic doctor St Thomas of Aquino."

Pica.

The first fruit of Mirandola's devotion to sacred literature was the Heptaplus, or Comment upon the Six Days of the first Chapter of Genesis, which was written in 1491. Two years afterwards he published a treatise in ten chapters, *de Ente et Uno*; the object of which was to reconcile the doctrines of Plato and Aristotle, and to demonstrate that the disputes of their respective followers originated in a misconception of the opinions of these philosophers relative to the *Ens* and *Unum*, at that time a subject of mighty strife among the learned. This treatise was held in high esteem by both sides. It was the last work of consequence that the author lived to complete; but he had laid the plan of a vast and comprehensive work, which his early death prevented the execution of. This was no less than to confound the seven enemies of the Christian church, by examining and refuting all their errors. In the prosecution of this design, he had composed and perfected before his death twelve books against astrology, the most popular and the most pernicious superstition which then infested the world. Paulus Jovius, bishop of Nocera, has left a testimony to the merits of this work, which is above all other encomiums:—"In this excellent though unfinished work, Mirandola attacked the astrologers with such erudition and keenness, and so ably exposed the absurdity and vanity of the whole art of divination, that he seems to have deterred the professors of the occult sciences from writing*."

This great design, as well as many others which Mirandola had formed, particularly that of a more complete essay towards reconciling the opinions of Plato and Aristotle, was frustrated by his death. From the time that he left Rome, which was soon after the publication of the Apologia, Mirandola generally resided either at Ferrara or at Florence. The friendship of the prince of Ferrara and its vicinity to his paternal seat attracted him to the former place; but Florence was the most agreeable to him, on account of the society of literary men which it afforded, and particularly of *Politian* and *Lorenzo de Medici*, with whom he entertained a close friendship. Besides these two illustrious men, his society was cultivated by other eminent scholars, among whom was the learned and unfortunate Hieronymus Savanarola, and Hermolaus Barbarus: Petrus Crinitus, the pupil of Politian†, mentions him as excelling all his companions in the erudition and eloquence of his conversation. The same author has left us an account of Pica's laborious studies; for when Politian had expressed in his presence high admiration of his great genius and learning, Mirandola with singular modesty answered, that he deserved no praise but for his assiduous application—"Gratulandum potius, intelligite, assiduis vigiliis atque lucubrationibus, quam nostro ingenio plaudendum‡."

His library likewise is celebrated by the same writer, and is said by Francisco de Mirandola to have cost 7000 pieces of gold. His accomplishments were not confined to subjects of abstruse literature; in his youth he was much attached to music, in which he acquired such skill, that

* Paul. Jov. Elog. Doct. Vir. p. 92.

‡ Ib. lib. ii c. 2.

Pica.

that some of his melodies were publicly received, and held in great esteem. It might also be concluded, from an anecdote related by Petrus Crinitus, that he was not unacquainted with physic; for according to that author, when Hermolaus Barbarus was seized at Rome with a dangerous fever, Mirandola sent him from Florence a medicine prepared by himself. No man ever testified a more sincere devotion for learning and philosophy, to the contempt of all other qualifications, than the Prince of Mirandola. He possessed a very large estate, which he bestowed almost entirely upon works of charity, except what was spent in collecting books, and entertaining and providing for literary men. At length, however, about three years before his death, he made over to his nephew Francisco his principality and possessions in Mirandola, and obtained a confirmation of the grant from Maximilian, the Roman emperor, to whom that principality was subject. He reserved to himself only enough to purchase a small estate near Ferrara, where he spent the remainder of his life, except when he resided at Florence, in elegant and learned retirement. His mother, under whose care he received his education, had destined him for the church; and he was often urged by his friends to embrace the sacred profession, with the certainty of the highest honours and emoluments: but nothing could induce him to quit the life that he had chosen. He died of a fever at Florence, in the year 1494, in the 31st year of his age, on the same day that Charles IX. of France entered that city on his famous expedition into Italy. That monarch, hearing of Mirandola's illness, as he approached the city, sent two of his own physicians to his assistance; but in spite of their aid, the violence of his disorder put an end to his existence in 13 days.

With respect to the works of this author, something has already been said, and little more remains to be observed. The *Conclusiones* afford a very complete specimen of the learning of the age, and of what were deemed the most valuable purposes to which learning could be applied. However useless and unprofitable these purposes may appear to us, it will not be denied by any one, who has the curiosity to look through the *Conclusiones*, that the mass of learning, which must have been possessed by the proposer of them, is prodigious; when it is recollected that, at the time he proposed them, he was no more than 23 years of age. For there is not the least reason to suppose, that a person whose works prove him to have been a man of profound learning, and who, in an age and nation distinguished by some of the brightest scholars that ever appeared, was ranked by their own judgment amongst the first, should have challenged the discussion of any of the proposed subjects, without being well provided with the knowledge necessary for such a debate. The manner in which the questions were propounded leave little room to doubt that the author was deeply versed in the respective subjects of them; and the Apology for the accused propositions, particularly those *de Salute Origenis* and *de Magiâ atque Cabalâ*, discover familiarity with the writings of the Fathers, as well as with the Greek and Hebrew classics, and a facility of language and argument that could not be acquired at that age without extraordinary powers of mind. It would be worth while to transcribe the whole of this curious piece for the amusement of such of our readers as may not have access to the original, but our limits do not admit of it.

It is curious to observe how greatly the sudden growth of learning outstripped that of solid science. No age, perhaps, was ever so remarkable for the learning which it produced as the period from the middle of the 15th century to the beginning of the 16th; yet, except the inestimable obligations we owe to the learned men of that time for their editions of the classics, later ages have been little benefited by their works, which are either lost or neglected, and even the sciences they treated of exploded and ridiculed. School-divinity and metaphysics, though the most attended to, were not the only studies in which the vast erudition of that age was wasted. The mysterious doctrines of the Cabala formed a favourite study of some of the most learned scholars. The proposition which laid Pica open to the indignation of the church, was that in which he asserted the orthodoxy of Origen; for Origen, notwithstanding his meritorious labours in the cause of Christianity, his daring zeal and self-martyrdom, and notwithstanding the defence of Eusebius, was consigned by the sentence of the church to inevitable damnation, on account of his errors in the mysteries of the faith. To question his perdition, therefore, was to deny that the church was the interpreter of the divine intentions. The defence of this part of the *Conclusiones* is written with a boldness that could hardly be expected from an Italian of the 15th century. But the hardiest of these propositions was that in which it is asserted, that faith is not in a man's own power. In defending this and the other propositions, which were taxed with heresy, Pica probably relied less on the spirit and ability of his justification, than on his own high rank and station, together with the countenance and protection of his powerful friends, particularly the Medici, whose liberality of sentiment in regard to religious points was so notorious, that even Leo. X. has been directly charged, not only with heresy, but infidelity *.

* Milner's Hist. of the Church, vol. iv.

By the Cabala, a term at this time generally misapprehended, was understood sometimes a species of divine magic operating by the agency of good spirits, as magic commonly so called was supposed to do by that of evil beings; but the true definition of it, as received by the best of its professors, is given by Reuchlinus (A), in his treatise addressed to Lorenzo de Medici, *Divinæ Revelationis ad salutiferam Dei et formarum separatarum contemplationem traditæ symbolica receptio*,—a symbolic acceptation of the Mosaic history (for that is meant by *divina revelatio*) which produced a pure and perfect acquaintance with the nature of the divinity and of spirits; and according to the opinions of some, which seem to be revived by the modern Swedenborgians, this knowledge, when sublimed to the highest perfection it was capable of, and accompanied with perfect purity, was believed to

(A) This treatise, which contains the whole learning upon a subject once held in the highest veneration by men of learning, is very curious, and is to be found in the folio edition of Mirandola's works, published at Basil in 1557.

Pica. to raise the mind to an absolute familiarity with good angels, by whose assistance the possessors of the cabalic secrets were enabled to do miraculous things. This art was derived from the rabbinical doctors, who were at first called Thalmudists; and, about the middle of the 15th century, according to Pica de Mirandola *, its professors were denominated Cabalici, Cabalæi, or Cabalistæ, according to their different degrees of perfection: they afterwards, however, departed from their masters the Thalmudists; the latter, according to Reuchlinus, being chiefly intent upon the law and the explanation of it, while the former, paying less regard to what concerned human affairs, aimed chiefly at elevation of mind and thought. The ideas and doctrines of the Cabalists seem to have been well known to Milton, and perhaps suggested some passages in Paradise Lost. In Reuchlinus's Exposition of their mysteries there is a curious passage describing the speech of the Deity to the heavenly spirits after the fall of Adam, with the future prospect of redemption by the incarnation of the Messiah, whom the Cabalists recognised in the character of a celestial Adam (B); and, among the books relating to these doctrines, which are said to be lost, mention is made of *Liber Bellorum Domini*. The mysteries of the Pythagorean philosophy, which, according to Philolaus apud Reuchlinum, sprung from the same source, were also studied and taught with great fervency during this period. Mirandola and Paulus Riccius were the first who explained the Cabalistic mysteries in Latin, and the former in his Apology, has employed much labour and learning in defending them, as well as the science of natural magic, from the vulgar idea that necromancy was at the bottom of them. His writings, however, upon that subject were few, and we do not know whether they still exist; but it may be collected from the following proposition in his *Conclusiones*, and some others of a similar nature, that he, like all the scholars of his time, had bestowed much attention upon this useless learning: "Qui scierit quid sit denarius in Arithmetica formali, et cognoverit natura primi numeri sphærici, sciet secretum quinquaginta portarum intelligentiæ et magni jobelæi, et millesimæ generationis, et regnum omnium seculorum." Those who are well acquainted with the tenets of the modern millenarians will be able to tell whether there be any connection between them and the allusions in the concluding part of this proposition.

* *Reuchlinus de Arte Cabalist.*

Magic also entered deeply into the learning of this era. This comprises two distinct sciences, that of natural magic, and that of dæmonology: the first was concerned only in the properties of numbers and figures, and some of the more hidden properties of nature. This knowledge enabled its possessors to produce many effects from natural causes, which, when science was less diffused than at present, appeared to be the effect of something superior to the common limits of human power. Albertus, commonly called Magnus, the friend and tutor of Roger Bacon, was the most celebrated of those who excelled in this sort of knowledge. This science has been productive of many admirable discoveries in mathematics and chemistry. Magic, in its common signification, or necromancy, was also eagerly studied at this time, as appears from Cornelius Agrippa's strange work upon that subject; and we may judge of the estimation in which it was held, by the confession that writer makes in his book *De vanitate omnium Scientiarum*, that while he professed that science, he derived more credit and profit from it, than from any other use he ever could make of his learning. The first master in this way was said to be * Solomon, whose magic ring and glass are still famous in eastern dæmonology.

* *P. Crinitus de hon. Discip. lib. ix. c. 5.*

But the most dangerous, the most popular, and the most pernicious delusion which the darkness of the preceding ages had entailed upon mankind, was astrology, which will perhaps never be utterly exterminated from the minds of the vulgar, but which then possessed all ranks. When these considerations are taken into the account, it must be looked upon as no despicable application of learning and talents, to have exposed the fallacy and absurdity of this delusion; and when we recollect the great learning and credit of some of its upholders, among whom our countryman Roger Bacon was the most esteemed; the almost universal belief entertained of it, and the few lights which mankind then possessed, as to the real and constant laws obeyed by the celestial bodies; it cannot be denied that the twelve books written by Mirandola against astrology, the effect of which, in opening men's eyes upon that subject is testified by a respectable cotemporary author, were the work of a very superior and enlightened mind. When we congratulate ourselves upon our freedom from these superstitions, we ought not to forget, that we owe something to those who gave the first blow to them. Proud of the lights of the age we live in, when astrology and such like cheats are no longer in vogue, we are too apt to overlook the merit of those exertions which first exposed and refuted them; and to persuade ourselves, that in these days of genius and philosophy, such exertions would have been unnecessary; not recollecting that if we enjoy many superiorities of this kind, we are less indebted for them to our own genius than to the labours of those who first paved the way for the detection of superstitious errors; our merit is, that we do not shut our eyes to the light of science; but while we enjoy its blaze, we ought to be grateful to those who struck the first sparks.

John Pica of Mirandola has been represented by writers, whose ideas are taken from the encomiums of his cotemporaries, as a mighty prodigy of learning and genius. The distaste which the present times entertain towards those subjects upon which he wrote, renders it very difficult, upon a review of his works, to think those encomiums justified. But making allowance for this change of opinion, and weighing the impartial testimony of his equals, and the early age at which he obtained their admiration, it may be fairly concluded, he was in reality, a man of very extraordinary powers. These memoirs are principally collected from his letters, and the account given of him by his nephew Francisco, himself

(c) Conjicimus sane, alterum esse Adam cælestem angelis in cœlo demonstratum, unum ex Deo, quem verbo fecerat et alterum esse Adam terrenum, repulsum à Deo, quem ex luto manibus suis finxerat. *Reuchlinus*, p. 750.

self an eminent scholar. Such a biographer might naturally be suspected of partiality; but the evidence of other writers fully confirms his account. Paulus Jovius, in his *Elogia Doctorum Virorum*, gives the following character of him*. "John Pica of Mirandola, has been justly styled the phœnix; for in him, the immortal gods, besides the splendour of his family, assembled all the rarest gifts of body and mind."

* P. 92.

Petrus Riccius, commonly called Petrus Crinitus, who was the pupil of Politian and the companion of Mirandola, laments the death of him and Politian, which happened in the same year, as a public misfortune, more severely felt at that particular time, when learning, obstructed by the incursion of the French into Italy, wanted the support and assistance of such men ‡. To these may be added the testimony of Hieronymus Savanarola, who, though afterwards put to death by Pope Alexander for a heretic, was a man of great consideration on account of his learning and talents. In a dispute which took place between him and Mirandola, concerning the philosophy of the ancients; the former, yielding to the superiority of his opponent, rose up and embracing him said, "Unus tu es, Pice, ætate nostra qui omnium veterum philosophiam ac religionis Christianæ præcepta et leges percalleas ‖. The following epitaph, written by Hercules Strozza, is preserved by Paulus Jovius:

‡ *Pet. Crin. de honesta Discip.*

‖ *Ib.* iii. c. 2.

Joannes jacet hic Mirandola; cætera norunt
Et Tagus et Ganges, forsan et Antipodes.

Dr Johnson in his Essay on Epitaphs, has taken notice of this pompous distich, as a warning to epitaph writers. "Thus, says he, have their expectations been disappointed, who honoured Picus of Mirandola with this pompous epitaph. His name, then celebrated in the remotest corners of the earth, is now almost forgotten; and his works, then studied, admired, and applauded, are now mouldering in obscurity." *Monthly Mag.*

PICARD, a native of the Netherlands, who founded a sect the professors of which were called *Picards*. See PICARDS.

PICARD, *John*, an able mathematician, and one of the most learned astronomers of the 17th century, was born at Fleche, and became priest and prior of Rillie in Anjou. Going to Paris, he was in 1666 received into the Academy of Sciences in quality of astronomer. In 1671, he was sent, by order of the king, to the castle of Uraniburg, built by Tycho Brahe in Denmark, to make astronomical observations there; and from thence he brought the original manuscripts wrote by Tycho Brahe, which are the more valuable as they differ in many places from the printed copies, and contain a book more than has yet appeared. He made important discoveries in astronomy; and was the first who travelled through several parts of France, to measure a degree of the meridian. His works are, 1. A treatise on levelling. 2. Fragments of dioptrics. 3. *Experimenta circa aquas effluentes*. 4. *De mensuris*. 5. *De mensura liquidorum & aridorum*. 6. A voyage to Uraniburg, or astronomical observations made in Denmark. 7. Astronomical observations made in several parts of France, &c. These, and some other of his works, which are much esteemed, are in the sixth and seven volumes of the Memoirs of the Academy of Sciences.

PICARDS, a religious sect which arose in Bohemia in the 15th century.

Picard, the author of this sect, from whom it derived its name, drew after him, as has been generally said, a number of men and women, pretending he would restore them to the primitive state of innocence wherein man was created: and accordingly he assumed the title of the *New Adam*. With this pretence he taught his followers to give themselves up to all impurity; saying that therein consisted the liberty of the sons of God; and that all those not of their sect were in bondage. He first published his notions in Germany and the Low Countries, and persuaded many people to go naked, and gave them the name of *Adamites*. After this he seized on an island in the river Lausnecz, some leagues from Thabor, the head quarters of Zisca, where he fixed himself and his followers. His women were common, but none were allowed to enjoy them without his permission: so that when any man desired a particular woman, he carried her to Picard, who gave him leave in these words, *Go, increase, multiply, and fill the earth.*

At length, however, Zisca, general of the Hussites, (famous for his victories over the emperor Sigismund), hurt at their abominations, marched against them, made himself master of their island, and put them all to death except two; whom he spared, that he might learn their doctrine.

Such is the account which various writers, relying on the authorities of Æneas Sylvius and Varillas, have given of the Picards, who appear to have been a party of the Vaudois, that fled from persecution in their own country, and sought refuge in Bohemia. It is indeed doubtful whether a sect of this denomination, chargeable with such wild principles and such licentious conduct, ever existed; and it is certainly astonishing that Mr Bayle, in his art. *Picards*, should adopt the reproachful representations of the writers just mentioned: for it appears probable at least that the whole is a calumny invented and propagated in order to disgrace the Picards, merely because they deserted the communion and protested against the errors of the church of Rome. Lasitius informs us, that Picard, together with 40 other persons, besides women and children, settled in Bohemia in the year 1418. Balbinus the Jesuit, in his *Epitome Rerum Bohemicarum*, lib. ii. gives a similar account, and charges on the Picards none of the extravagancies or crimes ascribed to them by Sylvius. Schlecta, secretary of Ladislaus, king of Bohemia, in his letters to Erasmus, in which he gives a particular account of the Picards, says that they considered the pope, cardinals, and bishops of Rome, as the true Antichrists, and the adorers of the consecrated elements in the eucharist as downright idolaters; that they denied the corporeal presence of Christ in this ordinance; that they condemned the worship of saints, prayers for the dead, auricular confession, the penance imposed by priests, the feasts and vigils observed in the Romish church; and that they confined themselves to the observance of the sabbath, and of the two great feasts of Christmas and Pentecost. From this account it would appear that they were no other than the Vaudois; and M. de Beausobre has shewn that they were both of the same sect, though under different denominations. Besides, it is certain that the Vaudois were

were settled in Bohemia in the year 1178, where some of them adopted the rites of the Greek, and others those of the Latin church. The former were pretty generally adhered to till the middle of the 14th century, when the establishment of the Latin rites caused great disturbance. On the commencement of the national troubles in Bohemia, on account of the opposition to the papal power (see MORAVIANS), the Picards more publicly avowed and defended their religious opinions; and they formed a considerable body in an island by the river Launitz or Lausnecz, in the district of Bechin, and recurring to arms, were defeated by Zisca. *Encyclop.* art. Picards.

PICARDY, a province in France, is bounded on the north by Hainault, Artois, and the straits of Calais; on the east by Champagne; on the south by the Isle of France; and on the west by Normandy and the English channel (A). This province is long and narrow, being usually compared to a bent arm; and in this figure is nearly 150 miles in length, but not above 40 in breadth, and in many places not above 20. It is generally a level country; and produces wine, fruit of all kinds, plenty of corn, and great quantities of hay: but wood being scarce, most of the inhabitants burn turf. They have, however, some pit-coal, but it is not so good as that of England. It was united to the crown of France in the year 1643. It nearly corresponds with the present department of the Somme.

Its principal rivers are the Somme, the Oise, the Canche, the Lanthie, the Lys, the Aa, the Scarpe, and the Deule.

The situation of this province on the sea, its many navigable rivers and canals, with the industry of the inhabitants, render it the seat of a flourishing trade. In it are many beautiful silk stuffs, woollen stuffs, coarse linen, lawn, and soap; it also carries on a large trade in corn and pit coal. In the districts of Calais and Boulogne are annually bred 5000 or 6000 colts, which being afterwards turned loose in the pastures of Normandy, are sold for Norman horses. The fisheries on this coast are also very advantageous. This province was formerly divided into Upper, Middle, and Lower Picardy, and again subdivided into four deputy governments. The principal town is Amiens.

PICCOLOMINI, ALEXANDER, archbishop of Patras, and a native of Sienna, where he was born about the year 1508, was of an illustrious and ancient family, which came originally from Rome, but afterwards settled at Sienna. He composed with success for the theatre; but he was not more distinguished by his genius, than by the purity of his manners, and his regard to virtue. His charity was very great; and was chiefly exerted in relieving the necessities of men of letters. He has left behind him a number of works in Italian; the most remarkable of which are, 1. Various Dramatic pieces, which laid the first foundation of his character as a writer. 2. A Treatise on the Sphere. 3. A Theory of the Planets. 4. A Translation of Aristotle's Art of Rhetoric and Poetry, in 4to. 5. A System of Morality published at Venice, 1575, in 4to; translated into French by Peter de Larivey in 4to; and printed at Paris, 1581. These, with a variety of other works, prove his extensive knowledge in natural philosophy, mathematics, and theology. He was the first who made use of the Italian language in writing upon philosophical subjects. He died at Sienna the 12th of March 1578, aged 70. A particular catalogue of his works may be seen in the Typographical Dictionary. There is one performance ascribed to this author, entitled *Dialogo della bella Creanta delle Donne*, (printed at Milan, 1558, and at Venice, 1574, in 8vo.); which but ill suits the dignity of a prelate. It is filled with maxims which have an evident tendency to hurt the morals of young women. Piccolomini's name, indeed, is not in the title page; and it has all the appearance of being a juvenile production. It is very scarce; and the public would sustain no loss by its being entirely out of print. It was translated into French by F. d'Amboise, and published at Lyons, in 16mo, under the title of *Instruction des jeunes dames*. It was afterwards reprinted in 1583, under that of *Dialogue et Devis des Demoiselles*.

PICCOLOMINI, *Francis*, of the same family with the foregoing, was born in 1520, and taught philosophy with success for the space of 22 years, in the most celebrated universities of Italy, and afterwards retired to Sienna, where he died, in 1604, at the age of 84. This city went into mourning on his death. His works are, 1. Some Commentaries upon Aristotle, printed at Mayence, 1608, in 4to. 2. *Universa Philosophia de Moribus*, printed at Venice, 1583, in folio. He laboured to revive the doctrine of Plato, and endeavoured also to imitate the manners of that philosopher. He had for his rival the famous James Zabarella, whom he excelled in facility of expression and neatness of discourse; but to whom he was much inferior in point of argument, because he did not examine matters to the bottom as the other did, but passed too rapidly from one proposition to another.

PICCOLOMINI of *Arragon, Octavius*, duke of Amalfi, prince of the empire, a general of the emperor's army, and knight of the order of the Golden Fleece, was born in 1599. He first bore arms among the Spanish troops in Italy. He afterwards served in the army of Ferdinand II. who sent him to the relief of Bohemia, and entrusted him with the command of the imperial troops in 1634. After having signalized himself at the battle of Nortlingue, he made Marshal de Chatillon raise the siege of St Omer. He had the good fortune to gain a victory over Marquis de Feuquieres in 1639: nor did the loss of the battle of Wolfenbuttle, in 1651, impair his glory. He died on the 10th of August 1656, being five years after, aged 57, without issue; and with the character of an able negotiator and an active general. The celebrated Caprara was his nephew.

PICCOLOMINI,

(A) The origin of the name of this province does not date earlier than A. D. 1200. It was an academical joke; an epithet first applied to the quarrelsome humour of those students in the university of Paris who came from the frontier of France and Flanders, and hence to their country. *Valesii Notitia Galliarum*, p. 447. *Longuerac, Description de la France*, p. 52.

PICCOLOMINI, *James*, whose proper name was *Ammanati*, took that of *Piccolomini* in honour of his patron Pius II. He was born in a village near Lucca in 1422. He became bishop of Massa, afterwards of Frescati; a cardinal in 1461, under the name of *Cardinal de Pavie*; and died in 1479, at the age of 57, of an indigestion of figs. He left 8000 pistoles in the bankers hands, which Pope Sixtus IV. claimed; and of which he gave a part to the Hospital of the Holy Ghost. His works, which consist of some Letters, and a history of his own time, were printed at Milan, in 1521, in folio. His history, entitled *Commentaries*, commences the 18th of June 1464, and ends the 6th of December 1469. They may very properly be considered as a Sequel of Pope Pius II.'s Commentaries, which end with the year 1463.

PICCOLOMINI, ÆNEAS SYLVIUS. See PIUS II.

PICENTIA, (Strabo, Pliny), the capital of the Picentini, whose territory, called *Ager Picentinus*, a small district, lay on the Tuscan sea, from the *Promontorium Minervæ*, the south boundary of Campania on the coast, to the river Silarus, the north boundary of Lucania, extending within-land as far as the Samnites and Hirpini, though the exact termination cannot be assigned. The Greeks commonly confound the *Pincentini* and *Picentes*, but the Romans carefully distinguish them. The former, with no more than two towns that can be named, *Silcrnum* and *Picentia*; the situation of both doubtful: only Pliny says the latter stood within-land, at some distance from the sea. Now thought to be *Bicenza*, (Holstenius), in the Principato Citra of Naples.

PICENUM, (Cæsar, Pliny, Florus); PICENUS AGER, (Cicero, Sallust, Livy, Tacitus); *Ager Picentium*, (Varro): a territory of Italy, lying to the east of Umbria, from the Apennine to the Adriatic; on the coast extending from the river Aesis on the north, as far as the *Prætutiani* to the south. In the upper or northern part of their territory the Umbri excluded them from the Appennine, as far as Camerinum, (Strabo); but in the lower or southern part they extended from the Adriatic to the Apennine. A very fruitful territory, and very populous. *Picentes*, the people, (Cicero); from the singular *Picens*, (Livy): different from the *Picentini* on the Tuscan sea, though called so by the Greeks; but Ptolemy calls them *Piceni*, as does also Pliny. Their territory at this day is supposed to form the greatest part of the March of Ancona, (Cluverius).

PICHFORD, in the county of Salop in England; on the south-east side of Shrewsbury, near Condover. It is noted for a spring of pitchy water (from whence some derive its name), on the top of which there always flows a sort of liquid bitumen. Over most of the coal pits in this neighbourhood there lies a stratum of blackish rock; of which, by boiling and grinding, they make pitch and tar, and also distil an oil from it.

PICHINCHA, or PINCHINCA, a mountain in Peru. See PERU, N° 56.

PICKERING, in the north riding of Yorkshire in England, 13 miles from Scarborough, and 125 from London, is a pretty large town belonging to the duchy of Lancaster, on a hill among the wild mountains of Blakemore; having the forest of Pickering on the north, and Pickering-common on the south. It is said to have been built 270 years before Christ by Peridurus, a king of the Britons, who was buried here. It had once a castle, the ruins of which are still to be seen; to whose jurisdiction many of the neighbouring villages were subject: and the adjacent territory, commonly called Pickering-Lath, or the liberty or forest of Pickering, was given by Henry III. to his son Edmund earl of Lancaster. A court is kept here for all actions under 40s. arising within the honour of Pickering.

PICKERY, in *Scots Law*, petty theft, or stealing things of small value.

PICKETS, in fortification, stakes sharp at one end, and sometimes shod with iron, used in laying out the ground, of about three feet long; but, when used for pinning the fascines of a battery, they are from three to five feet long.

PICKETS, in artillery, are about five or six feet long, shod with iron, to pin the park lines, in laying out the boundaries of the park.

PICKETS, in the camp, are also stakes of about six or eight inches long, to fasten the tent cords, in pitching the tents; also of about four or five feet long, driven into the ground near the tents of the horsemen, to tie their horses to.

PICKET, an out-guard posted before an army, to give notice of an enemy approaching.

PICKET, a kind of punishment so called, where a soldier stands with one foot upon a sharp-pointed stake; the time of his standing is limited according to the offence.

PICKLE, a brine or liquor, commonly composed of salt, vinegar, &c. sometimes with the addition of spices, wherein meat, fruit, and other things, are preserved and seasoned.

PICO, one of the Azores islands, is so called from some lofty mountains on it; or rather from one very high mountain, terminating like Teneriffe in a peak, and reputed by some writers equal to it in height. This island lies about four leagues south-west from St George, twelve from Tercera, and about three leagues south-east of Fayal; in W. Long. 28. 21. and N. Lat. 38. 29. The mountain Pico, which gives name to the island, is filled with dismal dark caverns or volcanoes, which frequently vomit out flames, smoke, and ashes, to a great distance. At the foot of this mountain towards the east is a spring of fresh water, generally cold, but sometimes so heated with the subterraneous fire, as to rush forth in torrents with a kind of ebullition like boiling water; equalling that in heat, and sending forth a steam of sulphureous fetid vapours, liquefied stones, minerals, and flakes of earth, all on fire, in such quantities, and with such a violence, as to have formed a kind of promontory vulgarly called *Mysterios*, on the declivity of the coast, and at the distance of 1200 paces from the fountain. Such at least is the account of Ortelius; though we do not find this last circumstance of the promontory confirmed by later observations. The circumference of Pico is computed at about 15 leagues: and its most remarkable places are Pico, Lagoas, Santa Cruce or Cruz, San Sebastian, Pesquin, San Roko, Playa, and Magdalena; the inhabitants of which live wholly on the produce of the island, in great plenty and felicity. The cattle are various, numerous, and excellent in their several kinds: it is the same with the vine; and its juice, prepared into different wines, the best in the Azores. Besides

Besides cedar and other timber, they have a kind of wood which they call *teixo*, solid and hard as iron; and veined, when finely polished, like a rich scarlet tabby; which colour it has in great perfection. The longer it is kept, the more beautiful it grows: hence it is, that the teixo tree is felled only for the king's use or by his order; and is prohibited from being exported as a common article of trade.

Pico *Marino*, a sea fish common at Kongo in Africa, derives its name from the resemblance of its mouth to the beak of a woodpecker. It is of large size, and prodigious strength, has four fins on its back, three under its belly, and one on each side of its head; its tail is large and forked, by which it cuts the waves with surprising force and velocity. It is at war with every fish that swims, and with every thing it meets in its way, without being intimidated by the largest vessels; a surprising instance of which intrepidity, we are told by some missionaries, whose ship was attacked by one of them, near these coasts, in the dead of night. The violence of the shock which it gave to the vessel quickly awakened the captain and the rest of the people; who immediately ran to the ship's side, where they perceived, by moonlight, this huge monster fastened by its forehead to the vessel, and making the strongest efforts to disengage itself; upon which some of them tried to pierce him with their pikes, but he got off before they could accomplish their aim. On the next morning, upon visiting that side of the vessel, they found a piece of the bony snout stuck fast into the wood, and two or three inches of it projecting outwards. In the inside of the ship, there was discovered about five or six inches more of the point of the horn, which had penetrated through the plank. But we must observe, that the credulity of the times probably rendered this animal thus formidable.

Mod. Univ. History vol xiii. p. 46. &c.

PICQUERING, flying war, or skirmish, made by soldiers detached from two armies for pillage, or before a main battle begins.

PICQUET, or Picket. See Piquet.

PICRAMNIA, a genus of plants belonging to the diœcia class; and in the natural method ranking with those that are doubtful. See Botany *Index*.

PICRANIA amara, or *Bitter Wood*, is a tall and beautiful timber tree, common in the woods of Jamaica, belonging to the pentandria class of plants. The name is expressive of its sensible qualities.

Every part of this tree is intensely bitter; and even after the tree has been laid for floors many years, whoever rubs or scrapes the wood, feels a great degree of bitterness in their mouth or throat. Cabinet-work made of this wood is very useful, as no insect will live near it.

This tree has a great affinity to the *Quassia Amara* of Linnæus; in lieu of which it is used as an antiseptic in putrid fevers. When used, less of it will do than of the *Quassia Amara* of Surinam. See Quassia, Botany and Materia Medica *Index*.

PICRIS, Ox-tongue; a genus of plants belonging to the syngenesia class. See Botany *Index*.

PICRIUM, a genus of plants belonging to the tetandria class; and in the natural method ranking with those that are doubtful. See Botany *Index*.

PICTET, Benedict, a celebrated divine, was born at Geneva, in 1655, of a distinguished family, and prosecuted his studies with great success. After having travelled into Holland and England, he taught theology in his own country with an extraordinary reputation. The university of Leyden, after the death of Spantreina, solicited him to come and fill his place; but he thought that his own country had the best right to his services; and for that generosity he received its thanks by the mouth of the members of council. A languishing disorder, occasioned by too much fatigue, hastened his death: which happened on the 9th of June 1724, at the age of 69 years. This minister had much sweetness and affability in his manner. The poor found in him a comforter and a father. He published a great number of works in Latin and French, which are much esteemed in Protestant countries. The principal of these are, 1. A System of Christian Theology in Latin, 3 vols. in 4to; the best edition of which is that of 1721. 2. Christian Morality, printed at Geneva, 1710, 8 vols. in 12mo. 3. The History of the 11th and 12th centuries; intended as a sequel to that of Sueur, printed in 1713, 2 vols. in 4to. The Continuator is held in higher estimation than the first author. 4. Several Controversial Treatises. 5. A great number of tracts on morality and piety; among which we must distinguish "the Art of Living and Dying well;" published at Geneva, 1705, in 12mo. 6. Some Letters. 7. Some Sermons, from 1697 to 1721; 4 vols. in 8vo. With a vast number of other books, the names of which it would be tedious to mention; but which, as Mr Sennebier says, "all show evident marks of piety and good sense."

Pictet, *John-Louis*, a counsellor of Geneva, born in 1739, was of the same family. He was member of the Council of Two Hundred; counsellor of State and Syndic; and died in 1781. He applied himself to the study of astronomy, and made several voyages into France and England for his improvement. Few men were ever blessed with a clearer or more enlightened understanding. He has left in manuscript the "Journal of a Voyage which he made to Russia and Siberia in 1768 and 1769, in order to observe the transit of Venus over the sun's disk:" A work very interesting, from the lively descriptions which it gives both of men and of nature.

PICTLAND. See Pentland.

1 Name.

PICTS, the name of one of those nations who anciently possessed the north of Britain. It is generally believed that they were so called from their custom of painting their bodies; an opinion which Camden supports with great erudition. (See Gough's edition, Vol. I. p. xci. of the preface). It is certainly liable, however, to considerable objections; for as this custom prevailed among the other ancient inhabitants of Britain, who used the *glastum* of Pliny and the *vitrum* of Mela for the like purpose, it may be asked, Why the name of *Picti* was confined by the Romans to only one tribe, when it was equally applicable to many others? Why should they design them only by an epithet, without ever annexing their proper name? Or why should they impose a new name on this people only, when they give their proper name to every other tribe which they have occasion to speak of? As these questions cannot be answered in any satisfactory manner, it is plain we must look for some other derivation of the name.

The Highlanders of Scotland, who speak the ancient language of Caledonia, express the name of this once famous

Picts.

mous nation by the term *Pictich*; a name familiar to the ears of the most illiterate, who could never have derived it from the Roman authors. The word *Pictich* means *pilferers* or *plunderers*. The appellation was probably imposed upon this people by their neighbours, or assumed by themselves, some time after the reign of Caracalla, when the unguarded state of the Roman province, on which this people bordered, gave them frequent opportunities of making incursions thither, and committing depredations. Accordingly this name seems to have been unknown till the end of the 3d century. Eumenius the panegyrist is the first Roman author who mentions this people under their new name of *Pictich*, or, with a Latin termination, *Picti*. When we say that this name may have been probably assumed for the reason just now mentioned, we must observe, that, in those days of violence, the character of a robber was attended with no disgrace. If he had the address to form his schemes well, and to execute them successfully, he was rather praised than blamed for his conduct; providing he made no encroachments on the property of his own tribe or any of its allies. We mean this as no peculiar stigma upon the Picts; for other nations of antiquity, in the like rude state, thought and acted as they did. See *Thucydides*, lib. iii. p. 3. and *Virg. Æn.* vii. 745 et 749.

2 Origin. Concerning the origin of the Picts, authors are much divided. Boethius derives them from the Agathyrsi, Pomponius Lætus from the Germans, Bede from the Scythians, Camden (A) and Father Innes from the ancient Britons, Stillingfleet from a people inhabiting the Cimbrica Chersonesus, and Keating and O'Flaherty, on the authority of the Cashel Psalter, derive them from the Thracians. But the most probable opinion is, that they were the descendants of the old Caledonians. Several reasons are urged in support of this opinion by Dr Macpherson; and the words of Eumenes, "Caledonum, aliorumque Pictorum, silvus," &c. plainly imply that the Picts and Caledonians were one and the same people.

As there has been much dispute about the origin of the Picts, so there has been likewise about their language. There are many reasons which make it plain that their tongue was the Gaelic or Celtic; and these reasons are a further confirmation of their having been of Caledonian extract. Through the east and north-east coasts of Scotland (which were possessed by the Picts) we meet with an innumerable list of names of places, rivers, mountains, &c. which are manifestly Gaelic. From a very

3 Language. old register of the priory of St Andrew's (Dalrymple's Collections, p. 122.) it appears, that in the days of Hungus, the last Pictish king of that name, St Andrew's was called *Mukross*; and that the town now called *Queensferry* had the name of *Ardchinneachan*. Both these words are plain Gaelic. The first signifies "the heath or promontory of boars;" and the latter, "the height or peninsula of Kenneth." In the list of Pictish kings published by Father Innes, most of the names are obviously Gaelic, and in many instances the same with the names in the list of Scottish or Caledonian kings published by the same author. Had Innes understood any thing of this language, he would not have supposed with Camden that the Picts spoke the British tongue. It was unlucky that the two words on which they built their conjecture (*Strath* and *Aber*) are as common in the Gaelic as they could have been in the British, and at this day make a part of the names of places in countries to which the Pictish empire never extended. The names of *Strathfillan* and *Lochaber* may serve as instances.

The venerable Bede, as much a stranger to the Celtic as either of the antiquaries just now mentioned, is equally unhappy in the specimen which he gives of the Pictish language in the word *penuahel*, "the head of the wall." Allowing the commutation of the initial *p* into *c*, as in some other cases, this word has still the same meaning in Gaelic which Bede gives it in the Pictish. It is true, there might have been then, as well as now, a considerable difference between various dialects of the Celtic; and thus, perhaps, that pious author was led to discover five languages in Britain *agreeably to the five books of Moses*: A conceit from which the good man derived a great deal of harmless satisfaction.

The Picts of the earliest ages, as appears from the joint testimony of all writers who have examined the subject, possessed only the east and north-east coast of Scotland. On one side, the ancient Drumalbin, or that ridge of mountains reaching from Lochlomond near Dumbarton to the frith of Tain, which separates the county of Sutherland from a part of Ross, was the boundary of the Pictish dominions. Accordingly we find in the life of Columba, that, in travelling to the palace of Brudius, king of the Picts, he travelled over Drumalbin, the *Dorsum Britanniæ* of Adamnan. On the other side, the territory of the Picts was bounded by the Roman province. After Britain was relinquished by the emperor Honorius, they and the Saxons by turns were masters of those countries which lie between the frith of Edinburgh and the river Tweed. We learn from Bede, that the Saxons were masters of Galloway when he finished his Ecclesiastical History. The Picts, however, made a conquest of that country soon after; so that, before the extinction of their monarchy, all the territories bounded on the one side by the Forth and Clyde, and on the other by the Tweed and Solway, fell into their hands. 4 Territory.

The history of the Picts, as well as of all the other ancient inhabitants of Britain, is involved in obscurity. The Irish historians give us a long list of Pictish kings, who reigned over Pictavia for the space of 11 or 13 centuries before the Christian era. After them Innes, in his Critical Essay, gives us a list of above fifty, of whom no less than five held the sceptre, each for a whole century. It is probable that these writers had confounded the history of the Picts with that of their ancestors the old Caledonians. In any other view, their accounts of them are highly fabulous; and have been long ago confuted by Dr Macpherson of Slate, an antiquary of much learning and research. The Picts, as has been already 5 History.

(A) See *Gough's edition of Camden*, Vol. I. Preface, p. xc. and the *Ancient Universal History*, Vol. XVII. p. 39, &c.

Picts.

already observed, were probably not known by that name before the 2d or 3d century. Adamnan, abbot of Iona, is the first author that expressly mentions any Pictish king; and the oldest after him is Bede. We are informed by these two writers, that St Columba converted Brudius king of the Picts to the Christian faith. Columba came into Britain in the year of the vulgar era 565. Before that period we have no general record to ascertain so much as the name of any Pictish king. The history of *Drust* or *Drest*, who is said to have reigned over the Picts in the beginning of the fifth century, when St Ninian first preached the gospel to that nation, has all the appearance of fiction (B). His having reigned a hundred years, and his putting an end to a hundred wars, are stories which exceed all the bounds of probability.

Brudius, the contemporary of Columba, is the first Pictish king mentioned by any writer of authority.

What figure his ancestors made, or who were his successors on the throne of Pictavia, cannot be ascertained. Bede informs us, that, during the reign of one of them, the Picts killed Egfred king of Northumberland in battle, and destroyed the greatest part of his army. The same author mentions another of their kings called *Naitan*, for whom he had a particular regard. It was to this *Naitan* that Ceolfrid, abbot of Wiremouth, wrote his famous letter concerning Easter and the Tonsure (C); a letter in which Bede himself is supposed to have had a principal hand. Roger Hoveden and Simon of Durham mention two other Pictish kings *Onnust* and *Kinoth*, the first of whom died in 761, and the latter flourished about the 744, and gave an asylum to Alfred of Northumberland, who was much about that time expelled his kingdom. The accounts given by the Scots historians of several other Pictish kings cannot be depended on; nor are the stories told by the British historians, Geoffroy of Monmouth and the author of the *Eulogium Britanniæ*, worthy of much greater credit.

In the ninth century the Pictish nation was totally subdued by the Scots in the reign of Kenneth Macalpin. Since that time their name has been lost in that of the conquerors, with whom they were incorporated after this conquest; however, they seem to have been treated by the Scottish kings with great lenity, so that for some ages after they commanded a great deal of respect. The prior of Hogulstead, an old English historian, relates, that they made a considerable figure in the army of David the Saint, in his disputes with Stephen king of England. In a battle fought in the year 1136, by the English on one side, and the Scots and Picts on the other, the latter insisted on their hereditary right of leading the van of the Scots army, and were indulged in that request by the king.

The principal seat of the Pictish kings was at Abernethy. Brudius, however, as appears from the accounts given by Adamnan, in his life of Columba, had a palace at Inverness, which was probably near the extremity of his territory in that quarter; for there is no good reason for believing, with Camden, that this king had any property in the Western Isles, or that he had made a gift of Iona to St Columba when he visited him in that place. 6

Manners.

With respect to the manners and customs of the Picts, there is no reason to suppose they were any other than those of the old Caledonians and Scots, of which many particulars are related in the Greek and Roman writers who have occasion to speak of those nations.

Upon the decline of the Roman empire, cohorts of barbarians were raised, and Picts were invited into the service, by Honorius, when peace was everywhere restored, and were named *Honoriaci*. Those under Constantine opened the passes of the Pyrenean mountains, and let the barbarous nations into Spain. From this period we date the civilization of their manners, which happened after they had by themselves, and then with the Scots, ravaged this Roman province.

PICTS Wall, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf strengthened with palisadoes, till the emperor Severus, coming into Britain in person, built it with solid stone. This wall, part of which still remains, began at the entrance of the Solway frith in Cumberland, and running north-east extended to the German ocean. See ADRIAN and SEVERUS.

PICTURE, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like. See PAINTING.

PICTURESQUE BEAUTY, says a late writer on that subject, refers to "such beautiful objects as are suited to the pencil." This epithet is chiefly applied to the works of nature, though it will often apply to works of art also. Those objects are most properly denominated picturesque, which are disposed by the hand of nature with a mixture of *varied rudeness*, *simplicity*, and *grandeur*. A plain neat garden, with little variation in its plan, and no striking grandeur in its position, displays too much of art, design, and uniformity, to be called picturesque. "The ideas of *neat* and *smooth* (says Mr Gilpin), instead of being picturesque, in fact disqualify the object in which they reside from any pretensions to picturesque beauty. Nay, farther, we do not scruple to assert, that roughness forms the most essential point of difference between the beautiful and the picturesque; as it seems to be that particular quality which makes

(B) According to Camden, this conversion happened about the year 630, in the southern Pictish provinces; while the northern, which were separated by fruitful mountains, were converted by Columba.

