fancy of printing (as nothing is complete at its first invention) the back sides of the pages were pasted together, that they might not by their nakedness betray their deformity. These beechen letters he afterwards charged for leaden ones, and those again for a mixture of tin and lead (stannum) as a less flexible and more solid and durable substance. Of the remains of which types, when they were turned to waste metal, those old wine-pots were cast, that are still preserved in the family-house, which looks into the market-place, inhabited afterwards by his great-grandson Gerard Thomas, a gentleman of reputation; whom I mention for the honour of the family, and who died old a few years since. A new invention never fails to engage curiosity. And when a commodity never before seen excited purchasers, to the advantage of the inventor, the admiration of the art increased, dependents were enlarged, and workmen multiplied; the first calamitous incident! Among these was one John, whether, as we suspect, he had ominously the name of Faustus (b), unfaithful and unlucky to his master, or whether it was really a part of that name, I shall not much inquire; being unwilling to molest the silent shades, who suffer from a consciousness of their past actions in this life. This man, bound by oath to keep the secret of printing, when he thought he had learned the art of joining the letters, the method of casting the types, and other things of that nature, taking the most convenient time that was possible, on Christmas eve, when every one was customarily employed in lustral sacrifices, seiz'd the collection of types, and all the implements his master had got together, and, with one accomplice, marches off to Amsterdam, thence to Cologne, and at last settled at Menzis, as at an asylum of security, where he might go to work with the tools he had stolen. It is certain, that in a year's time, viz. in 1443, the Doctrinale of Alexander Galus, which was a grammar much used at that time, together with the Tracts of Peter of Spain, came forth there, from the same types as Laurentius had made use of at Haerlem.

Thus far the narrative of Junius, which he had frequently heard from Nicolaus Galus; to whom it was related by Cornelius himself, who lived to a great age, and used to burst into tears upon reflecting on the loss his master had sustained, not only in his substance, but in his honour, by the roguery of his servant, his former associate and bed fellow. Cornelius, as appears by the registers of Haerlem cathedral, died either in 1515, or the beginning of the following year; so that he might very well give this information to Nicolaus Galus, who was schoolmaster to Hadrian Junius.

Though this circumstance is probable as to the main fact, yet we must set aside the evidence of it in some particulars. 1. The first obvious difficulty is noticed by Scriverius; “that the types are said to be made of the rind of beach, which could not be strong enough to bear the impress of the press;” though this is removed, for instead of the bark, we substitute a bough of the beech. The idea of the bark, when Junius wrote this, was perhaps strong in his mind, from what Virgil tells us (Ecl. v. 13.) of its being usual to cut words on the bark of a beech; and thence he was easily led to make a wrong application of it here.

2. The letters were at first wooden, and are said to be afterwards exchanged for metal types; from which the wine-pots were formed, remaining in the time of Junius. According to tradition, printing was carried on in the same place long after the time of Laurentius: these pots might therefore be formed from the waste metal of the printing-house, after the use of fustel types became universal. But Laurentius seems to have carried the art no farther than separate wooden types. What is a remarkable confirmation of this, Henry Spiechel, who wrote, in the 16th century, a Dutch poem entitled Hertspiegel, expresses himself thus: “Thou first, Laurentius, to supply the defect of wooden tablets, adapted wooden types, and afterwards didst connect them with a thread, to imitate writing. A treacherous servant surreptitiously obtained the honour of the discovery. But truth itself, though destitute of common and wide-spread fame; truth, I say, still remains.” No mention in the poem of metal types; a circumstance which, had he been robbed of such, as well as of wooden ones, would scarcely have been passed over in silence.

When Laurentius first devised his rough specimen of the art, can only be guessed at. He died in 1440, after having published the Speculum Belicum, and two editions of Donatus, all with different wooden types; which is probable (considering the difficulties he had to encounter, and the many artists whom he must necessarily have had occasion to consult) cost him some years to execute; so that the first essay might be about 1430, which nearly agrees with Petrus Scriverius, who says, the invention was about 10 or 12 years before 1440. See Laurentius.

3. What was the specimen he first diverted himself with in cutting, at the distance of three centuries, one would think impossible to be discovered. And yet Joh. Emschedius, a printer, thinks he was so happy as to find it, being an old parchment Horarium, printed on both sides, in eight pages, containing the Letters of the Alphabet, the Lord's Prayer, the Apostles Creed and three short prayers. And Mr Meerman having shewn this to proper artists who were judges of these matters, they gave it as their opinion that it agreed exactly with the description of Junius. It is conformable to the first editions of the Dutch Speculum Salvationis, and the fragments of both Donatus's of Holland, both which are the works of the same Laurentius, and were preceded by this. In these types, which are certainly moveable, cut, and uneven, there is a rudeness which Mr Meerman has not observed in any other instances. There are no numbers to the pages, no signatures, no direction-words, no divisions at the end of the lines; on the contrary, a syllable divided in the middle is seen, thus, Spis rutis, in p. 8. l. 2, 3. There are neither distinctions nor points, which are seen in the other works of Laurentius; and the letter i is not marked with an accent, but with a dot at the top. The lines through-

(b) John Faust, or Fust, is by many supposed to have derived his name from faustus, "happy;" and Dr Faustus seems to carry an air of grandeur in the appellation: but very erroneously. John Faust, or Fust, is no more than John Hand, whence our name Fist.
II. Some of Laurentius’s types were stolen from him by one of his servants (c) John Geinslech senior; who fled thither to Mentz. Having introduced the art from Haerlem into this his native city, he set with all diligence to carry it on; and published, in 1442, _Alexandrni Galli Dottrinae_, and _Petri Hispani Tractatus_; two works, which, being small, best suited his circumstances; and for which, being much used in the schools, he might reasonably expect a profitable sale. They were executed with wooden types, cut after the model of those he had stolen.

In 1443 he hired the house Zum Jungern; and was assisted

(c) Authors differ as to the person who committed this robbery. It is clear from all accounts that his name was John; but what his surname was is the disputed point. Junius, after some hesitation, ascribes it to John Fust; but with justice: for he was a wealthy man, who assisted the first printers at Mentz with money; and though he afterwards was proprietor of a printing-office, yet he never, as far as appears, performed any part of the business with his own hands, and consequently he could never have been a servant to Laurentius. Nor is the conjecture of Sèrverierus better founded, which fixes it upon John Gutenberg, who (as appears by authentic testimonies) resided at Strasburg from 1436 to 1444, and during all that period employed much fruitless labour and expense in endeavouring to attain this art. Mr Meerman once thought, "it might be either John Meidenbachius, (who, we are told by Seb. Munster and the author of _Chronographia Magnae_.) was an assistant to the first Mentz printers; or John Petersheimus (who was sometime a servant to Fust and Schoeffer, and set up a printing-house at Frankfort in 1459): or, lastly, some other person, who, being unable through poverty to carry on the business, discovered it to Geinslech at Mentz." But more authentic intelligence afterwards convinced him there were two persons of this name; and that John Geinslech was the dishonest servant, who was born at Mentz, and who in the papers published by Kohlerus, we find there in the year 1441, and not before: for though he was of a good family, yet he was poor, and seems to have been oblige[d], as well as his brother, to seek his livelihood in a foreign country; and perhaps was content to be under Laurentius, that when he had learned the art, he might follow it in his own. But, to leave conjecture, we may produce some certain testimonies.

7. It is what Junius himself says, that the person who stole the types did it with a view to set up elsewhere; nor is it likely that he would either make no use of an art he had seen so profitable to Laurentius, or that he would teach it to another and submit to be again a servant.

The Lambeth Record (which is printed below, from Mr. Atkyns) tells us, that "Mentz gained the art by the brother of one of the workmen of Haerlem, who learned it at home of his brother, who after set up for himself at Mentz."—By the strictest examination of the best authorities, it is plain, that by these two brothers the two Geinslechs must be meant. But as the younger (Gutenberg) was never a servant to Laurentius, it must be the senior who carried off the types, and instructed his brother in the art; who first applied himself to the business at Strasburg, and afterwards joined his elder brother, who had in the mean time settled at Mentz.

What is still stronger, two chronologers of Strasburg, the one named _Dan Speklius_, the other anonymous (in Meerman’s _Documenta_, No. LXXXV. LXXXVI.), tell us expressly, that John Geinslech (viz. the senior, whom they distinguished from Gutenberg), having learned the art by being servant to its _first inventer_, carried it by theft into Mentz his native country. They are right in the fact, though mistaken in the application of it; for they make Strasburg the place of the invention, and Mentelius the inventor, from whom the types were stolen. But this is plainly an error: for Geinslech lived at Mentz in 1441, as appears from undoubted testimonies; and could not be a servant to Mentelius, to whom the before-mentioned writers ascribe the invention in 1440, though more ancient ones do not attempt to prove that he began to print before 1444 or 1448. Nor will the narrative agree better with Gutenberg, who was an earlier printer than Mentelius; since, among the evidences produced by him in his law-suit, 1439, no Geinslech senior appears, nor any other servant but Laurentius Beiliker. The narration therefore of the theft of Geinslech, being spread by various reports through the world, and subsisting in the time of these chronologers, was applied by them (to serve the cause they wrote for) to Strasburg; but serves to confirm the truth, since no writer derives the printing spoils from any other country than Holland or Alsacia. The chronologers have likewise, instead of Fust, called Gutenberg the wealthy man; who, from all circumstances, appears to have been poor. They also call Schoeffer the son-in-law of Mentelius; when it is clear that he married the daughter of Fust.

* He was called Geinslech & _schr;_ the other was distinguished by the name of Gutenberg. They were both poor; though of a family distinguished by kindred. They were both married men; and were probably brothers, as it was not uncommon in that age for two brothers to have the same Christian name. These both appear in a disputable light. The eldest robbed his master, with many aggravating circumstances. The youngest was remarkably contentious; and after entering into a contract of marriage with Anna, a noble girl of _The Iron Gate_, refused to marry her till compelled by a judicial decree; and afterwards cared not what became of the lady, but left her behind at Strasburg when he removed to Mentz. He had not only frequent quarrels with his wife; but with Andrea Drischken, Andrea Helmman, and John Pals, all of whom were associated with him at Strasburg in his different employments of making of looking glasses, polishing of precious stones, and endeavouring to obtain the art of printing; and, with these he involved himself in three law-suits. See Meerman, vol. i. p. 163, &c. N.
Printing assisted with money by Fust, a wealthy person, who in return had a share of the business: and about the same time John Meidlenbachius was admitted a partner, as were some others whose names are not transmitted to our times; and in 1444 they were joined by Gutenberg, who for that purpose quitted Strasbourg. Wooden types being found not sufficiently durable, and not answering expectation in other respects, the two brothers first invented cut metal types. But while these were preparing, which must have been a work of time, several works were printed, both on wooden separate types and on wooden blocks; which were well adapted to small books of frequent use, such as the Tabula Alphabeticus, the Catholicon, Donatus Grammaticus, and the Confessionals.

From the above-mentioned printers in conjunction, after many smaller essays, the Bible was published in 1450, with large cut metal types (d). And it is no wonder, considering the immense labour this work cost, that it should be seven or eight years in completing. In this same year the partnership was dissolved, and a new one entered into, in August, between Fust and Gutenberg; the former supplying the money, the latter skill, for their common benefit. Various difficulties arising, occasioned a law-suit for the money which Fust had advanced; which was determined against Gutenberg. A dissolution of this partnership ensued in 1455; and in 1457 a magnificent edition of the Psalter was published by Fust and Schoeffer, with a remarkable commendation, in which they assumed to themselves the merit of a new invention (viz. of metal type), ad inventionem artificiosam imprimitu ac characterisandi. This book was uncommonly elegant, and in some measure the work of Gutenberg; as it was four years in the press, and came out but 18 months after the partnership was dissolved between him and Fust.

The latter continued in possession of the printing-office and Gutenberg, by the pecuniary assistance of Conrad Humery syndic of Mentz (e), and others, opened another office in the same city; whence appeared, in 1460, without the printer’s name, the Catholicon Jo. de Janua, with a pompous colophon in praise of its beauty, and ascribing the honour of the invention to the city of Mentz. It was a very handsome book, though inferior to the Psalter which had been published in 1457 by Fust and Schoeffer. Both the Psalter and Catholicon were printed on cut metal types (g). It may not be improper to observe here, that as the Psalter is the earliest book which is known to have a genuine date, it became a common practice, after that publication, for printers to claim their own performances, by adding their names to them.

III. The progress of the art has been thus traced through its second period, the invention of cut metal types. But the honour of completing the discovery is due to Peter Schoeffer (c) of Germersheim.

A very clear account of this final completion of the types is preserved by Triheinis (h). Post hanc invenit inventionem successerunt subtiliora, inveniuntur modum fundendi; est eas formas omnium Latinorum alphabetorum literarum, quas ipse matricis nominabant: ex quibus rursum ansecie sine stannos caracteres fundebant, ad omnem pressuram sufficiens, quos prius manus libri sculpsent. Et reversa sicut ante xxx terma annos ex ore Petri Opitii de Germersheim, civis Moguntini, qui gener erat primi artis inventoris, audivi, magnam praemium sese hanc impressionem habuit difficiiltatem.—Petrus autem memoratus Opilio, tum fumus postea gener, sicut diximus, inventor primi Johannes Fust, homo ingeniosus et prudent, fideliter modum fundendi charactares exiguitavit, et artei ut nunc est, complexit.

Another ample testimony in favour of Schoeffer is given by Jo. Fric. Faustus of Aschaffenburg, from papers preserved in his family: "Peter Schoeffer of Germersheim, perceiving his master Fust’s design, and being himself ardently desirous to improve the art, found out (by the good providence of God) the method of cutting (incendit) the characters in a matrix, that the letters might easily be singly cast instead of being cut. He privately cut matrices for the whole alphabet; and when he showed his master the letters cast from these matrices, Fust was so pleased with the contrivance, that he promised Peter to give him his only daughter, Christina, in marriage;"

(d) Many writers have supposed that this was the edition of which some copies were sold in France, by Fust, as manuscripts, for the great price of 500 or 600 crowns, which he afterwards lowered to 60, and at last to less than 40. But it was the second and more expensive edition of 1462, that was thus disposed of, when Fust went to Paris in 1466, and which had cost 4000 florins before the third quaternion (or quire of four sheets) was printed. MEERMAN, vol. i. p. 6. 151, 152.

(e) At the death of Gutenberg, Conrad Humery took possession of all his printing materials; and engaged to the archbishop Adolphus, that he never sell them to any one but a citizen of Mentz. They were, however, soon disposed of to Nicholas Rechermontz of Altavilla, who, in 1469, published Vocabularium Latino-Teutonicum, which was printed with the same types which had been used in the Catholicon. This very curious and scarce Vocabulary was shown to Mr Meerman, by Mr Bryant, in the duke of Marlborough’s valuable library at Blenheim. It is in quarto, 35 lines long, contains many extracts from the Catholicon, and is called Ex quo, from the preface beginning with those words. MEERMAN, vol. ii. p. 96.

(f) Gutenberg never used any other than either wooden or cut metal types till the year 1462. In 1465 he was admitted inter Articulam by the elector Adolphus, with an annual pension; and died in February 1488. His elder brother Gnesheim died in 1462. Their epitaphs are printed by Mr Meerman, vol. ii. p. 154, 295.

(g) In German, Schofer; in Latin, Opitio; in English, Shepherd. He is supposed by Mr Meerman to have been the first engraver on copperplates.

(h) Annales Hirsauenses, tom. ii. ad ann. 1450.—As this book was finished in 1514, and Triheinis tells us he had the narrative from Schoeffer himself about 50 years before; this will bring us back to 1484, when Schoeffer must have been advanced in years, and Triheinis about 22 years old, who died in 1516. See Voss. Hist. Lat. I. c. 10. Fabr. Med. & Infin. Et. 1. 9.
Printing; a promise which he soon after performed. But there were as many difficulties at first with these letters, as there had been before with wooden ones; the metal being too soft to support the force of the impression: but this defect was soon remedied, by mixing the metal with a substance which sufficiently hardened it (1).

Fust and Schoeffer concealed this new improvement, by administering an oath of secrecy to all whom they intrusted, till the year 1462; when, by the dispersion of their servants into different countries, at the soliciting of Mentz by the archbishop Adolphius, the invention was publicly divulged.

The first book printed with these improved types was Durandi Rationale, in 1453; at which time, however, they seem to have had only one size of cast letters, all the larger characters which occur being cut types, as appears plainly by an inspection of the book. From this time to 1466, Fust and Schoeffer continued to print a considerable number of books; particularly two famous editions of Tully's Office. In their earliest books, they printed more copies on vellum than on paper, which was the case both of their Bibles and Tully's Office. This, however, was soon inverted; and paper introduced for the greatest part of their impressions; a few only being printed on vellum for curiosities, and for the purpose of being illuminated.

How long Fust lived, is uncertain; but in 1471 we find Schoeffer was in partnership with Conrad Hentlf and a kinsman of his master Fust. He published many books after the death of his father-in-law; the last of which that can be discovered is a third edition of the Psalter in 1490, in which the old cut types of the first edition were used.

IV. With regard to the claim of Strasburg.

It has already been mentioned, that Gutenberg was engaged in that city in different employments; and, among others, in endeavouring to attain the art of printing. That these endeavours were unsuccessful, is plain from an authentic judicial decree of the senate of Strasburg in 1439, after the death of Andrew Drizehen (k).

But there are many other proofs that Gutenberg and his partners were never able to bring the art to perfection.

1. Wimphelingius *, the oldest writer in favour of Strasburg, tells us, that Gutenberg was the inventor of "a new art of writing," *ars impressoria, which might also be called a divine benefit, and which he happily completed at Mentz; but does not mention one book of his printing: though he adds, that Mentelius printed many volumes correctly and beautifully, and acquired great wealth; whence we may conclude that he perfected what Gutenberg had in vain essayed.

2. Wimphelingius, in another book, tells us, that the art of printing was found out by Gutenberg incomplete; Epic to which implies, not that he practised the art in an imperfect manner (as Laurentius had done at Haerlem), but rather that he had not been able to accomplish what he aimed at.

3. Gutenberg, when he left Strasburg in 1444 or the following year, and entered into partnership with Geinsflech senior and others, had occasion for his brother's assistance to enable him to complete the art; which shows that his former attempts at Strasburg had been unsuccessful (j).

4. These particulars are remarkably confirmed by Trithemius, who tells us, in two different places, that Gutenberg spent all his substance in quest of this art; and met with such insuperable difficulties, that, in despair, he had nearly given up all hopes of attaining it, till he was assisted by the liberality of Fust, and by his brother's skill, in the city of Mentz.

5. Ulric Zell says || the art was completed at Mentz; but that some books had been published in Holland earlier than in that city. Is it likely that Zell, who was a German, would have omitted to mention Strasburg, if it had preceded Mentz in printing?

There is little doubt, therefore, that all Gutenberg's labours at Strasburg amounted to no more than a fruitless attempt, which he was at last under the necessity of relinquishing: and there is no certain proof of a single book having been printed in that city till after the dispersion of the printers in 1462, when Mentelius and Eggestenius successfully pursued the business.

In fine, the pretensions of Strasburg fall evidently to be set aside. And as to the other two cities, Haerlem and Mentz, the disputes between them seem easily cleared up, from the twofold invention of printing above mentioned: the first with separate wooden types at Haerlem, by Laurentius, about 1430, and after continued by his family; the other with metal types, first cut, and afterwards cast, which were invented at Mentz, but not used in Holland till brought thither by Theodoric Martens at Alost about 1472.

From this period printing made a rapid progress in most of the principal towns of Europe. In 1450, it reached Constantinople; and, according to Mr. Palmer, p. 281, &c. it was extended, by the middle of the next century, to Africa and America. It was introduced into Russia about 1560: but, from motives either of policy

---

(1) See Meerman, vol. i. p. 183, who copied this testimony from Wolfius, Monument. Typograph, vol. i. p. 468. et seq.

(k) Their first attempts were made about 1436 with wooden types. Mr Meerman is of opinion that Geinsflech junior (who was of an enterprising genius, and had already engaged in a variety of projects) gained some little insight into the business by visiting his brother who was employed by Laurentius at Haerlem, but not sufficient to enable him to practise it. It is certain that, at the time of the law-suit in 1439, much money had been expended, with but any profit having arisen; and the unfortunate Drizehen, in 1438, on his death-bed, laments to his confesser, that he had been at great expense, without any reimbursement of a single obolus. Nor did Gutenberg (who persisted in his fruitless endeavours) reap any advantage from them; for, when he quitted Strasburg, he was overwhelmed in debt, and under a necessity of selling every thing he was in possession of. [Meerman, vol. i. p. 198—202.] All the depositions in the law-suit abovementioned (with the judicial decree) are printed by Mr Meerman, vol. ii. p. 58.—68. N.
policy or superstition, it was speedily suppressed by the ruling powers; and, even under the present enlightened empress, has scarcely emerged from its obscurity. — That it was early practised in the inhospitable regions of Iceland, we have the respectable authority of Mr. Bryant: "Arngrim Jonas was born amidst the snows of Iceland; yet as much prejudiced in favour of his country as those who are natives of a happier climate. This is visible in his Cymogean, but more particularly in his *Anatome Blfskiniwm.* I have in my possession this curious little treatise, written in Latin by him in his own country, and printed *Typus Holensibus in Islandia Boreali anno 1612.* *Hola* is placed in some maps within the Arctic circle, and is certainly not far removed from it. I believe it is the farther north of any place where arts and sciences have ever resided." *Observations and Inquiries relating to various parts of Ancient History, 1767,* p. 277.

It was a constant opinion, delivered down by our historians, as hath been observed by Dr. Middleton, that the Art of Printing was introduced and first practised in England by William Caxton, a mercer and citizen of London; who, by his travels abroad, and a residence of many years in Holland, Flanders, and Germany, in the affairs of trade, had an opportunity of informing himself of the whole method and process of the art; and by the encouragement of the great, and particularly of the abbot of Westminster, first set up a press in that abbey, and began to print books soon after the year 1471.

This was the tradition of our writers; till a book, which had scarce been observed before the Restoration, was then taken notice of by the curious, with a date of its impression from Oxford, anno 1468, and was considered immediately as a clear proof and monument of the exercise of printing in that university several years before Caxton began to deal in it.

This book, which is in the public library at Cambridge, is a small volume of 41 leaves in 4to, with this title: *Expositio Sancti Jeronimi in Simbolum Apostolorum ad Papam Laurentium: et at the end, Explicit expositio, &c. Impressa Oxonie et finita Anno Domini MCCCCLXVIII. XVII. die Decembris.*

The appearance of this book has robbed Caxton of a glory that he had long possessed, of being the author of printing in this kingdom; and Oxford has ever since carried the honour of the first press. The only difficulty was, to account for the silence of history in an event so memorable, and the want of any memorial in the university itself concerning the establishment of a new art amongst them of such use and benefit to learning. But this difficulty has been cleared up by the discovery of a record, which had lain obscure and unknown at Lambeth-palace, in the Register of the See of Canterbury, and gives a narrative of the whole transaction, drawn up at the very time.

An account of this record was first published in a thin quarto volume, in English; with this title: "The Original and Growth of Printing, collected out of History, and the Records of this Kingdom: wherein is also demonstrated, that Printing appertaineth to the Prerogative Royal, and is a Flower of the Crown of England." By Richard Atkyns, esq.—Whitehall, April the 25, 1664. By order and appointment of the right honourable Mr. Secretary Morrice, let this be printed, Tho. Rycart, London: Printed by John Streeter, for the Author, 1664." 4to.

It sets forth in short, "That as soon as the art of printing made some noise in Europe, Thomas Bourchier, archbishop of Canterbury, moved the then king (Henry VI.) to use all possible means for procuring a printing mould (for so it was then called) to be brought into this kingdom. The king (a good man, and much given to works of this nature) readily heartened to the motion; and taking private advice how to effect his design, concluded it could not be brought about without great secrecy, and a considerable sum of money given to such person or persons as would draw off some of the workmen of Haerlem in Holland, where John Gutenberg had newly invented it, and was himself personally at work. It was resolved, that less than 1000 marks would not produce the desired effect; towards which sum the said archbishop presented the king 300 marks. The money being now prepared, the management of the design was committed to Mr. Robert Turnour, who then was master of the robes to the king, and a person most in favour with him of any of his condition. Mr. Turnour took to his assistance Mr. Caxton, a citizen of good abilities, who traded much into Holland; which was a creditable pretence, as well for his going, as stay in the Low Countries. Mr. Turnour was in disguise (his beard and hair shaven quite off); but Mr. Caxton appeared known and public. They, having received the said sum of 1000 marks, went first to Amsterdam, then to Leyden, not daring to enter Haerlem itself; for the town was very jealous, having imprisoned and apprehended divers persons who came from other parts for the same purpose. They said till they had spent the whole thousand marks in gifts and expenses; so as the king was fain to send 500 marks more, Mr. Turnour having written to the king that he had almost done his work; a bargain, as he said, being struck betwixt him and two Hollanders, for bringing off one of the workmen, whose name was Frederick Corsella (or rather Corsellis), who late one night stole from his fellows in disguise into a vessel prepared before for that purpose; and so, the wind favouring the design, brought him safe to London. It was not thought so prudent to set him on work at London: but, by the archbishop's means (who had been vice-chancellor and afterwards chancellor of the university of Oxon), Corsellis was carried with a guard to Oxon; which guard constantly watched, to prevent Corsellis from any possible escape, till he had made good his promise in teaching them how to print. So that at Oxford, printing was first set up in England which was before there was any printing-press or printer in France, Spain, Italy, or Germany (except the city of Mentz), which claims seniority, as to printing, to Haerlem itself, calling her city, *Urbem Magnothian artis typographicae inventris propter,* though it is known to be otherwise, that city gaining the art by the brother of one of the workmen of Haerlem, who had learnt it at home of his brother, and after set up for himself at Mentz. This press at Oxford was at least ten years before there was any printing in Europe, except at Haerlem and Mentz, where it was but new-born. This press at Oxford was afterwards found inconvenient to be the sole printing-place of England; as being too far from London and the sea. Wherefore the king set up a press.
press at St Alban's, and another in the city of Westminster, where they printed several booke of divinity and physick: for the king (for reasons best known to himself and council) permitted them no law-books to be printed; nor did any printer exercise that art, but only such as were the king’s sworn servants; the king himself having the price and enulements for printing books. — By this means the art grew so famous, that anno primo Richard III. c. 9. when an act of parliament was made for restrainment of aliens for using any handicrafts here (except as servants to natives), a special proviso was inserted, that strangers might bring in printed or written books to sell at their pleasure, and exercise the art of printing here, notwithstanding that act: so that in the space of 30 or 50 years, by the indulgence of Edward IV. Edward V. Richard III. Henry VII. and Henry VIII. the English proved so good proficients in printing, and grew so numerous, as to furnish the kingdom with books; and so skillful, as to print them as well as any beyond the seas; as appears by the act 25 Hen. VIII. c. 15. which abbreviates the said proviso for that reason. And it was further enacted in the said statute, that if any person bought foreign books bound, he should pay 6s. 8d. per book. And it was further provided and enacted, that in case the said printers or sellers of books were unreasonable in their prices, they should be moderated by the lord chancellor, lord treasurer, the two lords chief justices, or any two of them, who also had power to fine them 30 40s. for every book whose price should be enhanced. — But when they were by charter corporated with bookbinders, booksellers, and founders of letters, 3 and 4 Philip and Mary, and called The Company of Stationers, they kick’d against the power that gave them life, &c. — Queen Elizabeth, the first year of her reign, grants by patent the privilege of sole printing all books that touch or concern the common laws of England, to Tottel a servant to her majesty, who kept it entire to his death; after him, to one Yest Weir, another servant to her majesty; after him, to Weight and Norton; and after them, King James grants the same privilege to More, one of the signet; which grant continues to this day, &c."

12 Whether Caxton or Corseilis was the first printer.

Ans. — Caxton tells us, in the preface to The History of Trogo, that he began that translation March 1. 1468, at Bruges; that he proceeded on with it at Ghent; that he finished it at Cologne in 1471; and printed it, probably, in that city with his own types. He was 30 years abroad, chiefly in Holland; and lived in the court of Margaret duchess of Burgundy, sister of Edward IV. It was therefore much easier to print his book at Cologne, than to cross the sea to learn the art at Oxford. But further, there was a special occasion for his printing it abroad. Corseilis had brought over so far the art of printing as he had learned it at Haelem, which was the method of printing on wooden separate types, having the face of the letter cut upon them. But the art of casting metal types being divulged in 1462 by the workmen of Mentz, Caxton thought proper to learn that advantageous branch before he returned to England. This method of casting the types was such an improvement, that they looked on it as the original of printing; and Caxton, as most others do, ascribes that to Mentz. — Caxton was an assistant with Turnour in getting off Corseilis; but it is nowhere supposed that he came with him into England. (See Meerman, vol. ii. p. 34. B.)

Obj. 3. — "As the Lambeth record was never heard of before the publication of Atkyn’s book, so it has never since been seen or produced by any man; though the registers of Canterbury have on many occasions been diligently
lentently and particularly searched for it. They were examined, without doubt, very carefully by Archbishop Parker, for the compiling his Antiquities of the British Church; where, in the life of Thomas Bourchier, though he congratulates that age on the noble and useful invention of printing, yet he is silent as to the introduction of it into England by the endeavours of that archbishop: nay, his giving the honour of the invention to Strasburg clearly shews that he knew nothing of the story of Corsellis conveyed from Haelem, and that the record was not in being in his time. Palmer himself owns, "That it is not to be found there now; for that the late earl of Pembroke assured him, that he had employed a person for some time to search for it, but in vain:" (Hist. of Printing, p. 341.) On these grounds we may pronounce the record to be a forgery; though all the writers above mentioned take pains to support its credit, and call it an authentic piece.

Atkyns, who by his manner of writing seems to have been a bold and vain man, might possibly be the inventor; for he had an interest in imposing it upon the world, in order to confirm the argument of his book, that printing was of the prerogative royal; in opposition to the company of stationers, with whom he was engaged in an expensive suit of law, in defence of the king's patents, under which he claimed some exclusive powers of printing. For he tells us, p. 3. 'That, upon considering the thing, he could not but think that a public person, more eminent than a mercer, and a public purse, must needs be concerned in so public a good: and the more he considered, the more inquisitive he was to find out the truth. So that he had formed his hypothesis before he had found his record; which he published, he says, as a friend to truth; not to suffer one man to be intitled to the worthy achievements of another; and as a friend to himself, not to lose one of his best arguments of intitling the king to this art.' But, if Atkyns was not himself the contriver, he was imposed upon at least by some more crafty man; who imagined that his interest in the cause, and the warmth that he shewed in pursuing it, would induce him to swallow for genuine whatever was offered of the kind.

*Answer.*—On the other hand, is it likely that Mr Atkyns would dare to forge a record, to be laid before the king and council, and which his adversaries, with whom he was at law, could disprove?—(2.) He says he received this history from a person of honour, who was some time keeper of the Lambeth library. It was easy to have confuted this evidence, if it was false, when he published it, April 25, 1664.—(3.) John Bagford (who was born in England in 1651, and might know Mr Atkyns, who died in 1677), in his History of Printing at Oxford, blames those who doubted of the authenticity of the Lambeth MS.; and tells us that he knew Sir John Birkenhead had an authentic copy of it, when in 1655 [which Bagford by some mistake calls 1664, and is followed in it by Meerman] he was appointed by the house of commons to draw up a bill relating to the exercise of that art. This is confirmed by the Journals of that house, Friday Oct. 27, 1665, vol. viii. p. 622, where it is ordered, that this Sir John Birkenhead should carry the bill on that head to the house of lords for their consent. The bill was accordingly sent to the upper house on Tuesday Oct. 31, and received the royal assent on the same day; immediately after which the parliament was prorogued. See Journals of the House of Lords, vol. xi. p. 700.—It is probable, then, that after Mr Atkyns had published his book in April 1664, the parliament thought proper, the next year, to inquire into the right of the king's prerogative; and that Sir John Birkenhead took care to inspect the original, then in the custody of Archbishop Sheldon: and, finding it not sufficient to prove what Mr Atkyns had cited it for, made no report of the MS. to the house; but only moved that the former law should be renewed. The MS. was probably never returned to the proper keeper of it; but was afterwards burnt in the fire of London, Sept. 13, 1666.—(4.) That printing was practised at Oxford, was a prevailing opinion long before Atkyns. Bryan Twyne, in his Apologia pro Antiquitate Academiae Oxfordensis, published 1608, tells us, it is so delivered down in ancient writings: having heard, probably, of this Lambeth MS. And King Charles I. in his letter patent to the University of Oxford, March 5, in the eleventh of his reign, 1635, mentions printing as brought to Oxford from abroad. As to what is objected, "that it is not likely that the press should undergo a ten or eleven years sleep, viz. from 1468 to 1479," it is probably urged without foundation. Corssellis might print several books without date or name of the place, as Ulric Zell did at Cologne, from 1467 to 1473, and from that time to 1494. Corssellis's name, it may be said, appears not in any of his publications; but neither does that of Joannes Petersheimus. [See Meerman, vol. i. p. 34; vol. ii. p. 21-27, &c.]

Further, the famous Shakespeare, who was born in 1564, and died 1616, in the Second Part of Henry VI. act iv. sc. 7. introduces the rebel John Cade, thus upbraiding Lord Treasurer Say: "Thou hast most traiterously corrupted the youth of the realm, in creating a grammar-school: and whereas, before, our forefathers had no other book but the score and the tally, thou hast cause Printing to be used; and, contrary to the king, his crown, and dignity, thou hast built a paper-mill."—Whence now had Shakespeare this accusation against Lord Say? We are told in the Poetical Register, vol. ii. ed. Lond. 1724, that it was from Fabian, Pol Vergel, Hall, Hollingshed, Grafton, Stow, Speed, &c. But not one of these ascribes printing to the reign of Henry VI. On the contrary, Stow, in his Annals, printed at London, 1562, p. 686, gives it expressly to William Caxton, 1471. "The noble science of printing was about this time found out in Germany at Magunce, by one John Guthurburgus a knight. One Conradus an Almaine brought it into Rome: William Caxton of London, mercer, brought it into England about the year 1471, and first practised the same in the abbe of St Peter at Westminster; after which time it was likewise practised in the abbeys of St Augustine at Canterburie, Saint Albons, and other monasteries of England." What then shall we say, that the above is an anachronism arbitrarily put into the mouth of an ignoraut fellow out of Shakespeare's head? We might believe so, but that we have the record of Mr Atkyns confirming the same in King Charles II.'s time. Shall we say, that Mr Atkyns borrowed the story from Shakespeare, and published it with some improvements of money laid out by Henry VI. from whence it might be received by Charles II. as a prerogative of the crown? But this is improbable, since Shakespeare makes Lord
Printing. Treasurer Say the instrument of importing it, of whom Mr Atkyns mentions not a word. Another difference there will still be between Shakespeare and the Lambeth MS; the poet placing it before 1449, in which year Lord Say was beheaded; the MS between 1454 and 1459, when Bourchier was archbishop. We must say, then, that Lord Say first laid the scheme, and sent some one to Haerlem, though without success; but after some years it was attempted happily by Bourchier. And we must conclude, that as the generality of writers have overlooked the invention of printing at Haerlem with wooden types, and have ascribed it to Mentz where metal types were first made use of; so in England they have passed by Corseilles (or the first Oxford Printer, whoever he was, who printed with wooden types at Oxford), and only mention Caxton as the original artist who printed with metal types at Westminster. [See Merck, vol. ii. 7. 8.] It is strange, that the learned commentators on our great dramatic poet, who are so minutely particular upon less important occasions, should every one of them, Dr Johnson excepted, pass by this curious passage, leaving it entirely unnoticed. And how has Dr Johnson trifled, by slightly remarking, "that Shakespeare is a little too early with this accusation!"—The great critic had undertaken to decipher obsolete words, and investigate unintelligible phrases; but never, perhaps, bestowed a thought on Caxton or Corseilles, on Mr Atkyns or the authenticity of the Lambeth Record.

But, independent of the record altogether, the book stands firm as a monument of the exercise of printing in Oxford six years older than any book of Caxton's with a date. In order to get clear of this strong fact, Dr Middleton, 1. Supposes the date in question to have been falsified originally by the printer, either by design or mistake; and an X to have been adopted or omitted in the age of its impression. Examples of this kind, he says, are common in the history of printing. And, "whilst I am now writing, an unexpected instance is fallen into my hands, to the support of my opinion; an Inauguration Speech of the Woodwardian Professor, Mr Mason, just fresh from the press, with its date given 10 years earlier than it should have been, by the omission of an x, viz. MDCCXXXIV; and the very blunder exemplified in the last piece printed at Cambridge, which I suppose to have happened in the first from Oxford."—To this it has been very properly answered, That we should not pretend to set aside the authority of a plain date, without very strong and cogent reasons; and what the Doctor has in this case advanced will not appear, on examination to carry that weight with it that he seems to imagine. There may be, and have been, mistakes and forgeries in the date both of books and of records too; but this is never allowed as a reason for suspecting such as bear no mark of either. We cannot from a blunder in the last book printed at Cambridge, infer a like blunder in the first book printed at Oxford. Besides, the type used in this our Oxford edition seems to be no small proof of its antiquity. It is the German letter, and very nearly the same with that used by Fust [who has been supposed to be] the first printer; whereas Caxton and Rood use a quite different letter, something between his German and our old English letter, which was soon after introduced by De Wode and Fynson.

2. "For the probability of his opinion (he says), the book itself affords sufficient proof: for, not to insist on what is lea material, the neatness of the letter, and regularity of the page, &c. above those of Caxton, it has one mark, that seems to have carried the matter beyond probable, and to make it even certain, viz. the use of signatures, or letters of the alphabet placed at the bottom of the page, to show the sequel of the pages and leaves of each book; an improvement contrived for the direction of the bookbinders; which yet was not practised or invented at the time this book is supposed to be printed; for we find no signatures in the books of Faust or Schoctier at Mentz, nor in the improved or beautiful impressions of John de Spira and Jenson at Venice till several years later. We have a book in our library, that seems to fix the very time of their invention, at least in Venice; the place where the art itself received the greatest improvements: Balditi lectura super Codic. &c. printed by John de Colonio and Jo. Manthém de Ghertzeom, anno mccccclxxvi. It is a large and fair volume in folio, without signatures, till about the middle of the book, in which they are first introduced, and so continued forward: which makes it probable, that the first thought of them was suggested during the impression; for we have likewise Lectura Bartholii super Codic. &c. in two noble and beautiful volumes in folio, printed the year before at the same place, by Vindelina de Spira, without them; yet from this time forward they are generally found in all the works of the Venetian printers, and from them propagated to the other printers of Europe. They were used at (L) Cologne, in 1475; at Paris, 1476; by Caxton, not before 1480: but if the discovery had been brought into England, and practised at Oxford 12 years before, it is not probable that he would have printed so long at Westminster without them Mr Palmer indeed tells us, p. 54, 180, that Anthony Zarat was esteemed the inventor of signatures; and that they are found in a Terence printed by him at Milan in the year 1470, in which he first printed. I have not seen that Terence; and can only say that I have observed the want of them in some later works of this

(L) Dr Middleton is mistaken in the time and place of the invention of signatures. They are to be found even in very ancient MSS. which the earliest printers very studiously imitated; and they were even used in some editions from the office of Lawrence Coster (whence Corseilles came), which consisted of wooden cuts, as in Figure typica et antitypica, Novi Testamenti; and in some editions with metal types, as in Geneva, Pemmene, epistolar, published at Paris, without a date, but printed A. D. 1472, (Maistare * Annal. vol. i. p. 25;) and in Mammotrepsus, printed by Helias de Lioffen, at Bern in Switzerland, 1470; and in De Tondeli visione, at Antwerp, 1472. Venice, therefore, was not the place where they were first introduced. They began to be used in Baldus, it seems, when the book was half finished. The printer of that book might not know, or did not think, of the use of them before. See Merck, vol. ii. p. 18; and Phil. Trans. vol. xiii. No 208. p. 1509.
another way for this distance of time, without altering
the date. The Civil Wars broke out in 1469; this
might probably oblige our Oxford printer to shut up his
press; and both himself and his readers be otherwise en-
gaged. If this were the case, he might not return to
his work again till 1479; and the next year, not meet-
ing with that encouragement he deserved, he might
remove to some other country with his types.

Dr Middleton concludes with apologizing for his
"spending so much pains on an argument so inconsider-
able, to which he was led by his zeal to do a piece of
justice to the memory of our worthy countryman Will-
iam Caxton; nor suffer him to be robbed of the glory,
so clearly due to him, of having first imported into this
kingdom an art of great use and benefit to mankind: a
kind of merit, that, in the sense of all nations, gives the
best title to true praise, and the best claim to be com-
memorated with honour to posterity."

The fact, however, against which he contends; but
the real
derm which it seems impossible to overturn, does by no means
derogue from the honour of Caxton, who, us has been
shown, was the first person in England that practised the
art of printing with fusile types, and consequently the first
which he brought it to perfection; whereas Corseil
drawn with separate cut types in wood, being the only
method which he had learned at Haerlem. Into this
detail, therefore, we have been led, not so much by the
importance of the question, as on account of several
anecdotes connected with it, which seemed equally cal-
culated to satisfy curiosity and afford entertainment.

Caxton had been bred very reputedly in the way of
trade, and served an apprenticeship to one Robert Large,
a mercer; who, after having been sheriff and lord mayor
of London, died in the year 1441, and left by will, as
may be seen in the prerogative office, xxiii marks to his
apprentice William Caxton: a considerable legacy in
those days, and an early testimonial of his good char-
acter and integrity.

From the time of his master's death, he spent the
following thirty years beyond sea in the business of mer-
chandise: where, in the year 1466, we find him em-
ployed by Edward IV. in a public and honourable ne-
gociation, jointly with one Richard Whitehill, Esq. to
transact and conclude a treaty of commerce between the
king and his brother-in-law the duke of Burgundy, to
whom Flanders belonged. The commission styles them,
ambassadors, procuratores, nuncios, et deputos spec-
tales; and gives to both or either of them full powers
to treat, &c.

Whoever turns over his printed works, must contract
a respect for him, and be convinced that he preserved
the same character through life, of an honest, modest,
man; greatly industrious to do good to his country, to
the best of his abilities, by spreading among the people
such books as he thought useful to religion and good
manners, which were chiefly translated from the French.
The novelty and usefulness of his art recommended him
to the special notice and favour of the great; under
whose protection, and at whose expense, the greatest
part of his works were published. Some of them are
addressed to King Edward IV. his brother the duke of
Clarence, and their sister the duchess of Burgundy; in
whose service and pay he lived many years before he
began to print, as he often acknowledges with great
gratitude. He printed likewise for the use, and by

Printing.

the express order, of Henry VII. his son Prince Arthur, and many of the principal nobility and gentry of that age.