(C) We are told by sume authors that Columba taught the Picts to celebrate Easter always on a Sunday between the 14th and 20th of March, and to observe a different method of tonsure from the Romans, leaving an imperfect appearance of a crown. This occasioned much dispute till Naitan brought his subjects at length to the Roman rule. In that age many of the Picts went on a pilgrimage to Rome, according to the custom of the times; and amongst the rest we find two persons mentioned in the antiquities of St Peter's church. *Asterius* count of the Picts, and *Syra* with his countrymen, performed their vow.

Picturesque Beauty.

makes objects chiefly pleasing in painting. I use the general term *roughness*; but properly speaking roughness relates only to the surfaces of bodies: when we speak of their delineation, we use the word *ruggedness*. Both ideas, however, equally enter into the picturesque, and both are observable in the smaller as well as in the larger parts of nature; in the outline and bark of a tree, as in the rude summit and craggy sides of a mountain.

Let us then examine our theory by an appeal to experience, and try how far these qualities enter into the idea of picturesque beauty, and how far they mark that difference among objects which is the ground of our inquiry.

"A piece of Palladian architecture may be elegant in the last degree; the proportion of its parts, the propriety of its ornaments, and the symmetry of the whole, may be highly pleasing; but if we introduce it in a picture, it immediately becomes a formal object, and ceases to please. Should we wish to give it picturesque beauty, we must use the mallet instead of the chissel; we must beat down one half of it, deface the other, and throw the mutilated members around in heaps; in short, from a smooth building we must turn it into a rough ruin. No painter who had the choice of the two objects would hesitate a moment.

"Again, why does an elegant piece of garden-ground make no figure on canvas? the shape is pleasing, the combination of the objects harmonious, and the winding of the walk in the very line of beauty. All this is true; but the smoothness of the whole, though right and as it should be in nature, offends in picture. Turn the lawn into a piece of broken ground, plant rugged oaks instead of flowering shrubs, break the edges of the walk, give it the rudeness of a road, mark it with wheel tracks, and scatter around a few stones and brushwood; in a word, instead of making the whole smooth, make it rough, and you make it also picturesque. All the other ingredients of beauty it already possessed." On the whole, picturesque composition consists in uniting in one whole, a variety of parts, and these parts can only be obtained from rough objects.

It is possible, therefore, to find picturesque objects among works of art, and it is possible to make objects so; but the grand scene of picturesque beauty is nature in all its original variety, and in all its irregular grandeur. "We seek it (says our author) among all the ingredients of landscape, trees, rocks, broken grounds, woods, rivers, lakes, plains, valleys, mountains, and distances. These objects in themselves produce infinite variety; no two rocks or trees are exactly the same; they are varied a second time by combination; and almost as much a third time by different lights and shades and other aerial effects. Sometimes we find among them the exhibition of a whole, but oftener we find only beautiful parts."

Sublimity or grandeur alone cannot make an object picturesque: for, as our author remarks, "however grand the mountain or the rock may be, it has no claim to this epithet, unless its form, its colour, or its accompaniments, have some degree of beauty. Nothing can be more sublime than the ocean; but wholly unaccompanied, it has little of the picturesque. When we talk therefore of a sublime object, we always understand that it is also beautiful; and we call it sublime or beautiful only as the ideas of sublimity or simple beauty prevail. But it is not only the form and the composition of the objects of landscape which the picturesque eye examines; it connects them with the atmosphere, and seeks for all those various effects which are produced from that vast and wonderful storehouse of nature. Nor is there in travelling a greater pleasure than when a scene of grandeur bursts unexpectedly upon the eye, accompanied with some accidental circumstance of the atmosphere which harmonizes with it, and gives it double value."

There are few places so barren as to afford no picturesque scene.

————————Believe the muse,
She does not know that inauspicious spot
Where beauty is thus niggard of her store.
Believe the muse, through this terrestrial waste
The seeds of grace are sown, profusely sown,
Even where we least may hope.——

Mr Gilpin mentions the great military road between Newcastle and Carlisle as the most barren tract of country in England; and yet there, he says, there is "always something to amuse the eye. The interchangeable patches of heath and green-sward make an agreeable variety. Often too on these vast tracts of intersecting grounds we see beautiful lights, softening off along the sides of hills; and often we see them adorned with cattle, flocks of sheep, heath-cocks, grouse, plover, and flights of other wild fowl. A group of cattle standing in the shade on the edge of a dark hill, and relieved by a lighter distance beyond them, will often make a complete picture without any other accompaniment. In many other situations also we find them wonderfully pleasing, and capable of making pictures amidst all the deficiencies of landscape. Even a winding road itself is an object of beauty; while the richness of the heath on each side, with the little hillocks and crumbling earth, give many an excellent lesson for a foreground. When we have no opportunity of examining the grand scenery of nature, we have everywhere at least the means of observing with what a multiplicity of parts, and yet with what general simplicity, she covers every surface.

"But if we let the imagination loose, even scenes like these administer great amusement. The imagination can plant hills; can form rivers and lakes in valleys; can build castles and abbeys; and, if it find no other amusement, can dilate itself in vast ideas of space."

Mr Gilpin, after describing such objects as may be called picturesque, proceeds to consider their sources of amusement. We cannot follow our ingenious author through the whole of this consideration, and shall therefore finish our article with a short quotation from the beginning of it. "We might begin (says he) in moral style, and consider the objects of nature in a higher light than merely as amusement. We might observe, that a search after beauty should naturally lead the mind to the great origin of all beauty; to the

————first good, first perfect, and first fair.

But though in theory this seems a natural climax, we insist the less upon it, as in fact we have scarce ground to hope that every admirer of picturesque beauty is an admirer

admirer also of the beauty of virtue; and that every lover of nature reflects, that

> Nature is but a name for an *effect*,
> Whose *cause* is God.————

If, however, the admirer of nature can turn his amusements to a higher purpose; if its great scenes can inspire him with a religious awe, or its tranquil scenes with that complacency of mind which is so nearly allied to benevolence, it is certainly the better. *Apponat lucro.* It is so much into the bargain; for we dare not promise him more from picturesque travel than a rational and agreeable amusement. Yet even this may be of some use in an age teeming with licentious pleasure; and may in this light at least be considered as having a moral tendency.

PICUIPINIMA, is the Brasilian name of a species of pigeon, which is so very small as scarcely to exceed the lark in size.

PICUMNUS and PILUMNUS, were two Roman deities, who presided over the auspices required before the celebration of nuptials. Pilumnus was supposed to patronize children, as his name seems in some manner to indicate *quod pellat mala infantiæ*. The manuring of land was first invented by Picumnus, from which reason he is called *Sterquilinius*. Pilumnus is also invoked as the god of bakers and millers, as he is said to have first invented the art of grinding corn.

PICUS, the WOODPECKER, a genus of birds belonging to the order of Picæ. See ORNITHOLOGY *Index*.

PICUS, in fabulous history, a king of Latium, son of Saturn. He married Venilia, also called Canens, by whom he had Faunus. He was tenderly loved by the goddess Pomona, and he returned her affection. As he was one day hunting in the woods, he was met by Circe, who became deeply enamoured of him, and who changed him into a woodpecker, called by the name of *picus* among the Latins. His wife Venilia was so disconsolate when she was informed of his death, that she pined away. Some suppose that Picus was the son of Pilumnus, and that he gave out prophecies to his subjects by means of a favourite woodpecker; from which circumstance originated the fable of his being metamorphosed into a bird.

PICUS, *John Francis*, prince of Mirandola, nephew of John Pica or Picus, mentioned above, was born about the year 1469. He cultivated learning and the sciences after the example of his uncle; but he had a principality and dominion to superintend, which involved him in great troubles, and at last cost him his life. He was twice driven from his principality, and twice restored; and at last, in 1533, was, together with his eldest son Albert, assassinated in his own castle by his nephew Galeoti. He was a great lover of letters; and such of his works as were then composed were inserted in the Strasburg edition of his uncle's in 1504, and continued in future impressions, besides some others which were never collected.

PIECE, in matters of money, signifies sometimes the same thing with species; and sometimes, by adding the value of the pieces, it is used to express such as have no other particular name. For the piece of eight, or piastre, see MONEY TABLE.

PIECE, is also a kind of money of account, or rather manner of accounting, used among the negroes on the coast of Angola in Africa. See MONEY *Table*.

PIECE, in *Heraldry*, denotes an ordinary or charge. The honourable pieces of the shield are the chief, fess, bend, pale, bar, cross, saltier, chevron, and in general all those which may take up one-third of the field, when alone, and in what manner soever it be. See HERALDRY.

PIECES, in the military art, include all sorts of great guns and mortars. Battering pieces are the larger sort of guns used at sieges for making the breaches; such are the 24-pounder and culverine, the one carrying a 24 and the other an 18 pound ball. Field-pieces are 12 pounds, demiculverines, 6-pounders, sackers, minions, and 3-pounders, which march with the army, and encamp always behind the second line, but in day of battle are in the front. A soldier's firelock is likewise called his *piece*.

PIEDMONT, a country of Italy, having formerly the title of a principality, is bounded on the north by Savoy and Italy; on the west by France; on the south by the Mediterranean and the republic of Genoa; and on the east by the duchies of Montferrat and Milan; extending about 150 miles from north to south, but much less from east to west. It is called Piedmont, and in Latin *Piedmontium*, from its situation at the foot of the mountains, or Alps, which separate France from Italy. This country is in some parts mountainous, but is everywhere very fruitful. The plains produce fine corn, and Montferrat and the Milanese yield great quantities of Turkey wheat, which commonly serves for bread, and with which the people of the middle rank mix rye; the pods are used for fuel, and the stalks being thick serve to mend the roads. The hills produce plenty of wine, which, like the Italian wines, is very luscious when new, especially the white. There is also a tartish red wine called *vino brusco*, said to be very wholesome for fat people, and, on the other hand, the sweet wine is recommended as a stomachic. The neighbourhood of Turin is famous for its fine fruits, and many long walks of chesnut and mulberry trees, which produce both pleasure and profit. Marons, or large chesnuts, are a favourite dainty among the common people. These are put into an oven, and, when thoroughly hot, and cooled in red wine, are dried a second time in the oven, and afterwards eaten cold. Truffles grow here in such abundance, that Piedmont has obtained the name of the *truffle country*. Some are black, others white marbled with red. Their price is rated according to their size. Sometimes they are found of 12 or 14 pounds weight; and many country people earn from 60 to 70 dollars a-year merely by digging for them. The trade in cattle is said to bring into Piedmont no less than three millions of livres per annum. The cultivation of silk is also a profitable article, the Piedmontese silk being, on account of its fineness and strength, esteemed the best in Italy. The Piedmontese gentry breed vast numbers of silk-worms under the care of their tenants, who have the eggs and mulberry leaves delivered to them, and in return they give half the silk to their masters. This principality comprehends eleven small provinces: Piedmont proper, the valleys between France and Italy, the valley of Saluza, the county of Nice, the marquisate of Susa, the duchy of Aost, the Canavese, the lordship of Vetsail,

sail, the county of Ast, and the Langes. It was formerly a part of Lombardy, but now belongs to the king of Sardinia, and lies at the foot of the Alps, which separate France from Italy. It contains many high mountains, among which there are rich and fruitful valleys, as pleasant and populous as any part of Italy. In the mountains are mines of several kinds, and the forests afford a great deal of curious game, among which the *tumor* is an useful animal. "The mules (says Mr Watkins) are very fine in this country; but the inhabitants have other beasts, or rather monsters, which they find very serviceable, though vicious and obstinate. These are produced by a cow and an ass, or mare and bull, and called *jumarres* or *gimerri* (A). I cannot say that I have ever seen any of them, but I am told they are very common."

The Piedmontese are said to be more intelligent than the Savoyards, but less sincere. Some authors represent them as lively, artful, and witty, the inhabitants of the mountain of Aosta excepted, who are farther distinguished by large wens, as even their horses, dogs, and other animals. Mr Baretti, however, in his *Account of Italy*, vol. ii. p. 116. gives the following account of them. "One of the chief qualities (says he), which distinguish the Piedmontese from all other Italians, is their want of cheerfulness. Piedmont never produced a single good poet, as far as the records of the country can go, whereas there is no other province of Italy but what can boast of some poet ancient or modern; and yet the Piedmontese are not deficient in several branches of learning, and some of them have succeeded tolerably well in civil law, physic, and the mathematics. It is likewise observed of this people, that none of them ever attained to any degree of excellence in the polite arts, and it is but lately that they can boast of a painter, Cavaliero Bomente; a statuary, Signor Lodetto; and some architects, Conte Alfieri, Signor Borra, and others, who yet, to say the truth, are far inferior to numberless artists produced by the other provinces of Italy. They have, on the other hand, greatly advanced when considered as soldiers; though their troops have never been very numerous, every body conversant in history knows the brave stand they made for some centuries past against the French, Spaniards, and Germans, whenever they have been invaded by these nations. The skill of the Piedmontese in fortification is likewise very great, and their Benlas and Pintos have shown as much genius as the Vaubans and Cohorns, in rendering impregnable several places which inferior engineers would only have made secure."

Payne's Geog. vol. ii.

The chief trade of this principality consists in hemp and silk. Indeed, so great is their trade in raw silk, that the English alone have purchased to the value of 200,000 lib. in a year. The silk worm thrives so well, that many peasants make above (B) 100 lib. of silk annually; and it is not only abundant, but universally known to be stronger and finer than any in Italy. The land owners divide the profit with their tenants. The Piedmontese workmen, however, are said to want expertness, though they finish their work equally well with those of other natoins. The high duty and land-carriage on mules likewise tend to lessen the value of this trade. They have besides corn, rice, wine, fruits, flax, and cattle.

In the valleys of Lucerne, Peyrouse, and St Martin, which have always belonged to Piedmont, live the celebrated Waldenses or Vaudois, a name which signifies *people of the valleys*. These have rendered themselves famous in history for their dissent from the Romish church long before the time of Luther and Calvin, and for the persecutions they have suffered on that account; but since the year 1730 they have not been openly molested for their religion, but, in order to suppress them by degrees, a popish church has been built in every parish. They are heavily taxed, and labour under great oppressions. The number of people in these valleys scarce at present exceeds 10,000, of which 1000 are Catholics. The chief river of Piedmont is the Po, which flows out of Mount Viso. The river Sesia, the Doria, Baltea, the ancient Druria, the Tenaro, and several others, run into it. The Var, anciently called the Varus, rises in the county of Nice, and after watering it empties itself into the Mediterranean. The language of the Piedmontese is a mixture of French and Italian. In this country are about 50 earldoms, 15 marquisates, a multitude of lordships, and 20 abbeys. Though the country be entirely popish, except some valleys inhabited by the Waldenses, the king reserves to himself the greatest part of the power in church affairs, which in many other places is given up to the pope, and the constitution *unigenitus* is here universally opposed. Towards the end of the 17th century, the French king persuaded the duke of Savoy to drive them out of the country; in consequence of which 200,000 of them retired to Germany, England, and Holland, and yet they are not all extirpated, though, as we have observed, they are obliged to have a Roman Catholic church in every parish.

Turin, formerly the residence of the king of Sardinia, to whom this principality belonged, is the chief city. See TURIN. The number of inhabitants, Mr Watkins says, in Piedmont and Savoy, amount to 2,695,727 souls, of which Turin contains about 77,000. Piedmont was long subject to France, but was restored to the king of Sardinia with the rest of his continental dominions in 1814.

PIENES, a small island of Japan, opposite to the harbour of Saccai, is famed not only for the beauty of its walks, to which crowds of people resort from the city, but for a deity worshipped there, to which vast numbers of persons devote themselves. They go from his temple to the sea side, where they enter into a boat provided

(A) These equivocal animals, however, if we may so term them, are so generally mentioned by travellers in this part of Europe, that we have no doubt of their existence, or of their being found hardy and serviceable as labourers.

(B) Each pound is valued in Piedmont at 18s. The little village of La Tour, in the valley of Lucerne, makes above 50,000 lb. annually, and the exports every year to the single city of Lyons amount to more than 160,000l. sterling.

provided for the purpose; then, launching into the deep, they throw themselves overboard, loaded with stones, and sink to the bottom. The temple of that deity, which is called Canon, is very large and lofty, and so are many others in the city itself; one in particular, dedicated to the gods of other countries, is thought the finest in the whole empire.

PIEPOUDRE, Court of, the lowest, and at the same time the most expeditious, court of justice known to the law of England. It is called PIEPOUDRE, (*curia pedis pulverizati*), from the dusty feet of the suitors; or, according to Sir Edward Coke, because justice is there done as speedily as dust can fall from the foot: Upon the same principle that justice among the Jews was administered in the gate of the city, that the proceedings might be the more speedy, as well as public. But the etymology given us by a learned modern writer is much more ingenious and satisfactory; it being derived, according to him, from *pied puldreaux*, "a pedlar," in old French, and therefore signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record incident to every fair and market; of which the steward of him who owns or has the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one. So that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer. The court hath cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of an action arose there. From this court a writ of error lies, in the nature of an appeal, to the courts at Westminster. The reason of its institution seems to have been, to do justice expeditiously among the variety of persons that resort from distant places to a fair or market; since it is probable, that no other inferior court might be able to serve its process, or execute its judgments, on both or perhaps either of the parties; and therefore, unless this court had been erected, the complaint must necessarily have resorted even in the first instance to some superior judicature.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortress to the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

Piers of a Bridge. See Bridge.

PIERCEA. See Rivinia.

PIERIA, in *Ancient Geography*, a district of Macedonia, contained between the mouths of the rivers Ludias and Peneus; extended by Strabo beyond the Ludias, to the river Axios on the north, and on the south no farther than the Aliacmon, along the west side of the Sinus Thermaicus.—Another *Pieria* of Syria, the north part of Seleucia, or the *Antiochena*, situated on the Sinus Issicus, and lying next Cilicia to the north-west.

PIERIDES, in fabulous history, the daughters of Pierus a Macedonian prince, presuming to dispute with the muses for the prize of poetry, were turned into magpies. The name of *Pierides* was also given to the muses, from Mount Pieris in Thessaly, which was consecrated to them; or, according to others, from Pieris, a Thessalian poet, who was the first who sacrificed to them. See Pieris.

PIERINO del Vaga, an eminent Italian painter, born of poor parents in Tuscany, about the year 1500. He was placed apprentice with a grocer in Florence, and got some instructions from the painters to whom he was sent with colours and pencils; but a painter named *Vaga* taking him to Rome, he was called *Del Vaga*, from living with him, his real name being *Buanacorsi*. He studied anatomy with the sciences necessary for his profession; and had somewhat of every thing that was good in his compositions. After Raphael's death, he joined with Julio Romano and Francisco Penni to finish the works in the Vatican which were left imperfect by their common master; and to confirm their friendship married Penni's sister. He gained the highest reputation by his performances in the palace of Prince Doria at Genoa: but the multiplicity of his business, and the vivacity of his imagination, drained his spirits in the flower of his age; for he died in the year 1547. Of all Raphael's disciples, Pierino kept the character of his master longest, i. e. his exterior character and manner of designing; for he fell very short of the fineness of Raphael's thinking. He had a particular genius for the decoration of places according to their customs. His invention in that kind of painting was full of ingenuity; grace and order are everywhere to be met with, and his dispositions, which are ordinary in his pictures, are wonderful in his ornaments: some of these he has made little, and some great, and placed them both with so much art, that they set off one another by comparison and contrast. His figures are disposed and designed according to Raphael's gusto; and if Raphael gave him at first some slight sketches of ornaments, as he did to Giovanni d'Udine, he executed them to admiration. The tapestries of the seven planets, in seven pieces, which Pierino designed for Diana de Poitiers, and which were, when De Piles wrote, with Monsieur the first president at Paris, show sufficiently what he was, and that the above character does not exceed the truth.

PIERIS, in *Ancient Geography*, a mountain which is thought to have given name to Pieria of Macedonia; taking its name from Pierus a poet, who was the first that sacrificed to the Muses, thence called *Pierides*, if credit may be given to an ancient scholiast on Juvenal.

PIERRE d'automne is a French name, translated from the Chinese, of a medicinal stone, celebrated in the east for curing all disorders of the lungs. Many imagine it had its name of the autumn-stone from its being only to be made at that season of the year; but it may certainly be made equally at all times. The Chinese chemists refer the various parts of the body to the several seasons of the year, and thus they refer the lungs to autumn. This is evident in their writings, and thus the stone for diseases of the lungs came to be called *autumn-stone*. It is prepared as follows: They put 30 pints of the urine of a strong and healthy young man into a large iron pot, and set it over a gentle fire. When it begins to boil, they add to it, drop by drop, about a large tea-cup-full of rape oil. They then leave it on the fire till the whole is evaporated to a thick substance like black mud. It is then taken out of the pot, and

and laid on a flat iron to dry, so that it may be powdered very fine. The powder is moistened with fresh oil, and the mass is put into a double crucible, surrounded with coals, where it stands till it be thoroughly dried again. This is again powdered, and put into a china vessel, which being covered with a silk cloth and a double paper, they pour on it boiling water, which makes its way, drop by drop, through those coverings, till so much is got in as is sufficient to reduce it to a paste. This paste is well mixed together in the vessel it is kept in, and this is put into a vessel of water, and the whole set over the fire. The matter thus becomes again dried in *balneo mariæ*, and is then finished. *Observ. sur les Cout. de l'Asie*, p. 258.

PIERRE, *St*, is a large river in North America, scarcely inferior to the Rhine or the Danube, and navigable almost to its source. Together with many other large streams, it falls into the river Mississippi.

PIERRE, *St*, or *St Peter's*, the capital of Martinico, was built in 1665, in order to overawe the mutineers of the island who rebelled against its proprietors, the second West India Company, who were at the same time the proprietors of all the French Antilles. It is situated on the western side of the island. The town extends along the shore, and a battery that commands the road is erected on the west side, which is washed by the river Royolan, or St Peter. The town is divided into three wards; the middle, which is properly St Peter's, begins at the fort, and runs westward to the battery of St Nicholas. Under the walls of the second ward ships at anchor ride more securely than under the fort, on which account this ward is called the *Anchorage*. The third ward, called the *Gallery*, extends along the sea side from Fort St Peter to the Jesuits River, and is the most populous part of the city. The houses of St Peter's ward are neat, commodious, and elegant, particularly those of the governor of the island, the intendant, and the other officers. The parish church of St Peter is a magnificent stone building which belonged to the Jesuits, with a noble front of the Doric order. The church of the Anchorage, which belongs to the Jacobine friars, is likewise of stone. It is a place of considerable trade, and is built with tolerable regularity. The houses are mostly constructed of a gray pumice-stone or lava, which is found on the strand; and the high-street is, according to Dr Isert, above an English mile in length. It is supposed to contain about 2000 houses, and 30,000 inhabitants, including negroes. St Pierre, with the whole of the flourishing island of Martinico, was taken from the French in the month of March 1794, by the British troops: 125 vessels loaded with the produce of the island, and of great value, were captured, 71 of which were in the harbour of St Pierre.

PIETISTS, a religious sect, sprung up among the Protestants of Germany, seeming to be a kind of mean between the Quakers of England and the Quietists of the Romish church. They despise all sorts of ecclesiastical polity, all school theology, and all forms and ceremonies, and gave themselves up to contemplation and the mystic theology. Many gross errors are charged on the Pietists, in a book entitled *Manipulus Observationum Antipietisticarum*; but they have much of the air of polemical exaggeration, and are certainly not at all just. Indeed there are Pietists of various kinds: Some running into gross illusions, and carrying their errors to the overturning of a great part of the Christian doctrine, while others are only visionaries; and others are very honest and good, though perhaps misguided, people. They have been disgusted with the coldness and formality of other churches, and have thence become charmed with the fervent piety of the Pietists, and attached to their party, without giving into the grossest of their errors. See *Mosheim's Eccl. History*, vol. iv. p. 454.

PIETISTS, otherwise called the *Brethren and Sisters of the Pious and Christian Schools*, a society formed in the year 1678 by Nicholas Barre, and obliged by their engagements to devote themselves to the education of poor children of both sexes.

PIETOLA, anciently called *Andes*, is a place within two Italian miles of Mantua, famous for being the birthplace of Virgil.

PIETY, is a virtue which denotes veneration for the Deity, and love and tenderness to our friends. This distinguished virtue, like many others, received among the Romans divine honours, and was made one of their gods. Acilius Glabrio first erected a temple to this divinity, which he did upon the spot on which a woman had fed with her own milk her aged father, who had been imprisoned by order of the senate, and deprived of all aliments. The story is well known, and is given at length in authors which are in the hands of every schoolboy. See *Cicero de div.* I. and *Valerius Maximus*, v. c. 4. and our article *FILIAL Piety*.

If piety was thus practised and thus honoured in Heathen antiquity, it surely ought not to be less so, among Christians, to whom its nature is better defined, and to the practice of which they have motives of greater cogency. A learned and elegant writer has said that the want of piety arises from the want of sensibility; and his observations and arguments are so just and so well expressed, that we cannot do better than transcribe them.

"It appears to me (says Dr Knox), that the mind of man, when it is free from natural defects and acquired corruption, feels no less a tendency to the indulgence of devotion than to virtuous love, or to any other of the more refined and elevated affections. But debauchery and excess contribute greatly to destroy all the susceptible delicacy with which nature usually furnishes the heart; and, in the general extinction of our better qualities, it is no wonder that so pure a sentiment as that of piety should be one of the first to expire.

"It is certain that the understanding may be improved in a knowledge of the world, and in the arts of succeeding in it, while the heart, or whatever constitutes the seat of the moral and sentimental feelings, is gradually receding from its proper and original perfection. Indeed experience seems to evince, that it is hardly possible to arrive at the character of a complete man of the world, without losing many of the most valuable sentiments of uncorrupted nature. A complete man of the world is an artificial being; he has discarded many of the native and laudable tendencies of his mind, and adopted a new system of objects and propensities of his own creation. These are commonly gross, coarse, sordid, selfish, and sensual. All, or either of these attributes, tend directly to blunt the sense of every thing liberal, enlarged, disinterested; of every thing which participates more of an intellectual than of a sensual nature. When the heart is tied down to the earth by lust and avarice, it is not extraordinary that the eye should be seldom

 seldom lifted up to heaven. To the man who spends his Sunday (because he thinks the day fit for little else) in the counting-house, in travelling, in the tavern, or in the brothel, those who go to church appear as fools, and the business they go upon as nonsense. He is callous to the feelings of devotion; but he is tremblingly alive to all that gratifies his senses or promotes his interest.

"It has been remarked of those writers who have attacked Christianity, and represented all religions merely as diversified modes of superstition, that they were indeed, for the most part, men of a metaphysical and a disputatious turn of mind, but usually little distinguished for benignity and generosity. There was, amidst all their pretensions to logical sagacity, a cloudiness of ideas, and a coldness of heart, which rendered them very unfit judges on a question in which the heart is chiefly interested; in which the language of nature is more expressive and convincing, than all the dreary subtleties of the dismal metaphysicians. Even the reasoning faculty, on which we so greatly value ourselves, may be perverted by excessive refinement; and there is an abstruse, but vain and foolish philosophy, which philosophizes us out of the noblest parts of our noble nature. One of those parts of us is our instinctive sense of religion, of which not one of those brutes which the philosophers most admire, and to whose rank they wish to reduce us, is found in the slightest degree to participate.

"Such philosophers may be called, in a double sense, the enemies of mankind. They not only endeavour to entice man from his duty, but to rob him of a most exalted and natural pleasure. Such, surely, is the pleasure of devotion. For when the soul rises above this little orb, and pours its adoration at the throne of celestial majesty, the holy fervour which it feels is itself a rapturous delight. Neither is this a declamatory representation, but a truth felt and acknowledged by all the sons of men; except those who have been defective in sensibility, or who hoped to gratify the pride or the malignity of their hearts by singular and pernicious speculation.

"Indeed all disputatious, controversial, and metaphysical writings on the subject of religion, are unfavourable to genuine piety. We do not find that the most renowned polemics in the church militant were at all more attentive than others to the common offices of religion, or that they were actuated by any peculiar degree of devotion. The truth is, their religion centered in their heads, whereas its natural region is the heart. The heart! confined, alas! in colleges or libraries, unacquainted with all the tender charities of husband, father, brother, friend; some of them have almost forgotten that they possess a heart. It has long ceased to beat with the pulsations of love and sympathy, and has been engrossed by pride on conquering an adversary in the syllogistic combat, or by impotent anger on a defeat. With such habits, and so defective a system of feelings, can we expect that a doctor of the Sorbonne, or the disputing professor of divinity, should ever feel the pure flame of piety that glowed in the bosoms of Mrs Rowe, Mrs Talbot, or Mr Nelson?

"It is however certain, that a devotional taste and habit are very desirable in themselves, exclusive of their effects in meliorating the morals and disposition, and promoting present and future felicity. They add dignity, pleasure, and security to any age: but to old age they are the most becoming grace, the most substantial support, and the sweetest comfort. In order to preserve them, it will be necessary to preserve our sensibility; and nothing will contribute so much to this purpose as a life of temperance, innocence, and simplicity."

Of piety, as it denotes love and tenderness to our friends, there have been many distinguished instances both in ancient and modern times. See *Filial Piety*, *Fraternal* and *Parental Affection*, &c.

The following example of filial piety in China, taken from P. Du Halde's description of that country, will not we trust be disagreeable to our readers. "In the commencement of the dynasty of the Tang, Lou-tao-tsong, who was disaffected to the government, being accused of a fault, which touched his life, obtained leave from those who had him in custody, to perform the duties of the Tao to one of his diseased friends. He managed matters so well, that giving his keepers the slip, he fled to the house of Lou Nan-kin, with whom he had a friendship, and there hid himself. Lou Nan-kin, notwithstanding the strict search that was made, and the severity of the court against those who conceal prisoners that have escaped, would not betray his friend. However, the thing coming to be discovered, Lou Nan-kin was imprisoned; and they were just on the point of proceeding against him, when his younger brother presenting himself before the judge, *It is I, Sir*, said he, *who have hidden the prisoner; it is I who ought to die, and not my elder brother*. The eldest maintained on the contrary, that his younger brother accused himself wrongfully, and was not at all culpable. The judge, who was a person of great sagacity, sifted both parties so effectually, that he not only discovered that the younger brother was innocent, but even made him confess it himself: *It is true, Sir*, said the younger all in tears, *I have accused myself falsely; but I have very strong reasons for so doing. My mother has been dead for some time, and her corpse is not yet buried; I have a sister also who is marriageable, but is not yet disposed of: these things which my brother is capable of managing, I am not, and therefore desire to die in his stead. Vouchsafe to admit my testimony*. The commissioner gave an account of the whole affair to the court, and the emperor at his solicitation pardoned the criminal."

PIG, see Sus, } Mammalia *Index*.
Guinea-Pig, see Mus, }

Pig of lead, the eighth part of a fother, amounting to 250 pounds weight.

PIGANIOL de la Force, John Aymar de, a native of Auvergne, of a noble family, applied himself with ardour to the study of geography and of the history of France. With the view of improving himself in this study, he travelled into different provinces; and, in the course of his travels, made some important observations on the natural history, the commerce, the civil and ecclesiastical government of each province. These observations were of great use to him in compiling the works he has left behind him, of which the chief are, 1. An Historical and Geographical Description of France; the largest edition of which is that of 1753, in 15 vols. 12mo. It is the best work which has hitherto appeared upon that subject, though it contains a great number of inaccuracies and even errors. 2. A Description of Paris, in 10 vols. 12mo; a work equally entertaining and instructive, and much more complete than the description given by Germain Brice: besides, it is written with an elegant simplicity.

simplicity. He published an abridgement of it in 2 vols. 12mo. 3. A Description of the Castle and Park of Versailles, Marly, &c. in 2 vols. 12mo: it is very amusing, and pretty well executed. Piganiol had also a concern with Abbé Nadal in the journal of Trevoux. He died at Paris in February 1753, at the age of 80 years. This learned man was as much to be respected for his manners as for his talents. To a profound and varied knowledge he united great probity and honour, and all the politeness of a courtier.

PIGEON, see COLUMBA, ORNITHOLOGY *Index*.

PIGEON-House is a house erected full of holes within, for the keeping, breeding, &c. of pigeons, otherwise called a *dove-cot*.

Any lord of manor may build a pigeon-house on his land, but a tenant cannot do it without the lord's licence. When persons shoot at or kill pigeons within a certain distance of the pigeon-house, they are liable to pay a forfeiture.

In order to erect a pigeon-house to advantage, it will be necessary, in the first place, to pitch upon a convenient situation; of which none is more proper than the middle of a spacious court-yard, because pigeons are naturally of a timorous disposition, and the least noise they hear frightens them. With regard to the size of the pigeon-house, it must depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too little; and as to its form, the round should be preferred to the square ones; because rats cannot so easily come at them in the former as in the latter. It is also much more commodious; because you may, by means of a ladder turning upon an axis, easily visit all the nests in the house, without the least difficulty; which cannot so easily be done in a square house. In order to hinder rats from climbing up the outside of the pigeon-house, the wall should be covered with tin plates to a certain height, about a foot and a half will be sufficient; but they should project out three or four inches at the top, to prevent their clambering any higher.

The pigeon-house should be placed at no great distance from water, that the pigeons may carry it to their young ones; and their carrying it in their bills will warm it, and render it more wholesome in cold weather. The boards that cover the pigeon-house should be well joined together, so that no rain may penetrate through it: and the whole building should be covered with hard plaster, and white-washed within and without, white being the most pleasing colour to pigeons. There must be no window, or other opening in the pigeon-house to the eastward; these should always face the south, for pigeons are very fond of the sun, especially in winter.

The nests or covers in a pigeon-house should consist of square holes made in the walls, of a size sufficient to admit the cock and hen to stand in them. The first range of these nests should not be less than four feet from the ground, that the wall underneath being smooth, the rats may not be able to reach them. These nests should be placed in quincunx order, and not directly over one another. Nor must they be continued any higher than within three feet of the top of the wall: and the upper row should be covered with a board projecting a considerable distance from the wall, for fear the rats should find means to climb the outside of the house.

M. Duhamel thinks that pigeons neither feed upon the green corn, nor have bills strong enough to search for its seeds in the earth; but only pick up the grains that are not covered, which would infallibly become the prey of other animals, or be dried up by the sun. "From the time of the sprouting of the corn, says he, pigeons live chiefly upon the seeds of wild uncultivated plants, and therefore lessen considerably the quantity of weeds that would otherwise spring up; as will appear from a just estimate of the quantity of grain necessary to feed all the pigeons of a well-stocked dove-house." But Mr Worlidge and Mr Lisle allege facts in support of the contrary opinion. The latter relates, that a farmer in his neighbourhood assured him he had known an acre sowed with pease, and rain coming on so that they could not be harrowed in, every pea was fetched away in half a day's time by pigeons: and the former says, "It is to be observed, that where the flight of pigeons falls, there they fill themselves and away, and return again where they first rose, and so proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground, they know how to find it. I have seen them lie so much upon a piece of about two or three acres sown with pease, that they devoured at least three parts in four of the seed, which, I am sure, could not be all above the surface of the ground. That their smelling is their principal director, I have observed; having sown a small plat of pease in my garden, near a pigeon-house, and covered them so well that not a pea appeared above ground. In a few days, a parcel of pigeons were hard at work in discovering this hidden treasure; and in a few days more I had not above two or three peas left out of about two quarts that were planted; for what they could not find before, they found when the buds appeared, notwithstanding they were hoed in, and well covered. Their smelling alone directed them, as I supposed, because they followed the ranges exactly. The injury they do at harvest on the pease, vetches, &c. is such that we may rank them among the greatest enemies the poor husbandman meets withal; and the greater, because he may not erect a pigeon-house, whereby to have a share of his own spoils; none but the rich being allowed this privilege, and so severe a law being also made to protect these winged thieves, that a man cannot encounter them, even in defence of his own property. You have therefore no remedy against them, but to affright them away by noises or such like. You may, indeed, shoot at them; but you must not kill them; or you may, if you can, take them in a net, cut off their tails, and let them go; by which means you will impound them: for when you are in their houses, they cannot bolt or fly out of the tops of them, but by the strength of their tails; after the thus weakening of which, they remain prisoners at home."

Mr Worlidge's impounding the pigeons reminds us of a humorous story of a gentleman, who, upon a neighbouring farmer's complaining to him, that his pigeons were a great nuisance to his land, and did sad mischief to his corn, replied jokingly, Pound them, if you catch them trespassing. The farmer, improving the hint, steeped a parcel of pease in an infusion of *coculus indicus*, or some other intoxicating drug, and strewed them upon his grounds. The pigeons swallowed them, and soon remained motionless on the field: upon which the farmer threw a net over them, inclosed them in it, and carried

ried them to an empty barn, from whence he sent the gentleman word that he had followed his directions with regard to the pounding of his pigeons, and desired him to come and release them.

Carrier-PIGEON. See CARRIER-*Pigeon* and COLUMBA, ORNITHOLOGY *Index*.

PIGEON, *Peter Charles Francis*, curate of St Peter du Regard, in the diocese of Bayeux, was one of the priests lately belonging to the king's house at Winchester. He was born in Lower Normandy, of honest and virtuous parents, and of a decent fortune. His inclinations early led him to embrace the ecclesiastical state, from which neither the solicitations of his friends, nor the prospect of a more ample fortune on the death of his elder brother, could withdraw him. Several of his schoolfellows and masters, who are now resident in the king's house at Winchester, bear the most ample testimony to his assiduity, regularity, piety, and the sweetness of his disposition, during the whole course of his education. The sweetness of temper, in particular, was so remarkable, and so clearly depicted on his countenance, as to have gained him the esteem and affection of such of the inhabitants of Winchester as by any means had become acquainted with him. He was seven years employed in quality of vicar, or, as we should call it *curate*, of a large parish in the diocese of Seez, where his virtues and talents had ample scope for exertion. His practice was to rise at five o'clock every morning, and to spend the whole time till noon (the usual time of dining for persons in his station) in prayer and study. The rest of the day, till evening, he devoted to visiting the sick, and other exterior duties of his function. In 1789, the year of the French revolution, M. Pigeon was promoted to a curacy, or rather a rectory, in the diocese of Bayeux, called the *parish of St Peter du Regard*, near the town of Condè sur Noereau. It was easy for him to gain the good-will and the protection of his parishioners; but a Jacobin club in the above-mentioned town seemed to have no other subject to deliberate upon than the various ways of harassing and persecuting M. Pigeon and certain other priests in the neighbourhood, who had from motives of conscience refused the famous civic oath. It would be tedious to relate the many cruelties which were at different times exercised upon him, and the imminent danger of losing his life to which he was exposed, by the blows that were inflicted on him, by his being thrown into water, and being obliged to wander in woods and other solitary places, without any food or place to lay his head, in order to avoid his persecutors. We may form some judgment of the spirit of his persecutors from the following circumstance. Being disappointed on a particular occasion in the search they were making after M. Pigeon, with the view of amusing themselves with his sufferings, they made themselves amends by seizing his mother, a respectable lady of 74 years of age, and his two sisters, whom they placed upon asses with their faces turned backwards, obliging them in derision to hold the tails of these animals. Thus they were conducted in pain and ignominy throughout the whole town of Condè, for no other alleged crime except being the nearest relations of M. Pigeon. At length the decree for transporting all the ecclesiastics arrived; and this gentleman, with several others, after having been stripped of all their money, was shipped from Port Bessin, and landed at Portsmouth, where he was shortly after received into the establishment at Forton, and, upon that being dissolved in order to make room for prisoners of war, into the king's house at Winchester. Being of a studious turn, he was accustomed, as many of his brethren also were, to betake himself to the neighbouring lanes and thickets for the sake of greater solitude. With this view having, about ten o'clock in the morning, Aug. 28. 1793, retired to a certain little valley, on the north-east side of a place called *Oram's Arbour*, the same place where the county elections for Hampshire are held, he was there found, between three and four o'clock in the afternoon, murdered, with the upper part of his skull absolutely broken from the lower part, and a large hedge-stake, covered with blood, lying by him, as were the papers on which he had been transcribing a manuscript sermon with the hearing of which he had been much edified, and the sermon itself which he was copying, together with his pen, imbrued in blood. His watch was carried away, though part of the chain, which had been by some means broken, was left behind. He was writing the word *paradise*, the last letters of which remained unwritten when the fatal blow was given him, which appears evidently to have been discharged upon him from a gap in a hedge which was immediately behind him. At first the suspicion of this cruel murder fell upon the French democrats, who, to the number of 200, are prisoners of war, at the neighbouring town of Alresford, as one of that number, who had broke his parole, had, about three weeks before, being taken up at Winchester, and both there and at Alresford had repeatedly threatened to murder his uncle, a priest, whom he understood to be then at Winchester, not without fervent wishes of having it in his power to murder the whole establishment, consisting of more than 600 persons. However, as no French prisoner was seen that day in the neighbourhood of Winchester, as none of them were known to have left Alresford, it is evidently reasonable to acquiesce in the verdict of the coroner; namely, that the murder was committed by a person or persons unknown. The most noble marquis of Buckingham, whose munificence and kindness to those conscientious exiles, the emigrant French clergy, can only be conceived by those who have been witnesses of the same, with the truly respectable corps of the Buckinghamshire militia then quartered at Winchester, joined in paying the last mark of respect to the unfortunate deceased, by attending his funeral, which was performed at the Roman Catholic burying-ground, called *St James's*, near the said city, on Saturday, Aug. 29. He was just 38 years of age when he was murdered.

PIGMENTS, preparations used by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours. See COLOUR-*Making*, and DYEING.

PIGNEROL is a town of Italy in the province of Piedmont, in E. Long. 7. 15. N. Lat. 44. 45. situated on the river Chizon, 10 miles south-west of Turin, at the foot of the Alps, and the confines of Dauphiny. The town is small, but populous, and extremely well fortified by the king of Sardinia, since the treaty of Utrecht. It is defended by a citadel, on the top of the mountain near which is the castle of Perouse, which was built at the entrance of the valley of that name.

PIGNUT, or *Earthnut*. See BUNIUM, BOTANY *Index*.

PIGUS, in *Ichthyology*, is the name of a species of leather-mouthed fish, very much resembling the nature of the common carp; being of the same shape and size, and its eyes, fins, and fleshy palate, exactly the same; from the gills to the tail there is a crooked dotted line; the back and sides are bluish, and the belly reddish. It is covered with large scales; from the middle of each of which there rises a fine pellucid prickle, which is very sharp. It is an excellent fish for the table, being perhaps preferable to the carp; and it is in season in the months of March and April. It is caught in lakes in some parts of Italy, and is mentioned by Pliny, though without a name. Artedi says it is a species of cyprinus, and he calls it the *cyprinus*, called *piclo* and *pigus*.

PI-HAHIROTH, (Moses); understood to be a mouth or narrow pass between two mountains, called *Chiroth* or *Eiroth*, and lying not far from the bottom of the western coast of the Arabian gulf; before which mouth the children of Israel encamped, just before their entering the Red sea, (Wells).

PIISKER, in *Ichthyology*, is a fish of the mustela kind, commonly called the *fossil mustela*, or *fossil-fish*. This fish is generally found as long as an ordinary man's hand is broad, and as thick as the finger; but it sometimes grows much longer: the back is of gray, with a number of spots and transverse streaks, partly black and partly blue; the belly is yellow, and spotted with red, white, and black; the white are the larger, the others look as if they were made with the point of a needle; and there is on each of the sides a longitudinal black and white line. There are some fleshy excrescences at the mouth, which are expanded in swimming; and when out of the water, they are contracted. These fishes run into caverns of the earth, in the sides of rivers, in marshy places, and penetrate a great way, and are often dug up at a distance from waters. Often, when the waters of brooks and rivers swell beyond their banks, and again cover them, they make their way out of the earth into the water; and when it deserts them, they are often left in vast numbers upon the ground, and become a prey to swine. It is thought to be much of the same kind with the fisgum fish; and is indeed possible that that the pœcilia of Schonefeldt is the same.

PIKE. See Esox, Ichthyology *Index*.