It has been generally asserted and believed, that all his books were printed in the abbey of Westminster; yet we have no assurance of it from himself, nor any mention of the place before the year 1477: so that he had been printing several years without telling us where.

There is no clear account left of Caxton's age: but he was certainly very old, and probably above fourscore, at the time of his death. In the year 1471 he complained of the infirmities of age creeping upon him, and feebing his body: yet he lived 23 years after, and pursued his business, with extraordinary diligence, in the abbey of Westminster, till the year 1494, in which he died; not in the year following, as all who write of him affirm. This appears from some verses at the end of a book, called "Hilton's Scale of Perfection," printed in the same year:

Infinite laude with thankynge many fold
I yield to God me socouring with his grace
This boke to finyshe which that ye beholde
Scale of perfection calde in every place
Whereof th' auter Walter Hilton was
And Wynke de Worde this hath sett in print
In William Caxtons how so fyll the case,
God rest his soule.
In joyther mot it synpt.
Impressus anno salutis MCCCLXXXIII.

Though he had printed for the use of Edward IV. and Henry VII. yet there appears no ground for the notion which Palmer takes up, that the first printers, and particularly Caxton, were sworn servants and printers to the crown; for Caxton, as far as can be observed, gives not the least hint of any such character or title; though it seems to have been instituted not long after his death; for of his two principal workmen, Richard Pynson and Wynkyn de Worde, the one was made printer to the king, the other to the king's mother the lady Margaret. Pynson gives himself the first title, in The Imutation of the Life of Christ; printed by him at the commandment of the lady Margaret, who had translated the fourth book of it from the French, in the year 1504: and Wynkyn de Worde assumes the second, in The Seven Penitential Psalms, expounded by Bishop Fisher, and printed in the year 1509. But there is the title of a book given by Palmer, that seems to contradict what is here said of Pynson; viz. Psalterium ex mandato victoriosissimi Anglie Regis Henriici Septimi. per Gulielmum Fauque, impressorem regionum, anno 1511; which being the only work that has ever been found of this printer, makes it probable that he died in the very year of its impression, and was succeeded immediately by Richard Pynson. No book hath yet been discovered printed in Scotland in this period, though the English printers were able to export some of their works to other countries. See Henry's History of Great Britain, vol. v. p. 471.

Before 1465, the uniform character was the old Gothic or German; whence our Black was afterwards formed. But in that year an edition of Lactantius was printed in a kind of Semi-Gothic, of great elegance, and approaching nearly to the present Roman type; which last was first used at Rome in 1467, and soon after brought to great perfection in Italy, particularly by Jenson.

Towards the end of the 15th century, Aldus invented the Italic character which is now in use, called, from his name, Aldine or cursivus. This sort of letter he contrived to prevent the great number of abbreviations that were then in use.

The first essays in Greek that can be discovered are a few sentences which occur in the edition of Tully's Op. phil. 1465, at Mentz; but these were miserably incorrect and barbarous, if we may judge from the specimens Mr Maittaire has given us, of which the following is one:

Oviotcerarxapetpapu eum tertium.

In the same year, 1465, was published an edition of Lactantius's Institutes, printed in monasterio Sublacensi, in the kingdom of Naples, in which the quotations from the Greek authors are printed in a very neat Greek letter. They seem to have had but a very small quantity of Greek types in the monastery; for, in the first part of the work, whenever a long sentence occurred, a blank was left, that it might be written in with a pen: after the middle of the work, however, all the Greek that occurs is printed.

The first printers who settled at Rome were Conrad Sweynheym and Arnold Pannartz, who introduced the present Roman type, in 1466, in Cicero's Epistles Familiaris: in 1469 they printed a beautiful edition of Petrus Gellius, with the Greek quotations in a fair character, without accents or spirits, and with very few abbreviations.

The first whole book that is yet known is the Greek Grammar of Constantine Lascaris, in quarto, revised by Demetrius Cretensis, and printed by Dionysius Palaivinus, at Milan, 1476. In 1481, the Greek Psalter was printed here, with a Latin translation, in folio; as was Æsop's Fables in quarto.

Venice soon followed the example of Milan; and in 1485 were published in that city the Greek Psalter and the Bchairomopoeia, the former by Alexander, and the latter by Laonicus, both natives of Crete. They were printed in a very uncommon character; the latter of them with accents and spirits, and also with syllabic.

In 1488, however, all former publications in the language were eclipsed by a fine edition of Homer's Works at Florence, in folio, printed by Demetrius, a native of Crete. Thus printing, says Mr Maittaire, (p. 185,) seems to have attained its ægis of perfection, after having exhibited the most beautiful specimens of Latin, Greek, and Hebrew.

In 1493, a fine edition of Isocrates was printed at Milan, in folio, by Henry German and Sebastian Pantremolo. All the above works are prior in time to those of Aldus, who has been erroneously supposed to be the first Greek printer: the beauty, however, correctness, and number of his editions, place him in a much higher rank than his predecessors; and his characters in general were more elegant than any before used. He was born in 1445, and died in 1515.

Though the noble Greek books of Aldus had raised an universal desire of reviving that tongue, the French were backward in introducing it. The only pieces printed...
When the art of printing was first established, it was the glory of the learned to be correctors of the press to the eminent printers. Physicians, lawyers, and bishops themselves, occupied this department. The printers then added frequently to their names those of the correctors of the press; and editions were then valued according to the abilities of the corrector.

In the productions of early printing may be distinguished the various splendid editions they made of Primers or Prayer-books. They were embellished with cuts finished in a most elegant taste: many of them were ludicrous, and several were obscene. In one of them an angel is represented crowning the Virgin Mary, and God the Father himself assisting at the ceremony. We have seen in a book of natural history the Supreme Being represented as reading on the seventh day, when he rested from all his works. Sometimes St Michael is seen overcoming Satan; and sometimes St Anthony appears attacked by various devils of most hideous forms. The Prayers of Salisbury, 1533, is full of cuts: at the bottom of the title page there is the following remarkable prayer:

God be in my Bede,
And in my Understandyng.
God be in my Eyen,
And in my Lookyng.
God be in my Mouthe,
And in my Spekyng.
God be in my Herte,
And in my thinking.
God be at myn ende,
And at my departyng.

Stereotype Printing. Different persons in different countries have claimed the merit of this invention; but from Mr Nicholls’s Biographical memoirs of William Ged, it appears undeniable that he was the first by whom it was invented. Mr Tilloch, the editor of the Philosophical Magazine informs us, that he had turned Vol. 2. his attention to the subject for a number of years, and having hit at last upon the discovery, he flattered himself that it was purely original, even feeling vexed when given to understand that he had been anticipated by Mr Ged of Edinburgh, who had printed books from plates about 50 years before.

So far back as the year 1725, we find that Mr Ged had begun to prosecute plate-making. In 1727, he entered into a contract with a person who had a small capital, but who was so intimidated by the insinuations of some printer, that he expended no more than 22l. in the course of two years. In this manner he had printed both bibles and common prayer-books, but the compositors when they corrected one fault, purposely made half a dozen more; and the pressmen when the masters were absent, battered the letter to second the compositors. In consequence of these abominable proceedings, the books were suppressed by authority, and the plates sent to the King’s printing-house, and from thence to the foundery.

In consequence of Mr Tilloch’s invention and improvement, Stereotype printing was afterwards practised by him in conjunction with Mr Foulis, printer to the university of Glasgow, who obtained patents both for England and Scotland, as Mr Ged’s invention had died with...
with his son. This art, therefore, may be said to have been twice invented in Britain; after which Didot, a French printer, published several Latin classics in the same manner, and to whom some of his countrymen wished to ascribe the merit of the invention, which must be a mistake. We admit it possible that he might have discovered the secret of the art for himself; but it is not supposed that he could be ignorant of God’s progress and that of Mr Foulis, especially since, when patents are obtained, a specification of the process must be put upon record, of which any one may obtain an office copy at a small expense.

Neither it is at all probable that stereotype printing was the invention of a Dutchman, who is said to have practised the art even before God; since we are assured that God himself had offered from Holland repeatedly, either to go over there, or sell his invention, which could not possibly have been the case, had it been in possession of their own countrymen.

Founding of pages, on the first view of it, promises many advantages of an economical nature, and to science it holds out what can never be obtained in any other way; we mean editions of books without a single error. From books cast into solid pages, no more copies would be printed than might be wanted for immediate sale; the money thus saved from being sunk in paper, to be piled up in warehouses for years, as is the case at present, would serve as surplus capital to print other works; thus the printer, his workmen, and the booksellers, would all be benefited.

Some are of opinion, that the expense of stereotype precludes the use of it, except in the case of standard authors, whose works are sure of an extensive sale; but the very reverse of this is the truth. If there would be an advantage in applying the stereotype art to books of rapid sale, there would be a still greater one in the case of such whose sale would not be so certain, as at the worst there could only be the loss of the plates, instead of that of the paper and press-work of a whole edition, which in almost every instance would amount to a much larger sum. To the advantages already mentioned we may add a few others, as stated by Mr Wilson, Stereotype office Duke street, Lincoln’s Inn Fields. The expense of Stereotype plates is not 20 per cent. of that of moveable type pages. A room that is fire-proof will hold Stereotype plates of works, of which the dead stock in printed paper would require a warehouse twenty times the size; and thus warehouse rent and insurance are saved; with the additional advantage, in case of accident by fire, that the stereotype plates may be instantly put to press, instead of going through the tedious operations of moveable type printing; and thus no loss will be sustained from the works being out of print. In stereotype, every page of the most extensive work has a separate plate; of consequence all the pages of the said work must be equally new and beautiful. The types of each sheet are distributed by the old method, by which the subsequent sheets are composed; so that, although the first few sheets of a volume may be well composed, the last part of the volume will appear to be executed in a very inferior manner. Stereotype plates admit of alteration; and it will be found that they will yield at least twice the number of impressions that moveable types are capable of producing. It seems evident upon the whole, says Mr Wilson, that a saving of from 25 to 40l. per cent. will accrue to the public in the prices of all books of standard reputation and sale, which, he believes, are pretty accurately ascertained to comprehend three-fourths of all the book printing of England, Scotland, and Ireland. It is fair to conclude, therefore, that both foreign and domestic sales will be much increased, and that the duties on paper will be proportionally productive; so that the public will reap advantage in a twofold way by the general adoption and encouragement of the stereotype art.

The advantages of this mode of printing now mentioned, are such as have been suggested by men who were competent judges; but we leave it to our readers to determine for themselves, whether the adoption of the stereotype art of printing would be more beneficial to society at large, than the publishing of books by means of moveable types.

The workmen employed in the art of printing are of two kinds: compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author; and pressmen, who apply ink upon the same, and take off the impression. The types being cast, the compositor distributes each kind by itself among the divisions of two wooden frames, an upper and an under one, called cases; each of which is divided into little cells or boxes. Those of the upper case are in number 98: these are all of the same size; and in them are disposed the capitals, small capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower case, which are 54, are placed the small letters, with the points, spaces, &c. The boxes are hoxe of different sizes, the largest being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letter oftest wanted are nearest the compositor’s hand. Each case is placed a little alope, that the compositor may the more easily reach the upper boxes. The instrument in which the letters are set is called a composing-stick (fig. 1.), which consists of a long and narrow plate of brass or iron, &c. on the right side of which arises a ledge, which runs the whole length of the plate, and serves to sustain the letters, the sides of which are to rest against it; along this ledge is a row of holes, which serve for introducing the screw a, in order to lengthen or shorten the extent of the line, by moving the sliders b c farther from or nearer to the shorter ledge at the end d. Where marginal notes are required in a work, the two sliding-pieces b c are opened to a proper distance from each other in such a manner, as that while the distance between d c forms the length of the line in the text, the distance between the two sliding-pieces forms the length of the lines for the notes on the side of the page. Before the compositor proceeds to compose, he puts a rule or thin slip of brass-plate, cut to the length of the line, and of the same height as the letter, in the composing-stick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his stick in his left-hand, his thumb being over the slider c; with the right he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by pressing them to the end of the slider c, the other hand being con-
Printing

stantly employed in setting in other letters: the whole
being performed with a degree of expedition and address
not easy to be imagined.

A line being thus composed, if it end with a word
or syllable, and exactly fill the measure, there needs no
further care; otherwise more spaces are to be put in, or
else the distances lessen'd, between the several words,
in order to make the measure quite full; so that every
line may end even. The spaces here used are pieces of
metal exactly shaped like the shanks of the letters: they
are of various thicknesses, and serve to support the let-
ters, and to preserve a proper distance between the
words; but not reaching so high as the letters, they
make no impression when the work is printed. The
first line being thus finished, the compositor proceeds
to the next; in order to which he removes the brass
rule from behind the former, and places it before it,
and thus composes another line against it after the same
manner as before; going on thus till his stick is full,
when he empties all the lines contained in it into the
gally.

The compositor then fills and empties his composing-
stick as before, till a complete page be formed; when
he tie it up with a cord or pack-thread; and setting
it by, proceeds to the next, till the number of pages to
be contained in a sheet is completed; which done, he
carry them to the imposing-stone, there to be ranged
in order, and fastened together in a frame called a chess;
and this is termed imposing. The chess is a rectangular
iron frame, of different dimensions according to the size
of the paper to be printed, having two cross-pieces of
the same metal, called a long and short cross, mortised
at each end so as to be taken out occasionally. By the
different situations of these crosses the chess is fitted for
different volumes: for quartos and octavos, one traverses
the middle lengthwise, the other broadwise, so as to in-
tersect each other in the centre: for twelves and twen-
ty-fours, the short cross is shifted nearer to one end of
the chess; for folios, the long cross is left entirely out,
and the short one left in the middle; and for broad-
sides, both crosses are set aside. To dress the chess, or
range and fix the pages therein, the compositor makes
use of a set of furniture, consisting of slips of wood of
different dimensions, and about half an inch high, that
they may be lower than the letters: some of these are
placed at the top of the pages, and called head-sticks;
others, between them, to form the inner margin; others
on the sides of the crosses, to form the outer margin,
where the paper is to be doubled; and others in the
form of wedges to the sides and bottoms of the pages.
Thus all the pages being placed at their proper dis-
tances, and secured from being injured by the chess and
furniture placed about them, they are all united, and
fastened together by driving small pieces of wood called
quotas, cut in the wedge-form, up between the slanting
side of the foot and the side-sticks and the chess, by
means of a piece of hard wood and a mallet; and all
being thus bound fast together, so that none of the let-
ters will fall out, it is ready to be committed to the
pressmen. In this condition the work is called a form;
and as there are two of these forms required for every
sheet, when both sides are to be printed, it is necessary
the distances between the pages in each form should be
placed with such exactness, that the impression of the
pages in one form shall fall exactly on the back of the
pages of the other, which is called register.

As it is impossible but that there must be some mis-
takes in the work, either through the oversight of the
compositor, or by the casual transposition of letters in
the cases; a sheet is printed off, which is called a proof;
and given to the corrector; who reading it over and,
rectifying it by the copy, making the alterations in the
margin, it is delivered back to the compositor to be cor-
rected.

The compositor then unlocking the form upon the
correcting-stone, by loosening the quotas or wedges
which bound the letters together, rectifies the mistakes
by picking out the faulty or wrong letters, and useing
its place, putting those others into their places. After this another proof is made, sent to
the author and corrected as before; and lastly, there
is another proof called a revise, which is made in order
to see whether all the mistakes marked in the last proof
are corrected.

The pressman’s business is to work off the forms thus
prepared and corrected by the compositor; in doing
which there are four things required, paper, ink, balls,
and a press. To prepare the paper for use, it is to be
first wetted by dipping several sheets together in water:
these are afterwards laid in a heap over each other; and
to make them take the water equally, they are all pres-
sed down with a weight at the top. The ink is
made of oil and lamp-black; for the manner of prepa-
ing which, see Printing-Ink. The balls, by which the
ink is applied on the forms, are a kind of wooden fun-
nels with handles, the cavities of which are filled with
wool or hair, as is also a piece of alum leather or pelt
nailed over the cavity, and made extremely soft by soak-
ing in urine, and by being well rubbed. One of these
pressmen takes in each hand; and applying one of
them to the ink-block, daubs and works them together
to distribute the ink equally; and then blackens the
form which is placed on the press, by beating with the
balls upon the face of the letter.

The printing-press, represented fig. 2, is a very cu-
Fig. 2.
Fig. 2.

rious though complex machine. The body consists of
two strong cheeks a, a, placed perpendicularly, and join-
ed together by four cross-pieces, the cap b; the head
c, which is moveable, being partly sustained by two iron
pins or long bolts, that pass the cap; the till or shelf
d, by which the spindle and its apparatus are kept in
their proper position; and the winter e, which bears
the carriage, and sustains the effort of the press beneath.
The spindle f is an upright piece of iron pointed with
steel, having a male screw which goes into the female
one in the head about four inches. Through the eye
g of this spindle is fastened the bar K, by which the press-
man makes the impression. The spindle passes through
a hole in the middle of the till; and its point works in-
to a brass pan or nut, supplied with oil, which is fixed
to an iron plate let into the top of the platten.
The body of the spindle is sustained in the centre of an open
frame of polished iron, 1, 1, 2, 2, 3, 3, fixed to it in
such a manner as, without obstructing its free play, to
keep it in a steady direction; and at the same time to
serve for suspending the platten. This frame consists of
two parts; the upper called the garter, 1, 1, and the
under, called the crame, 2, 2. These are connected
together
is adapted with some slight variations in its construction for printing on paper, linen, cotton, and woollen. Three particulars are to be attended to in the invention.

1st. The manner of preparing and placing the types, engravings, or carvings, from which the impression is to be made; 2dly. In applying the ink or colouring matter to types or engravings; and, 3dly, In taking off the impression.

1st. The moulds, punches, and matrices, for casting letters, are made in the same manner, and with the same materials, as other letter-founders do, excepting that, instead of leaving a space in the mould for the stem of one letter only, he leaves spaces for two, three, or more letters, to be cast at one pouring of the metal; and at the lower extremity of each of those spaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the usual way. And moreover, he brings the stem of his letters to a due form and finish, not only by rubbing it upon a stone, and scraping it when arranged in the finishing-stick, but likewise by scraping it, on warmer or more cold, in a finishing-stick whose covering of paper is less deep at the inner than at the outer side. He calls that side of the groove which is nearest the face of the disposed letter, the outer side; and the purpose accomplished by this method of scraping is, that of rendering the tail of the letter gradually smaller the more remote it is, or farther from the face. Such letters may be firmly imposed upon a cylindrical surface, in the same manner as common letters are imposed upon a flat stone.

2dly. The ink or colouring matter is applied to the types, forms, or plates, by causing the surface of a cylinder, smeared or wetted with the colouring matter, to roll over the surfaces of the said forms or plates, or by causing the forms or plates apply themselves successively to the surface of the cylinder. The surface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton cloth. When the colour to be used is thin, as in calico-printing, and in almost every case, the covering is supported by a firm elastic stuffing, consisting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering consists of woollen cloth, the stuffing must be defended by leather or oilkne, to prevent its imbidding too much colour, and by that means losing its elasticity. It is absolutely necessary that the colouring matter be evenly distributed over the surface of the cylinder; and for this purpose, when the colour is thick and stiff, as in letter-press printing, he applies two, three, or more small cylinders, called distributing-rollers, longitudinally against the colouring cylinders, so that they may be turned by the motion of the latter; and the effect of this application is, that every lump or mass of colour which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be pressed, spread, and partly taken up, and carried by the small rollers to the other parts of the colouring cylinder; so that this last will very speedily acquire and preserve an even face of colour.

But if the colouring matter be thinner, he does not apply more than one or two of these distributing-rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a straight brush, or both of these last, against the colouring cylinder, for the purpose of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or
through the interstices of a perforated pattern, as in the manufacturing of some kinds of paper hangings, he uses a cylinder entirely covered with hair or bristles in the manner of a brush.

3dly, The impressions, even in letter-press printing, are performed by the action of a cylinder or cylindrical surface. The following is the construction of this machine. Fig. 3. represents a printing-press, more especially applicable to the printing of books. A and E are two cylinders, running or turning in a strong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being pressed with more or less force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwise, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by straps, so as to draw it backwards and forwards by the motion of its handle L. The table is kept in the same line by the grooves on its sides, which contain the cylinder A. D is a chess, containing letter set up and imposed. B is a box, containing a colouring-roller, with its distributing-rollers CC; it is supported by the arm N. O is a cylinder faced with leather, and lying across an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has passed into the position R, a workman places or turns down a tympan with paper upon it (this tympan differs in no respect from the usual one, except that its hinge opens sideways); it then proceeds to pass under the cylinder A, which presses it successively through its whole surface. On the other side, at S, the workman takes off the paper and leaves the tympan up. This motion causes the cylinder B to revolve continually, and consequently renders its inked surface very uniform, by the action of its distributing-rollers CC; and, when the table has passed its extreme distance in the direction now spoken of, the arm C touches the lever L, and raises the cylinder O off the ink-block, by which means it dabs against one of the distributing-rollers, and gives it a small quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the process of printing another sheet goes on as before.

Fig. 4. is another printing-press. In this, B is the inking-cylinder; A is a cylinder, having the letter imposed upon its surface; and E is a cylinder, having its uniform surface covered with woollen cloth: these three cylinders are connected, either by coggs or straps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a sheet of paper to the surface of E, where it is retained, either by points in the usual manner, or by the apparatus to be described in treating of fig. 4. The paper passes between E and A, and receives an impression; after which the workman takes it off, and applies another sheet; and in the mean time the surface of A passes round against the surface of B, and receives ink during the rotation of B. The distributing-rollers CC do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raises the ink-piece G, so as to cause it to touch one of the distributing-rollers, and supply it with ink. In this way therefore the repeated printing of sheet after sheet goes on.

Fig. 5. is a printing-press, more particularly adapted to print cottons, silks, paper hangings, or other articles which run of a considerable length. A is a cylinder covered with woollen cloth, or other soft substance. The web or piece of cotton, or other goods, is passed round this cylinder, from the carrying-roller F to the receiving-rollers GH: which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel, sewed round them; the rotation of this towel carries away the printed stuff or goods, and deposits them at I. K L is a movable box, containing three rollers, which move against each other in rotation. The lowest roller C revolves in a mass of colour, contained in a trough or vessel in the bottom part of the box K L; the surface of this colour is represented by the line MN. The next roller B is stuffed and covered as described in section 2. The pressure of need against C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and impresses it upon the web as it passes round the cylinder A; in this way the constant and effectual action of the machine is sufficiently obvious. It must be observed, that the cylinders ADB and G are connected together by cog-wheels, straps, or other well-known equivalent contrivances; so that the handle P drives the whole, without their necessarily depending on any adhesion or friction at their surfaces. The pressure of B against D is governed by an adjustment of the axis of D, whose sockets are capable of a small motion; and the pressure of D against A is governed by the position of the whole box K L. When it is required to print more than one colour upon the same piece, it must pass two or more times through the machine; or, in those cases where the materials are liable to change their dimensions, it is necessary to apply, at one and the same time, two or more such boxes as K L, with their respective cylinders, so that the pattern cylinder of each may make its impression upon the web or material by the process of fig. 6. is a printing-press, chiefly of use for books and fig. 6. papers. 1, 2, 3, 4, represent a long table, with ledges on each side; so that the two cylinders A and B can run backwards and forwards without any side shake. In one of these ledges is placed a strip or plate of metal cut into teeth, which lock into correspondent teeth in each cylinder; by which means the two cylinders roll along, without the possibility of changing the relative positions of their surfaces at any determinate part of the table. This may also be effected by straps, and may indeed be accomplished with tolerable accuracy, by the mere rolling of the cylinders on the smooth or flat ledges without any provision. A is the printing-cylinder, covered with woollen cloth, and B is the inking-cylinder, with its distributing-rollers. The table may be divided into four compartments marked with a thicker bounding line than the rest and numbered 1, 2, 3, 4. At 1 is placed a sheet of paper; at 2 is the form or chess, containing letter set and imposed; at 3 is an apparatus for receiving the printed sheet; and 4 is employed in the manner than as a place of standing for the carriage E, after it has passed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thrust forward by the workman, and as the roller A passes over the space numbered 1, it takes up the sheet of paper previously laid there, while the roller B runs over the form and inks the letter. The sheet of paper being wrapped round

3 B
round the cylinder A, is pressed against the form as that cylinder proceeds, and consequently it receives an impression. When A arrives at the space numbered 3, it lets go the sheet of paper, while the prominent part of the carriage G strikes the lever P, and raises the inking piece, which applies itself against one of the distributing rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another sheet of paper ready in the space numbered 1. Thus it is that the operation proceeds in the printing of one sheet after another.

The preceding description is not encumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in several ways: Fig. 11. and 12. represent one of the methods. DE is a lever, moving on the centre pin C, and having its end D pressed upwards by the action of the spring G. The shoulder which contains the pin C is fixed in another piece F, which is inserted in a groove in the surface of the cylinder A (fig. 6.), so that it is capable of moving in and out, in a direction parallel to the axis of that cylinder. As that cylinder proceeds, it meets a pin in the table; which (letter P, fig. 11.) acting on the inclined plane at the other end of the lever, throws the whole inwards, in the position represented in fig. 12.; in which case the extremity D shoots inwards, and applies itself against the side of the cylinder.

In fig. 13. is a representation of part of the table; the dotted square represents a sheet of paper, and the four small shaded squares denote holes in the board, with pins standing beside them. When the lever DE (fig. 12.) shoots forward, it is situated in one of these holes, and advances under the edge of the paper, which consequently it presses and retains against the cylinder with its extremity D. Nothing more remains to be said respecting the taking up, but that the cylinder is provided with two pair of these claps or levers, which are so fixed as to correspond with four holes represented in fig. 13. It will be easy to understand how the paper is deposited in the compartment No. 3 (fig. 6.). A pin P (fig. 12.) rising out of the platform or table, acts against a pin E, projecting sidewise out of the lever, and must of course draw the slider and its lever to the original position; the paper consequently will be let go, and its disengagement is rendered certain by an apparatus fixed in the compartment numbered 3 (fig. 6.) of exactly the same kind as that upon the cylinder, and which, by the action of a pin duly placed in the surface of the cylinder A, takes the paper from the cylinder in precisely the same manner as that cylinder originally took it up in the compartment numbered 1 (fig. 6.).

Fig. 7, 8, and 9. represent a simpler apparatus for accomplishing the same purpose. If A a a B b (fig. 9.) be supposed to represent a thick plate of metal of a circular form, with two pins, A and B, proceeding sidewise or perpendicularly out of its plane, and diametrically opposite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A, so as to press it into the position a (by turning the plate on its axis or centre X), will at the same time cause the pin G to acquire the position g; and, on the other hand, when B is at b, or the dotted representation of the side-pin, if any pressure be applied to restore its original position at B, the pin g will return back to G. Now the figures 7 and 8 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and p, properly fixed in the table to re-act upon the apparatus, will cause its prominent part G either to apply to the cylinder and clasp the paper, or to rise up and let it go. The compartment numbered 3 (fig. 6.) must of course have an apparatus of the same kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumstance belonging to this machine which remains to be explained. When the carriage E (fig. 6.) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, press the form of letter in their passage; but in their return back again the roller A, having no paper upon it, would itself become soiled, by taking a faint impression from the letter, if it were not prevented from touching it: the manner of effecting this may be understood from fig. 14. The apparatus there represented is fixed upon the outside of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this project is sidewise beyond the edge of the table, except the small truck or wheel B. The irregularly triangular piece, which is shaded by the stroke of the pen, carries this, and also a catch movable on the axis or pin E. The whole piece is moveable on the pin A, which connects it to the carriage, CD, or the part which is shaded by dotting, is a dentit, which serves to hold the piece down in a certain position. It may be observed, that both the dentit and the triangular piece are furnished each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harmonichord, or resembling certain pieces used in clock and watch making, as is clearly represented in the figure. These claws overhang the side of the table, and their effect is as follows: There is a pin C (fig. 6.) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 14. where GH represents the table. In the outward run of the carriage these claws strike that pin, but with no other effect than that they yield for an instant, and as instantly resume their original position by the action of their respective slender back springs. When the carriage returns, the claw of the dentit indeed strikes the pin, but with as little effect as before, because its derangement is instantly removed by the action of the back spring of the dentit itself; but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, so as to lift that end of the carriage, and the dentit, catching on the piece at C, prevents the former position from being recovered. The consequence of this is, that the carriage runs upon the truck B (and its corresponding truck on the opposite side) instead of the cylinder A, which is too much raised to take the letter, and soil itself; but as soon as the end of the carriage has passed clear of the letter, another pin R (fig. 6.) takes the claw of the detit, and draws it off the triangular piece; at which instant the cylinder A subsides to its usual place, and performs its functions as before. This last pin R does not affect the claw of the triangular piece, because it is placed too low; and the claw of the detit is made the longest, on purpose that it may strike this pin.

Fig.
Fig. 10. represents an instrument for printing floor-cloths, paper-hangings, and the like, with a stiff paint and a brush. D is a copper or metallic cylinder fixed in a frame A, like a garden-roller; its carved part is thin, and is cut through in various places, according to the desired pattern. A strong axis passes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a vessel or box of the same kind, and answering the same purpose as the box K.L in fig 5. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P; and a third cylinder B, whose exterior surface is covered with hair, after the manner of a brush, and revolves in contact with E. This cylinder C is adjusted by its axis, in such a manner that its brush-part sweeps in the perforated parts of the metallic cylinder D. The circle C represents a cog-wheel fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any surface, its cog-wheel C drives the brush B in the contrary direction; and this brush cylinder, being connected by cogs or otherwise with E and P, causes these also to rotate and supply it with colour. As the successive openings of the cylinder D, therefore, come in contact with the ground, the several parts of the brush, not traversing the unperforated part of that ground, and paint the pattern upon it. The wheel C, being kept lightly on the ground, serves to determine the line of contact, that it shall be the part opposite to B, and no other.

Chinese Printing, is performed from wooden planks or blocks, cut like those used in printing of calico, paper, cards, &c.

Rolling-press Printing, is employed in taking off prints or impressions from copper plates engraved, etched, or scraped, as in mezzotintos. See Engraving.

This art is said to have been as ancient as the year 1540, and to owe its origin to Finiguerra, a Florentine goldsmith, who, pouring some melted brimstone on an engraved plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur: upon this he attempted to do the same on silver plates with wet paper, by rolling it smoothly with a roller; and this succeeded: but this art was not used in England till the reign of King James I when it was brought from Antwerp by Speed. The form of the rolling-press, the composition of the ink used therein, and the manner of applying both in taking off prints, are as follows:

The rolling-press is shown in fig. 15, may be divided into two parts, the body and carriage: the body consists of two wooden cheeks PP, placed perpendicularly on a stand or foot LM, which sustains the whole press. From the foot likewise are four other perpendicular pieces, c, c, c, c, joined by other cross or horizontal ones, d, d, d, which serve to sustain a smooth even plank or table HIK, about four feet and half a foot long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DE, FG, about six inches in diameter, bored up at each end by the cheeks, whose ends, which are lessened to about two inches diameter, and called trunnions, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate the motion. Lastly, To one of the trunnions of the upper roller is fastened a cross, consisting of two levers AB, or pieces of wood, traversing each other, the arms of which cross serve instead of the bar or handle of the letter-press, by turning the upper roller, and when the plank is between the two rollers, giving the same motion to the under one, by drawing the plank forward and backward.

The ink used for copper plates, is a composition made of the stones of peaches and apricots, the bones of sheep and ivory, all well burnt, and called Frankfort black, mixed with nut-oil that has been well boiled, and ground together on a marble, after the same manner as painters do their colours.

The method of printing from copper plates is as follows: They take a small quantity of this ink on a rubber made of linens, strongly bound about each other, and therewith smear the whole face of the plate as it lies on a grate over a charcoal fire. The plate being sufficiently inked, they first wipe it over with a foul rag, then with the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they rub it from time to time in whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman consists. The plate thus prepared is laid on the plank of the press; over the plate is laid the paper, first well moistened, to receive the impression; and over the paper two or three folds of flannel. Things thus disposed, the arms of the cross are pulled, and by that means the plate with its furniture passed through between the rollers, which pinching very strongly, yet equally, press the moistened paper into the strokes of the engraving, whence it licks out the ink.

PRINTS, the impression taken from a copper plate. See the last article, and Engraving.

From the facility of being multiplied, prints have derived an advantage over paintings by no means inconceivable. They are found to be more durable; which may, however, in some degree be attributed to the different methods in which they are preserved. Many of the best paintings of the early masters have generally had the misfortune to be either painted on walls, or deposited in large and unfrequented, and consequently damp and destructive buildings; whilst a print, passing at distant intervals, from the porte fecile of one collector to that of another, is preserved without any great exertion of its owner. And hence it happens, that whilst the pictures of Raphael have moulder from their walls or deserted the canvas, the prints of his friend and contemporary Mark Antonio Raimondi continue in full perfection to this day, and give us a lively idea of the beauties of these paintings, which, without their assistance, had been lost to us for ever; or at least, could have been only known to us, like those of Zeuxis and Apelles, by the descriptions which former writers on these subjects have left us.

Independent of the advantages which prints afford us, when considered as accurate representations of paintings, and imitations of superior productions, they are no less valuable for their positive merit, as immediate representations of nature. For it must be recollected, that the art of engraving has not always been confined to the copying of other productions, but has frequently
I myself aspired to originality, and has, in this light, produced more instances of its excellence than in the other. Albert Dürer, Goltzius, and Rembrandt, amongst the Dutch and Germans; Parmigianino and Della Bella amongst the Italians, and Callot amongst the French, have published many prints, the subjects of which, there is great reason to suppose, were never painted. These prints may therefore be considered as original pictures of those masters, deficient only in those particulars in which a print must necessarily be inferior to the original painting.

The preceding distinction may perhaps throw some light on the proper method of arranging and classing a collection of prints, which has been a matter of no small difficulty. As an art imitating another, the principal should take the lead, and the design, composition, and drawing, in a print, being previous requisites, to the manner of execution and finishing; prints engraved after paintings should be arranged under the name of the painter; and every person who looks upon engraving only as auxiliary to painting, will consequently adopt this mode of arrangement. But when engraving is considered as an original art, as imitating nature without the intervention of other methods, then it will certainly be proper to regulate the arrangement according to the names of the engravers.

Prints, method of cleaning. The following method of cleaning prints is recommended as safe and efficacious.

Provide a certain quantity of the common muriatic acid, for example three ounces, in a glass bottle, with a ground stopper, of such a capacity that it may be only half full. Half an ounce of mineral must then be added; immediately after which the stopper is to be put in, and the bottle set in a cold and dark place. The heat, which soon becomes perceptible, shows the beginning of the new combination. The minimum abandons the greatest part of its oxygen with which the fluid remains impregnated, at the same time that it acquires a fine golden yellow, and emits the detestable smell of oxygenated muriatic acid. It contains a small portion of muriate of lead; but this is not at all noxious in the subsequent process. It is also necessary to be observed, that the bottle must be strong, and the stopper not too firmly fixed, otherwise the active elastic vapour might burst it. The method of using this prepared acid is as follows:

Provide a sufficiently large plate of glass, upon which one or more prints may be separately spread out. Near the edges let there be raised a border of soft white wax half an inch high, adhering well to the glass and flat at top. In this kind of trough the print is to be placed in a bath of fresh urine, or water containing a small quantity of ox-gall, and kept in this situation for three or four hours. The fluid is then to be decanted off, and pure warm water poured on, which must be changed every three or four hours until it passes limpid and clear. The impurities are sometimes of a resinous nature, and resist the action of pure water. When this is the case, the washed print must be left to dry, and alcohol is then to be poured on and left for a time. After the print is thus cleaned, and all the moisture drained off, the muriatic acid prepared with mineral is to be poured on in sufficient quantity to cover the print; immediately after which another plate of glass is to be laid in contact with the rim of wax, in order to prevent the inconvenient exhalation of the oxygenated acid. In this situation the yellowest print will be seen to recover its original whiteness in a very short time. One or two hours are sufficient to produce the desired effect; but the print will receive no injury if it be left in the acid for a whole night. Nothing more is necessary to complete the work, than to decant off the remaining acid, and wash away every trace of acidity, by repeated effusions of pure water. The print being then left to dry (in the sun if possible) will be found white, clear, firm, and in no respect damaged, either in the texture of the paper, or the tone and appearance of the impression.

It is further recommended to those who shall adopt the whole process for clearing prints, to make the first trial with a print of little value, and in this way he will discover what portion of water should be employed in diluting the acid to prevent the corrosive action of the latter on the paper. Nichol. Journ. ii. 265. 410.

Prior, in general, something before or nearer the beginning than another, to which it is compared.

Prior, more particularly denotes the superior of a conven or convent of monks, or the next under the abbot. See Abbot.

Priors are either clausstral or conventual. Conventual are the same as abbots. Clausstral prior, is he who governs the religious of an abbey or priory in commendam, having his jurisdiction wholly from the abbot.

Grand Prior, is the superior of a large abbey, where several superiors are auxiliary to the prior.

Prior, Matthew, an eminent English poet, was born at London in 1664. His father dying while he was very young, an uncle, a vintner, having given him some education at Westminster school, took him home in order to breed him up to his trade. However, at his leisure hours he prosecuted his study of the classics and particularly of his favourite Horace. This introduced him to some polite company who frequented his uncle's house; among whom the earl of Dorset took particular notice of him, and procured him to be sent to St John's college in Cambridge, where, in 1686, he took the degree of A. B. and afterwards became fellow of that college. Upon the revolution, Mr Prior was brought to court by the earl of Dorset; and in 1690 he was made secretary to the earl of Berkeley, plenipotentiary at the Hague; as he was afterward to the ambassador and plenipotentiaries at the treaty of Ryswick in 1697; and the year following to the earl of Portland, ambassador to the court of France. He was in 1697 made secretary of state for Ireland; and in 1700 was appointed one of the lords commissioners of trade and plantations. In 1710, he was supposed to have had a share in writing The Examiner. In 1711, he was made one of the commissioners of the customs; and was sent minister plenipotentiary to France, for the negotiating a peace with that kingdom. Soon after the accession of George 1. to the throne in 1714, he presented a memorial to the court of France, requiring the demolishing of the canal and new works at Mardyke. The year following he was recalled; and upon his arrival was taken up by a warrant from the house of commons, and strictly examined by a committee of the privy-council. Robert Walpole, Esq. moved the house of commons for an impeachment against him; and Mr Prior was ordered into
PRI [ 381 ]

PRI

Henry IV. began his reign with showing some favour to the alien priories, restoring all the conventual ones, only reserving to himself in time of war what they paid in time of peace to the foreign abbey.

They were all dissolved by act of parliament. 2 Henry V. and all their estates vested in the crown, except some lands granted to the college of Fotheringhay. The act of dissolution is not printed in the statute book, but it is to be found entire in Rymer's 

iv. p. 22. In general, these lands were appropriated to religious uses. Henry VI. endowed his foundations at Eton and Cambridge with the lands of the alien priories in pursuance of his father's design to appropriate them all to a noble college at Oxford. Others were granted in fee to the prelates, nobility, or private persons. Such as remained in the crown were granted by Henry VI. 1440, to Archbishop Chicley, &c. and they became part of his and the royal foundations. See Some Account of Alien-Priorities, &c. in two volumes octavo.

PRIORITY, the relation of something considered as prior to another.

PRIORITY, in Law, denotes an antiquity of tenure, in comparison of another less ancient.

PRISCIANUS, an eminent grammarian, born at Caesarea, taught at Constantinople with great reputation about the year 525. Laurentius Valla calls Priscian, Donatus, and Servius, 

triunviri in re grammatica; and thinks none of the ancients who wrote after them fit to be mentioned with them. He composed a work 

De arte grammatica, which was first printed by Aldus at Venice in 1476; and another, De naturalibus questionibus, which he dedicated to Chosroes king of Persia: beside which, he translated Dionysius's description of the world into Latin verse. A person who writes false Latin, is proverbially said "to break Priscian's head."

PRISCIillianists, in church history, Christian heretics, so called from their leader Priscillian, a Spaniard by birth, and bishop of Avila. He is said to have practised magic, and to have maintained the principal errors of the Manichees; but his peculiar tenet was, That it is lawful to make false oaths in order to support one's cause and interests.

PRISME, in Geometry, is a solid body, whose two ends are any plane figures which are parallel, equal, and similar; and its sides, connecting those ends, are parallelograms.

PRISMOID, is a solid body, somewhat resembling a prism, but its ends are any dissimilar parallel plane figures of the same number of sides, the upright sides being trapezoids. If the ends of the prismoid be bounded by dissimilar curves, it is sometimes called a cylindroid.

PRISON, a gaol, or place of confinement.

Lord Coke observes, that a prison is only a place of safe custody, salve custodia, not a place of punishment. If this be the case, prisons ought not to be, what they have been in most, and still are in some places of Europe,

(A) Apportas or apporlogiam (from portare), an acknowledgement, oblation, or obversion, to the mother house or church. Du Cange.
Any place where a person is confined may be said to be a prison; and when a process is issued against one, he must, when arrested thereon, either be committed to prison or be bound in recognizance with sureties, or else give bail, according to the nature of the case, to appear at a certain day in court, there to make answer to what is alleged against him. Where a person is taken and sent to prison, in a civil case, he may be released by the plaintiff in the suit; but if it be for treason or felony, he may not regularly be discharged, until he is indicted of the fact and acquitted. See INDICTMENT.

But a prison is not only to be considered as a place of safe custody, according to its original design, but also as a place of temporary punishment for certain crimes, and perhaps this punishment might be substituted more frequently than it is, for transportation and death. Probably this is done in no country to better purpose than in Pennsylvania; and no where has imprisonment been more abused than in Venice under the old government.

By the laws of Pennsylvania, imprisonment is imposed, not merely as an expiation for past offences, but also for the reformation of the criminal's morals. The regulations of the gaol are calculated to produce this effect in the speediest manner possible, so that such a building may rather be denominated a penitentiary house than a gaol. When a criminal is committed to prison, he is made to wash; his hair is shorn, and he is furnished with clean apparel, if he has no decent clothes of his own. He is then put into a solitary cell, where he is excluded from the sight of every living being except the gaoler, whose duty it is to attend to his mere necessities, but not to converse with him upon any account. If committed for an atrocious crime, he is even debarred from the light of Heaven. The treatment of each prisoner varies in proportion to the nature of his crime, and his symptoms of repentance. The longest period of confinement is for a rape, which is not to be less than ten years, nor to exceed 21; and for high treason it is not to be under 6, nor above 12.