The pike never swims in shoals as most other fish do, but always lies alone; and is so bold and ravenous, that he will seize upon almost any thing less than himself. Of the ravenous nature of this fish we shall give the following instances. At Rycott in Oxfordshire, in the year 1749, in a moat surrounding the earl of Abingdon's seat, there was a jack or pike of such a monstrous size, that it had destroyed young swans feathers and all. An old cobb swan having hatched five young, one after another was lost till four were gone. At length an under gardener saw the fish seize the fifth. The old one fought him with her beak, and, with the assistance of the gardener, released it, although he had got it under water. In the year 1765 a large pike was caught in the river Ouze, which weighed upwards of 28 pounds, and was sold for a guinea. On gutting the fish, a watch with a black ribbon and two steel seals were found in its stomach, which, by the maker's name, &c. was found to belong to a person who had been drowned about six weeks before. This fish breeds but once in a year, which is in March. It is found in almost all fresh waters; but it is very different in goodness, according to the nature of the places where it lives. The finest pike are those which feed in clear rivers; those in ponds and meres are inferior, and the worst of all are those of the fen ditches. They are very plentiful in these last places, where the water is foul and coloured, and their food, such as frogs and the like, very plentiful, but very coarse; so that they grow large, but are yellowish and high bellied, and differ greatly from those which live in the clearer waters.

The fishermen have two principal ways of catching the pike; by the ledger, and by the walking-bait.

The ledger-bait is fixed in one certain place, and may continue while the angler is absent. This must be a live bait, a fish or frog: and among fish, the dace, roach, and gudgeon, are the best; of frogs, the only caution is to choose the largest and yellowest that can be met with. If the bait be a fish, the hook is to be stuck through the upper lip, and the line must be 14 yards at least in length; the other end of this is to be tied to a bough of a tree, or to a stick driven into the ground near the pike's haunt, and all the line wound round a forked stick, except about half a yard. The bait will by this means keep playing so much under water, and the pike will soon lay hold of it.

If the bait be a frog, then the arming wire of the hook should be put in at the mouth, and out at the side; and with a needle and some strong silk, the hinder leg of one side is to be fastened by one stitch to the wire-arming of the hook. The pike will soon seize this, and must have line enough to give him leave to get to his haunt and poach the bait.

The trolling for pike is a pleasant method also of taking them: in this a dead bait serves, and none is so proper as a gudgeon.

This is to be pulled about in the water till the pike seizes it; and then it is to have line enough, and time to swallow it: the hook is small for this sport, and has a smooth piece of lead fixed at its end to sink the bait; and the line is very long, and runs through a ring at the end of the rod, which must not be too slender at top.

The art of feeding pike, so as to make them very fat, is the giving them eels; and without this it is not to be done under a very long time; otherwise perch, while small, and their prickly fins tender, are the best food for them. Bream put into a pike-pond are a very proper food; they will breed freely, and their young ones make excellent food for the pike, who will take care that they shall not increase over much. The numerous shoals of roaches and ruds, which are continually changing place, and often in floods get into the pike's quarters, are food for them for a long time.

Pike, when used to be fed by hand, will come up to the very shore, and take the food that is given them out of the fingers of the feeder. It is wonderful to see with what courage they will do this, after a while practising; and it is a very diverting sight when there are several of them nearly of the same size, to see what striving and fighting there will be for the best bits when they are thrown in. The most convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the offal of the feedings will all lie in one place, and the deep water will

will serve for a place to retire into and rest in, and will be always clean and in order.

Carp may be fed in the same manner as pike; and though by nature a fish as remarkably shy and timorous as the pike is bold and fearless, yet by custom they will come to take their food out of the person's hand; and will, like the pike quarrel among one another for the nicest bits.

PIKE, in *War*, an offensive weapon, consisting of a wooden shaft, 12 or 14 feet long, with a flat steel head, pointed, called the *spear*. This weapon was long in use among the infantry; but now the bayonet, which is fixed on the muzzle of the firelock, is substituted in its stead. It is still used by some of the officers of infantry, under the name of *sponton*. The Macedonian phalanx was a battalion of pikemen. See PHALANX.

PILA MARINA, or the *sea-ball*, in *Natural History*, is the name of a substance very common on the shores of the Mediterranean, and elsewhere. It is generally found in the form of a ball about the size of the balls of horse dung, and composed of a variety of fibrillæ irregularly complicated. Various conjectures have been given of its origin by different authors. John Bauhine tells us, that it consists of small hairy fibres and straws, such as are found about the sea plant called *alga vitriariorum*; but he does not ascertain what plant it owes its origin to. Imperatus imagined it consisted of the exuviæ both of vegetable and animal bodies. Mercatus is doubtful whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the sea water, or whether it be not the workmanship of some sort of beetle living about the sea shore, and analogous to our common dung beetle's ball, which it elaborates from dung for the reception of its progeny. Schreckius says it is composed of the filaments of some plant of the reed kind: and Welchius supposes it is composed of the pappous part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus; and others think it that of the phoca or sea calf. Klein, who had thoroughly and minutely examined the bodies themselves, and also what authors had conjectured concerning them, thinks that they are wholly owing to, and entirely composed of, the capillaments which the leaves, growing to the woody stalk of the *alga vitriariorum*, have when they wither and decay. These leaves, in their natural state, are as thick as a wheat straw, and they are placed so thick about the tops and extremities of the stalks, that they enfold, embrace, and lie over one another; and from the middle of these clusters of leaves, and indeed from the woody substance of the plant itself, there arise several other very long, flat, smooth, and brittle leaves. These are usually four from each tuft of the other leaves; and they have ever a common vagina, which is membranaceous and very thin. This is the style of the plant, and the *pila marina* appears to be a cluster of the fibres of the leaves of this plant, which cover the whole stalk, divided into their constituent fibres; and by the motion of the waves first broken and worn into short shreds, and afterwards wound up together into a roundish or longish ball.

PILA, was a ball made in a different manner according to the different games in which it was to be used. Playing at ball was very common amongst the Romans of the first distinction, and was looked upon as a manly exercise, which contributed both to amusement and health. The pila was of four sorts: 1st, *Follis* or *balloon*; 2d, *Pila Trigonalis*; 3d, *Pila Paganica*; 4th, *Harpastum*. All these come under the general name of pila. For the manner of playing with each of them, see the articles FOLLIS, TRIGONALIS.

PILASTER, in *Architecture*. See there, N° 50, &c.

PILATE, or PONTIUS PILATE, was governor of Judea when our Lord was crucified. Of his family or country we know but little, though it is believed that he was of Rome, or at least of Italy. He was sent to govern Judea in the room of Gratus, in the year 26 or 27 of the vulgar era, and governed this province for ten years, from the 12th or 13th year of Tiberius to the 22d or 23d. He is represented both by Philo and Josephus as a man of an impetuous and obstinate temper, and as a judge who used to sell justice, and to pronounce any sentence that was desired, provided he was paid for it. The same authors make mention of his rapines, his injuries, his murders, the torments that he inflicted upon the innocent, and the persons he put to death without any form of process. Philo, in particular, describes him as a man that exercised an excessive cruelty during the whole time of his government, who disturbed the repose of Judea, and gave occasion to the troubles and revolt that followed after. St Luke (xiii. 1, 2, &c.) acquaints us, that Pilate had mingled the blood of the Galileans with their sacrifices; and that the matter having been related to Jesus Christ, he said, "Think you that these Galileans were greater sinners than other Galileans, because they suffered this calamity. I tell you nay; and if you do not repent, you shall all perish in like manner." It is unknown upon what occasion Pilate caused these Galileans to be slain in the temple while they were sacrificing; for this is the meaning of that expression of mingling their blood with their sacrifices. Some think they were disciples of Judas the Gaulonite, who taught that the Jews ought not to pay tribute to foreign princes; and that Pilate had put some of them to death even in the temple; but there is no proof of this fact. Others think that these Galileans were Samaritans, whom Pilate cut to pieces in the village of Tirataba *, as they were preparing to go up to Mount Gerizim, where a certain impostor had promised to discover treasures to them; but this event did not happen before the year 35 of the common era, and consequently two years after the death of Jesus Christ. At the time of our Saviour's passion, Pilate made some endeavours to deliver him out of the hands of the Jews. He knew they had delivered him up, and pursued his life with so much violence, only out of malice and envy (Matt. xxvii. 18.). His wife, also, who had been disturbed the night before with frightful dreams, sent to tell him she desired him not to meddle in the affair of that just person (ib. 19.) He attempted to appease the wrath of the Jews, and to give them some satisfaction, by whipping Jesus Christ (John xix. 1. Matt. xxvii. 26.). He tried to take him out of their hands, by proposing to deliver him or Barabbas, on the day of the festival of the passover. Lastly, he had a mind to discharge himself from pronouncing judgment against him, by sending him to Herod king of Galilee (Luke xxiii. 7, 8.). When he saw all this would not satisfy the Jews, and that they even threatened him in some manner, saying he could be no friend to the emperor if he let him go (John xix. 12, 15.), he caused water

* Joseph. Antiq. lib. xviii. c. 5.

water to be brought, washed his hands before all the people, and publicly declared himself innocent of the blood of that just person (Matt. xxvii. 23, 24.); yet at the same time he delivered him up to his soldiers, that they might crucify him. This was enough to justify Jesus Christ, as Calmet observes, and to show that he held him as innocent; but it was not enough to vindicate the conscience and integrity of a judge, whose duty it was as well to assert the cause of oppressed innocence as to punish the guilty and criminal. He ordered to be put over our Saviour's cross, as it were an abstract of his sentence, and the motive of his condemnation (John xix. 9.), *Jesus of Nazareth, king of the Jews*, which was written in Latin, Greek, and Hebrew. Some of the Jews found fault with it, and remonstrated to Pilate that he ought to have written *Jesus of Nazareth who pretended to be king of the Jews.* But Pilate could not be prevailed with to alter it, and gave them this peremptory answer, *That what he had written he had written.*

Towards evening, he was applied to for leave to take down the bodies from the cross, that they might not continue there the following day, which was the passover and the sabbath-day (John xix. 31.). This he allowed, and granted the body of Jesus to Joseph of Arimathea, that he might pay his last duties to it, (ib. 33.). Lastly, when the priests, who had solicited the death of our Saviour, came to desire him to set a watch about the sepulchre, for fear his disciples should steal him away by night, he answered them, that they had a guard, and might place them there themselves (Matt. xxvii. 65.). This is the substance of what the gospel tells us concerning Pilate.

Justin Martyr, Tertullian, Eusebius, and after them several others both ancient and modern, assure us, that it was formerly the custom for Roman magistrates to prepare copies of all verbal processes and judicial acts which they passed in their several provinces, and to send them to the emperor. And Pilate, in compliance to this custom, having sent word to Tiberius of what had passed relating to Jesus Christ, the emperor wrote an account of it to the senate, in a manner that gave reason to judge that he thought favourably of the religion of Jesus Christ, and showed that he should be willing they would decree divine honours to him. But the senate was not of the same opinion, and so the matter was dropped. It appears by what Justin says of these acts, that the miracles of Jesus Christ were mentioned there, and even that the soldiers had divided his garments among them. Eusebius insinuates that they spoke of his resurrection and ascension. Tertullian and Justin refer to these acts with so much confidence as would make one believe they had them in their hands. However, neither Eusebius nor St Jerome, who were both inquisitive, understanding persons, nor any other author that wrote afterwards, seem to have seen them, at least not the true and original acts; for as to what we have now in great number, they are not authentic, being neither ancient nor uniform. There are also some pretended letters of Pilate to Tiberius, giving a history of our Saviour, but they are universally allowed to be spurious.

Pilate being a man that, by his excessive cruelties and rapine, had disturbed the peace of Judea during the whole time of his government, was at length deposed by Vitellius the proconsul of Syria, in the 36th year of Jesus Christ and sent to Rome to give an account of his conduct to the emperor. But though Tiberius died before Pilate arrived at Rome, yet his successor Caligula banished him to Vienne in Gaul, where he was reduced to such extremity that he killed himself with his own hands. The evangelists call him governor, though in reality he was no more than procurator of Judea, not only because governor was a name of general use, but because Pilate in effect acted as one, by taking upon him to judge in criminal matters; as his predecessors had done, and other procurators in the small provinces of the empire where there was no proconsul, constantly did. See *Calmet's Dictionary*, *Echard's Ecclesiastical Dictionary*, and *Beausobre's Annot.*

With regard to Pilate's wife, the general tradition is, that she was named Claudia Procula or Proscula; and in relation to her dream, some are of opinion that as she had intelligence of our Lord's apprehension, and knew by his character that he was a righteous person, her imagination, being struck with these ideas, did naturally produce the dream we read of; but others think that this dream was sent providentially upon her, for the clearer manifestation of our Lord's innocence.

PILATRE DU ROZIER, *Francis*, was born at Metz the 30th of March 1756. He was first apprentice to an apothecary there, and afterwards went to Paris in quest of farther improvement. He applied himself to the study of natural history and of natural philosophy, and had already acquired some reputation, when the discovery of M. de Montgolfier had just astonished the learned world. On the 25th of October 1783, he attempted an aerial voyage with the marquis of Arlande. He performed several other excursions in this way with brilliant success, in the presence of the royal family of France, of the king of Sweden, and of Prince Henry of Prussia. He then resolved to pass into England by means of his aerial vehicle, and for that purpose he repaired to Boulogne, whence he rose about 7 o'clock in the morning of the 15th June 1785; but in half an hour after he set out, the balloon took fire, and the aeronaut, with his companion M. Romaine, were crushed to death by the fall of that machine, which was more ingenious, perhaps, than useful *. Pilatre's social virtues and courage, which were very distinguished, heightened the regret of his friends for his loss. His merit as a chemist, and his experiments as an aeronaut, procured him some pecuniary reward, and some public appointments. He had a pension from the king, was intendant of Monsieur's cabinets of natural philosophy, chemistry, and natural history, professor of natural philosophy, a member of several academies, and principal director of Monsieur's museum.

* See *Aerostation*, N° 34.

PILCHARD, in *Ichthyology*, a fish which has a general resemblance to the herring, but differs in some essential particulars. The body of the pilchard is less compressed than that of the herring, being thicker and rounder: the nose is shorter in proportion, and turns up; the under jaw is shorter. The back is more elevated; the belly less sharp. The dorsal fin of the pilchard is placed exactly in the centre of gravity, so that when taken up by it, the body preserves an equilibrium, whereas that of the herring dips at the head. The scales of the pilchard adhere very closely, whereas those of the herring very easily drop off. The pilchard is in general less than the herring; but it is fatter, or more full of oil.

The

Pilchard, Pile.

The pilchard appears in vast shoals off the Cornish coasts about the middle of July, disappearing the beginning of winter, yet sometimes a few return again after Christmas. Their winter retreat is the same with that of the herring, and their motives for migrating the same †. They affect, during summer, a warmer latitude; for they are not found in any quantities on any of our coasts except those of Cornwall, that is to say, from Fowey harbour to the Scilly isles, between which places the shoals keep shifting for some weeks. The approach of the pilchard is known by much the same signs as those that indicate the arrival of the herring. Persons, called in Cornwall *huers*, are placed on the cliffs, to point to the boats stationed off the land the course of the fish. By the 1st of James I. c. 23. fishermen are empowered to go on the grounds of others to hue, without being liable to actions of trespass, which before occasioned frequent law-suits.

† See Clupea.

The emoluments that accrue to the inhabitants of that country are great, and are best expressed in the words of Dr W. Borlace, in his *Account of the Pilchard Fishery*. "It employs a great number of men on the sea, training them thereby to naval affairs; employs men, women, and children, at land, in salting, pressing, washing, and cleaning, in making boats, nets, ropes, casks, and all the trades depending on their construction and sale. The poor is fed with the offals of the captures; the land with the refuse of the fish and salt; the merchant finds the gains of commission and honest commerce; the fisherman, the gains of the fish. Ships are often freighted hither with salt, and into foreign countries with the fish, carrying off at the same time part of our tin. The usual number of hogsheads of fish exported each year, for 10 years, from 1747 to 1756 inclusive, from the four ports of Fowey, Falmouth, Penzance, and St Ives, in all amounts to 29,794; since it appears that Fowey has exported yearly 1732 hogsheads; Falmouth, 14,631 hogsheads and two-thirds; Penzance and Mounts-Bay, 12,149 hogsheads and one-third; St Ives, 1282 hogsheads. Every hogshead for ten years last past, together with the bounty allowed for each when exported, and the oil made out of each, has amounted, one year with another at an average, to the price of 1l. 13s. 3d.; so that the cash paid for pilchards exported has, at a medium, annually amounted to the sum of 49,532l. 10s." The numbers that are taken at one shooting out of the nets is amazingly great. Mr Pennant says, that Dr Borlase assured him, that on the 5th of October 1767, there were at one time inclosed in St Ives bay 7000 hogsheads, each hogshead containing 35,000 fish, in all 245,000,000.

PILE, in *Heraldry*, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the shield.

PILE, among the Greeks and Romans, was a pyramid built of wood, whereon were laid the bodies of the deceased to be burnt. It was partly in the form of an altar, and differed in height according to the quality of the person to be consumed. Probably it might originally be considered as an altar, on which the dead were consumed as a burnt-offering to the infernal deities. The trees made use of in the erection of a funeral pile were such as abounded in pitch or rosin as being most combustible; if they used any other wood, it was split that it might the more easily catch fire. Round the pile were placed cypress boughs to hinder the noisome smell. See FUNERAL.

Pile.

PILE, in *Building*, is used for a large stake rammed into the ground in the bottom of rivers, or in marshy land, for a foundation to build upon.

PILE is also used among architects for a mass of building.

PILE, in *Coinage*, denotes a kind of puncheon, which, in the old way of coining with the hammer, contained the arms or other figure and inscription to be struck on the coin. See COINAGE.

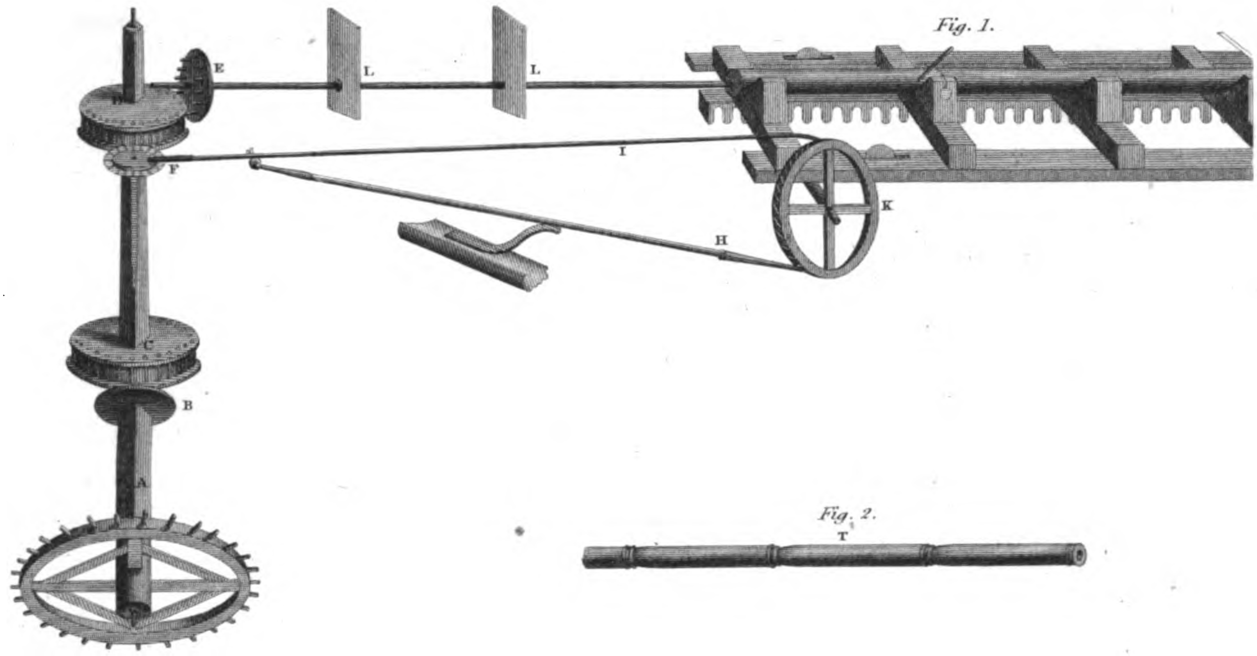
Accordingly we still call the arms side of a piece of money the *pile*, and the head the *cross*; because in ancient coin, a cross usually took the place of the head in ours.

PILE-Engine, a very curious machine invented by Mr Vauloue for driving the piles of Westminster-bridge. A is a great upright shaft or axle, on which are the great wheel B, and the drum C, turned by horses joined to the bars S, S. The wheel B turns the trundle X, on the top of whose axis is the fly O, which serves to regulate the motion, and also to act against the horses, and to keep them from falling when the heavy ram Q is discharged to drive the pile P down into the mud in the bottom of the river. The drum C is loose upon the shaft A, but is locked to the wheel B by the bolt Y. On this drum the great rope HH is wound; one end of the rope being fixed to the drum, and the other to the follower G, to which it is conveyed over the pulleys I and K. In the follower G is contained the tongs F, that takes hold of the ram Q by the staple R, for drawing it up. D is a spiral or fusy fixed to the drum, on which is wound the small rope T that goes over the pulley U, under the pulley V, and is fastened to the top of the frame at 7. To the pulley-block V is hung the counterpoise W, which hinders the follower T from accelerating as it goes down to take hold of the ram; for as the follower tends to acquire velocity in its descent, the line T winds downwards upon the fusy, on a larger and larger radius, by which means the counterpoise W acts stronger and stronger against it; and so allows it to come down with only a moderate and uniform velocity. The bolt Y locks the drum to the great wheel, being pushed upward by the small lever 2, which goes through a mortise in the shaft A, turns upon a pin in the bar 3, fixed to the great wheel B, and has a weight 4, which always tends to push up the bolt Y through the wheel into the drum. L is the great lever turning on the axis *m*, and resting upon the forcing bar 5, 5, which goes through a hollow in the shaft A, and bears up the little lever 2.

Plate CCCCXII.

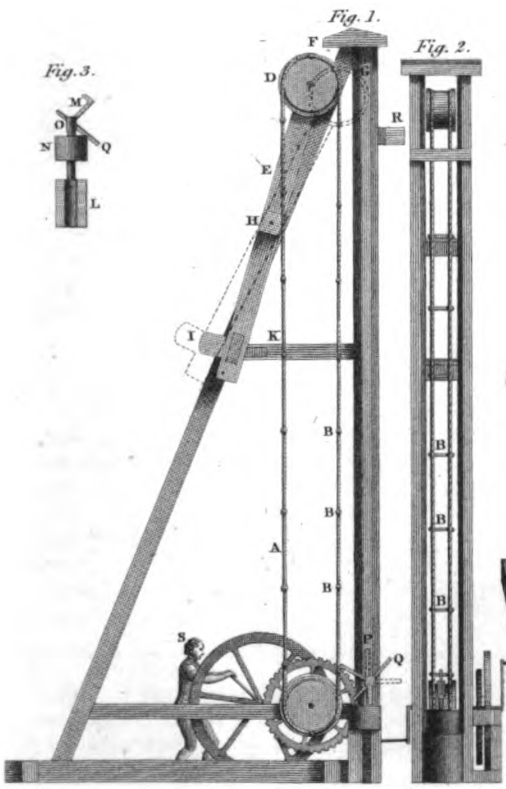
By the horses going round, the great rope H is wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, until the tongs come between the inclined planes E; which, by shutting the tongs at the top, opens it at the foot, and discharges the ram, which falls down between the guides *b b* upon the pile P, and drives it by a few strokes as far into the mud as it will go; after which, the top part is sawed off close to the mud by an engine for that purpose. Immediately after the ram is discharged, the piece 6 upon the follower G takes hold of the ropes *a a*, which raise the end of the lever L, and causes its end N to descend and press down the forcing bar 5 upon the little lever

Machine for boring wooden PIPES. *PLATE CCCCXIX.*

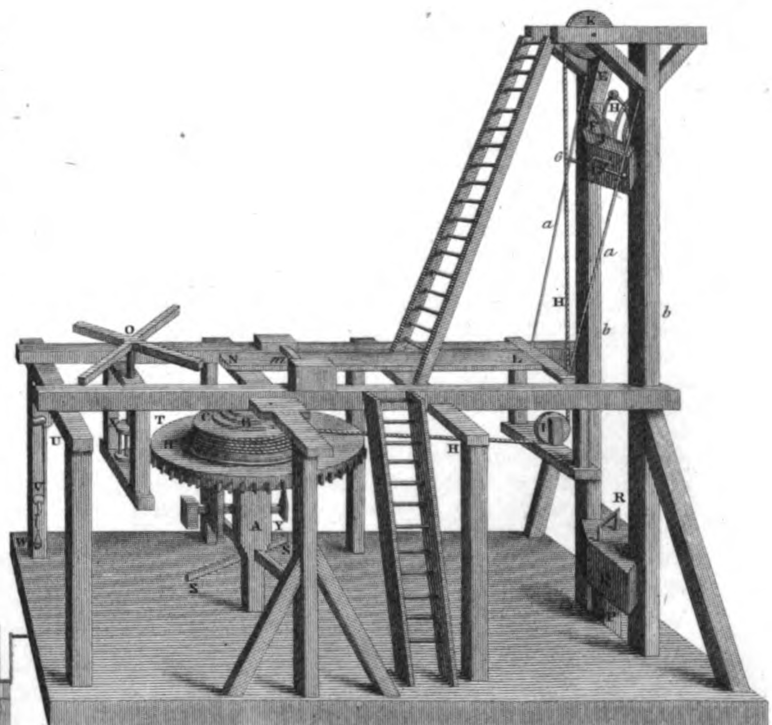


PILE Engine.

BUNCE'S PILE ENGINE.



VAULOUE'S PILE ENGINE.



Williams sculp.ᵗ

lever 2, which, by pulling down the bolt Y, unlocks the drum C from the great wheel B; and then the follower being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs slip over the staple R, and the weight of their heads causes them to fall outward, and shut upon it. Then the weight 4 pushes up the bolt Y into the drum, which locks it to the great wheel, and so the ram is drawn up as before.

As the follower comes down, it causes the drum to turn backward, and unwinds the rope from it, whilst the horses, great wheel, trundle, and fly, go on with an uninterrupted motion; and as the drum is turning backward, the counterpoise W is drawn up, and its rope T wound upon the spiral fusy D.

There are several holes in the under side of the drum, and the bolt Y always takes the first one that it finds when the drum stops by the falling of the follower upon the ram; until which stoppage the bolt has not time to slip into any of the holes.

This engine was placed upon a barge on the water, and so was easily conveyed to any place desired. The ram was a ton weight; and the guides *b b*, by which it was let fall, were 30 feet high.

A new machine for driving piles has been invented by Mr Bunce of Kirby street, Hatton street, London. It will drive a greater number of piles in a given time than any other; and can be constructed more simply to work by horses than Mr Vauloue's engine above described.

Plate CCCCXIX. Fig. 1 and 2 represent a side and front section of the machine. The chief parts are A, fig. 1, which are two endless ropes, or chains, connected by cross pieces of iron B (see fig. 2), corresponding with two cross grooves cut diametrically opposite in the wheel C (fig. 1.), into which they are received; and by which means the rope or chain A is carried round. FHK is a side-view of a strong wooden frame moveable on the axis H. D is a wheel, over which the chain passes and turns within at the top of the frame. It moves occasionally from F to G upon the centre H, and is kept in the position F by the weight I fixed to the end K. Fig. 3. L is the iron ram, which is connected with the cross pieces by the hook M. N is a cylindrical piece of wood suspended at the hook at O, which by sliding freely upon the bar that connects the hook to the ram, always brings the hook upright upon the chain when at the bottom of the machine, in the position of GP. See fig. 1.

When the man at S turns the usual crane work, the ram being connected to the chain, and passing between the guides, is drawn up in a perpendicular direction; and when it is near the top of the machine, the projecting bar Q of the hook strikes against a cross piece of wood at R (fig. 1.); and consequently discharges the ram, whilst the weight I of the moveable frame instantly draws the upper wheel into the position shown at F, and keeps the chain free of the ram in its descent. The hook, while descending, is prevented from catching the chain by the wooden piece N. For that piece being specifically lighter than the iron weight below, and moving with a less degree of velocity, cannot come in contact with the iron till it is at the bottom and the ram stops. It then falls and again connects the hook with the chain, which draws up the ram, as before.

Mr Bunce has made a model of this machine, which performs perfectly well; and he observes, that, as the motion of the wheel C is uninterrupted, there appears to be the least possible time lost in the operation.

Pile-Worms, are a kind of worms found in the piles of the sea dikes in Holland. They are of very various sizes; for some of the young ones are not above an inch or two in length, while others have been found thirteen or fourteen inches long. The heads of these creatures are covered with two hard shells or hemicrania; which together form a figure resembling an augre; and with which they bore the wood. The best remedy against them is, to perforate the pile with many small holes about an inch asunder; then it must be done over with a varnish in the hottest sun; and, while the varnish is hot, brick dust must be strewed over it: and this being several times repeated, the pile will be covered with a strong crust absolutely impenetrable to all insects.

PILES, in *Medicine*, the same with hæmorrhoids. See Medicine, N° 240, &c.

PILEUS, in Roman antiquity, was the ordinary cap or hat worn at public shows and sacrifices, and by the freedmen. It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining freedom.

PILEWORT, (*Ranunculus ficaria*, Lin.), the root. This is a very small plant, found in most meadows and by hedge sides. The roots consist of slender fibres with some little tubercles among them, which are supposed to resemble the hæmorrhoids. From thence it has been concluded, that this root must needs be of wonderful efficacy for the cure of that distemper: to the taste, it is little other than mucilaginous; and although still retained in several of the foreign pharmacopœias, it is hardly in use in this country.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relicks of dead saints. See Pilgrimage.

The word is formed from the Flemish *pelgrim*, or Italian *pelegrino*, which signifies the same; and those originally from the Latin *peregrinus*, a "stranger or traveller."

PILGRIMAGE, a kind of religious discipline, which consists in taking a journey to some holy place in order to adore the relicks of some deceased saint. Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the 11th century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella (A), and Tours; but the greatest numbers now resort

(A) It deserves to be remarked here, that in the year 1428, under the reign of Henry VI. abundance of licences were granted from the crown of England to captains of English ships, for carrying numbers of devout persons to the shrine of St James of Compostella in Spain; provided, however, that those pilgrims should first take an oath not resort to Loretto, in order to visit the chamber of the blessed virgin, in which she was born, and brought up her son Jesus till he was 12 years of age. For the pilgrimage of the followers of Mahomet, see MAHOMETANISM.

In every country where popery was established, pilgrimages were common; and in those countries which are still popish, they continue. In England, the shrine of St Thomas à Becket was the chief resort of the pious; and in Scotland, St Andrews; where, as tradition informs us, was deposited a leg of the holy apostle. In Ireland they still continue; for, from the beginning of May till the middle of August every year, crowds of popish penitents from all parts of that country resort to an island near the centre of *Lough fin*, or *White Lake*, in the county of Donnegal, to the amount of 3000 or 4000. These are mostly of the poorer sort, and many of them are proxies for those who are richer; some of which, however, together with some of the priests and bishops on occasion, make their appearance there. When the pilgrim comes within sight of the holy lake, he must uncover his hands and feet, and thus walk to the water side, and is taken to the island for sixpence. Here there are two chapels and 15 other houses; to which are added confessionals, so contrived, that the priest cannot see the person confessing. The penance varies according to the circumstances of the penitent; during the continuance of which (which is sometimes three, six, or nine days) he subsists on oatmeal, sometimes made into bread. He traverses sharp stones on his bare knees or feet, and goes through a variety of other forms, paying sixpence at every different confession. When all is over, the priest bores a gimblet-hole through the pilgrim's staff near the top, in which he fastens a cross peg; gives him as many holy pebbles out of the lake as he cares to carry away, for amulets to be presented to his friends, and so dismisses him, an object of veneration to all other papists not thus initiated, who no sooner see the pilgrim's cross in his hands, than they kneel down to get his blessing.

There are, however, other parts of Ireland sacred to extraordinary worship and pilgrimage; and the number of holy wells, and miraculous cures, &c. produced by them, is very great. That such things should exist in this enlightened age, and in a Protestant country, is indeed strange; but our wonder ceases, when we reflect that it is among the lowest, and perhaps the worst of the people. They who carry external religion to an extreme, and place that confidence in ceremony which belongs only to the spirit of it, are seldom distinguished either for their wisdom or their virtue. We do not deny, however, that they who carry matters to the other extreme, may be equally destitute of real knowledge and genuine morality.

Dr Johnson, in his *Rasselas*, gives us some observations on pilgrimage, which are so much to the purpose, that we think we cannot do better than lay them before our readers. "Pilgrimage (said Imlac, into whose mouth the observations are put), like many other acts of piety, may be reasonable or superstitious according to the principles upon which it is performed. Long journeys in search of truth are not commanded. Truth, such as is necessary to the regulation of life, is always found where it is honestly sought: change of place is no natural cause of the increase of piety, for it inevitably produces dissipation of mind. Yet since men go every day to view the fields where great actions have been performed, and return with stronger impressions of the event, curiosity of the same kind may naturally dispose us to view that country whence our religion had its beginning: and I believe no man surveys those awful scenes without some confirmation of holy resolutions. That the Supreme Being may be more easily propitiated in one place than in another, is the dream of idle superstition; but that some places may operate upon our own minds in an uncommon manner, is an opinion which hourly experience will justify. He who supposes that his vices may be more successfully combated in Palestine, will, perhaps, find himself mistaken; yet he may go thither without folly: he who thinks they will be more freely pardoned, dishonours at once his reason and religion."

PILKINGTON, LÆTITIA, a famous poetical genius, the daughter of Dr Van Lewin, a physician of Dublin, where she was born in 1712. She was married very young to the Rev. Matthew Pilkington, a poet also of no inconsiderable merit; and the two wits, as is often the case, lived very unhappily together. They were at length totally separated, on the husband accidentally discovering a gentleman in her bedchamber at two o'clock in the morning; a circumstance which she accounted for in a very unsatisfactory manner. The story is told at large in her Memoirs where she says, "Lovers of Learning, I am sure, will pardon me, as I solemnly declare it was the attractive charms of a new book, which the gentleman would not lend me, but consented to stay till I read it through, that was the sole motive of my detaining him." As there are not wanting some who form objections to marrying learned wives, the chance of such literary assignations may perhaps be added to the list of them. After this unlucky adventure, Mrs Pilkington came to London; and having recourse to her pen for subsistence, through the means of Colley Cibber, she lived for some time on the contributions of the great. She was however thrown into the Marshalsea for debt; and being set a liberty, opened a pamphlet shop. She raised at length a handsome subscription for her Memoirs; which are written with great sprighliness and wit, containing several entertaining anecdotes of Dean Swift, with whom she was intimate, as well as many pretty little pieces of her own poetry. This ingenious woman is said at last to have killed herself with drinking. She died at Dublin, in 1750.

PILL, in *Pharmacy*, a form of medicine resembling a little ball, to be swallowed whole; invented for such as

---

not to take any thing prejudicial to England, not to reveal any of its secrets, nor to carry out with them any more gold or silver than what would be sufficient for their reasonable expences. In this year there went out thither from England, on the said pilgrimage, the following number of persons. From London 280 Bristol 200, Weymouth 122, Dartmouth 90, Yarmouth 60, Jersey 60, Plymouth 40, Exeter 30, Poole 24, Ipswich 20, in all 926 persons.

as cannot take bitter and ill-tasted medicinal draughts: as also to keep in readiness for occasional use without decaying. See MATERIA MEDICA *Index*.

PILLAR, in *Architecture*. See ARCHITECTURE.

PILLAR, in the manege, is the centre of the ring, or manege-ground, round which a horse turns, whether there be a pillar in it or not. Besides this, there are pillars on the circumference or sides of the manege-ground, placed at certain distances, by two and two, from whence they are called the *two pillars*, to distinguish them from that of the centre. The use of the pillar in the centre is for regulating the extent of ground, that the manege upon the volts may be performed with method and justness, and that they may work in a square, by rule and measure, upon the four lines of the volts; and also to break unruly high-mettled horses, without endangering the rider. The two pillars are placed at the distance of two or three paces one from the other; and the horse is put between those, to teach him to rise before and yerk out behind, and put himself upon raised airs, &c. either by the aids or chastisements.

Pompey's PILLAR. See ALEXANDRIA.

PILLARS, in antiquarian topography, are large single stones set up perpendicularly. Those of them which are found in this country have been the work of the Druids; but as they are the most simple of all monuments, they are unquestionably more ancient than druidism itself. They were placed as memorials recording different events; such as remarkable instances of God's mercies, contracts, singular victories, boundaries, and sometimes sepulchres. Various instances of these monuments erected by the patriarchs occur in the Old Testament: such was that raised by Jacob at Luz, afterwards by him named *Bethel;* such also was the pillar placed by him over the grave of Rachel. They were likewise marks of execrations and magical talismans.

These stones, from having long been considered as objects of veneration, at length were by the ignorant and superstitious idolatrously worshipped; wherefore, after the introduction of Christianity, some had crosses cut on them, which was considered as snatching them from the service of the devil. Vulgar superstition of a later date has led the common people to consider them as persons transformed into stone for the punishment of some crime, generally that of sabbath-breaking; but this tale is not confined to single stones, but is told also of whole circles: witness the monuments called the *hurlers* in Cornwall, and *Rollorick stones* in Warwickshire. The first are by the vulgar supposed to have been once men, and thus transformed as a punishment for playing on the Lord's day at a game called *hurling;* the latter, a pagan king and his army.

At Wilton, where the earl of Pembroke has a very magnificent house, there is a pillar of one piece of white Egyptian granite, which was brought from the temple of Venus Genetrix at Rome, near 14 feet high and 22 inches diameter, with an inscription to Astarte or Venus.

PILLORY (*collistrigium*, "collum stringens;" *pilloria*, from the French *pilleur*, i. e. *depeculator;* or *pelori*, derived from the Greek πυλη, *janua*, a "door," because one standing on the pillory puts his head as it were through a door, and ὁρaω, *video*), is an engine made of wood to punish offenders, by exposing them to public view, and rendering them infamous. There is a *statute of the pillory*, 51 Hen. III. And by statute it is appointed for bakers, forestallers, and those who use false weights, perjury, forgery, &c. 3. *Inst.* 219. Lords of leets are to have a pillory and tumbrel, or it will be the cause of forfeiture of the leet; and a village may be bound by prescription to provide a pillory, &c. 2 *Hawk.* P. C. 73.

PILOT, the officer who superintends the navigation, either upon the sea-coast or on the main ocean. It is, however, more particularly applied by our mariners to the person charged with the direction of a ship's course on or near the sea-coast, and into the roads, bays, rivers, havens, &c. within his respective district.

Pilots of ships, taking upon them to conduct any ship from Dover, &c. to any place up the river Thames, are to be first examined and approved by the master and wardens of the society of Trinity House, &c. or shall forfeit 10l. for the first offence, 20l. for the second, and 40l. for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may pilot his own vessel up the river: and if any ship be lost through the negligence of any pilot, he shall be for ever after disabled to act as a pilot. 3 Geo. I. c. 13. Also the lord-warden of the cinque ports may make rules for the government of pilots, and order a sufficient number to ply at sea to conduct ships up to the Thames: 7 Geo. I. c. 21. No person shall act as a pilot on the Thames, &c. (except in collier ships) without a licence from the master and wardens of Trinity House at Deptford, on pain of forfeiting 20l. And pilots are to be subject to the government of that corporation; and pay ancient dues, not exceeding 1s. in the pound, out of wages, for the use of the poor thereof. Stat. 5 Geo. II. c. 20.

By the former laws of France, no person could be received as pilot till he had made several voyages and passed a strict examination; and after that, on his return in long voyages, he was obliged to lodge a copy of his journal in the admiralty; and if a pilot occasioned the loss of a ship, he had to pay 100 livres fine, and to be for ever deprived of the exercise of pilotage; and if he did it designedly, be punished with death. *Lex Mercat.* 70, 71.

The laws of Oleron ordain, That if any pilot designedly misguide a ship, that it may be cast away, he shall be put to a rigorous death, and hung in chains: and if the lord of a place, where a ship be thus lost, abet such villains in order to have a share of the wreck, he shall be apprehended, and all his goods forfeited for the satisfaction of the persons suffering; and his person shall be fastened to a stake in the midst of his own mansion, which, being fired on the four corners, shall be burned to the ground, and he with it. *Leg. Ol.* c. 25. And if the fault of a pilot be so notorious that the ship's crew see an apparent wreck, they may lead him to the hatches, and strike off his head; but the common law denies this hasty execution: an ignorant pilot is sentenced to pass thrice under the ship's keel by the laws of Denmark. *Lex Mercat.* 70.

The regulations with regard to pilots in the royal navy are as follow: "The commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as pilots, and to remove all their objections

Pilot. jections to his majesty's service, are strictly charged to treat them with good usage, and an equal respect with warrant officers.

"The purser of the ship is always to have a set of bedding provided on board for the pilots; and the captain is to order the boatswain to supply them with hammocks, and a convenient place to lie in, near their duty, and apart from the common men; which bedding and hammocks are to be returned when the pilots leave the ship.

"A pilot, when conducting one of his majesty's ships in pilot-water, shall have the sole charge and command of the ship, and may give orders for steering, setting, trimming, or furling the sails; tacking the ship; or whatever concerns the navigation; and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to observe the conduct of the pilot; and if he judges him to behave so ill as to bring the ship into danger, he may remove him from the command and charge of the ship, and take such methods for her preservation as shall be judged necessary; remarking upon the log book, the exact hour and time when the pilot was removed from his office, and the reasons assigned for it.

"Captains of the king's ships, employing pilots in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the pilot, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval officer there, the captain of his majesty's ship shall pay him, and send the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

"Captains of his majesty's ships, employing foreign pilots to carry the ships they command into or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them: whose receipts being duly vouched, and sent, with a certificate of the service performed, to the navy-board, they shall cause them to be paid with the same exactness as they do bills of exchange." *Regulations and Instructions of the Sea-service*, &c.

Pilot-Fish. See Gasterosteus, Ichthyology *Index*.

Osbec tells us, that they are shaped like those mackerels which have a transverse line upon the body. "Sailors (continues he) give them the name of *pilots*, because they closely follow the dog fish, swimming in great shoals round it on all sides. It is thought that they point out some prey to the dog-fish. They are not only not touched, but also preserved by it against all their enemies.

It likewise follows the shark, apparently for the purpose of devouring the remains of its prey. It is pretended that it acts as its pilot. The manner in which it attends the shark, according to M. Daubenton, may have given rise to this name. It is said to swim at the height of a foot and a half from the snout of this voracious animal, to follow and imitate all its movements, and to seize with address every part of its prey which the shark allows to escape, and which is light enough to buoy up towards the surface of the water. When the shark, which has its mouth below, turns to seize any fish, the pilot-fish starts away; but as soon as the shark resumes his ordinary position, it returns to its former place. It is said, that in the gulf of Guinea those fishes follow ships for the sake of the offals and human excrements; and hence the Dutch give them the name of *dung-fish*. It is remarkable, that though so small they can keep pace with ships in their swiftest course.

Pilot ‖ Pimento.

PILTEN, a division of Courland, which lies in Courland properly so called, derives its name from the ancient castle or palace of Pilten, built by Valdemar II. King of Denmark about the year 1220, when he founded a bishop's see in this country for the more effectual conversion of its Pagan inhabitants. This district afterwards successively belonged to the Germans, then again to the king of Denmark, the duke of Courland, and to Poland; and by virtue of the instrument of regency drawn up for this district in the year 1717, the government is lodged in seven Polish senators or counsellors, from whom an appeal lies to the king. The bishop of Samogitia also styles himself bishop of Pilten.

The most remarkable part of this district is the promontory of Domesness, which projects northward into the gulf of Livonia. From this cape, a sand-bank runs four German miles farther into the sea, half of which lies under water, and cannot be discerned. To the east of this promontory is an unfathomable abyss, which is never observed to be agitated. For the safety of vessels bound to Livonia, two square beacons have been erected on the coast, near Domesness church, opposite to the sand bank, and facing each other. One of these is twelve fathoms high, and the other eight; and a large fire is kept burning on them from the first of August to the first of January. When the mariners see these fires appear as one in a direct line, they may conclude that they are clear of the extremity of the sand bank, and consequently out of danger; but if they see both beacons, they are in danger of running upon it. The district of Pilten contains seven parishes, but no towns worthy of notice. The inhabitants are chiefly of the Lutheran persuasion.

PILUM, a missive weapon used by the Roman soldiers, and in a charge darted upon the enemy. Its point, we are told by Polybius, was so long and small, that after the first discharge it was generally so bent as to be rendered useless. The legionary soldiers made use of the pilum, and each man carried two. The pilum underwent many alterations and improvements, insomuch that it is impossible with any precision to describe it. Julius Scaliger laboured much to give an accurate account of it, and would have esteemed success on this head amongst the greatest blessings of his life. This weapon appears, however, to have been sometimes round, but most commonly square, to have been two cubits long in the staff, and to have had an iron point of the same length hooked and jagged at the end. Marius made a material improvement in it; for during the Cimbrian war, he so contrived it, that when it stuck in the enemies shield it should bend down in an angle in the part where the wood was connected with the iron, and thus become useless to the person who received it.

PIMENTO, Piemento, Jamaica Pepper, or *Allspice*, a species of myrtus. See Myrtus, Botany *Index*.

"The pimento trees grow spontaneously, and in great abundance, in many parts of Jamaica, but more particularly on hilly situations near the sea, on the northern side of that island; where they form the most

most delicious groves that can possibly be imagined; filling the air with fragrance, and giving reality, though in a very distant part of the globe, to our great poet's description of those balmy gales which convey to the delighted voyager

'Sabean odours from the spicy shore
'Of Araby the blest.
'Cheer'd with the grateful smell, old ocean smiles.'

"This tree is purely a child of nature, and seems to mock all the labours of man in his endeavours to extend or improve its growth: not one attempt in fifty to propagate the young plants, or to raise them from the seeds, in parts of the country where it is not found growing spontaneously, having succeeded. The usual method of forming a new pimento plantation (in Jamaica it is called a *walk*) is nothing more than to appropriate a piece of woodland, in the neighbourhood of a plantation already existing, or in a country where the scattered trees are found in a native state, the woods of which being fallen, the trees are suffered to remain on the ground till they become rotten and perish. In the course of twelve months after the first season, abundance of young pimento plants will be found growing vigorously in all parts of the land, being without doubt produced from ripe berries scattered there by the birds, while the fallen trees, &c. afford them both shelter and shade. At the end of two years it will be proper to give the land a thorough cleansing, leaving such only of the pimento trees as have a good appearance, which will then soon form such groves as those I have described, and except perhaps for the first four or five years, require very little attention afterwards.

"Soon after the trees are in blossom, the berries become fit for gathering; the fruit not being suffered to ripen on the tree, as the pulp in that state, being moist and glutinous, is difficult to cure, and when dry becomes black and tasteless. It is impossible, however, to prevent some of the ripe berries from mixing with the rest; but if the proportion of them be great, the price of the commodity is considerably injured.

"It is gathered by the hand; one labourer on the tree, employed in gathering the small branches, will give employment to three below (who are generally women and children) in picking the berries; and an industrious picker will fill a bag of 70lbs. in the day.

"The returns from a pimento walk in a favourable season are prodigious. A single tree has been known to yield 150lbs. of the raw fruit, or one cwt. of the dried spice; there being commonly a loss in weight of one third in curing; but this, like many other of the minor productions, is exceedingly uncertain, and perhaps a very plenteous crop occurs but once in five years."

PIMPINELLA, Burnet Saxifrage; a genus of plants belonging to the pentandria class. See Botany *Index*.

PIMPLE, in *Medicine*, a small pustule arising on the face. By mixing equal quantities of the juice of house-leek (*sedum minus*), passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed, which Dr Bughart commends for curing pimples of the face; and says, that the thin liquor separated from it with sugar-candy is an excellent remedy for thick viscid phlegm in the breast.

PIN, in commerce, a little necessary instrument made of brass-wire, chiefly used by women in fastening and adjusting their dress.

In the year 1543, by statute 34 and 35 of Henry VIII. cap. 6. it was enacted, "That no person shall put to sale any pinnes but only such as shall be double-headed, and have the heads soldered fast to the shank of the pins, well smoothed, the shank well-shapen, the points well and round filed, cauted, and sharpened." From the above extract it should appear that the art of pin-making was but of late invention, probably introduced from France; and that our manufactories since that period have wonderfully improved.

Though pins are apparently simple, their manufacture is, however, not a little curious and complex. We shall therefore give our readers an account of it from Ellis's *Campagna* of London.

"When the brass-wire, of which the pins are formed, is first received at the manufactory, it is generally too thick for the purpose of being cut into pins. The first operation therefore is that of winding it off from one wheel to another with great velocity, and causing it to pass between the two, through a circle in a piece of iron of smaller diameter: the wire being thus reduced to its proper dimensions, is straightened by drawing it between iron pins, fixed on a board in a zig-zag manner, but so as to leave a straight line between them: afterwards it is cut into lengths of three or four yards, and then into smaller ones, every length being sufficient to make six pins; each end of these is ground to a point, which was performed when I viewed the manufactory by boys who sat each with two small grinding stones before him, turned by a wheel. Taking up a handful, he applies the ends to the coarsest of the two stones, being careful at the same time to keep each piece moving round between his fingers, so that the points may not become flat: he then gives them a smoother and sharper point, by applying them to the other stone, and by that means a lad of 12 or 14 years of age is enabled to point about 16,000 pins in an hour. When the wire is thus pointed, a pin is taken off from each end, and this is repeated till it is cut into six pieces. The next operation is that of forming the heads, or, as they term it, *head spinning*; which is done by means of a spinning-wheel, one piece of wire being thus with astonishing rapidity wound round another, and the interior one being drawn out, leaves a hollow tube between the circumvolutions: it is then cut with sheers; every two circumvolutions or turns of the wire forming one head; these are softened by throwing them into iron pans, and placing them in a furnace till they are red hot. As soon as they are cold, they are distributed to children, who sit with anvils and hammers before them, which they work with their feet, by means of a lathe, and taking up one of the lengths, they thrust the blunt end into a quantity of the heads which lie before them, and catching one at the extremity, they apply them immediately to the anvil and hammer, and by a motion or two of the foot, the point and the head are fixed together in much less time than can it be described, and with a dexterity only to be acquired by practice; the spectator being in continual apprehension

sion for the safety of their fingers ends. The pin is now finished as to its form, but still it is merely brass; it is therefore thrown into a copper containing a solution of tin and the leys of wine. Here it remains for some time; and when taken out assumes a white though dull appearance: in order therefore to give it a polish, it is put into a tub containing a quantity of bran, which is set in motion by turning a shaft that runs through its centre, and thus by means of friction it becomes perfectly bright. The pin being complete, nothing remains but to separate it from the bran, which is performed by a mode exactly similar to the winnowing of corn; the bran flying off and leaving the pin behind fit for immediate sale. I was the more pleased with this manufactory, as it appeared to afford employment to a number of children of both sexes, who are thus not only prevented from acquiring the habits of idleness and vice, but are on the contrary initiated in their early years in those of a beneficial and virtuous industry." See NEEDLES.

PINACIA, among the Athenians, were tablets of brass inscribed with the names of all those citizens in each tribe who were duly qualified and willing to be judges of the court of Areopagus. These tablets were cast into a vessel provided for the purpose, and the same number of beans, a hundred being white and all the rest black, were thrown into another. Then the names of the candidates and the beans were drawn out one by one, and they whose names were drawn out together with the white beans were elected judges or senators. In Solon's time there were only four tribes, each of which chose 100 senators; but the number of tribes afterwards increasing, the number of senators and judges increased to so many hundreds more.

PINANG, the Chinese name of the *Areca Catechu* Lin. See ARECA, BOTANY *Index*.

PINCHBECK, a factitious metallic substance, or an alloy of zinc three parts, and of copper, four. See CHEMISTRY *Index*.

PINDAR, the prince of lyric poets, was born at Thebes, about 520 years B. C. He received his first musical instructions from his father, who was a flute-player by profession; after which, according to Suidas, he was placed under Myrtis, a lady of distinguished abilities in lyric poetry. It was during this period that he became acquainted with the poetess Corinna, who was likewise a student under Myrtis. Plutarch tells us, that Pindar profited from the lessons which Corinna, more advanced in her studies, gave him at this school. It is very natural to suppose, that the first poetical effusions of a genius so full of fire and imagination as that of Pindar would be wild and luxuriant; and Lucian has preserved six verses, said to have been the exordium of his first essay; in which he crowded almost all the subjects for song which ancient history and mythology then furnished. Upon communicating this attempt to Corinna, she told him smiling, that he should sow with the hand, and not empty his whole sack at once. Pindar, however, soon quitted the leading strings of these ladies, his poetical nurses, and became the disciple of Simonides, now arrived at extreme old age: after which he soon surpassed all his masters, and acquired great reputation over all Greece: but, like a true prophet, he was less honoured in his own country than elsewhere; for at Thebes he was frequently pronounced to be vanquished, in the musical and poetical contests, by candidates of inferior merit.

The custom of having these public trials of skill in all the great cities of Greece was now so prevalent, that but little fame was to be acquired by a musician or poet any other way than by entering the lists; and we find, that both Myrtis and Corinna publicly disputed the prize with him at Thebes. He obtained a victory over Myrtis, but was vanquished five different times by Corinna. The judges, upon occasions like these, have been frequently accused of partiality or ignorance, not only by the vanquished, but by posterity; and if the merit of Pindar was pronounced inferior to that of Corinna five several times, it was, says Pausanias, because the judges were more sensible to the charms of beauty than to those of music and poetry (A). Was it not strange, said the Scythian Anacharsis, that the Grecian artists were never judged by artists, their peers?

Pindar, before he quitted Thebes, had the vexation to see his Dithyrambics traduced, abused, and turned into ridicule, by the comic poets of his time; and Athenæus tells us, that he was severely censured by his brother lyrics, for being a lipogrammatist, and composing an ode from which he had excommunicated the letter S. Whether these censures proceeded from envy or contempt cannot now be determined; but they were certainly useful to Pindar, and it was necessary that he should be lashed for such puerilities. Thebes seems to have been the purgatory of our young bard: when he quitted that city, as his judgement was matured, he avoided most of the errors for which he had been chastised, and suddenly became the wonder and delight of all Greece. Every hero, prince, and potentate, desirous of lasting fame, courted the muse of Pindar.

He seems frequently to have been present at the four great festivals, of the Olympian, Pythian, Nemean, and Isthmian games, as may be inferred from several circumstances and expressions in the odes which he composed for the victors in them all. Those at Olympia, who were ambitious of having their achievements celebrated by Pindar, applied to him for an ode, which was first sung in the Prytaneum or town-hall of Olympia, where there was a banqueting room, set apart for the entertainment of the conquerors. Here the ode was rehearsed by a chorus, accompanied by instruments. It was afterwards performed in the same manner at the triumphal entry of the victor into his own country, in processions, or at the sacrifices that were made with great pomp and solemnity on the occasion.

Pindar,

(A) Pausanias says, that Corinna was one of the most beautiful women of her time, as he judged by a picture of her which he saw at Tanagris at the place where the public exercises were performed. She was represented with her head ornamented by a riband, as a memorial of the victories she had obtained over Pindar at Thebes.

Pindar, in his second Isthmian ode, has apologized for the mercenary custom among poets, of receiving money for their compositions. "The world (says he) is grown interested, and thinks in general with the Spartan philosopher Aristodemus, that *money only makes the man*: a truth which this sage himself experienced, having with his riches lost all his friends." It is supposed that Pindar here alludes to the avarice of Simonides, who first allowed his muse to sell her favours to the highest bidder.

There is no great poet in antiquity whose moral character has been less censured than that of Pindar. Plutarch has preserved a single verse of his *Epicedium* or *Dirge* that was sung at his funeral; which, short and simple as it is, implies great praise: *This man was pleasing to strangers, and dear to his fellow-citizens.* His works abound with precepts of the purest morality: and it does not appear that he ever traduced even his enemies; comforting himself, for their malignity, by a maxim which he inserted in his first *Pythic*, and which afterwards became proverbial, *That it is better to be envied than pitied.*

Pausanias says, that the character of poet was truly consecrated in the person of Pindar, by the god of verse himself; who was pleased, by an express oracle, to order the inhabitants of Delphos to set apart for Pindar one half of the first-fruit offerings brought by the religious to his shrine, and to allow him a conspicuous place in his temple, where, in an iron chair, he used to sit and sing his hymns in honour of that god. This chair was remaining in the time of Pausanias, several centuries after, and shown to him as a relick not unworthy of the sanctity and magnificence of that place.

But though Pindar's muse was pensioned at Delphos, and well paid by princes and potentates elsewhere, she seems, however, sometimes to have sung the spontaneous strains of pure friendship. Of this kind were, probably, the verses bestowed upon the musician Midas, of Agrigentum in Sicily, who had twice obtained the palm of victory by his performance on the flute at the Pythic games (B). It is in his 12th Pythic ode that Pindar celebrates the victory of Midas *over all Greece, upon that instrument which Minerva herself had invented* (C).

Fabricius tells us, that Pindar lived to the age of 90; and, according to the chronology of Dr Blair, he died 435 years B. C. aged 86. His fellow citizens erected a monument to him in the Hippodrome at Thebes, which was still subsisting in the time of Pausanias; and his renown was so great after his death, that his posterity derived very considerable honours and privileges from it. When Alexander the Great attacked the city of Thebes, he gave express orders to his soldiers to spare the house and family of Pindar. The Lacedæmonians had done the same before this period; for when they ravaged Bœotia and burned the capital, the following words were written upon the door of the poet: *Forbear to burn this house; it was the dwelling of Pindar.* Respect for the memory of this great poet continued so long, that, even in Plutarch's time, the best part of the sacred victim at the Theoxenian festival was appropriated to his descendants.

PINDARIC ODE, in *Poetry*, an ode formed in imitation of the manner of Pindar. See POETRY, N° 136, &c.

PINDUS, in *Ancient Geography*, not a single mountain, but a chain of mountains, inhabited by different people of Epirus and Thessaly; separating Macedonia, Thessaly, and Epirus: An extensive chain, having Macedonia to the north, the Perrhœbi to the west, the Dolopes to the south, and the mountain itself of Thessaly (Strabo).

PINDUS, a Doric city of Ætolia, situated on the cognominal river, which falls into the Cephissus (Strabo).

PINE, in *Botany*. See PINUS, BOTANY *Index*.

PINE-Apple. See BROMELIA, BOTANY *Index*; and for an account of the mode of cultivating the pine-apple, see GARDENING.

PINEA, or PIGNE, in commerce, is a term used in Peru and Chili, for a kind of light, porous masses, or lumps, formed of a mixture of mercury and silver-dust from the mines. The ore, or mineral, of silver, when dug out of the veins of the mine, is first broken and then ground in mills for the purpose, driven by water with iron pestles, each of 200 pounds weight. The mineral, when thus pulverized, is next sifted, and then worked up with water into a paste; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about 2500 pounds.

Each piece or cuerpo is again kneaded up with sea-salt, which, dissolving, incorporates with it. They then add mercury, from 10 to 20 pounds for each cuerpo, kneading the paste afresh until the mercury be incorporated therewith. This office, which is exceedingly dangerous on account of the noxious qualities of the mercury, is always made the lot of the poor Indians. This amalgamation is continued for eight or nine days; and some add lime, lead, or tin ore, &c. to forward it; and, in some mines, they are obliged to use fire. To try whether or no the mixture and amalgamation be sufficient, they wash a piece in water; and if the mercury be white, it is a proof that it has had its effect: if black, it must be still farther worked.

(B) This Midas is a very different personage from his long-eared majesty of Phrygia, whose decision in favour of Pan had given such offence to Apollo; as is manifest, indeed, from his having been contemporary with Pindar.

(C) The most extraordinary part of this musician's performance that can be gathered from the scholiast upon Pindar, was his finishing the solo, without a reed or mouth-piece, which broke accidentally while he was playing. The legendary account given by the poet in this ode, of the occasion upon which the flute was invented by Minerva, is diverting: "It was (says he) to imitate the howling of the Gorgons, and the hissing of their snakes, which the goddess had heard when the head of Medusa (one of these three anti-graces) was cut off by Perseus."

ed. When finished, it is sent to the lavatories, which are large basons that empty successively into one another. The paste, &c. being laid in the uppermost of these, the earth is then washed from it into the rest by a rivulet turned upon it; an Indian, all the while, stirring it with his feet, and two other Indians doing the like in the other basons. When the water runs quite clear out of the basons, the mercury and silver are found at bottom incorporated. This matter they call *pella*, and of this they form the pineas, by expressing as much of the mercury as they can; first, by putting it in woollen bags, and pressing and beating it strongly; then, by stamping it in a kind of wooden mould, of an octagonal form, at bottom whereof is a brass plate pierced full of little holes. The matter, when taken out of the mould, is laid on a trivet, under which is a large vessel full of water; and the whole being covered with an earthen head, a fire is made round it.

The mercury still remains in the mass, and is thus reduced into fumes, and, at length, condensing, it is precipitated into the water, leaving behind it a mass of silver grains of different figures, which, only joining or touching at the extremes, render the matter very porous and light. This, therefore, is the pinea, or pigne, which the workmen endeavour to sell, secretly to vessels trading to the South sea; and from which those, who have ventured to engage in so dangerous a commerce, have made such vast gains. Indeed the traders herein must be very careful; for the Spanish miners are arrant knaves, and to make the pignes weigh the more, they often fill the middle with sand or iron.

PINEAL GLAND. See BRAIN, ANATOMY *Index*.

PINEAU, GABRIEL DU, a distinguished lawyer, was born at Angers in 1573. He went afterwards to Paris, and pled with eclat before the parliament and great council. Upon his return to Angers, he became a counsellor in the presidial court. He was consulted by all the neighbouring provinces, and had an active hand in all the great affairs of his time. Mary de Medicis conferred upon him the office of master of requests, and in her disgrace wished to support herself by his credit and counsels; but Du Pineau, always attentive to what he owed on the one hand to the mother of his king, and on the other to the king himself, never ceased to inspire that princess with sentiments of peace.

In 1632 Louis XIII. by way of reward, appointed him mayor and captain-general of the city of Angers; a situation in which he merited the flattering title of *Father of the People*. He had no respect of persons; for he was equally accessible to the poor and the great. This worthy citizen died the 15th of October 1644, at the age of 71. His house was a kind of academy, where regular conferences were held, and attended by young officers, advocates, and other literary characters. In those conferences every one freely stated the difficulties which occurred to him upon subjects either of law or history; and when Pineau spoke, all was made clear; but he was always the last in delivering his sentiments, because he perceived that too much deference was paid to his opinion. His writings are, 1. Latin notes, in addition to those of Du Moulin, upon the canon law, and printed along with the works of that eminent lawyer by the care of Francis Pinson. 2. Commentaries, observations, and consultations, upon several important questions respecting the laws both of Anjou and of France, with some dissertations upon different subjects, &c. reprinted in 1725, in 2 vols. folio, by the care of Livoniere, who has enriched them with very useful remarks. The editor says, that "Du Pineau is a little inferior to the celebrated Du Moulin on the civil law, but that he is more accurate than the other upon the canon law."—Menage made these two verses upon his death:

Pinellus periit, Themidis pius ille sacerdos,
In proprio judex limine perpetuus.

PINEDA, JOHN, a writer of history, was born at Seville of a noble family, and entered into the society of Jesuits in 1572. He taught philosophy and divinity in several colleges; and devoted his time to the study of the Holy Scriptures. That he might render that study the easier, he made himself master of the oriental languages. We have of his writings, 1. Two volumes of Commentaries upon the book of Job, in folio. 2. Two upon Ecclesiastes. 3. A General History of the Church, in Spanish, 4 vol. in folio. 4. A History of Ferdinand III. in the same language, in folio. He died in 1637, much regretted by the members of his society, and by the public in general.

PINELLI, JOHN VINCENT, a distinguished literary character, was born at Naples, and was son of Count Pinelli, a noble Genoese, who had settled in that city, and had acquired a handsome fortune in the way of trade. After receiving a liberal education, he quitted the place of his nativity, and repaired to Padua, where he took up his residence at the age of 24. Being a great lover of science, he gave a preference to that city on account of its famous university, which brought to it a number of learned men. He had an excellent library, which consisted of a choice collection of books and manuscripts, and which he continued to enrich till the hour of his death. His literary correspondence, not only in Italy, but through the most of Europe, procured him all the new works which were worthy of a place in his collection. The authors themselves were often forward to pay their respects to him. In many cities of Italy he had persons employed to search, at least once a month, the stalls of those artificers who make use of old parchments, such as lute-makers, sievewrights, and others; and by this means he had the good fortune often to save from destruction some valuable fragments. His passion for knowledge embraced all the sciences; but history, medals, antiquities, natural history, and particularly botany, were his favourite studies. He was consulted from all quarters, and the extent of his acquaintance with the learned world was very great. He corresponded with Justus Lipsius, Joseph Scaliger, Sigonius, Possevin, Peter Pithou, and a great many others, who have all paid the highest compliments to his erudition. Insensible to all the pleasures of life, and acquainted only with those of the mind, he had a great dislike to plays, entertainments, shows, and every thing which most excites the curiosity of other men. During the space of 43 years that he lived at Padua, he was never known to be out of the city but twice; once on occasion of a plague which infested it; and afterwards on a voyage to Naples, which he made at the earnest solicitation of his friends. In short, Pinelli was generous,

ous, sympathizing, and compassionate, particularly to men of letters, whose wants he often anticipated. His zeal for the progress and advancement of science rendered him very communicative of his knowledge and of his books; but this was always done with judgment and discretion. He died in 1601, aged 68, without having published any work. Paul Gualdo, who has written Pinelli's life, does not specify the number of volumes of which his rich library consisted: he only informs us, that when it was transported by sea to Naples, it was packed up in 130 chests, of which 14 contained manuscripts; but it did not go wholly to his heirs. The senate of Venice caused their seal to be set upon the manuscripts, and took away whatever concerned the affairs of the republic, to the number of 200 pieces.—"I compare (says President de Thou) Pinelli to Titus Pomponius; for, as that illustrious Roman was called *Attick*, Pinelli also bore the title of *Venetian*, on account of the great affection which the republic of Venice had for him.

PINET, Antony du, lord of Noroy, an ecclesiastical writer, who lived in the 16th century, and was a native of Besançon in France. He was strongly attached to the Protestant religion, and a bitter enemy to the church of Rome. His book, entitled *La Conformité des Eglises Reformés de France, et de l'Eglise primitive*, printed at Lyons, 1564, in 8vo; and the notes which he added to the French translation of the Fees of the Pope's Chancery, which was printed at Lyons, in 8vo, 1564, and reprinted at Amsterdam in 1700, in 12mo, plainly discover his sentiments. He published the last mentioned performance under this title: *Taxé des parties casuelles de la boutique du Pape*, in Latin and French, with some notes taken from decrees, councils, and canons, in order to ascertain the discipline anciently observed in the church. In the epistle dedicatory, he assumes the tone of a declared enemy to the court of Rome. He apologizes for having presented this book "to a society so holy as yours (the Protestants), in which are heard only hymns, psalms, and praises, to the Lord our God: but it is proper to show to the villain his villany, and the fool his folly, lest one should be thought to resemble them." We see by this specimen, that Pinet had no more politeness in his style than in his manners. His translation of Pliny's Natural History, printed at Lyons in 2 vols folio, 1566, and at Paris, 1608, was formerly much read. Though there are many errors in it, it is yet very useful, especially for those who do not understand Pliny's Latin, on account of the translators researches, and a great number of marginal notes. Pinet also published "Plans of the principal fortresses in the world," at Lyons, 1564, in folio.

Grosier's General Description of China, vol. i. p. 92.

PING-leang-fou, a city of China in the province of Chen-si. It is one of the most considerable cities of the western part of the province, and is situated on the river Kin-ho. The air here is mild; and the agreeable views which the surrounding mountains present, added to the streams which water the country, render it a very delightful residence. It has under its jurisdiction three cities of the second class and seven of the third. In this district is a valley so deep and narrow, that it is almost impervious to the light: a large highway, paved with square stones, runs through it.

PINGUICULA, Butterwort; a genus of plants belonging to the diandria class. See Botany *Index*.

PINGUIN, or Penguin, in *Ornithology*, a genus of birds of the order anseres. See Aptenodytes, Ornithology *Index*, or page 507.

PINION, in *Mechanics*, an arbor, or spindle, in the body whereof are several notches, which catch the teeth of a wheel that serves to turn it round; or it is a lesser wheel that plays in the teeth of a larger.

PINK, a name given to a ship with a very narrow stern; whence all vessels, however small, whose sterns are fashioned in this manner, are called *pink-sterned*.

Pink. See Dianthus, Botany *Index*.

PINNA, in *Zoology*, a genus of shell-fish belonging to the order of vermes testacea. See Conchology *Index*.—Pliny, who gives some account, perhaps not very correct, of the history of some of the species of this genus (lib. ix. 51.) says, the smallest of all the kinds is called the *pinnoteres*, and therefore liable to injury; this has the prudence to hide itself in the shells of oysters. Again, lib. ix. 66. he says, the pinna is of the genus of shell-fish; it is produced in muddy waters, always erect, nor ever without a companion, which some call the *pinnoteres*, others the *pinnophylax*. This sometimes is a small squill, sometimes a crab, that follows the pinna for the sake of food. The pinna, upon opening its shell, exposes itself as a prey to the smallest kind of fishes; for they immediately assault her, and, growing bolder upon finding no resistance, venture in. The guard, watching its time, gives notice by a bite; upon which the pinna, closing its shell, shuts in, kills, and gives part of whatever happens to be there to its companion.

The pinna and the crab together dwell,
For mutual succour, in one common shell.
They both to gain a livelihood combine;
That takes the prey, when this has given the sign.
From hence this crab, above his fellows fam'd,
By ancient Greeks was *pinnoteres* nam'd.—Oppian.

PINNACE, a small vessel navigated with oars and sails, and having generally two masts, which are rigged like those of a schooner.

Pinnace is also a boat usually rowed with eight oars. See the article Boat.

PINNACLE, in *Architecture*, the top or roof of a house, terminating in a point. This kind of roof among the ancients was appropriated to temples; their ordinary roofs were all flat, or made in the platform way.

PINNATED leaves. See Botany *Index*.

PINNATIFID leaves. See Botany *Index*.

PINNOTERUS, or Pinnophylax, is a kind of crab-fish, furnished with very good eyes. It is said to be the companion of the pinna marina. They live and lodge together in the same shell, which belongs to the latter. When it has occasion to eat, it opens its valves, and sends out its faithful purveyor to procure food. If during their labour the pinnoterus perceives the polypus, it immediately returns to warn its blind friend of the danger, when, by shutting its valves, it escapes the rage of its enemy; but when the pinnoterus loads itself with booty without molestation, it makes a gentle noise at the opening of the shell, and when admitted

mitted the two friends feast on the fruits of its industry. See PINNA, &c.

PINT *(pinta)*, a vessel or measure, used in estimating the quantity of liquids, and even sometimes of dry things.—Budæus derives the word from the Greek πινθα; others from the German *pint*, a little measure of wine; Nicod from the Greek πινειν, "to drink."

The *English pint* is twofold; the one for wine measure, the other for beer and ale measure. See MEASURE.

PINTADA, a species of PROCELLARIA.

PINTLES, certain points or hooks fastened upon the back part of the rudder, with their points downwards, in order to enter into, and rest upon, the *googings*, fixed in the stern-post, to hang the rudder. See HELM.

PINTOR, PETER, physician, was born at Valentia in Spain, in the year 1420, and was physician to Alexander VI. whom he followed to Rome, where he practised with great success. He has left behind him two performances of considerable merit, 1. *Aggregator Sententiarum Doctorum de Curatione in Pestilentia*, printted at Rome 1499, in folio. 2. *De Morbo Fœdo et Occulto his Temporibus Affligenti*, &c. printed at Rome, 1500, in 4to, black letter: a book extremely scarce, unknown to Luisini and Astruc, and which traces the venereal disease to the year 1496. Pintor died at Rome in 1503, aged 83 years.

PINTURICCIO, BERNARDINO, a celebrated Italian painter, was born at Perusia in 1454. He was the disciple of Peter Perugino, under whom he became so good an artist, that he employed him on many occasions as his assistant. He principally painted history and grotesque; but he also excelled in portraits, among which those of Pope Pius II. and Innocent VIII. of Giulia Farnese, Cæsar Borgia, and Queen Isabella of Spain, are particularly distinguished. The most memorable performance of Pinturiccio is the history of Pius II. painted in ten compartments in the monastery of Sienna; in which undertaking, Raphael, then a young man, and bred under the same master, assisted him so far as to sketch out cartoons of many parts of the composition. The story of his death is worth relating, especially as it illustrates his character. The last work he was engaged in was a *Nativity* for the monastery of St Francis at Sienna: the monks accommodated him with a chamber to work in, which they cleared of all the furniture, except one old trunk or chest that appeared too rotten to move; but Pinturiccio, naturally positive and peevish, insisted on its being taken away, and the monks, willing to gratify him, complied. It was no sooner stirred than one of the planks bursting, out tumbled 500 pieces of gold, which had been secreted there for many years. The monks were overjoyed at finding this treasure, and the painter proportionably mortified at losing his chance of the discovery by his indiscreet obstinacy: it affected his spirits so much that he survived but a few months, and it was generally considered as the cause of his death.

PINUS, the PINE-TREE; a genus of plants belonging to the monœcia class. See BOTANY *Index*. The pine-tree was well known to the ancients, and has been described and celebrated both by their philosophers and poets. Pliny enumerates no less than six species of trees of this genus; and it is mentioned by Virgil both in his Eclogues, his Georgics, and his Æneid; by Horace in his Odes; by Ovid in his Metamorphoses; by Statius; and by Catullus, &c. Macrobius relates an anecdote concerning the cones of pine-trees, which in common language were called *poma pinea*, "pine-apples." There lived in the Augustan age one Vatinius, who by some means had irritated the Roman people so much that they pelted him with stones. When he entertained them with gladiators, to save himself from such treatment for the future, he procured an edict from the ediles, that no person should throw any thing but apples in the amphitheatre. It accidentally happened that at this time Cascellius, eminent for his wit as well as knowledge of the law, was consulted on the question, whether a pine-apple (the cone of the pine) was legally included in the term *pomum*, "an apple?" It is an apple (said he) if you intend to fling it at Vatinius *. A decision by which the edict in his favour did not much mend his situation: for Martial represents it dangerous to come under this tree, because the cones in his time were of so great a size and weight, probably enlarged by cultivation for ages.

* Saturn. lib. ii cap. 6.

Nuces Pineæ.
Poma sumus Cybeles: procul hinc discede, viator,
Ne cadat in miserum nostra ruina caput †.

† Lib. xiii Ep. 25.

There are generally reckoned 14 species of this genus; of which the most remarkable are these following:

1. The *Pinea, pineaster*, or wild pine, grows naturally on the mountains in Italy and the south of France. It grows to the size of a large tree; the branches extend to a considerable distance; and while the trees are young, they are fully garnished with leaves, especially where they are not so close as to exclude the air from those within; but as they advance in age, the branches appear naked, and all those which are situated below become unsightly in a few years; for which reason they are now much less in esteem than formerly.

2. The *pinus pinea*, or stone pine, is a tall evergreen tree, native of Italy and Spain. It delights in a sandy loam, though like most others it will grow well in almost any land. Respecting the uses of this species, Hanbury tells us that "the kernels are eatable, and by many preferred to almonds. In Italy they are served up at table in their desserts.—They are exceeding wholesome, being good for coughs, colds, consumptions, &c. on which account only this tree deserves to be propagated." Hanbury continues: "It may be very proper here to take notice of a very great and dangerous mistake Mr Miller has committed, by saying, under his article of stone-pine, that seeds kept in the cones will be good, and grow if they are sown ten or twelve years after the cones have been gathered from the trees; whereas the seeds of this sort, whether kept in the cones or taken out, are never good after the first year; and though sometimes a few plants will come up from the seeds that are kept in the cones for two years before, yet this is but seldom; neither must a tenth part of a crop be expected. This caution is the more necessary, as several gentlemen who had cones, upon reading Mr Miller's book, and finding the seeds would take no damage when kept there, deferred the work for a season or two, when they thought they should have more conveniency either of men or ground for their purpose; and were afterwards wholly disappointed, no plants appearing.

Pinus.

pearing, the seeds being by that time spoiled and worth nothing."

3. The *rubra*, commonly called the *Scots fir* or *pine*. It is common throughout Scotland, whence its name; though it is also found in most of the other countries of Europe. M. du Hamel, of the Royal Academy of Sciences, mentions his having received some seeds of it from St Domingo in the West Indies; and thence concludes, that it grows indifferently in the temperate, frigid, and torrid zones. The wood of this tree is the red or yellow deal, which is the most durable of any of the kinds yet known. The leaves of this tree are much shorter and broader than those of the former sort, of a grayish colour, growing two out of one sheath; the cones are small, pyramidal, and end in narrow points; they are of a light colour, and the seeds are small.

4. The *pinus picea*, or yew-leaved fir, is a tall evergreen, and a native of Scotland, Sweden, and Germany. This species includes the silver fir and the balm of Gilead fir. The first of these is a noble upright tree. Mr Marsham says, "The tallest trees I have seen were spruce and silver firs in the valleys in Switzerland. I saw several firs in the dockyards in Venice 40 yards long; and one of 39 yards was 18 inches diameter at the small end. I was told they came from Switzerland."

Treatise on Planting and Ornamental Gardening.

The branches are not very numerous, and the bark is smooth and delicate. The leaves grow singly on the branches, and their ends are slightly indented. Their upper surface is of a fine strong green colour, and their under has an ornament of two white lines running lengthwise on each side the midrib; on account of which silvery look this sort is called the *silver fir*. The cones are large, and grow erect; and, when the warm weather comes on, they soon shed their seeds; which should be a caution to all who wish to raise this plant, to gather the cones before that happens.

The balm of Gilead fir has of all the sorts been most coveted, on account of the great fragrance of its leaves; though this is not its only good property: for it is a very beautiful tree, naturally of an upright growth, and the branches are so ornamented with their balmy leaves, as to exceed any of the other sorts in beauty. The leaves, which are very closely set on the branches, are broad; and their ends are indented. Their upper surface, when healthy, is of a fine dark-green colour, and their under has white lines on each side the midrib, lengthwise, nearly like those of the silver fir. These leaves when bruised are very finely scented; and the buds, which swell in the autumn for the next year's shoot, are very ornamental all winter, being turgid, and of a fine brown colour: and from these also exudes a kind of fine turpentine, of the same kind of (though heightened) fragrancy. The tree being wounded in any part, emits plenty of this turpentine; and Hanbury says, "it is supposed by many to be the sort from whence the balm of Gilead is taken, which occasions this tree being so called. But this is a mistake; for the true balm of Gilead is taken from a kind of terebinthus: though I am informed, that what has been collected from this tree has been sent over to England from America (where it grows naturally), and often sold in the shops for the true sort."

The silver fir is very hardy, and will grow in any soil or situation, but always makes the greatest progress in rich loamy earth. The balm of Gilead fir must be planted in deep, rich, good earth; nor will it live long in any other. The soil may be a black mould, or of a sandy nature, if it be deep enough, and if the roots have room enough to strike freely.

5. The *pinus abies*, or European spruce fir, a native of the northern parts of Europe and of Asia, includes the Norway spruce and long-coned Cornish fir. The former of these is a tree of as much beauty while growing, as its timber is valuable when propagated on that account. Its growth is naturally like the silver, upright: and the height it will aspire to may be easily conceived, when we say that the white deal, so much coveted by the joiners, &c. is the wood of this tree; and it may perhaps satisfy the curious reader to know, that from this fir pitch is drawn. The leaves are of a dark-green colour; they stand singly on the branches, but the younger shoots are very closely garnished with them. They are very narrow; their ends are pointed; and they are possessed of such beauties as to excite admiration. The cones are eight or ten inches long, and hang downwards.

Ibid.

The better the soil is, the faster will the spruce fir grow, though it will thrive very well in most of our English lands. In strong loamy earth it makes a surprising progress; and it delights in fresh land of all sorts, which never has been worn out by ploughing, &c. though it be ever so poor. The long-coned Cornish fir differs scarcely in any respect from the Norway spruce, except that the leaves and the cones are larger.

6. The *pinus Canadensis*, American or Newfoundland spruce fir, a native of Canada, Pennsylvania, and other parts of North America, includes three varieties. The white Newfoundland spruce, the red Newfoundland spruce, and the black Newfoundland spruce. These however, differ so little, that one description is common to them all. They are of a genteel upright growth, though they do not shoot so freely or grow so fast with us as the Norway spruce. The leaves are of the same green, and garnish the branches in the same beautiful manner as those of that species; only they are narrower, shorter, and stand closer. The greatest difference is observable in the cones; for these are no more than about an inch in length, and the scales are closely placed. In the cones, indeed, consists the difference of these three sorts: those of the white species are of a very light brown colour; those of the red species more of a nut-brown or reddish colour; and those of the black species of a dark or blackish colour. Besides this, there is scarcely any material difference; though it is observable, that this trifling variation seems to be pretty constant in the plants raised from the like seeds. These sorts will often flower, and produce cones when only about five or six feet high; and indeed look then very beautiful: but this is a sign of weakness in the plant, which it does not often fairly get over.

7. The *pinus balsamea*, or hemlock fir, a native of Virginia and Canada, possesses as little beauty as any of the fir tribe; though, being rather scarce in proportion, it is deemed valuable. It is called by some the *yew-leaved fir*, from the resemblance of the leaves to those of the yew-tree. It is a tree of low growth, with but few branches; and these are long and slender, and spread abroad without order. The leaves do not garnish the branches

branches so plentifully as those of any other sort of fir. The cones are very small and rounded; they are about half an inch long; and the scales are loosely arranged. We receive these cones from America, by which we raise the plants; though this caution should be given to the planter, that this tree is fond of moist rich ground, and in such a kind of soil will make the greatest progress.

8. The *pinus orientalis*, or oriental fir, a native of the East, is a low but elegant tree. The leaves are very short, and nearly square. The fruit is exceeding small, and hangs downward; and the whole tree makes an agreeable variety with the other kinds.

9. The *strobus*, Lord Weymouth's pine, or North American white pine. This grows sometimes to the height of 100 feet and upwards, and is highly valued on account of its beauty. The bark of the tree is very smooth and delicate, especially when young; the leaves are long and slender, five growing out of one sheath; the branches are pretty closely garnished with them, and thus make a fine appearance. The cones are long, slender, and very loose, opening with the first warmth of the spring; so that if they are not gathered in winter, the scales open and let out the seeds. The wood of this sort is esteemed for making masts for ships. In Queen Anne's time there was a law made for the preservation of these trees, and for the encouragement of their growth in America. Within these last 50 years they have been propagated in Britain in considerable plenty.

With respect to the culture of this species, Mr Hanbury, after some more general directions, continues thus, "I have known gentlemen, who, in attempting to raise these trees, have seen the young plants go off without perceiving the cause; and the more watering and pains they have taken, have found the plants persist in this way more and more, to their great mortification and astonishment. In the spring following these plants should be pricked out in beds half a foot asunder each way; and here they may stand two years, when they may be either finally planted out, or removed into the nursery, at the distance of one foot asunder, and two feet in the rows. If care has been taken of them in the nursery, they may be removed at a considerable height with great assurance of success: for it is much easier to make this pine grow than any of the other sorts: so that where they are wanted for ornament in parks, open places, &c. a show of them may be made in a little time.

"The soil the Weymouth pine delights in most is a sandy loam; but it likes other soils of an inferior nature: and although it is not generally to be planted on all lands like the Scotch fir, yet I have seen it luxuriant and healthy, making strong shoots, on blue and red clays, and other sorts of strong ground. On stony and slaty ground, likewise, I have seen some very fine trees; so that I believe whoever is desirous of having plantations of this pine, need not be curious in the choice of his ground."

10. The *pinus tæda*, or swamp-pine, is a tall evergreen tree, a native of the swamps of Virginia and Canada. There are several varieties of this genus which Hanbury enumerates and describes: such as, 1st, The three-leaved American swamp-pine. 2d, The two-leaved American pine. 3d, The yellow American pine, the yellow tough pine, and the tough pine of the plains; among which there is but little variety. 4th, The bastard pine. 5th, The frankincense pine. And 6th, the dwarf pine.

"There are (continues our author) many other sorts of American pines, which we receive from thence with the like cant names of those of the above, which I have chosen to retain, as they will probably be continued to be sent over; and that the gardener receiving them as such may best know what to do with them. In many of those sorts I see at present no material difference; so am induced to think they are the same, sent over with different names. Some of the sorts above mentioned differ in very few respects; but I have chosen to mention them, as a person may be supplied with the seeds from Pennsylvania, Jersey, Virginia, Carolina, &c. where they all grow naturally: and having once obtained the seeds, and from them plants, they will become pleasing objects of his nicest observations."

11. The *pinus cedrus*, ranked by Tournefort and others under larix, famous for its duration, is that popularly called by us the *cedar of Lebanon*, by the ancients *cedrus magna* or the *great cedar;* also *cedrelate*, κεδρελατη; and sometimes the Phœnician or Syrian cedar, from the country where it grows in its greatest perfection. It is a coniferous evergreen, of the bigger sort, bearing large roundish cones of smooth scales, standing erect, the leaves being small, narrow, and thick set.—They sometimes counterfeit cedar, by dyeing wood of a reddish hue: but the smell discovers the cheat, that of true cedar being very aromatic. In some places, the wood of the cajou tree passes under the name of cedar, on account of its reddish colour and its aromatic smell which somewhat resemble that of santal. Cedar-wood is reputed almost immortal and incorruptible; a prerogative which it owes chiefly to its bitter taste, which the worms cannot endure. For this reason it was that the ancients used cedar tablets to write upon, especially for things of importance, as appears from that expression of Persius, *Et cedra digna locutus.* A juice was also drawn from cedar, with which they smeared their books and writings, or other matters, to preserve them from rotting; which is alluded to by Horace: by means of which it was, that Numa's books, written on papyrus, were preserved entire to the year 535, as we are informed by Pliny.

Solomon's temple, as well as his palace, were both of this wood. That prince gave King Hiram several cities for the cedars he had furnished him on these occasions. Cortes is said to have erected a palace at Mexico, in which were 7000 beams of cedar, most of them 120 feet long, and 12 in circumference, as we are informed by Herrera. Some tell us of a cedar felled in Cyprus 130 feet long, and 18 in diameter. It was used for the main-mast in the galley of King Demetrius. Le Bruyn assures us, that the two biggest he saw on Mount Lebanon, measured, one of them 57 palms, and the other 47, in circumference. In the temple of Apollo at Utica, there were cedar trees near 2000 years old; which yet were nothing to that beam in an oratory of Diana at Seguntum in Spain, said to have been brought thither 200 years before the destruction of Troy. Cedar is of so dry a nature, that it will not endure to be fastened with iron nails, from which it usually shrinks; so that they commonly fasten it with pins of the same wood.

"The

"The statue (says Hanbury) of the great goddess at Ephesus was made of this material; and, if this tree abounded with us in great plenty, it might have a principal share in our most superb edifices. The effluvia constantly emitted from its wood are said to purify the air, and make rooms wholesome. Chapels and places set apart for religious duties, being wainscotted with this wood, inspire the worshippers with a more solemn awe. It is not obnoxious to worms; and emits an oil which will preserve cloth or books from worms or corruption. The saw-dust will preserve human bodies from putrefaction; and is therefore said to be plentifully used in the rites of embalming, where practised."

It is remarkable that this tree is not to be found as a native in any other part of the world than Mount Libanus, as far as hath yet been discovered. What we find mentioned in Scripture of the lofty cedars can be nowise applicable to the common growth of this tree; since, from the experience we have of those now growing in England, as also from the testimony of several travellers who have visited those few remaining trees on Mount Libanus, they are not inclined to grow very lofty, but on the contrary extend their branches very far; to which the allusion made by the Psalmist agrees very well, when he is describing the flourishing state of a people, and says, "They shall spread their branches like the cedar-tree."

Rauwolf, in his Travels, says, there were not at that time (i. e. anno 1574) upon Mount Libanus more than 26 trees remaining, 24 of which stood in a circle; and the other two, which stood at a small distance, had their branches almost consumed with age; nor could he find any younger tree coming up to succeed them, though he looked about diligently for some. These trees (he says) were growing at the foot of a small hill on the top of the mountains, and amongst the snow. These having very large branches, commonly bend the tree to one side, but are extended to a great length, and in so delicate and pleasant order, as if they were trimmed and made even with great diligence, by which they are easily distinguished, at a great distance, from fir-trees. The leaves (continues he) are very like to those of the larch tree, growing close together in little branches upon small brown shoots.