The prisoners must bathe twice in the week, having proper conveniences within the prison, and they are regularly supplied with a change of linen. Prisoners in solitary confinement subsist upon bread and water; and such as labour are allowed broth, puddings, &c. They are allowed meat in small quantities twice a week, and no beverage except water is brought into the prison. One room is set apart for shoe-makers, another for tailors, and so of every other trade. There are stone-cutters, smiths, nailers, &c. in the yards. Such a prison has all the advantages of the ransping house of Amsterdam, without any of its enormous defects.

The following account of the common prison at Venice, is given by Dr Mosely who visited this horrible place in September 1787.

"I was conducted (says he) through the prison by one of its inferior dependants. We had a torch with us. We crept along narrow passages as dark as pitch. In some of them two people could scarcely pass each other. The cells are made of massy marble; the architecture of the celebrated Sansovini.

The cells are not only dark, and black as ink, but being surrounded and confined with huge walls, the smallest breath of air can scarcely find circulation in them. They are about nine feet square on the floor, arched at the top, and between six and seven feet high in the highest part. There is to each cell a round hole of eight inches diameter, through which the prisoner's daily allowance of twelve ounces of bread and a pot of water is delivered. There is a small iron door to the cell. The furniture of the cell is a little straw and a small tub; nothing else. The straw is renewed and the tub emptied through the iron door occasionally.

"The diet is ingeniously contrived for the perpetuation of punishment. Animal food, or a cordial nutritious regimen, in such a situation, would bring on disease, and defeat the end of this Venetian justice. Neither can the soul, if so inclined, steal away, wrap up in slumbering delusion, or sink to rest; from the admonition of her sad existence, by the gaoler's daily return.

"I saw one man who had been in a cell thirty years; two who had been twelve years; and several who had been eight and nine years in their respective cells.

"By my taper's light I could discover the prisoners' horrid countenances. They were all naked. The man who had been there thirty years, in face and body was covered with long hair. He had lost the arrangement of words and order of language. When I spoke to him, he made an unintelligible noise, and expressed fear and surprise; and, like some wild animals in deserts, which have suffered by the treachery of the human race, or have an instinctive abhorrence of it, he would have fled like lightning from me if he could.

"One whose faculties were not so obliterated; who still recollected the difference between day and night; whose eyes and ears, though long closed with a silent blanket, still languished to perform their natural functions—implored, in the most piercing manner, that I would prevail on the gaoler to murder him, or to give him some instrument to destroy himself. I told him I had no power to serve him in this request. He then entreated I would use my endeavours with the inquisitors to get him hanged, or drowned in the Canal Orfano. But even in this I could not serve him: death was a favour I had not interest enough to procure for him.

"This kindness of death, however, was, during my stay in Venice, granted to one man, who had been from the cheerful ways of man cut off thirteen years.

"Before he left his dungeon I had some conversation with him; this was six days previous to his execution. His transport at the prospect of death was surprising. He longed for the happy moment. No saint ever exhibited more fervour in anticipating the joys of a future state, than this man did at the thoughts of being released from life, during the four days mockery of his trial.

"It is the Canal Orfano where vessels from Turkey and the Levant perform quarantine. This place is the watery grave of many who have committed political or personal offences against the state or senate, and of many who have committed no offences at all. They are carried out of the city in the middle of the night, tied up in a sack with a large stone fastened to it, and thrown into the water. Fishermen are prohibited, on forfeiture
of their lives, against fishing in this district. The presence is the plague. This is the secret history of people being lost in Venice.

"The government, with age, grew feeble; was afraid of the discussion of legal process and of public executions; and navigated this rotten Bucentaur of the Adriatic by spies, prisons, assassination, and the Canal! Orfano."

PRISONER, a person restrained or kept in prison upon an action civil or criminal, or upon commenc- ment: and one may be a prisoner on matter of record or matter of fact. A prisoner upon matter of record, is he who, being present in court, is by the court committed to prison; and the other is one carried to prison upon arrest, whether it be by the sheriff, constable, or other officer.

PRISTIS, the SAWFISH, is generally considered as a species of the squlaus or shark genus, comprehending under it several varieties. See SQUALUS, IC THOLOGY Index. But Mr Latham is of opinion that it ought to be considered as a distinct genus, and that the characteristics of the several varieties are sufficient to constitute distinct species.

PRIVATEERS, are a kind of private men of war, the persons concerned wherein administer at their own costs a part of a war, by fitting out these ships of force, and providing them with all military stores; and they have, instead of pay, leave to keep what they take from the enemy, allowing the admiral his share, &c.

Privateers may not attempt any thing against the laws of nations; as to assault an enemy in a port or haven, under the protection of any prince or republic, whether he be friend, ally, or neutr; for the peace of such places must be inviolably kept; therefore, by a treaty made by King William and the States of Holland, before a commission shall be granted to any privateer, the commander is to give security, if the ship be not above 150 tons, in 1500l. and if the ship exceeds that burden, in 3000l. that they will make satisfaction for all damages which they shall commit in their course at sea, contrary to the treaties with that state, or pain of forfeiting their commissions; and the ship is made liable.

Besides these private commissions, there are special commissions for privateers, granted to commanders of ships, &c. who take pay; who are under a marine discipline; and if they do not obey their orders, may be punished with death: and the wars in later ages have given occasion to princes to issue these commissions, to annoy the enemies in their commerce, and hinder such supplies as might strengthen them or lengthen out the war; and likewise to prevent the separation of ships of greater force from their fleets or squadrons.

Ships taken by privateers were to be divided into five parts; four parts whereof to go to the persons interested in the privateer, and the fifth to his majesty: and as a farther encouragement, privateers, &c. destroying any French man of war or privateer, shall receive, for every piece of ordnance in the ship so taken, 10l. reward, &c.

By a particular statute lately made, the lord admiral, or commissioners of the admiralty, may grant commissions to commanders of privateers, for taking ships, &c., which being adjudged prize, and the tenth part paid to the admiral, &c. wholly belong to the owners of the privateers and the captors, in proportions agreed on between themselves.

PRIVATION, in a general sense, denotes the absence or want of something; in which sense darkness is only the privation of light.

PRIVATIVE, in Grammar, a particle, which, prefixed to a word, changes it into a contrary sense. Thus, among the Greeks, the α is used as a privative; as in α-κραυγή, αἰθετής, αἰθετος, &c.—The Latins have their privative in; as, α-κεραυνός, α-κραυγή, α-κραυγώτρια, &c.—The English, French, &c. on occasion borrow both the Latin and Greek privatives.

PRIVERNUM, (Livy, Virgil); a town of the Volsci, in Latium, to the east of Setia. Privernates, the people. Whose ambassadors being asked, What punishment they deserved for their revolt? answered, What those deserve who deem themselves worthy of liberty. And again, being asked by the Roman consul, should the punishment be remitted, What peace was to be expected with them? If you granted a good peace, you may hope to have it sincere and lasting; but if a bad one, you may well expect it of short continuance. At which answer, the Romans were so far from being displeased, that by a vote of the people they had the freedom of the city granted them. Privernates, it is, the epithet. The town is now called Piperno Vecchio, situated in the Campania of Rome. E. Long. 10 o. N. Lat. 41° 30'.

PRIVET. See Ligustrum, Botany Index.

PRIVILEGE, in Law, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law. Privileges are said to be personal or real. Personal privileges are such as are extended to peers, ambassadors, members of parliament, and of the convocation, &c. See Lords, Ambassador, Parliament, Arrest, &c.

A real privilege is that granted to some particular place; as the king's palace, the courts at Westminster, the universities, &c. Privileges of the Clergy. See Clergy.

PRIVY, in Law, is a partaker, or person having an interest, in any action or thing. In this sense they say, privies in blood: every heir in tail is privy to recover the land entails. In old law-books, merchutis privy are opposed to merchants strangers. Coke mentions four kinds of privies. Privies in blood, as the heir to his father; privies in representation, as executors and administrators to the deceased; privies in estate, as he in reversion and he in remainder, donor and donee, lessor and lessee: lastly, privy in tenure, as the lord by escheat; i.e. when land escheats to the lord for want of heirs.

PRIVY-COUNCIL. See Council. The king's will is the sole constituent of a privy-councillor; and it also regulates their number, which in ancient times was about twelve. Afterwards it increased to so large a number, that it was found inconvenient for secrecy and dispatch; and therefore Charles II. in 1679, limited it to 30; whereof 15 were principal officers of state, and to be councillors ex officio; and the other 15 were composed of 10 lords and 5 commoners of the king's choosing. Since that time, however, the number has
has been much augmented, and now continues indefinite. At the same time also the ancient office of lord president of the council was revived, in the person of Anthony earl of Shaftesbury. Privy-counsellors are made by the king’s nomination, without either patent or grant; and, on taking the necessary oaths, they become immediately privy-councillors during the life of the king that chooses them, but subject to removal at his discretion.

Any natural born subject of England is capable of being a member of the privy-council; taking the proper oaths for security of the government, and the test for security of the church. By the act of settlement, 12 and 13 W. III. cap. 2, it is enacted, that no person born out of the dominions of the crown of England, unless born of English parents, even though naturalized by parliament, shall be capable of being a privy-councillor. The duty of a privy-counsellor appears from the oath of office, which consists of seven articles.

1. To advise the king according to the best of his cunning and discretion. 2. To advise for the king’s honour and good of the public, without partiality, through affection, love, meed, doubt, or dread. 3. To keep the king’s counsel secret. 4. To avoid corruption. 5. To help and strengthen the execution of what shall be there resolved. 6. To withstand all persons who would attempt the contrary. And, lastly, in general, 7. To observe, keep, and do all that a good and true counsellor ought to do to his sovereign lord.

The privy-council is the *primus mobile* of the state, and that which gives the motion and direction to all the inferior parts. It is likewise a court of justice of great antiquity, the primitive and ordinary way of government in England being by the king and privy-council. It has been frequently used by all our kings for determining controversies of great importance: the ordinary judges have sometimes declined giving judgment till they had consulted the king and privy-council; and the parliament have frequently referred matters of high moment to the same, as being by long experience better able to judge of, and by their secrecy and expedition, to transact some state affairs, than the lords and commons. At present, the privy-council takes cognizance of few or no matters except such as cannot well be determined by the known laws and ordinary courts; such as matters of complaint and sudden emergencies: their constant business being to consult for the public good in affairs of state. This power of the privy-council is to inquire into all offences against the government, and to commit the offenders to safe custody, in order to take their trial in some of the courts of law. But their jurisdiction herein is only to inquire, and not to punish; and the persons committed by them are intituled to their habeas corpus by statute 16 Car. I. cap. 10. as much as if committed by an ordinary justice of the peace.

In plantation or admiralty cases, which arise out of the jurisdiction of this kingdom, and in matters of lunacy and idiocy, the privy-council has cognizance, even in questions of extensive property, being the court of appeal in such causes; or, rather, the appeal lies to the king’s majesty himself in council. From all the dominions of the crown, excepting Great Britain and Ireland, an appellate jurisdiction (in the last resort) is vested in this tribunal; which usually exercises its judicial authority in a committee of the whole privy-council, who hear the allegations and proofs, and make their report to his majesty in council, by whom the judgment is finally given.

Anciently, to strike in the house of a privy-council, or elsewhere in his presence, was grievously punished: by 3 Hen. VII. cap. 14, if any of the king’s servants of his household conspire or imagine to take away the life of a privy-counsellor, it is felony, though nothing shall be done upon it; and by 9 Ann. cap. 16. it is enacted, that any persons who shall unlawfully attempt to kill, or shall unlawfully assault, and strike, or wound, any privy counsellor in the execution of his office, shall be felons, and suffer death as such. With advice of this council, the king issues proclamations that bind the subject, provided they be not contrary to law. In debates, the lowest delivers his opinion first, the king last; and thereby determines the matter. A council is never held without the presence of a secretary of state.

The dissolution of the privy-council depends upon the king’s pleasure; and he may, whenever he thinks proper, discharge any particular member, or the whole of it, and appoint another. By the common law also it was dissolved *ipso facto* by the king’s demise, as deriving all its authority from him. But now, to prevent the inconveniences of having no council in being at the accession of a new prince, it is enacted, by 6 Ann. cap. 7, that the privy-council shall continue for six months after the demise of the crown, unless sooner determined by the successor. *Blackst. Com.* book 1. p. 229, &c.

The officers of the privy-council are four clerks of the council in ordinary, three clerks extraordinary, a keeper of the records, and two keepers of the council-chamber. See President.

**PRIVY SEAL**, a seal which the king uses previously to such grants, &c. as are afterwards to pass the great seal.

The privy seal is also sometimes used in matters of less consequence, which do not require the great seal. **Lord Privy Seal.** See Keeper of the Privy Seal. **Clerks of the Privy Seal.** See Clerk. **Privy Chamber.** See Chamber. **PRIZE, or Prize,** in maritime affairs, a vessel taken at sea from the enemies of a state, or from pirates; and that either by a man of war, a privateer, &c. having a commission for that purpose.

Vessels are looked on as prize, if they fight under any other standard than that of the state from which they have their commission; if they have no charter-party, invoice, or bill of lading abroad; if loaded with effects belonging to the king’s enemies, or with contraband goods.

In ships of war, the prizes are to be divided among the officers, seamen, &c. as his majesty shall appoint by proclamation; but among privaters, the division is according to the agreement between the owners.

By stat. 13 Geo. II. c. 4, judges and officers, failing of their duty in respect to the condemnation of prizes, forfeit 500l. with full costs of suit; one moiety to the king, and the other to the informer.

**PROA, Flying,** in navigation, is a name given to a vessel used in the South seas, because with a brisk trade-wind.
of circumstances tending to the same point, though they Probability amount not to what, in strictness of language, should be called proof, afford to the mind a very high degree of evidence, upon which, with the addition of one direct testimony, the laws of many countries take away the life of a man.

Probability of an Event, in the Doctrine of Chances, is greater or less according to the number of chances by which it may happen or fail. (See Expectation). The probability of life is liable to rules of computation. In the Encyclopaedia Methodica, we find a table of the probabilities of the duration of life, constructed from that which is to be found in the seventh volume of the Supplément à l'Histoire de M. de Buffon, of which the following is an abridgement.

Of 23904 children born at the same time there will probably die

PROBATE of a will or testament, in Law, is the exhibiting and proving of last wills and testaments before the ecclesiastical judge delegated by the bishop, who is ordinary of the place where the party died.

PROBATION, in the universities, is the examination and trial of a student who is about to take his degree.

PROBATION, in a monastic sense, signifies the year of a novice, which a religious must pass in a convent, to prove his virtue and vocation, and whether he can bear the severities of the rule.

PROBATION, in Scots Law. See Law Index.

PROBATIONER, in the church of Scotland, a student in divinity, who bringing a certificate from a professor in an university of his good morals, and having performed his exercises to approbation, is admitted to undergo several trials; and, upon his acquitting himself properly in these, receives a licence to preach.

PROBATUM EST (It is proved), a term frequently subjoined to a receipt for the cure of some disease.

PROBE, a surgeon's instrument for examining the circumstances of wounds, ulcers, and other cavities, searching for stones in the bladder, &c.

PROBITY means honesty, sincerity, or veracity; and consists in the habit of actions useful to society, and in the constant observance of the laws which justice...
PROBLEM, in Logic, is a proposition that neither appears absolutely true nor false; and, consequently, may be asserted either in the affirmative or negative.

PROBLEM, in Geometry, is a proposition wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See Geometry.

PROBOSCIS, in Natural History, is the trunk or snout of an elephant, and some other animals and insects.

Flies, gnats, &c. are furnished with a proboscis or trunk; by means of which they suck the blood of animals, the juice of vegetables, &c. for their food.

PROBUS, Marcus Aurelius, was the son of a gardener, and became, by his great valour as a soldier, and his eminent virtues, emperor of Rome, to which dignity he was raised by the army. Having subdued the barbarous nations who made incursions into different parts of the empire, where they committed horrid cruelties, he managed the affairs of government with great wisdom and clemency. He was massacred in the year 282, and the 7th of his reign, by some soldiers who were weary of the public works at which he made them labour.

PROCATARCTIC CAUSE, in Medicine, the pre-existing, or predisposing cause or occasion of a disease.

PROCELESMATICUS, in the ancient poetry, a foot consisting of four short syllables, or two pyrrhythchus; as hominibus.

PROCELLARIA, a genus of birds, belonging to the order of anseres. See Ornithology Index. Clusius makes the procellaria pelagica or stormy petrel the Camilla of the sea.

Fel mare per medium fluctus suspenso tumenti
Ferret iter, celeres nec tingeret aequore plantas. VIRG.

She swept the seas; and, as she skimmed along
Her flying feet unbathed on billows hung. DRYDEN.

These birds are the cypselis of Pliny, which places among the apodes of Aristotle; not because they wanted feet, but were sanguo, or had bad or useless ones; an attribute he gives to these species, on a supposition that they were almost always on the wing.

PROCESS, in Law, denotes the proceedings in any cause, real or personal, civil or criminal, from the original writ to the end thereof.

In a more limited sense, process denotes that by which a man is called first into any temporal court.

It is the next step for carrying on the suit, after suing out the original writ. See SUIT and WRIT.

It is the method taken by the law to compel a compliance with the original writ, of which the primary step is by giving the party notice to obey it. This notice is given upon all real proceed; and also upon all personal writs for injuries not against the peace, by summons; which is a warning to appear in court at the return of the original writ, given to the defendant by Blaik, two of the sheriff’s messengers called summoners, either in person, or left at his house or land: in like manner as in the civil law the first process is by personal citation, in jus vocando. This warning on the land is given, in real actions, by erecting a white stick or wand on the defendant’s grounds (which stick or wand among the northern nations is called the baculus vincitorius), and by statute 31 Eliz. c. 3., the notice must also be proclaimed on some Sunday before the door of the parish church.

If the defendant disobeys this verbal mention, the next process is by writ of attachment, or pone; so called from the words of the writ, pone per vadum et salvo pliegos, “put by gage and safe pledges A. B. the defendant,” &c. This is a writ not issuing out of chancery, but out of the court of common pleas, being grounded on the non-appearance of the defendant at the return of the original writ; and thereby the sheriff is commanded to attach him, by taking gage, that is, certain of his goods, which he shall forfeit if he do not appear; or by making him find safe pledges or sureties, which shall be ascased in case of his non-appearance. This is the first and immediate process, without any previous summons, upon actions of trespasses et armis, or for other injuries, which though not forcible, are yet trespasses against the peace, as decretal conspiracy; where the violence of the wrong requires more speedy remedy, and therefore the original writ commands the defendant to be at once attached, without any precedent warning.

If, after attachment, the defendant neglects to appear, he not only forfeits this security, but is moreover to be farther compelled by writ of distraining, or distress infinite: which is a subsequent process issuing from the court of common pleas, commanding the sheriff to distrain the defendant from time to time, and continually afterwards, by taking his goods and the profits of his lands, which are called issues, and which he forfeits to the king if he do not appear. But the issues may be sold, if the court shall so direct, in order to defray the reasonable costs of the plaintiff. In like manner, by the civil law, if the defendant absconds, so that the citation is of no effect, militat adversarius in possessionem bonorum ejus.

And here, by the common as well as the civil law, the process ended in case of injuries without force: the defendant if he had any substance, being gradually stripped of it by all repeated distresses, till he rendered obedience to the king’s writ; and, if he had no substance, the law held him incapable of making satisfaction, and therefore looked upon all farther process as nugatory. And besides, upon feudal principles, the person of a feuodary was not liable to be attached for injuries merely civil, lest thereby his lord should be deprived of his personal services. But, in cases of injury accompanied with force, the law, to punish the breach of the peace and prevent its disturbance for the future, provided also a process against the defendant’s person, in case he neglected to appear upon the former process of attachment, or had no substance whereby to be attached; sub-
jecting his body to imprisonment by the writ of copias ad respondendum. But this immunity of the defendant’s person, in case of peaceable though fraudulent injuries, producing great contempt of the law in indigent wrong-doers, a copias was also allowed, to arrest the person in actions of account, though no breach of the peace be suggested, by the statutes of Marlbridge, 52 Hen. III. c. 23, and Westm. 2. 13. Edw. I. c. 11, in actions of debt and detinue, by statute 25 Edw. III. c. 17, and in all actions on the cause, by statute 10 Hen. VII. c. 9.

Before which last statute a practice had been introduced of commencing the suit by bringing an original writ of trespass quare clausum fregit, by breaking the plaintiff’s close, vi et armis, which; by the old common law, subjected the defendant’s person to be arrested by writ of copias: and then afterwards, by connivance of the court, the plaintiff might proceed to prosecute for any other less forcible injury. This practice (through custom rather than necessity, and for saving some trouble and expense, in suing out a special original adapted to the particular injury) still continues in almost all cases, except in actions on the case, but in that case, by virtue of the statutes above cited and others, a copias might be had upon almost every species of complaint.

If therefore the defendant, being summoned or attacked, makes default, and neglects to appear; or if the sheriff returns a nulla, or that the defendant hath nowhere be may be summoned, attacked, or distracted, the copias now usually issues: being a writ commanding the sheriff to take the body of the defendant, if he may be found in his bailiwick or county, and him safely to keep, so that he may have him in court on the day of the return, to answer to the plaintiff of a plea of debt, or trespass, &c. as the case may be. This writ, and all others subsequent to the original writ, not issuing out of chancery, but from the court into which the original was returnable, and being grounded on what has passed in that court in consequence of the sheriff’s return, are called judicial, not original, writs; they issue under the privy seal of that court, and not under the great seal of England, and are tested, not in the king’s court, but in that of the chief justice thereupon. And these several writs being grounded on the sheriff’s return, must respectively bear date the same day on which the writ immediately preceding was returnable.

This is the regular and orderly method of process. But it is now usual in practice to sue out the copias in the first instance, upon a supposed return of the sheriff; especially if it be suspected that the defendant, upon notice of the action, will abscond; and afterwards a fictitious original is drawn up, with a proper return thereupon, in order to give the proceedings a colour of regularity. When this copias is delivered to the sheriff, he by his under-sheriff grants a warrant to his inferior officers or bailiffs to execute it on the defendant. And, if the sheriff of Oxfordshire (in which county the injury is supposed to be committed and the action is laid) cannot find the defendant in his jurisdiction, he returns that he is not found, non est inventus, in his bailiwick: whereupon another writ issues, called a testatum copias, directed to the sheriff, in that county where the defendant is supposed to reside, as of Berkshire, reciting the former writ, and that it is testified, testatum est, that the defendant lurks or wanders in his bailiwick, where he is commanded to take him, as in the former copias. But here also, when the action is brought in one county and the defendant lives in another, it is usual, for saving trouble, time, and expense, to make out a testatum copias at the first; supposing not only an original, but also a former copias, to have been granted; which in fact never was. And this fiction, being beneficial to all parties, is readily acquiesced in, and is now become the settled practice; being one among many instances to illustrate that maxim of law, that in fictione juris consistit aequitas.

But where a defendant absconds, and the plaintiff would proceed to an outlawry against him, an original writ must then be sued out regularly, and after that a copias. And if the sheriff cannot find the defendant upon the first writ of copias, and returns a non est inventus, there issues out an alias writ, and after that a pluries, to the same effect as the former: only after these words “we command you,” this clause is inserted, “as we have formerly,” or, “as we have often commanded you?”—“sicuit alias,” or, “sicuit pluries proculosis.” And if a non est inventus is returned upon all of them, then a writ of exigent or exigent facias, which requires the sheriff to cause the defendant to be proclaimed, required or exacted, in five county-courts successively, to render himself; and if he does, then to take him, as in a copias; but if he does not appear, and is returned quinto exactus, he shall then be outlawed by the coroners of the county. Also by statute 6 Hen. VII. c. 4, and 31 Eliz. c. 3, whether the defendant dwells within the same or another county than that wherein the exigent is sued out, a writ of proclamation shall issue out at the same time with the exigent, commanding the sheriff of the county, wherein the defendant dwells, to make three proclamations thereof in places the most notorious, and most likely to come to his knowledge, a month before the outlawry shall take place. Such outlawry is putting a man out of the protection of the law, so that he is incapable to bring an action for redress of injuries; and it is also attended with a forfeiture of all one’s goods and chattels to the king. And therefore, till some time after the conduit, no man could be outlawed but for felony: but in Bracton’s time, and somewhat earlier, process of outlawry was ordained to lie in all actions for trespasses vi et armis. And since, by a variety of statutes (the same which allow the writ of copias before mentioned) process of outlawry doth lie in divers actions that are merely civil; providing they be commenced by original and not by bill. If after outlawry the defendant appears publicly, he may be arrested by a writ of copias utlaggerum, and committed till the outlawry be reversed. Which reversal may be had by the defendants appearing personally in court (and in the king’s bench without any personal appearance, so that he appears by attorney, according to statute 4 & 5 W. & M. c. 18.) and any plausible cause, however slight, will in general be sufficient to reverse it, being considered only as a process to compel an appearance. But then the defendant must pay full costs, and put the plaintiff in the same condition as if he had appeared before the writ of exigent facias was awarded.

Such is the first process in the court of common pleas. In the king’s bench they may also (and frequently do) proceed in certain causes, particularly in actions of ejectment and trespass, by original writ, with attachment and copias thereon; returnable, not at Westminster, where

the common pleas are now fixed in consequence of magnum charta, but ubique fuerimus in Anglia, wheresoever the king shall then be in England; the king's bench being removable into any part of England at the pleasure and discretion of the crown. But the more usual method of proceeding therein is without any original, but by a peculiar species of process entitled a bill of Middlesex; and therefore so entitled, because the court now sits in that county; for if it sat in Kent, it would then be a bill of Kent. For, though, as the justices of this court have, by its fundamental constitution, power to determine all offences and trespasses, by the common law and custom of the realm, it needed no original writ from the crown to give it cognizance of any misdemeanour in the county wherein it resides; yet as, by this court's coming into any county, it immediately superseded the ordinary administration of justice by the general commissioners of eyre and of oyer and terminer, a process of its own became necessary, within the county where it sat, to bring in such persons as were accused of committing any forcible injury. The bill of Middlesex (which was formerly always founded on a plaint of trespass quare clausum fregit, entered on the records of the court) is a kind of copias, directed to the sheriff of that county, and commanding him to take the defendant, and have him before our lord the king at Westminster on a day prefixed, to answer to the plaintiff of a plea of trespass. For this accusation of trespass it is that gives the court of king's bench jurisdiction in other civil causes, since, when once the defendant is taken into custody of the marshal, or prison-keeper of this court, for the supposed trespass, he being then a prisoner of this court, may here be prosecuted for any other species of injury. Yet, in order to found this jurisdiction, it is not necessary that the defendant be actually the marshal's prisoner; for, as soon as he appears, or puts in bail, to the process, he is deemed by so doing to be in such custody of the marshal as will give the court a jurisdiction to proceed. And, upon these accounts, in the bill or process, a complaint of trespass is always suggested, whatever else may be the real cause of action. This bill of Middlesex must be served on the defendant by the sheriff, if he finds him in that county: but if he returns, non est inventus, then there issues out a writ of latitatum, to the sheriff of another county, as Berks: which is similar to the testatum copias in the common pleas, and recites the bill of Middlesex and the proceedings thereon, and that it is testified that the defendant latitatum et discurririt, lurks and wanders about in Berks; and therefore commands the sheriff to take him, and have his body in court on the day of the return. But as in the common pleas the testatum copias may be sued out upon only a supposed, and not an actual proceeding, so in the king's bench a latitatum is usually sued out upon only a supposed, and not an actual, bill of Middlesex. So that, in fact, a latitatum may be called the first process in the court of king's bench, as the testatum copias is in the common pleas. Yet, as in the common pleas, if the defendant lives in the county wherein the action is laid, a common copias suffices; so in the king's bench likewise, if he lives in Middlesex, the process must still be by bill of Middlesex only.

In the exchequer the first process is by writ of quo minus, in order to give the court jurisdiction over pleas between party and party. In which writ the plaintiff is alleged to be the king's farmer or debtor, and that the defendant hath done him the injury complained of, quo minus sufficiens existit, by which he is the less able to pay the king his rent or debt. And upon this the defendant may be arrested as upon a copias from the common pleas.

Thus differently do the three courts set out at first, in the commencement of a suit, in order to entitle the two courts of king's bench and exchequer to hold pleas in subjects causes, which by the original constitution of Westminster-hall they were not empowered to do. Afterwards, when the case is once drawn into the respective courts, the method of pursuing it is pretty much the same in all of them.

If the sheriff had found the defendant upon any of the former writs, the copias latitatum, &c. he was anciently obliged to take him into custody, in order to produce him in court upon the return, however small and minute the cause of action might be. For, not having obeyed the original summons, he had shown a contempt of the court, and was no longer to be trusted at large. But when the summons fell into disuse, and the copias became in fact the first process, it was thought hard to imprison a man for a contempt which was only supposed: and therefore, in common cases, by the gradual indulgence of the courts (at length authorised by statute 12 Geo. I. c. 29, which was amended by statute 5 Geo. II. c. 27, and made perpetual by statute 21 Geo. II. c. 3.) the sheriff or his officer can now only personally serve the defendant with the copy of the writ or process, and with notice in writing to appear by his attorney in court to defend this action, which in effect reduces it to a mere summons. And if the defendant think proper to appear upon this notice, his appearance is recorded, and he puts in sureties for his future attendance and obedience; which sureties are called common bail, being the same two imaginary persons that were pledges for the plaintiff's prosecution, John Doe and Richard Roe. Or, if the defendant does not appear upon the return of the writ, or within four (or in some cases eight) days after, the plaintiff may enter an appearance for him, as if he had really appeared; and may file common bail in the defendant's name, and proceed thereupon as if the defendant had done it himself.

But if the plaintiff will make affidavit, or assert upon oath, that the cause of action amounts to ten pounds or upwards, then in order to arrest the defendant, and make him put in substantial sureties for his appearance, called special bail, it is required by statute 13 Car. II. stat. 2. c. 2. that the true cause of action should be expressed in the body of the writ or process; else no security can be taken in a greater sum than 40l. This statute (without any such intention on the makers') had like to have ousted the king's bench of all its jurisdiction over civil injuries without force; for as the bill of Middlesex was framed only for actions of trespass, a defendant could not be arrested and held to bail thereupon for breaches of civil contracts. But to remedy this inconvenience, the officers of the king's bench devised a method of adding what is called a clause of occasitiam to the usual complaint of trespass; the bill of Middlesex commanding the defendant to be brought in to answer the plaintiff of a plea of trespass, and also to a bill of debt: the complaint or trespass giving cognizance to the court, and that of debt authorising the arrest.
In imitation of which, lord chief justice North, a few years afterwards, in order to save the suits of his court the trouble and expense of suing out special originals, directed, that in the common pleas, besides the usual complaint of breaking the plaintiff's close, a clause of ac etiam might also be added to the writ of capias, containing the true cause of action; as, "that the said Charles the defendant may answer to the plaintiff of a plea of trespass in breaking his close; and also, ac etiam may answer him, according to the custom of the court, in a certain plea of trespass upon the case, upon promises, to the value of 20l. &c." The sum sworn to by the plaintiff is marked upon the back of the writ; and the sheriff, or his officer the bailiff, is then obliged actually to arrest or take into custody the body of the defendant, and, having so done, to return the writ with a cess corpus indorsed thereon. See ARREST.

When the defendant is regularly arrested, he must either go to prison, for safe custody; or put in special bail to the sheriff. For, the intent of the arrest being only to compel an appearance in court at the return of the writ, that purpose is equally answered, whether the sheriff arrests his person, or takes sufficient security for his appearance, called bail (from the French word bailer, "to deliver," because the defendant is bailed, or delivered, to his sureties, upon their giving security for his appearance; and is supposed to continue in their friendly custody instead of going to gaol. See BAIL.

The method of putting in bail to the sheriff is, by entering into a bond or obligation, with one or more sureties, (not fictitious persons, as in the former case of common bail, but real, substantial, responsible bondsmen,) to insure the defendant's appearance at the return of the writ; which obligation is called the bail-bond. The sheriff, if he pleases, may let the defendant go without any sureties; but that is at his own peril: for, after once taking him, the sheriff is bound to keep him safely, so as to be forthcoming in court; otherwise an action lies against him for an escape. But on the other hand, he is obliged, by statute 23 Hen. VI. c. 10. to take (if it be tendered) a sufficient bail-bond; and, by statute 12 Geo. I. c. 29. the sheriff shall take bail for another sum than such as is sworn to by the plaintiff, and indorsed on the back of the writ.

Upon the return of the writ, or within four days after, the defendant must appear according to the exigency of the writ. This appearance is effected by putting in and justifying bail to the action; which is commonly called putting in bail above. If this be not done, and the bail that were taken by the sheriff below are responsible persons, the plaintiff may take an assignment from the sheriff of the bail-bond (under the statute 4 and 5 Ann. c. 16.) and bring an action thereupon against the sheriff's bail. But if the bail so accepted by the sheriff be insolvent persons, the plaintiff may proceed against the sheriff himself, by calling upon him, first to return the writ (if not already done), and afterwards to bring in the body of the defendant. And if the sheriff does not then cause sufficient bail to be put in above, he will himself be responsible to the plaintiff.

The bail above, or bail to the action, must be put in either in open court, or before one of the judges thereof; or else, in the country, before a commissioner appointed for that purpose by virtue of the statute 4 W. and M. c. 4. which must be transmitted to the court.

These bail, who must at least be two in number, must enter into a recognizance in court, or before the judge or commissioner, whereby they do jointly and severally undertake, that if the defendant be condemned in the action, he shall pay the costs and condemnation, or render himself a prisoner, or that they will pay it for him: which recognizance is transmitted to the court in a slip of parchment, intitled a bail-piece. And, if required, the bail must justify themselves in court, or before the commissioner in the country, by swearing themselves housekeepers, and each of them to be worth double the sum for which they are bail, after payment of all their debts. This answers in some measure to the stipulatio or satisdatio of the Roman laws, which is mutually given by each litigant party to the other: by the plaintiff that he will prosecute his suit, and pay the costs if he loses his cause; in like manner as our law still requires nominal pledges of prosecution from the plaintiff: by the defendant, that he shall continue in court, and abide the sentence of the judge, much like our special bail; but with this difference, that the fidiusjusors were there absolutely bound judicium solvere, to see the costs and condemnation paid at all events: whereas our special bail may be discharged, by surrendering the defendant into custody within the time allowed by law; for which purpose they are at all times entitled to a warrant to apprehend him.

Special bail is required (as of course) only upon actions of debt, or actions on the case in trover, or for money due, where the plaintiff can swear that the cause of action amounts to ten pounds: but in actions where the damages are precarious, being to be assessed ad libitum by a jury, as in actions for words, ejectment, or trespass, it is very seldom possible for a plaintiff to swear to the amount of his cause of action; and therefore no special bail is taken thereon, unless by a judge's order, or the particular directions of the court, in some particular species of injuries, as in cases of mayhem or atrocious battery; or upon such special circumstances as make it absolutely necessary that the defendant should be kept within the reach of justice. Also in actions against heirs, executors, and administratores, for debts of the deceased, special bail is not demanded: for the action is not so properly against them in person, as against the effects of the deceased in their possession. But special bail is required even of them, in actions for a devastavit, or wasting the goods of the deceased; that wrong being of their own committing.

Thus much for process; which is only meant to bring the defendant into court, in order to contest the suit, and abide the determination of the law. When he appears either in person as a prisoner, or out upon bail, then follow the pleadings between the parties. See PLEADINGS.

Process upon an Indictment. See PROSECUTION. The proper process on an indictment for any petty misdemeanor, or on a penal statute, is a writ of venire fascias, which is in the nature of a summons to cause the party to appear. And if by the return to such venire it appears that the party hath lands in the county where-by he may be distrained, then a distress infinite shall be issued from time to time till he appears. But if the sheriff returns, that he hath no lands in the bailiwick, then (upon his non-appearance) a writ of conspiracy shall issue, which commands the sheriff to take his body, and have
have him at the next assizes; and if he cannot be taken upon the first copias, a second and a third shall issue, called an *alias* and a *pluris copias*. But, on indictments for treason or felony, a *copias* is the first process: and, for treason or homicide, only one shall be allowed to issue, or two in the case of other felonies, by statute 25 Edw. III. c. 14, though the usage is to issue only one in any felony; the provisions of this statute being in most cases found impracticable. And so in the case of misdemeanors, it is now the usual practice for any judge of the court of king’s bench, upon certificate of an indictment found, to award a writ of *copias* immediately, in order to bring in the defendant. But if he absconds, and it is thought proper to pursue him to an outlawry, then a greater exactness is necessary. For, in such case, after the several writs have issued in a regular number, according to the nature of the respective crimes, without any effect, the offender shall be put in the *exigent* in order to his outlawry: that is, he shall be exacted, proclaimed, or required, to surrender at five county-courts; and if he be returned *quinto exactus*, and does not appear at the fifth exaction or requisition, then he is adjudged to be outlawed or put out of the protection of the law; so that he is incapable of taking the benefit of it in any respect, either by bringing actions or otherwise.

The punishment for outlawries upon indictments for misdemeanors, is the same as for outlawries upon civil actions; viz. forfeiture of goods and chattels. But an outlawry in treason or felony amounts to a conviction and attainer of the offence charged in the indictment, as much as if the offender had been found guilty by his country. His life is, however, still under the protection of the law, as hath elsewhere been observed; (see *Homicide*): that though anciently an outlawed felon was said to have *caput lapinum*, and might be knocked on the head like a wolf, by any one that should meet him; because, having renounced all law, he was to be dealt with as in a state of nature, when every law that should find him might slay him; yet now, to avoid such inhumanity, it is held that no man is intitled to kill him wantonly or wilfully; but in so doing is guilty of murder, unless it happens in the endeavour to apprehend him. For any person may arrest an outlaw on a criminal prosecution, either of his own head, or by writ or warrant of *copias uitulatam*, in order to bring him to execution. But such outlawry may be frequently reversed by writ of error, the proceedings therein being (as it is fit they should be) exceedingly nice and circumstantial; and if any single minute point be omitted or misconducted, the whole outlawry is illegal, and may be reversed; upon which reversal the party accused is admitted to plead to, and defend himself against, the indictment.

Thus much for process to bring in the offender after indictment found; during which stage of the prosecution it is that writs of *certiorari facias* are usually had, though they may be had at any time before trial, to certify and remove the indictment, with all the proceedings thereon, from any inferior court of criminal jurisdiction into the court of king’s bench; which is the sovereign ordinary court of justice in causes criminal. And this is frequently done for one or these four purposes; either, 1. To consider and determine the validity of appeals or indictments and the proceedings thereon; and to quash or confirm them as there is cause; or, 2. Where it is surmised that a partial or insufficient trial will probably be had in the court below, the indictment is removed, in order to have the prisoner or defendant tried at the bar of the court of king’s bench, or before the justices of *nisi prius*; or, 3. It is so removed, in order to plead the king’s pardon there; or, 4. To issue process of outlawry against the offender, in those counties or places where the process of the inferior judges will not reach him. Such writ of *certiorari*, when issued and delivered to the inferior court for removing any record or other proceeding, as well upon indictment as otherwise, supersedes the jurisdiction of such inferior court, and makes all subsequent proceedings therein entirely erroneous and illegal; unless the court of king’s bench reminds the record to the court below, to be there tried and determined. A *certiorari* may be granted at the instance of either the prosecutor or the defendant: the former as a matter of right, the latter as a matter of discretion; and therefore it is seldom granted to remove indictments from the justices of gaol-delivery, or after issue joined, or confession of the fact in any of the courts below.

At this stage of prosecution also it is, that indigcentness found by the grand jury against a person, must in consequence of a writ of *certiorari*, be certified and transmitted into the court of parliament, or into that of the lord high steward of Great Britain; and that, in places of exclusive jurisdiction, as the two universities, indictment must be delivered (upon challenge and claim of cognizance) to the courts therein established by charter, and confirmed by act of parliament, to be there respectively tried and determined. See Plea.

**Process**, in *Chemistry*, the whole course of an experiment or series of operations, tending to produce something new.

**Process**, in *Anatomy*, denotes any protuberance or eminence in a bone.

**Procession**, a ceremony in the Roman church, consisting of a formal march of the clergy and people, putting up prayers, &c. and in this manner visiting some church, &c. They have also processions of the host or sacrament, &c. See Host.

**Prochein Amy**, in law, the person next of kin to a child in non-age, and who, in that respect, is allowed to act for him, and be his guardian, &c. if he be hold land in soccage.

To sue, an infant is not allowed to make an attorney; but the court will admit his next friend as plaintiff, or his guardian as defendant.

**Prockia**, a genus of plants belonging to the polyandra class; and in the natural method ranking with those of which the order is doubtful. See Botany Index.

**Proclamation**, a public notice given of any thing of which the king thinks proper to advertise his subjects.

Proclamations are a branch of the king’s prerogative; and have then a binding force, when (as Sir Edward Coke observes) they are grounded upon and enforce the laws of the realm. For though the making of laws is entirely the work of a distinct part, the legislative branch of the sovereign power, yet the manner, time, and circumstances of putting those laws in execution, must frequently be left to the discretion of the executive magistrate. And therefore his constitutions or edicts, concerning those points which we call

Proclamations,
Proclamations, are binding upon the subject, where they do not either contradict the old laws, or tend to establish new ones; but only enforce the execution of such laws as are already in being, in such manner as the king shall judge necessary. Thus the established law is, that the king may prohibit any of his subjects from leaving the realm: a proclamation therefore forbidding this in general for three weeks, by laying an embargo upon all shipping in time of war, will be equally binding as an act of parliament, because founded upon a prior law. But a proclamation to lay an embargo in time of peace upon all vessels laden with wheat, (though in the time of a public scarcity,) being contrary to law, and particularly to statute 22 Car. II. c. 15. the advisers of such a proclamation, and all persons acting under it, found it necessary to be indemnified by a special act of parliament, 7 Geo. III. c. 7. A proclamation for disarming Papists is also binding, being only in execution of what the legislature has first ordained: but a proclamation for allowing arms to Papists, or for disarming any Protestant subjects, will not bind; because the first would be to assume a dispensing power, the latter a legislative one; to the vesting of either of which in any single person the laws of England are absolutely strangers. Indeed, by the stat. 31 Hen. VIII. c. 8. it was enacted, that the king’s proclamations should have the force of acts of parliament; a statute, which was calculated to introduce the most despotic tyranny: and which must have proved fatal to the liberties of this kingdom, had it not been luckily repealed in the minority of his successor, about four years after. By a late act of parliament the king is empowered to raise regiments of Roman Catholics to serve in the present war.