Maundrel, in his Travels, says, there were but 16 large trees remaining when he visited the mountain, some of which were of a prodigious bulk, but that there were many more young ones of a smaller size: he measured one of the largest, and found it to be 12 yards six inches in girth, and yet sound, and 37 yards in the spread of its boughs. At about five or six yards from the ground it was divided into five limbs, each of which was equal to a great tree. What Maundrel hath related was confirmed by a gentleman who was there in the year 1720, with this difference only, viz. in the dimensions of the branches of the largest tree, which he measured, and found to be 22 yards diameter. Now, whether Mr Maundrel meant 37 yards in circumference of the spreading branches, or the diameter of them, cannot be determined by his words; yet either of them well agrees with this last account.

12. There is another species, viz. the *larch tree*, which the old botanists ranked under larix, with deciduous leaves, and oval obtuse cones. It grows naturally upon the Alps and Apennines, and of late has been very much propagated in Britain. It is of quick growth, and the trunk rises to 50 feet or more; the branches are slender, their ends are generally hanging downward, and are garnished with long narrow leaves which arise in clusters from one point, spreading open above like the hair of a painter's brush: they are of a light green, and fall away in autumn. In the month of April the male flowers appear, which are disposed in form of small cones; the female flowers are collected into oval obtuse cones, which in some species have bright purple tops, and in others they are white: these differences are accidental; the cones are about an inch long, obtuse at their points; the scales are smooth, and lie over each other: under each scale there are generally lodged two seeds which have wings. There are other two varieties of this tree, one of which is a native of America, and the other of Siberia. The cones of the American kind which have been brought to Britain seem in general to be larger than those of the common sort.

"Many encomiums (says Hanbury when speaking of this species) have been bestowed on the timber of the larch: and we find such a favourable account of it in ancient authors, as should induce us to think it would be proper for almost any use. Evelyn recites a story of Witsen, a Dutch writer, that a ship built of this timber and cypress had been found in the Numidian sea, twelve fathoms under water, sound and entire, and reduced to such a hardness as to resist the sharpest tool, after it had lain submerged above 1400 years. Certain it is this is an excellent wood for ship and house-building. At Venice this wood is frequently used in building their houses, as well as in Switzerland, where these trees abound: so that, without all doubt, the larch excels for masts for ships, or beams for houses, doors, windows, &c. particularly as it is said to resist the worm.

"In Switzerland (A) their houses are covered with boards of this wood cut out a foot square; and, as it emits a resinous substance, it so diffuses itself into every joint and crevice, and becomes so compact and close, as well as so hardened by the air, as to render the covering proof against all weather. But as such covering for houses would cause great devastation in case of fire, the buildings

(A) "Between Bex and Bevieux (says Coxe in his *Travels in Switzerland*), I observed the larch in great plenty. Painters, from the time of Pliny to that of Ráphael, trusted their works to this wood, which the Roman naturalist stiles *immortale lignum*. The wood is reckoned excellent for all works which are to lie under water: and the borderers on the lake of Geneva prefer it for building their vessels. In these parts I saw most beautiful woods of chesnut. Haller says that they extend some leagues: he also informs us, that they are found in other parts of Switzerland, and even in desert places in some of the transalpine parts. Accident must have brought them thither, as it appears from Pliny that these trees were first introduced into Europe from Sardis."

buildings are confined to a limited distance by an order of police from the magistrates. The wood, when first laid on the houses, is said to be very white; but this colour, in two or three years is changed, by means of the sun and resin, to a black, which appears like a smooth shining varnish."

Of the common larch there are several varieties. The flowers which the commonest sort exhibits early in the spring are of a delicate red colour; another sort produces white flowers at the same season, and these have a delightful effect among those of the red sort; whilst another, called the *Black Newfoundland larix*, increases the variety, though by an aspect little differing from the others. There are also larches with greenish flowers, pale red, &c. all of which are accidental varieties from seeds. These varieties are easily distinguished, even when out of blow: the young shoots of the white-flowering larch are of the lightest green, and the cones when ripe are nearly white. The red flowering larch has its shoots of a reddish cast, and the cones are of a brown colour; whilst the cones and shoots of the black Newfoundland larch are in the same manner proportionally tinged. The cones, which are a very great ornament to several sorts of the pines, are very little to these. Their chief beauty consists in the manner of their growth, the nature and beauty of their pencilled leaves and fair flowers; for the cones that succeed them are small, of a whitish, a reddish, or a blackish-brown colour, and make no figure.

The pinus cedrus and pinus larix are propagated by sowing in March on a bed of light earth exposed to the morning sun. The seed must be covered half an inch thick with fine light earth, and the beds watered at times when the weather is dry. In about six weeks the plants will appear; they must at this time be carefully guarded from the birds, shaded from the sun and winds, and kept very clear of weeds. In the latter end of April the following year, they may be removed into beds of fresh earth, placing them at ten inches distance every way. They are to be kept here two years, and such of them as seem to bend must be tied up to a stake to keep them upright. They may afterwards be planted in the places where they are to remain. They thrive well on the sides of barren hills, and make a very pretty figure there.

Respecting the uses of this tree, Dr Pallas, in his *Flora Rossica*, informs us, that if it is burnt, and the wood consumed, the internal part of the wood distils copiously a drying reddish gum, a little less glutinous than gum arabic, somewhat of a resinous taste, but wholly soluble in water. At the instigation of M. Kinder, this gum has lately been sold in the Russian shops under the name of *gummi Orenburgensis*, but which our author thinks should be called *gummi Uraliense* or *laricis*. It is eaten by the Woguli as a dainty, and is said to be nutritious and antiscorbutic. Some manna was gathered from the green leaves, but it could never be condensed. The Russians use the boletus laricinus as an emetic in intermittents, and to check the leucorrhœa. At Baschir and Siberia the inhabitants sprinkle the dry powder on the wounds of oxen and horses, as a detergent and anthelmintic. The nuts of the pinus cembra, the same author asserts, are eaten as luxuries in Russia, and are even exported with the same view. The unripe cones give a very fragrant oil, termed balsamic. The inhabitants of Siberia use the tender tops, and even the bark rubbed off in the spring, as an antiscorbutic. The kernels of the nuts of the amygdalus nana give a very pleasing flavour to brandy; and, when pressed, afford a bitter oil in large quantities. The way of destroying the bitter is by digesting it in the sun with spirit of wine, and it then becomes sweet and extremely agreeable.

From the larch-tree is extracted what is erroneously called *Venice turpentine*. This substance, or natural balsam, flows at first without incision; when it has done dropping, the poor people who wait in the fir woods make incisions at about two or three feet from the ground into the trunks of the trees, into which they fix narrow troughs about 20 inches long. The end of these troughs is hollowed like a ladle; and in the middle is a small hole bored for the turpentine to run into the receiver which is placed below it. As the gummy substance runs from the trees, it passes along the sloping gutter or trough to the ladle, and from thence runs through the holes into the receiver. The people who gather it visit the trees morning and evening from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, Venice turpentine is clear like water, and of a yellowish white; but as it grows older, it thickens and becomes of a citron colour. It is procured in the greatest abundance in the neighbourhood of Lyons, and in the valley of St Martin near Lucern in Switzerland.

Though we have already noticed the manner of cultivating some of the particular species of this genus, and have also remarked the uses of some of them, we shall finish the article with a few general observations on the culture and uses of the whole.

Culture. All the sorts of pines are propagated by seeds produced in hard woody cones. The way to get the seeds out of these cones is to lay them before a gentle fire, which will cause the cells to open, and then the seed may be easily taken out. If the cones are kept entire, the seeds will remain good for some years; so that the surest way of preserving them is to let them remain in the cones till the time for sowing the seeds. If the cones are kept in a warm place in summer, they will open and emit the seeds; but if they are not exposed to the heat, they will remain close for a long time. The best season for sowing the pines is about the end of March. When the seeds are sown, the place should be covered with nets to keep off the birds; otherwise, when the plants begin to appear with the husk of the seed on the top of them, the birds will peck off the tops, and thus destroy them.

Uses. From the first species is extracted the common turpentine, much used by farriers, and from which is drawn the oil of that name. The process of making pitch, tar, resin, and turpentine, from these trees is very familiar. In the spring time, when the sap is most free in running, they pare off the bark of the pine tree, to make the sap run down into a hole which they cut at the bottom to receive it. In the way, as it runs down, it leaves a white matter like cream, but a little thicker, This is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of flambeaux instead of white bees wax. The matter that is received in the hole at the bottom is taken up with ladles, and put in a large basket. A great part of this immediately runs through, and this is the common

mon turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, adding a large quantity of water. They distil this as long as any oil is seen swimming upon the water. This oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine. The remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all that they can from the sap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with these billets, and setting them on fire, there runs from them, while they are burning, a black thick matter. This naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil. If this hole be made too large, it sets the whole quantity of the tar on fire; but, if small enough, it runs quietly out.

The tar, being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it. It is then suffered to boil a while, and being then let out, is found when cold to be what we call pitch.

A decoction of the nuts or seeds of the first species in milk, or of the extremities of the branches pulled in spring, is said, with a proper regimen, to cure the most inveterate scurvy. The wood of this species is not valued; but that of the Scots pine is superior to any of the rest. It is observable of the Scots pine, that when planted in bogs, or in a moist soil, though the plants make great progress, yet the wood is white, soft, and little esteemed; but when planted in a dry soil, though the growth of the trees is there very slow, yet the wood is proportionably better. Few trees have been applied to more uses than this. The tallest and straightest are formed by nature for masts to our navy. The timber is resinous, durable, and applicable to numberless domestic purposes, such as flooring and wainscotting of rooms, making of beds, chests, tables, boxes, &c. From the trunk and branches of this, as well as most others of the pine tribe, tar and pitch are obtained. By incision, barras, Burgundy pitch, and turpentine, are acquired and prepared. The resinous roots are dug out of the ground in many parts of the Highlands, and, being divided into small splinters, are used by the inhabitants to burn, instead of candles.—At Loch-Broom, in Ross-shire, the fishermen make ropes of the inner bark; but hard necessity has taught the inhabitants of Sweden, Lapland, and Kamtschatka, to convert the same into bread. To effect this, they, in the spring season, make choice of the tallest and fairest trees; then stripping off carefully the outer bark, they collect the soft, white, succulent interior bark, and dry it in the shade. When they have occasion to use it, they first toast it at the fire, then grind, and after steeping the flour in warm water to take off the resinous taste, they make it into thin cakes, which are baked for use. On this strange food the poor inhabitants are sometimes constrained to live for a whole year; and, we are told, through custom, become at last even fond of it. Linnæus remarks, that this same bark-bread will fatten swine; and humanity obliges us to wish, that men might never be reduced to the necessity of robbing them of such a food. The interior bark, of which the above-mentioned bread is made, the Swedish boys frequently peel off the trees in the spring, and eat raw with greedy appetite. From the cones of this tree is prepared a diuretic oil, like the oil of turpentine, and a resinous extract, which has similar virtues with the balsam of Peru. An infusion or tea of the buds is highly commended as an antiscorbutic. The farina, or yellow powder, of the male-flowers, is sometimes in the spring carried away by the winds, in such quantities, where the trees abound, as to alarm the ignorant with the notion of its raining brimstone. The tree lives to a great age; Linnæus affirms to 400 years.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army, for mending the ways, for working on intrenchments and fortifications, and for making mines and approaches. The soldiers are likewise employed for all these purposes. Most of the foreign regiments of artillery have half a company of pioneers, well instructed in that important branch of duty. Our regiments of infantry and cavalry have three or four pioneers each, provided with aprons, hatchets, saws, spades, and pickaxes. Each pioneer must have an axe, a saw, and an apron; a cap with a leather crown, and a black bears-skin front, on which is to be the king's crest in white, on a red ground; and the number of the regiment is to be on the back part of it.

PIP, or PEP, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding. It usually arises from want of water, or from the drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with salt. Hawks are particularly liable to this disease, especially from feeding on stinking flesh.

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other liquids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are usually made of oak or elder. Those of iron are cast in forges; their usual length is about two feet and a half: several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augres, of different sizes, beginning with a less, and then proceeding with a larger successively; the first being pointed, the rest being formed like spoons, increasing in diameter, from one to six inches and more: they are fitted into the extremities of each other (as represented fig. 2.), and are sold by the foot. Plate CCCCXIX. fig. 2.

Wooden pipes are bored as follows. The machine represented fig. 1. is put in motion by the wheel A, Fig. 1. which is moved by a current of water; upon the axle of this wheel is a cog-wheel B, which causes the lanterns C, D, to turn horizontally, whose common axis is consequently in a perpendicular direction. The lantern D turns at the same time two cog-wheels, E and F: the first, E, which is vertical, turns the augre which bores the wood; and the second F, which is horizontal, causes the carriage bearing the piece to advance by means of the arms H, I, which take hold of the notches

ches in the wheel K. The first, H, by means of the notches, draws the wheel towards F; and the other, I, pushes the under-post of the wheel in an opposite direction; both which motions tend to draw the carriage towards F, and consequently cause the augre to pierce the wood. The augre being from 9 to 12 feet in length, and of a proportionable bigness, it will be necessary to have two pieces, as L, L, to support its weight, and cause it to enter the piece to be bored with the same uniformity.

For the construction of leaden pipes, see the article PLUMBERY.

Air-PIPES. See *AIR-Pipes.*

PIPES of an Organ. See ORGAN.

Bag-PIPE. See *BAG-Pipe.*

Horn-PIPE. See HORNPIPE.

Tobacco-PIPE, a machine used in the smoking of tobacco, consisting of a long tube, made of earth or clay, having at one end a little case, or furnace, called the *bowl*, for the reception of the tobacco, the fumes whereof are drawn by the mouth through the other end. Tobacco pipes are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use pipes three or four feet long, made of rushes, or of wood bored, at the end whereof they fix a kind of a pot of baked earth, which serves as a bowl, and which they take off after smoking.

PIPE, also denotes a vessel or measure for wine, and things measured by wine-measure. See BARREL and MEASURE.

PIPE, in *Mining*, is where the ore runs forwards endwise in a hole, and doth not sink downwards or in a vein.

PIPE, *Pipa*, in *Law*, is a roll in the exchequer, called also the *great roll.* See the next article.

PIPE-Office, is an office wherein a person called the *clerk of the pipe*, makes out leases of crown-lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer. The clerk of the pipe makes out also all accounts of sheriffs, &c. and gives the accountants their *quietus est.* To this office are brought all accounts which pass the remembrancer's office, and remain there, that if any stated debt be due from any person, the same may be drawn down into the great roll of the pipe: upon which the comptroller issues out a writ, called the *summons of the pipe*, for recovery thereof; and if there be no goods or chattels, the clerk then draws down the debts to the lord treasurer's remembrancer, to write estreats against their lands. All tallies which vouch the payment of any sum contained in such accounts are examined and allowed by the chief secondary of the pipe. Besides the chief clerk in this office, there are eight attorneys or sworn clerks, and a comptroller.

PIPE-Fish. See SYNGNATHUS, ICHTHYOLOGY *Index.*

Sea PIPES, the trivial name of univalve shells belonging to the genus *dentalis.* See CONCHOLOGY *Index.*

PIPER, a species of fish. See TRIGLA, ICHTHYOLOGY *Index.*

PIPER, *Pepper;* a genus of plants belonging to the diandria class. See BOTANY *Index.* There are 20 species, of which the most remarkable is the siriboa, with oval, heart-shaped, nerved leaves, and reflexed spikes. This is the plant which produces the pepper so much used in food. It is a shrub whose root is small, fibrous, and flexible; it rises into a stem, which requires a tree or prop to support it. Its wood has the same sort of knots as the vine; and when it is dry, it exactly resembles the vine-branch. The leaves, which have a strong smell and a pungent taste, are of an oval shape; but they diminish towards the extremity, and terminate in a point. From the flower-buds, which are white, and are sometimes placed in the middle and sometimes at the extremity of the branches, are produced small berries resembling those of the currant tree. Each of these contains between 20 and 30 corns of pepper; they are commonly gathered in October, and exposed to the sun seven or eight days. The fruit which was green at first, and afterwards red, when stripped of its covering assumes the appearance it has when we see it. The largest, heaviest, and least shrivelled, is the best.

The pepper plant flourishes in the islands of Java, Sumatra (A), and Ceylon, and more particularly on the Malabar coast. It is not sown, but planted; and great nicety is required in the choice of the shoots. It produces no fruit till the end of three years; but bears so plentifully the three succeeding years, that some plants yield between six and seven pounds of pepper. The bark then begins to shrink; and the shrub declines so fast, that in 12 years time it ceases bearing.

The culture of pepper is not difficult: it is sufficient to plant it in a rich soil, and carefully to pull up the weeds that grow in great abundance round its roots, especially the three first years. As the sun is highly necessary to the growth of the pepper plant, when it is ready to bear, the trees that support it must be lopped to prevent their shade from injuring the fruit. When the season is over, it is proper to crop the head of the plant. Without this precaution, there would be too much wood, and little fruit.

The pepper exported from Malabar, which was formerly entirely in the hands of the Portuguese, and was afterwards divided between the Dutch, British, and French, amounted to about 10,000,000 weight. Betel, or betle, is a species of this genus. See BETEL. It is a creeping and climbing plant like the ivy; and its leaves a good deal resemble those of the citron, though they are longer and narrower at the extremity. It grows in all parts of India, but thrives best in moist places. The natives cultivate it as we do the vine, placing props for it to run and climb upon; and it is a common practice to plant it against the tree which bears the areca-nut.

At all times of the day, and even in the night, the Indians chew the leaves of the betel, the bitterness of which is corrected by the areca that is wrapped up in them. There is constantly mixed with it the chinam, a

(A) See a copious account of the mode of cultivating pepper in Sumatra, in Mr Marsden's *History of Sumatra*, or in the *New Annual Register* for 1783, p. 147.

a kind of burnt lime made of shells. The rich frequently add perfumes, either to gratify their vanity or their sensuality.

It would be thought a breach of politeness among the Indians to take leave for any long time, without presenting each other with a purse of betel. It is a pledge of friendship that relieves the pain of absence. No one dares to speak to a superior unless his mouth is perfumed with betel; it would even be rude to neglect this precaution with an equal. The women of gallantry are the most lavish in the use of betel, as being a powerful incentive to love. Betel is taken after meals; it is chewed during a visit; it is offered when you meet, and when you separate; in short, nothing is to be done without betel. If it is prejudicial to the teeth, it assists and strengthens the stomach. At least, it is a general fashion that prevails throughout India.

London Medical Journal, vol. viii. part iii p. 276, &c.

The *piper amalago*, or black pepper, and the *piper inequale*, or long pepper of Jamaica, with some other species, are indigenous, and known by the names of *joint wood*, or *peppery elders*. The first bears a small spike, on which are attached a number of small seeds of the size of mustard. The whole of the plant has the exact taste of the East India black pepper. The long pepper bush grows taller than the amalago. The leaves are broad, smooth, and shining. The fruit is similar to the long pepper of the shops, but smaller. The common people in Jamaica season their messes with the black pepper. To preserve both, the fruit may be slightly scalded when green, then dried, and wrapped in paper. Perhaps hereafter they may be deemed worthy of attention.

PIPRA, a genus of birds, of the order of *passeres*. See Ornithology *Index*.

PIQUET, or Picket, a celebrated game at cards, much in use throughout the polite world.

It is played between two persons, with only 32 cards; all the deuces, threes, fours, fives, and sixes, being set aside.

In reckoning at this game, every card goes for the number it bears, as a ten for ten; only all court cards go for ten, and the ace for eleven: and the usual game is one hundred up. In playing, the ace wins the king, the king the queen, and so down.

Twelve cards are dealt round, usually by two and two; which done, the remainder are laid in the middle: if one of the gamesters finds he has not a court card in his hand, he is to declare he has *carte-blanche*, and tell how many cards he will lay out, and desire the other to discard, that he may show his game, and satisfy his antagonist that the carte-blanche is real; for which he reckons ten.

Each person discards, i. e. lays aside a certain number of his cards, and takes in a like number from the stock. The first of the eight cards may take three, four, or five; the dealer all the remainder, if he pleases.

After discarding, the eldest hand examines what suit he has most cards of; and reckoning how many points he has in that suit, if the other have not so many in that or any other suit, he tells one for every ten of that suit. He who thus reckons most is said to win the point.

The point being over, each examines what *sequences* he has of the same suit, viz. how many tierces, or sequences of threes, quartes or fours, quintes or fives, sixiemes, or sixes, &c. For a tierce they reckon three points, for a quarte four, for a quinte 15, for a sixieme 16, &c. And the several sequences are distinguished in dignity by the cards they begin from: thus ace, king, and queen, are called *tierce major;* king, queen, and knave, *tierce to a king;* knave, ten, and nine, *tierce to a knave*, &c. and the best tierce, quarte, or quinte, i. e. that which takes its descent from the best card, prevails, so as to make all the others in that hand good, and destroy all those in the other hand. In like manner, a quarte in one hand sets aside a tierce in the other.

The sequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three of any sort, three: but here too, as in sequences, he that with the same number of threes has one that is higher than any the other has, e. gr. three aces, has all his others made good hereby, and his adversary's all set aside. But four of any sort, which is called a *quatorze*, always sets aside three.

All the game in hand being thus reckoned, the eldest proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the suit; and the highest card of the suit wins the trick. Note, unless a trick be won with a card above a nine (except the last trick), nothing is reckoned for it, though the trick serves afterwards towards winning the cards; and that he who plays last does not reckon for his cards unless he wins the trick.

The cards being played out, he that has most tricks reckons ten for winning the cards. If they have tricks alike, neither reckons any thing. The deal being finished, and each having marked up his game, they proceed to deal again as before, cutting afresh each time for the deal.

If both parties be within a few points of being up, the carte-blanche is the first thing that reckons, then the point, then the sequences, then the quatorzes or threes, then the tenth cards.

He that can reckon 30 in hand by carte-blanche, points, quintes, &c. without playing, before the other has reckoned any thing, reckons 90 for them; and this is called a *repique*. If he reckons above 30, he reckons so many above 90. If he can make up 30, part in hand and part play, ere the other has told any thing, he reckons for them 60. And this is called a *pique*. Whence the name of the game. He that wins all the tricks, instead of ten, which is his right for winning the cards, reckons 40. And this is called a *capot*.

Mr de Moivre, who has made this game the object of mathematical investigation, has proposed and solved the following problems: 1. To find at piquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more. 2. To find at piquet the probability which the eldest has of taking an ace or more in five cards, he having no ace in his hand. Answer: 232 to 91, or 5 to 2, nearly. 3. To find at piquet the probability which the eldest hand has of taking an ace and a king in five cards, he having none in his hand. Answer: the odds against the eldest hand taking

taking an ace and a king are 331 to 315, or 21 to 20 nearly. 4. To find at piquet the probability of having 12 cards dealt to, without king, queen, or knaves, which case is commonly called *cartes blanches*. Answer; the odds against cartes-blanches are 1791 to 1 nearly. 5. To find how many different sets, essentially different from one another, one may have at piquet before taking in. Answer; 28,967,278. This number falls short of the sum of all the distinct combinations, whereby 12 cards may be taken out of 32, this number being 225,792,840; but it must be considered that in that number several sets of the same import, but differing in suit, might be taken, which would not introduce an essential difference among the sets. The same author gives also some observations on this game, which he had from an experienced player. See *Doctrine of Chances*, p. 179, &c. M. de Monmort has treated of piquet in his *Analyse des Jeux de Hazard*, p. 162.

PIRA, is a name by which a variety of foreign fishes are distinguished. The *pira aca* is a little horned fish of the West Indies, called by Clusius and others the *monoceros* or *unicorn-fish*. The *pira acangata* is the name of a Brasilian fish, which resembles the perch both in size and shape. It seldom exceeds four or five inches in length; its mouth is small; its tail forked. On the back it has only one long fin, which is supported by rigid and prickly spines. This fin it can depress at pleasure, and sink within a cavity made for it in the back. Its scales are of a silvery white colour; it is wholesome and well tasted. *Pira bebe* is the name of the milvus, or kite-fish. *Pira coaba* is an American fish of the truttaceous kind, of a very delicate flavour. It grows to the length of 12 inches; its nose is pointed, and its mouth large, but without teeth; the upper jaw is longer than the under one, and hangs over like a cartilaginous prominence; its eyes are very large, and its tail is forked; under each of the gill fins there is a beard made of six white filaments, and covered with silvery scales. *Pira jurumenbeca* is a Brasilian fish otherwise called *bocca molle*. It lives in the muddy bottom of the American seas, and is a long-bodied not flatted fish. It grows to a great size, being found nine, and sometimes even ten or eleven, feet long, and two feet and a half thick. It has one long fin on the back, the anterior part of which is thin and pellucid. There is also a cavity on the back, as in the pira acangata, into which the fin can be depressed at pleasure; the tail is not forked, and the scales are all of a silvery colour and brightness. The fish is very well tasted; the *pira pixanga* is another Brasilian fish of the turdus or wrasse kind, and called by some the *gutvisch*. It is generally about four or five inches long; its mouth is pretty large, and furnished with very small and very sharp teeth; its head is small, but its eyes are large and prominent, the pupil being of a fine turquoise colour, and the iris yellow and red in a variety of shades. The coverings of the gills end in a triangular figure, and are terminated by a short spine or prickle; its scales are very small, and so evenly arranged, and closely laid on the flesh, that it is very smooth to the touch; its tail is rounded at the end; its whole body, head, tail, and fins, are of a pale yellow colour, variegated all over with very beautiful blood-coloured spots; these are round, and of the bigness of hemp-seed on the back and sides, and something larger on the belly; the fins are all spotted in the same manner, and are all marked with an edge of red. It is caught among the rocks, and about the shores, and is a very well tasted fish. *Piranha* is an American fish, more generally known by the name *piraya*. *Piraquiba*, or *ipiraquiba*, is the name of a fish originally Brasilian, which some writers apply to the *remora* or *sucking fish*.

PIRÆUS PORTUS, in *Ancient Geography*, a celebrated port to the west of Athens, consisting naturally of three harbours or basons, (Thucydides); which lay neglected, till Themistocles put the Athenians on making it a commodious port, (Nepos); the Phalerus, a small port, and not far from the city, being what they used before that time, (Pausanias, Nepos). Piræus was originally a village of Attica, (Pausanias); an island (Strabo); and though distant 40 stadia from Athens, was joined to it by two long walls, (Thucydides), and itself locked or walled round, (Nepos:) A very commodious and safe harbour. The whole of its compass was 60 stadia, including the Munichia. Not far from the Piræus stood the sepulchre of Themistocles; whither his friends conveyed his bones from Magnesia, into the Hither Asia, (Cicero, Plutarch, Pausanias). The entrance of the Piræus is narrow, and formed by two rocky points, one belonging to the promontory of Eetion, the other to that of Alcimus. Within were three stations for shipping; Kantharus, so named from a hero; Aphrodisium, from a temple of Venus; and Zea, the resort of vessels laden with grain. By it was a demos or borough town of the same name before the time of Themistocles, who recommended the exchanging its triple harbour for the single one of Phalerum, both as more capacious and as better situated for navigators. The wall was begun by him when archon, in the second year of the 75th Olympiad, 477 years before Christ; and afterwards he urged the Athenians to complete it as the importance of the place deserved. This whole fortification was of hewn stone, without cement or other material, except lead and iron, which were used to hold together the exterior ranges or facings. It was so wide that loaded carts could pass on it in different directions, and it was 40 cubits high, which was about half what he had designed. *Chandler's Travels in Greece, p. 19, &c.*

The Piræus, as Athens flourished, became the common emporium of all Greece. Hippodamus an architect, celebrated, besides other monuments of his genius, as the inventor of many improvements in house-building, was employed to lay out the ground. Five porticoes, which uniting formed the *Long Portico*, were erected by the ports. Here was an *agora*, or market-place, and farther from the sea, another called *Hippodamia*. By the vessels were dwellings for the mariners. A theatre was opened, temples were raised, and the Piræus, which surpassed the city in utility, began to equal it in dignity. The cavities and windings of Municia, natural and artificial, were filled with houses; and the whole settlement, comprehending Phalerum and the ports of the Piræus, with the arsenals, the storehouses, the famous armoury of which Philo was the architect, and the sheds for 300, and afterwards 400, triremes, resembled the city of Rhodes, which had been planned by the same Hippodamus. The ports, on the commencement of the

Peloponnesian,

Peloponnesian war, were secured with chains. Centinels were stationed, and the Piræus was carefully guarded.

The Piræus was reduced with great difficulty by Sylla, who demolished the walls, and set fire to the armoury and arsenals. In the civil war it was in a defenceless condition. Calenus, lieutenant to Cæsar, seized it, invested Athens, and ravaged the territory. Strabo, who lived under the emperors Augustus and Tiberius, observes, that the many wars had destroyed the long walls, with the fortress of Munychia, and had contracted the Piræus into a small settlement by the ports and the temple of Jupiter Saviour. This fabric was then adorned with wonderful pictures, the works of illustrious artists, and on the outside with statues. In the second century, besides houses for triremes, the temple of Jupiter and Minerva remained, with their images in brass, and a temple of Venus, a portico, and the tomb of Themistocles.

The port of the Piræus has been named *Porto Lione*, from the marble lion seen in the chart, and also *Porto Dracco*. The lion has been described as a piece of admirable sculpture, 10 feet high, and as reposing on its hinder parts. It was pierced, and, as some have conjectured, had belonged to a fountain. Near Athens, in the way to Eleusis, was another, the posture couchant; probably its companion. Both these were removed to Venice by the famous general Morosini, and are to be seen there before the arsenal. At the mouth of the port are two ruined piers. A few vessels, mostly small craft, frequent it. Some low land at the head seems an introachment on the water. The buildings are a mean customhouse, with a few sheds; and by the shore on the east side, a warehouse belonging to the French, and a Greek monastery dedicated to St Spiridion. On the opposite side is a rocky ridge, on which are remnants of the ancient wall, and of a gateway towards Athens. By the water edge are vestiges of building; and going from the customhouse to the city on the right hand, traces of a small theatre in the side of the hill of Munychia.

PIRACY, the crime of robbery and depredation upon the high seas.

By the ancient common law, piracy, if committed by a subject, was held to be a species of treason, being contrary to his natural allegiance; and by an alien, to be felony only: but now, since the statute of treasons, 25 Edw. III. c. 2. it is held to be only felony in a subject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law. But, it being inconsistent with the liberties of the nation, that any man's life should be taken away, unless by the judgment of his peers, or the common law of the land, the statute 28 Hen. VIII. c. 15. established a new jurisdiction for this purpose; which proceeds according to the course of the common law.

The offence of piracy, by common law, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony there. But, by statute, some other offences are made piracy also: as, by statute 11 and 12 W. III. c. 7. if any natural born subject commits any act of hostility upon the high seas, against others of his majesty's subjects, under colour of a commission from any foreign power; this, though it would only be an act of war in an alien, shall be construed piracy in a subject. And farther, any commander, or other seafaring person, betraying his trust, and running away with any ship, boat, ordnance, ammunition, or goods; or yielding them up voluntarily to a pirate; or conspiring to do these acts; or any person assaulting the commander of a vessel, to hinder him from fighting in defence of his ship; or confining him, or causing or endeavouring to cause a revolt on board; shall, for each of these offences, be adjudged a pirate, felon, and robber, and shall suffer death, whether he be principal, or merely accessory by setting forth such pirates, or abetting them before the fact, or receiving or concealing them or their goods after it. And the statute 4 Geo. I. c. 11. expressly excludes the principals from the benefit of clergy. By the statute 8 Geo. I. c. 24. the trading with known pirates, or furnishing them with ammunition, or fitting out any vessel for that purpose, or in any wise consulting, combining, confederating, or corresponding with them; or the forcibly boarding any merchant vessel, though without seizing or carrying her off, and destroying or throwing any of the goods overboard; shall be deemed piracy: and such accessories to piracy as are described by the statute of King William are declared to be principal pirates; and all pirates convicted by virtue of this act are made felons without benefit of clergy. By the same statutes also, (to encourage the defence of merchant-vessels against pirates), the commanders or seamen wounded, and the widows of such seamen as are slain, in any piratical engagement, shall be entitled to a bounty to be divided among them, not exceeding one-fiftieth part of the value of the cargo on board: and such wounded seamen shall be entitled to the pension of Greenwich hospital; which no other seamen are, except only such as have served in a ship of war. And if the commander shall behave cowardly, by not defending the ship, if she carry guns or arms; or shall discharge the mariners from fighting, so that the ship falls into the hands of pirates; such commander shall forfeit all his wages, and suffer six months imprisonment. Lastly, by statute 18 Geo. II. c. 30. any natural-born subject or denizen, who in time of war shall commit hostilities at sea against any of his fellow-subjects, or shall assist an enemy on that element, is liable to be tried and convicted as a pirate.

PIRATE, (πειρατης, Gr.); a sea-robber, or an armed ship that roams the seas without any legal commission, and seizes or plunders every vessel she meets indiscriminately, whether friends or enemies.

The colours usually displayed by pirates are said to be a black field, with a death's head, a battle-axe, and hour-glass. The last instrument is generally supposed to determine the time allowed to the prisoners, whom they take, to consider whether they will join the pirates in their felonious combination, or be put to death, which is often perpetrated in the most cruel manner.

Among the most celebrated pirates of the north is recorded Alvilda, daughter of a king of the Goths named *Syparaus*. She embraced this occupation to deliver herself from the violence imposed on her inclination, by a marriage with Alf, son of Sigarus king of Denmark. She dressed herself as a man; and composed her band of rowers, and the rest of her crew, of a number of young women attired in the same manner. Among the first of her cruizes, she touched at a place where a company of of pirates bewailed the death of their captain. The strangers were captivated with the agreeable maners of Alvilda, and chose her for their chief. By this reinforcement she became so formidable upon the sea, that Prince Alf came to engage her. She sustained his attacks for a considerable time; but in a vigorous action, Alf boarded her vessel, and having killed the greatest part of her crew, seized the captain, namely herself; whom nevertheless he knew not, because the princess had a casque which covered her visage. Being master of her person, he removed the casque; and in spite of her disguise, instantly recognized her, and offered her his hand in wedlock.

PIRENE, (Pliny); a fountain sacred to the muses, springing below the top of the Acrocorinthus, a high and steep mountain which hangs over Corinth. Its waters were agreeable to drink, (Pausanias); extremely clear, (Strabo); very light, (Athenæus); and pale, (Persius): having relation either to the grief of Pirene, mother of Cenchrea, from whose tears this fountain arose, (Pausanias); or to the paleness brought on by the too eager pursuits of the muses.

PIROMALLI, Paul, a dominican of Calabria, was sent a missionary into the east. He remained a long time in Armenia, where he had the happiness to bring back to the church many schismatics and Eutycheans, and the patriarch himself who had before thrown every obstacle in his way. He afterwards passed into Georgia and Persia, then into Poland, in quality of Pope Urban VIII.'s nuncio, in order to appease the disturbances which had been occasioned there by the disputes of the Armenians, who were very numerous in that country. Piromalli united them in the profession of the same faith, and observance of the same ceremonies. In his return to Italy he was taken by some corsairs who carried him prisoner to Tunis. As soon as he was ransomed he went to Rome, and gave an account of his mission to the pope, who conferred upon him some signal marks of his esteem. His holiness entrusted him with the revisal of an Armenian bible, and sent him again into the east, where he was promoted, in 1655, to the bishopric of Nassivan. After having governed that church for nine years, he returned to Italy, and took the charge of the church of Bassignano, where he died three years after in 1667. His charity, his zeal, and other virtues, did honour to the episcopal office. There are extant of his writings, 1. Some works of Controversy and Theology. 2. Two Dictionaries; the one a Latin-Persian, and the other an Armenian Latin. 3. An Armenian Grammar. 4. A Directory, which is of great use in correcting Armenian books. All these works equally distinguish him for virtue and for learning.

PIRON, Alexis, a French poet, was born at Dijon in July 1689, where his father was an apothecary, and where he passed more than 30 years in idle and destructive dissipation. He was at length obliged to quit the place of his nativity, in order to avoid the reproaches of his fellow-citizens, on account of an ode which he had written, and which gave great offence. His relations not being able to give him much assistance, he supported himself at Paris by means of his pen, the strokes of which were as beautiful and fair as those of an engraver. He lived in the house of M. de Belleisle as his secretary, and afterwards with a financier, who did not know that he had a man of genius under his roof. His reputation as a writer commenced with some pieces which he published for the entertainment of the populace, and which showed strong marks of original invention; but what fully established his character in this way was his comedy intitled *Metromany*, which was the best that had appeared in France since Regnard's Gamester. This performance, in five acts, well conducted, replete with genius, wit, and humour, was acted with the greatest success upon the French stage in 1738. The author met with every attention in the capital which was due to a man of real genius, and whose flashes of wit were inexhaustible. We shall insert a few anecdotes of him, which will serve to show his character and turn of mind. In Burgundy the inhabitants of Beaune are called the *Asses of Beaune*. Piron often indulged his satirical disposition at their expence. One day as he was taking a walk in the neighbourhood of that city, he diverted himself with cutting down all the thistles which he met with. When a friend asked him his reason for doing so, he replied, *J'ai à me plaindre des Beaunois; je leur coupe les vivres*, i. e. "I am sorry indeed for the Beaunians; for I am cutting down their food." Being told again that these people would certainly be revenged of him,

> *Allez*, (says he) *Allez: je ne crains point leur impuissant couroux;*
> *Et quand je serois seul, je les batterois tous.*

"Get you gone, get you gone: I fear not their feeble revenge; for though alone, I shall beat them all." Going into a theatre one time where a play was acting, he asked what it was? The Cheats of Scapin, gravely replied a young Beaunian. "Ah! Sir, (says Piron, after thanking him), I took it to be the Cheats of Orestes." In the time of the play, some body addresses the company with "Silence there, gentlemen, we don't hear." "It is not at least (cried Piron) for want of ears." A bishop one day asked Piron, during the disputes about Jansenism, "Did you read my mandate, Mr Piron?" No, my lord; and you——The conversation turning very warm, the bishop reminded him of the distance which birth and rank had put between them. "Sir (says Piron), I have plainly the superiority over you at this moment; for I am in the right, and you are in the wrong."—Voltaire's Semiramis did not meet with a very favourable reception the first time it was acted. The author finding Piron behind the scenes, asked him what he thought of his performance? "I think (replied he) you would have been pleased that I had been the author of it." The performer of the character Ferdinand Cortez (the title of one of Piron's tragedies) having requested some corrections to be made on the play the first time it was acted, Piron fired at the word *corrections*. The player, who was deputed to wait upon the author with this request, cited the example of Voltaire, who corrected some of his pieces in order to gratify the taste of the public. "The cases are widely different (replied Piron); Voltaire works in chequer-work, and I cast in brass." If this answer be not very modest, we must allow that it does not want wit. He thought himself, if not superior, at least equal to Voltaire. Some person congratulating him on having composed the best comedy of this age, he answered, with more frankness than modesty, "Add too, and the best tragedy."

Piron, Pisa.

gedy." The following verses are well known, in which he says:

En deux mots voulez-vous distinguer et connoitre
Le rimeur Dijonnois et le Parisien?
Le premier ne fut rien, et ne voulut rien etre;
L'autre voulut tout etre, et ne fut presque rien.

We see by these different traits that Piron had a sufficient stock of self-conceit. What helped to increase it, and make him fancy himself superior to the most celebrated of his contemporaries, was, that his company, on account of his original humour, of which he had an uncommon share, was more courted than that of Voltaire, who was otherwise too lively, too captious, and crabbed. But those who have favoured us with an account of his many witticisms in conversation, would have done more honour to his memory if they had passed over such as were either indecent or insipid. A thing often pleases over a glass of wine, which will not give the same satisfaction when it is repeated, especially if, in repeating it, you want to make it appear of some importance. Be that as it may, Piron's mischievous ingenuity was partly the cause which excluded him from the French Academy.—"I could not (said he) make thirty-nine people think as I do, and I could less think as thirty-nine do." He called that celebrated society very unjustly *les invalides du bel esprit*, "the invalids of wit;" and yet he often endeavoured to be one of those invalids. His death was hastened by a fall which he got a little before. He died the 21st of January 1773, at the age of 83. He had prepared for himself the following epitaph, in the way of an epigram:

Ci gît Piron, qui ne fut rien,
Pas même académicien.

"Here lies Piron, who was nothing, not even an academician."

His wife Maria Theresa Quenandon, who died in 1751, he describes as a sweet and most agreeable companion. They lived together for several years; and no husband ever discharged his duty with more fidelity and attention.

A collection of his works appeared in 1776, in 7 vols. 8vo, and 9 vols. 12mo. The principal pieces, are, The School of Fathers; a comedy acted in 1728 under the title of Ungrateful Sons. Callisthenes; a tragedy, the subject of which is taken from Justin. The Mysterious Lover, a comedy. Gustavus and Ferdinand Cortez, two tragedies; some scenes of which discover an original genius, but the versification neither pleases the ear nor affects the heart. Metromany, a comedy. The Courses of Tempe, an ingenious pastoral, in which the manners both of the town and country are pleasantly drawn. Some odes, poems, fables, and epigrams. In this last kind of poetry he was very successful, and he may be placed after Marot and Rousseau. There was no occasion for loading the public with 7 vols of his works; the half of that number might have sufficed. For, excepting Metromany, Gustavus, the Courses of Tempe, some odes, about 20 epigrams, three or four fables, and some epistles, the rest are but indifferent, and have no claim to any extraordinary merit.

PISA, a large town of Tuscany in Italy, situated on the river Arno, 52 miles from Florence. It was a famous republic, till subdued, first by the duke of Milan, and then by the Florentines in the year 1406. Before it lost its freedom, it is said to have contained near 150,000 inhabitants, but now it has not above 16,000 or 17,000. It was founded we are told by the Pisans of Peloponnesus, and afterwards become one of the 12 municipia of Tuscany. Its neighbourhood to Leghorn, which is now the chief port in the Mediterranean, though formerly of little or no note for trade, has contributed greatly to the decay of Pisa, which, however, begins to lift up its head again, under the auspices of the present grand duke, who has made it his winter residence. Between Pisa and Leghorn is a canal 16 Italian miles in length.—Its territory is very fruitful; abounding in corn, wine, and fruit, and fine cattle. The houses are well built, and the streets even, broad, and well paved; but in many places overrun with grass. The university is well endowed, and has able professors, but is not in a very flourishing condition. The exchange is a stately structure, but little frequented. The grand duke's galleys are built, and commonly stationed here. This city is also the principal residence of the order of St Stephen, and the see of an archbishop. The cathedral, a large Gothic pile, contains a great number of excellent paintings and other curiosities. This church is dedicated to St Mary; is very advantageously situated in the middle of a large piazza, and built out of a great heap of wrought marble, such as pillars, pedestals, capitals, cornices, and architraves, part of the spoils which the Pisans took in their eastern expeditions, when the republic was in a flourishing condition. The roof is supported by 76 high marble pillars of different colours, and finely gilt. Both the church and the cupola are covered with lead. The choir is painted by good hands, and the floor is mosaic work. The brazen doors are curiously wrought with the history of the Old and New Testament, by Bonanno, an ancient statuary. The chapel of St Rainerius is richly adorned with gilt metals, columns of porphyry, and fine paintings. In the middle of the nave of the church you see two brazen tombs, raised upon pillars. The marble pulpit was carved by John Pisano, and the choir by Julian da Majana. Joining thereto is the altar, over which is preserved a hollow globe or vessel of marble, wherein they kept the sacrament for the new baptized, according to the opinion of Father Mabillon. In the square before the church, you see a pillar upon which is the measure of the ancient Roman talent. In the same square with the dome, stands the baptistery, a round fabric supported by stately pillars, and remarkable for a very extraordinary echo.

On the north side of the cathedral is the burying-place, called *Campo Santo*, being covered with earth brought from the Holy Land. This burying-place is inclosed with a broad portico, well painted, and paved with grave stones. Here are a great many ancient tombs, among the rest that of Beatrix, mother of the countess Mathilda, with marble basso relievos, which the Pisans brought from Greece, where you see the hunt of Meleager, which assisted Nicholas of Pisa in the restoration of sculpture. The walls of the Campo Santo are painted by the best masters of their times. Giotto has drawn six historical pieces of Job; and Andrea Orgagna has given a fine piece of the last judgment. Under the portico there is a decree of the city, ordering the inhabitants to wear mourning a year for the death of Cæsar.

Near

Near the church you see a steeple in the form of a cylinder, to which you ascend by 153 steps; it inclines 15 feet on one side, which some ascribe to art, but others to the sinking of the foundation. Its inclination is so great that a plumb-line let fall from the top touches the ground at the distance of almost 15 feet from the bottom. It was built by John of Inspruck and Bonanno of Pisa, in 1174. Near this steeple is a fine hospital, dependent on that of St Maria Nuova in Florence.

The steeple of the church of the Augustinians is also very fine, being an octagon, adorned with pillars, and built by Nicholas of Pisa. In the great market-place there is a statue of Plenty, by Pierino da Vinci. In the church of St Matthew, the painting of the ceiling by the brothers Melani, natives of this city, is an admired performance. The church of the knights of St Stephen, decorated with the trophies taken from the Saracens, is all of marble, with marble steps, and a front adorned with marble statues. In the square there is a statue of Cosmo I. upon a very fine pedestal. Contiguous to the church is the convent or palace of the knights, which is worth seeing, as also the churches Della Madonna and Della Spina; the last of which was built by a beggar, whose figure you may see on the outside of the wall. It is pretended that one of the thorns of the crown which was placed on our Saviour's head is preserved here. Belonging to the university there is a great number of colleges, the chief of which is the Sapienza, where the professors read their public lectures; next to which are the colleges Puteano, Ferdinando, Ricci, and others. Besides the public palace, and that of the grand duke, there are several others with marble fronts, the finest of which is that of Lanfranchi, which, with the rest along the banks of the Arno, makes a very fine appearance. There is here a good dock, where they build the galleys, which are conveyed by the Arno to Leghorn. They have a famous aqueduct in this town, consisting of 5000 arches, which conveys the water from the hills at five miles distance. This water is esteemed the best in Italy, and is carried in flasks to Florence and Leghorn. The neighbouring country produces great store of corn and wine, but the latter is not much esteemed. They have very good butter in this neighbourhood, which is a scarce commodity in Italy. The city for its defence has a moat, walls, a castle, fort, and citadel; the last of which is a modern work. The Arno is of a considerable breadth here, and has three bridges over it, one of them of marble: two leagues below the town it falls into the sea. The physic-garden is very spacious, contains a great number of plants, and is decorated with waterworks: over the door leading into it are these words, *Hic Argus sed non Briareus esto*: i. e. "Employ the eyes of Argus, but not the hands of Briareus. The air is said to be unwholesome here in summer, on account of the neighbouring morasses. Many buffaloes are bred in the neighbouring country, and their flesh is commonly eaten. Between Pisa and Lucca are hot baths. E. Long. 10. 17. N. Lat. 43. 43.

PISCARY, in our ancient statutes, the liberty of fishing in another man's waters.

PISCES, in *Astronomy*, the 12th sign or constellation of the zodiac.

PISCIDIA, a genus of plants belonging to the diadelphia class. See BOTANY *Index*.

PISCIDIA *Erythrina*, or *Dogwood-tree*, is employed to intoxicate fish. For this purpose, the bark is pounded small, put into bags, and soaked in salt water. The juice, which is of a red colour, makes the fish stupid, so that they are easily taken.

PISCINA, in antiquity, a large bason in a public place or square, where the Roman youth learned to swim: and which was surrounded with a high wall, to prevent filth from being thrown into it.—This word is also used for a lavatory among the Turks, placed in the middle court of a mosque or temple, where the Mussulmans wash themselves before they offer their prayers.

PISISTRATUS, an Athenian who early distinguished himself by his valour in the field, and by his address and eloquence at home. After he had rendered himself the favourite of the populace by his liberality and by the intrepidity with which he had fought their battles, particularly near Salamis, he resolved to make himself master of his country. Every thing seemed favourable to his ambitious views; but Solon alone, who was then at the head of affairs, and who had lately enforced his celebrated laws, opposed him, and discovered his duplicity and artful behaviour before the public assembly. Pisistratus was not disheartened by the measures of his relation Solon, but he had recourse to artifice. In returning from his country-house, he cut himself in various places; and after he had exposed his mangled body to the eyes of the populace, deplored his misfortunes, and accused his enemies of attempts upon his life, because he was the friend of the people, the guardian of the poor, and the reliever of the oppressed, he claimed a chosen body of 50 men from the populace to defend his person in future from the malevolence and the cruelty of his enemies. The unsuspecting people unanimously granted his request, though Solon opposed it with all his influence; and Pisistratus had no sooner received an armed band on whose fidelity and attachment he could rely, than he seized the citadel of Athens, and made himself absolute. The people too late perceived their credulity; yet, though the tyrant was popular, two of the citizens, Megacles and Lycurgus, conspired together against him, and by their means he was forcibly ejected from the city. His house and all his effects were exposed to sale; but there was found in Athens only one man who would buy them. The private dissensions of the friends of liberty proved favourable to the expelled tyrant; and Megacles, who was jealous of Lycurgus, secretly promised to restore Pisistratus to all his rights and privileges in Athens, if he would marry his daughter. Pisistratus consented; and by the assistance of his father-in-law, he was soon enabled to expel Lycurgus, and to re-establish himself. By means of a woman called *Phya*, whose shape was tall, whose features were noble and commanding, he imposed upon the people, and created himself adherents even among his enemies. Phya was conducted through the streets of the city, and showing herself subservient to the artifice of Pisistratus, she was announced as Minerva, the goddess of wisdom, and the patroness of Athens, who was come down from Heaven to re-establish her favourite Pisistratus in a power which was sanctioned by the will of Heaven, and favoured by the affection of the people. In the midst of his triumph, however, Pisistratus found himself unsupported; and some time after, when

Bibliotk. des Classiq. by Lempriere.

when he repudiated the daughter of Megacles, he found that not only the citizens, but even his very troops, were alienated from him by the influence, the intrigues, and the bribery of his father-in-law. He fled from Athens where he no longer could maintain his power, and retired to Eubœa. Eleven years after he was drawn from his obscure retreat, by means of his son Hippias, and he was a third time received by the people of Athens as their master and sovereign. Upon this he sacrificed to his resentment the friends of Megacles, but he did not lose sight of the public good, and while he sought the aggrandizment of his family, he did not neglect the dignity and the honour of the Athenian name. He died about 528 years before the Christian era, after he had enjoyed the sovereign power at Athens for 33 years, and he was succeeded by his son Hipparchus. Pisistratus claims our admiration for his justice, his liberality, and his moderation. If he was dreaded and detested as a tyrant, the Athenians loved and respected his private virtues and his patriotism as a fellow-citizen: and the opprobrium which generally falls on his head may be attributed not to the severity of his administration, but to the republican principles of the Athenians, who hated and exclaimed against the moderation and equity of the mildest sovereign, while they flattered the pride and gratified the guilty desires of the most tyrannical of their fellow subjects. Pisistratus often refused to punish the insolence of his enemies; and when he had one day been virulently accused of murder, rather than inflict immediate punishment upon the man who had criminated him, he went to the areopagus, and there convinced the Athenians that the accusations of his enemies were groundless, and that his life was irreproachable. It is to his labours that we are indebted for the preservation of the poems of Homer; and he was the first, according to Cicero, who introduced them at Athens in the order in which they now stand. He also established a public library at Athens; and the valuable books which he had diligently collected were carried into Persia when Xerxes made himself master of the capital of Attica. Hipparchus and Hippias the sons of Pisistratus, who had received the name of *Pisistratidæ*, rendered themselves as illustrious as their father; but the flames of liberty were too powerful to be extinguished. The Pisistratidæ governed with great moderation, but the name of tyrant or sovereign was insupportable to the Athenians. Two of the most respectable of the citizens, called *Harmodius* and *Aristogiton*, conspired against them, and Hipparchus was dispatched in a public assembly. This murder was not, however, attended with any advantages; and though the two leaders of the conspiracy, who have been celebrated through every age for their patriotism, were supported by the people, yet Hippias quelled the tumult by his uncommon firmness and prudence, and for a while preserved that peace in Athens which his father had often been unable to command. This was not long to continue. Hippias was at last expelled by the united efforts of the Athenians and of their allies, and he left Attica, when he found himself unable to maintain his power and independence. The rest of the family of Pisistratus followed him in his banishment; and after they had refused to accept the liberal offers of the princes of Thessaly, and the king of Macedonia, who wished them to settle in their respective territories, the Pisistratidæ retired to Sigæum, which their father had in the summit of his power conquered and bequeathed to his posterity. After the banishment of the Pisistratidæ, the Athenians became more than commonly jealous of their liberty, and often sacrificed the most powerful of their citizens, apprehensive of the influence which popularity and a well-directed liberality might gain among a fickle and unsettled populace. The Pisistratidæ were banished from Athens about 18 years after the death of Pisistratus.

PISMIRES, or Ants, are a kind of insects very common in Africa; of which there is so great a variety, and such innumerable swarms, that they destroy not only the fruits of the ground but sometimes even men and beasts in so little time as one single night; and would, without all doubt, prove more fatally destructive to the inhabitants, were they not so happily destroyed by a proportionable number of monkeys and other animals, who greedily devour them. The far greater part of the vast continent of Africa is afflicted with these and some other grievous plagues, and particularly with the horrid visitation of locusts, which seldom fail a year of laying waste some of the provinces.

PISO, Lucius Calpurnius, surnamed *Frugi* on account of his frugality, was descended of the illustrious family of the Pisos, which gave so many great men to the Roman republic. He was tribune of the people in the year 149 before Christ, and afterwards consul. During his tribuneship, he published a law against the crime of concussion or extortion, intitled *Lex Calpurnia de pecuniis repetundis*. He happily ended the war in Sicily. To reward the services of one of his sons, who had distinguished himself in that expedition, he left him by his will a golden crown, weighing 20 pounds. Piso joined to the qualties of a good citizen the talents of a lawyer, an orator, and historian.

Piso, *Caius Calpurnius*, a Roman consul in the year 67 before Christ, was author of the law which forbade canvassing for public offices, intitled *Lex Calpurnia de ambitu*. He displayed all the firmness worthy of a consul in one of the most stormy periods of the republic. The Roman people, deceived by the flattery of Marcus Palicanus, a turbulent and seditious fellow, were on the eve of loading themselves with the greatest disgrace, by putting the supreme authority into the hands of this man, who deserved punishment rather than honours. The tribunes of the people, by their harangues, inflamed the blind fury of the multitude, already sufficiently mutinous of themselves. In this situation, Piso mounted the rostrum, and being asked if he would declare Palicanus consul, in case the suffrages of the people should concur in the nomination, he instantly replied, that "he did not think the republic was yet involved in such darkness and despair as to be capable of committing so infamous an action." Being afterwards strongly and repeatedly called upon to say, "what he would do, if the thing should happen?" his answer was, "No, I would not name him." By this firm and laconic answer he deprived Palicanus of the dignity to which he aspired. Piso, according to Cicero, was not possessed of a quick conception, but he thought maturely, and with judgment, and, by a proper firmness, he appeared to be an abler man than he really was.

PISO, *Cneius Calpurnius*, was consul in the reign of Augustus, and governor of Syria under Tiberius, whose confidant he was. It is said, that by the order of this emperor he caused Germanicus to be poisoned. Being accused of that crime, and seeing himself abandoned by every body, he laid violent hands on himself in the 20th year of our Lord. He was a man of insupportable pride and excessive violence. Some instances of his wicked cruelty have been handed down to us. Having given orders in the heat of his passion to conduct to punishment a soldier, as guilty of the death of one of his companions, because he had gone out of the camp with him and returned without him, no prayers or intreaty could prevail with Piso to suspend the execution of this sentence until the affair should be properly investigated. The soldier was led without the entrenchments, and had already presented his head to receive the fatal stroke, when his companion whom he was accused of having killed made his appearance again. Whereupon the centurion, whose office it was to see the sentence executed, ordered the executioner to put up his sword into the scabbard. Those two companions, after embracing each other, are conducted to Piso, amidst the acclamations of the whole army, and a prodigious crowd of people. Piso, foaming with rage, ascends his tribune, and pronounces the same sentence of death against the whole three, without excepting the centurion who had brought back the condemned soldier, in these terms: "You I order to be put to death because you have been already condemned: you, because you have been the cause of the condemnation of your comrade; and you, because having got orders to put that soldier to death, you have not obeyed your prince."

PISSASPHALTUM, or ASPHALTUM, EARTH-PITCH; a fluid, opaque, mineral body, of a thick consistence, strong smell, readily inflammable, but leaving a residuum of grayish ashes after burning. It arises out of the cracks of the rocks, in several places in the island of Sumatra, and some other places in the East Indies, where it is much esteemed in paralytic disorders. There is a remarkable mine of it in the island of Bua, (see BUA), of which the following curious description is given by the abbé Fortis. "The island is divided into two promontories between the north and west. Crossing over the top of the latter, which is not half a mile broad, and descending in a right line towards the sea, one is conducted to a hole well known to the inhabitants. This hole extends not much above 12 feet, and from its bottom above 25 feet perpendicular, arise the marble strata which sustain the irregular masses that surround the top of the mountain.

This pissasphaltum is of the most perfect quality, black and shining, very pure, odorous, and cohesive; and it comes out almost liquid, but hardens in large drops when the sun sets. On breaking many of these drops on the spot, I found that almost every one of them had an inner cavity full of very clear water.

"The greatest breadth of the tears that I saw was two inches, and the common breadth is half an inch. The chinks and fissures of the marble, from whence this bituminous pitch transudes, are not more than the thickness of a thread; and for the most part are so imperceptible, that were it not for the pitch itself, whereby they are blackened, they could not by any means be distinguished by the naked eye. To the narrowness of these passages is, no doubt, in part owing the small quantity of pissasphaltum that transpires."

After some conjectures about the origin of this mine, our author proceeds to inform us that the pissasphaltum of Bua is correspondent to that fossil production which by Hasselquist, in his Travels, is called *mumia minerale*, and *mumia nativa Persiana* by Kempfer, which the Egyptians made use of to embalm their kings (A). It is found in a cave of Mount Caucasus, which is kept shut, and carefully guarded by order of the king of Persia. One of the qualities assigned by Linnæus to the finest bitumen is to smoke when laid on the fire, as ours does, emitting a smell of pitch not disagreeable. He believes it would be very good for wounds, as the oriental mumia is, and like the pitch of Castro, which is frequently used by the Roman chirurgeons for fractures, contusions, and in many external applications. See ASPHALTUM, MINERALOGY *Index*.

PISSELÆUM INDICUM, *Barbadoes Tar*; a mineral fluid of the nature of the thicker bitumens, and of all others the most approaching, in appearance, colour, and consistence, to the true pissasphaltum, but differing from it in other respects. It is very frequent in many parts of America, where it is found trickling down the sides of mountains in large quantities, and sometimes floating on the surface of the waters. It has been greatly recommended internally in coughs and other disorders of the breast and lungs.

PISTACIA, TURPENTINE-TREE, *Pistachia nut* and *Mastich-tree*; a genus of plants belonging to the diœcia class. The most remarkable species are, 1. The terebinthus, or pistachia-tree, which grows naturally in Arabia, Persia, and Syria, whence the nuts are annually brought to Europe. In those countries it grows to the height

(A) "Mumiahi, or native Persian mummy. It proceeds from a hard rock in very small quantity. It is a bituminous juice, that transudes from the stony superficies of the hill, resembling in appearance coarse shoemakers wax, as well in its colour as in its density and ductility. While adherent to the rock it is less solid, but is formed by the warmth of the hands. It is easily united with oil, but repels water; it is quite void of smell, and very like in substance to the Egyptian mummy. When laid on burning coals, it has the smell of sulphur tempered a little with that of naphtha, not disagreeable. There are two kinds of this mummy; the one is valuable for its scarcity and great activity. The native place of the best mummy is far from the access of men, from habitations, and from springs of water, in the province of Daraab. It is found in a narrow cave, not above two fathoms deep, cut like a well out of the mass, at the foot of the rugged mountain Caucasus."—*Kempfer. Amœn. Pers.*

This description agrees perfectly with the pissasphaltum or fossil mummy of Bua, differing only in the privation of smell, which it is difficult to imagine is totally wanting in the Persian mummy.

Pistachia. height of 25 or 30 feet: the bark of the stem and old branches is of a dark russet colour, but that of the young branches is of a light brown. These are garnished with winged leaves, composed sometimes of two, at other times of three, pair of lobes, terminated by an odd one; these lobes approach towards an oval shape, and their edges are turned backward; and these, when bruised, emit a smell similar to that of the shell of the nut. Some of these trees produce male and others female flowers, and some have both male and female on the same tree. The male flowers come out from the sides of the branches in loose bunches or catkins. They have no petals, but five small stamina crowned by large four-cornered summits filled with farina; and when this is discharged, the flowers fall off. The female flowers come out in clusters from the sides of the branches: they have no petals, but a large oval germen supporting three reflexed styles, and are succeeded by oval nuts. 2. The lentiscus, or common mastich tree, grows naturally in Portugal, Spain, and Italy. Being an evergreen, it has been preserved in this country in order to adorn the green-houses. In the countries where it is a native, it rises to the height of 18 or 20 feet, covered with a gray bark on the stem; but the branches, which are very numerous, are covered with a reddish brown bark, and are garnished with winged leaves, composed of three or four pair of small spear-shaped lobes, without an odd one at the end. 3. The orientalis, or true mastich tree of the Levant, from which the mastich is gathered, has been confounded by most botanical writers with the lentiscus, or common mastich tree, above described, though there are considerable differences between them. The bark of the tree is brown; the leaves are composed of two or three pair of spear-shaped lobes, terminated by an odd one: the outer lobes are the largest; the others gradually diminish, the innermost being the least. These turn of a brownish colour towards the autumn, when the plants are exposed to the open air; but if they are under glasses, they keep green. The leaves continue all the year, but are not so thick as those of the common sort, nor are the plants so hardy.

Culture. The first species is propagated by its nuts, which should be planted in pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed to bring up the plants; when these appear, they should have a large share of air admitted to them, and by degrees they should be exposed to the open air, which at last they will bear in all seasons, though not without great danger of being destroyed in severe winters. The second sort is commonly propagated by laying down the branches, though it may also be raised from the seed in the manner already directed for the pistachia-nut tree: and in this manner also may the true mastich-tree be raised. But this being more tender than any of the other sorts, requires to be constantly sheltered in winter, and to have a warm situation in summer.

Pistachia nuts are moderately large, containing a kernel of a pale greenish colour, covered with a reddish skin. They have a pleasant, sweet, unctuous taste, resembling that of almonds; and they abound with a sweet and well-tasted oil, which they yield in great abundance on being pressed after bruising them: they are reckoned among the analeptics, and are wholesome and nutritive, and are by some esteemed very proper to be prescribed by way of restoratives, eaten in small quantity, to people emaciated by long illness.

Pistachia ‖ Pisum.

PISTIL, among botanists, the little upright column which is generally found in the centre of every flower. According to the Linnæan system, it is the female part of generation, whose office is to receive and secrete the pollen, and produce the fruit. It consists of three parts, viz. germen, stylus, and stigma. See Botany *Index*.

PISTOIA is a city of Italy, in the duchy of Tuscany, situated on the river Stella, in a beautiful plain near the foot of the Apennine mountains. By Pliny it is called *Pistorium*, and is said to have been once a Roman colony. At present it is a bishop's see, suffragan of Florence. The streets are broad and regular, the houses tolerably well built, but poorly inhabited for want of trade. Formerly it was an independent republic, but since it was subdued by the Florentines in 1200, it has been in a declining condition. The cathedral has a very handsome cupola, and a magnificent staircase to ascend to it. In the chapel dedicated to St James, where his relics are preserved, the walls are almost covered with plates of silver. Here are four marble statues of very good workmanship. The marble pulpit, the basso-relievos, the vessel that holds the holy water, and the square-steeple, are the work of John Pisano. The Jesuits have a very fine college, and the Franciscans, Dominicans, and Augustinians, good churches. In the church of Madonna dell' Umilta there are two statues, one of Leo X. and the other of Clement VII. The public palace, situated in a large square, is a handsome building; several of the nobility have also very good houses. In the neighbouring mountains, called by the name of Pistoia, there are many large villages, the chief of which is that of S. Marcello, belonging to the family of Cartoli. These mountains are a part of the Apennines, and border on the territory of Bologna and the county of Vernio; higher up is the source of the river Reno. The country about Pistoia, especially towards Florence, is exceeding fertile and delightful, covered with all sorts of fruits, corn, wine, &c. and containing a vast number of little towns, wealthy villages, and country seats, so as to be reckoned the richest and most beautiful in all Tuscany. It is about 20 miles N. W. of Florence, and 30 N. E. of Pisa. E. Long. 11. 29. N. Lat. 43. 55.

PISTOL, the smallest piece of fire-arms, borne at the saddle-bow, in the girdle, and in the pocket.

PISTOLE, a gold coin, struck in Spain and in several parts of Italy, Switzerland, &c.—The pistole has its augmentations and diminutions, which are quadruple pistoles, double pistoles, and half pistoles. See Money-*Table*.

PISTON, in pump-work, is a short cylinder of metal or other solid substance, fitted exactly to the cavity of the barrel or body of the pump. See Hydrodynamics.

PISUM, Pease; a genus of plants belonging to the diadelphia class. See Botany *Index*. The species are, 1. The sativum, or greater garden-pea, whose lower stipulæ are roundish, indented, with taper foot-stalks, and many flowers on a foot-stalk. 2. The humile, or dwarf pea, with an erect branching stalk, and leaves having two pair of round lobes. 3. The umbellatum, rose or crown-pea, with four pointed acute stipuli, and foot-stalks

Pisum. stalks bearing many flowers, which terminate the stalks. 4. The maritimum, or sea-pea, with foot-stalks which are plain on their upper side, an angular stalk, arrow-pointed stipulæ, and foot-stalks bearing many flowers. 5. The Americanum, commonly called *Cape-Horn pea*, with an angular trailing stalk, whose lower leaves are spear-shaped, sharply indented, and those at the top arrow-pointed. 6. The ochrus, with membranaceous running foot-stalks, having two leaves and one flower upon a foot-stalk.

There is a great variety of garden-pease now cultivated in Britain, which are distinguished by gardeners and seedsmen, and have their different titles; but as great part of these have been seminal variations, so if they are not very carefully managed, by taking away all those plants which have a tendency to alter before the seeds are formed, they will degenerate into their original state: therefore all those persons who are curious in the choice of their seeds, look carefully over those which they design for seeds at the time when they begin to flower, and draw out all the plants which they dislike from the other. This is what they call *roguing their pease;* meaning hereby the taking out all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which, they always do it before the flowers open. By thus diligently drawing out the bad, reserving those which come earliest to flower, they have greatly improved their pease of late years, and are constantly endeavouring to get forwarder varieties; so that it would be to little purpose in this place to attempt giving a particular account of all the varieties now cultivated: we shall therefore only mention the names by which they are commonly known, placing them according to their time of coming to the table, or gathering for use.

The golden hotspur.	Nonpareil.
The Charlton.	Sugar dwarf.
The Reading hotspur.	Sickle pea.
Master's hotspur.	Marrowfat.
Essex hotspur.	Rose or crown pea.
The dwarf pea.	Rouncival pea.
The sugar pea.	Gray pea.
Spanish Morotto.	Pig pea; with some others.

The English sea-pea is found wild upon the shore in Sussex and several other counties in England, and is undoubtedly a different species from the common pea.

The fifth species hath a biennial root, which continues two years. This was brought from Cape Horn by Lord Anson's cook, when he passed that cape, where these pease were a great relief to the sailors. It is kept here as a curiosity, but the pease are not so good for eating as the worst sort now cultivated in Britain. It is a low trailing plant; the leaves have two lobes on each foot-stalk: those below are spear-shaped, and sharply indented on their edges; but the upper leaves are small, and arrow-pointed. The flowers are blue, each foot-stalk sustaining four or five flowers; the pods are taper, near three inches long; and the seeds are round, about the size of tares.

The sixth sort is annual. This grows naturally among the corn in Sicily and some parts of Italy, but is here preserved in botanic gardens for the sake of variety. It hath an angular stalk, rising near three feet high; the leaves stand upon winged foot-stalks, each sustaining two oblong lobes. The flowers are of a pale yellow colour, shaped like those of the other sort of pea, but are small, each foot-stalk sustaining one flower; these are succeeded by pods about two inches long, containing five or six roundish seeds, which are a little compressed on their sides. These are by some persons eaten green; but unless they are gathered very young, they are coarse, and at best not so good as the common pea. It may be sown and managed in the same way as the garden pea.

For an account of the method of cultivating the several sorts of garden pease, so as to continue them throughout the season, see GARDENING.

The gray and other large winter pease are seldom cultivated in gardens, because they require a great deal of room; they are therefore usually sown in fields. For the proper method of managing them, see AGRICULTURE.

In the *Museum Rusticum*, vol. i. p. 109. we find the following method of preparing pease for hog-meat, which we shall give in the words of the ingenious farmer who communicated it.

"A few years ago (says he), I had a plentiful crop of pease on a ten acre piece, which lies near my house: when they were full poded and nearly ripe, I had them hooked in the usual manner; but before I could get them in, there came a heavy shower of rain which wetted them through and through; and the dull heavy weather, with frequent showers which followed, prevented their drying for a considerable time.

"I caused the wads to be from time to time turned, to prevent the haulm from rotting; and at length a few days sunshine dried them enough to be inned; for as they lay hollow, the wind was greatly assistant to the operation.

"Before I got them in, on examining some of the pods, I found that the pease were all sprouted to a considerable length: this was what I had expected, as I gave my crop over for lost, till after a little recollection, as the weather still continued fine, I determined to thresh them in the field.

"This was accordingly done; and the corn, after it was cast and riddled to separate it from the rubbish, was dried on my malt kiln.

"When this operation was over, I began to reflect in what manner I should dispose of my pease, being sensible that they could not be proper for seed, and standing no chance of disposing of them to any advantage in the market.

"At length, as it was then a time of war, and of course there was a great demand for pork for the use of the navy, I determined to buy a considerable number of lean hogs, that I might by their means consume this crop on my own premises, and in that manner make the most of it.

"My expectations were more than answered; for I found, by repeated experience, that three bushels of the pease I have mentioned went nearly as far in fattening the hogs I bought as four bushels got in dry and hard in the manner usually practised.

"This discovery I made several years ago, and it has turned out to my advantage; for since that time I have been quite indifferent as to the weather in which my pease are hooked, being rather better pleased, as far as relates to them, with wet than dry weather;

ther; but if the weather happens to be dry at the time they are ripe, I always cause as many as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the same manner nearly as my barley: this management has of late succeeded very well with me, and I therefore intend to continue it.

"Besides feeding my hogs with these malted pease, I have often given them to my horses, with which they agree very well, and are heartening food.

"Turkeys will fatten apace on them also, and be fine meat.

"I have applied my malted pease to many other uses, which I have not at present time to enumerate: but were they only used for feeding hogs and horses, it is still worth while to prepare some in this manner every year."

PIT-COAL, or STONE-COAL. See COAL, MINERALOGY *Index* and COALERY.

The coal-trade is of infinite importance to Great Britain, which never could have arrived at its present commercial eminence without it; and this eminence it will be impossible to retain if coal should ever become scarce. This we trust is not likely to be the case, though Mr Williams expresses great fears for it, and informs us that at Newcastle and in many parts of Scotland, the mines near the sea are already wasted, the first consequence of which must be an enormous rise in the price. See his observations on this subject in his *Natural History of the Mineral Kingdom*. This author says, that coal was not discovered till between the middle of the 12th and beginning of the 13th centuries: it is, therefore, according to him, 400 years since it was first discovered in Britain, but they have not been in common use for more than 200 years. The same author makes many excellent observations on the appearances and indications of coal, instructions about searching for it, remarks on false and doubtful symptoms of coal; for all which, together with his observations on the different kinds of Scots coal, we shall refer our readers to the work itself; the first part of which, occupying a large proportion of it, is upon the *strata of coal*, and on the *concomitant strata*. See GEOLOGY and STRATA *of the earth*.

PITAHAYA (*Cactus Pitajaya*. Lin. *Syst. Vegetabilium*. *Jacquin*. *Amer*. 151. ed. 2d. p. 75. M. *E. Carthagena*), a shrub peculiar to California, the fruit of which forms the greatest part of the harvest of the natives. Its branches are finely fluted, and rise vertically from the stem, so as to form a very beautiful top. The fruit is like a horse-chesnut; in some white, in others yellow, and in others red, but always exquisitely delicious, being a rich sweet, tempered with a grateful acid. See CACTUS, BOTANY *Index*.

PITCAIRNE, DR ARCHIBALD, an eminent physician and ingenious poet, was descended from the ancient family of the Pitcairnes of Pitcairne in Fifeshire, and was born at Edinburgh on the 25th of December 1652. He commenced his studies at the school of Dalkeith; and from thence he was removed to the university of Edinburgh, where he improved himself in classical learning, and completed a regular course of philosophy. His friends, according to the authors of the *Biographia Britannica*, were desirous that he should follow the profession of theology. The unpleasant gloom, however, which at that time hung over religion and its professors in Scotland, could not but very ill suit with that native cheerfulness of temper and liberality of mind which made him, long after, a mark for the arrows of preciseness and grimace. The law seems to have been his own choice, and to this science he turned his attention. With an ardour peculiar to himself, and an ambition to excel in whatever he undertook, he pursued it with so much intenseness, that his health began to be impaired. On this account, his physicians advised him to set out for the south of France. By the time he reached Paris, he was happily so far recovered, that he determined to renew his studies; but being informed that there was no able professor of law in that city, and finding several gentlemen of his acquaintance engaged in the study of physic, he went with them to the lectures and hospitals, and employed himself in this manner for several months till his affairs called him home.

On his return, he applied himself chiefly to the mathematics. It is not usual to see the briars of this science and the flowers of poetry growing in the same soil. Here, however, they were happily united; and to this union perhaps was owing that singular command of judgment, over one of the liveliest of fancies, which appears in every part of his works. His intimacy with Dr David Gregory, the celebrated mathematical professor, began about the same time; and probably conduced to cherish his natural aptitude for this study. It was then in a great measure, new to him; it soon became his principal delight; his progress in it was rapid, and correspondent to his progress in other pursuits. His improvements on the method of infinite series then adopted, which Dr Wallis of Oxford afterwards published, were a conspicuous and early proof of his abilities in this science.

Had Dr Pitcairne continued to prosecute the study of the law, and could he have moulded his principles to the times, the first offices and honours of the state might have been looked for without presumption as the probable reward of such talents as he possessed. Struck, however, with the charms of mathematical truth which had been lately introduced into the philosophy of medicine, and hoping to reduce the healing art to geometrical method, he unalterably determined on this less aspiring profession. At the period when he formed this resolution, the ideas of the medical world, already sufficiently confused, were still farther jumbled by the discovery of the circulation of the blood, which had as yet produced nothing but doubt, uncertainty, and astonishment. In Edinburgh at that time there was no school, no hospital, no opportunity of improvement but the chamber and the shop. He therefore soon after returned to Paris. Genius and industry are unhappily not often united in the same character: of such an union, however, Dr Pitcairne is a celebrated instance. During his residence in France, he cultivated the object of his pursuit with his natural enthusiasm, and with a steadiness from which he could not be diverted by the allurements of that joy which, in his hours of social and festive intercourse, he always felt and always gave. Among his various occupations, the study of the ancient physicians seems to have had a principal share. This appears from a treatise which he published some time after his return; and it shows, that he wisely determined to know the progress of medicine from its earliest periods, before he attempted to reform and improve that science.

On the 13th of August 1680, he received, from the faculty of Rheims, the degree of Doctor; which, on the 7th of August 1699, was likewise conferred on him by the university of Aberdeen; both being attended with marks of peculiar distinction. Other medical honours are said to have been conferred on him in France and elsewhere; but nothing affords a more unequivocal testimony to his abilities than that which the surgeons of Edinburgh gave, in admitting him, freely and unsolicited, a member of their college. None had such opportunities of judging of his merit as a practitioner, and on no physician did they ever bestow the same public mark of respect. Soon after his graduation at Rheims, he returned to Edinburgh; where, on the 29th of November 1681, the Royal College of Physicians was instituted; and his name, among others, graced the original patent from the crown.

In his *Solutio Problematis de Inventoribus*, the treatise above alluded to, he discovers a wonderful degree of medical literature, and makes use of it in a manner that does great honour both to his head and his heart. His object is to vindicate Dr Harvey's claim to the discovery of the circulation of the blood. The discovery was, at first, controverted by envy, and reprobated by ignorance. When at length its truth was fully established, many invidiously attempted to tear the laurels from the illustrious Englishman, and to plant them on the brows of Hippocrates and others. Had the attempt been directed against himself, the generous soul of Pitcairne could not have exerted more zeal in a defence; and his arguments remain unanswered.

During his residence in Scotland, his reputation became so considerable, that, in the year 1691, the university of Leyden solicited him to fill the medical chair, at that time vacant. Such an honourable testimony of respect, from a foreign nation, and from such an university, cannot perhaps be produced in the medical biography of Great Britain. The lustre of such characters reflects honour on their profession, and on the country which has the good fortune of giving them birth; and serves to give the individuals of that country not only a useful estimation in their own eyes, but in those also of the rest of the world. Dr Pitcairne's well-known political principles excluded him from public honours and promotion at home: he therefore accepted the invitation from abroad; and, on the 26th of April 1692, delivered, at Leyden, his elegant and masterly inaugural oration: *Oratio qua ostenditur medicinam ab omni philosophorum secta esse liberam.* In this he clears medicine from the rubbish of the old philosophy; separates it from the influence of the different sects; places it on the broad and only sure foundation of experience; shows how little good inquiries into the manner how medicines operate have done to the art; and demonstrates the necessity of a sedulous attention to their effects, and to the various appearances of disease.

Nothing (says an elegant panegyrist * of our author) marks a superiority of intellect so much as the courage requisite to stem a torrent of obstinately prevailing and groundless opinions. For this the genius and talents of Pitcairne were admirably adapted; and, in his oration, he displays them to the utmost. It was received with the highest commendations; and the administrators, to testify their sense of such an acquisition to their university, greatly augmented the ordinary appointment of his chair.

* Dr Chas. Webster, in the Harveian Oration at Edinburgh for the year 1781; from which performance the present article is chiefly extracted.

He discharged the duties of his office at Leyden so as to answer the most sanguine expectations. He taught with a perspicuity and eloquence which met with universal applause. Independently of the encomiums of Boerhaave and Mead, who were his pupils, the numerous manuscript copies of his lectures, and the mutilated specimen of them † which found its way into the world without his knowledge, show how justly it was bestowed. At the same time, he was not more celebrated as a professor than as a practical physician; and notwithstanding the multiplicity of his business in both these characters, he found leisure to publish several treatises on the circulation, and some other of the most important parts of the animal economy (A).

† *Elementa Medicinae.*

At the close of the session he set out for Scotland, with an intention of returning in time for the succeeding one. On his marrying (B) the daughter of Sir Archibald Stevenson, the object of his journey, her relations would on no account consent to part with him again. He was therefore reluctantly obliged to remain; and he wrote the university a polite apology, which was received with the utmost regret. He even declined the most flattering solicitations and tempting offers to settle in London. Indeed he soon came into that extensive practice to which his abilities entitled him, and was also appointed titular professor of medicine in the university of Edinburgh.

The uniformity of a professional life is seldom interrupted by incidents worthy of record. Specimens, however, of that brilliant wit with which he delighted his friends in the hours of his leisure, continue to entertain us (C): and the effects of that eminent skill which he exerted

(A) Dr Boerhaave gives the following character of these and some other of Dr Pitcairne's dissertations, which were collected and published at Rotterdam, anno 1701: "Hæc scripta optima sunt et perfecta, sive legas Dissertationem de Motu Sanguinis per Pulmones, sive alia opuscula, sive ultimum tractatum de Opio." *Methodus studii, ab Hallero edita*, p. 569.

(B) He had been married before to a daughter of Colonel James Hay of Pitfour, by whom he had a son and daughter, who both died young.

(C) Vide *Pitcarnii Poemata*.—Several of his poems, however, are obscure, and some of them totally unintelligible without a key. In those of them which are of a political kind, he wished not to express himself too clearly; and in others, he alludes to private occurrences which were not known beyond the circle of his companions. His poem *(Ad Lindesium)*, addressed to his friend Lindsey, is commented on by the authors of the *Biographia Britannica;* and it is to be regretted that it is the only one on which they have been solicitous to throw light, Pitcairne. exerted in the cure of disease, still operate to the good of posterity.

The discovery of the circulation, while in some measure it exploded the chemical and Galenical doctrines, tended to introduce mathematical and mechanical reasoning in their stead. Of this theory (D) Dr Pitcairne was the principal support, and the first who introduced it into Britain. A mathematical turn of mind, and a wish for mathematical certainty in medicine, biassed him in its favour, and he pushed it to its utmost extent. One is at a loss whether most to admire or regret such a waste of talents in propping a theory which, though subversive of former ones, was to fall before others but a little more satisfactory than itself. Mechanical physicians expected more from geometry than that science could grant. They made it the foundation instead of an auxiliary to their inquiries, and applied it to parts of nature not admitting mathematical calculations. By paying more attention afterwards to the supreme influence of the living principle, the source of all the motions and functions of the body, it was found that these could not be explained by any laws of chemistry or mechanism. They are still, however, involved in obscurity; and notwithstanding the numberless improvements which have taken place in the sciences connected with medicine, will perhaps remain inscrutable while man continues in his present stage of existence.

In a science so slowly progressive as that of medicine, Dr Pitcairne did a great deal. By labouring in vain for truth in one road, he saved many the same drudgery, and thereby showed the necessity of another. He not only exploded many false notions of the chemists and Galenists which prevailed in his time, but many of those too of his own sect. In particular, he showed the absurdity of referring all diseases and their cures to an alkali or an acid (E). He refuted the idea of secretion being performed by pores differently shaped (F), Bellini's opinion of effervescences in the animal spirits with the blood, and Borelli's of air entering the blood by respiration (G). He proved the continuity of the arteries and veins (H); and seems to have been the first who showed that the blood flows from a smaller capacity into a larger; that the aorta, with respect to the arterial system, is the apex of a cone (I). In this therefore he may be considered as the latent spring of the discoveries respecting the powers moving the blood. He introduced a simplicity of prescription unknown in pharmacy before his time (K); and such was the state of medicine in this country, that scarcely have the works of any cotemporary or preceding author been thought worthy even of preservation (L). As to the errors of his philosophy, let it be remembered, that no theory has as yet stood the test of many years in an enlightened period. His own hung very loosely

---

light. "Some parts (say they) of this poem, are hardly intelligible, without knowing a circumstance in the doctor's life, which he often told, and never without some emotion. It is a well known story of the two Platonic philosophers, who promised one another, that whichever died first should make a visit to his surviving companion. This story being read by Mr Lindsey and our author together, they being both then very young, entered into the same engagement. Soon after, Pitcairne, at his father's house in Fife, dreamed one morning that Lindsey, who was then at Paris, came to him, and told him he was not dead, as was commonly reported, but still alive, and lived in a very agreeable place, to which he could not yet carry him. By the course of the post news came of Lindsey's death, which happened very suddenly the morning of the dream. When this is known, the poem is easily understood, and shines with no common degree of beauty.

"Lyndesi! Stygias jamdudum vecte per undas,
"Stagnaque Cocyti non adeunda mihi;
"Excute paulisper Lethæi vincula somni,
"Ut feriant animum carmina nostra tuum.
"Te nobis, te redde tuis, promissa daturus
"Gaudia; sed proavo sis comitante redux:
"Namque novos viros mutataque regna videbis,
"Passaque Teutonicas sceptra Britanna manus *.

* Written in 1689.

"He then proceeds to exclaim against the principles and practices which produced this Teutonic violence upon the British sceptre; and concludes with a wish, that Lindsey might bring Rhadamanthus with him to punish them.

"Unus abest scelerum vindex Rhadamanthus; amice,
"Dii faciant reditus sit comes ille tui.

"Every one sees how much keener an edge is given to the satire upon the Revolution, by making it an additional reason for his friend's keeping his promise to return him a visit after his death."

loosely about him (M); and the present generally received practice differs from his very little in reality. He treated inflammatory and hemorrhagic diseases by bleeding, purging, and blistering, as has been done uniformly and solely on the different theories since. His method of administering mercury and the bark is observed at this day; and with respect to febrile, nervous, glandular and dropsical affections, they seem to be as often the opprobriums of the art now as they were then.

Dr Pitcairne was universally considered as the first physician of his time. No one appears ever to have had so much practice in this country, or so many consultations from abroad; and no one, from all accounts, ever practised with greater sagacity and success. The highest thought themselves honoured by his acquaintance, and the lowest were never denied his assistance and advice. The emoluments of his profession must have been great; but his charities are known to have been correspondent. The possession of money he postponed to more liberal objects; he collected one of the finest private libraries in the world; which was purchased, after his death, by the Czar of Muscovy. Notwithstanding the fatigues he underwent in the exercise of his profession, his constitution was naturally delicate. About the beginning of October 1713, he became affected with his last illness; and on the 23d he died, regretted by science as its ornament, by his country as its boast, and by humanity as its friend. He left a son and four daughters: of whom only one of the latter now survives. The present noble family of Kelly are his grandchildren.

Some anonymous publications are attributed to Dr Pitcairne, particularly a treatise *De Legibus Historiæ Naturalis*, &c.; but the only ones he thought proper to legitimate are his *Dissertationes Medicæ*, and a short essay *De Salute*.

PITCAITHLY. See PITKEATHLY.

PITCH, a tenacious oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various arts: or it is more properly tar inspissated by boiling it over a slow fire. See TAR.

Fossil PITCH. See PETROLEUM, MINERALOGY *Index*.

PITCHING, in sea-affairs, may be defined the vertical vibration which the length of a ship makes about her centre of gravity; or the movement by which she plunges her head and after-part alternately into the hollow of the sea. This motion may proceed from two causes: the waves which agitate the vessel; and the wind upon the sails, which makes her stoop to every blast thereof. The first absolutely depends upon the agitation of the sea, and is not susceptible of inquiry; and the second is occasioned by the inclination of the masts, and may be submitted to certain established maxims.

When the wind acts upon the sails, the mast yields to its effort, with an inclination which increases in proportion to the length of the mast, to the augmentation of the wind, and to the comparative weight and distribution of the ship's lading.

The repulsion of the water, to the effort of gravity, opposes itself to this inclination, or at least sustains it, by as much as the repulsion exceeds the momentum, or absolute effort of the mast, upon which the wind operates. At the end of each blast, when the wind suspends its action, this repulsion lifts the vessel; and these successive inclinations and repulsions produce the movement of pitching, which is very inconvenient; and, when it is considerable, will greatly retard the course, as well as endanger the mast, and strain the vessel.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees *. * See Plant.

PITHO, in fabulous history, the goddess of persuasion among the Romans. She was supposed to be the daughter of Mercury and Venus, and was represented with a diadem on her head, to intimate her influence over the hearts of man. One of her arms appeared raised as in the attitude of an orator haranguing in a public assembly; and with the other she holds a thunderbolt and fetters, made with flowers, to signify the powers of reasoning and the attractions of eloquence. A caduceus, as a symbol of persuasion, appears at her feet, with the writings of Demosthenes and Cicero, the two most celebrated among the ancients, who understood how to command the attention of their audience, and to rouse and animate their various passions.—A Roman courtezan. She received this name on account of the allurements which her charms possessed, and of her winning expressions.

PITHOM, one of the cities that the children of Israel built for Pharaoh in Egypt (Exod. i. 11.) during the time of their servitude. This is probably the same city with Pathumos mentioned by Herodotus, which he places upon the canal made by the kings Necho and Darius to join the Red sea with the Nile, and by that means with the Mediterranean. We find also in the ancient geographers, that there was an arm of the Nile called *Pathmeticus*, *Phatmicus*, *Phatnicus*, or *Phatniticus*. Bochart says, that Pithom and Raamses are about five leagues above the division of the Nile, and beyond this river; but this assertion has no proof from antiquity. This author contents himself with relating what was said of Egypt in his own time. Marsham will have Pithom to be the same as Pelusium or Damietta.