Proclus, surnamed Diadoces, a Greek philosopher and mathematician, was born in Lycia, and lived about the year 500. He was the disciple of Syrius, and had a great share in the friendship of the emperor Anastasius. It is said, that when Vitalian laid siege to Constantinople, Proclus burnt his ships with large braziers speculums. This philosopher was a Pagan, and wrote against the Christian religion. There are still extant his Commentaries on some of Plato’s books, and other of his works written in Greek.

Proconsul, a Roman magistrate, sent to govern a province with consular authority.

The proconsuls were appointed out of the body of the senate; and usually as the year of any one’s consulate expired, he was sent proconsul into some province.

The proconsuls decided cases of equity and justice, either privately in their prætorium or palace, where they received petitions, heard complaints, granted writs under their seal, and the like; or else publicly, in the common hall, with the usual formalities observed in the court of judicature at Rome. They had besides, by virtue of their edicts, the power of ordering all things relating to the tributes, taxes, contributions, and provisions of corn and money, &c. Their office lasted only a year. See Consul.

Procopius, a famous Greek historian, born in Cesarea, acquired great reputation by his works in the reign of Justinian, and was secretary to Belisarius during all the wars carried on by that general in Persia, Africa, and Italy. He at length became senator, obtained the title of illustrious, and was made pretor of Constantinople.

Procration, the begetting and bringing forth young. See Generation and Semen.

Proctor, a person commissioned to manage another person’s cause in any court of the civil or ecclesiastical law.

Proctor, in the English universities. See University.

Procuration, an act or instrument by which a person is empowered to treat, transact, receive, &c. in another person’s name.

Procurator. See Proctor.

Procyon, in Astronomy, a fixed star of the second magnitude, situated in canis minor, or the little dog.

Prodigality, means extravagance, profusion, waste, or excessive liberality, and is the opposite extreme to the vice of parsimony. By the Roman law, if a man by notorious prodigality was in danger of wasting his estate, he was looked upon as non compositus, and committed to the care of curators, or tutors, by the praetor. And by the laws of Solon, such prodigals were branded with perpetual infamy.

Product, in Arithmetic and Geometry, the factum of two or more numbers, or lines, &c. into one another: thus $5 \times 4 = 20$ the product required.

Proedri, among the Athenians, were magistrates, who had the first seats in the public assemblies, and whose office it was to propose at each assembly the things to be deliberated upon and determined. Their office always ended with the meeting. Their number was nine, so long as the tribes were ten in number.

Profanation, the acting disrespectfully to sacred things.

Profane, a term used in opposition to holy; and in general is applied to all persons who have not the sacred character, and to things which do not belong to the service of religion.

Profession means a calling, vocation, or known employment. In Knox’s Essays, vol. i. page 234, we find an excellent paper on the choice of a profession, which that elegant writer concludes thus: “All the occupations of life (says he) are found to have their advantages and disadvantages admirably adapted to preserve the just equilibrium of happiness. This we may confidently assert, that whatever are the inconveniences of any of them, they are all preferable to a life of inaction; to that wretched listlessness, which is constrained to pursue pleasure as a business, and by rendering it the object of severe and unvaried attention, destroys its very essence.”

Among the Romanists profession denotes the entering into a religious order, whereby a person offers himself to God by a vow of inviolably observing obedience, chastity, and poverty.

Professor, in the universities, a person who teaches or reads public lectures in some art or science from a chair for that purpose.

Profil-e, in Architecture, the draught of a building, fortification, &c. wherein are expressed the several heights, widths, and thicknesses, such as they would appear were the building cut down perpendicularly from the roof to the foundation. Whence the prefix is also called the section, sometimes orthographical section, and by Vitruvius also stignography.
Profile, in this sense, amounts to the same with elevation; and stands opposed to plan or ichnography. Profile is also used for the contour or outline of a figure, building, member of architecture, or the like; as a base, a cornice, &c. Hence profiling is sometimes used for designing, or describing the member with rule, compass, &c.

Profile, in sculpture and painting.—A head, a portrait, &c. are said to be in profile, when they are represented sidewise, or in a side-view; as, when in a portrait there is but one side of the face, one eye, one cheek, &c. shown, and nothing of the other. On almost all medals, the faces are represented in profile.

PROFLUVIUM, in Medicine, denotes a flux, or liquid evacuation of any thing.

PROGNOSTIC, among physicians, signifies a judge-

Thus

\[
\begin{align*}
& a, a+d, a+2d, a+3d, \ldots, & \text{&c. increasing} \\
& a, a-d, a-2d, a-3d, \ldots, & \text{&c. decreasing}
\end{align*}
\]

In numbers

\[
\begin{align*}
2, 4, 6, 8, 10, \ldots, & \text{&c. increasing} \\
10, 8, 6, 4, 2, \ldots, & \text{&c. decreasing}
\end{align*}
\]

Geometric Progression, or Continued Geometric Proportion, is when the terms do increase or decrease by equal ratios: thus,

\[
\begin{align*}
a, \frac{a}{r}, \frac{a}{r^2}, \frac{a}{r^3}, \ldots, & \text{&c. increasing} \\
2, 4, 8, 16, 32, 64, \ldots, & \text{&c. decreasing}
\end{align*}
\]

See the articles Fluxions, Geometry, and Series.

PROJECTILES.

This is the name for that part of mechanical philosophy which treats of the motion of bodies anyhow projected from the surface of this earth, and influenced by the action of terrestrial gravity.

It is demonstrated in the physical part of astronomy, that a body so projected must describe a conic section, having the centre of the earth in one focus; and that it will describe round that focus areas proportional to the times. And it follows from the principles of that science, that if the velocity of projection exceeds 36700 feet in a second, the body (if not resisted by the air) would describe a hyperbola; if it be just 36700, it would describe a parabola; and if it be less than this, it would describe an ellipse. If projected directly upwards, in the first case, it would never return, but proceed for ever; its velocity continually diminishing, but never becoming less than an assignable portion of the excess of the initial velocity above 36700 feet in a second; in the second case, it would never return, its velocity would diminish without end, but never be extinguished. In the third case, it would proceed till its velocity was reduced to an assignable portion of the difference between 36700 and its initial velocity; and would then return, regaining its velocity by the same degrees, and in the same places, as it lost it. These are necessary consequences of a gravity directed to the centre of the earth, and inversely proportional to the square of the distance. But in the greatest projections that we are able to make, the gravitations are so nearly equal, and in directions so nearly parallel, that it would be ridiculous affectation to pay any regard to the deviations from equality and parallelism. A bullet rising a mile above the surface of the earth loses only \( \frac{1}{2000} \) of its weight, and a horizontal range of 4 miles makes only \( \frac{1}{10} \) of deviation from parallelism.

Let us therefore assume gravitation as equal and parallel. The errors arising from this assumption are quite insensible in all the uses which can be made of this theory.

The theory itself will ever be regarded with some veneration and affection by the learned. It was the first fruits of mathematical philosophy. Galileo was the first who applied mathematical knowledge to the motions of free bodies, and this was the subject on which he exercised his fine genius.

Gravity must be considered by us as a constant or uniform accelerating or retarding force, according as it uniformly produces the descent, or retards the ascent, of a body. A constant or invariable accelerating force is one which produces an uniform acceleration; that is, which in equal times produces equal increments of velocity, and therefore produces increments of velocity proportional to the times in which they are produced. Forces are of themselves imperceptible, and are seen only in their effects; and they have no measure but the effect, or what measures the effect; and every thing which we can discover with regard to those measures, we must affirm with regard to the things of which we assume them as the measures. Therefore,
The motion of a falling body, or of a body projected directly downwards, is uniformly accelerated; and that of a body projected directly upwards is uniformly retarded: that is, the acquired velocities are as the times in which they are acquired by falling, and the extinguished velocities are as the times in which they are extinguished.

Cor. 1. If bodies simply fall, not being projected downwards by an external force, the times of the falls are proportional to the final velocities; and the times of ascents, which terminate by the action of gravity alone, are proportional to the initial velocities.

2. The spaces described by a heavy body falling from rest are as the squares of the acquired velocities; and the differences of these spaces are as the differences of the squares of the acquired velocities; and, on the other hand, the heights to which bodies projected upwards will rise, before their motions be extinguished, are as the squares of the initial velocities.

3. The spaces described by falling bodies are proportional to the squares of the times from the beginning of the fall; and the spaces described by bodies projected directly upwards are as the squares of the times of the ascents.

4. The space described by a body falling from rest is one half of the space which the body would have uniformly described in the same time, with the velocity acquired by the fall. And the height to which a body will rise, in opposition to the action of gravity, is one half of the space which it would uniformly describe in the same time with the initial velocity.

In like manner the difference of the spaces which a falling or rising body describes in any equal successive parts of its fall or rise, is one half of the space which it would uniformly describe in the same time with the difference of the initial and final velocities.

This proposition will be more conveniently expressed for our purpose thus: A body moving uniformly during the time of any fall with the velocity acquired thereby, will in that time describe a space double of that fall; and a body projected directly upwards will rise to a height which is one half of the space which it would, uniformly continued, describe in the time of its ascent with the initial velocity of projection.

These theorems have already been demonstrated in a popular way, in the article GUNNERY. But we would recommend to our readers the 39th prop. of the first book of Newton's Principia, as giving the most general investigation of this subject; equally easy with these more loose methods of demonstration, and infinitely superior to them, by being equally applicable to every variation of the accelerating force. See an excellent application of this proposition by Mr. Robins, for defining the motion of a ball discharged from a cannon, in the article GUNNERY, No. 15.

It is a matter of observation and experience, that a heavy body falls 16 feet and an inch English measure in a second of time; and therefore acquires the velocity of 32 feet 2 inches per second. This cannot be ascertained directly, with the precision that is necessary. A second is too small a portion of time to be exactly measured and compared with the space described; but it is done with the greatest accuracy by comparing the motion of a falling body with that of a pendulum. The time of a vibration is to the time of falling through half the length of the pendulum, as the circumference of a circle is to its diameter. The length of a pendulum can be ascertained with great precision; and it can be lengthened or shortened till it makes just 86,400 vibrations in a day: and this is the way in which the space fallen through in a second has been accurately ascertained.

As all other forces are ascertained by the accelerations which they produce, they are conveniently measured by comparing their accelerations with the acceleration of gravity. This therefore has been assumed by all the later and best writers on mechanical philosophy, as the unit by which every other force is measured. It gives us a perfectly distinct notion of the force which retains the moon in its orbit, when we say it is the 360th part of the weight of the moon at the surface of the earth. We mean by this, that if a bullet were here weighed by a spring steelyard, and pulled it out to the end, it would make 3600; if it were then taken to the distance of the moon, it would pull it out only to the mark 1. And we make this assertion on the authority of our having observed that a body at the distance of the moon falls from that distance 1 in 30 part of 16 feet in a second.

We do not, therefore, compare the forces, which are imperceptible things; we compare the accelerations, which are their indications, effects, and measures.

This has made philosophers so anxious to determine two modes with precision, the fall of heavy bodies, in order to have an exact value of the accelerating power of terrestrial fall of heavy bodies. Now we must here observe, that this measure of the space may be taken in two ways: we may take the space through which the heavy body falls in a second; or we may take the velocity which it acquires in consequence of gravity having acted on it during a second. The last is the proper measure; for the last is the immediate effect on the body. The action of gravity has changed the state of the body—in what way? By giving it a determination to motion downwards, this both points out the kind and the degree or intensity of the force of gravity. The space described in a second by falling, is not an invariable measure; for, in the successive seconds, the body falls through 16, 48, 80, 112, &c. feet, but the changes of the body's state in each second is the same. At the beginning it had no determination to move with any appreciable velocity; at the end of the first second it had a determination by which it would have gone on for ever (had no subsequent force acted on it) at the rate of 32 feet per second. At the end of the second second, it had a determination by which it would have moved for ever, at the rate of 64 feet per second. At the end of the third second, it had a determination by which it would have moved for ever, at the rate of 96 feet per second, &c. &c. The difference of these determinations is a determination to the rate of 32 feet per second. This is therefore constant, and the indication and proper measure of the constant or invariable force of gravity. The space fallen through in the first second is of use only as it is one half of the measure of this determination; and as halves have the proportion of their wholer, different accelerating forces may be safely affirmed to be in the proportion of the spaces through which they uniformly impel bodies in the same time. But we should always recollect, that this is but one half of the true measure of the accelerating force. Mathematicians of the first rank have
have committed great mistakes by not attending to this; and it is necessary to notice it just now, because cases will occur in the prosecution of this subject, where we shall be very apt to confound our reasonings by a confusion in the use of those measures. Those mathematicians who are accustomed to the geometrical consideration of curvilinear motions, are generally disposed to take the actual deflection from the tangent as the measure of the deflecting force; while those who treat the same subject algebraically, by the assistance of fluxions, take the change of velocity, which is measured by twice the deflection. The reason is this: when a body passes through the point B of a curve ABC, fig. 1, if the deflecting force were to cease at that instant, the body would describe the tangent BD in the same time in which it describes the arch BC of the curve, and DC is the deflection, and is therefore taken for the measure of the deflecting force. But the algebraist is accustomed to consider the curve by means of an equation between the abscissae $x, y$, and their respective ordinates $a, b, c$; and he measures the deflections by the changes made on the increments of the ordinates. Thus the increment of the ordinate $a$, while the body describes the arch $AB$ of the curve, is $BG$. If the deflecting force were to cease when the body is at $B$, the next increment would have been equal to $BG, that is, it would have been $EF$; but in consequence of the deflection, it is only $CF$: therefore he takes $EC$ for the measure of the deflection, and of the deflecting force. Now $EC$ is ultimately twice $DC$; and thus the measure of the algebraist (derived solely from the nature of the differential method, and without any regard to physical considerations) happens to coincide with the true physical measure. There is therefore great danger of mixing these measures. Of this we cannot give a more remarkable instance than Leibnitz's attempt to demonstrate the elliptical motion of the planets in the Leipsic Acts, 1689. He first considers the subject mechanically, and takes the deflection or DC for the measure of the deflecting force. He then introduces his differential calculus, where he takes the difference of the increments for the measure; and thus brings himself into a confusion, which luckily compensates for the false reasoning in the preceding part of his paper, and gives his result the appearance of a demonstration of Newton's great discovery, while, in fact, it is a confused jumble of assumptions, self-contradictory, and inconsistent with the very laws of mechanics which are used by him in the investigation. Seventeen years after this, in 1706, having been criticised for his bad reasoning, or rather accused of an envious and unsuccessful attempt to appropriate Newton's invention to himself, he gives a correction of his paralogism, which he calls a correction of language. But he either had not observed where the paralogism lay, or would not let himself down by acknowledging a mistake in what he wished the world to think his own calculus (fluxions); he applied the correction where no fault had been committed, for he had measured both the centrifugal force and the solicitation of gravity in the same way, but had applied the fluxionary expression to the last and not to the first; and, by so doing, he completely destroyed all coincidence between his result and the planetary motions. We mention this instance, not only as a caution to our mathematical readers, but also as a very curious literary anecdote. This dissertation of Leibnitz is one of the most obscure of his obscure writings, but deserves the attention of an intelligent and curious reader, and cannot fail of making an indelible impression on his mind, with relation to the modesty, candour, and probity of the author. It is preceded by a dissertation on the subject which we are now entering upon, the motion of projectiles in a resisting medium. Newton's Principia had been published a few years before, and had been reviewed in a manner shamefully slight, in the Leipsic Acts. Both these subjects make the capital articles of that immortal work. Mr Leibnitz published these dissertations, without (says he) having seen Newton's book, in order to show the world that he had, some years before, discovered the same theorems. Mr Nicholas Fatio carried a copy of the Principia from the author to Hanover in 1686, where he expected to find Mr Leibnitz; he was then absent, but Fatio saw him often before his return to France in 1687, and does not say that the book was not given him. Read along with these dissertations Dr Keill's letter to John Bernoulli and others, published in the Journal Litteraire de la Haye 1714, and to John Bernoulli in 1719.

Newton has been accused of a similar oversight by Dr Keill. John Bernoulli, who indeed calls it a mistake in principle in his Proposition x. book 2. on the very subject we are now considering. But Dr Keill has shown it to be only an oversight, in drawing the tangent on the wrong side of the ordinate. For in this very proposition Newton exhibits, in the strictest and most beautiful manner, the difference between the geometrical and algebraical manner of considering the subject, and expressly warns the reader, that his algebraical symbol expresses the deflection only, and not the variation of the increment of the ordinate. It is therefore in the last degree improbable that he would make this mistake. He most expressly does not; and as to the real mistake, which he corrected in the second edition, the writer of this article has in his possession a manuscript copy of notes and illustrations on the whole Principia, written in 1693 by Dr David Gregory, Savilian professor of astronomy at Oxford, at the desire of Mr Newton, as preparatory for a new edition, where he has rectified this and several other mistakes in that work, and says that Mr Newton had seen and approved of the amendments. We mention these particulars, because Mr Bernoulli published an elegant dissertation on this subject in the Leipsic Acts in 1713, in which he charges Newton (though with many protestations of admiration and respect) with this mistake in principle; and says, that he communicated his correction to Mr Newton, by his nephew Nicholas Bernoulli, that it might be corrected in the new edition, which he heard was in the press. And he afterwards adds, that it appeared by some sheets being cancelled, and new ones substituted in this part of the work, that the mistake would have continued, had he not corrected it. We would desire our readers to consult this dissertation, which is extremely elegant, and will be of service to us in this article; and let them compare the civil things which is here said of the vir incomparabilis, omni laude major, the summus Newtonus, with what the same author, in the same year, in the Leipsic Acts, but under a borrowed name, says of him. Our readers will have no hesitation in ascribing this letter to this author. For, after praising John Bernoulli as summus geometer, notus
PROJECTILES.

Natus ad summorum geometrarum paralogismos corrigendos, summi candoris ut et modestie, he betrays himself by an unguarded warmth, when defending J. B.'s demonstration of the inverse problem of centripetal forces, by calling it MEAM demonstrationem.

Let our readers now consider the scope and intention of this dissertation on projectiles, and judge whether the author's aim was to instruct the world, or to acquire fame, by correcting Newton. The dissertation does not contain one theorem, one corollary, nor one step of argument, which is not to be found in Newton's first edition; nor has he gone farther than Newton's single proposition the xth. To us it appears an exact companion to his proposition on centripetal forces, which he boasts of having first demonstrated, although it is in every step a transcript of the 42d of the first Book of Newton's Principia, the geometrical language of Newton being changed into algebraic, as he has in the present case changed Newton's algebraic analysis into a very elegant geometrical one.

We hope to be forgiven for this long digression. It is a very curious piece of literary history, and shows the combination which envy and want of honourable principle had formed against the reputation of our illustrious countryman; and we think it our duty to embrace any opportunity of doing it justice.—To return to our subject:

The accurate measure of the accelerative power of gravity, is the fall \[16\frac{2}{3}\] feet, if we measure it by the space, or the velocity of \[32\frac{1}{3}\] feet per second, if we take the velocity. It will greatly facilitate calculation, and will be sufficiently exact for all our purposes, if we take 16 and 32, supposing that a body falls 16 feet in a second, and acquires the velocity of 32 feet per second. Then, because the heights are as the squares of the times, and as the squares of the acquired velocities, a body will fall one foot in one fourth of a second, and will acquire the velocity of eight feet per second. Now let \(h\) express the height in feet, and call it the producing height; \(v\) the velocity in feet per second, and call it the produced velocity, the velocity due; and \(t\) the time in seconds. We shall have the following formula, which are of easy recollection, and will serve, without tables, to answer all questions relative to projectiles.

I. \[v = 8 \sqrt{h} = 8 \times 4 = 32t\]

II. \[t = \frac{\sqrt{h}}{4} = \frac{v}{32}\]

III. \[\sqrt{h} = \frac{v}{8} = 4t\]

IV. \[h = \frac{v^2}{64} = 16t^2\]

Examples and their use.

1. To find the time of falling through 256 feet. Here \(h = 256, \sqrt{256} = 16, \text{ and } 16 = 4\). Answer 4.

2. To find the velocity acquired by falling four seconds. \(t = 4, 32 \times 4 = 128\) feet per second.

3. To find the velocity acquired by falling 625 feet. \(h = 625, \sqrt{625} = 25, 8 \sqrt{h} = 200\) feet per second.

4. To find the height to which a body will rise when projected with the velocity of 36 feet per second, or the height through which a body must fall to acquire this velocity.

\[v = 36, \frac{8}{3} = 7, = \sqrt{h}, 7^2 = h, = 49\] feet.

or \[56^2 = 3136, \frac{3136}{64} = 49\] feet.

5. Suppose a body projected directly downwards with the velocity of 10 feet per second; what will be its velocity downwards after four seconds? In four seconds it will have acquired, by the action of gravity, the velocity of \(4 \times 32\), or 128 feet, and therefore its whole velocity will be 138 feet per second.

6. To find how far it will have moved, compound its motion of projection, which will be 40 feet in four seconds, with the motion which gravity alone would have given it in that time, which is 256 feet; and the whole motion will be 296 feet.

7. Suppose the body projected as already mentioned, and that it is required to determine the time it will take to go 296 feet downwards, and the velocity it will have acquired.

Find the height \(x\), through which it must fall to acquire the velocity of projection, 10 feet, and the time \(t\) of falling from this height. Then find the time of falling through the height 296 + \(x\), and the velocity \(v\) acquired by this fall. The time of describing the 296 feet will be \(t\) = \(t\), and \(v\) is the velocity required.

From such examples, it is easy to see the way of answering every question of the kind.

Writers on the higher parts of mechanics always more generally compute the actions of other accelerating and retarding forces by comparing them with the acceleration of gravity, and in order torender their expressions more general, use a symbol, such as \(g\) for gravity, leaving the reader to convert it into numbers. Agreeably to this view, the general formulæ will stand thus:

I. \[v = \sqrt{2gh}, \text{ i.e. } \sqrt{2gh} = g t,\]

II. \[t = \frac{\sqrt{h}}{g} = \sqrt{\frac{h}{g}} = \sqrt{\frac{2h}{g}}\]

III. \[h = \frac{v^2}{2g}\]

In all these equations, gravity, or its accelerating power, is estimated as it ought to be, by the change of velocity which it generates in a particle of matter in an unit of time. But many mathematicians, in their investigations of curvilinear and other varied motions, measure it by the deflection which it produces in this time from the tangent of the curve, or by the increment by which the space described in an unit of time exceeds the space described in the preceding unit. This is but one half of the increment which gravity would have produced, had the body moved through the whole moment with the acquired addition of velocity. In this sense of the symbol \(g\), the equations stand thus:

I. \[v = 2\sqrt{gh} = 2g t\]

II. \[t = \frac{\sqrt{h}}{g} = \frac{v}{g}, \text{ and } \sqrt{h} = \frac{v}{2g}\]

It is also very usual to consider the accelerating force
of gravity as the unit of comparison. This renders the expressions much more simple. In this way, \( v \) expresses not the velocity, but the height necessary for acquiring it, and the velocity itself is expressed by \( \sqrt{v} \). To reduce such an expression of a velocity to numbers, we must multiply it by \( \sqrt{2g} \) or by \( 2\sqrt{g} \); according as we make \( g \) to be the generated velocity, or the space fallen through in the unit of time.

This will suffice for the perpendicular ascents or descents of heavy bodies, and we proceed to consider their motions when projected obliquely. The circumstance which renders this an interesting subject, is, that the flight of cannon shot and shells are instances of such motion, and the art of gunnery must in a great measure depend on this doctrine.

Let a body \( B \) (fig. 2), be projected in any direction \( BC \), not perpendicular to the horizon, and with any velocity. Let \( AB \) be the height producing this velocity; that is, let the velocity be that which a heavy body would acquire by falling freely through \( AB \). It is required to determine the path of the body, and all the circumstances of its motion in this path?

1. It is evident, that by the continual action of gravity, the body will be continually deflected from the line \( BC \), and will describe a curve line \( B V G \), concave towards the earth.

2. This curve line is a parabola, of which the vertical line \( ABF \) is a diameter, \( B \) the vertex of this diameter, and \( BC \) a tangent in \( B \).

Through any two points \( V, G \) of the curve draw \( VC, GH \) parallel to \( AB \), meeting \( BC \) in \( C \) and \( H \), and draw \( VE, GK \) parallel to \( BC \), meeting \( AB \) in \( E, K \). It follows, from the composition of motions, that the body would arrive at the points \( V, G \) of the curve in the same time that it would have uniformly described \( BC, BH \), with the velocity of projection; or that it would have fallen through \( BE, BK \), with a motion uniformly accelerated by gravity; therefore the times of describing \( BC, BH \) uniformly, are the same with the times of falling through \( BE, BK \). But, because the motion along \( BH \) is uniform, \( BC \) is to \( BH \) as the time of describing \( BC \) to the time of describing \( BH \), which we may express thus, \( BC : BH = T : T \); \( BC : BH = \sqrt{T} \). But, because the motion along \( BK \) is uniformly accelerated, we have \( BE : BK = BE : \sqrt{T} \), \( \sqrt{E} = \sqrt{BC} : BH \), \( = \sqrt{EV} : K \); therefore the curve \( B V G \) is such, that the abscissae \( BE \), \( BK \) are the squares of the corresponding ordinates \( EV, KG \); that is, the curve \( B V G \) is a parabola, and \( BC \), parallel to the ordinates, is a tangent in the point \( B \).

3. If through the point \( A \) there be drawn the horizontal line \( AD \), it is the directrix of the parabola.

Let \( BE \) be taken equal to \( AB \). The time of falling through \( BE \) is equal to the time of falling through \( AB \); but \( BC \) is described with the velocity acquired by falling through \( AB \); and therefore by \( \sqrt{g} \), of perpendicular descents, \( BC \) is double of \( AB \), and \( EV \) is double of \( BE \); therefore \( EV = 2BE \), \( = 4 \sqrt{BE} \times AB \), and \( 4 \sqrt{BE} \) is the parameter or latus rectum of the parabola \( B V G \), and \( AB \) being one-fourth of the parameter, \( AD \) is the directrix.

4. The times of describing the different arches \( BV \), \( VG \) of the parabola are as the portions \( BC, BH \) of the tangent, or as the portions \( AD, d \) of the directrix, intercepted by the same vertical lines \( AB, CV, HG \); for the times of describing \( BV, VG \) are the same with those of describing the corresponding parts \( BC, BH \) of the tangent, and are proportional to those parts, because the motion along \( BH \) is uniform; and \( BC, BH \) are proportional to \( AD, d \).

Therefore the motion estimated horizontally is uniform.

5. The velocity in any point \( G \) of the curve is the same with that which a heavy body would acquire by falling from the directrix along \( dG \). Draw the tangent \( GT \), cutting the vertical \( AB \) in \( T \); take the points \( a, f \), equidistant from \( A \) and \( d \), and extremely near them, and draw the verticals \( ab, fg \); let the points \( a, f \), continually approach \( A \) and \( d \), and ultimately coincide with them. It is evident that \( Bb \) will ultimately be to \( gG \), in the ratio of the velocity at \( B \) to the velocity at \( G \); for the portions of the tangent ultimately coincide with the portions of the curve, and are described in equal times; but \( Bb \) is to \( gG \) as \( BH \) to \( TG \); therefore the velocity at \( B \) is to that at \( G \) as \( BH \) to \( TG \). But, by the properties of the parabola, \( BH \) is to \( TG \) as \( AB \) to \( dG \); and \( AB \) is to \( dG \) as the square of the velocity acquired by falling through \( AB \) to the square of the velocity acquired by falling through \( dG \); and the velocity in \( BH \), or in the point \( B \) of the parabola, is the velocity acquired by falling along \( AB \); therefore the velocity in \( BG \), or in the point \( G \) of the parabola, is the velocity acquired by falling along \( dG \).

These few simple propositions contain all the theory of the motion of projectiles in vacuo, or independent of the resistance of the air; and being a very easy and neat piece of mathematical philosophy, and connected with very interesting practice, and a very respectable profession, they have been much commented on, and have furnished matter for many splendid volumes. But the air's resistance occasions such a prodigious diminution of motion in the great velocities of military projectiles, that this parabolic theory, as it is called, is hardly of any use. A musket ball, discharged with the ordinary allotment of powder, issues from the piece with the velocity of 1670 feet per second; this velocity would be acquired by falling from the height of 80 feet. If the piece be elevated to an angle of 45°, the parabola should be of such extent that it would reach 16 miles on the horizontal plain; whereas it does not reach above half a mile. Similar deficiencies are observed in the ranges of cannon shot.

We do not propose, therefore, to dwell much on this short theory, and shall only give such a synoptical view of it as shall make our readers understand the more general circumstances of the theory, and be masters of the language of the art.

Let \( OB \) (fig. 3.) be a vertical line. About the Fig. 3. centres \( A \) and \( B \), with the distance \( AB \), describe the semicircles \( ODB, AHK \), and with the axis \( AB \), and semiaxis \( GE \), equal to \( AB \), describe the semi-ellipse \( AEB \); with the focus \( B \), vertex \( A \), diameter \( AB \), and tangent \( AD \), parallel to the horizon, describe the parabola \( APS \).

Let a body be projected from \( B \), in any direction \( BC \).
PROJECTILES.

BC, with the velocity acquired by falling through AB. By what has already been demonstrated, it will describe a parabola BVPM. Then,

1. ADL parallel to the horizon is the directrix of every parabola which can be described by a body projected from B with this velocity. This is evident.

2. The semicircle AHK is the focus of all the foci of these parabolas. For the distance BH of a point B of any parabola from the directrix AD is equal to its distance BF from the focus F of that parabola; therefore the foci of all the parabolas which pass through B, and have AD for their directrix, must be in the circumference of the circle which has AB for its radius, and B for its centre.

3. If the line of direction BC cut the upper semicircle in C, and the vertical line CF be drawn, cutting the lower semicircle in F, F is the focus of the parabola BVPM, described by the body which is projected in the direction BC, with the velocity acquired by falling through BA: for drawing AC, BF, it is evident that ACFB is a rhombus, and that the angle AFB is bisected by BC, and therefore the lines in the face BF; but it also lies in the circumference ACFK, and therefore in F.

If C is in the upper quadrant of ODB, F is in the upper quadrant of AFG; and if C be in the lower quadrant of ODB (as when BC is the line of direction) then the focus of the corresponding parabola BcM is in the lower quadrant of AHF, as at f.

4. The ellipse AEF is the focus of the vertex of all the parabolas, and the vertex V of any one of them BVPM is in the intersection of this ellipse with the vertical CF; for let this vertical cut the horizontal lines AD, CE, BN, in a, λ, N. Then it is plain that NA is half of Nλ, and λV is half of Vc; therefore NV is half of NC, and V is the vertex of the axis.

If the focus is in the upper or lower quadrant of the circle AHE, the vertex is in the upper or the lower quadrant of the ellipse AEF.

5. If BP be drawn through the focus of any one of the parabolas, such as BVPM, cutting the parabola APS in P, the parabola BVPM touches the parabola APS in P: for drawing PX parallel to AB, cutting the directrix Ox of the parabola APS in x, and the directrix AL of the parabola BVPM in z, then PB = Px; but BF = BA = AO = aλ; therefore Pz = PF, and the point P is in the parabola BVPM. Also the tangents to both parabolas in P coincide for they bisect the angle xPB; therefore the two parabolas having a common tangent, touching each other in P.

Cor. All the parabolas which can be described by a body projected from B, with the velocity acquired by falling through AB, will touch the concavity of the parabola APS, and lie wholly within it.

6. P is the most distant point of the line BP which can be hit by a body projected from B with the velocity acquired by falling through AB. For if the direction is more elevated than BC, the focus of the parabola described by the body will lie between F and A, and the parabola will touch APS in some point between P and A; and being wholly within the parabola APS, it must cut the line BP in some point within P. The same thing may be shown when the direction is less elevated than BC.

7. The parabola APS is the focus of the greatest ranges on any planes BP, BS, &c. and no point lying without this parabola can be struck.

8. The greatest range on any plane BP is produced when the line of direction BC bisects the angle OBP formed by that plane with the vertical: for the parabola described by the body in this case touches APS in P, and its focus is in the line BP, and therefore the tangent BC bisects the angle OBP.

Cor. The greatest range on a horizontal plane is made with an elevation of 45°.

9. A point M in any plane BS, lying between B and S, may be struck with two directions, BC and BE; and these directions are equidistant from the direction Bt, which gives the greatest range on that plane: for if about the centre M, with the distance ML from the directrix AL, we describe a circle LMt, it will cut the circle AIHK in two points F and f, which are evidently the foci of two parabolas BV, BtM, having the directrix AL and diameter ABK. The intersection of the circle ODB, with the vertical FC, fC, determine the directions BC, Bc of the tangents. Draw A t parallel to BS, and join t B, Cc F; then OB = ft GBS, and B t is the direction which gives the greatest range on the plane BS: but because FC is the chord of the circles described round the centres B and M, FF is perpendicular to BM, and Cc to A t, and the arches Ct, ct are equal; and therefore the angles CB t, cB t are equal.

Thus we have given a general view of the subject, which shows the connection and dependence of every circumstance which can influence the result; for it is evident that to every velocity of projection there belongs a set of parabolas, with their directions and ranges, and every change of velocity has a line AB corresponding to it, to which all the others are proportional. As the height necessary for acquiring any velocity increases or diminishes in the duplicate proportion of that velocity, it is evident that all the ranges with given elevations will vary in the same proportion, a double velocity giving a quadruple range, a triple velocity giving a nuncupule range, &c. And, on the other hand, when the ranges are determined beforehand (which is the usual case), the velocities are in the subduplicate proportion of the ranges. A quadruple range will require a double velocity, &c.

On the principles now established is founded the ordnary theory of gunnery, furnishing rules which are to principally direct the art of throwing shot and shells, so as to hit the mark with a determined velocity.

But we must observe, that this theory is of little service for directing us in the practice of cannonading.

Here it is necessary to come as near as we can to the object aimed at, and the hurry of service allows no time for geometrical methods of pointing the piece after each discharge. The gunner either points the cannon directly to the object, when within 200 or 300 yards of it, in which case he is said to shoot point blank (pointer au blanc, i.e. at the white mark in the middle of the gunners target); or, if at a greater distance, he estimates to the best of his judgment the deflection corresponding to his distance, and points the cannon accordingly. In this he is aided by the greater thickness at the breech of a piece of ordnance. Or lastly, when the intention is not to batter, but to rake along a line occupied.
occupied by the enemy, the cannon is elevated at a considerable angle, and the shot discharged with a small force, so that it drops into the enemy's post, and bounds along the line. In all these services the gunner is directed entirely by trial, and we cannot say that this parabolic theory can do him any service.

The principal use of it is to direct the bombardier in throwing shells. With these it is proposed to break down or set fire to buildings, to break through the vaulted roofs of magazines, or to intimidate and kill troops by bursting among them. These objects are always under cover of the enemy's work, and cannot be touched by a direct shot. The bombs and carcasses are therefore thrown upwards, so as to get over the defences and produce their effect.

These shells are of very great weight, frequently exceeding 200 lbs. The mortars from which they are discharged must therefore be very strong, that they may resist the explosion of gunpowder which is necessary for throwing such a mass of matter to a distance; they are consequently unwieldy, and it is found most convenient to make them almost a solid and immovable lump. Very little change can be made in their elevation, and therefore their ranges are regulated by the velocities given to the shell. These again are produced by the quantities of powder in the charge; and experience (confirming the best theoretical notions that we can form of the subject) has taught us, that the ranges are nearly proportional to the quantities of powder employed, only not increasing quite so fast. This method is much easier than by differences of elevation; for we can select the elevation which gives the greatest range on the given plane, and then we are certain that we are employing the smallest quantity of powder with which the service can be performed: and we have another advantage, that the deviations which unavoidable causes produce in the real directions of the bomb will then produce the smallest possible deviation from the intended range. This is the case in most mathematical maxima.

In military projectiles the velocity is produced by the explosion of a quantity of gunpowder; but in our theory it is conceived as produced by a fall from a certain height, by the proportions of which we can accurately determine its quantity. Thus a velocity of 1600 feet per second is produced by a fall from the height of 4000 feet, or 1333 yards.

Fig. 4.

The height CA (fig. 4.) for producing the velocity of projection is called, in the language of gunnery, the IMPETUS. We shall express it by the symbol h.

The distance AB to which the shell goes on any plane AB is called the AMPLITUDE of the RANGE, r.

It is evident that AZ : AD = S, ADZ = S, AZD, = S, DBA = S, DAB, = S, p = S, e

And AD : DB = S, DBA = S, DAB, = S, p = S, e

And DB : AB = S, DAB = S, DBA, = S, e = S, w

Therefore AZ : AB = S, p = S, e = S, w, and 4 S, p = S, e = S, w, and 4 S = S, w, and 4 S, p = S, w

Hence we obtain the relations wanted.

Thus h = r S, p = 4 S, e = S, w, and r = 4 S, e = S, w

And S, w = r S, p = 4 S, e = S, w, and S, e = r S, p = 4 S, e = S, w

The only other circumstance in which we are interested is the time of the flight. A knowledge of this is necessary for the bombardier, that he may cut the fuse of his shells to such lengths as that they may burst at the very instant of their hitting the mark.

Now AB : DB = S, DAB = S, DAB, = S, z = S, e, and DB = S, z. But the time of the flight is
the same with the time of falling through DB, and 16 feet : DB = 17 : t". Hence \( t" = \frac{r \times 5.5}{16 S, s^2} \) and we have

the following easy rule.

From the sum of the logarithms of the range, and of the sine of elevation, subtract the sum of the logarithms of 16, and of the sine of the zenith distance, half the remainder is the logarithm of the time in seconds.

This becomes still easier in practice; for the mortar should be so elevated that the range is a maximum : in which case AB = DB, and then half the difference of the logarithms of AB and of 16 is the logarithm of the time in seconds.

Such are the deductions from the general propositions which constitute the ordinary theory of gunnery. It remains to compare them with experiment.

In such experiments as can be performed with great accuracy in a chamber, the coincidence is as great as can be wished. A jet of water, or mercury, gives us the finest example, because we have the whole parabola exhibited to us in the simultaneous places of the succeeding particles. Yet even in these experiments a deviation can be observed. When the jet is made on a horizontal plane, and the curve carefully traced on a perpendicular plane held close by it, it is found that the distance between the highest point of the curve and the mark is less than the distance between it and the spout, and that the descending branch of the curve is more perpendicular than the ascending branch. And this difference is more remarkable as the jet is made with greater velocity, and reaches to a greater distance. This is evidently produced by the resistance of the air, which diminishes the velocity, without affecting the gravity of the projectile. It is still more sensible in the motion of bombs. These can be traced through the air by the light of their fuses; and we see that their highest point is always much nearer to the mark than to the mortar on a horizontal plane.

The greatest horizontal range on this plane should be when the elevation is 45°. It is always found to be much lower.

The ranges on this plane should be as the sines of twice the elevation.

A ball discharged at the elev. 19° 5' ranged 445 yards at 9:45 330

It should have ranged by theory 241

The range at an elevation of 45° should be twice the impetus. Mr Robins found that a musket-ball, discharged with the usual allotment of powder, had the velocity of 1700 feet in a second. This requires a fall of 45156 feet, and the range should be 90312, or 17½ miles: whereas it does not much exceed half a mile. A 24 pound ball discharged with 16 pounds of powder should range about 16 miles; whereas it is generally short of 3 miles.

Such facts show incontrovertibly how deficient the parabolic theory is, and how unfit for directing the practice of the artillerist. A very simple consideration is sufficient for rendering this obvious to the most un instructed. The resistance of the air to a very light body may greatly exceed its weight. Any one will feel this in trying to move a fan very rapidly through the air; therefore this resistance would occasion a greater deviation from uniform motion than gravity would in that body. Its path, therefore, through the air may differ more from a parabola than the parabola itself deviates from the straight line.

It is for such cogent reasons that we presume to say, that the voluminous treatises which have been published on this subject are nothing but ingenious amusements for young mathematicians. Few persons who have been much engaged in the study of mechanical philosophy have missed this opportunity in the beginning of their studies. The subject is easy. Some property of the parabola occurs, by which they can give a neat and systematic solution of all the questions; and at this time of study it seems a considerable essay of skill. They are tempted to write a book on the subject; and it finds readers among other young mechanicians, and employs all the mathematical knowledge that most of the young gentlemen of the military profession are possessed of. But these performances deserve little attention from the practical artillerist. All that seems possible to do for his education is, to multiply judicious experiments on real pieces of ordnance, with the charges that are used in actual service, and to furnish him with tables calculated from such experiments.

These observations will serve to justify us for having given so concise an account of this doctrine of the parabolic flight of bodies.

But it is the business of a philosopher to inquire into the causes of such a prodigious deviation from a well-defined theory, and having discovered them, to ascertain precisely the deviations they occasion. Thus we shall obtain another theory, either in the form of the parabolic theory corrected, or as a subject of independent discussion. This we shall now attempt.

The motion of projectiles is performed in the atmo sphere. The air is displaced, or put in motion. What the atmosphere it requires must be taken from the bullet. Sphere. The motion communicated to the air must be in the proportion of the quantity of air put in motion, and of the velocity communicated to it. If, therefore, the displaced air be always similarly displaced, whatever be the velocity of the bullet, the motion communicated to it, and lost by the bullet, must be proportional to the square of the velocity of the bullet and to the density of the air jointly. Therefore the diminution of its motion must be greater when the motion itself is greater, and in the very great velocity of shot and shells it must be prodigious. It appears from Mr Robins's experiments that a globe of 4½ inches in diameter, moving with the velocity of 25 feet in a second, sustained a resistance of 31.5 grains, nearly 1 of an ounce. Suppose this ball to move 800 feet in a second, that in 32 times faster; its resistance would be 32×32 times 1 of an ounce, or 768 ounces or 48 pounds. This is four times the weight of a ball of cast iron of this diameter; and if the initial velocity had been 1600 feet per second, the resistance would be at least 16 times the weight of the ball. It is indeed much greater than this.

This resistance, operating constantly and uniformly on the ball, must take away four times as much from its velocity as its gravity would do in the same time.

We know that in one second gravity would reduce the velocity 800 to 768 if the ball were projected straight upwards. This resistance of the air would therefore reduce it in one second to 672, if it operated uniformly; but as the velocity diminishes continually by the resistance, and the resistance diminishes along with the velocity,
city, the real diminution will be somewhat less than 128 feet. We shall, however, see afterwards that in one second its velocity will be reduced from 800 to 687. From this simple instance, we see that the resistance of the air must occasion great deviation from parabolic motion.

In order to judge accurately of its effect, we must consider it as a retarding force, in the same way as we consider gravity. The weight \( W \) of a body is the aggregate of the action of the force of gravity \( g \) on each particle of the body. Suppose the number of equal particles, or the quantity of matter, of a body to be \( M \), then \( W \) is equivalent to \( gM \). In like manner, the resistance \( R \), which we observe in any experiment, is the aggregate of the action of a retarding force \( R' \) on each particle, and is equivalent to \( R'M \); and as \( g \) is equal to \( W/M \), so \( R' \) is equal to \( R/M \). We shall keep this distinction in view, by adding the differential mark \( \prime \) to the letter \( R \) or \( r \), which expresses the aggregate resistance.

If we, in this manner, consider resistance as a retarding force, we can compare it with any other such force by means of the retardation which it produces in similar circumstances. We would compare it with gravity by comparing the diminution of velocity which its uniform action produces in a given time with the diminution produced in the same time by gravity. But we have no opportunity of doing this directly; for when the resistance of the air diminishes the velocity of a body, it diminishes it gradually, which occasions a gradual diminution of its own intensity. This is not the case with gravity, which has the same action on a body in motion or at rest. We cannot, therefore, observe the uniform action of the air's resistance as a retarding force. We must fall on some other way of making the comparison. We can state them both as dead pressures. A ball may be fitted to the rod of a spring stilliard, and exposed to impulse of the wind. This will compress the stilliard to the mark 3, for instance. Perhaps the weight of the ball will compress it to the mark 6. We know that half this weight would compress it to 3. We account this equal to the pressure of the air, because they balance the same elasticity of the spring. And in this way we can estimate the resistance by weights, whose pressures are equal to its pressure, and we can thus compare it with other resistances, weights, or any other pressures. In fact, we are measuring them all by the elasticity of the spring. This elasticity in its different positions is supposed to have the proportions of the weights which keep it in these positions. Thus we reason from the nature of gravity, no longer considered as a dead pressure, but as a retarding force; and we apply our conclusions to resistances which exhibit the same pressures, but which we cannot make to act uniformly. This sense of the words must be carefully remembered whenever we speak of resistances in pounds and ounces.

The most direct and convenient way of stating the comparison between the resistance of the air and the accelerating force of gravity, is to take a case in which we know that they are equal. Since the resistance is here assumed as proportional to the square of the velocity, it is evident that the velocity may be so increased that the resistance shall equal or exceed the weight of the body. If a body be already moving downwards with this velocity, it cannot accelerate; because the accelerating force of gravity is balanced by an equal retarding force of resistance. It follows from this remark, that this velocity is the greatest that a body can acquire by the force of gravity only. Nay, we shall afterwards see that it never can completely attain it; because as it approaches to this velocity, the remaining accelerating force decreases faster than the velocity increases. It may therefore be called the limiting or terminal velocity by gravity.

Let \( a \) be the height through which a heavy body must fall, in vacuo, to acquire its terminal velocity in air. If projected directly upwards with this velocity, it will rise again to this height, and the height is half the space which it would describe uniformly, with this velocity, in the time of its ascent. Therefore the resistance to this velocity being equal to the weight of the body, it would extinguish this velocity, by its uniform action, in the same time, and after the same distance, that gravity would.

Now let \( g \) be the velocity which gravity generates or extinguishes during an unit of time, and let \( v \) be the terminal velocity of any particular body. The theorems for perpendicular ascents give us \( g = \frac{2a}{a^2} \), \( a \) and \( a \) being both numbers representing units of space; therefore, in the present case, we have \( v' = \frac{2n}{v} \). The whole resistance \( r \), or \( rM \), is supposed equal to the weight, or to \( gM \); and therefore \( r' = \frac{g}{2a} \), and \( v = \frac{g}{3a} \). There is a consideration which ought to have place here. A body descends in air, not by the whole of its weight, but by the excess of its weight above that of the air which it displaces. It descends by its specific gravity only as a stone does in water. Suppose a body 32 times heavier than air, it will be buoyed up by a force equal to \( \frac{1}{32} \) of its weight; and instead of acquiring the velocity of 32 feet in a second, it will only acquire a velocity of \( 31 \), even though it sustained no resistance from the inertia of the air. Let \( p \) be the weight of the body and \( \pi \) that of an equal bulk of air: the accelerative force of relative gravity on each particle will be \( g \times \pi = \frac{2\pi}{p} \); and this relative accelerative force might be distinguished by another symbol \( \gamma \). But in all cases in which we have any interest, and particularly in military projectiles, \( \pi \) is so small a quantity that it would be pedantic affectation to attend to it. It is much more than compensated when we make \( g \equiv 32 \) feet instead of \( 32^\frac{1}{2} \) which it should be.

Let \( e \) be the time of this ascent in opposition to gravity. The same theorems give us \( e = 2a \); and since the resistance competent to this terminal velocity is equal to gravity, \( e \) will also be the time in which it would be extinguished by the uniform action of the resistance; for which reason we may call it the extinguishing time for this velocity. Let \( R \) and \( E \) mark the resistance and extinguishing time for the same body moving with the velocity 1.

Since the resistances are as the squares of the velocities, and the resistance to the velocity \( u \) is \( \frac{u^2}{2a} \), \( R \) will
PROJECTILES.

be \(\frac{1}{2a}\). Moreover, the times in which the same velocity will be extinguished by different forces, acting uniformly, are inversely as the forces, and gravity would extinguish the velocity in the time \(\frac{1}{g}\) (in these measures) to \(\frac{1}{u_0} = \frac{2a}{u^2}\). Therefore we have the following proportion \(\frac{1}{2a} = \frac{2a}{u^2}\) and \(2a\) is equal to \(E\), the time in which the velocity will be extinguished by the uniform action of the resistance competent to this velocity.

The velocity would in this case be extinguished after a motion uniformly retarded, in which the space described is one-half of what would be uniformly described during the same time with the constant velocity. Therefore the space thus described by a motion which begins with the velocity \(v\), and is uniformly retarded by the resistance competent to this velocity, is equal to the height through which this body must fall in vacuo in order to acquire its terminal velocity in air.

All these circumstances may be conceived in a manner which, to some readers, will be more familiar and palpable. The terminal velocity is that where the resistance of the air balances and is equal to the weight of the body. The resistance of the air to any particular body is as the square of the velocity; therefore let \(R\) be the whole resistance to the body moving with the velocity \(v\), and \(r\) the resistance to its motion with the terminal velocity \(u\); we must have \(r = R \times \frac{u^2}{v^2}\), and this must be \(= W\) the weight. Therefore, to obtain the terminal velocity, divide the weight by the resistance to the body \(v^2\), and the quotient is the square of the terminal velocity, or \(\frac{W}{R} = u^2\). And this is a very expeditious method of determining it, if \(R\) be previously known.

Then the common theorems give \(a\), the fall necessary for producing this velocity in vacuo \(= \frac{1}{2a}\), and the time of the fall \(= \frac{1}{g}\), and \(uv = 2a\), \(=\) the space uniformly described with the velocity \(u\) during the time of the fall, or its equal, the time of the extinction by the uniform action of the resistance \(r\); and, since \(r\) extinguishes it in the time \(\frac{1}{g}\), which is \(u^2\) times smaller, will extinguish it in the time \(\frac{1}{u^2}\), and \(R\) will extinguish the velocity \(v\), which is \(u\) times less than \(u\), in the time \(\frac{1}{u}\), that is, in the time \(2a\); and the body, moving uniformly during the time \(2a\), \(= E\), with the velocity \(v\), will describe the space \(2a\); and, if the body begin to move with the velocity \(v\), and be uniformly opposed by the resistance \(R\), it will be brought to rest when it has described the space \(2a\); and the space in which the resistance to the velocity \(v\) will extinguish that velocity by its uniform action, is equal to the height through which that body must fall in vacuo in order to acquire its terminal velocity in air. And thus every thing is regulated by the time \(E\) in which the velocity \(v\) is extinguished by the uniform action of the corresponding resistance, or by \(2a\), which is the space uniformly described during this time, with the velocity \(v\). And \(E\) and \(2a\) must be expressed by the same number. It is a number of units, of time, or of length.

Having ascertained these leading circumstances for the computation of the resistance of an object of any other magnitude, we shall always make the similar circumstances for any other magnitude, in order to avoid unnecessary complications, we shall always suppose the bodies to be spheres, differing only in diameter and density.

First, then, let the velocity be increased in the ratio of \(1\) to \(v\).

The resistance will now be \(\frac{1}{2a} \times \frac{u^2}{v^2} = \frac{r}{v}\), and \(v = 2a\); so that the rule is general, that the space along which any velocity will be extinguished by the uniform action of the corresponding resistance, is equal to the height necessary for communicating the terminal velocity to that body by gravity. For \(v = 2a\) in the space through which the body moves while the velocity \(v\) is extinguished by the uniform resistance.

In the 2d place, let the diameter increase in the proportion of \(1\) to \(d\). The aggregate of the resistance changes in the proportion of the surface similarly resisted, that is, in the proportion of \(1\) to \(d^2\). But the quantity of matter, or number of particles among which this resistance is to be distributed, changes in the proportion of \(1\) to \(d^2\). Therefore the retarding power of the resistance changes in the proportion of \(1\) to \(d^2\). When the diameter was \(1\), the resistance to a velocity \(v\) was \(\frac{1}{2a}\). It must now be \(\frac{1}{2a}\). The time in which this diminished resistance will extinguish the velocity \(v\) must increase in the proportion of the diminution of force, and must now be \(E \times d\), or \(2a\), and the space uniformly described during this time with the initial velocity \(1\) was \(2a\); and this must still be twice the height necessary for communicating the terminal velocity to this body. We must still have \(g = \frac{u^2}{2a}\), and therefore \(w = \frac{2a}{a}\); and \(w = \frac{\sqrt{2g}}{\sqrt{a}}\); and the height necessary for communicating it is \(a\). Therefore the terminal velocity varies in the subduplicate ratio of the diameter of the ball, and the fall necessary for producing it varies in the simple ratio of the diameter. The extinguishing time for the velocity \(v\) must now be \(\frac{E \times d}{v}\).

If, in the 3d place, the density of the ball be increased in the proportion of \(1\) to \(n\), the number of particles among which the resistance is to be distributed is increased in the same proportion, and therefore the retarding force of the resistance is equally diminished; and if the density of the air is increased in the proportion of \(1\) to \(n\), the retarding force of the resistance increases in the same proportion; hence we easily deduce these general expressions.

The terminal velocity is \(a \sqrt{\frac{d}{n}} = \sqrt{\frac{2g}{a} \frac{d}{n}}\).

The producing fall in vacuo is \(a \frac{d^m}{n}\). The
The retarding power of resistance to any velocity is

$$r' = \frac{v^4}{2adm}$$

The extinguishing time for any velocity is

$$\tau = \frac{Edm}{vn}$$

And thus we see that the chief circumstances are regulated by the terminal velocity, or are conveniently referred to it.

To render the deductions from these premises perspicuous, and for communicating distinct notions or ideas, it will be proper to assume some convenient units, by which all these quantities may be measured; and, as this subject is chiefly interesting in the case of military projectiles, we shall adapt our units to this purpose. Therefore, let a second be the unit of time, a foot the unit of space and velocity, an inch the unit of diameter of a ball or shell, and a pound avoirdupois the unit of pressure, whether of weight or of resistance; therefore $g$ is 32 feet.

The great difficulty is to procure an absolute measure of $r$, or $u$, or $a$; any one of these will determine the others.

Sir Isaac Newton has attempted to determine $r$ by theory, and employs a great part of the second book of the *Principia* in demonstrating, that the resistance of a sphere moving with any velocity, is to the force which would generate or destroy its whole motion in the time that it would uniformly move over $\frac{1}{2}$ of its diameter with this velocity, as the density of the air is to the density of the sphere. This is equivalent to demonstrating that the resistance of the air to a sphere moving through it with any velocity, is equal to half the weight of a column of air having a great circle of the sphere for its base, and for its altitude the height from which a body must fall in *vacuo* to acquire this velocity. This appears from Newton's demonstration; for, let the specific gravity of the air be to that of the ball as $1$ to $m$; then, because the times in which the same velocity will be extinguished by the uniform action of different forces are inversely as the forces, the resistance to this velocity would extinguish it in the time of describing $\frac{1}{2} m d$, $d$ being the diameter of the ball. Now $t$ is to $m$ as the weight of the displaced air to the weight of the ball, or as $\frac{1}{2}$ of the diameter of the ball to the length of a column of air of equal weight. Call this length $a$; $a$ is therefore equal to $\frac{1}{2} m d$. Suppose the ball, to fall from the height $a$ in the time $t$, and acquire the velocity $u$. If it moved uniformly with this velocity during this time, it would describe a space $= 2a$, or $\frac{1}{2} m d$. Now its weight would extinguish this velocity, or destroy this motion, in the same time, that is, in the time of describing $\frac{1}{2} m d$; but the resistance of the air would do this in the time of describing $\frac{1}{2} m d$; that is, in twice the time. The resistance therefore is equal to half the weight of the ball, or to half the weight of the column of air whose height is the height producing the velocity. But the resistances to different velocities are as the squares of the velocities, and therefore, as their producing heights; and, in general, the resistance of the air to a sphere moving with any velocity, is equal to the half weight of a column of air of equal section, and whose altitude is the height producing the velocity. The result of this investigation has been acquiesced in by all Sir Isaac Newton's commentators. Many faults have indeed been found with his reasoning, and even with his principles; and it must be acknowledged that his results, although this investigation is by far the most ingenious of any in the *Principia*, and sets its acuteness and address in the most conspicuous light, his reasoning is liable to serious objections, which his most ingenious commentators have not completely removed. However, the conclusion has been acquiesced in, as we have already stated, but as if derived from other principles, or by more logical reasoning. We cannot, however, say that the reasoning or assumptions of these mathematicians are much better than Newton's; and we must add, that all the causes of deviation from the duplicate ratio of the velocities, and the causes of increased resistance, which the latter authors have valued themselves for discovering and introducing into their investigations, were pointed out by Sir Isaac Newton, but purposely omitted by him, in order to facilitate the discussion in re difficiliora. (See *Schol. prop. 37. book ii.)*

It is known that the weight of a cubic foot of water is $\frac{621}{4}$ pounds, and that the medium density of the air is $\frac{1}{42}$ of water; therefore, let $a$ be the height producing the velocity (in feet), and $d$ the diameter of the ball (in inches), and $w$ the periphery of a circle whose diameter is $d$; the resistance of the air will be

$$\frac{w \times \frac{1}{2} \times \frac{a}{2} \times d^2}{4 \times 144} = \frac{a d^2}{40288}$$

pounds, very nearly,

$$= \frac{a}{v^3} d^2 - \frac{a}{v^3} d^2$$

pounds.

We may take an example. A ball of cast iron weighing 12 pounds, is $\frac{4}{3}$ inches in diameter. Suppose this ball to move at the rate of $25700$ feet in a second (the reason of this choice will appear afterwards). The height which will produce this velocity in a falling body is $92$ feet. The area of its great circle is $0.11044$, or $\frac{143}{300}$ of one foot. Suppose water to be $830$ times heavier than air, the weight of the air incumbent on this great circle, and $92$ feet high, is $0.08111$ pounds: half of this is $0.040375$, or nearly $\frac{1}{2}$ of a pound. This should be the resistance of the air to this motion of the ball.

In all matters of physical discussion, it is prudent to confront every theoretical conclusion with experiment. This is particularly necessary in the present instance, because the theory on which this proposition is founded is extremely uncertain. Newton speaks of it with the most cautious diffidence, and secures the justness of the conclusions by the conditions which he assumes in his investigation. He describes with the greatest precision the state of the fluid in which the body must move, so as that the demonstrations may be strict, and leaves it to others to pronounce, whether this is the real constitution of our atmosphere. It must be granted that it is not; and that many other suppositions have been introduced by his commentators and followers, in order to suit his investigation (for we must assert that little or nothing has been added to it) to the circumstances of the case.

Newton himself, therefore, attempted to compare his Newton's propositions with experiment. Some were made by dropping balls from the dome of St Paul's cathedral; and all these showed as great a coincidence with his theory as they did with each other: but the irregularities
ties were too great to allow him to say with precision what was the resistance. It appeared to follow the proportion of the squares of the velocities with sufficient exactness; and though he could not say that the resistance was equal to the weight of the column of air having the height necessary for communicating the velocity, it was always equal to a determinate part of it; and might be stated \( \frac{2}{5} \alpha \), \( \alpha \) being a number to be fixed by numerous experiments.

One great source of uncertainty in his experiments seems to have escaped his observation: the air in that dome is almost always in a state of motion. In the summer season there is a very sensible current of air downwards, and frequently in winter it is upwards; and this current bears a very great proportion to the velocity of the descents. Sir Isaac takes no notice of this.

He made another set of experiments with pendulums; and has pointed out some very curious and unexpected circumstances of their motions in a resisting medium. There is hardly any part of his noble work in which his address, his patience, and his astonishing penetration, appear in greater lustre. It requires the utmost importunity of thought to follow him in these disquisitions; and we cannot enter on the subject at present; some notice will be taken of these experiments in the article Resistance of fluids. Their results were much more uniform, and confirmed his general theory; and as we have said above, it has been acquiesced in by the first mathematicians of Europe.

But the deductions from this theory were so inconsistent with the observed motions of military projectiles, when the velocities are prodigious, that no application could be made which could be of any service for determining the path and motion of cannon shot and bombs; and although Mr John Bernoulli gave, in 1718, a most elegant determination of the trajectory and motion of a body projected in a fluid which resists in the duplicate ratio of the velocities (a problem which even Newton did not attempt), it has remained a dead letter. Mr Benjamin Robins, equally eminent for physical science and mathematical genius, was the first who suspected the true cause of the imperfection of the usually received theories; and in 1737 he published a small tract, in which he showed clearly, that even the Newtonian theory of resistance must cause a cannon ball, discharged with a full allotment of powder, to deviate farther from the parabola, in which it would move in vacuo, than the parabola deviates from a straight line. But he farther asserted, on the authority of good reasoning, that in such great velocities the resistance must be much greater than this theory assigns; because, besides the resistance arising from the inertia of the air which is put in motion by the ball, there must be a resistance arising from a condensation of the air on the anterior surface of the ball, and a rarefaction behind it: and there must be a third resistance, arising from the statical pressure of the air on its anterior part, when the motion is so swift that there is a vacuum behind. Even these causes of disagreement with the theory had been foreseen and mentioned by Newton (see the Scholium to prop. 37. book ii. Principi); but the subject seems to have been little attended to. The eminent mathematicians had few opportunities of making experiments; and the professional men, who were in the service of princes, and had their countenance and aid in this matter, were generally too deficient in mathematical knowledge to make a proper use of their opportunities. The numerous and splendid volumes which these gentlemen have been enabled to publish by the patronage of sovereigns are little more than prolix extensions of the same theory of Galileo. Some of them, however, such as St Bremy, Antonini, and Le Blond, have given most valuable collections of experiments, ready for the use of the profound mathematician.

Two or three years after this first publication, Mr Observations on Mr Robins's Math. Works, vol. i. page 205, hit upon that ingenious method of measuring the great velocities of military projectiles, which has handed down his name to posterity with great honour. And having ascertained these velocities, he discovered, the prodigious resistance of the air, by observing the diminution of velocity which it occasioned. This made him anxious to examine what was the real resistance to any velocity whatever, in order to ascertain what was the law of its variation; and he was equally fortunate in this attempt. His method of measuring the resistance has been fully described in the article GUNNERY, Nos. 9, &c.

It appears (Robins's Math. Works, vol. i. page 205,) that a sphere of \( \frac{4}{5} \) inches in diameter, moving at the rate of \( \frac{2}{3} \) feet in a second, sustained a resistance of \( 0.04914 \) pounds, or \( \frac{1}{5} \) of a pound. This is a greater resistance than that of the Newtonian theory, which gave \( \frac{1}{5} \) of the proportion of 1211, or very nearly in the proportion of five to six in small numbers. And we may adopt as a rule in all moderate velocities, that the resistance is equal to \( \frac{2}{5} \) of the weight of a column of air having the great circle of the sphere for its base, and for its altitude the height through which a heavy body must fall in vacuo to acquire the velocity of projection.

This experiment is peculiarly valuable, because the ball is precisely the size of a 12 pound shot of cast iron; and its accuracy may be depended on. There is but one source of error. The whirling motion must have occasioned some whirl in the air, which would continue till the ball again passed through the same point of its revolution. The resistance observed is therefore probably somewhat less than the true resistance to the velocity of \( \frac{2}{3} \) feet, because it was exerted in a relative velocity which was less than this, and it is, in fact, the resistance competent to this relative and smaller velocity.

Accordingly, Mr Smeaton, a most sagacious naturalist, places great confidence in the observations of Mr Rouse and De Borda, Mr Rouse of Leicestershire, whom measured the resistance by the effect of the wind on a plane properly exposed to it. He does not tell us in what way the velocity of the wind was ascertained; but our deference for his great penetration and experience disposes us to believe that this point was well determined. The resistance observed by Mr Rouse exceeds that resulting from Mr Robins's experiments nearly in the proportion of 7 to 10; and their conclusions. Chevalier de Borda made experiments similar to those of Mr Robins, and his results exceed those of Robins in the proportion of 5 to 6. These differences are so considerable, that we are at a loss what measure to abide by. It is much to be regretted, that in a subject so interesting both to the philosopher and the man of the world, experiments have not been multiplied. Nothing would tend so much to perfect the science of...
PROJECTILES.

of gunnery; and indeed till this be done, all the labours of mathematicians are of no avail. Their investigations must remain an unintelligible cipher, till this key be supplied. It is to be hoped that Dr Charles Hutton of Woolwich, who has so ably extended Mr Robins’s Examination of the Initial Velocities of Military Projectiles, will be encouraged to proceed to this part of this subject. We should wish to see, in the first place, a numerous set of experiments for ascertaining the resistances in moderate velocities; and in order to avoid all error from the resistance and inertia of the machine, which is necessarily blended with the resistance of the ball, in Mr Robins’s form of the experiment, and is separated with great uncertainty and risk of error, we would recommend a form of experiment somewhat different.

Let the axis and arm which carries the ball be connected with wheelwork, by which it can be put in motion, and gradually accelerated. Let the ball be so connected with a bent spring, that this shall gradually compress it as the resistance increases, and leave a mark of the degree of compression; and let all this part of the apparatus be screened from the air except the ball. The velocity will be determined precisely by the revolutions of the arm, and the resistance by the compression of the spring. The best method would be to let this part of the apparatus be made to slide along the revolving arm, so that the ball can be made to describe larger and larger circles. An intelligent mechanic will easily contrive an apparatus of this kind, held at any distance from the axis by a cord, which passes over a pulley in the axis itself, and is then brought along a perforation in the axis, and comes out at its extremity, where it is fitted with a swivel, to prevent it from snapping by being twisted. Now let the machine be put in motion. The centrifugal force of the ball and apparatus will cause it to fly out as far as it is allowed by the chord; and if the whole is put in motion by connecting it with some mill, the velocity may be most accurately ascertained. It may also be fitted with a bell and hammer like Gravesande’s machine for measuring centrifugal forces. Now by gradually veering off more cord, the distance from the centre, and consequently the velocity and resistance increase, till the hammer is disengaged and strikes the bell.

Another great advantage of this form of the experiment is, that the resistance to very great velocities may be thus examined, which was impossible in Mr Robins’s way. This is the great desideratum, that we may learn in what proportion of the velocities the resistances increase.

In the same manner, an apparatus, consisting of Dr Lynd’s Anemometer, described in the article Pneumatics, No. 311, &c. might be whirled round with prodigious rapidity, and the fluid on it might be made clammy, which would leave a mark at its greatest elevation, and thus discover the resistance of the air to rapid motions.

Nay, we are of opinion that the resistance to very rapid motions may be measured directly in the conduit pipe of some of the great cylinder bellows employed in blast furnaces: the velocity of the air in this pipe is ascertained by the capacity of the cylinder and the strokes of the piston. We think it our duty to point out, to such as have the opportunities of trying them, methods which promise accurate results for ascertaining this most desirable point.

We are the more puzzled what measure to abide by, because Mr Robins himself, in his practical propositions, does not make use of the result of his experiments, but takes a much lower measure. We must not content ourselves, however, with this experimental measure, because it is as yet only one of which any accuracy can be given, or well-founded opinion formed.

Therefore, in order to apply our formula, we must apply to reduce this experiment, which was made on a ball of the form 45 inches diameter, moving with the velocity of 255 feet per second, to what would be the resistance to a ball of one inch, having the velocity 1 foot. This will evidently give us $R = \frac{0.04914}{45.5 \times 25.2}$, being diminished in the duplicate ratio of the diameter and velocity. This gives us $R = \frac{0.0000381973}{0.00000001}$ pounds, or $3.81973$ of a pound. The logarithm is $4.58204$. The resistance here determined is the same whatever substance the ball be of; but the retardation occasioned by it will depend on the proportion of the resistance to the via insita of the ball; that is, to its quantity of motion. This in similar velocities and diameters is as the density of the ball. The balls used in military service are of cast iron or of lead, whose specific gravities are $7.207$ and $11.37$ nearly, water being 1. There is considerable variety in cast iron, and this density is about the medium. These data will give us

<table>

These numbers are of frequent use in all questions on this subject.

Mr Robins gives an expeditious rule for readily finding $a$, which he calls $F$ (see the article GUNNERY), by which it is made 900 feet for a cast iron ball of an inch diameter. But no theory of resistance which he professes to use will make this height necessary for producing the terminal velocity. His $F$ therefore is an empirical quantity, analogous indeed to the producing height, but accommodated to his theory of the trajectory of cannon-shot, which he promised to publish, but did not live to execute. We need not be very anxious about this; for all our quantities change in the same proportion with $R$, and need only a correction by a multiplier or divisor, when $F$ shall be accurately established.

We may illustrate the use of these formula by an example or two.

1. Then, to find the resistance to a 24 pound ball, moving with the velocity of 1670 feet in a second, of the form which is nearly the velocity communicated by 100 lb. of powder. The diameter is 5.02 inches.
PROJECTILES.

Log. R  
Log. $d^a$  
Log. $1670^4$  
Log. 334.4 lbs.  

But it is found, by unequivocal experiments on the retardation of such a motion, that it is 504 lbs. This is owing to the causes often mentioned, the additional resistance to great velocities, arising from the condensation of the air, and from its pressure into the vacuum left by the ball.

2. Required the terminal velocity of this ball?

</table>

Mr. Muller, in his writings on this subject, gives a much smaller measure of resistance, and consequently a much greater terminal velocity: but his theory is a mistake from beginning to end (See his Supplement to his Treatise of Artillery, art. a, &c.). In art. 148, he assumes an algebraic expression for a principle of mechanical argument; and from its consequences draws erroneous conclusions. He makes the resistance of a cylinder one third less than Newton supposed it; and his reason is false. Newton's measure is demonstrated by his commentators Le Seur and Jaquier to be even a little too small, upon his own principles, (Not. 277. Prop. 36. B. II.). Mr. Muller then, without any seeming reason, introduces a new principle, which he makes the chief support of his theory, in opposition to the theories of other mathematicians. The principle is false, and even absurd, as we shall have occasion to show by and by. In consequence, however, of this principle, he is enabled to compare the results with many experiments, and the agreement is very flattering. But we shall soon see that little dependence can be had on such comparisons. We notice these things here, because Mr Muller being head of the artillery school in Britain, his publications have become a sort of text-books. We are miserably deficient in works on this subject, and must have recourse to the foreign writers.

We now proceed to consider these motions through the whole course; and we shall first consider them considered affected by the resistance only; then we shall consider through the perpendicular ascents and descents of heavy bodies through the air; and, lastly, their motion in a curvilinear trajectory, when projected obliquely. This must be done by the help of the abstruser parts of fluxionary mathematics. To make it more conspicuous, we shall, by way of introduction, consider the simply resisted rectilinear motions geometrically, in the manner of Sir Isaac Newton. As we advance, we shall quit this track, and prosecute it algebraically, having by this time acquired distinct ideas of the algebraic quantities.

We must keep in mind the fundamental theorems of Preliminary observations.

1. The momentary variation of the velocity is proportional to the force and the moment of time jointly, and may therefore be represented by $\pm v = f t$, where $v$ is the momentary increment or decrement of the velocity, $f$ the accelerating or retarding force, and $t$ the moment or increment of the time $t$.

2. The momentary variation of the square of the velocity is as the force, and as the increment or decrement of the space jointly; and may be represented by $\pm v^2 = f s$. The first proposition is familiarly known. The second is the 39th of Newton's Principia, B. I. It is demonstrated in the article Optics, and is the most extensively useful proposition in mechanics.

These things being premised, let the straight line AC (fig. 5) represent the initial velocity $v$, and let the CO, perpendicular to AC, be the time in which this velocity would be extinguished by the uniform action of the resistance. Draw through the point A an equilateral hyperbola A e B, having OF, OCD for its asymptotes; then let the time of the resisted motion be represented by the line CB, C being the first instant of the motion. If there be drawn perpendicular ordinates $a, g, f, DB$, &c. to the hyperbola, they will be proportional to the velocities of the body at the instants $e, D, &c.$ and the hyperbolic areas $AC \times e$, $AC \times f$, $ACDB$, &c. will be proportional to the spaces described during the times $e, C, CB$, &c.

For, suppose the time divided into an indefinite number of small and equal moments, C c, D d, &c. draw the ordinates $a, b, d$, and the perpendiculars $b, a, a$. Then, by the nature of the hyperbola, $AC : a = OC : OC$; and $AC - a : a = OCR - OC : OC$, that is, $A a : a = OCR : OC$, and $A a = OCR : AC : a = AC - a : AC - OCR$; in like manner, $B b : D d = BD - BD : BD - OD$. Now D OCR, because the moments of time were taken equal, and the rectangles $AC - OCR, BD - OD$, are equal, by the nature of the hyperbola; therefore $A a : B b = AC - a : BD - d$; but as the points c, d continually approach, and ultimately coincide with C, D, the ultimate ratio of $AC - a : BD - d$ is that of $AB^2 : BD^2$; therefore the momentary decrements of $AC$...
PROJECTILES.

AC and BD are as AC* and BD*. Then, because the resistance is measured by the momentary diminution of velocity, these diminutions are as the squares of the velocities; therefore the ordinates of the hyperbola and the velocities diminish by the same law; and the initial velocity was represented by AC: therefore the velocities at all the other instants a, g, D, are properly represented by the corresponding ordinates. Hence,

1. Since the abscissae of the hyperbola are as the times, and the ordinates are as the velocities, the areas will be as the spaces described, and AC x e is to A e g f as the space described in the time C a to the space described in the time C g (1st Theorem on varied motions).

2. The rectangle ACOF is to the area ACDB as the space formerly expressed by 2 a, or E to the space described in the resisting medium during the time CD: for AC being the velocity V, and OC the extinguishing time e, this rectangle is —V, or E, or 2 a, of our former disquisitions: and because all the rectangles, such as ACOF, BDG, &c., are equal, this corresponds with our former observation, that the space uniformly described with any velocity during the time in which it would be uniformly extinguished by the corresponding resistance is a constant quantity, viz., that in which we always had 2 a = E, or 2 a.

3. Draw the tangent A a; then, by the hyperbola C a = CO: now C a is the time in which the resistance to the velocity AC would extinguish it; for the tangent coinciding with the elemental arc A a of the curve, the first impulse of the uniform action of the resistance is the same with the first impulse of its varied action. By this the velocity AC is reduced to a c. If this operated uniformly like gravity, the velocities would diminish uniformly, and the space described would be represented by the triangle AC a.

This triangle, therefore, represents the height through which a heavy body must fall in vacuo, in order to acquire the terminal velocity.

4. The motion of a body resisted in the duplicate ratio of the velocity will continue without end, and a space will be described which is greater than any assignable space, and the velocity will grow less than any that can be assigned; for the hyperbola approaches continually to the asymptote, but never coincides with it. There is no velocity BD so small, but a smaller ZP will be found beyond it; and the hyperbolic space may be continued till it exceeds any surface that can be assigned.

5. The initial velocity AC is to the final velocity BD as the sum of the extinguishing time and the time of the retarded motion, is to the extinguishing time alone: for AC : BD = OD (or OC + CD) : OC; or V : V = e + t : e.

6. The extinguishing time is to the time of the retarded motion as the final velocity is to the velocity lost during the retarded motion: for the rectangles AFOC, BDG are equal; and therefore AVGF and BVCD are equal, and VC : VA = VG : VB; therefore t = V = e = t = V = e.

7. Any velocity is reduced in the proportion of m : m to n in the time e m = n. For, let AC : BD = n : m; then DO : CO = m : n, and DC : CO = m = n : m, or t = m = n. Therefore any velocity is reduced to one half in the time in which the initial resistance would have extinguished it by its uniform action.

Thus may the chief circumstances of this motion be determined by means of the hyperbola, the ordinate and abscissa exhibiting the relations of the times and velocities, and the areas exhibiting the relations of both to the spaces described. But we may render the conception of these circumstances infinitely more easy and simple, by expressing them all by lines, instead of this combination of lines and surfaces. We shall accomplish this purpose by constructing another curve LKP, having the line MLK, parallel to OD, for its axis, and of such a nature, that if the ordinates to the hyperbola AC, e n, f g, BD, &c. be produced till they cut this curve in L, n, p, m, K, &c., and the abscissae in L, n, p, m, K, &c., the ordinates to these points may be proportional to the hyperbolic areas e AC n, f AB g, D K.

Let us examine what kind of curve this will be.

Make OC : O a = O : g; then (Hamilton's miscell. IV. 14. Cor.), the areas AC a e, e n g f are equal; therefore drawing p s, n t perpendicular to OM, we shall have (by the assumed nature of the curve LKP), M s = t; and if the abscissa OD be divided into any number of small parts in geometrical progression (reckoning the commencement of them all from 0), the s is V of this curve will be divided by its ordinates into the same number of equal parts; and this curve will have its ordinates LM, p s, n t, &c. in geometrical progression, and its abscissae in arithmetical progression.

Also, let KN, MV touch the curve in K and L, and let OC be supposed to be to O c, as OD to O d, and therefore C c to D d as OC to OD; and let these lines C c, D d be indefinitely small; then (by the nature of the curve) L c is equal to K r: for the areas a AC c, b BD d are in this case equal. Also k o is to k r, as LM to Kf, because C c : D d = CO : DO.

Therefore IN : IK = r K : r k
IK : ML = r k : o l
ML : MV = l : L
and IN : MN = r K : o L

That is, the subtangent IN, or MV, is of the same magnitude, or is a constant quantity in every part of the curve.

Lastly, the subtangent IN, corresponding to the point K of the curve, is to the ordinate K D as the rectangle BDOG or ACOF to the parabolic area BDCA.

For if e f h n be an ordinate very near to BDK; and let h n cut the curve in n, and the ordinate K in q; then we have

K g : q n = KL : IN, or
D g : q n = DO : IN;
but BD : AC = CO : DO;
therefore B D : D G : AC = q n : CO : IN.

Therefore the sum of all the rectangles BD, D G is to the sum of all the rectangles AC, q n, as CO to IN; but
PROJECTILES.

but the sum of the rectangles $BD \cdot DG$ is the space
$ACDB$; and, because $AC$ is given, the sum of the rect-
angles $AC \cdot qn$ is the rectangle of $AC$ and the sum of
all the lines $qn$; that is, the rectangle of $AC$ and $RL$;
therefore the space $ACDB = AC \cdot RL = CO \cdot IN$, and
$ACDB \times IN = AC \cdot CO \cdot RL$; and therefore $IN \cdot RL$
$= AC \cdot CO \cdot ACDB$.

Hence it follows that $QL$ expresses the area $BVA$, and
in general, that the part of the line parallel to $OM$, which
lies between the tangent $KN$ and the curve $LpK$, ex-
presses the corresponding area of the hyperbola which
lies without the rectangle $BDOG$.

And now, by the help of this curve, we have an easy
way of convincing and computing the motion of a body
through the air. For the subtangent of our curve now
represents twice the height through which the ball must
fall in vacuo, in order to acquire the terminal velocity;
and therefore serves for a scale on which to measure all
the other representatives of the motion.

But it remains to make another observation on the
curve $LpK$, which will save us all the trouble of
graphical operations, and reduce the whole to a very
simple arithmetical computation. It is of such a na-
ture, that when $MI$ is considered as the abscissa, and
is divided into a number of equal parts, and ordinates
are drawn from the points of division, the ordinates are a
series of lines in geometrical progression, or are conti-
nual proportionals. Whatever is the ratio between the
first and second ordinate, there is the same between the
second and third, between the third and fourth, and so
on; therefore the number of parts into which the ab-
scissa is divided is the number of these equal ratios
which is contained in the ratio of the first ordinate to the
last: For this reason, this curve has got the name of
the logistic or logarithmic curve; and it is of immense
use in the modern mathematics, giving us the solution
of many problems in the most simple and expeditious
manner, on which the genius of the ancient mathematicians
had been exercised in vain. Few of our readers are
ignorant, that the numbers called logarithms are of
equal utility in arithmetical operations, enabling us
not only to solve common arithmetical problems with
astonishing dispatch, but also to solve others which are
quite inaccessible in any other way. Logarithms are no-
things more than the numerical measures of the abscissa
of this curve, corresponding to ordinates, which are
measured on the same or any other scale by the natural
numbers; that is, if $ML$ be divided into equal parts,
and from the points of division lines be drawn parallel to
$MI$, cutting the curve $LpK$, and from the points of
intersection ordinates be drawn to $MI$, these will divide
$MI$ into portions, which are in the same proportion to
the ordinates that the logarithms bear to their natural
numbers.

In constructing this curve we were limited to no par-
ticular length of the line $LR$, which represented the
space $ACDB$; and all that we had to take care of was,
that when $OC$, $Oa$, $Og$ were taken in geometrical
progression, $M_s$, $M_t$ should be in arithmetical progression.
The abscissae having ordinates equal to $os$, $nt$, &c., might
have been twice as long, as is shown in the dotted curve
which is drawn through $L$. All the lines which serve to
measure the hyperbolic spaces would then have been
doubled. But $MI$ would also have been doubled, and
our proportions would have still held good; because this
subtangent is the scale of measurement of our figure, as
$E$ or $2a$ is the scale of measurement for the motions.

Since then we have tables of logarithms calculated for
every number, we may make use of them instead of
this geometrical figure, which still requires consid-
erable trouble to suit it to every case. There are two
sets of logarithmic tables in common use. One is called
a table of hyperbolic or natural logarithms. It is
suited to such a curve as is drawn in the figure, where
the subtangent is equal to that ordinate $tv$ which corre-
sponds to the side $\pi O$ of the square $\pi tO$ inserted be-
tween the hyperbola and its asymptotes. This square
is the unit of surface, by which the hyperbolic areas
are expressed; its side is the unit of length, by which
the lines belonging to the hyperbola are expressed; $tv$
is $\pi tO$, or the unit of numbers to which the logarithms
are suited, and then $IN$ is also $\pi tO$. Now the square
$\pi tO$ being unity, the area $BACD$ will be some number;
$O$ being also unity, $OD$ is some number: Call it $\pi$.
Then, by the nature of the hyperbola, $OB : O = \pi t$ : $DB$.
That is, $\pi t = 1 : \frac{t}{\pi}$ so that $DB = \frac{t}{\pi}$

Now calling $D \frac{dx}{x}$ the area $BD \frac{db}{b}$, which is the
fluxion (ultimately) of the hyperbolic area, is $\frac{dx}{x}$.

Now in the curve $LpK$, $MI$ has the same ratio to $NI$ that
$BACD$ has to $\pi tO$: Therefore, if there be a scale of
which $NI$ is the unit, the number on this scale cor-
sponding to $MI$ has the same ratio to $1$ which the
number measuring $BACD$ has to $1$; and $1i$, which
corresponds to $BD \frac{db}{b}$, is the fluxion (ultimately) of
$MI$: Therefore, if $MI$ be called the logarithm of $x$,
$\frac{dx}{x}$ is properly represented by the fluxion of $MI$. In
short the line $MI$ is divided precisely as the line of
numbers on a Gunter's scale, which is therefore a
line of logarithms; and the numbers called logarithms
are just the lengths of the different parts of this line
measured on $\pi$ scale of equal parts. Therefore, when
we meet with such an expression as $\frac{dx}{x}$ viz. the fluxion
of a quantity divided by the quantity itself, we consider
it as the fluxion of the logarithm of that quantity,
because it is really so when the quantity is a number; and
it is therefore strictly true that the fluent of $\frac{dx}{x}$ is the
hyperbolic logarithm of $x$.

Certain reasons of convenience have given rise to an-
tother set of logarithms; these are suited to a logistic
curve whose subtangent is only $\frac{1}{\pi} \approx 0.535$ of the ordinate
$tv$, which is equal to the side of the hyperbolic square,
and which is assumed for the unit of number. We shall
suit our applications of the preceding investigation to
both these, and shall first use the common logarithms
whose subtangent is $0.43420$.

The whole subject will be best illustrated by taking an
example of the different questions which may be prop-
exposed.

Recollect that the rectangle $ACOF$ is $2a$, or $\frac{a}{x}$, or
$\frac{1}{x}$.
PROJECTILES.

E, for a ball of cast-iron one inch diameter, and if it has the diameter \( d \), it is \( \frac{\pi d^2}{4} \) or \( 2ad \), or \( E d \).

I. It may be required to determine what will be the space described in a given time \( t \) by a ball setting out with a given velocity \( V \), and what will be its velocity \( v \) at the end of that time.

Here we have \( NI = MI = ACOF \), \( BDCA \); now \( NI \) is the subtangent of the logistic curve; \( MI \) is the difference between the logarithms of \( OD \) and \( OC \); that is, the difference between the logarithms of \( e + t \) and \( e \); \( ACOF \) is \( 2ad \), or \( \frac{\pi d^2}{4} \), or \( E d \).

Therefore by common logarithms \( 0.43429 \) : log. \( e + t \) : log. \( e \) = \( 2ad : S \), = space described,

or \( 0.43429 \) : log. \( \frac{e + t}{e} \) = \( 2ad : S \),

and \( S = \frac{2ad}{0.43429} \times \log. \frac{e + t}{e} \),

by hyperbolic logarithms \( S = 2ad \times \log. \frac{e + t}{e} \).

Let the ball be a 12 pounder, and the initial velocity be 1600 feet, and the time 20 seconds. We must first find \( e \), which is \( \frac{2ad}{V} \).

Therefore, log. \( 2a \) = +3.02236,

log. \( d \) (4.5) = +0.5321,

log. \( V \) (1600) = +3.20415

Log. of \( 3^\circ.03 = e \) = 0.48145

And \( e + t \) is \( 23^\circ.03 \), of which the log. is 1.356229 from which take the log. of \( e \) = 0.48145

remains the log. of \( \frac{e + t}{e} \) = 0.88084

This must be considered as a common number by which we must multiply \( 2ad \).