PITHOU, or PITHOEUS, *Peter*, a Frenchman of great literary eminence, was descended from an ancient and noble family in Normandy, and born at Troyes in 1539. His taste for literature appeared very early, and his father cultivated it to the utmost. He first studied at Troyes, and was afterwards sent to Paris, where he became first the scholar, and then the friend, of Turnebus. Having finished his pursuits in languages and the belles lettres, he was removed to Bourges, and placed under Cujacius in order to study civil law. His father was well skilled in his profession, and has left no inconsiderable

(M) Patet *(says he)* medicinam esse memoriam eorum quæ cuilibet morbo usus ostendit fuisse utilia. Nam notas non esse corporum intra venas fluentium aut consistentium naturas, adeoque sola observatione innotescere quid cuique morbo conveniat postquam sæpius eadem eidem morbo profuisse comperimus. *De Div. Morb.*

Pithou, Pitiscus.

inconsiderable specimen of his judgment in the advice he gave his son with regard to acquiring a knowledge of it; which was, not to spend his time and pains upon voluminous and barren commentators, but to confine his reading chiefly to original writers. He made so rapid a progress, that at seventeen he was able to speak extempore upon the most difficult questions; and his master was not ashamed to own, that even himself had learned some things of him. Cujacius afterwards removed to Valence; and Pithœus followed him, and continued to profit by his lectures till the year 1560. He then returned to Paris, and frequented the bar of the parliament there, in order to join practical forms and usages to his theoretic knowledge.

In 1563, being then 24, he published *Adversaria Subcesiva*, a work highly applauded by Turnebus, Lipsius, and other learned men; and which laid the foundation of that great and extensive fame he afterwards acquired. Soon after this, Henry III. advanced him to some considerable posts; in which, as well as at the bar, he acquitted himself most honourably. Pithœus being a Protestant, it was next to a miracle that he was not involved in the terrible massacre of St Bartholomew in 1572; for he was at Paris when it was committed, and in the same lodgings with several Huguenots, who were all killed. It seems indeed to have frightened him out of his religion; which having, according to the custom of converts, examined and found to be erroneous, he soon abjured, and openly embraced the Catholic faith. He afterwards attended the duke of Montmorency into England; and on his return, from his great wisdom, good nature, and amiable manners, he became a kind of oracle to his countrymen, and even to foreigners, who consulted him on all important occasions; an instance of which we have in Ferdinand the grand duke of Tuscany, who not only consulted him, but even submitted to his determination in a point contrary to his interests. Henry III. and IV. were greatly obliged to him for combating the League in the most intrepid manner, and for many other services, in which he had recourse to his pen as well as to other means.

Pithœus died upon his birth-day in 1596, leaving behind him a wife whom he had married in 1579, and some children. Thuanus says he was the mot excellent and accomplished man of the age in which he lived; and all the learned have agreed to speak well of him. He collected a very valuable library, containing a variety of rare manuscripts, as well as printed books; and he took many precautions to hinder its being dispersed after his death, but in vain. He published a great number of works upon law, history, and classical literature; and he gave several new and correct editions of ancient writers. He was the first who made the world acquainted with the Fables of Phædrus: which, together with the name of their author, were utterly unknown and unheard of, till published from a manuscript of his.

PITISCUS, Samuel, a learned antiquary, was born at Zutphen, and was rector of the college of that city, and afterwards of St Jerome at Utrecht, where he died on the first of February 1717, aged 90. He wrote, 1. *Lexicon Antiquitatum Romanarum*, in two volumes folio; a work which is esteemed. 2. Editions of many Latin authors, with notes; and other works.

Pitkeathly, Pitot.

PITKEATHLY, or Pitcaithly, is the name of an estate in Strathern in Scotland, famous for its mineral waters. An intelligent traveller * gives the following account of it. "The situation of the mineral spring at Pitcaithly, the efficacy with which its waters are said to operate in the cure of the diseases for which they are used, and the accommodations which the neighbourhood affords, are all of a nature to invite equally the sick and the healthy. Two or three houses are kept in the style of hotels for the reception of strangers. There is no long-room at the well; but there are pleasing walks through the adjoining fields. Good roads afford easy access to all the circumjacent country. This delightful tract of Lower Strathern is filled with houses and gardens, and stations from which wide and delightful prospects may be enjoyed: all of which offer agreeable points to which the company at the well may direct their forenoon excursions; conversation, music, dances, whist, and that best friend to elegant, lively, and social converse, the tea-table, are sufficient to prevent the afternoons from becoming languid: and in the evenings nothing can be so delightful as a walk when the setting-sun sheds a soft slanting light, and the dew has just not begun to moisten the grass.—Thus is Pitcaithly truly a rural watering-place. The company cannot be at any one time more in number than two or three families. The amusements of the place are simply such as a single family might enjoy in an agreeable situation in the country: only the society is more diversified by the continual change and fluctuation of the company." The waters of this place are of a sulphureous nature.

* Heron's *Journey through the Western Counties of Scotland*.

PITOT, Henry, of a noble family in Languedoc, was born at Aramont in the diocese of Usez, on the 29th of May 1695, and died there on the 27th of December 1771, aged 76. He learned the mathematics without a master, and went to Paris in 1718, where he formed a close friendship with the illustrious Reaumur. In 1724, he was admitted a member of the Royal Academy of Sciences at Paris, and in a few years rose to the degree of a pensioner. Besides a vast number of Memoirs printed in the collection of that society, he published in 1731 the Theory of the Working of Ships, in one volume 4to; a work of considerable merit, which was translated into English, and made the author be admitted into the Royal Society of London. In 1740, the states-general of Languedoc made choice of him for their chief engineer, and gave him at the same time the appointment of inspector general of the canal which unites the two seas. That province is indebted to him for several monuments of his genius, which will transmit his name with lustre to posterity. The city of Montpellier being in want of water, Pitot brought from the distance of three leagues the water of two springs which furnish a plentiful supply of that necessary article. They are brought to the magnificent Place du Peyron, and thence are distributed through the city. This astonishing work is the admiration of all strangers. The illustrious marshal de Saxe was the great patron and friend of Pitot, who had taught this hero the mathematics. In 1754 he was honoured with the order of St Michael. In 1735, he had married Maria Leonina Pharambier de Sabballoua, descended of a very ancient noble family of Navarre. By this marriage he had only one son, who was first advocate-general of the court of accounts, aids,

aids, and finances of Montpellier. Pitot was a practical philosopher, and a man of uncommon probity and candour. He was also a member of the Royal Society of Sciences of Montpellier; and his eulogium was pronounced in 1772 by M. de Ratte perpetual secretary, in presence of the states of Languedoc; as it likewise was at the Royal Academy of Sciences of Paris by Abbé de Fouchi, who was then secretary.

PITS, JOHN, the biographer, was born in 1560, at Aulton in Hampshire, and educated at Wykeham's school, near Winchester, till he was about 18 years of age: when he was sent to New-college in Oxford, and admitted probationer fellow. Having continued in that university not quite two years, he left the kingdom as a voluntary Romish exile, and retired to Douay; thence he went to the English college at Rheims, where he remained about a year; and then proceeded to Rome, where he continued a member of the English college near seven years, and was made a priest. In 1589 he returned to Rheims; and there, during two years, taught rhetoric and the Greek language. He now quitted Rheims on account of the civil war in France; and retired to Pont à Mousson in Lorrain, where he took the degrees of master of arts and bachelor in divinity. Hence he travelled into Germany, and resided a year and a half at Triers, where he commenced licentiate in his faculty. From Triers he visited several of the principal cities in Germany; and continuing three years at Ingoldstadt in Bavaria, took the degree of doctor in divinity. Thence having made the tour of Italy, he returned once more to Lorrain; where he was patronised by the cardinal of that duchy, who preferred him to a canonry of Verdun; and about two years after he became confessor to the duchess of Cleves, daughter to the duke of Lorrain. During the leisure he enjoyed in this employment, he wrote in Latin the lives of the kings, bishops, apostolical men, and writers of England. The last of these, commonly known and quoted by this title, *De illustribus Angliæ scriptoribus*, was published after his death. The three first remain still in manuscript among the archives of the collegiate church of Liverdun. The duke of Cleves dying after Pits had been about twelve years confessor to the duchess, she returned to Lorrain, attended by our author, who was promoted to the deanery of Liverdun, which, with a canonry and officialship, he enjoyed to the end of his life. He died in 1616, and was buried in the collegiate church. Pits was undoubtedly a scholar, and not an inelegant writer; but he is justly accused of ingratitude to Bale, from whom he borrowed his materials, without acknowledgement. He quotes Leland with great familiarity, without ever having seen his book; his errors are innumerable, and his partiality to the Romish writers most obvious; nevertheless we are obliged to him for his account of several popish authors, who lived abroad at the beginning of the Reformation.

PITT, CHRISTOPHER, an eminent English poet, celebrated for his excellent translation of Virgil's Æneid, was born in the year 1699. Having studied four years at New-college, Oxford, he was presented to the living of Pimperne in Dorsetshire, which he held during the remainder of his life. He had so poetical a turn, that while he was a school-boy he wrote two large folios of manuscript poems, one of which contained an entire translation of Lucan. He was much esteemed while at the university; particularly by the celebrated Dr Young, who used familiarly to call him his *son*. Next to his fine translation of Virgil, Mr Pitt gained the greatest reputation by his excellent English translation of Vida's Art of Poetry. This amiable poet died in the year 1748, without leaving, it is said, one enemy behind him.

PITT, *William*, earl of Chatham, a most celebrated British statesmen and patriot, was born in November 1708. He was the youngest son of Robert Pitt, Esq. of Boconnock in Cornwall; and grandson of Thomas Pitt, Esq. governor of Fort St George in the East Indies, in the reign of Queen Anne, who sold an extraordinary diamond to the king of France for 135,000l. and thus obtained the name of *Diamond Pitt*. His intellectual faculties and powers of elocution very soon made a distinguished appearance; but at the age of 16 he felt the attacks of an hereditary and incurable gout, by which he was tormented at times during the rest of his life.

His lordship entered early into the army, and served in a regiment of dragoons. Through the interest of the duchess of Marlborough he obtained a seat in parliament before he was 21 years of age. His first appearance in the house was as representative of the borough of Old Sarum, in the ninth parliament of Great Britain. In the 10th he represented Seaford, Aldborough in the 11th, and the city of Bath in the 12th; where he continued till he was called up to the house of peers in 1766. The intention of the duchess in bringing him thus early into parliament was to oppose Sir Robert Walpole, whom he kept in awe by the force of his eloquence. At her death the duchess left him 10,000l. on condition, as was then reported, that he never should receive a place in administration. However, if any such condition was made, it certainly was not kept on his lordship's part. In 1746, he was appointed vice-treasurer of Ireland, and soon after paymaster general of the forces, and sworn a privy-counsellor. He discharged the office of paymaster with such honour and inflexible integrity, refusing even many of the perquisites of his office, that his bitterest enemies could lay nothing to his charge, and he soon became the darling of the people. In 1755 he resigned the office of paymaster, on seeing Mr Fox preferred to him. The people were alarmed at this resignation; and being disgusted with the unsuccessful beginning of the war, complained so loudly, that, on the 4th December 1756, Mr Pitt was appointed secretary of state in the room of Mr Fox afterwards Lord Holland; and other promotions were made in order to second his plans. He then took such measures as were necessary for the honour and interest of the nation; but in the month of February 1757, having refused to assent to the carrying on a war in Germany for the sake of his majesty's dominions on the continent, he was deprived of the seals on the 5th of April following. Upon this the complaints of the people again became so violent, that on the 29th of June he was again appointed secretary, and his friends filled other important offices. The success with which the war was now conducted is universally known; yet on the 5th of October 1761, Mr Pit, to the astonishment of almost the whole kingdom, resigned the seals into his majesty's own hands. The reason of this was, that Mr

Pitt. Pitt, having received certain intelligence that the family-compact was signed between France and Spain, and that the latter was about to join France against us, thought it necessary to prevent her by commencing hostilities first. Having communicated this opinion in the privy-council, the other ministers urged that they would think twice before they declared war against that kingdom. "I will not give them leave to think (replied Mr Pitt); this is the time, let us crush the whole house of Bourbon. But if the members of this board are of a different opinion, this is the last time I shall ever mix in its councils. I was called into the ministry by the voice of the people, and to them I hold myself answerable for my conduct. I am to thank the ministers of the late king for their support; I have served my country with success; but I will not be responsible for the conduct of the war any longer than while I have the direction of it." To this bold declaration, the lord who then presided in council made the following reply. "I find the gentleman is determined to leave us; nor can I say that I am sorry for it, since he would otherwise have certainly compelled us to leave him. But if he is resolved to assume the right of advising his majesty, and directing the operations of the war, to what purpose are we called to this council? When he talks of being responsible to the people, he talks the language of the house of commons, and forgets that at this board he is responsible only to the king. However, though he may possibly have convinced himself of his infallibility, still it remains that we should be equally convinced before we can resign our understandings to his direction, or join with him in the measure he proposes."

This conversation, which was followed by Mr Pitt's resignation, is sufficient to show the haughtiness and imperious temper of our minister. However, these very qualities were sometimes productive of great and good consequences, as appears from the following anecdote. —Preparatory to one of the secret expeditions during the war which ended in 1763 the minister had given orders to the different presiding officers in the military, navy, and ordnance departments, to prepare a large body of forces, a certain number of ships, and a proportionable quantity of stores, &c. and to have them all ready against a certain day. To these orders he received an answer from each of the officers, declaring the total impossibility of a compliance with them. Notwithstanding it was then at a very late hour, he sent immediately for his secretary; and after expressing his resentment at the ignorance or negligence of his majesty's servants, he gave the following commands:— "I desire, Mr Wood, that you will immediately go to Lord Anson; you need not trouble yourself to search the admiralty, he is not to be found there; you must pursue him to the gaming-house, and tell him from me, that if he does not obey the orders of government, which he has received at my hands, that I will most assuredly impeach him. Proceed from him to Lord Ligonier; and though he should be bolstered with harlots, undraw his curtains, and repeat the same message. Then direct your course to Sir Charles Frederick, and assure him that if his majesty's orders are not obeyed, they shall be the last which he shall receive from me." In consequence of these commands, Mr Wood proceeded to White's, and told his errand to the first lord of the admiralty; who insisted that the secretary of state was out of his senses, and it was impossible to comply with his wishes: "however, (added he), as madmen must be answered, tell him that I will do my utmost to satisfy him." From thence he went to the commander in chief of the forces, and delivered the same message. He also said that it was an impossible business; "and the secretary knows it, (added the old lord): nevertheless, he is in the right to make us do what we can; and what it is possible to do, inform him, shall be done." The surveyor general of the ordnance was next informed of Mr Pitt's resolution; and, after some little consideration, he began to think that the orders might be completed within the time prescribed. The consequence at last was, that every thing, in spite of impossibilities themselves, was ready at the time appointed.

After his resignation in 1761, Mr Pitt never had any share in administration. He received a pension of 3000l. a-year, to be continued after his decease, during the survivancy of his lady and son; and this gratuity was dignified with the title of *Baroness of Chatham* to his lady, and that of *Baron* to her heirs male. Mr Pitt at that time declined the title of nobility; but in 1766 accepted of a peerage under the title of *Baron Pynsent and Earl of Chatham*, and at the same time he was appointed lord privy-seal.

This acceptance of a peerage proved very prejudicial to his lordship's character. However, he continued stedfast in his opposition to the measures of administration. His last appearance in the house of lords was on the 2d of April 1778. He was then very ill and much debilitated: but the question was important, being a motion of the duke of Richmond to address his majesty to remove the ministers, and make peace with America on any terms. His lordship made a long speech, which had certainly overcome his spirits: for attempting to rise a second time, he fell down in a convulsive fit; and though he recovered for that time, his disorder continued to increase till the 11th of May, when he died at his seat at Hayes. His death was lamented as a national loss. As soon as the news reached the house of commons, which was then sitting, Colonel Barré made a motion, that an address should be presented to his majesty, requesting that the earl of Chatham should be buried at the public expence. But Mr Rigby having proposed the erecting of a statue to his memory, as more likely to perpetuate the sense of his great merits entertained by the public, this was unanimously carried. A bill was soon after passed, by which 4000l. a-year was settled upon John now earl of Chatham, and the heirs of the late earl to whom that title may descend.— His lordship was married in 1754 to Lady Hester, sister to the earl of Temple; by whom he had three sons and two daughters.

Never perhaps was any life so multifarious as that of Lord Chatham; never did any comprise such a number of interesting situations. To bring the scattered features of such a character into one point of view, is an arduous task. The author of the history * of his life has attempted to do it; and with the outlines of what he has said in summing up his character, we shall finish our biographical sketch of this wonderful man.

* *History of the Life of William Pitt, Earl of Chatham.*

"One of the first things that strikes us, in the recollection of Chatham's life, is the superior figure he makes among his contemporaries. Men of genius and attraction, a Carteret, a Townshend, and I had almost said

Pitt. said a Mansfield, however pleasing in a limited view, appear evidently in this comparison to shrink into narrower dimensions, and walk a humbler circle. All that deserves to arrest the attention, in taking a general survey of the age in which he lived, is comprised in the history of Chatham. No character ever bore the more undisputed stamp of originality. Unresembled and himself, he was not born to accommodate to the genius of his age. While all around him were depressed by the uniformity of fashion, or the contagion of venality, he stood aloof. He consulted no judgment but his own; and he acted from the untainted dictates of a comprehensive soul.

"The native royalty of his mind is eminently conspicuous. He felt himself born to command; and the free sons of Britain implicitly obeyed him. In him was realised the fable of Orpheus; and his genius, his spirit, his eloquence, led millions in his train, subdued the rugged savage, and disarmed the fangs of malignity and envy. Nothing is in its nature so inconsistent as the breath of popular applause: and yet that breath was eminently his during the greater part of his life. Want of success could not divert it; inconsistency of conduct could not change its tenor. The astonishing extent of his views, and the mysterious comprehension of his plans, did not in one respect set him above little things: nothing that was necessary to the execution of his designs was beneath him. In another respect, however, he was infinitely estranged to little things: swallowed up in the business of his country, he did not think of the derangement of his own private affairs; for, though indisposed to all the modes of dissipated expence, his affairs, even when his circumstances were much improved, were always deranged. But the features that seem most eminently to have characterised him, were spirit and intrepidity: they are conspicuous in every action and in every turn of his life; nor did this spirit and intrepidity leave him even at the last.

"The manners of Lord Chatham were easy and bland, his conversation was spirited and gay, and he readily adapted himself to the complexion of those with whom he associated. That artificial reserve, which is the never-failing refuge of self-diffidence and cowardice, was not made for him. He was unconstrained as artless infancy, and generous as the noon-day sun: yet had he something impenetrable that hung about him. By an irresistible energy of soul, he was haughty and imperious. He was incapable of associating councils, and he was not formed for the sweetest bands of society. He was a pleasing companion, but an unpliant friend.

"The ambition of our hero, however generous in its strain, was the source of repeated errors in his conduct. To the resignation of Lord Carteret, and again, from the commencement of the year 1770, his proceedings were bold and uniform. In the intermediate period they were marked with a versatility, incident only in general to the most flexible minds. We may occasionally trace in them the indecision of a candidate, and the suppleness of a courtier. In a word, he aimed at the impossible task of flattering at once the prejudices of a monarch, and pursuing unremittedly the interests of the people.

"A feature, too, sufficiently prominent in his character, was vanity, or perhaps pride and conscious superiority. He dealt surely somewhat too freely with invective. He did not pretend to an ignorance of his talents, or to manage the display of his important services. Himself was too often the hero of his tale; and the successes of the last war the burden of his song *.

"Patriotism was also the source of some of his imperfections. He loved his country too well; or, if that may sound absurd, the benevolence at least, that embraces the species, had not sufficient scope in his mind. He once styled himself *a lover of honourable war;* and in so doing he let us into one trait of his character. The friend of human kind will be an enemy to all war. He indulged too much a puerile antipathy to the house of Bourbon: and it was surely the want of expansive affections that led him to so unqualified a condemnation of American independency.

"But the eloquence of Lord Chatham was one of his most striking characteristics. He far outstripped his competitors, and stood alone the rival of antiquity.

"His eloquence was of every kind. No man excelled him in close argument and methodical deduction: but this was not the style into which he naturally fell. His oratory was unlaboured and spontaneous: he rushed at once upon the subject; and usually illustrated it rather by glowing language and original conception, than by cool reasoning. His person was tall and dignified; his face was the face of an eagle; his piercing eye withered the nerves, and looked through the souls of his opponents; his countenance was stern, and the voice of thunder sat upon his lips: anon, however, he could descend to the easy and the playful. His voice seemed scarcely more adapted to energy and to terror, than it did to the melodious, the insinuating, and the sportive. If, however, in the enthusiasm of admiration, we can find room for the frigidity of criticism, his action seemed the most open to objection. It was forcible, uniform, and ungraceful. In a word, the most celebrated orators of antiquity were in a great measure the children of labour and cultivation. Lord Chatham was always natural and himself."

To the misfortune of letters, and of posterity, it has been said, his lordship never published any thing. Lord Chesterfield says, "that he had a most happy turn for poetry; but it is more than probable that Chesterfield was deceived; for we are told by his biographer that his verses to Garrick were very meagre, and Lord Chatham himself said that he seldom indulged and seldom avowed it. It should seem, then, that he himself set no great value upon it. Perhaps a proper confidence of one's self is essential to all extraordinary merit. Why should we ambitiously ascribe to one mind every species of human excellence? But though he was no poet, it is more than probable, that he would have excelled as much in writing prose as he did in speaking it.

Pitt, *the Right Honourable William*, was the fourth child of that illustrious orator and consummate statesman, William Pit, the first earl of Chatham, and was born on the 28th of May 1759. Nicholas Pitt, who lived in the reign of Henry VI. was the common ancestor of the noble families of Chatham, Camelford, and Rivers. Thomas Pitt, the first of the name who attained any considerable eminence, was governor of Fort St George in the East Indies, where he purchased, as noticed in the preceding life, for 20,400l. sterling, the extraordinary diamond called the *regent*, weighing 127 carats, and which was sold to the king of France for the enormous sum of 135,000l. sterling. The diamond it is said, now occupies a conspicuous place in the imperial diadem of Bonaparte,

* Ending in 1763.

Bonaparte. By means of this vast sum he was enabled to purchase a considerable estate in Cornwall; yet his grand-children were poorly provided for, particularly the great earl of Chatham, but what he wanted in opulence was abundantly supplied by the uncommon talents and abilities, which nature conferred upon him in the profusest manner. Although he betook himself for support to the profession of arms, he never rose higher than to the rank of a cornet of horse, of which Sir Robert Walpole, with unexampled meanness, deprived him, because he had the boldness and integrity to oppose his administration. This, however, proved no real obstacle to his preferment in the state, for in the year 1756 he became prime minister.

As the present earl of Chatham was destined for the army, and another son James-Charles for the navy, lord Chatham resolved to train up William to the profession of a statesman. Having therefore confided the care of his other two sons to others, he took William under his own immediate inspection, whose rapid progress cheered the solitude, and illumed the declining days of this extraordinary man, who already began to presage his future greatness. His school exercises were performed under the care of a private tutor, a Mr, afterwards Dr Wilson, while his noble father embraced every opportunity of conversing with him on every interesting topic with the utmost freedom, in order to expand his mind, and mature his judgment. He also made him declaim from a chair or a table, well knowing that the gift of eloquence is a valuable acquisition for a young man who wishes to arrive at eminence, and that it had supplied the deficiencies of fortune in his own person.

It was resolved on, at a proper period, to send William to one of the universities, and on this occasion Cambridge was preferred to Oxford, from a decided opinion entertained by many, that the political doctrines inculcated at the former were more liberal than those usually propagated at the latter. He was accordingly placed under the tuition of Dr Turner of Pembroke Hall. Dr Prettyman, afterwards bishop of Lincoln, also participated in the care of his education, and was his private instructor. During his residence at Cambridge, it appears certain that the morals and conduct of Mr Pitt were unimpeachable, not in the smallest degree contaminated by the powerful example of the young nobility. Here he took his bachelor's degree, and also that of A. M. and acquired such reputation in the university for talents, industry, and propriety of deportment, as proved of great advantage to him in his subsequent pursuits through life.

When Mr Pitt left the university, he was entered at Lincoln's Inn, much about the same time with Mr Addington, whose father had been both the physician and friend of his family, and was enabled to be called to the bar in the space of three years, having received some marks of favour on account of his degree. He made choice of the western circuit as the scene of his first efforts; but having little practice as a lawyer, he had of consequence but little celebrity; and it is probable that he was ill qualified, on the score of patient and laborious investigation, for a pursuit in which nothing great can be accomplished, without the persevering industry of a whole life.

Fortune at this time seemed eager to heap favours upon him of another kind. Being bred a statesman, the house of commons was of course the place where he was to begin his political career. He was advised by numerous friends to propose himself a candidate for the university of Cambridge, but he failed of success from the want of sufficient influence. Accident, however, brought about what the designs of his friends could not accomplish. The duke of Rutland asked Sir James Lowther (afterwards earl of Lonsdale), if he could possibly make room in any of his boroughs, to bring in his young friend Mr Pitt, who had thus lost his election for Cambridge. He was chosen member for the borough of Appleby. About this time the American war was raging with unabated violence, which Mr Pitt, following the example and advice of his father, reprobated as one of the most shameful and ruinous conflicts of modern times. Having espoused the constitutional and popular side of this important question, his opening talents were displayed to no common advantage, and he was not only regarded as a promising speaker, but destined at some future period to rank high in the councils of his native country. This was truly honourable to so young a man, when it is remembered that one house could then boast of a Rockingham, a Richmond, and a Shelburne, and the other of a Saville, a Dunning, a Burke, a Barré, and a Fox. Yet there was still room for our juvenile orator, and the recollection of the eloquence, the talents, and the meritorious services of his father, contributed greatly to fix the attention of mankind on the deportment of a favourite son.

About this time the extent of the royal prerogative engaged the attention both of the parliament and the public, and a vote of the commons, "that the influence of the crown had increased, was increasing, and ought to be diminished," plainly pointed to an object, whether real or imaginary, which occasioned a considerable degree of discontent. Mr Burke, then in the zenith of his popularity, encouraged by numerous symptoms of jealousy, once more brought forward his plan of economy, which being founded on a progressive retrenchment, appeared admirably calculated to diminish the influence of the crown. It is needless to add that it was opposed by the minister (Lord North), but it was ably supported by Mr Pitt, who forcibly ridiculed every objection that could be brought against it. The bill was rejected after a long debate, but afterwards introduced at a more auspicious period, and to a certain extent carried into effect.

Mr Fox having moved that ministers should immediately take every possible measure for concluding a peace with our American colonies, he was powerfully supported by Mr Pitt, whose commanding eloquence engaged the whole attention of the house, while he reprobated the cruelty and impolicy of the contest with our colonies. He declared that it was conceived in injustice, nurtured and brought forth in folly, and its footsteps were marked with blood, slaughter, persecution, and devastation. Many handsome compliments were paid him by two eminent judges of real merit, we mean the lord advocate of Scotland (now Viscount Melville), and Mr Wilkes. The former, in particular, declared that his powerful abilities and brilliant eloquence were universally acknowledged proofs, that the astonishing extent and force of an exalted understanding had descended, in an hereditary line, from the late illustrious possessor of them, to a son equally endowed with all the fire, and strength, and grace of oratory.

Pitt.

A more equal representation of the people in parliament was one of the principal objects to which the nation directed its attention, next to the American war. It was admitted to be the undoubted prerogative of the crown to declare war; but as the supplies were entrusted to the management of the representatives of the people, it was affirmed by some that ministers could not have carried on a contest accompanied with the waste of so much blood and treasure, had it not been owing to the corruption and venality of parliament. To derive advantage from past experience; to confer on the people their due importance in such a mixed government as that of Britain, and restore the constitution to its original purity, became by this time the grand object of Mr Pitt's exertions. He was as yet untainted by the fascinating charms of power and authority, and considered a well-earned fame as the best, the only reward of his laudable endeavours. He accordingly brought the principles and conduct of his opponents to such a test as they successfully employed against himself, in order to wound his feelings, and convict him of inconsistency, by turning his back on his once favourite sentiments. When many cities and counties endeavoured to obtain a reform in parliament, Mr Pitt actually sat in a convention of delegates, met together in the neighbourhood of the place where the legislature held its sittings.

The American war in the mean time was drawing to a termination, and the spoils of the office of the former minister became the reward of those who opposed him. During the short existence of the Rockingham administration, contractors were excluded from the house of commons; officers belonging to the customs and excise were declared unqualified to vote at elections; the proceedings respecting the Middlesex election were rescinded: and while a more liberal policy was adopted with regard to Ireland, many superfluous offices were abolished in England by means of a reform bill, which tended powerfully to destroy corruption. Many more important reforms would have been accomplished, had not the death of the distinguished Rockingham brought about great and sudden changes.

Mr Fox retired in consequence of new arrangements, and Lord Shelburne, as first lord of the treasury, made choice of Mr Pitt as chancellor of the exchequer, who declared, although only 23 years of age, that he would accept of no inferior office. Peace now seemed to be an object generally desireable at any rate, and without much regarding what sacrifices might be made in order to procure it; but the terms met with powerful opposition from two men formerly considered as mortal enemies, viz. Lord North and Mr Fox, the latter of whom retired from office. Soon after the dismission of Mr Fox, Mr Pitt again brought forward the question respecting a reform in parliament, which he fondly hoped would be the means of restoring him to his wonted popularity, and pave the way to the increase of his power. He therefore submitted three different motions to the consideration of the house; but although in these motions he was ably supported, he was left in a minority.

The coalition ministry, as it was called, had still a considerable majority in parliament, notwithstanding the popularity belonging to the name and talents of Mr Pitt, but the celebrated India bill was productive of a change. This bill owed its origin to Mr Burke, but it received a regular and systematical opposition from the ex-chancellor of the exchequer. It was carried, however, in the house of commons by a great majority, but in the house of lords it was opposed by the duke of Richmond, Lord Thurlow, and Earl Temple (afterwards marquis of Buckingham); and on the 17th of December 1783, it was finally rejected by a majority of 19.

The king in the mean time determined on an entire change of administration, and the two secretaries were informed on the 18th of December 1783, about 12 o'clock at night, that his majesty had no further occasion for their services. In consequence of this change, the important offices of first lord of the treasury and chancellor of the exchequer were bestowed on Mr Pitt, who thus became prime minister before he was full 24 years of age. Thurlow was created lord chancellor, the duke of Richmond keeper of the privy seal; the marquis of Caermarthen and Lord Sidney were chosen secretaries of state, and Mr Dundas, treasurer of the navy.

Much about this time Mr Pitt brought forward a new bill for the better government of India. He proposed that a board of controul should be instituted, the nomination of whose members was to be vested in the crown, and to them the dispatches of the company were to be submitted. He also proposed that the appointment of the commander in chief should belong to his majesty, and having thus secured the political interests of the company, he left those of a commercial nature entirely to the court of directors. This bill, after a short debate, was rejected by a majority of eight. Such was the present temper of the house of commons, that a coalition or immediate dissolution became absolutely necessary; and the former having been unsuccessfully attempted, the latter was suddenly adopted, on the 25th of March 1784. Mr Pitt having been returned for the university of Cambridge, again brought forward his bill in an amended state for the regulation of India, and carried it in triumph through both houses of parliament. The remaining part of the session gave birth to an act for the better prevention of smuggling, and the commutation act, by virtue of which certain duties were transferred from tea to windows.

When Mr Alderman Sawbridge (June 16th 1784) made a motion for inquiring into the present state of the commons of Great Britain in parliament, Mr Pitt, whose political sentiments had undergone a revolution, felt himself considerably embarrassed, as he was reminded that he had brought forward questions on the same subject upon a former occasion. Mr Pitt, however, declined it, on account of the pressure of public business, and observed that, in his opinion, the present was not the proper time for bringing forward the question, and that it might be urged with greater probability of success on some future occasion. He did not wish it to be discussed in a precipitate manner, yet the business itself should have every support he was able to afford it.

Having now attained the summit of power and influence as prime minister, Mr Pitt exercised every function of his important office, without any check or controul. Possessed of a great majority in both houses of parliament, as well as in the cabinet, his whole deportment in the language of his opponents, seems to have become lofty in the extreme; and he paid little or no regard to that popularity which he had formerly courted.

A commercial treaty about this time was entered into with France, the terms of which have been generally acknowledged

acknowledged to be advantageous to Britain. Mr Pitt, who deserves great credit for giving the plan his countenance, adopted, much about the same time, another respecting the finances, from which he derived a high degree of reputation; and, as he pointed at a period when the national debt might, in all probability, be extinguished, the country, if it was not altogether satisfied, appeared to be at least contented under his administration: and it is not a little to the credit of his financial system, that his opponents, when in power, not only approved, but adopted and extended it.

In this manner a commercial country began again to flourish, by turning its attention to the arts of peace; but, during his administration, its prosperity was threatened to be interrupted by the preparation for an attack upon Russia at one time, and by an open rupture with Spain at another, relative to Nootka Sound. In both cases the blow was warded off by negociation, and a good understanding restored. The restoration of the stadtholder, by the intervention of a Prussian army, and his strenuous opposition of the prince of Wales's appointment to the regency during the king's indisposition, were also two important measures pursued and discussed in the course of his ministry.

Soon after the commencement of the French revolution, Mr Pitt deemed a war with that country inevitable. But for a full detail of the events of this war, see Britain. Having held the reins of government during 18 years, Mr Pitt, and all the members of the cabinet, suddenly retired from office in 1801. On this occasion all parties appeared to rejoice at the appointment of Mr Addington; and France, from that moment, as some assert, seemed to have neither friends nor advocates in this island. When the articles of the treaty of Amiens were debated in the house of commons, Mr Pitt defended the new minister with the whole force of his abilities and influence.

On the 15th of March 1804, Mr Pitt made a direct attack on the administration; and the admiralty board was accused by him of imbecility. He zealously supported Mr Fox's proposition relative to the Irish militia bill for the national defence, which was lost on a division. The minister's majority having dwindled to 37, on the army of reserve suspension bill, Mr Addington and some of his friends retired, and the ex-minister resumed his former seat. When parliament met on the 15th of January 1805, Mr Pitt warmly defended the war with Spain; and, on the motion for an address, he had a majority of 207.

But, in the mean time, a gouty habit, the predisposing causes of which appear to have been hereditary, and which, perhaps, was increased by his own manner of living, seized on a constitution never very strong. It is alleged, by his opponents, that this, combined with the miscarriage of his schemes, and the aspect of affairs on the continent, preyed so much upon his mind, that he is said to have died of a broken heart, at his house near Putney, between four and five on Wednesday morning, January 23. 1806, in the 47th year of his age.

As a financier, no man has obtained more praise, who ever presided at the board of exchequer. During his ministry some of our manufactures languished, but many flourished, and our exports were greatly increased. As a speaker he was unrivalled, and his generous scorn of wealth must be admired. In 20 years his debts amounted only to 40,000l. They were paid out of the public purse. The house of commons also passed a vote, that the expences of his funeral, and a monument to his memory, should be defrayed by the nation.

PITTACUS, a native of Mitylene in Lesbos, was one of the seven wise men of Greece: his father's name was Hyrradius. With the assistance of the sons of Alcæus, he delivered his country from the oppression of the tyrant Melanchrus; and in the war which the Athenians waged against Lesbos, he appeared at the head of his countrymen, and challenged to single combat Phrynon the enemy's general. As the event of the war seemed to depend upon this combat, Pittacus had recourse to artifice; and when he engaged, he entangled his adversary in a net which he had concealed under his shield, and easily dispatched him. He was amply rewarded for this victory; and his countrymen, sensible of his merit, unanimously appointed him governor of their city with unlimited authority. In this capacity Pittacus behaved with great moderation and prudence; and after he had governed his fellow-citizens with the strictest justice, and after he had established and enforced the most salutary laws, he voluntarily resigned the sovereign power after having enjoyed it for 10 years, observing that the virtues and innocence of private life were incompatible with the power and influence of a sovereign. His disinterestedness gained him many admirers; and when the Mityleneans wished to reward his public services by presenting him with an immense tract of territory, he refused to accept more land than what should be contained in the distance to which he he could throw a javelin. He died in the 70th year of his age, about 579 years before Christ, after he had spent the last 10 years of his life in literary ease and peaceful retirement.

The following maxims and precepts are ascribed to Pittacus: The first office of prudence is to foresee threatening misfortunes, and prevent them. Power discovers the man. Never talk of your schemes before they are executed; lest, if you fail to accomplish them, you be exposed to the double mortification of disappointment and ridicule. Whatever you do, do it well. Do not that to your neighbour which you would take ill from him. Be watchful for opportunities.

Many of his maxims were inscribed on the walls of Apollo's temple at Delphi, to show to the world how great an opinion the Mityleneans entertained of his abilities as a philosopher, a moralist, and a man. By one of his laws, every fault committed by a man when intoxicated deserved double punishment.

PITTENWEEM, a small town situated on the frith of Forth, towards the eastern extremity of the county of Fife in North Britain. It takes its name from a small cave in the middle of it, anciently called a *weem;* and is remarkable for nothing but the ruins of a religious house, which is sometimes called an *abbey* and sometimes a *priory*. Which of these is the proper denomination it is hardly worth while to inquire; but it appears from the arms of the monastery, still preserved over the principal gate, that the superior, by whatever title he was called, had the privilege of wearing a mitre. This edifice, which seems never to have been large, was, with other monuments of mistaken piety, alienated from the church at the Reformation; and what parts of it now remain

are

are put to very different uses. Some of the cells of the monks furnish habitations tolerably convenient for the servants of him who, in the ceaseless change of property, has got possession of the lands which formerly belonged to them. That which seems to have been the granary is a decent parish church. The porch of the chapel, the only part of that building which exists, has been alternately employed as a stable and a slaughter-house; and the meat killed there has been commonly exposed to sale in the lower part of the steeple of that edifice which is now dedicated to the offices of parochial devotion. Had the moralizing traveller *, who composed the beautiful and pathetic meditation on the ruins of *Jona*, condescended to visit Pittenweem, he would not have viewed the abbey without emotion. Insignificant as the place at present is, it seems to have been of some consequence in the last century; and we are led to infer, from the following extract from the records, that the inhabitants were opulent, and that the town was fortified.

* Johnson.

"Pittenweem, decimo quarto Feb. 1651. The bailies and council being convened, and having received information that his majesty is to be in progress with his court along the coast to-morrow, and to stay at Anstruther house that night, have thought it expedient, according to their bounden duty, with all reverence and due respect, and with all the same solemnity they can, to wait upon his majesty, as he comes through this his majesty's burgh, and invite his majesty to eat and drink as he passes; and for that effect hath ordained, that the morn afternoon the town's colours be put upon the bertisene of the steeple, and that at three o'clock the bells begin to ring, and ring on still till his majesty comes hither, and passes to Anstruther: And sicklike, that the minister be spoken to, to be with the bailies and council, who are to be in their best apparel, and with them a guard of 24 of the ablest men, with partizans, and other 24 with muskets, all in their best apparel, William Sutherland commanding as captain of the guard; and to wait upon his majesty, and to receive his highness at the West Port, bringing his majesty and court through the town, until they come to Robert Smith's yeet, where an table is to be covered with my Lord's † best carpet: and that George Hetherwick have in readiness, of fine flour, some great bunns, and other wheat-bread of the best order, baken with sugar, cannell, and other spices fitting; and that James Richardson and Walter Airth have care to have ready eight or ten gallons of good strong ale, with Canary, sack, Rhenish wine, tent, white and claret wines, that his majesty and his court may eat and drink; and that in the mean time, when his majesty is present, the guard do diligently attend about the court; and so soon as his majesty is to go away, that a sign be made to Andrew Tod, who is appointed to attend the colours on the steeple head, to the effect he may give sign to those who attend the cannon of his majesty's departure, and then the *hail thirty six cannons to be all shot at once*. It is also thought fitting, that the minister and James Richardson the oldest bailie, when his majesty comes to the table, show the great joy and sense this burgh has of his majesty's condescendence to visit the same, with some other expressions of loyalty. All which was acted." The population of this town, in 1790, was computed at 1157. N. Lat. 56. 11. W. Long. 2. 49.

† The Earl of Kelly.

PITTOSPORUM, a genus of plants belonging to the pentandria class. See Botany *Index*.

PITUITARY gland. See Anatomy *Index*.

PITYOCAMPASIS, in *Entomology*, the caterpillar of the pine-tree, received its compound name from that substance. It was considered as a poison, and as a remedy, according to its different mode of application. Our chief information, concerning this caterpillar, is derived from M. Reaumur, who has attentively observed its manner of life. The animal cannot bear much cold, and is therefore never found in the higher latitudes. It is styled processionary, because it never leaves its hold, where many families reside, till the evening, when it feeds in trains, led on by two or three, and this train leaves a ribband of silk in its way; for those behind follow exactly the steps of those which preceded, and each leaves its fibre of silk. Their nests are found in autumn; they are produced in the middle of September, become torpid in December, and recover their strength again in spring. They then descend from the trees, plunge into the earth, and undergo their last change. It is the bombix pityocampa of Fabricius, (*Mantissa Insector*. tom. ii. p. 114. N° 66.), and greatly resembled the processionary caterpillar of the oak. The ancients used it as a vesicatory, and the acrimony seems to reside chiefly in a dust which is concealed in receptacles on its back. This is its offensive weapon, for it is thrown out at will, and produces very troublesome effects, though the hair of the animal and every part of its body seem to have a similar, but weaker power. The effect is also weaker in winter; but this may depend on the diminished irritability of the human body, as well as on the torpid state of the insect. Their silk is not sufficiently strong for the loom, and in hot water melts almost to a paste. In the earth it forms nests of stronger silk, but it is then found with difficulty: in boxes its silk is extremely tender. Adding to all these inconveniences, handling the cones produces all the bad effects of the dust. Matthiolus recommends them as a styptic, and perhaps they may serve for burning on the skin, instead of moxa the downy silk of a species of artemisia. The ancients, afraid of its hurtful qualities, used them with caution, and enacted laws against their being sold promiscuously: the modern planter is chiefly afraid of them, because they destroy the beauty of his trees, and he endeavours to collect the eggs by cutting off the branches which are burnt immediately.

PIVAT, or Pivot, a foot or shoe of iron or other metal, usually conical or terminating in a point, whereby a body, intended to turn round, bears on another fixed at rest, and performs its revolutions. The pivot usually bears or turns round in a sole, or piece of iron or brass hollowed to receive it.

PIUS II. (Æneas Sylvius Piccolomini), was born on the 18th of October 1405, at Corsigni in the Siennese, the name of which he afterwards changed into that of *Pienza*. His mother Victoria Forteguerra, when she was with child of him, dreamed that she should be delivered of a mitred infant; and as the way of degrading clergymen at that time was by crowning them with a paper mitre, she believed that Æneas would be a disgrace to his family. But what to her had the appearance of being a disgrace, was a presage of the greatest honours. Æneas was carefully educated, and made considerable proficiency in the belles lettres. After having

Pius. ving finished his studies at Sienna, he went in 1431 to the council of Bale with Cardinal Capranica, surnamed *De Fermo*, because he was entrusted with the government of that church. Æneas was his secretary, and was then only 26 years of age. He afterwards acted in the same capacity to some other prelates, and to Cardinal Albergati. The council of Bale honoured him with different commissions, in order to recompense him for the zeal with which he defended that assembly against Pope Eugene IV. He was afterwards secretary to Frederic III. who decreed to him the poetic crown, and sent him ambassador to Rome, Milan, Naples, Bohemia, and other places. Nicholas V. advanced him to the bishopric of Trieste, which he quitted some time after for that of Sienna. At last, after having distinguished himself in various nunciatures, he was invested with the Roman purple by Calixtus III. whom he succeeded two years after, on the 27th of August 1458. Pius II. now advanced to the holy see, made good the proverb, *Honores mutant mores.* From the commencement of his pontificate, he appeared jealous of the papal prerogatives. In 1460 he issued a bull, "declaring appeals from the pope to a council to be null, erroneous, detestable, and contrary to the sacred canons." That bull, however, did not prevent the procurator-general of the parliament of Paris from appealing to a council in defence of the Pragmatic Sanction, which the pope had strenuously opposed. Pius was then at Mantua, whither he had gone in order to engage the Catholic princes to unite in a war against the Turks. The greater part of them had agreed to furnish troops or money; others refused both, particularly France, who from that moment incurred his holiness's aversion. That aversion abated under Louis XI. whom he persuaded in 1461 to abolish the Pragmatic Sanction, which the parliament of Paris had supported with so much vigour.