Therefore add the logarithms of \( 2ad \) = +3.68557

log. \( e + t \) = +9.94490

log. \( 0.43429 \) = -9.63778

Log. \( S = 9823 \) feet

For the final velocity, \( OD : OC = AC : BD, \) or \( e + t : e \) = \( V : v \).

\( 23^\circ.03 : 3^\circ.03 = 1600 : 210 \frac{1}{2} \), \( = v \).

The ball has therefore gone 3298 yards, and its velocity is reduced from 1600 to 210.

It may be agreeable to the reader to see the gradual progress of the ball during some seconds of its motion.

\[ \begin{array}{ccc}
T. & S. & Diff. V. & Diff. \\
1" & 1383 & 1203 & 397 \\
2" & 2456 & 2073 & 383 \\
3" & 3326 & 2564 & 762 \\
4" & 4058 & 2314 & 1144 \\
5" & 4775 & 1664 & 1111 \\
6" & 5294 & 569 & 337 \\
\end{array} \]

The first column is the time of the motion, the second is the space described, the third is the difference of the spaces, showing the motion during each successive second; the fourth column is the velocity at the end of the time \( t \); and the last column is the difference of velocity, showing its diminution in each successive second.

We see that at the distance of 1000 yards the velocity is reduced to one half, and at the distance of less than a mile it is reduced to one-third.

II. It may be required to determine the distance at which the initial velocity \( V \) is reduced to any other quantity \( v \). This question is solved in the very same manner, by substituting the logarithms of \( V \) and \( v \) for those of \( e + t \) and \( e \); for \( AC : BD = OD : OC \), and therefore \( \log. \frac{AC}{V} = \log. \frac{OD}{OC} \), or \( \log. \frac{e + t}{e} = \log. \frac{t}{v} \).

Thus it is required to determine the distance in which the velocity 1780 of a 24 pound ball (which is the medium velocity of such a ball discharged with 16 pounds of powder) will be reduced to 1500.

Here \( d \) is 5.68, and therefore the logarithm of \( 2ad \) is +3.78671

Log. of \( \frac{V}{v} = 0.07433 \), of which the log. is +8.87116

Log. of \( 0.43429 \) = -9.53778

Log. 1047.3 feet, or 349 yards 3.02009

This reduction will be produced in about \( \frac{1}{4} \) of a second.

III. Another question may be to determine the time which a ball, beginning to move with a certain velocity, employs in passing over a given space, and the diminution of velocity which it sustains from the resistance of the air.

We may proceed thus:

\[ 2ad : S = 0.43429 : \log. \frac{e + t}{e} = t \]. Then to log. \( \frac{e + t}{e} \) add log. \( e \), and we obtain log. \( e + t \), and \( e + t ; e \), from which if we take \( e \) we have \( t \). Then to find \( v \), say \( e + t \); \( e = V \); \( v \).

We shall conclude these examples by applying this last rule to Mr. Robins's experiments on a musket bullet of an experiment of \( \frac{1}{2} \) of an inch in diameter, which had its velocity reduced from 1670 to 1425 by passing through 100 feet of air. This we do in order to discover the resistance which it sustained, and compare it with the resistance to a velocity of 1 foot per second.

We must first ascertain the first term of our analogy.

The ball was of lead, and therefore \( 2ad \) must be multiplied by \( d \) and by \( m \), which expresses the ratio of the density of lead to that of cast iron. \( d \) is 0.75, and \( m \) is 11.37 = 7.21.

Therefore log. \( 2a \) = 3.03326

\[ \frac{7.21}{d} = 9.87066 \]

\[ \frac{m}{0.19782} = 0.763 \]

But \( e = 2ad \) = 0.763, and its logarithm = 0.88237.

which, added to 0.03408, gives 0.91660, which is the log. of \( e + t \), or 0.825, from which take \( e \), and there remains...
PROJECTILES.

followed the proportion of the hyperbolic areas, we
showed the nature of another curve, where lines could
be found which increase in the very same manner as the
path of the projectile increases; so that a point describing
the abscissa MI of this curve moves precisely as the
projectile does. Then, discovering that this line is
the same with the line of logarithms on a Gunter's
scale, we showed how the logarithm of a number really
represents the path or space described by the projectile.

Having thus, we hope, enabled the reader to con-
ceive distinctly the quantities employed, we shall leave
the geometrical method, and prosecute the rest of the
subject in a more compendious manner.

We are, in the next place, to consider the perpen-
dicular ascents and descents of heavy projectiles, where
the resistance of the air is combined with the action of
gravity; and we shall begin with the descents.

Let $u_1$, as before, be the terminal velocity, and $g$ the
accelerating power of gravity: When the body moves
with the velocity $u_1$, the resistance is equal to $g$; and
in every other velocity $v$, we must have $u: v = g: v$,
$v$, for the resistance to that velocity. In the
descent the body is urged by gravity $g$, and opposed
by the resistance $g v^2: u^2$: therefore the remaining ac-
celerating force, which we shall call $f$, is $g - \frac{g v^2}{u^2}$, or
$\frac{u^2 - g v^2}{u^2}$, or $\frac{u^2 g (u^2 - v^2)}{u^2}$, = $f$.

Now the fundamental theorem for varied motions is
$\frac{dv}{u^2 - v^2} = \frac{du}{g}$, and $\int \frac{dv}{u^2 - v^2} = \frac{u^2}{g} \times \int \frac{du}{u^2 - v^2} + C$. Now the fluent of $\frac{dv}{u^2 - v^2}$ is
$= -\text{hyperb. log. of } \sqrt{u^2 - v^2}$. For the fluxion of
\[ \sqrt{u^2 - v^2} = \frac{u v}{u^2 - v^2}, \]
this divided by the quantity $\sqrt{u^2 - v^2}$, of which it is the fluxion, gives
precisely $\frac{u v}{u^2 - v^2}$, which is therefore the fluxion of
its hyperbolic logarithm. Therefore $S = \frac{u^2}{g} \times L \sqrt{u^2 - v^2} + C$. Where $L$ means the hyperbolic lo-

The constant quantity $C$ for completing the fluent is
determined from this consideration, that the space
described is $a$, when the velocity is $a$: therefore
$= \frac{a^2}{g} \times L \sqrt{u^2 - a^2} = a$, and $C = \frac{a^2}{g} \times L \sqrt{a^2}$, and the
complete fluent $S = \frac{a^2}{g} \times L \sqrt{u^2 - a^2} - \sqrt{u^2 - v^2}$,

$= \frac{a^2}{g} \times L \sqrt{u^2 - a^2} = \frac{a^2}{g} \times L \sqrt{a^2}$,
or (putting $F$ for $0.43429$, the modulus of subtangent
of the common logistic curve $\frac{a^2}{M g} \times \lambda \sqrt{a^2 - v^2}$.

$3 F$ This
This equation establishes the relation between the space fallen through, and the velocity acquired by the fall. We obtain by it \( \frac{S}{u - v^2} = \frac{L}{u^2 - v^2} \), or, which is still more convenient for us, \( \frac{M \times 2gS}{u^2} = \lambda \frac{u^2 - v^2}{u^2 - v^2} \), that is, equal to the logarithm of a certain number; therefore having found the natural number corresponding to the fraction \( \frac{M \times 2gS}{u^2} \), consider it as a logarithm, and take out the number corresponding to it: call this \( n \). Then, since \( n \) is equal to \( \frac{u^2}{u^2 - v^2} \), we have \( n u^2 - n v^2 = u^2 \), and \( n u^2 - n v^2 = n v^2 \), or \( n v^2 = u^2 \times n - v^2 \), and \( v^2 = u^2 \times n - n \).

To expedite all the computations on this subject, it will be convenient to have multipliers ready computed for \( M \times 2gS \), and its half,

\[ \begin{array}{c|c|c}
\text{v.} & \text{log.} & \text{val.} \\
27,794 & 1.44396 & 13,897 \\
13,897 & 1.42923 & 6,948
\end{array} \]

But \( v \) may be found much more expeditiously by observing that \( \sqrt{\frac{u^2}{u^2 - v^2}} \) is the secant of an arch of a circle whose radius is \( u \), and whose sine is \( v \), or whose radius is unity and sine \( \frac{u}{v} \): therefore, considering the above fraction as a logarithmic secant, look for it in the tables, and then take the sine of the arc of which this is the secant, and multiply it by \( u \); the product is the velocity required.

We shall take an example of a ball whose terminal velocity is 6899 feet, and ascertain its velocity after a fall of 1848 feet. Here,

\[ \begin{align*}
u^2 &= 47,1200 \quad \text{and its log.} \\
u &= 6899 \quad \text{2.83844} \\
g &= 32 \quad \text{-} \\
S &= 1848 \quad \text{-} \\
\text{log.} 27,794 &= 1.44396 \\
\text{log.} S &= 1.42923 \\
\text{log.} u^2 &= 2.83844
\end{align*} \]

Log. of 0.10809 = log. \( n \) = 9.03378

0.10809 is the logarithm of \( 1,2826 = n \), and \( n - 1 = \frac{0.2826}{n} \times n - 1 = 323.6, = u^2 \), and \( v = 323.6 \).

In like manner, 0.054045 (which is half of 0.10809) will be found to be the logarithmic secant of 28°, whose sine 0.46947 multiplied by 6899 gives 324 for the velocity.

The process of this solution suggests a very perspicuous manner of conceiving the law of descent; and it may be thus expressed:

\( \frac{M}{u^2} \) is to the logarithm of the secant of an arch whose sine is \( \frac{u}{v} \) and radius \( u \), as \( 2a \) is to the height through \( u \), which the body must fall in order to acquire the velocity \( v \). Thus, to take the same example.

1. Let the height \( h \) be sought which will produce the velocity 323.62 the terminal velocity of the ball being 689.44. Here \( 2a \), or \( \frac{u^2}{v} = 148.50 \), and \( 323.62 = \frac{689.44}{v} \), which is the sine of 28°. The logarithmic secant of this arch is 0.05407. Now \( M \) or 0.43429: 0.05407 = 148.50 : 1848, the height wanted.

2. Required the velocity acquired by the body by falling 1848 feet. Say 148.50 : 1848 = 0.43429: 0.05407. Look for this number among the logarithmic sines. It will be found at 28°, of which the logarithmic sine is 0.46947.

Add to this the log. of \( u \) = 2.83844

The sum = 2.51005 is the logarithm of 323.62, the velocity required.

We may observe, from these solutions, that the acquired velocity continually approaches to, but never equals, the terminal velocity. For it is always expressed by the sine of an arch of which the terminal velocity is the radius. We cannot help taking notice here of a very strange assertion of Mr. Muller, late professor of mathematics and director of the royal academy at Woolwich. He maintains, in his Treatise on Fluxions, and in many of his numerous works, that a body cannot possibly move through the air with a greater velocity than this; and he makes this a fundamental principle, on which he establishes a theory of motion in a resisting medium, which he asserts with great confidence to be the only just theory; saying, that all the investigations of Bernoulli, Euler, Robins, Simpson, and others, are erroneous. We use this strong expression, because, in his criticisms on the works of those celebrated mathematicians, he lays aside good manners, and taxes them not only with ignorance, but with dishonesty; saying, for instance, that it required no small dexterity in Robins to confirm by his experiments a theory founded on false principles; and that Thomas Simpson, in attempting to conceal his obligations to him for some valuable propositions, by changing their form, had ignorantly fallen into gross errors.

Nothing can be more palpably absurd than this assertion of Mr. Muller. A blown bladder will have but a small terminal velocity; and when moving with this velocity, or one very near it, there can be no doubt that it will be made to move much swifter by a smart stroke. Were the assertion true, it would be impossible for a portion of air to be put into motion through the rest, for its terminal velocity is nothing. Yet this author makes this assertion a principle of argument, saying, that it is impossible that a ball can issue from the mouth of a cannon with a greater velocity than this; and that Robins and others are grossly mistaken, when they give them velocities three or four times greater, and resistances which are 10 or 20 times greater than is possible; and by thus compensating his small velocities by still smaller resistances, he confirms his theory by many experiments adduced in support of the others. No reason whatever can be given for the assertion. Newton, or perhaps Huygens, was the first who observed that there was a limit to the velocity which gravity could communicate to a body; and this limit was found by his commentators to be a term to which it was vastly convenient to refer all other motions. It therefore became
became an object of attention; and Mr. Muller, through
inadvertency, or want of discernment, has fallen into
this mistake, and with that arrogance and self-conceit
which mark all his writings, has made this mistake a
fundamental principle, because it led him to establish a
novel set of doctrines on this subject. He was fretted
at the superior knowledge and talents of Mr. Simpson,
his inferior in the academy, and was guilty of several
mean attempts to hurt his reputation. But they were
unsuccessful.

We might proceed to consider the motion of a body
projected downwards. While the velocity of projection
is less than the terminal velocity, the motion is deter-
mined by what we have already said: for we must com-
pute the height necessary for acquiring this velocity
in the air, and suppose the motion to have begun there.
But if the velocity of projection be greater, this method
fails. We pass it over (though not in the least more
difficult than what has gone before), because it is of
more curiosity, and never occurs in any interesting case.
We may just observe, that since the motion is swifter
than the terminal velocity, the resistance must be greater
than the weight, and the motion will be retarded.
The very same process will give us the space describ-
ed $S = \frac{u^2}{2} \times \frac{\sqrt{v^2 - u^2}}{v} \times L \sqrt{V - u}$, V being the velocity of
projection, greater than $u$. Now as this space evidently
increases continually (because the body always falls),
but does not become infinite in any finite time, the frac-
tion $\frac{\sqrt{v^2 - u^2}}{v}$ does not become infinite; that is, $\frac{v}{u}$ does
not become equal to $\frac{u}{v}$: therefore although the velocity
$V$ is continually diminished, it never becomes so small
as $u$. Therefore $u$ is a limit of diminution as well as of
augmentation.

We must now ascertain the relation between the time
of the descent and the space described, or the velocity
acquired. For this purpose we may use the other funda-
mental proposition of varied motions $i = -\frac{u}{v}$, which, in
the present case, becomes $\frac{v^2 - u^2}{v} = \frac{u}{v}$. Therefore $i = \frac{u^2}{2} \times \frac{v}{u} = \frac{u}{v} \frac{v}{u} - \frac{u}{v}$. Now
(article Fluxiones) $\int \frac{u}{v} \frac{v}{u} = L \sqrt{u + v}$. Therefore
$\int \frac{u}{v} \frac{v}{u} = \frac{u}{v} \frac{v}{u} \frac{v}{u}$. This fluent
needs no constant quantity to complete it, or rather
$C = 0$; for $t$ must be $= 0$ when $u = 0$. This will
evidently be the case: for then $L \sqrt{u + v} = \frac{u}{v}$, or
$\frac{u}{v}$.

But how does this quantity $\frac{u}{v}$ signify a
time? Observe, that in whatever numbers, or by what-
ever units of space and time, $u$ and $g$ are expressed,
$u$ expresses the number of units of time in which the ve-
locity $u$ is communicated or extinguished by gravity;
and $\sqrt{\frac{u + v}{v} \frac{v}{u}}$ is always an abstract
number, multiplying this time.

We may illustrate this rule by the same example. In
what time will the body acquire the velocity $323,62$?
Here $u + v = 10,412,96$, $u - v = 356,72$; therefore
$\lambda \sqrt{\frac{u + v}{v} \frac{v}{u}} = 0.22122$, and $\frac{u}{v}$ (in feet and seconds) is
$21^\prime, 542$. Now, for greater perspicuity, convert the
equation $\frac{u}{v} = \lambda \sqrt{\frac{u + v}{v} \frac{v}{u}}$ into a proportion: thus
$M : \lambda \sqrt{\frac{u + v}{v} \frac{v}{u}} = t$, and we have $0.43429 : 0.22122$
$= 21^\prime, 542 : 10^\prime, 973$ the time required.

This is by far the most distinct way of conceiving
the subject; and we should always keep in mind that
the numbers or symbols which we call logarithms are
really parts of the line MI in the figure of the logistic
curve, and that the motion of a point in this line is pre-
cisely similar to that of the body. The Marquis Po-
leni, in a dissertation published at Padua in 1725, has
with great ingenuity constructed logarithms suited to
all the cases which can occur. Herman, in his Phoro-
nomia, has borrowed much of Poleni's methods, but has
observed them by an affectation of language geometrically
precise, but involving the very obscure notion of abst-
act ratios.

It is easy to see that $\sqrt{\frac{u + v}{v} \frac{v}{u}}$ is the cotangent
of the $\frac{1}{2}$ complement of an arc, whose radius is $r$, and
whose sine is $\frac{v}{u}$. For let KC (fig. 6) be $= u$, and Fig. 6.
BE $= v$; then KD $= u + v$, and DA $= u - v$. Join KB
and BA, and draw CG parallel to KB. Now GA is the
tangent of $\frac{1}{2}$ BA, $= \frac{1}{2}$ complement of HB. Then,
by similarity of triangles, GA : AC $= AB : BK =$
$\sqrt{AD} : \sqrt{DK} = \sqrt{\frac{v}{u}} : \sqrt{u + v}$ and $\frac{AC}{GA} (= \cotan.$
$\frac{1}{2} BA) = \sqrt{\frac{u + v}{v}}$; therefore look for $\frac{v}{u}$ among the na-
tural sines, or for $\log \frac{v}{u}$ among the logarithmic sines,
and take the logarithmic cotangent of the half comple-
ment of the corresponding arch. This, considered as a
common number, will be the second term of our propor-
tion. This is a shorter process than the former.

By reversing this proportion we get the velocity cor-
responding to a given time.

To compare this descent of 1848 feet in the air Fall of a
with the fall of the body in vacuo during the same body in air
time, say $21^\prime, 542^2 : 10^\prime, 973^2 = 1848 : 1926,6$, which
makes a difference of 79 feet.

Cor. 1. The time in which the body acquires the
velocity $v$ by falling through the air, is to the time of
acquiring the same velocity by falling in vacuo, as $u$.

$\frac{u}{v}$ to $v$; for it would acquire this velocity in
$\frac{u}{v}$ vacuo.
PROJECTILES.

Here \( \frac{V}{u} \) will be found the tangent of 30.48\(^\circ\), the logarithmic secant of which is 0.06606. This, multiplied by \( \frac{u^2}{M} \) gives 2259 feet for the height. It would have risen 2640 feet in a void.

Suppose this body to fall down again. We can compare the velocity of projection with which it again reaches the ground. The ascent and descent are equal: therefore \( \sqrt{u^6 + V^6} \), which makes the genet, multiplies the constant factor in the ascent, is equal to \( \sqrt{u^6 + v^6} \), the multiplier in the descent. The first is the secant of an arch whose tangent is \( u \); the other is the secant of an arch whose sine is \( u \). These secants are equal, or the arches are the same; therefore the velocity of projection is to the final returning velocity as the tangent to the sine, or as the radius to the cosine of the arch. Thus suppose the body projected with the terminal velocity, or \( V = u \); then \( v = \frac{u}{\sqrt{2}} \).

If \( V = 680 \), \( v = 487 \).

We must in the last place ascertain the relation of the space and the time.

Here \( \frac{L}{u} \) \( i = \frac{u}{v} \times \frac{v}{u} \), and \( i = \frac{u}{v} \times \frac{v}{u} \). Now (art. Fluxions) \( \int \frac{U}{u} \frac{V}{u} \frac{u}{v} \) is an arch whose tangent is \( \frac{u}{v} \) and radius \( 1 \); therefore \( i = \frac{u}{v} \times \text{arc. tan.} \frac{v}{u} \). This must be \( o \) when \( v = V \), or \( C = \frac{u}{v} \times \text{arc. tan.} \frac{V}{u} \), and the complete fluent is \( t = \frac{u}{v} \times \text{arc. tan.} \frac{V}{u} \), and the contained quantity within the brackets express a portion of the arch of a cicle whose radius is unity; and are therefore abstract numbers, multiplying \( \frac{u}{v} \), which we have shown to be the number of units of time in which a heavy body falls in vacuo from the height \( a \), or in which it acquires the velocity \( a \).

We learn from this expression of the time, that however great the velocity of projection, and the height \( \text{ascend} \) to which this body will rise, may be, the time of its mind ascent is limited.

It never can exceed the time of falling from the height \( a \) in vacuo in a greater proportion than that of a quadrantl arch to the radius, nearly the proportion of 8 to 5. A 24 pound iron ball cannot continue rising above 14 seconds, even if the resistance to quick motions did not increase faster than the square of the velocity. It probably will attain its greatest height in less than 12 seconds, let its velocity be ever so great.

In the preceding example of the whole ascent, \( v = 60 \), and...
and the time \( t = \frac{x}{g} \cdot \tan \frac{\alpha}{2} \), or \( t = \frac{x}{g} \cdot \tan 30^\circ \cdot 48^\prime \).
Now \( 30^\circ \cdot 48^\prime = 1848^\prime \), and the radius \( r \) contains \( 3438^\prime \);
therefore the arch \( = \frac{1848}{3438^\prime} \cdot 0.5376 \); and \( \frac{x}{g} = 21^\prime \cdot 54^\prime \).
Therefore \( t = 21^\prime \cdot 54 \times 0.5376 = 11^\prime \cdot 538 \), or nearly \( 11^\prime \) \( 5 \) seconds.
The body would have risen to the same height in a void in \( 10^\prime \) \( 3 \) seconds.

Cor. 1. The time in which a body, projected in the air with any velocity \( V \), will attain its greatest height, is that in which it would attain its greatest height in vacuo, as the arc whose tangent expresses the velocity is to the tangent; for the time of the ascent in the air is \( \frac{x}{g} \times \text{arc} \), and the time of the ascent in vacuo is \( \frac{V}{g} \).

Now \( V = \frac{x}{g} \cdot \tan \text{and} V = u \cdot \tan \frac{x}{g} \), and \( V = \frac{u}{x} \cdot \tan \frac{x}{g} \).

It is evident, by inspecting fig. 6, that the arc \( AI \) is to the tangent \( AG \) as the sector \( ICA \) to the triangle \( GCA \); therefore the time of attaining the greatest height in the air is to that of attaining the greatest height in vacuo (the velocities of projection being the same), as the circular sector to the corresponding triangle.

If therefore a body be projected upwards with the terminal velocity, the time of its ascent will be to the time of acquiring this velocity in vacuo as the area of a circle to the area of the circumscribed square.

2. The height \( H \) to which a body will rise in a void, is to the height \( h \) to which it would rise through the air when projected with the same velocity \( V \) as \( M \cdot V^2 \) to \( u^2 + V^2 \); for the height to which it will rise in vacuo is \( \frac{V^3}{2g} \), and the height to which it rises in the air is

\[
\frac{\sqrt{u^2 + V^2} - V}{\frac{u^2}{M^2} + \frac{V^2}{g^2}}; \quad \text{therefore} \quad H = \frac{V^3}{2g};
\]

\[
\frac{\sqrt{u^2 + V^2} - V}{\frac{u^2}{M^2} + \frac{V^2}{g^2}} = \frac{V^3}{M^2} \cdot 2 \cdot \frac{\sqrt{u^2 + V^2}}{u^2}, \quad V^3;
\]

\[
\frac{u^2 + V^2}{u^2} = M \cdot V^2 \cdot \frac{u^2 + V^2}{u^2}.
\]

Therefore if the body be projected with its terminal velocity, so that \( V = u \), the height to which it will rise in the air is \( \frac{30103}{4349} \) of the height to which it will rise in vacuo, or \( \frac{5}{7} \) in round numbers.

We have been thus particular in treating of the perpendicular ascents and descents of heavy bodies through the air, in order that the reader may conceive distinctly the quantities which he is thus combining in his algebraic operations, and may see their connection in nature with each other. We shall also find that, in the present state of our mathematical knowledge, this simple state of the case contains almost all that we can determine with any confidence. On this account it were to be wished that the professional gentlemen would make many experiments on these motions. There is no way that promises so much for assisting us in forming accurate notions of the air's resistance. Mr. Robins's method with the pendulum is impracticable with great shot; and the experiments which have been generally resorted to for this purpose, viz. the ranges of shot and shells on a horizontal plane, are so complicated in themselves, that the utmost mathematical skill is necessary for making any inferences from them; and they are subject to such irregularities, that they may be brought to support almost any theory whatever on this subject. But the perpendicular flights are affected by nothing but the initial velocity and the resistance of the air; and a considerable deviation from their intended direction does not cause any sensible error in the consequences which we may draw from them for our purpose.

But we must now proceed to the general problem, of ob-
to determine the motion of a body projected in any di-
rection and, with any velocity. Our readers will be en-
lightened beforehand that this must be a difficult subject,
when they see the simplest cases of rectilinear motion ab-
undantly abstruse: it is indeed so difficult, that Sir Iaac Newton has not given a solution of it, and has not pro-
thought himself well employed in making several ap-
proximations, in which the fertility of his genius appears solved by
in great lustre. In the tenth and subsequent propositions of the second book of the Principia, he shows what state of density in the air will comport with the motion of a body in any curve whatever: and then, by applying this discovery to several curves which have some similarity to the path of a projectile, he finds one which is not very different from what we may suppose to obtain in our atmosphere. But even this approximation was involved in such intricate calculations, that it seemed impossible to make any use of it. In the second edition of the Principia, published in 1713, Newton corrects some mistakes which he had committed in the first, and carries his approximations much farther, but still does not attempt a direct investigation of the path which a body will describe in our atmosphere. This is somewhat surprising. In prop. 14, &c. he shows how a body, actuated by a centripetal force, in a medium of a density varying according to certain laws, will describe an eccentric spiral, of which he assigns the properties, and the law of description. Had he supposed the density constant, and the difference between the greatest and least distances from the centre of centripetal force exceedingly small in comparison with the distances themselves, his spiral would have coincided with the path of a projectile in the air of uniform density, and the steps of his investigation would have led him immediately to the complete solution of the problem. For this is the real state of the case. A heavy body is not acted on by equal and parallel gravity, but by a gravity inversely proportional to the square of the distance from the centre of the earth, and in lines tending to that centre nearly; and it was with the view of simplifying the investigation, that mathematicians have adopted the other hypothesis.

Soon after the publication of this second edition of Disputes the Principia, the dispute about the invention of the among fluxionary calculus became very violent, and the great foreign promoters of that calculus upon the continent were in the habit of proposing difficult problems to exercise the talents of the mathematician. Challenges of this kind frequently passed between the British and foreigners.
PRO养成히.

Dr Keill of Oxford had keenly espoused the claim of Sir Isaac Newton to this invention, and had engaged in a very acrimonious altercation with the celebrated John Bernoulli of Basle. Bernoulli had published in the Acta Eruditorum Lipsiae an investigation of the law of forces, by which a body moving in a resisting medium might describe any proposed curve, reducing the whole to the simplest geometry. This is perhaps the most elegant specimen which he has given of his great talents. Dr Keill proposed to him the particular problem of the trajectory and motion of a body moving through the air, as one of the most difficult. Bernoulli very soon solved the problem in a way much more general than it had been proposed, viz. without any limitation either of the law of resistance, the law of the centripetal force, or the law of density, provided only that they were regular, and capable of being expressed algebraically. Dr Brook Taylor, the celebrated author of the Method of Increments, solved it at the same time, in the limited form in which it was proposed. Other authors since that time have given other solutions. But they are all (as indeed they must be) the same in substance with Bernoulli's. Indeed they are all (Bernoulli's not excepted) the same with Newton's first approximations, modified by the steps introduced into the investigation of the spiral motions mentioned above; and we still think it most strange that Sir Isaac did not perceive that the evaporation of curvature, which he introduced in that investigation, made the whole difference between his approximations and the complete solution. This we shall point out as we go along. And we now proceed to the problem itself, of which we shall give Bernoulli's solution, restricted to the case of uniform density and a resistance proportional to the square of the velocity. This solution is more simple and perspicuous than any that has since appeared.

**Problem.** To determine the trajectory, and all the circumstances of the motion of a body projected through the air from A (fig. 7.) in the direction AB, and resisted in the duplicate ratio of the velocity.

Let the arch AM be put = x, the time of describing it t, the abscissa AP = x, the ordinate PM = y. Let the velocity in the point M = v, and let MN = z, be described in the moment t; let r be the resistance of the air, g the force of gravity, measured by the velocity which it will generate in a second; and let a be the height through which a heavy body must fall in ac to acquire the velocity which would render the resistance of the air equal to its gravity: so that we have $r = \frac{2a}{v^2}$; because, for any velocity $u$, and producing height h, we have $g = \frac{u^2}{2h}$.

Let $Mm$ touch the curve in M; draw the ordinate $PNm$, and draw $mo$, $Nn$ perpendicular to $Np$ and $Mm$. Then we have $MN = z$, and $Mm = x$, also $mo$ is ultimately $= y$ and $Mm$ is ultimately $= MN$ or $z$.

Lastly, let us suppose $x$ to be a constant quantity, the elementary ordinates being supposed equidistant.

The action of gravity during the time $t$ may be measured by $mN$, which is half the space which it would cause the body to describe uniformly in the time $t$ with the velocity which it generates in that time. Let this be resolved into $mN_1$, by which it deflects the body into a curvilinear path, and $mN_2$, by which it retards the ascent and accelerates the descent of the body along the tangent. The resistance of the air acts solely in retarding the motion, both in ascending and descending, and has no deflective tendency. The whole action of gravity then is to its accelerating or retarding tendency as $mN_1$ to $mN_2$, or (by similarity of triangles) as $mM$ to $mN$.

Or $\begin{array}{l} x : y = g : gy, \\
\text{and the whole retardation is} \\
\frac{2a}{v^2} \\
\text{the ascent will be} r + \frac{gy}{v^2}. \end{array}$

The same fluxional symbol will express the retardation during the descent, because in the descent the ordinates decrease, and $y$ is a negative quantity.

The diminution of velocity is $\frac{r + \frac{gy}{v^2}}{v}$. This is proportional to the retarding force and to the time of its action jointly, and therefore $\frac{r + \frac{gy}{v^2}}{v} = \frac{r + \frac{gy}{v^2}}{v} = \frac{2a}{v^2}$. Because $mN$ is the deflection by gravity, its is as the force $g$ and the square of the time $t$ jointly (the momentary action being held as uniform). We have therefore $mNx$, or $y = \frac{r}{v}$. (Observe that $mN$ is in fact only the half of $y$; but $g$ being twice the fall of a heavy body in a second, we have $y$ strictly equal to $\frac{r}{v}$). But $r = \frac{2a}{v^2}$; therefore $y = \frac{g^2}{v}$,

and $v = \frac{2a}{v^2}$. The fluxion of $-y$ this equation is $-v \frac{dy}{dx}$. $2v \frac{dy}{dx} = 2g \frac{dx}{dx}$; but, because $\frac{dy}{dx} = \frac{y}{x}$, we have $\frac{2a}{v^2} = y$. Therefore $2g \frac{dy}{dx} = 2g \frac{dx}{dx} = -2v \frac{dy}{dx}$, and $-2v \frac{dy}{dx} = -2v \frac{dy}{dx} = -2g \frac{dx}{dx}$, and finally $\frac{dy}{dx} = 2a \frac{dy}{dx}$, or $y = a \frac{dy}{dx}$, for the fluxional equation of the curve.

If we put this into the form of a proportion, we have $a : \frac{dy}{dx} = \frac{y}{x}$, or $y = \frac{a}{x}$. Now this evidently establishes a relation between the length of the curve and its variation of curvature; and between the curve itself and its evolute, which are the very circumstances introduced by Sir d.

Newton cornut.
Newton into his investigation of the spiral motions. And
the equation \( \frac{x}{y} = \frac{y}{x} \) is evidently an equation connected
with the logarithmic curve and the logarithmic spiral.
But we must endeavour to reduce it to a lower order of
fluctions, before we can establish a relation between \( \frac{z}{x} \), \( x \),
and \( y \).

Let \( p \) express the ratio of \( y \) to \( x \), that is, let \( p \) be
\( \frac{y}{x} \), or \( p \frac{x}{y} = \frac{y}{x} \). It is evident that this expresses the
inclination of the tangent at \( M \) to the horizon, and that
\( p \) is the tangent of this inclination, radius being unity.
Or it may be considered merely as a number, multiplying
\( x \), so as to make it = \( y \). We now have \( y = p^2 \frac{x}{x} \),
and since \( 2x = x^2 + y^2 \), we have \( x = x^2 + p^2 \frac{x^2}{x} \).
Moreover, because we have supposed the abscissa \( x \)
to increase uniformly, and therefore \( x \) to be constant,
we have \( y = x \frac{p}{p} \), and \( x = x \frac{p}{p} \). Now let \( q \) express
the ratio of \( p \) to \( x \), that is, make \( \frac{p}{p} = q \), or \( x = x \frac{p}{p} \).
This gives us \( x = q \frac{p}{p}, \) and \( x^2 = x \frac{p}{p} \).

By these substitutions our former equation \( y = \frac{y}{x} \)
changes to \( x^2 = x \frac{p}{p} + p^2 \frac{x}{x} \), or \( y = p \frac{p}{p} + p^2 \frac{x}{x} \),
and, taking the fluent on both sides, we have \( y = \int p \frac{p}{p} + p^2 \frac{x}{x} + C \), \( C \) being the constant quantity
required for completing the fluent according to the
limitting conditions of the case. Now \( x = \frac{p}{p}, \) and \( \frac{1}{p} = \frac{a}{p} \).
Therefore \( x = \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \).
Also, since \( y = p \frac{p}{p} = \frac{p}{p} \), we have \( y = \frac{a}{p} \).
\( \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \).
Also \( \frac{x}{x} = x \frac{p}{p} = \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} \),
\( \Rightarrow \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \).
The values of \( x, y, z, \), give us
\( x = \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \), \( y = \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \), \( z = \int \frac{a}{p} \frac{p}{p} + p^2 \frac{x}{x} + C \).

The process therefore of describing the trajectory is, first,
to find \( q \) in terms of \( p \) by the area of the curve whose
abscissa is \( p \) and the ordinate is \( \frac{1}{p} \).

2d, We get \( x \) by the area of another curve whose
abscissa is \( p \), and the ordinate is \( \frac{1}{q} \).

3d, We get \( y \) by the area of a third curve whose
abscissa is \( p \), and the ordinate is \( \frac{q}{p} \).

The problem of the trajectory is therefore completely
solved, because we have determined the ordinate, abscissa,
and arch of the curve for any given position of its
tangent. It now only remains to compute the magnitudes of these ordinates and abscissa, or to draw them
determined by a geometrical construction. But in this consists the
of the ordi-

The areas of these curves, which express the movements of
lengths of \( x \) and \( y \), can neither be computed nor exhibited
geometrically, by any accurate method yet discovered,
and we must content ourselves with approximations.
These render the description of the trajectory exceedingly difficult and tedious, so that little advantage has as yet been derived from the knowledge we have got
of its properties. It will however greatly assist our conception of the subject to proceed some length in this
construction; for it must be acknowledged that very
few distinct notions accompany a mere algebraic opera-
tion, especially if in any degree complicated, which we
confess is the case in the present question.

Let \( B = NR \) (fig. 8.) be an equilateral hyperbola, of
Plate which \( B \) is the vertex, \( BA \) the semistatus axis, \( CCCC \)
which we shall assume for the unit of length. Let \( AV \) fig. 8.
be the semiconjugate axis = \( BA \), = unity, and \( AS \) the
asymptote, bisecting the right angle \( BAV \). Let \( PN \), \( \frac{p}{p} \) be two ordinates to the conjugate axis, exceedingly
near to each other. Join \( BP, AN \), and draw \( BS, B \)
perpendicular to the asymptote, and \( B C \) parallel to \( AP \).
It is well known that \( BP \) is equal to \( NP \). Therefore
\( PN^2 = BA^2 + AP^2 \). Now since \( BA = \frac{p}{p} \), if we make
\( AP = \frac{p}{p} \) of our formula, \( PN \) is \( \sqrt{1+p^2} \), and \( p \)
the area \( BAPN = \int \frac{p}{p} \sqrt{1+p^2} \): That is to say,
the number \( \int \frac{p}{p} \sqrt{1+p^2} \) (for it is a number) has
the same proportion to unity of number that the area
\( BAPN \) has to \( BCVA \), the unit of surface. This
area consists of two parts, the triangle \( APN \), and the
hyperbolic sector \( ABN \). \( APN = \frac{1}{2} \frac{p}{p} \times PN \), \( PN = \frac{1}{2} \frac{p}{p} \sqrt{1+p^2} \), and the hyperbolic sector \( ABN = BN \), \( S \),
which is equivalent to the hyperbolic logarithm of the
number represented by \( S \) when \( \frac{1}{2} \) is unity.
Therefore it is equal to \( \frac{1}{2} \) the logarithm of \( p + \sqrt{1+p^2} \).

Hence we see by the bye that \( \int \frac{p}{p} \sqrt{1+p^2} = \frac{1}{2} \sqrt{1+p^2} + \frac{1}{2} \) hyperbolic logarithm \( p + \sqrt{1+p^2} \).

Now let \( AMD \) be another curve, such that its ordinates
\( Vm, PD, \&c. \) may be proportional to the areas
\( AB \), \( V \), \( ABNP \) and may have the same proportion to
\( AB \), the unity of length, these areas have to
\( ABCV \), the unity of surface. Then \( VM : VC = \frac{1}{2} \frac{p}{p} \times VA \), \( VCB \), and \( PD : P \frac{2}{2} = \frac{PB}{PB} \), \( VCBA \),
\&c. These ordinates will now represent \( \int \frac{p}{p} \sqrt{1+p^2} \)
with reference to a linear unit, as the areas to the
hyperbola represented it in reference to a superficial
unit.

Again,
PROJECTILES.

Again, in every ordinate make PD: P Q = P O, and thus we obtain a reciprocal to PD, or to \( \int p \sqrt{1+p^2} \), equivalent to \( \int \frac{1}{p \sqrt{1+p^2}} \). This will evidently be \( \frac{a}{ap} \) and PO \( \text{p} \) will be \( \frac{a}{a} \), and the area contained between the lines AF, AW, and the curve GEOH, and cut off by the ordinate PO, will represent \( \frac{a}{a} \).

Lastly, make PO: PQ = AV: AP, = i: p; and then PQ \( \text{q} \) will represent \( \frac{y}{a} \), and the area ALEQP will represent \( \frac{y}{a} \).

But we must here observe that the fluxions expressed by these different areas require what is called the correction to accommodate them to the circumstances of the case. It is not indifferent from what ordinate we begin to reckon the area. This depends on the initial direction of the projectile, and that point of the abscissa AP must be taken for the commencement of all the areas which gives a value of \( \text{p} \) suited to the initial direction. Thus, if the projection has been made from A (fig. 7) at an elevation of 45°, the ratio of the fluxions \( \frac{a}{a} \) and \( \frac{a}{a} \) is that of equality; and therefore the point E of fig. 8, where the two curves intersect and have a common ordinate, evidently corresponds to this condition. The ordinate EV passes through V, so that AV or \( \text{p} = 0 \), \( \text{r} = \text{r} \), \( \text{t} = \text{t} \), tangent 45°, as the case requires. The values of \( \frac{a}{a} \) and \( \frac{a}{a} \) corresponding to any other point of the trajectory, such as that which has AP for the tangent of the angle which it makes with the horizon, are now to be had by computing the areas VEOP, VEQP.

Another curve might have been added, of which the ordinates would exhibit the fluxions of the arch of the trajectory \( \frac{a}{a} \), \( \frac{a}{a} \), \( \frac{a}{a} \), \( \frac{a}{a} \); and which the area would exhibit the arch itself. And this would have been very easy, for it is \( \frac{a}{a} \), \( \frac{a}{a} \), \( \frac{a}{a} \), \( \frac{a}{a} \), which is evidently the fluxion of the hyperbolic logarithm of \( \int p \sqrt{1+p^2} + C \). But it is needless, since \( \frac{a}{a} \), \( \frac{a}{a} \), and we have already got \( \frac{a}{a} \). It is only increasing PD in the ratio of BA to BP.

And thus we have brought the investigation of this problem to considerable length, having ascertained the form of the trajectory. This is surely done when the ratio of the arch, abscissa, and ordinate, and the position of its tangent, is determined in every point. But it is still very far from a solution, and much remains to be done before we can make any practical application of it.

The only general consequence that we can deduce from the premises is, that in every case where the resistance in any point bears the same proportion to the force of gravity, the trajectory will be similar. Therefore, two balls, of the same density, projected in the same direction, will describe similar trajectories if the velocities are in the subduplicate ratio of the diameters. This we shall find to be of considerable practical importance. But let us now proceed to determine the velocity in the different points of the trajectory; and the time of describing different portions.

Recollect, therefore, that \( \frac{a}{a} = \frac{a}{a} \), and \( \frac{a}{a} = \frac{a}{a} \).

\[ \begin{align*}
  x^2 + p^2 & \quad \text{and} \quad y = \frac{x}{p}. \\
  \text{This gives} \quad \frac{a}{a} & = \frac{a}{a} \\
  \text{But} \quad \frac{a}{a} & = \frac{a}{a}.
\end{align*} \]

Therefore \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \).

Also \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \).

If we now substitute for \( \frac{a}{a} \) its value just found, we obtain \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \), \( \frac{a}{a} = \frac{a}{a} \).

The greatest difficulty still remains, viz. the accommodating these formulæ, which appear abundantly simple, to the particular cases. It would seem at first sight, that all trajectories are similar; since the ratio of the fluxions of the ordinates and abscissa corresponding to any particular angle of inclination to the horizon seems the same in all; but a due attention to what has been hitherto said on the subject will show us that we have as yet only been able to ascertain the velocity in the point of the trajectory, which has a certain inclination to the horizon, indicated by the quantity \( \text{p} \), and the time (reckoned from some assigned beginning) when the projectile is in that point.

To obtain absolute measures of these quantities, the term of commencement must be fixed upon. This will be expressed by the constant quantity \( C \), which is assumed for completing the fluents of \( p \sqrt{1+p^2} \), which is the basis of the whole construction. We there found \( q = \int \frac{a}{a} \).

\[ \frac{a}{a} \]

This fluent is in general \( \frac{a}{a} \), \( \frac{a}{a} \), \( \frac{a}{a} \), and the constant quantity \( C \) is to be accommodated to some circumstances of the case. Different authors have selected different circumstances.
Euler, in his Commentary on Robins, and in a dissertation in the Memoirs of the Academy of Berlin published in 1753, takes the vertex of the curve for the beginning of its abscissa and ordinate. This is the simplest method of any, for C must then be so chosen that the whole fluent may vanish when \( p = 0 \), which is the case in the vertex of the curve, where the tangent is parallel to the horizon. We shall adopt this method.

Therefore, let \( AP \) (fig. 9) = \( x \), \( PM = y \), \( AM = z \). Put the quantity \( C \) which is introduced into the fluent equal to \( \frac{n}{a} \). It is plain that \( n \) must be a number; for it must be homologous with \( p \sqrt{1 + p^2} \), which is a number. For brevity's sake let us express the fluent of \( p \sqrt{1 + p^2} \) by the single letter \( P \); and thus we shall have

\[
x = a \times \int \frac{p}{\sqrt{n + P}}, \quad y = a \times \int \frac{pP}{\sqrt{n + P}}, \quad z = a \times \int \frac{P}{\sqrt{n + P}}.
\]

And \( \phi = -a \frac{g(1 + p^2)}{n + P} \). Now the height \( h \) necessary for communicating any velocity \( e \) is

\[
\phi = -a \frac{g(n + P)}{2g(n + P)^2}, \quad = -a \frac{u(1 + p^2)}{n + P}.
\]

And lastly,

\[
t = \frac{\sqrt{P}}{\sqrt{g(n + P)}}.
\]

These fluents, being all taken so as to vanish at the vertex, where the computation commences, and where \( P \) is \( = 0 \) (the tangent being parallel to the horizon), we obtain in this case \( h = \frac{a}{n} = \frac{a}{2n} \) and \( n = \frac{a}{2h} \).

Hence we see that the circumstance which modifies all the curves, distinguishing them from each other, is the velocity (or rather its square) in the highest point of the curve. For \( h \) being determined for any body whose terminal velocity is \( u \), \( n \) is also determined; and this is the modifying circumstance. Considering it geometrically, it is the area which must be cut off from the area DMAP of fig. 8, in order to determine the ordinates of the other curves.

We must further remark, that the values now given relate only to that part of the area where the body is descending from the vertex. This is evident; for, in order that \( y \) may increase as we recede from the vertex, its fluxion must be taken in the opposite sense to what it was in our investigation. There we supposed \( y \) to increase as the body ascended, and then to diminish during the descent; and therefore the fluxion of \( y \) was first positive and then negative.

The same equations, however, will serve for the ascending branch CNA of the curve, only changing the sign of \( P \); for if we consider \( y \) as decreasing during the ascent, we must consider \( q \) as expressing \( \frac{-p}{x} \), and therefore \( P \), or \( \int p \sqrt{1 + p^2} \), which is \( = \frac{q}{a} \), must be taken negatively. Therefore, in the ascending branch, we have \( AQ \) or \( x \) (increasing as we recede from \( A \))—

\[
a \times \int \frac{p}{n - P}, \quad QN \quad y = a \times \int \frac{PP}{n - P}, \quad AN \quad z = \frac{a}{G}.
\]

VOL. XVII. Part II.

Hence we learn by the bye, that in no part of the Remark, ascending branch can the inclination of the tangent be equal to \( n \); and that if we suppose the curve \( P \) equal to \( n \) in any point of the curve, the velocity in that point will be infinite. That is to say, there is a certain assignable elevation of the tangent which cannot be exceeded in a curve which has this velocity in the vertex. The best way for forming a conception of this circumstance in the nature of the curve, is to invert the motion, and suppose an accelerating force, equal and opposite to the resistance, to act on the body in conjunction with gravity. It must describe the same curve, and this branch ANC must have an asymptote LO, which has this limiting position of the tangent. For, as the body descends in this curve, its velocity increases to infinity by the joint action of gravity and this accelerating force, and yet the tangent never approaches so near the perpendicular position as to make \( P = a \). This remarkable property of the curve was known to Newton, as appears by his approximations, which all lead him to curves of a hyperbolic form, having one asymptote inclined to the horizon. Indeed it is pretty obvious: For the resistance increasing faster than the velocity, there is no velocity of projection so great but that the curve will come to deviate so from the tangent, that in a finite time it will become parallel to the horizon. Were the resistance proportional to the velocity, then an infinite velocity would produce a rectilinear motion, or rather a deflection from it less than any that can be assigned.

We now see that the particular form and magnitude of this trajectory depends on two circumstances, \( a \) and \( n \). \( a \) affects chiefly the magnitude. Another circumstance might indeed be taken in, viz. the diminution of the accelerating force of gravity by the statical effect of the air's gravity. But, as we have already observed, this is too trifling to be attended to in military projectiles.

\[
\frac{y}{x} \text{ was made equal to } \frac{e}{p}.
\]

Therefore the radius of curvature, determined by the ordinary methods, is

\[
\frac{a(1 + p^2)}{n + P} \sqrt{1 + p^2}, \quad \text{and, because } \frac{e}{p} \text{ is } \text{Simpson's Fluxions}, \quad \frac{a}{n + P} \text{ for the descending branch of the curve, the}
\]

\[
\text{radius of curvature at } M \text{ in } a \frac{(x + p^2)\sqrt{1 + p^2}}{n + P}, \quad \text{and, in the ascending branch at } N, \text{ it is } a \frac{(x + p^2)\sqrt{1 + p^2}}{n - P}.
\]

On both sides, therefore, when the velocity is infinitely great, and \( P \) by this means supposed to equal or exceed \( a \), the radius of curvature is also infinitely great. We also see that the two branches are unlike each other, and that when \( p \) is the same in both, that is, when the tangent is equally inclined to the horizon, the radius of curvature, the ordinate, the absciss, and the arc, are all greater in the ascending branch. This is pretty obvious.
vions. For as the resistance acts entirely in diminishing the velocity, and does not affect the deflection occasioned by gravity, it must allow gravity to incurvate the path so much the more (with the same inclination of its line of action) as the velocity is more diminished. The curvature, therefore, in those points which have the same inclination of the tangent, is greatest in the descending branch, and the motion is swiftest in the ascending branch. It is otherwise in a void, where both sides are alike. Here \( n \) becomes infinite, or there is no terminal velocity; and \( n \) also becomes infinite, being \( \frac{a}{2h} \).

It is therefore in the quantity \( P \), or \( \int p \sqrt{1+p^2} \),

that the difference between the trajectory in a void and in a resisting medium consists; it is this quantity which expresses the accumulated change of the ratio of the increments of the ordinate and abscissa. In vacuo the second increment of the ordinate is constant when the first increment of the abscissa is \( 1+p \), and the whole increment of the ordinate is \( 1+p \). And this difference is so much the greater as \( P \) is greater in respect of \( n \). \( P \) is nothing at the vertex, and increases along with the angle \( MT \); and when this is a right angle, \( P \) is infinite. The trajectory in a resisting medium will come therefore to deviate infinitely from a parabola, and may even deviate farther from it than the parabola deviates from a straight line. That is, the distance of the body in a given moment from that point of its parabolic path where it would have been in a void, is greater than the distance between that point of the parabola from the point of the straight line where it would have been, independent of the action of gravity. This must happen whenever the resistance is greater than the weight of the body, which is generally the case in the beginning of the trajectory in military projectiles; and this (were it now necessary) is enough to show the inutility of the parabolic theory.

Although we have no method of describing this trajectory, which would be received by the ancient geometers, we may ascertain several properties of it, which will assist us in the solution of the problem. In particular, we can assign the absolute length of any part of it by means of the logistic curve. For because

\[
\int p \sqrt{1+p^2} = P,
\]

and therefore \( a \), which was \( a \times \int p \sqrt{1+p^2} + C \), or \( a \times \int \frac{p}{\sqrt{1+p^2}} \),

\[
\int n + P \] may be expressed by logarithms; or \( a = a \times \text{hyp. log. of } \frac{n+P}{n} \), since at the vertex \( A \), where \( \omega \) must be \( \frac{a}{2h} \), \( P \) is also \( \frac{a}{2h} \).

Being able, in this way, to ascertain the length \( AM \) of the curve (counted from the vertex), corresponding to any inclination \( p \) of the tangent at its extremity \( M \), we can ascertain the length of any portion of it, such as \( Mm \), by first finding the length of the part \( A \), and then of the part \( AM \). This we do more expeditiously thus. Let \( p \) express the position of the tangent in \( M \), and

\[
g \text{ its position at } m; \text{ then } AM = a \times \log. \frac{n+P}{n}, \text{ and } AM = a \times \log. \frac{n+Q}{n}, \text{ and therefore } Mm \text{ is } = a \times \log. \frac{n+Q}{n+P}.
\]

Thus we can find the values of a great number of small portions and the inclination of the tangents at their extremities. Then to each of these portions we can assign its proportion of the abscissa and ordinate, without having recourse to the values of \( x \) and \( y \). For the portion of abscissa corresponding to the arch \( Mm \), whose middle point is inclined to the horizon in the angle \( b \), will be \( Mm \times \cos \theta \), and the corresponding portion of the ordinate will be \( Mm \times \sin \theta \). Then we obtain the velocity in each part of the curve by the equation

\[
h = \frac{a}{2} \times \frac{1+p}{\sqrt{n+P}};
\]

or, more directly the velocity

\[
u \text{ at } M \text{ will be } = \sqrt{a \frac{p}{\sqrt{n+P}}},
\]

Lastly, divide the length of the little arch by this, and the quotient will be the time of describing \( Mm \) very nearly. Add all these together, and we obtain the whole time of describing the arch \( AM \), but a little too great, because the motion in the small arch is not perfectly uniform. The error, however, may be as small as we please, because we may make the arch as small as we please; and for greater accuracy, it will be proper to take the \( p \) by which we compute the velocity, a medium between the \( p \) for the beginning and that for the end of the arch.

This is the method followed by Euler, who was one of the most expert analysts, if not the very first, in Europe. It is not the most elegant, and the methods offered by some other authors, who approximate directly to the areas of the curves which determine the values of \( x \) and \( y \), have a more scientific appearance; but they are not ultimately very different. For, in some methods, these areas are taken piecemeal, as Euler takes the arch; and by the methods of others, who give the value of the areas by Newton's method of describing a curve of the parabolic kind through any number of given points, the ordinates of these curves, which express \( x \) and \( y \), must be taken singly, which amounts to the same thing, with the great disadvantage of a much more complicated calculus, as any one may see by comparing the expressions of \( x \) and \( y \) with the expressions of \( z \). As to those methods which approximate directly to the areas or values of \( x \) and \( y \) by an infinite series, they all, without exception, involve us in most complicated expressions, with coefficients of sines and tangents, and ambiguous signs, and engage us in a calculation almost endless. And we know of no series which converges fast enough to give us tolerable accuracy, without such a number of terms as is sufficient to deter any person from the attempt. The calculation of the arches is very moderate, so that a person tolerably versant in arithmetical operations may compute an arch with its velocity and time in about five minutes. We have therefore no hesitation in preferring this method of Euler's to all that we have seen, and therefore proceed to determine some other circumstances which render its application more general.
PROJECTILES.

If there were no resistance, the smallest velocity would be at the vertex of the curve, and it would immediately increase by the action of gravity conspiring (in however small degree) with the motion of the body. But in a resisting medium, the velocity at the vertex is diminished by a quantity to which the acceleration of gravity in that point bears no assignable proportion. It is therefore diminished, upon the whole, and the point of smallest velocity is a little way beyond the vertex. For the same reasons, the greatest curve is a little way beyond the vertex. It is not very material for our present purpose to ascertain the exact positions of those points.

The velocity in the descending branch augments continually: but it cannot exceed a certain limit, if the velocity at the vertex has been less than the terminal velocity; for when the curve is infinite, p is also infinite, and \( \frac{\partial p}{\partial x} \), because n in this case is nothing in respect of p, which is infinite; and because p is infinite, the numerator log. p \( \times \sqrt{1 + p^2} \), though infinite, vanishes in comparison with \( p \times \sqrt{1 + p^2} \); so that in this case \( P = \frac{y}{p} \), and \( \alpha = \frac{y}{y} \), and \( \psi = \psi \) the terminal velocity.

If, on the other hand, the velocity at the vertex has been greater than the terminal velocity, it will diminish continually, and when the curve has become infinite, \( \nu \) will be equal to the terminal velocity.

In either case we see that the curve on this side will have a perpendicular asymptote. It would require a long and pretty intricate analysis to determine the place of this asymptote, and it is not material for our present purpose. The place and position of the other asymptote LO is of the greatest moment. It evidently distinguishes the kind of trajectory from any other. Its position depends on this circumstance, that if \( P \) marks the position of the tangent, \( n - P \), which is the denominator of the fraction expressing the square of the velocity, must be equal to nothing, because the velocity is infinite: therefore, in this place, \( P = n \), or \( n = \frac{y}{_4} \sqrt{1 + p^2} + \frac{1}{4} \log. p + \sqrt{1 + p^2} \).

In order, therefore, to find the point L, where the asymptote LO cuts the horizontal line AL, put \( P = n \), then AL = \( y \times \frac{\int p}{n - P} - \frac{1}{p} \int \frac{p p}{n - P} \).

It is evident that the logarithms used in these expressions are the natural or hyperbolic. But the operations may be performed by the common tables, by making the value of the arch \( M m \) of the curve \( = \frac{a}{M} \times \log. \frac{n + \infty}{n + P} \), &c. where \( M \) means the subtangent of the common logarithms, or 0,43429; also the time of describing this arch will be expeditiously had by taking a medium \( \mu \) between the values of \( \sqrt{1 + p^2} \) and \( \sqrt{n + P} \), \( n + \infty \), and making the time \( = \frac{a}{M \mu} \times \log. \frac{n + \infty}{n + P} \).

Such then is the process by which the form and magnitude of the trajectory, and the motion in it, may be determined. But it does not yet appear how this is to be applied to any question in practical artillery. In this process we have only learned how to compute the motion from the vertex in the descending branch till the ball has acquired a particular direction, and the motion to the vertex from a point of the ascending branch where the ball has another direction, and all this depending on the greatest velocity which the body can acquire by falling, and the velocity which it has in the vertex of the curve. But the usual question is, "What will be the motion of the ball projected in a certain direction with a certain velocity?"

The mode of application is this: Suppose a trajectory computed for a particular terminal velocity, produced by the fall \( \alpha \), and for a particular velocity at the vertex, which will be characterized by \( n \), and that the velocity at the point of the ascending branch where the inclination of the tangent is 30° is 900 feet per second. Then, we are certain, that if a ball, whose terminal velocity is that produced by the fall \( \alpha \), be projected with the velocity of 900 feet per second, and an elevation of 30°, it will describe this very trajectory, and the velocity and time corresponding to every point will be such as is here determined.

Now this trajectory will, in respect to form, answer an infinity of cases: for its characteristic is the proportion of the velocity in the vertex to the terminal velocity. When this proportion is the same, the number \( n \) will be the same. If, therefore, we compute the trajectories for a sufficient variety of these proportions, we shall find a trajectory that will nearly correspond to any case that can be proposed: and an approximation sufficiently exact will be had by taking a proportional medium between the two trajectories which come nearest to the case proposed.

Accordingly, a set of tables or trajectories have been computed by the English translator of Euler's Compendium or manuscript on Robins's Gunner. They are in number 18, trajectories distinguished by the position of the asymptote of the ascending branch. This is given for 5°, 10°, 15°, &c., to 85°, and the whole trajectory is computed as far as it can ever be supposed to extend in practice. The following table gives the value of the number \( n \) corresponding to each position of the asymptote.

</table>

Since the path of a projectile is much less incurvated, and more rapid in the ascending than in the descending branch, and the difference is so much the more remarkable in great velocities; it must follow, that the range on a horizontal or inclined plane depends most on the ascending branch: therefore the greatest range will not be made with that elevation which bisects the angle of position, but with a lower elevation; and the deviation from the bisecting elevation will be greater as the initial velocities

\[ \text{3 Q 2} \]
velocities are greater. It is very difficult to frame an
exact rule for determining the elevation which gives the
greatest range. We have subjoined a little table which
gives the proper elevation (nearly) corresponding to
the different initial velocities.

It was computed by the following approximation,
which will be found the same with the series used by
Newton in his Approximation.

Let \( e \) be the angle of elevation, \( a \) the height
producing the terminal velocity, \( h \) the height pro-
ducing the initial velocity, and \( c \) the number whose hy-
perbolic logarithm is \( i \) (i.e. the number 2.718).

Then,

\[
y = x \left( \tan e + \frac{a}{2h \cos e} \right) - \frac{a^2}{24} \left( \frac{2x}{Ca \cos e} - 1 \right),
\]

&c. Make \( y = v \), and take the maximum by vary-
ing \( e \), we obtain

\[
\sin e + \frac{a \sin e}{2h} = \text{hyperbol. log.}
\]

\[
\left(1 + \frac{2h}{a \sin e} \right),
\]

which gives us the angle \( e \).

The numbers in the first column, multiplied by the
terminal velocity of the projectile, give us the initial
velocity; and the numbers in the last column, being
multiplied by the height producing the terminal ve-
cocity, and by \( 2.3026 \), give us the greatest ranges.
The middle column contains the elevation. The table is not
computed with scrupulous exactness, the question not re-
quiring it. It may, however, be depended on within
one part of 2000.

To make use of this table, divide the initial vel-
ocity by the terminal velocity \( v \), and look for the quotient in
the first column. Opposite to this will be found the ele-
vation giving the greatest range; and the number in the
last column being multiplied by \( 2.3026 \times a \) (the height
producing the terminal velocity) will give the range.

</table>

But let us see what advantage we are likely to derive
from it.

In the first place it is very limited in its applica-
tion. There are few circumstances of general coinci-
dence, and almost every case requires an appropriated
calculus. Perhaps the only general rules are the two
following:

1. Balls of equal density, projected with the same
elevation, and with velocities which are the square
roots of their diameters, will describe similar curves.

This is evident, because, in this case, the resistance
will be in the ratio of their quantities of motion. Therefore
all the homologous lines of the motion will be in the
proportion of the diameters.

2. If the initial velocities of balls projected with the
same elevation are in the inverse subduplicate ratio of
the whole resistances, the ranges, and all the homo-
loguous lines of their track, will be inversely as those
resistances.

These theorems are of considerable use; for by means
of a proper series of experiments on one ball projected
with different elevations and velocities, tables may be
constructed which will ascertain the motions of an in-
finity of others.

But when we take a retrospective view of what we
have done, and consider the conditions which were as-
sumed in the solution of the problem, we shall find that
much yet remains before it can be rendered of great
practical use, or even satisfy the curiosity of the man of
science. The resistance is all along supposed to be in
the duplicate ratio of the velocity; but even theory
points out many causes of deviation from this law, such
as the pressure and condensation of the air, in the case
of very swift motions; and Mr. Robins's experiments are
sufficient to show us that the deviations must be ex-
ceedingly great in such cases. Mr. Euler and all sub-
sequent writers have allowed that it may be three times
greater, even in cases which frequently occur; and Eu-
ler gives a rule for ascertaining with tolerable accuracy
what this increase and the whole resistance may amount
to. Let \( H \) be the height of a column of air whose
weight is equivalent to the resistance taken in the
duplicate ratio of the velocity. The whole resistance
will be expressed by \( H + \frac{H^2}{28845} \). This number 28845 is the
height in feet of a column of air whose weight balances
its elasticity. We shall not at present call in question
his reasons for assigning this precise addition. They
are rather reasons of arithmetical convenience than of
physical import. It is enough to observe, that if this
measure of the resistance is introduced into the process
of investigation, it is totally changed; and it is not too
much to say, that with this complication it requires the
knowledge and address of a Euler to make even a par-
tial and very limited approximation to a solution.

Any law of the resistance, therefore, which is more
complicated than what Bernoulli has assumed, namely,
that of a simple power of the velocity, is abandoned by
all the mathematicians, as exceeding their abilities; and
they have attempted to avoid the error arising from the
assumption of the duplicate ratio of the velocity, either
by supposing the resistance throughout the whole tra-
jectory to be greater than what it is in general, or
they have divided the trajectory into different por-
tions, and assigned different resistances to each, which
vary.
PROJECTILES.

vary, through the whole of that portion, in the duplicate ratio of the velocities. By this kind of patchwork they make up a trajectory and motion which corresponds, in some tolerable degree, with what? With an accurate theory? No; but with a series of experiments. For, in the first place, every theoretical computation that we make proceeds on a supposed initial velocity; and this cannot be ascertained with any thing approaching to precision, by any theory of the action of gunpowder that we are yet possessed of. In the next place, our theories of the resisting power of the air are entirely established on the experiments on the flights of shot and shells, and are corrected and amended till they tally with the most approved experiments we can find. We do not learn the ranges of a gun by theory, but the theory by the range of the gun. Now the variety and irregularity of all the experiments which are appealed to are so great, and the acknowledged difference between the resistance to slow and swift motions is also so great, that there is hardly any supposition which can be made concerning the resistance, that will not agree in its results with many of those experiments. It appears from the experiments of Dr Hutton of Woolwich, in 1784, 1785, and 1786, that the shots frequently deviated to the right or left of their intended track 200, 300, and sometimes 400 yards. This deviation was quite accidental and anomalous to the theory; but the shot deviated from its intended and supposed elevation as much as it deviated from the intended vertical plane, and this without any opportunity of measuring or discovering the deviation. Now, when we have the whole range from one to three to choose among for our measure of resistance, it is evident that the confirmations which have been drawn from the ranges of shot are but feeble arguments for the truth of any opinion. Mr Robins finds his measures fully confirmed by the experiments at Metz and at Minorca. Mr Muller finds the same. Yet Mr Robins's measure both of the initial velocity and of the resistance are at least treble of Mr Muller's; but by compensation they give the same results. The Chevalier Borda, a very expert mathematician, has added the very same experiments in support of his theory, in which he abides by the Newtonian measure of the resistance, which is about \( \frac{2}{3} \) of Mr Robins's, and about \( \frac{3}{4} \) of Muller's.

What are we to conclude from all this? Simply this, that we have hardly any knowledge of the air's resistance, and that even the solution given of this problem has as yet greatly increased it. Our knowledge consists only in those experiments, and mathematicians are attempting to patch up some notion of the motion of a body in a resisting medium, which shall tally with them.

There is another essential defect in the conditions assumed in the solution. The density of the air is supposed uniform; whereas we are certain that it is less by one-fifth or one-sixth towards the vertex of the curve, in many cases which frequently occur, than it is at the beginning and end of the flight. This is another latitude given to authors in their assumptions of the air's resistance. The Chevalier de Borda has, with considerable ingenuity, accommodated his investigation to this circumstance, by dividing the trajectory into portions, and, without much trouble, has made one equation answer them all. We are disposed to think that his solution of the problem (in the Memoirs of the Academy of Paris for 1769) corresponds better with the physical circumstances of the case than any other. But this process is there delivered in too concise a manner to be intelligible to a person not perfectly familiar with all the resources of modern analysis. Therefore preferred John Bernoulli's, because it is elementary and rigorous.

After all, the practical artillerist must rely chiefly on the records of experiments contained in the books of practice at the academies, or those made in a more public manner. Even a perfect theory of the air's resistance can do him little service, unless the force of gunpowder were uniform. This is far from being the case even in the same powder. A few hours of a damp day will make a greater difference than occurs in any theory; and, in service it is only by trial that every thing is performed. If the first shell fall very much short of the mark, a little more powder is added; and, in cannonading, the correction is made by varying the elevation.

We hope to be forgiven by the eminent mathematicians for these observations on their theories. They by no means proceed from any disrespect for their labours. We are not ignorant of the almost insuperable difficulty of the task, and we admire the ingenuity with which some of them have contrived to introduce into their analysis reasonable substitutions for those terms which would render the equations intractable. We must still say, upon their own authority, that these are but ingenious guesses, and that experiment is the touchstone by which they would refute these substitutions; and when they have found a coincidence, they have no motive to make any alteration. Now, when we have such a latitude for our measure of the air's resistance, that we may take it of any value, from one to three, it is no wonder that compensations of errors should produce a coincidence; but where is the coincidence? The theorist supposes the ball to set out with a certain velocity, and his theory gives a certain range; and this range agrees with observation—but how? Who knows the velocity of the ball in the experiment? This is concluded from a theory incomparably more uncertain than that of the motion in a resisting medium.

The experiments of Mr Robins and Dr Hutton show, in the most incontrovertible manner, that the resistance to a motion exceeding 1000 feet in a second, is almost three times greater than in the duplicate ratio to the resistance to moderate velocities. Euler's translator, in his comparison of the author's trajectories with experiment, supposes it to be no greater. Yet the coincidence is very great. The same may be said of the Chevalier de Borda's. Nay, the same may be said of Mr Robins's own practical rules: for he makes his \( F \), which corresponds to our \( a \), almost double of what these authors do, and yet his rules are confirmed by practice. Our observations are therefore well founded.

But it must not be inferred from all this, that the theory of the physical theory of gunpowder is of no use to the practical artillerist, is still of some use in practice. This velocity is of no effect after 200 or 300 yards at farthest, because it is so rapidly reduced by the prodigious resistance of the air. Mr Robins has deduced several practical maxims of the greatest importance from what we already know of this subject, and which could hardly have been even conjectured without this knowledge. See GUNNERY.
And it must still be acknowledged, that this branch of physical science is highly interesting to the philosopher; nor should we despair of carrying it to a greater perfection. The defects arise almost entirely from our ignorance of the law of variation of the air's resistance. Experiments may be contrived much more conducive to our information here than those commonly resorted to. The oblique flights of projectiles are, as we have seen, of very complicated investigation, and ill fitted for instructing us; but numerous and well contrived experiments on the perpendicular ascents are of great simplicity, being affected by nothing but the air's resistance. To make them instructive, we think that the following plan might be pursued. Let a set of experiments be premised for ascertaining the initial velocities. Then let shells be discharged perpendicularly with great varieties of density and velocity, and let nothing be attended to but the height and the time; even a considerable deviation from the perpendicular will not affect either of these circumstances, and the effect of this circumstance can easily be computed. The height can be ascertained with sufficient precision for very valuable information by their light or smoke. It is evident that these experiments will give direct information of the air's retarding force; and every experiment gives us two measures, viz. the ascent and descent: and the comparison of the times of ascent and descent, combined with the observed height in one experiment made with a great initial velocity, will give us more information concerning the air's resistance than 50 ranges. If we should suppose the resistance as the square of the velocity, this comparison will give in each experiment an exact determination of the initial and final velocities, which no other method can give us. These, with experiments on the time of horizontal flights, with known initial velocities, will give us more instruction on this head than any thing that has yet been done; and the author of this kind of experiments is supposed to be Mr. Robins. Here is nothing of this kind that has been done before, we presume to say that the motion of bodies in a resisting medium will remain in the hands of the mathematicians as a matter of curious speculation. In the mean time, the rules which Mr. Robins has delivered in his Gunnery are very simple and easy in their use, and seem to come as near the truth as any we have met with. He has not informed us upon what principles they are founded, and we are disposed to think that they are rather empirical than scientific. But we profess great deference for his abilities and penetration, and doubt not but that he had framed them by means of as scientific a discussion as his knowledge of this new and difficult subject enabled him to give it.

We shall conclude this article, by giving two or three tables, computed from the principles established above, and which serve to bring into one point of view the chief circumstances of the motion in a resisting medium. Although the result of much calculation, as any person who considers the subject will readily see, they must not be considered as offering any very accurate results; or that, in comparison with one or two experiments, the differences shall not be considerable. Let any person consult the published registers of experiments which have been made with every attention, and he will see such enormous irregularities, that all expectations of perfect agreement with them must cease. In the experiments at Woolwich in 1735, which were continued for several days, not only do the experiments of one day differ among themselves, but the mean of all the experiments of one day differs from the mean of all the experiments of another no less than one-fourth of the whole. The experiments in which the greatest regularity may be expected, are those made with great elevations. When the elevation is small, the range is more affected by a change of velocity, and still more by any deviation from the supposed or intended direction of the shot.

The first table shows the distance in yards to which a ball projected with the velocity 1600 will go, while its velocity is reduced one-tenth, and the distance at which it drops 16 feet from the line of its direction. This table is calculated by the resistance observed in Mr Robins's experiments. The first column is the weight of the ball in pounds. The second column remains the same whatever be the initial velocity; but the third column depends on the velocity. It is here given for the velocity which is very usual in military service, and its use is to assist us in directing the gun to the mark. If the mark at which a ball of 24 pounds is directed is 474 yards distant, the axis of the piece must be pointed 16 feet higher than the mark. These deflections from the line of direction are nearly as the squares of the distances.

The next table contains the ranges in yards of a 2 pound shot, projected at an elevation of 45°, with the different velocities in feet per second, expressed in the first column. The second column contains the distances to which the ball would go in vacuo in a horizontal plane; and the third contains the distances to which it will go through the air. The fourth column is added, to show the height to which it rises in the air; and the fifth shows the ranges corrected for the diminution of the air's density as the bullet ascends, and may therefore be called the corrected range.

The
PROJECTILES.

The initial velocities can never be pushed as far as we have calculated for in this table; but we mean it for a table of more extensive use than appears at first sight. Recollect, that while the proportion of the velocity at the vertex to the terminal velocity remains the same, the curves will be similar: therefore, if the initial velocities are as the square-roots of the diameters of the balls, they will describe similar curves, and the ranges will be as the diameters of the balls.

Therefore, to have the range of a 12 pound shot, if projected at an elevation of 45°, with the velocity 1500; suppose the diameter of the 12-pounder to be d, and that of the 24-pounder D; and let the velocities be v and V: Then say, \( \sqrt{d} : \sqrt{D} = 1500 \) to a fourth proportional V. If the 24-pounder be projected with the velocity V, it will describe a curve similar to that described by the 12-pounder, having the initial velocity 1500. Therefore find (by interpolation) the range of the 24-pounder, having the initial velocity V. Call this R. Then \( \sqrt{D} : \sqrt{d} : R : R \), the range of the 12-pounder which was wanted, and which is nearly 3380 yards.

We see by this table the immense difference between the motions through the air and in a void. We see that the ranges through the air, instead of increasing in the duplicate ratio of the initial velocities, really increase slower than those velocities in all cases of military service; and in the most usual cases, viz. from 800 to 1600, they increase nearly as the square-roots of the velocities.

A set of similar tables, made for different elevations, would almost complete what can be done by theory, and would be much more expeditious in their use than Mr Euler's Trajectories, computed with great labour by his English translator.

The same table may also serve for computing the ranges of bomb-shells. We have only to find what must be the initial velocity of the 24 pound shot which corresponds to the proposed velocity of the shell. This must be deduced from the diameter and weight of the shell, by making the velocity of the 24-pounder such, that the ratio of its weight to the resistance may be as the same as in the shell.

That the reader may see with one glance the relation of those different quantities, we have given this table, expressed in a figure (fig. 10). The abscissa, Fig. 10, or axis DA, is the scale of the initial velocities in feet per second, measured in a scale of 400 equal parts in the different inches. The ordinates to the curve ACG express the quotient yards of the range on a scale containing 800 yards in titles in it. The ordinates to the curve A = γ express (by the same scale) the height to which the ball rises in the air.

The ordinate BC (drawn through the point of the abscissa which corresponds to the initial velocity 2000) is divided on the points 4, 9, 12, 18, 24, 32, 42, in the ratio of the diameters of cannon-shot of different weights; and the same ordinate is produced on the other side of the axis, till BO be equal to BA; and then BO is divided in the subduplicate ratio of the same diameters. Lines are drawn from the point A, and from any point D of the abscissa, to these divisions.

We see distinctly by this figure how the effect of the initial velocity gradually diminishes, and that in very great velocities the range is very little increased by its augmentation. The dotted curve APQR, shows what the ranges in vacuo would be.

By this figure may the problems be solved. Thus, to find the range of the 12-pounder, with the initial velocity 1500. Set off 1500 from B to F; draw FH parallel to the axis, meeting the line 12 A in H; draw the ordinate HK, draw HL parallel to the axis, meeting 24 B in L; draw the ordinate LM, cutting 12 B in N. MN is the range required.

If curves, such as ACG, were laid down in the same manner for other elevations, all the problems might be solved with great dispatch, and with much more accuracy than the theory by which the curves are drawn can pretend to.

Note, that fig. 10, as given on Plate CCCCCXLIII, is one-half less than the scale according to which it is described; but the practical mathematician will find no difficulty in drawing the figure on the enlarged scale to correspond to the description.

PROJECTION OF THE SPHERE.

The projection of the sphere is a perspective representation of the circles on the surface of the sphere; and is variously denominated according to the different positions of the eye and plane of projection.

There are three principal kinds of projection; the stereographic, the orthographic, and gnomonic. In the stereographic projection the eye is supposed to be placed on the surface of the sphere; in the orthographic it is supposed to be at an infinite distance; and in the gnomonic projection the eye is placed at the centre of the sphere. Other kinds of projection are, the globular, Mercator's, scrographic, &c. for which see the articles Geography, Navigation, Perspective, &c.

Definitions.

1. The plane upon which the circles of the sphere are described, is called the plane of projection, or the.

primitive circle. The pole of this circle is the pole Stereographic projection, and the place of the eye is the projecting.

point.

2. The line of measures of any circle of the sphere is that diameter of the primitive, produced indefinitely, which passes through the centre of the projected circle.

Axiom.

The projection, or representation of any point, is where the straight line drawn from it to the projecting point intersects the plane of projection.

SECTION I.

Of the Stereographic Projection of the Sphere.

In the stereographic projection of the sphere, the eye
PROJECTION OF THE SPHERE.

But if the circle MN (fig. 2.) be not parallel to the primitive circle BD, let the great circle ABCD, passing through the projecting point, cut it at right angles in the diameter MN, and the primitive in the diameter BD. Through M, in the plane of the great circle, let MF be drawn parallel to BD; let AM, AN be joined, and meet BD in m, n. Then, because AB, AD are quadrants, and BD, MF parallel, the arch AM is equal to AF, and the angle AMF or A mn is equal to A NM. Hence the conic surface described by the revolution of AM about the circle MN is cut by the primitive in a subcontrary position; therefore the section is in this case likewise a circle.

COROLLARIES.

1. The centres and poles of all circles parallel to the primitive have their projection in its centre.

2. The centre and poles of every circle inclined to the primitive have their projections in the line of measures.

3. All projected great circles cut the primitive in two points diametrically opposite; and every circle in the plane of projection, which passes through the extremities of a diameter of the primitive, or through the projections of two points that are diametrically opposite on the sphere, is the projection of some great circle.

4. A tangent to any circle of the sphere, which does not pass through the projecting point, is projected into a tangent to that circle's projection; also, the circular projections of tangent circles touch one another.

5. The extremities of the diameter, on the line of measures of any projected circle, are distant from the centre of the primitive by the semitangents of the least and greatest distances of the circle on the sphere, from the pole opposite to the projecting point.

6. The extremities of the diameter, on the line of measures of any projected great circle, are distant from the centre of the primitive by the tangent and cotangent of half the great circle's inclination to the primitive.

7. The radius of any projected circle is equal to half the sum, or half the difference of the semitangents of the least and greatest distances of the circle from the pole opposite to the projecting point, according as that pole is within or without the given circle.

PROPOSITION III. THEOREM III.

An angle formed by two tangents at the same point in the surface of the sphere, is equal to the angle formed by their projections.

Let FGI and GH (fig. 3.) be the two tangents, and A the projecting point; let the plane AGF cut the sphere in the circle AGL, and the primitive in the line BML. Also, let MN be the line of common section of the plane AGH with the primitive; then the angle FGH = LMN. If the plane FGH be parallel to the primitive BLD, the proposition is manifest. If not, through any point K in AG produced, let the plane FKH, parallel to the primitive, be extended to meet FGH in the line FH. Then, because the plane AGF meets the two parallel planes BLD, FKH, the lines of common section LM, FK are parallel; therefore...
PROJECTION OF THE SPHERE.

Stereographic projection of the sphere.

for the angle $AML = AKF$. But since $A$ is the pole $BDL$, the chords, and consequently the arcs $AB$, $AL$, are equal, and the arc $ABG$ is the sum of the arcs $AL$, $BG$; hence the angle $AML$ is equal to an angle at the circumference standing upon $AG$, and therefore equal to $AGI$ or $FGK$; consequently the angle $FGK = FKG$, and the side $FG = FK$. In like manner $HG = HK$; hence the triangles $GHI$, $KHF$ are equal, and the angle $FGH = FKH = LMN$.

COROLLARIES.

1. An angle contained by any two circles of the sphere is equal to the angle formed by their projections. For the tangents to these circles on the sphere are projected into straight lines, which either coincide with, or are tangents to, their projections on the primitive.

2. An angle contained by any two circles of the sphere is equal to the angle formed by the radii of their projections at the point of intersection.

PROPOSITION IV. THEOREM IV.

The centre of a projected great circle is distant from the centre of the primitive; the tangent of the inclination of the great circle to the primitive, and its radius, is the secant of its inclination.

Let $MNG$ (fig. 4) be the projection of a great circle, meeting the primitive in the extremities of the diameter $MN$, and let the diameter $BD$, perpendicular to $MN$, meet the projection in $F$, $G$. Bisect $FG$ in $H$, and join $NH$. Then, because any angle contained by two circles of the sphere is equal to the angle formed by the radii of their projections at the point of intersection; therefore the angle contained by the proposed great circle and the primitive is equal to the angle $ENH$, of which $EH$ is the tangent, and $NH$ the secant, to the radius of the primitive.

COROLLARIES.

1. All circles which pass through the points $M, N$, are the projections of great circles, and have their centres in the line $BG$; and all circles which pass through the points $F, G$, are the projections of great circles, and have their centres in the line $HI$, perpendicular to $BG$.

2. If $NF, NH$ be continued to meet the primitive in $L, F$; then $BL$ is the measure of the great circle's inclination to the primitive; and $MT = 2BL$.

PROPOSITION V. THEOREM V.

The centre of projection of a less circle perpendicular to the primitive, is distant from the centre of the primitive, the secant of the distance of the less circle from its nearest pole; and the radius of projection is the tangent of that distance.

Let $MN$ (fig. 5) be the given less circle perpendicular to the primitive, and $A$ the projecting point. Draw $AM, AN$ to meet the diameter $BD$ produced in $G$ and $H$; then $GH$ is the projected diameter of the less circle; bisect $GH$ in $C$, and $C$ will be its centre; join $NE, NC$. Then because $AE, NJ$ are parallel, the angle $INE = NEA$; but $NEA = 2NMA$.

$\square$NHG = NCG: hence ENC = INE + INC = NCG Stereographic projection of the Sphere.

+ INC = INC is a right angle; and therefore NC is a tangent to the primitive at N; but the arch $ND$ is the distance of the less circle from its nearest pole $D$: hence NC is the tangent, and EC the secant of the distance of the less circle from its pole to the radius of the primitive.

PROPOSITION VI. THEOREM VI.

The projection of the poles of any circle, inclined to the primitive, are, in the line of measures, distant from the centre of the primitive, the tangent, and cotangent, of half its inclination.

Let $MN$ (fig. 6.) be a great circle perpendicular to the primitive $ABCD$, and $A$ the projecting point; then $P, p$ are the poles of $MN$, and of all its parallels $m, m$, &c. Let $AP, A p$ meet the diameter $BD$ in $F, F$; which will therefore be the projected poles of $MN$ and its parallels. The angle $BEM$ is the inclination of the circle $MEN$, and its parallels, to the primitive: and because $BC$ and $MP$ are quadrants, and $MC$ common to both; therefore $PC = BM$: and hence $PEC$ is also the inclination of $MN$ and its parallels. Now $EF$ is the tangent of $EAF$, or of half the angle $PEC$ the inclination; and $EF$ is the tangent of the angle $EAf$; but $EaF$ is the complement of $EAF$, and $EF$ is the cotangent of half the inclination.

COROLLARIES.

1. The projection of that pole which is nearest to the projecting point is without the primitive, and the projection of the other within.

2. The projected centre of any circle is always between the projection of its nearest pole and the centre of the primitive; and the projected centres of all circles are contained between the projected poles.

PROPOSITION VII. THEOREM VII.

Equal arches of any two great circles of the sphere will be intercepted between two other circles drawn on the sphere through the remote poles of those great circles.

Let $AGB, CFD$ (fig. 7.) be two great circles of the sphere, whose remote poles are $E, P$; through which draw the great circle $PBCD, and less circle $PGE$, intersecting the great circles $AGB, CFD$ in the points $B, G, D, F$; then the arch $BG$ is equal to the arch $DF$.

Because $E$ is the pole of the circle $AGB$, and $P$ the pole of $CFD$, therefore the arches $EB, PD$ are equal; and since $BD$ is common to both, hence the arch $ED$ is equal to the arch $PB$. For the same reason, the arches $EF, PG$ are equal; but the angle $DEF$ is equal to the angle $BPG$: hence these triangles are equal, and therefore the arch $DF$ is equal to the arch $BG$.

PROPOSITION VIII. THEOREM VIII.

If from either pole of a projected great circle, two straight lines be drawn to meet the primitive and the projection, they will intercept similar arches of these circles.
PROJECTION OF THE SPHERE.

On the plane of projection $AGB$ (fig. 7.) let the great circle $CFD$ be projected into $cf_d$, and its pole $P$ into $p$; through $p$ draw the straight lines $pd, pf$, then are the arches $GB, fd$ similar.

Since $pd$ lies both in the plane $AGB$ and $APBE$, it is in their common section, and the point $B$ is also in their common section; therefore $pd$ passes through the point $B$. In like manner it may be shown that the line $pf$ passes through $C$. Now the points $D, F$ are projected into $d, f$; hence the arches $FD, fd$ are similar; but $GB$ is equal to $FD$, therefore the intercepted arch of the primitive $GB$ is similar to the projected arch $fd$.

COROLLARY.

Hence, if from the angular point of a projected spherical angle two straight lines be drawn through the projected poles of the containing sides, the intercepted arch of the primitive will be the measure of the spherical angle.

PROPOSITION IX. PROBLEM I.

To describe the projection of a great circle through two given points in the plane of the primitive.

Let $P$ and $B$ be given points, and $C$ the centre of the primitive.

1. When one point $P$ (fig. 8.) is the centre of the primitive, a diameter drawn through the given points will be the great circle required.

Fig. 9.

2. When one point $P$ (fig. 9.) is in the circumference of the primitive. Through $P$ draw the diameter $PD$; and an oblique circle described through the three points $P, B, D$, will be the projection of the required great circle.

3. When the given points are neither in the centre nor circumference of the primitive. Through either of the given points $P$ (fig. 10.) draw the diameter $ED$, and at right angles thereto draw the diameter $FG$.
From $F$ through $P$ draw the straight line $FPH$, meeting the circumference in $H$; draw the diameter $HF$, and draw the straight line $FKL$, meeting $ED$ produced in $K$; then an arch, terminated by the circumference, being described through the three points, $P, B, K$, will be the great circle.

PROPOSITION X. PROBLEM II.

To describe the representation of a great circle about any given point as a pole.

Let $P$ be the given pole, and $C$ the centre of the primitive.

1. When $P$ (fig. 8.) is in the centre of the primitive, then the primitive will be the great circle required.

Fig. 11.

2. When the pole $P$ (fig. 11.) is in the circumference of the primitive. Through $P$ draw the diameter $PE$, and the diameter $AB$ drawn at right angles to $PE$ will be the projected great circle required.