The following year, 1462, was rendered famous by a controversy which took place between the Cordeliers and Dominicans, whether or not the blood of Jesus Christ was separated from his body while he lay in the grave. It was also made a question whether it was separated from his divinity. The Cordeliers affirmed that it was, but the Dominicans were of an opposite opinion. They called each other heretics; which obliged the pope to issue a bull, forbidding them under pain of censure to brand one another with such odious epithets. The bull which his holiness published on the 26th of April, retracting what he had written to the council of Bale when he was its secretary, did not redound much to his honour. "I am a man (says he), and as a man I have erred. I am far from denying that a great many things which I have said and written may deserve condemnation. Like Paul, I have preached through deception, and I have persecuted the church of God through ignorance. I imitate the blessed Augustin, who having suffered some erroneous sentiments to creep into his works, retracted them. I do the same thing; I frankly acknowledge my ignorance, from a fear lest what I have written in my younger years should be the occasion of any error that might afterwards be prejudicial to the interests of the holy see. For if it be proper for any one to defend and support the eminence and glory of the first throne of the church, it is in a peculiar manner my duty, whom God, out of his mercy and goodness alone, without any merit on my part, has raised to the dignity of *vicar of Jesus Christ*. For all these reasons, we exhort and admonish you in the Lord, not to give credit to those writings of ours which tend in any degree to hurt the authority of the apostolic see, and which establish opinions that are not received by the Roman church. If you find, then, any thing contrary to her doctrine, either in our dialogues, in our letters, or in other of our works, despise these opinions, reject them, and adopt our present sentiments. Believe me rather now that I am an old man, than when I addressed you in my earlier days. Esteem a sovereign pontiff more than a private person; except against Æneas Sylvius, but receive Pius II." It might be objected to his holiness, that it was his dignity alone which had made him alter his opinion. He anticipates that objection, by giving a short account of his life and actions, with the whole history of the council of Bale, to which he went with Cardinal Capranica in 1431; "but (says he) I was then a young man, and without any experience, like a bird just come from its nest." In the mean time, the Turks were threatening Christendom. Pius, ever zealous in the defence of religion against the infidels, forms the resolution of fitting out a fleet at the expence of the church, and of passing over into Asia himself, in order to animate the Christian princes by his example. He repaired to Ancona with a design to embark; but he there fell sick with the fatigue of the journey, and died on the 16th of August 1464, aged 59 years. Pius was one of the most learned men of his time, and one of the most zealous pontiffs; but being of an ambitious and pliant disposition, he sometimes sacrificed to that ambition. His principal works are, 1. Memoirs of the council of Bale, from the suspension of Eugenius to the election of Felix. 2. The history of the Bohemians, from their origin to the year 1458. 3. Two books on cosmography. 4. The history of Frederic III. whose vice-chancellor he had been. This performance was published in 1785 in folio, and is believed to be pretty accurate and very particular. 5. A treatise on the education of children. 6. A poem upon the passion of Jesus Christ. 7. A collection of 432 letters, printed at Milan, 1473, in folio, in which are found some curious anecdotes. 8. The memoirs of his own life, published by John Gobelin Personne his secretary, and printed at Rome in 4to in 1584. There is no doubt of this being the genuine production of that pontiff. 9. *Historia rerum ubicumque gestarum*, of which only the first part was published at Venice in 1477 in folio. His works were printed at Helmstadt in 1700. in folio, at the beginning of which we find his life. That verse of Virgil's Æneid (lib. i. 382.) which begins thus,

Sum Pius Æneas,———

and the end of the following verse,

———*fama super æthera notus,*

have been applied to him.

Pius IV. (*John Angel, Cardinal de Medicis*), of a different family from that of Florence, was born at Milan in 1499. He was son to Bernardin de Medechini, and brother of the famous Marquis de Marignan. Charles V.'s general. He raised himself by his own merit, and filled several important offices under Popes Clement VII. and Paul III. Julius III. who had entrusted him with several legations, honoured him with a cardinal's hat

Pius.

hat in 1549. After the death of Paul IV. he was advanced to at Peter's chair on the 25th of December, 1559. His predecessor had rendered himself detestable to the Romans, who treated his memory with every mark of indignity, and Pius IV. commenced his pontificate by pardoning them. He did not, however extend the same clemency to the nephews of Pope Paul IV.; for he caused Cardinal Caraffe to be strangled in the castle of St Angelo, and his brother, the prince de Palliano, to be beheaded. His zeal was afterwards directed against the Turks and heretics. In order to stop, if possible, the progress of these last, he renewed the Council of Trent, which had been suspended. He knew well (says abbè de Choisy), that that council might make some regulations which would have the effect to lessen his authority; but, on the other hand, he perceived that great inconveniences might result from its not being assembled; and "*in the main* (said he to his confidants) *it is better to feel evil for once than to be always in dread of it.*" In 1561 he dispatched nuncios to all the Catholic and Protestant princes, to present them with the bull for calling that important assembly. An end was, however, put to it by the industry of his nephew, S. Charles Borromeus in 1563; and on the 26th of January the year following, he issued a bull for confirming its decrees. In 1565 a conspiracy was formed against his life by Benedict Acolti, and some other visionaries. Those madmen had taken it into their head that Pius IV. was not a lawful pope, and that after his death they would place another in St Peter's chair, with the title of *Pope Angelicus*, under whom errors might be reformed, and peace restored to the church. The conspiracy was discovered, and the fanatic Benedict put to death. This pontiff died a little time after, on the 9th of December 1565, aged 66 years, carrying to the grave with him the hatred of the Romans, whom his severities had exasperated. He was a man of great address, and very fruitful in his resources. He adorned Rome with several public edifices; but these ornaments tended greatly to impoverish it. If he was the instrument of raising his relations in the world, it must be allowed, at least, that the greater part of them did him honour.

Pius V. (*S. Michael Ghisleri*), born at Boschi or Bosco, in the diocese of Tortona, on the 17th of January 1504, was, according to Abbé de Choisy, son to a senator of Milan. He turned a Dominican friar. Paul IV. informed of his merit and virtue, gave him the bishopric of Sutri, created him cardinal in 1557, and made him inquisitor-general of the faith among the Milanese and in Lombardy; but the severity with which he exercised his office obliged him to quit that country. He was sent to Venice, where the ardour of his zeal met with still greater obstacles. Pius IV. added to the cardinal's hat the bishopric of Mondovi. After the death of that pontiff he was advanced to St Peter's chair in 1566. The Romans expressed but little joy at his coronation: he was very sensible of it, and said, "*I hope they will be as sorry at my death as they are at my election;*" but he was mistaken. Raised by his merit to the first ecclesiastical preferment in Christendom, he could not divest himself of the severity of his character; and the situation in which he found himself rendered, perhaps, that severity necessary. One of his first objects was to repress the luxury of the clergy, the pride of the cardinals, and the licentious manners of the Romans. He caused the decrees of reformation enacted by the Council of Trent to be put in execution; he prohibited bull-baiting in the Circus; he expelled from Rome the women of the town; and allowed the cardinals to be prosecuted for their debts. The errors which overflowed the Christian world gave him great uneasiness. After having employed gentle and lenient measures in the reclaiming of heretics, he had recourse to severity, and some of them ended their days in the flames of the inquisition. He particularly displayed his zeal for the grandeur of the holy see in 1568, by ordaining that the bull *In cœna domini*, which was published at Rome every year on *Maunday Thursday*, and which Clement XIV. suppressed, should be published likewise throughout the whole church. That bull, the work of several sovereign pontiffs, principally regards the jurisdiction of the ecclesiastical and civil power. It anathematizes those who appeal from the decrees of popes to a general council; those who favour the appellants; the universities which teach that the pope is subject to a general council; the princes who would restrain the ecclesiastical jurisdiction, or who exact contributions from the clergy. It was rejected by all the sovereign states, excepting a very few. In 1580, some bishops having endeavoured to introduce it into their dioceses, the parliament caused their temporalities to be seized upon, and declared those guilty of high treason who should imitate the fanaticism of those prelates. Pius V. for some time meditated an expedition against the Turks. He had the courage to make war on the Ottoman empire, by forming a league with the Venetians and Philip II. king of Spain. This was the first time that the standard of the two keys was seen displayed against the crescent. The naval armies came to an engagement, on the 7th of October 1571, in Lepanto bay, in which the confederate Christian princes obtained a signal victory over the Turks, who lost above 30,000 men, and near 200 galleys. This success was principally owing to the pope, who exhausted both his purse and person in fitting out that armament. He died of the gravel six months after, on the 30th of April 1572, aged 68. He repeated often, in the midst of his sufferings, "*O Lord! increase my pains and my patience.*" His name will for ever adorn the list of Roman pontiffs. It is true, that his bull against Queen Elizabeth, and his other bull in favour of the inquisition, with his rigorous prosecution of heretics both in France and Ireland, prove that he had more zeal than sweetness in his temper; but in other respects he possessed the virtues of a saint and the qualities of a king. He was the model of the famous Sixtus Quintus, to whom he gave an example of amassing in a few years such savings as were sufficient to make the holy see be regarded as a formidable power. Sultan Selim, who had no greater enemy than this pope, caused public rejoicings to be made at Constantinople for his death during the space of three days. The pontificate of Pius is also celebrated for the condemnation of Baius, the extinction of the order of Humilies, and the reformation of that of the Cistercians. He was canonized by Clement XI. in 1712. There are extant several of his letters, printed at Anvers in 1640, in 4to. Felibian, in 1672, published his *Life*, translated from the Italian of Agatio di Somma; but we cannot vouch for the fidelity of the translation.

PIX. See *Mint-Marks*.

PIZARRO, Francis, a celebrated Spanish general, the discoverer and conqueror of Peru, in conjunction with Diego Almagro, a Spanish navigator. They are both charged with horrid cruelties to the inhabitants; and they fell victims to their own ambition, jealousy, and avarice. Almagro revolting, was defeated and beheaded by Pizarro, who was assassinated by Almagro's friends in 1541. See Peru.

PLACE, Locus, in *Philosophy*, a mode of space, or that part of immoveable space which any body possesses. See Metaphysics, N° 185.

Place, in *Astronomy*. The place of the sun, a star, &c. denotes the sign and degree of the zodiac which the luminary is in; or the degree of the ecliptic, reckoning from the beginning of Aries, which the planet's or star's circle of longitude cuts: and therefore coincides with the longitude of the sun, planet, or star. As the sine of the sun's greatest declination 23° 30′: to the sine of any present declination given or observed, for instance, 23° 15′ : : so is the radius 10 : to the sine of its longitude 81° 52′; which, if the declination were north, would give 20° 52′ of Gemini; if south, 20° 52′ of Capricorn for the sun's place. See Declination, &c.

The place of the moon being that part of her orbit wherein she is found at any time, is of various kinds, by reason of the great inequalities of the lunar motions, which render a number of equations and reductions necessary before the just point be found. The moon's fictitious place is her place once equated; her place nearly true, is her place twice equated; and her true place thrice equated. See Astronomy, *passim*.

Place, in *War*, a general name for all kinds of fortresses where a party may defend themselves. Thus, 1. A strong or fortified place is one flanked, and covered with bastions. 2. A regular place, one whose angles, sides, bastions, and other parts, are equal; and this is usually denominated from the number of its angles, as a pentagon, hexagon, &c. 3. Irregular place is one whose sides and angles are unequal.—4. Place of arms is a strong city or town pitched upon for the chief magazine of an army; or, in a city or garrison, it is a large open spot of ground, usually near the centre of the place where the grand guard is commonly kept, and the garrison holds its rendezvous at reviews, and in cases of alarm to receive orders from the governor. 5. Places of arms of an attack, in a siege, is a spacious place covered from the enemy by a parapet or epaulement, where the soldiers are posted ready to sustain those at work in the trenches against the soldiers of the garrison. 6. Place of arms particular, in a garrison, a place near every bastion, where the soldiers sent from the grand place to the quarters assigned them relieve those that are either upon the guard or in sight. 7. Place of arms without, is a place allowed to the covert way for the planting of cannon, to oblige those who advance in their approaches to retire. 8. Place of arms in a camp, a large place at the head of the camp for the army to be ranged in and drawn up in battalia. There is also a place for each particular body, troop, or company, to assemble in.

Common-Place. See *Common-Place*.

PLACENTA, in *Anatomy* and *Midwifery*, a soft roundish mass, found in the womb of pregnant women; which, from its resemblance to the liver, was called by the ancients *hepar uterinum*, uterine liver.

PLACENTIA, called by the natives *Piacenza*, is a town of Italy, and capital of a duchy of the same name, with a bishop's see. It is seated about 100 paces from the river Po, in a very fertile pleasant plain watered by a great number of rivulets, and surrounded with hills, abounding in all sorts of fruits. In its territory there are salt-springs, from which they make a very white salt; and there are also mines of iron, woods, and warrens. It contains a great number of merchants, and is reckoned three miles in circumference. Its fortifications are inconsiderable, but the citadel is pretty strong. The streets are straight, and the principal street called *Stradone*, is 25 common paces broad, and 3000 feet long, in a direct line, with 600 stone posts for separating the foot from the carriage-way, and on both sides are 11 spacious convents. The other buildings of the city are not very remarkable, though it contains 45 churches, 28 convents, and two alms-houses. The cathedral is pretty much in the Gothic taste; but the church of the Augustines is reckoned the most beautiful, and esteemed worthy of its architect, the celebrataed Vignoli. The ducal palace, though large, makes no great appearance externally; but within there are some good apartments. In the area before the town-house stand two admirable brass statues of Alexander and Renatus IV. both of the house of Farnese, and dukes of Parma and Placentia. The bishop is suffragan to the archbishop of Milan. At this city begins the Via Æmilia, which extends as far as Rimini on the Adriatic. The number of the inhabitants is about 30,000, among whom there are 2000 ecclesiastics. This city has been taken several times in the wars of Italy. The king of Sardinia took possession of it in 1744, it being ceded to him by the queen of Hungary; but it was taken from him in 1746, after a bloody battle. The French got possession of it in 1796. It has a famous university, and the inhabitants are much esteemed for their politeness. The sovereignty of this duchy with that of Parma now belongs to Maria Louisa, late empress of France. Placentia is about 32 miles north-west of Parma and 83 east of Turin. E. Long. 10. 24. Lat. 45. 5.

PLAGIARY, in *Philology*, the purloining another man's works, and putting them off as our own. Among the Romans, *plagiarius* was properly a person who bought, sold, or retained a freeman for a slave; and was so called, because, by the Flavian law, such persons were condemned *ad plagas*, "to be whipped."

Thomasius has an express treatise *de plagio literario*; wherein he lays down the laws and measures of the right which authors have to one another's writings.—"Dictionary writers, at least such as middle with *arts and sciences* (as is pertinently observed by Mr Chalmers), seem exempted from the common laws of *meum* and *tuum*: they do not pretend to set up on their own bottom, nor to treat you at their own cost. Their works are supposed, in great measure, compositions of other peoples; and what they take from others, they do it avowedly, and in the open sun.—In effect, their quality gives them a title to every thing that may be for their purpose, wherever they find it; and if they rob, they do not do it any otherwise than as the bee does, for the public service. Their occupation is not pillaging, but collecting contributions; and, if you ask them their authority, they will produce you the practice of their predecessors of all ages and nations.

PLAGIUM, in *Law*. See KIDNAPPING.

PLAGUE, PESTILENCE, or *Pestilential Fever*, is a very acute, malignant, and contagious disease; being a putrid fever of the worst kind, and seldom failing to prove mortal. Though it is generally defined a malignant fever, Diemerbroock thinks they ought to be distinguished, since the fever is not the essence of the disease, but merely a symptom or effect of it. See MEDICINE, N° 221.

The plague, as is generally agreed, is never bred or propagated in Britain, but always imported from abroad, especially from the Levant, Lesser Asia, Egypt, &c. where it is very common. Sydenham has remarked that it rarely infests this country oftener than once in 40 years, and happily we have been free of it for a much longer period.

Authors are not as yet agreed concerning the nature of this dreadful distemper. Some think that insects are the cause of it, in the same way that they are the cause of blights, being brought in swarms from other climates by the wind, when they are taken into the lungs in respiration; the consequence of which is, that they mix with the blood and juices, and attack and corrode the viscera. Mr Boyle, on the other hand, thinks it originates from the effluvia or exhalations breathed into the atmosphere from noxious minerals, to which may be added stagnant waters and putrid bodies of every kind.

Mr Gibbon thinks that the plague is derived from damp, hot, and stagnating air, and the putrefaction of animal substances, especially locusts. See *Gibbon's Roman History*, 4to edit. vol. iv. p. 327—332, where there is also a very particular account of the plague which depopulated the earth in the time of the emperor Justinian.

The Mahometans believe that the plague proceeds from certain spirits, or goblins, armed with bows and arrows, sent by God to punish men for their sins; and that when the wounds are given by spectres of a black colour, they certainly prove fatal, but not so when the arrows are shot by those that appear white. They therefore take no precaution to guard themselves against it. The wiser professors of this religion, however, at present act otherwise; for we find a receipt recommended by Sidy Mohammed Zerroke, one of the most celebrated Marabouts, prefaced with these remarkable words: "The lives of us all are in the hands of God, when it is we must die. However, it hath pleased him to save many persons from the plague, by taking every morning while the infection rages, one pill or two of the following composition; viz. of myrrh two parts, saffron one part, of aloes two parts, of syrup of myrtle berries, *q. s.*" But this remedy is confined to the more enlightened; for the bigotry of the lower sort is so extreme as to make them despise all precautions which people of other nations use. Of this extreme and foolish prejudice Dr Chandler gives an interesting account when speaking of the plague at Smyrna. This learned author is of opinion that the disease arises from animalcules, which he supposes to be invisible. See *Chandler's Travels in Asia Minor*, p. 279, &c.

It is a remarkable fact, that *plagues* are sometimes partial, and that they only attack particular animals, or a particular description of persons, avoiding others altogether, or attacking them but slightly. Thus Fernelius informs us of a plague, or murrain, in 1514, which invaded only cats. Dionysius Halicarnasseus mentions a plague which attacked none but maids; and that which raged in the time of Gentilis, killed scarcely any women, and very few but lusty men. Boterus mentions another plague, which assaulted none but the younger sort; and we have instances of the same kind of a later standing (A). Cardan speaks of a plague at Basil, with which the Switzers were infected, and the Italians, Germans, or French, exempted: and John Utenhovius takes notice of a dreadful one at Copenhagen, which, though it raged among the Danes, spared the Germans, Dutch, and English, who went with all freedom, and without the least danger, to the houses of the infected. During the plague which ravaged Syria in 1760, it was observed that people of the soundest constitutions were the most liable to it, and that the weak and delicate were either spared or easily cured. It was most fatal to the Moors; and, when it attacked them, it was generally incurable.

When the plague raged in Holland in 1636, a young girl was seized with it, had three carbuncles, and was removed to a garden, where her lover, who was betrothed to her, attended her as a nurse, and slept with her as his wife. He remained uninfected, and she recovered, and was married to him. The story is related by Vinc. Fabricius in the *Misc. Cur. Ann. II. Obs.* 188.

Many methods have been adopted in different countries to prevent the importation of this dreadful scourge of the human race, and to stop the progress of infection after it has been imported. In England, mayors, bailiffs, head officers of corporations, and justices of peace, have power to tax inhabitants, houses, and lands, &c. within their precincts, for the relief of persons infected with the plague; and justices of the county may tax persons within five miles round, on a parish's inability; the tax to be levied by distress and sale of goods, or in default thereof by imprisonment. Infected persons going abroad, after being commanded to keep house for avoiding farther infections, may be resisted by watchmen, &c. and punished as vagrants, if they have no sores upon them; and if they have infectious sores on them it is felony. Justices of the peace, &c. are to appoint searchers, examiners, and buriers of the dead, in places infected, and administer oaths to them for the performance of their duties, &c. *stat.* 1 *Jac. I. cap.* 31. See QUARANTINE.

The commission at Moscow having, in the year 1770, invented a fumigation powder, which, from several lesser experiments, had proved efficacious in preventing the infection of the plague; in order more fully to ascertain its virtue in that respect, it was determined,

(A) See account of the *yellow fever* under the article PHILADELPHIA, where it appears that the disease was less fatal to some sorts of persons than to others.

termined, towards the end of the year, that ten male-factors under sentence of death should, without undergoing any other precautions than the fumigations, be confined three weeks in a lazaretto, be laid upon the beds, and dressed in the clothes, which had been used by persons sick, dying, and even dead, of the plague in the hospital. The experiment was accordingly tried, and none of the ten malefactors were then infected, or have been since ill. The fumigation powder is prepared as follows.

Powder of the first strength.] Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum wood pounded, of each six pounds; common saltpetre pounded, eight pounds; sulphur pounded, six pounds; Smyrna tar, or myrrh, two pounds: mix all the above ingredients together, which will produce a pood of the powder of fumigation of the first strength. [*N. B.* A pood is 40 pounds Russian, which are equal to 35 pounds and a half or 36 pounds English avoirdupoise.]

Powder of the second strength.] Take southernwood cut into small pieces, four pounds; juniper-berries pounded, three pounds; common saltpetre pounded, four pounds; sulphur pounded, two pounds and a half; Smyrna tar, or myrrh, one pound and a half: mix the above together which will produce half a pood of the powder of fumigation of the second strength.

Odoriferous powder.] Take the root called *kalmus* cut into small pieces, three pounds; leaves of juniper cut into small pieces, four pounds; frankincense pounded grossly, one pound; storax pounded, and rose flowers, half a pound; yellow amber pounded, one pound; common saltpetre pounded, one pound and a half; sulphur, a quarter of a pound: mix all the above together, which will produce nine pounds and three quarters of the odoriferous powder.

Remark on the powder of fumigation.] If guaiacum cannot be had, the cones of pines or firs may be used in its stead; likewise common tar of pines and firs may be used instead of the Smyrna tar, or myrrh, and mugwort may supply the place of southernwood.

Thucydides, who was himself infected, lib. ii. gives us an account of a dreadful plague which happened at Athens, about the year before Christ 430, while the Peleponnesians under the command of Archidamus wasted all their territory abroad; but of these two enemies the plague was by far the most dreadful and severe.

The most dreadful plague that ever raged at Rome was in the reign of Titus, A. D. 80. The emperor left no remedy unattempted to abate the malignity of the distemper, acting during its continuance like a father to his people. The same fatal disease raged in all the provinces of the Roman empire in the reign of M. Aurelius, A. D. 167, and was followed by a dreadful famine, by earthquakes, inundations, and other calamities. The Romans believed that Æsculapius sometimes entered into a serpent, and cured the plague.

About the year 430 the plague visited Britain, just after the Picts and Scots had made a formidable invasion of the southern part of the island. The plague raged with uncommon fury, and swept away most of those whom the sword and famine had spared, so that the living were scarcely sufficient to bury the dead.

About the year 1348 the plague became almost general over Europe. A great many authors give an account of this plague, which is said to have appeared first in the kingdom of Kathay in the year 1346, and to have proceeded gradually westward to Constantinople and Egypt. From Constantinople it passed into Greece, Italy, France, and Africa, and by degrees along the coasts of the ocean into Britain and Ireland, and afterwards into Germany, Hungary, Poland, Denmark and the other northern kingdoms. According to Antoninus archbishop of Florence the distemper carried off 60,000 people in that city, among whom was the historian John Villani.

In the year 1656 the plague was brought from Sardinia to Naples, being introduced into the city by a transport with soldiers on board. It raged with excessive violence, carrying off in less than six months 400,000 of the inhabitants. The distemper was at first called by the physicians a malignant fever; but one of them affirming it to be pestilential, the viceroy, who was apprehensive lest such a report would occasion all communication with Naples to be broke off, was offended with this declaration, and ordered him to be imprisoned. As a favour, however, he allowed him to return and die in his own house. By this proceeding of the viceroy, the distemper being neglected, made a most rapid and furious progress, and filled the whole city with consternation. The streets were crowded with confused processions, which served to spread the infection through all the quarters. The terror of the people increased their superstition; and it being reported that a certain nun had prophesied that the pestilence would cease upon building a hermitage for her sister nuns upon the hill of St Martin's, the edifice was immediately begun with the most ardent zeal. Persons of the highest quality strove who should perform the meanest offices; some loading themselves with beams, and others carrying baskets full of lime and nails, while persons of all ranks stripped themselves of their most valuable effects, which they threw into empty hogsheads placed in the streets to receive the charitable contributions. Their violent agitation, however, and the increasing heats, diffused the malady through the whole city, and the streets and the stairs of the churches were filled with the dead; the number of whom, for some time of the month of July, amounted daily to 15,000.

The viceroy now used all possible precautions to abate the fury of the distemper, and to prevent its spreading to the provinces. The infection, however, desolated the whole kingdom, excepting the provinces of Otranto and the Farther Calabria, and the cities of Gaeta, Sorrento, Paolo, and Belvidere. The general calamity was increased in Naples by malecontents, who insinuated that the distemper had been designedly introduced by the Spaniards, and that there were people in disguise who went through the city sowing poisoned dust. This idle rumour enraged the populace, who began to insult the Spanish soldiers, and threaten a sedition; so that the viceroy, to pacify the mob, caused a criminal to be broke upon the wheel, under pretence that he was a disperser of the dust. A violent and plentiful rain falling about the middle of August, the distemper began to abate; and on the eighth of December the physicians made a solemn declaration that the city was entirely free from infection.

Of the dreadful plague which raged at London in the

Plague.

the year 1665, the reader will find an account in the article LONDON, N° 21. In 1720 the city of Marseilles was visited with this destructive disease, brought in a ship from the Levant; and in seven months, during which time it continued, it carried off not less than 60,000 people. This desolation is not yet obliterated from the minds of the inhabitants; some survivors remained alive but a few years ago to transmit a traditional account of it to after ages. There are two fine pictures, painted by Puget, representing some of the horrid scenes of that time. "They are (says Lady Craven) only too well executed. I saw several dying figures taking leave of their friends, and looking their last anxious, kind, and wishful prayers on their sick infants, that made the tears flow down my cheeks. I was told the physicians and noblemen who were assisting the sick and dying, were all portraits: I can easily conceive it; for in some faces there is a look of reflection and concern which could only be drawn from the life." *Letters*, p. 34, 35. This fatal event has caused the laws of quarantine to be very strictly enforced in the lazaretto here, which is an extensive insulated building.

The ravages of this disease have been dreadful wherever it has made its appearance. On the first arrival of the Europeans at the island of Gran Canaria, it contained 14,000 fighting men, soon after which, two thirds of the whole inhabitants fell a sacrifice to the plague, which had doubtless been introduced by their new visitors. The destruction it has made in Turkey in Europe, and particularly in Constantinople, must be known to every reader; and its fatal effects have been particularly heightened there by that firm belief which prevails among the people of predestination, &c. as has been already mentioned. It is generally brought into European Turkey from Egypt; where it is very frequent, especially at *Grand CAIRO*. To give even a list of all the plagues which have desolated many flourishing countries, would extend this article beyond all bounds; and minutely to describe them all, would be impossible. For the plague at Smyrna, we refer to Chandler's Travels as above. Respecting that which raged in Syria in 1760, we refer to the Abbé Mariti's Travels through Cyprus, Syria, and Palestine, vol. i. p. 278—296. This plague was one of the most malignant and fatal that Syria ever experienced; for it scarcely made its appearance in any part of the body when it carried off the patient.

In addition to what the reader will find upon this subject in the article MEDICINE, and the observations which have now been offered, we beg leave to state the sentiments of Berthier on this subject, in his account of Bonaparte's expedition into Syria.

"At the time of our entry into Syria (says he), all the towns were infected by the plague; a malady which ignorance and barbarity render so fatal in the east. Those who are affected by it give themselves up for dead; they are immediately abandoned by every body, and are left to die, when they might have been saved by medicine and attention.

"Citizen Degenettes, principal physician to the army, displayed a courage and character which entitle him to the national gratitude. When our soldiers were attacked by the least fever, it was supposed that they had caught the plague, and these maladies were confounded. The fever hospitals were abandoned by the officers of health and their attendants. Citizen Degenettes repaired in person to the hospitals, visited all the patients, felt the glandular swellings, dressed them, declared and maintained that the distemper was not the plague, but a malignant fever with glandular swellings, which might easily be cured by attention, and keeping the patient's mind easy."

The views of Degenettes in making this distinction were worthy of the highest commendation; but Dr Moseley maintains that this fever was actually the plague. The physician, however, carried his courage so far, as to make two incisions, and to inoculate the suppurated matter from one of these buboes above his breast, and under his armpits, but was not affected with the malady. He thus eased the minds of the soldiers, the first step to a cure; and, by his assiduity and constant attendance in the hospitals, a number of men attacked with the plague were cured. His example was followed by other officers of health. "There are, says Dr Moseley, annual or seasonal disorders, more or less severe, in all countries; but the plague, and other great depopulating epidemics, do not always obey the seasons of the year. Like comets, their course is eccentric. They have their revolutions; but from whence they come, or whither they go after they have made their revolution, no mortal can tell.

"Diseases originating in the atmosphere seize some, and pass by others; and act exclusively on bodies graduated to received their impressions; otherwise whole nations would be destroyed. In some constitutions of the body the access is easy, in some difficult, and in others impossible.

"The air of confined places may be so vitiated as to be unfit for the purposes of the healthy existence of any person. Hence gaol, hospital, and ship fevers. But, as these distempers are the offspring of a local cause, that local cause, and not the distempered people, communicate the disease.

"The infection, were it not in the atmosphere, would be confined within very narrow limits; have a determinate sphere of action; and none but physicians and attendants on the sick would suffer; and these must suffer; and the cause and the effects would be palpable to our senses. Upon this ground, the precaution of quarantine would be rational. But who then would visit and attend the sick, or could live in hospitals, prisons, and lazarettoes?"

The author is convinced from these reasonings, that the bubo and carbuncle, of which we hear so much in Turkey, and read so much in our own history of plagues, arise from heating food and improper treatment; that they contain no infection; and consequently that they are not the natural deposit of the morbific virus separated from the contagion.

Speaking of the plague, Mr Brown says, "the first symptoms are said to be thirst; 2. Cephalagia; 3. A stiff and uneasy sensation, with redness and tumour about the eyes; 4. Watering of the eyes; 5. White pustules on the tongue. Not uncommonly, all these have successively shown themselves, yet the patient has recovered; in which case, where suppuration has had place, the skin always remains discoloured, commonly of a purple hue. Many who have been bled in an early stage of the disorder, have recovered without any fatal symptoms;

symptoms; but whether from that or any other cause, does not appear certain."

Oil rubbed into the skin acts as a preventive, as well as a cure of the plague. When the operation is performed to prevent infection, it is successfully performed with that view at Smyrna, as often as the plague make its appearance in the city. As it is not done for the purpose of promoting perspiration, it is not requisite that it should be performed with the same speed as when for curing the disorder; nor is it necessary to abstain from flesh, and to use soups; but it will be proper to use only fowls or veal for some days, without any seasoning. It will in fine be necessary to guard against indigestible food, and such liquors as might put in motion or inflame the mass of the blood.

This interesting discovery merits the attention of all medical men; for if olive oil has been found efficacious in curing or preserving against one species of infection, it is not absurd to suppose that the same or other kinds of oil might be productive of much benefit in other malignant infectious diseases. We hope soon to hear of some trial being made with it in this country. Would it be of any service in the yellow fever, so prevalent in the western world?

PLAIN, or PLANE, in general, an appellation given to whatever is smooth and even, or simple, obvious, and easy to be understood; and, consequently, stands opposed to rough, enriched, or laboured.

A plain figure, in geometry, is an uniform surface; from every point of whose perimeter right lines may be drawn to every other point in the same.

A plain angle is one contained under two lines, or surfaces, in contradistinction to a solid angle. See ANGLE under GEOMETRY.

The doctrine of plain triangles, as those included under three right lines, is termed *plain trigonometry*. See the article TRIGONOMETRY.

PLAIN-Chart. See the article CHART.

PLAIN-Sailing. See NAVIGATION.

PLAISE, the English name of a species of pleuronectes. See PLEURONECTES, ICHTHYOLOGY *Index*.

PLAN, in general, denotes the representation of something drawn on a plane; such are maps, charts, ichnographies, &c. See MAP, CHART, &c.

The term *plan*, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground, showing the extent, division, and distribution of its area or ground-plot into apartments, rooms, passages, &c.

A geometrical plan is that wherein the solid and vacant parts are represented in their natural proportions.

The raised plan of a building is the same with what is otherwise called an *elevation* or *orthography*. See ORTHOGRAPHY.

A perspective plan is that exhibited by degradations or diminutions, according to the rules of perspective. See PERSPECTIVE.

To render plans intelligible, it is usual to distinguish the massives with a black wash; the projectures of the ground are drawn in full lines, and those supposed over them in dotted lines. The augmentations or alterations to be made are distinguished by a colour different from what is already built; and the tints of each plan made lighter as the stories are raised.

In large buildings it is usual to have three several plans for the three first stories.

PLANCUS, FRANCIS, doctor of physic, was born at Amiens in 1696, and died on the 19th of September 1765, aged 69 years. He is the author of some works which have had considerable reputation. 1. A complete System of Surgery, in 2 vols in 12mo; a treatise much recommended by surgeons to their pupils. 2. A choice Library of Medicine, taken from periodical publications, both French and others: this curious collection, continued and completed by M. Goulin, makes 9 vols in 4to, or 18 vols in 12mo. 3. A Translation of Vander Wiel's Observations on Medicine and Surgery, 1758, 2 vols in 12mo. Plancus was also the editor of various editions of works on medicine and surgery, which he enriched with notes.

PLANE, in *Geometry*, denotes a plain surface, or one that lies evenly between its bounding lines: and as a right line is the shortest extension from one point to another, so a plane surface is the shortest extension from one line to another.

In astronomy, conics, &c. the term *plane* is frequently used for an imaginary surface, supposed to cut and pass through solid bodies; and on this foundation is the whole doctrine of conic sections built. See ASTRONOMY, CONIC *Sections*, &c.

In mechanics, planes are either horizontal, that is, parallel to the horizon, or inclined thereto. See MECHANICS.

The determining how far any given plane deviates from an horizontal line, makes the whole business of levelling. See the article LEVELLING.

In optics, the planes of reflection and refraction are those drawn through the incident and reflected or refracted rays. See OPTICS.

In perspective we meet with the perspective plane, which is supposed to be pellucid, and perpendicular to the horizon; the horizontal plane, supposed to pass through the spectator's eye, parallel to the horizon; the geometrical plane, likewise parallel to the horizon, wherein the object to be represented is supposed to be placed, &c. See PERSPECTIVE.

The plane of projection in the stereographic projection of the sphere, is that on which the projection is made, corresponding to the perspective plane. See PROJECTION.

PLANE, in joinery, an edged tool or instrument for paring and shaving of wood smooth. It consists of a piece of wood very smooth at bottom, as a stock or shaft; in the midst of which is an aperture, through which a steel edge, or chissel, placed obliquely, passes; which, being very sharp, takes off the inequalities of the wood along which it slides.

PLANE-Tree, in *Botany*. See PLATANUS.

PLANET, a celestial body, revolving round the sun as a centre, and continually changing its position with respect to the fixed stars; whence the name *planet*, which is a Greek word, signifying "wanderer."

The planets are usually distinguished into primary and secondary. The primary ones, called by way of eminence *planets*, are those which revolve round the sun as a centre; and the secondary planets, more usually called *satellites* or *moons*, are those which revolve round a primary planet as a centre, and constantly attend it in its revolution round the sun.

The

The primary planets are again distinguished into superior and inferior. The superior planets are those farther from the sun than our earth; as Mars, Jupiter, Saturn, and the Georgium Sidus; and the inferior planets are those nearer the sun than our earth, as Venus and Mercury. For an account of the planets lately discovered, see VESTA.

That the planets are opaque bodies, like our earth, is thought probable for the following reasons. 1. Since in Venus, Mercury, and Mars, only that part of the disk illuminated by the sun is found to shine; and again, Venus and Mercury, when between the earth and the sun, appear like dark spots or maculæ on the sun's disk; it is evident, that Mars, Venus, and Mercury, are opaque bodies, illuminated with the borrowed light of the sun. And the same appears of Jupiter, from its being void of light in that part to which the shadow of the satellites reaches, as well as in that part turned from the sun; and that his satellites are opaque, and reflect the sun's light, is abundantly shown. Again, since Saturn, with his ring and satellites, only yield a faint light, fainter considerably than that of the fixed stars, though these be vastly more remote, and than that of the rest of the planets; it is past doubt that he too with his attendants are opaque bodies. 2. Since the sun's light is not transmitted through Mercury and Venus, when placed against him, it is plain they are dense opaque bodies; which is likewise evident of Jupiter, from his hiding the satellites in his shadow; and therefore, by analogy, the same may be concluded of Saturn. 3. From the variable spots of Venus, Mars, and Jupiter, it is evident these planets have a changeable atmosphere; which changeable atmosphere may, by a like argument, be inferred of the satellites of Jupiter; and therefore, by similitude, the same may be concluded of the other planets. 4. In like manner, from the mountains observed in Venus, the same may be supposed in the other planets. 5. Since, then, Saturn, Jupiter, and the satellites of both, Mars, Venus, and Mercury, are opaque bodies shining with the sun's borrowed light, are furnished with mountains, and encompassed with a changeable atmosphere; they have, it is concluded, waters, seas, &c. as well as dry land, and are bodies like the moon, and therefore like the earth. And hence it seems also highly probable, that the other planets have their animal inhabitants as well as our earth.

PLANETARIUM, an astronomical machine, so called from its representing the motions, orbits, &c. of the planets, agreeable to the Copernican system. See ASTRONOMY.

PLANETARY, something that relates to the planets. Hence we say, planetary worlds, planetary inhabitants, &c. See PLANET.

PLANETARY System, is the system or assemblage of the planets, primary and secondary, moving in their respective orbits, round their common centre the sun. See ASTRONOMY.

PLANETARY Days.—Among the ancients, the week was shared among the seven planets, each planet having its day. This we learn from Dion Cassius and Plutarch, *Sympos.* l. 4. q. 7. Herodotus adds, that it was the Egyptians who first discovered what god, that is, what planet, presides over each day; for that among this people the planets were directors. And hence it is, that in most European languages the days of the week are still denominated from the planets; Sunday, Monday, &c. See WEEK.

PLANETARY Years, the periods of time in which the several planets make their revolutions round the sun or earth.—As from the proper revolution of the sun, the solar year takes its original; so from the proper revolutions of the rest of the planets about the earth, so many sorts of years do arise, viz. the Saturnian year, which is defined by 29 Egyptian years, 174 hours, 58 minutes, equivalent in a round number to 30 solar years. The Jovial year, containing 317 days, 14 hours, 59 minutes. —The Martial year, containing 321 days, 23 hours, 31 minutes. For Venus and Mercury, as their years, when judged of with regard to the earth, are almost equal to the solar year; they are more usually estimated from the sun, the true centre of their motions: in which case, the former is equal to 224 days, 16 hours, 40 minutes; the latter to 87 days, 23 hours, 14 minutes.

PLANIMETRY, that part of geometry which considers lines and plain figures, without considering their height or depth. See GEOMETRY.

PLANISPHERE, signifies a projection of the sphere, and its various circles, on a plane; in which sense, maps, whereon are exhibited the meridians and other circles of the sphere, are planispheres. See MAP.

PLANT is defined to be an organical body, destitute of sense and spontaneous motion, adhering to another body in such a manner as to draw from it its nourishment, and having a power of propagating itself by seeds.

The vegetation and economy of plants is one of those subjects in which our knowledge is extremely circumscribed. A total inattention to the structure and economy of plants is the chief reason of the small progress that has been made in the principles of vegetation, and of the instability and fluctuation of our theories concerning it; for which reason we shall give a short description of the structure of plants, beginning with the seed, and tracing its progress and evolution to a state of maturity.

1. *Of Seeds.*] The seeds of plants are of various figures and sizes. Most of them are divided into two lobes; though some, as those of the cress-kind, have six; and others, as the grains of corn, are not divided, but entire.

But as the essential properties of all seeds are the same, when considered with regard to the principles of vegetation, our particular descriptions shall be limited to one seed, viz. the great garden-bean. Neither is the choice of this seed altogether arbitrary; for, after it begins to vegetate, its parts are more conspicuous than many others, and consequently better calculated for investigation.

This seed is covered with two coats or membranes. The outer coat is extremely thin, and full of pores; but may be easily separated from the inner one (which is much thicker), after the bean has been boiled, or lain a few days in the soil. At the thick end of the bean there is a small hole visible to the naked eye, immediately over the radicle or future root, that it may have a free passage into the soil (fig. 1. A). When these coats are taken off, the body of the seed appears, which is divided Plate CCCCII.

Plant. ed into two smooth portions or lobes. The smoothness of the lobes is owing to a thin film or cuticle with which they are covered.

At the basis of the bean is placed the radicle or future root (fig. 3. A). The trunk of the radicle, just as it enters into the body of the seed, divides into two capital branches, one of which is inserted into each lobe, and sends off smaller ones in all directions through the whole substance of the lobes (fig. 4. AA). These ramifications become so extremely minute towards the edges of the lobes, that they require the finest glasses to render them visible. To these ramifications Grew and Malpighi have given the name of *seminal root;* because, by means of it, the radicle and plume, before they are expanded, derive their principal nourishment.

The plume, bud, or germ (fig. 3.), is inclosed in two small corresponding cavities in each lobe. Its colour and consistence is much the same with those of the radicle, of which it is only a continuation, but having a quite contrary direction; for the radicle descends into the earth, and divides into a great number of smaller branches or filaments; but the plume ascends into the open air, and unfolds itself into all the beautiful variety of stem, branches, leaves, flower, fruit, &c. The plume in corn shoots from the smaller end of the grain, and amongst maltsters goes by the name of *acrospire*.

The next thing to be taken notice of is the substance or parenchymatous part of the lobes. This is not a mere concreted juice, but is curiously organized, and consists of a vast number of small bladders resembling those in the pith of trees (fig. 5.)

Besides the coats, cuticle, and parenchymatous parts, there is a substance perfectly distinct from these, distributed in different proportions through the radicle, plume, and lobes. This inner substance appears very plainly in a transverse section of the radicle or plume. Towards the extremity of the radicle it is one entire trunk; but higher up it divides into three branches; the middle one runs directly up to the plume, and the other two pass into the lobes on each side, and spread out into a great variety of small branches through the whole body of the lobes (fig. 4.). This substance is very properly termed the *seminal root:* for when the seed is sown, the moisture is first absorbed by the outer coats, which are everywhere furnished with sap and air-vessels; from these it is conveyed to the cuticle; from the cuticle it proceeds to the pulpy part of the lobes; when it has got thus far, it is taken up by the mouths of the small branches of the seminal root, and passes from one branch into another, till it is all collected into the main trunk, which communicates both with the plume and radicle, the two principal involved organs of the future plant. After this the sap or vegetable food runs in two opposite directions: part of it ascends into the plume, and promotes the growth and expansion of that organ; and part of it descends into the radicle, for nourishing and evolving the root and its various filaments. Thus the plume and radicle continue their progress in opposite directions till the plant arrives at maturity.

It is here worth remarking, that every plant is really possessed of two roots, both of which are contained in the seed. The plume and radicle, when the seed is first deposited in the earth, derive their nourishment from the seminal root; but afterwards, when the radicle begins to shoot out its filaments, and to absorb some moisture, not, however, in a sufficient quantity to supply the exigencies of the plume, the two lobes, or main body of the seed, rise along with the plume, assume the appearance of two leaves, resembling the lobes of the seed in size and shape, but having no resemblance to those of the plume, for which reason they have got the name of *dissimilar leaves*. Plant.

These dissimilar leaves defend the young plume from the injuries of the weather, and at the same time, by absorbing dew, air, &c. assist the tender radicle in nourishing the plume, with which they have still a connection by means of the seminal root above described. But when the radicle or second root has descended deep enough into the earth, and has acquired a sufficient number of filaments or branches for absorbing as much aliment as is proper for the growth of the plume; then the semiual or dissimilar leaves, their utility being entirely superseded, begin to decay and fall off.

Plate CCCCXX. fig. 1. Fig. 1. A, the foramen or hole in the bean through which the radicle shoots into the soil.

Fig. 2. Fig. 2. A transverse section of the bean; the dots being the branches of the seminal root.

Fig. 3. Fig. 3. A, the radicle. B, the plume or bud.

Fig. 4. Fig. 4. A view of the seminal root branched out upon the lobes.