3. When the given pole is neither in the centre nor circumference of the primitive. Through the pole $P$ (fig. 12.) draw the diameter $AB$, and draw the diameter $DE$ perpendicular to $AB$; through $E$ and $P$ draw the straight line $EPF$, meeting the circumference in $F$.
Make $FG$ equal to $FD$; through $E$ and $G$ draw the straight line $EGH$, meeting the diameter $AB$ produced if necessary in $H$; then from the centre $H$, with the radius $HE$, describe the oblique circle $DIE$, and it will be the projection of the great circle required.

Or, make $DK$ equal to $FA$; join $EK$, which intersects the diameter $AB$ in $I$; then through the three points, $D, I, E$, describe the oblique circle $DIE$.

PROPOSITION XI. PROBLEM III.

To find the poles of a great circle.

1. When the given great circle is the primitive, its centre is the pole.

2. To find the pole of the right circle $ACB$ (fig. 11.). Draw the diameter $PE$ perpendicular to the given circle $AB$; and its extremities $P, E$ are the poles of the circle $ACB$.

3. To find the pole of the oblique circle $DEF$ (fig. 13.). Join $DF$, and perpendicular thereto draw the diameter $AB$, cutting the given oblique circle $DEF$ in $E$. Draw the straight line $FEG$, meeting the circumference in $G$. Make $GI, GH$, each equal to $AD$; then $FI$ being joined, cuts the diameter $AB$ in $P$, the lower pole; through $F$ and $H$ draw the straight line $FH$, meeting the diameter $AB$ produced in $p$, which will be the opposite or exterior pole.

PROPOSITION XII. PROBLEM IV.

To describe a less circle about any given point as a pole, and at any given distance from that pole.

1. When the pole of the less circle is in the centre of the primitive; then from the centre of the primitive, with the semitangent of the distance of the given circle from its pole, describe a circle, and it will be the projection of the less circle required.

2. If the given pole is in the circumference of the primitive, from $C$ (fig. 14.) the centre of the primitive, fig. 14 set off $CE$ the secant of the distance of the less circle from its pole $P$; then from the centre $E$, with the tangent of the given distance, describe a circle, and it will be the less circle required. Or, make $PG, PF$ each equal to the chord of the distance of the less circle from its pole. Through $B$, $G$ draw the straight line $BDG$ meeting $CP$ produced in $D$; bisect $GD$ in $H$, and draw $HE$ perpendicular to $GD$, and meeting $PD$ in $E$; then $E$ is the centre of the less circle.

3. When the given pole is neither in the centre nor circumference of the primitive. Through $P$ (fig. 15.), fig. 17 the given pole, and $C$ the centre of the primitive, draw the diameter $AB$, and draw the diameter $DE$ perpendicular to $AB$; join $EP$, and produce it to meet the primitive in $p$; make $Pr, Pp$, each equal to the chord of the distance of the less circle from its pole; join $EF$ which intersects the diameter $AB$ in $H$; from $E$ through $G$ draw the straight line $EGI$, meeting the diameter $AB$ produced in $I$; bisect $HI$ in $K$. Then a circle described from the centre $K$, at the distance $KH$ or $KI$, will be the projection of the less circle.

PROPOSITION XIII. PROBLEM V.

To find the poles of a given less circle.

The poles of a less circle are also those of its parallel great
PROJECTION OF THE SPHERE.

Sect. I.

If the parallel great circle be given, then its poles being found by Prob. III. will be those of the less circle. But if the parallel great circle be not given, let HMIN (fig. 15.) be the given less circle. Through its centre, and C the centre of the primitive, draw the line of measures IAHB; and draw the diameter DE perpendicular to it, also draw the straight line EHF meeting the primitive in F; make FP equal to the chord of the distance of the less circle from its pole: and its intersection P with the diameter AB is the interior pole. Draw the diameter p CL through E and L, draw ELq meeting the diameter AB produced in q; then q is the external pole. Or thus: Join EI intersecting the primitive in G; join also EH, and produce to meet the primitive in F; bisect the arch GH in p; from E to p, draw the straight line EPp, and P is the pole of the given less circle.

PROPOSITION XIV. PROBLEM VI.

To measure any arch of a great circle.

1. Arches of the primitive are measured on the line of chords.
2. Right circles are measured on the line of semitangents, beginning at the centre of the primitive. Thus, the measure of the portion AC (fig. 16.) of the right circle DE, is found by applying it to the line of semitangents. The measure of the arch DB is found by subtracting that of BC from 90°: the measure of the arch AE, lying on the same side of the centre, is obtained by adding the measures of AC and CF. Lastly, to measure the part AB, which is neither terminated at the centre nor circumference of the primitive, apply CA to the line of semitangents; then CB, and the difference between the measures of these arches, will be that of AB.

Or thus: Draw the diameter GH perpendicular to DE; then from either extremity, as D, of this diameter, draw lines through the extremities of the arch intended to be measured; and the intercepted portion of the primitive applied to the line of chords will give the measure of the required arch. Thus IK applied to the line of chords will give the measure of AB.

3. To measure an arch of an oblique circle: draw lines from its pole through the extremities of the arch to meet the primitive, then the intercepted portion of the primitive applied to the line of chords will give the measure of the arch of the oblique circle. Thus, let AB (fig. 17.), be an arch of an oblique circle to be measured, and P its pole; from P draw the lines PAD, PBE meeting the primitive in B and E; then the arch DE applied to the line of chords will give the measure of the arch of the oblique circle AB.

PROPOSITION XV. PROBLEM VII.

To measure any arch of a less circle.

Let DEG (fig. 18.) be the given less circle, and DE the arch to be measured; find its internal pole P; and describe the circle API parallel to the primitive, and whose distance from the projecting point may be equal to the distance of the given less circle from its pole P; then join FD, PE, which produce to meet the parallel circle in A and F. Now AF applied to a line of chords will give the measure of the arch DE of the given less circle.

PROPOSITION XVI. PROBLEM VIII.

To measure any spherical angle.

1. If the angle is at the centre of the primitive, it is measured as a plane angle.
2. When the angular point is in the circumference of the primitive; let A (fig. 19.) be the angular point, Fig. 19. and ABE an oblique circle inclined to the primitive. Through P, the pole of ABE, draw the line APp meeting the circumference in p; then the arc E p is the measure of the angle BAD, and the arch AFp is the measure of its supplement BAF: also p F is the measure of the angle BAC, and p E D that of its supplement.
3. If the angular point is neither at the centre nor circumference of the primitive. Let A (fig. 20.) be the angular point, and DAH, or GAF, the angle to be measured, P the pole of the oblique circle DAF, and p the pole of GAH; then from A, through the points Pp, draw the straight lines APM, A p N, and the arch MN will be the measure of the angle DAH; and the supplement of MN will be the measure of the angle HAF or DAG.

PROPOSITION XVII. PROBLEM IX.

To draw a great circle perpendicular to a projected great circle, and through a point given in it.

Find the pole of the given circle, then a great circle described through that pole and the given point will be perpendicular to the given circle. Hence if the given circle be the primitive, then a diameter drawn through the given point will be the required perpendicular. If the given circle is a right one, draw a diameter at right angles to it; then through the extremities of this diameter and the given point describe an oblique circle, and it will be perpendicular to that given. If the given circle is inclined to the primitive, let it be represented by BAD (fig. 21.), whose pole is P, and let A be the point through which the perpendicular is to be drawn; then, by Prob. I. describe a great circle through the points P and A, and it will be perpendicular to the oblique circle BAD.

PROPOSITION XVIII. PROBLEM X.

Through a point in a projected great circle, to describe another great circle to make a given angle with the former, provided the measure of the given angle is not less than the distance between the given point and circle.

Let the given circle be the primitive, and let A (fig. 19.) be the angular point. Draw the diameter AE, DF perpendicular to each other; and make the angle CAG equal to that given, or make CG equal to the tangent of the given angle; then from the centre G, with the distance GC, describe the oblique circle ABE, and it will make with the primitive an angle equal to that given.

If the given circle be a right one, let it be APB (fig. 22.) and let P be the given point. Draw the diameter
428

PROJECTION OF THE SPHERE.

GH perpendicular to AB; join GP, and produce it to a; make H b equal to twice A a; and G b being joined intersects AB in C. Draw CD perpendicular to AB, and equal to the cotangent of the given angle to the radius PC; or make the angle CPD equal to the complement of that given: then from the centre D, with the radius DP, describe the great circle FPE, and the angle APF, or BPE, will be equal to that given.

If APB (fig. 23.) is an oblique circle. From the angular point P, draw the lines PG, PC through the centres of the primitive and given oblique circle. Through C, the centre of APB, draw GCD at right angles to PG; make the angle GPD equal to that given; and from the centre D, with the radius DP, describe the oblique circle FPE, and the angle APF, or BPE, will be equal to that proposed.

PROPOSITION XIX. PROBLEM XI.

Any great circle cutting the primitive being given, to describe another great circle which shall cut the given one in a proposed angle, and have a given arch intercepted between the primitive and given circles.

If the given circle be a right one, let it be represented by APC (fig. 24.) ; and at right angles thereto draw the diameter BPM; make the angle BPF equal to the complement of the given angle, and PF equal to the tangent of the given arch; and from the centre of the primitive with the secant of the same arch describe the arch G G. Through F draw FG parallel to AC, meeting GG in G; then from the centre G, with the tangent PF, describe an arch a o, cutting APC in I, and join GI. Through G, and the centre P, draw the diameter HK; draw PL perpendicular to HK, and IL perpendicular to GI, meeting PL in L; then L will be the centre of the circle HK, which is that required.

But if the given great circle be inclined to the primitive, let it be ADB (fig. 25.), and E its centre: make the angle BDF equal to the complement of that given, and DF equal to the tangent of the given arch, as before. From P, the centre of the primitive, with the secant of the same arch, describe the arch G G, and from E, the centre of the oblique circle, with the extent EF, describe an arch intersecting GG in G. Now G being determined, the remaining part of the operation is performed as before.

When the given arch exceeds 90°, the tangent and secant of its supplement are to be applied on the line DF the contrary way, or towards the right; the former construction being reckoned to the left.

PROPOSITION XX. PROBLEM XII.

Any great circle in the plane of projection being given, to describe another great circle, which shall make given angles with the primitive and given circles.

Let ADC (fig. 26.) be the given circle, and Q its pole. About P the pole of the primitive, describe an arch m n, at the distance of as many degrees as are in the angle which the required circle is to make with the primitive. About Q the pole of the circle ADC, and at a distance equal to the measure of the angle which the required circle is to make with the given circle ADC, describe an arch o n, cutting m n in n. Then about n as a pole, describe the great circle EDF, cutting the primitive and given circle in E and D, and it will be the great circle required.

SCHOL. THEM.

It will hence be an easy matter to construct all the various spherical triangles. The reader is, however, referred to the article Spherical Trigonometry, for the method of constructing them agreeably to this projection; and also for the application to the resolution of problems of the sphere. For the method of projecting the sphere upon the plane of the meridian, and of the horizon, according to the stereographic projection, see the article GEOGRAPHY.

SECTION II.

Of the Orthographic Projection of the Sphere.

The orthographic projection of the sphere, is that in which the eye is placed in the axis of the plane of projection, at an infinite distance with respect to the diameter of the sphere; so that at the sphere all the visual rays are assumed parallel, and therefore perpendicular to the plane of projection.

Hence the orthographic projection of any point is where a perpendicular from that point meets the plane of projection; and the orthographic representation of any object is the figure formed by perpendiculars drawn from every point of the object to the plane of projection.

This method of projection is used in the geometrical delineation of eclipses, occultations, and transits. It is also particularly useful in various other projections, such as the analemma. See GEOGRAPHY, &c.

PROPOSITION I. THEOREM I.

Every straight line is projected into a straight line. If the given line be parallel to the plane of projection, it is projected into an equal straight line; but if it is inclined to the primitive, then the given straight line will be to its projection in the ratio of the radius to the cosine of inclination.

Let AB (fig. 27.) be the plane of projection, and let CD be a straight line parallel thereto: from the extremities C, D of the straight line CD, draw the lines CE, DF perpendicular to AB; then by 3. of 21. of Eucl. the intersection EF, of the plane CEF, with the plane of projection, is a straight line; and because the straight lines CD, EF are parallel, and also CE, DF; therefore by 34. of 1. of Eucl. the opposite sides are equal; hence the straight line CD, and its projection EF, are equal. Again, let GH be the proposed straight line, inclined to the primitive; then the lines GE, HF being drawn perpendicular to AB, the intercepted portion EF will be the projection of GH. Through G draw GI parallel to AB, and the angle IGH will be equal to the inclination of the given line to the plane of projection. Now GH being the radius, GI, or its equal EF, will be the cosine of IGH; hence the given line GH is to its projection EF as radius to the cosine or inclination.
PROJECTION OF THE SPHERE.

Corollaries.

1. A straight line perpendicular to the plane of projection is projected into a point.

2. Every straight line in a plane parallel to the primitive is projected into an equal and parallel straight line.

3. A plane angle parallel to the primitive is projected into an equal angle.

4. Any plane rectilineal figure parallel to the primitive is projected into an equal and similar figure.

5. The area of any rectilinear figure is to the area of its projection as radius to the cosine of its inclination.

Proposition II. Theorem II.

Every great circle, perpendicular to the primitive, is projected into a diameter of the primitive; and every arch of it, reckoned from the pole of the primitive, is projected into its sine.

Fig. 28.

Let BFD (fig. 28.) be the primitive, and ABCD a great circle perpendicular to it, passing through its poles A, C; then the diameter BFD, which is their line of common section, will be the projection of the circle ABCD. For if, from any point, as G, in the circle ABC, a perpendicular GH fall upon BD, it will also be perpendicular to the plane of the primitive: therefore H is the projection of G. Hence the whole circle is projected into BD, and any arch AG into EH equal to GH its sine.

Corollaries.

1. Every arch of a great circle, reckoned from its intersection with the primitive, is projected into its versed sine.

2. Every less circle perpendicular to the primitive is projected into its line of common section with the primitive, which is also its own diameter: and every arch of the semicircle above the primitive, reckoned from the middle point, is projected into its sine.

3. Every diameter of the primitive is the projection of a great circle; and every chord the projection of a less circle.

4. A spherical angle at the pole of the primitive is projected into an equal angle.

Proposition III. Theorem III.

A circle parallel to the primitive is projected into a circle equal to itself, and concentric with the primitive.

Fig. 29.

Let the less circle FIG (fig. 29.) be parallel to the plane of the primitive BND. The straight line HE, which joins their centres, is perpendicular to the primitive; therefore E is the projection of H. Let any radii HI and IN perpendicular to the primitive be drawn. Then IN, HE being parallel, are in the same plane; therefore IH, NE, the lines of common section of the plane IEC, with two parallel planes, are parallel; and the figure IHEN is a parallelogram. Hence NE = IH, and consequently FIG is projected into an equal circle KNL, whose centre is E.

Corollary.

The radius of the projection is the cosine of the distance of the parallel circle from the primitive, or the orthographic projection of the primitive.

Proposition IV. Theorem IV.

An inclined circle is projected into an ellipse, whose transverse axis is the diameter of the circle.

1. Let ELF (fig. 30.) be a great circle inclined to the primitive EBF, and EF their line of common section. From the centre C, and any other point K, in EF, let the perpendicular CK, KL be drawn in the plane of the primitive, and CL, KN, in the plane of the great circle, meeting the circumference in L, N. Let LG, ND be perpendicular to CK, KL; then G, D are the projections of L, N. And because the triangles LCG, NDK are equiangular, CL : CG :: KN : DK ; or EC : CG :: EK : DK ; therefore the points G, D are in the curve of an ellipse, of which EF is the transverse axis, and CG the semiconjugate axis.

Corollaries.

1. In a projected great circle, the semiconjugate axis is the cosine of the inclination of the great circle to the primitive.

2. Perpendiculars to the transverse axis intercept corresponding arches of the projection and the primitive.

3. The eccentricity of the projection is the sine of the inclination of the great circle to the primitive.

Case 2. Let AQ (fig. 31.) be a less circle, inclined to the primitive, and let the great circle LBM, perpendicular to both, intersect them in the lines AB, LM. From the centre O, and any other point N in the diameter AB, let the perpendiculars TOP, NO, be drawn in the plane of the less circle, to meet its circumference in T, P, Q. Also from the points A, N, O, B, let AG, NI, OC, BH, be drawn perpendicular to LM; and from P, Q, T, draw PE, QD, TF, perpendicular to the primitive; then G, I, C, H, E, D, F, are the projections of these points. Because OP is perpendicular to LMB, and OC, PE, being perpendicular to the primitive, are in the same plane, the plane COPE is perpendicular to LBM. But the primitive is perpendicular to LBM; therefore the common section EC is perpendicular to LBM, and to LM. Hence CE is a parallelogram, and EC = OP. In like manner, FC, DI, are proved perpendicular to LM, and equal to OT, NO. Thus ECF is a straight line, and equal to the diameter PT. Let QR, DK be parallel to AB, LM; then RO = NQ = DI = KC, and PX = RT = FK = XF. But AO : CG :: NO : CI; therefore AO : CG :: QR : DK ; and EC : CG :: EK : DK.

Corollaries.

1. The transverse axis is to the conjugate as radius to the cosine of the circle's inclination to the primitive.

2. Half the transverse axis is the cosine of half the sum of the greatest and least distances of the less circle from the primitive.

3. The extremities of the conjugate axis are in the line of measures, distant from the centre of the primitive by the cosines of the greatest and least distances of the less circle from the primitive.

4. If
PROJECTION OF THE SPHERE.

430
Orthogon- 
phic Proj- 
section of 
the Sphere.

4. If from the extremities of the conjugate axis of any elliptical projection perpendiculars be drawn (in the same direction if the circle do not intersect the primitive, but if otherwise in opposite directions), they will intersect an arch of the primitive, whose chord is equal to the diameter of the circle.

PROPOSITION V. Theorem V.
The projected poles of an inclined circle are in its line of measures distant from the centre of the primitive the sine of the inclination of the circle to the primitive.

Fig. 32. Let ABCD (fig. 32.) be a great circle, perpendicular both to the primitive and the inclined circle, and intersecting them in the diameters AC, MN. Then ABCD passes through the poles of the inclined circle: let these be P, Q; and let Pp, Qq, be perpendicular to AC; p, q are the projected poles; and it is evident that $PQ = \sin \theta$, or MA, the inclination.

COROLLARIES.
1. The centre of the primitive, the centre of the projection, the projected poles, and the extremities of the conjugate axis, are all in one and the same straight line.
2. The distance of the centre of projection from the centre of the primitive is to the cosine of the distance of the circle from its own pole, as the sine of the circle's inclination to the primitive is to the radius.

PROPOSITION VI. Problem I.
To describe the projection of a circle perpendicular to the primitive, and whose distance from its pole is equal to a given quantity.

Fig. 33. Let PA p B (fig. 33.) be the primitive circle, and P, p the poles of the right circle to be projected. Then if the circle to be projected is a great circle, draw the diameter AB at right angles to the axis PP, and it will be that required. But if the required projection is of a less circle, make PE, PF equal to the chord of the distance of the less circle from its pole; join EF, and it will be the projection of the less circle required.

PROPOSITION VII. Problem II.
Through a given point in the plane of the primitive to describe the projection of a great circle, having a given inclination to the primitive.

1. When the given inclination is equal to a right angle, a straight line drawn through the centre of the primitive, and the given point, will be the projection required.

2. When the given inclination is less than a right angle, and the given point in the circumference of the primitive. Let R (fig. 34.) be a point given in the circumference of the primitive, through which it is required to draw the projection of a great circle, inclined to the primitive in an angle measured by the arch $QP$ of the primitive.

Through the given point R draw the diameter RCS, and draw GC g at right angles to it. Make the arch $GV$ of the primitive equal to $QP$, and draw VA at right angles to GC; and in GC towards the opposite parts of C, take CB equal to AC; then, with the greater axis RS, and less axis AB, describe an ellipse, and it will be the projection of the oblique circle required.

3. When the distance of the given point from the primitive is equal to the cosine of the given inclination. Every thing remaining as in the preceding case; let A be the given point, and AC the cosine of an arch GV, equal to the given arch $QP$; then drawing the diameter RCS at right angles to ABC, the ellipse described with the given axis RS, $AB$ will be the projection of the inclined circle.

4. When the distance of the given point from the centre of the primitive is less than the semidiameter of primitive, but greater than the cosine of the given inclination.

Let D be the given point, through which draw the diameter DC; and at the point D draw DL perpendicular to DC meeting the primitive in L; also draw DK, making with LD the angle DLK equal to the complement of the given inclination. Let LK meet DC in K; then will DK be less than DC. On DC as diameter draw a circle, and make DH equal to the primitive $DC$; through H draw a diameter of the primitive parallel to RCS, and describe an ellipse through the points R, D, S, and it will be the projection of the inclined circle.

PROPOSITION VIII. Problem III.
Through two given points in the plane of the primitive to describe the projection of a great circle.

1. If the two given points and the centre of the primitive be in the same straight line, then a diameter of the primitive being drawn through these points will be the projection of the great circle required.

2. When the two given points are not in the same straight line with the centre of the primitive; and one of them is in the circumference of the primitive.

Let DR (fig. 35.) be the two given points, of which R is in the circumference of the primitive. Draw the diameters RCS, and GC g, FDh perpendicular to it, meeting the primitive in G $F$. Divide GC, $g$ C, in A, B, in the same proportion as FH is divided in D; and describe the ellipse whose axes are RS, AB, and centre C; and it will be the projection required.

3. When the given points are within the primitive, and not in the same straight line with its centre.

Let D, E (fig. 35.) be the two given points; through C the centre of the primitive draw the straight lines ID, KE $F$; draw DL perpendicular to I $i$, and EO perpendicular to K $k$, meeting the primitive in L, O. Through E, and towards the same parts of C, draw EP parallel to DC, and in magnitude a fourth proportional to LD, DC, OE. Draw the diameter CP meeting the primitive in R, $S$, and describe an ellipse through the points D and R, or S, and it will also pass through E. This ellipse will be the projection of the proposed inclined circle.

PROPOSITION IX. Problem IV.
To describe the projection of a less circle parallel to the primitive, its distance from the pole of the primitive being given.
PROJECTION OF THE SPHERE.

From the pole of the primitive, with the sine of the given distance of the circle from its pole, describe a circle, and it will be the projection of the given less circle.

PROPOSITION X. PROBLEM V.

About a given point as a projected pole to describe the projection of an inclined circle, whose distance from its pole is given.

Let P (fig. 36.) be the given projected pole, through which draw the diameter GG, and draw the diameter HB perpendicular thereto. From P draw PL perpendicular to GF meeting the circumference in L; through which draw the diameter LL. Make LT, LK each equal to the chord of the distance of the less circle from its pole, and join TK, which intersects LL, in Q. From the points T, Q, K, draw the lines FA, QS, KB, perpendicular to GG, and make OR, OS, each equal to QT, or QK. Then an ellipse described through the points A, B, R will be the projection of the proposed less circle.

PROPOSITION XI. PROBLEM VI.

To find the poles of a given projected circle.

1. If the projected circle be parallel to the primitive, the centre of the primitive will be its pole.

2. If the circle be perpendicular to the primitive, then the extremities of a diameter of the primitive drawn at right angles to the straight line representing the projected circle, will be the poles of that circle.

3. When the projected circle is inclined to the primitive.

Let ARBS (fig. 36, 37.) be the elliptical projection of any oblique circle; through the centre of which, and C the centre of the primitive, draw the line of measures CBA, meeting the ellipse in B, A, and the primitive in G, G. Draw CI, BK, AT perpendicular to GG, meeting the primitive in H, K, T. Bisect the arch KT in L, and draw LP perpendicular to GG; then P will be the projected pole of the circle, of which ARBS is the projection.

PROPOSITION XII. PROBLEM VII.

To measure any portion of a projected circle, and conversely.

1. When the given projection is that of a great circle.

Let ADBE (fig. 38.) be the given great circle, either perpendicular or inclined to the primitive, of which the portion DE is to be measured, and let MM be the line of measures of the given circle. Through the points D, E, draw the lines EG, DF parallel to MM, and the arch FG of the primitive will be the measure of the arch DE of the great circle, and conversely.

2. When the projection is that of a less circle parallel to the primitive.

Let DE (fig. 39.) be the portion to be measured, of the less circle DEH parallel to the primitive. From the centre C draw the lines CD, CE, and produce them to meet the primitive in the points B, F. Then the intercepted portion BF of the primitive will be the measure of the given arch DE of the less circle DEH.

3. If the given less circle, of which an arch is to be measured, is perpendicular to the primitive.

Let ADEB (fig. 40.) be the less circle, of which the measure of the arch DE is required. Through C, the centre of the primitive, draw the line of measures MM, and from the intersection O of the given right line, and the line of measures, with the radius OA, or OB, describe the semicircle AFGB; through the points D, E, draw the lines DF, EG parallel to the line of measures, and the arch FG will be the measure of DE, to the radius AO. In order to find a similar arch in the circumference of the primitive, join OF, OG, and at the centre C of the primitive, make the angle m CH equal to FOG, and the arch m H to the radius C m will be the measure of the arch DE.

4. When the great projection is of a less circle inclined to the primitive.

Let RDS (fig. 41.) be the projection of a less circle inclined to the primitive, and DE a portion of that circle to be measured. Through O the centre of the projected circle, and C the centre of the primitive, draw the line of measures MM, and from the centre O, with the radius OR, or OS, describe the semicircle BFG; through the points D, E, draw the lines DF, EG parallel to the line of measures, and FG will be the measure of the arch DE to the radius OR, or OS. Join OF, OG, and make the angle m CH equal to FOG, and the arch m H of the primitive will be the measure of the arch DE of the inclined circle RDS.

The converse of this proposition, namely, to cut off an arch from a given projected circle equal to a given arch of the primitive, is obvious.

The above operation would be greatly shortened by using the line of signs in the sector.

It seems unnecessary to insist farther on this projection, especially as the reader will see the application of it to the projection of the sphere on the planes of the Meridian, Equator, and Horizon, in the article Geography; and to the delineation of Eclipses in the article Astronomy. The Analemma, Plate CCXXXV., in the article Geography, is also according to this projection; and the method of applying it to the solution of astronomical problems is there exemplified.

SECTION III.

Of the Gnomonic Projection of the Sphere.

In this projection the eye is in the centre of the sphere, and the plane of projection touches the sphere in a given point parallel to a given circle. It is named gnomonic, on account of its being the foundation of dialling: the plane of projection may also represent the plane of a dial, whose centre being the projected pole, the semiaxis of the sphere will be the stile or gnomon of the dial.

As the projection of great circles is represented by straight lines, and less circles parallel to the plane of projection are projected into concentric circles; therefore many problems of the sphere are very easily resolved. Other problems, however, become more intricate on account of some of the circles being projected into ellipses, parabolas, and hyperbolas.

Proposition
PROJECTION OF THE SPHERE.

Proposition I. Theorem I.

Every great circle is projected into a straight line perpendicular to the line of measures; and whose distance from the circle is equal to the cotangent of its inclination, or to the tangent of its nearest distance from the pole of the projection.

Let BAD (fig. 42.) be the given circle, and let the circle CBED be perpendicular to BAD, and to the plane of projection; whose intersection CF with this last plane will be the line of measures. Now since the circle CBED is perpendicular both to the given circle BAD and to the plane of projection, the common section of the two last planes produced will therefore be perpendicular to the plane of the circle CBED produced, and consequently to the line of measures: hence the given circle will be projected into that section; that is, into a straight line passing through d, perpendicular to C d. Now C d is the cotangent of the angle C d A, the inclination of the given circle, or the tangent of the arch CD to the radius AC.

Corollaries.

1. A great circle perpendicular to the plane of projection is projected into a straight line passing through the centre of projection: and any arch is projected into its correspondent tangent.

2. Any point, as D, or the pole of any circle, is projected into a point d, whose distance from the pole of projection is equal to the tangent of that distance.

3. If two great circles be perpendicular to each other, and one of them passes through the pole of projection, they will be projected into two straight lines perpendicular to each other.

4. Hence if a great circle be perpendicular to several other great circles, and its representation pass through the centre of projection; then all these circles will be represented by lines parallel to one another, and perpendicular to the line of measures, for representation of that first circle.

Proposition II. Theorem II.

If two great circles intersect in the pole of projection, their representations will make an angle at the centre of the plane of projection, equal to the angle made by these circles on the sphere.

For since both these circles are perpendicular to the plane of projection, the angle made by their intersections with this plane is the same as the angle made by these circles.

Proposition III. Theorem III.

Any less circle parallel to the plane of projection is projected into a circle whose centre is the pole of projection, and its radius is equal to the tangent of the distance of the circle from the pole of projection.

Let the circle PI (fig. 42.) be parallel to the plane GF, then the equal arches PC, CI are projected into the equal tangents GC, CI; and therefore C the point of contact and pole of the circle PI and of the projection, is the centre of the representation C, H.

Corollary.

If a circle be parallel to the plane of projection, and 45 degrees from the pole, it is projected into a circle equal to a great circle of the sphere; and therefore may be considered as the primitive circle, and its radius the radius of projection.

Proposition IV. Theorem IV.

A less circle not parallel to the plane of projection is projected into a conic section, whose transverse axis is in the line of measures; and the distance of its nearest vertex from the centre of the plane of projection is equal to the tangent of its nearest distance from the pole of projection; and the distance of the other vertex is equal to the tangent of the greatest distance.

Any less circle is the base of a cone whose vertex is at A (fig. 43.); and this cone being produced, its intersection with the plane of projection will be a conic section. Thus the cone DAF, having the circle DF for its base, being produced, will be cut by the plane of projection in an ellipse whose transverse diameter is d f; and C d is the tangent of the angle CAD, and CF the tangent of CAF. In like manner, the cone AFE, having the side AE parallel to the line of measures d f; being cut by the plane of projection, the section will be a parabola, of which f is the nearest vertex, and the point into which E is projected is at an infinite distance. Also the cone AFG, whose base is the circle FG, being cut by the plane of projection, the section will be a hyperbola; of which f is the nearest vertex; and GA being produced gives d of the other vertex.

Corollaries.

1. A less circle will be projected into an ellipse, a parabola, or hyperbola, according as the distance of its most remote point is less, equal to, or greater than, 90 degrees.

2. If H be the centre, and K k, t the focus of the ellipse, hyperbola, or parabola; then HK = \( \frac{\Delta d + d f}{2} \) for the ellipse; H k = \( \frac{\Delta d + d f}{2} \) for the hyperbola; and f n being drawn perpendicular to AE f t = \( \frac{n E + F t}{2} \) for the parabola.

Proposition V. Theorem V.

Let the plane TW (fig. 44.) be perpendicular to the plane of projection TV, and BCD a great circle of the sphere in the plane TW. Let the great circle BED be projected into the straight line b e k. Draw CQ9 perpendicular to b k, and C m parallel to it and equal to CA, and make QS equal to Q m; then any angle QS t is the measure of the arch Q s of the projected circle.

Join AQ: then because C m is equal to CA, the angle QC m equal to QCA, each being a right angle, and the side QC common to both triangles; therefore Q m, or its equal QS, is equal QA. Again, since the plane ACQ is perpendicular to the plane TV, and b Q
PROJECTION OF THE SPHERE.

COROLLARY.

Hence, if from the projected pole of any circle a perpendicular be erected to the line of measures, it will cut off a quadrant from the representation of that circle.

PROPOSITION VIII. THEOREM VIII.

Let F n k (fig. 45,) be the projection of any circle F1, Fig. 45, and p the projection of its pole P. If C g be the cotangent of C A P, and g B perpendicular to the line of measures g C, let C A P be bisected by A a, and the line o B drawn to any point B, and also p B cutting F n k in d; then the angle g o B is the measure of the arch F d.

The arch PG is a quadrant, and the angle g o A = P A + o A P = g A C + o A P = g A C + C A o = g A o; therefore g A = g A o; consequently o is the dividing centre of g B, the representation of GA; and hence, by Prop. v, the angle g o B is the measure of g B. But since g p represents a quadrant, therefore p is the pole of g B; and hence the great circle p d B passing through the pole of the circles g B and F n will cut off equal arches in both, that is F d = g B = angle g o B.

COROLLARY.

The angle g o B is the measure of the angle g p B. For the triangle g p B represents a triangle on the sphere, wherein the arch which g B represents is equal to the angle which the angle p represents; because g p is a quadrant; therefore g o B is the measure of both.

PROPOSITION IX. THEOREM I.

To draw a great circle through a given point, and whose distance from the pole of projection is equal to a given quantity.

Let ADB (fig. 46,) be the projection, C its pole or Fig. 46, centre, and P the point through which a great circle is to be drawn: through the points P, C draw the straight line PCA, and draw CE perpendicular to it: make the angle CAE equal to the given distance of the circle from the pole of projection C; and from the centre C, with the radius CE, describe the circle EFG: through P draw the straight line PIK, touching the circle EFG in I, and it will be the projection of the great circle required.

PROPOSITION X. PROBLEM II.

To draw a great circle perpendicular to a great circle which passes through the pole of projection, and at a given distance from that pole.

Let ADB (fig. 46,) be the primitive, and CI the given circle: draw CL perpendicular to CI, and make the angle CLI equal to the given distance: then the straight line KP, drawn through I parallel to CL, will be the required projection.

PROPOSITION XI. PROBLEM III.

At a given point in a projected great circle, to draw another great circle to make a given angle with the former; and, conversely, to measure the angle contained between two great circles.

Let P (fig. 47,) be the given point in the given great circle.
PROJECTION OF THE SPHERE.

Sect. III.

To describe the projection of a less circle parallel to the plane of projection, and at a given distance from its pole.

Proposition XII. Problem IV.

Let ADB (fig. 46.) be the primitive, and C its centre: set the distance of the circle from its pole, from B to H, and from H to D; and draw the straight line AED, intersecting CE perpendicular to BC, in the point E: with the radius CR describe the circle EFG, and it is the projection required.

Proposition XIII. Problem V.

To draw a less circle perpendicular to the plane of projection.

Let C (fig. 48.) be the centre of projection, and TI a great circle parallel to the proposed less circle; at C make the angles ICN, TCO each equal to the distance of the less circle from its parallel great circle TI; let CL be the radius of projection, and from the extremity L draw LM perpendicular thereto; make CV equal to LM; or GF equal to CM: then with the vertex V and

* See Conic Sections.

asymptotes CN, CO describe the hyperbola WVK; or, with the focus F and CV describe the hyperbola, and it will be the perpendicular circle described.

Proposition XIV. Problem VI.

To describe the projection of a less circle inclined to the plane of projection.

Draw the line of measures d p (fig. 49.); and at C, the centre of projection, draw CA perpendicular to d p, and equal to the radius of projection: with the centre A, and radius AC, describe the circle DCFG; and draw RAE parallel to d p: then take the greatest and least distances of the circle from the pole of projection, and set them from C to D and F respectively, for the circle DF; and from A, the projecting point, draw the straight lines AF, and ADD; then d f will be the transverse axis of the ellipse; but if D fall beyond the line RE, as at G, then from G draw the line GAD, and d f is the transverse axis of an hyperbola: and if the point D fall in the line RE, as at E, then the line AE will not meet the line of measures, and the circle will be projected into a parabola whose vertex is f: bisect d f in H, the centre, and for the ellipse take half the difference of the lines Ad, Af, which laid from H will give K the focus: for the hyperbola, half the sum of Ad, Af being laid from H, will give k its focus: then with the transverse axis d f, and focus K, or k, describe the ellipse d M, or hyperbola f m, which will be the projection of the inclined circle: for the parabola, make EQ equal to F f; and draw f n perpendicular to AQ, and make f k equal to one half of n Q; then with the vertex f, and focus k, describe the parabola f m, for the projection of the given circle F E.

Proposition XV. Problem VII.

To find the pole of a given projected circle.

Let D MF (fig. 50.) be the given projected circle, whose line of measures is DF, and C the centre of projection; from C draw the radius of projection CA, perpendicular to the line of measures, and A will be the projecting point: join AD, AF, and bisect the angle DAF by the straight line AP; hence P is the pole. If the given projection be an hyperbola, the angle f AG (fig. 49.), bisected, will give its pole in the line of measures; and in a parabola, the angle f AE bisected will give its pole.

Proposition XVI. Problem VIII.

To measure any portion of a projected great circle, or to lay off any number of degrees thereon.

Let EP (fig. 51.) be the great circle, and IP a portion thereof to be measured: draw ICD perpendicular to IP; let C be the centre, and CB the radius of projection, with which describe the circle EBD; make IA equal to IB; then A is the dividing centre of EP; hence AP being joined, the angle IAP is the measure of the arch IP.

Or, if IAP be made equal to any given angle, then IP is the correspondent arch of the projection.

Proposition XVII. Problem IX.

To measure any arch of a projected less circle, or to lay off any number of degrees on a given projected less circle.

Let F n (fig. 52.) be the given less circle, and PI the pole: from the centre of projection C draw CA perpendicular to the line of measures GH, and equal to the radius of projection; join AP, and bisect the angle CAP by the straight line AO, to which draw AD perpendicular: describe the circle G H, as far distant from the pole of projection C as the given circle is from its pole F; and through any given point n, in the projected circle F n, draw D n i, then H i is the measure of the arch F n.

Or let the measure be laid from H to i, and the line D i joined will cut off F n equal thereto.

Proposition XVIII. Problem X.

To describe the gnemonic projection of a spherical triangle, when three sides are given; and to find the measures of either of its angles.

Let ABC (fig. 53.) be a spherical triangle whose three sides are given; draw the radius CD (fig. 54.) perpendicular to the diameter of the primitive EF; and at the point D make the angles DCA, CDG, ADI, equal respectively to the sides AC, BC, AB, of the spherical triangle ABC (fig. 53.), the lines DA, DG intersecting the diameter EF, produced if necessary in the points A and C; make DI equal to DG; then from the centre C, with the radius CG, describe an arch; and from A, with the distance AI, describe another arch, intersecting the former in B; join AB, CB, and ACB will be the projection of the spherical triangle (fig. 53.); and the rectilinear angle ACB is the measure of the spherical angle ACB (fig. 53.).
PROJECTION OF THE SPHERE.

Proposition XIX. Problem XI.

The three angles of a spherical triangle being given, to project it, and to find the measures of the sides.

Fig. 55.

Let ABC (fig. 55.) be the spherical triangle of which the angles are given; construct another spherical triangle EFG, whose sides are the supplements of the given angles of the triangle ABC; and with the sides of this supplementary triangle describe the gnomonic projection, &c. as before.

It may be observed, that the supplementary triangle EFG has also a supplemental part EF g; and when the sides GE, GF, which are substituted in place of the angles A, B, are obtuse, their supplements g E, g F are to be used in the gnomonic projection of the triangle.

Proposition XX. Problem XII.

Given two sides, and the included angle of a spherical triangle, to describe the gnomonic projection of that triangle, and to find the measures of the other parts.

Fig. 56.

Let the sides AC, CB, and the angle ACB (fig. 53.), be given; make the angles CDA, CDG (fig. 56.) equal respectively to the sides AC, CB (fig. 53.); also make the angle ACB (fig. 56.) equal to the spherical angle ACB (fig. 53.), and CB equal to CG, and ABC will be the projection of the spherical triangle.

To find the measure of the side AB: from C draw CL perpendicular to AB, and CM parallel thereto, meeting the circumference of the primitive in M; make LN equal to LM; join AN, BN, and the angle ANB will be the measure of the side AB.

To find the measure of either of the spherical angles, as BAC: from D draw DK perpendicular to AD, and make KH equal to KD: from K draw KI perpendicular to CK, and let AB produced meet KI in I, and join HI: then the rectilineal angle KHI is the measure of the spherical angle BAC. By proceeding in a similar manner, the measure of the other angle will be found.

Proposition XXI. Problem XIII.

Two angles and the intermediate side given, to describe the gnomonic projection of the triangle; and to find the measures of the remaining parts.

Let the angles CAB, ACB, and the side AC of the spherical triangle ABC (fig. 53.) be given: make the angle CDA (fig. 56.) equal to the measure of the given side AC (fig. 53.); and the angle ACB (fig. 56.) equal to the angle ACB (fig. 53.); produce AC to H, draw DK perpendicular to AD, and make KH equal to KD; draw KI perpendicular to CK, and make the angle KHI equal to the spherical angle CAB: from I, the intersection of KI, HI, to A draw IA, and let it intersect CB in B, and ABC will be the gnomonic projection of the spherical triangle ABC (fig. 53.). The unknown parts of this triangle may be measured by last problem.

Proposition XXII. Problem XIV.

Two sides of a spherical triangle, and an angle opposite to one of them given, to describe the projection of the triangle; and to find the measure of the remaining parts.

Let the sides AC, CB, and the angle BAC of the spherical triangle ABC (fig. 53.) be given: make the angles CDA, CDG (fig. 56.) equal respectively to the measures of the given sides AC, BC; draw DK perpendicular to AD, make KH equal to DK, and the angle KHI equal to the given spherical angle BAC; draw the perpendicular KI, meeting HI in I; join AI; and from the centre C, with the distance CG, describe the arch GB, meeting AI in B; join CB, and ABC will be the rectilinear projection of the spherical triangle ABC (fig. 53.) and the measures of the unknown parts of the triangle may be found as before.

Proposition XXIII. Problem XV.

Given two angles, and a side opposite to one of them, to describe the gnomonic projection of the triangle, and to find the measures of the other parts.

Let the angles A, B, and the side BC of the triangle ABC (fig. 55.) be given: let the supplemental triangle EFE be formed, in which the angles E, F, G, are the supplements of the sides BC, CA, AB, respectively, and the sides EF, FG, GE, the supplements of the angles C, A, B. Now at the centre C (fig. 56.) make the angles CDA, CDK equal to the measures of the sides GE, GF respectively, being the supplements of the angles B and A; and let the lines DA, DK intersect the diameter of the primitive EF in the points A and K; draw DG perpendicular to AD, make GH equal to DG, and at the point H make the angle GHI equal to the angle E, or to its supplement; and let EI, perpendicular to CH, meet HI in I, and join AI: then from the centre C, with the distance CG, describe an arch intersecting AI in B; join CB, and ABC will be the gnomonic projection of the given triangle ABC (fig. 53.); the supplement of the angle ACB (fig. 56.) is the measure of the side AB, (fig. 55.); the measures of the other parts are found as before.

It has already been observed, that this method of projection has, for the most part, been applied to dialling only. However, from the preceding propositions, it appears that all the common problems of the sphere may be more easily resolved by this than by either of the preceding methods of projection; and the facility with which these problems are resolved by this method has given it the preference in dialling. It may not perhaps be amiss in this place, to give a brief illustration of it in this particular branch of science.

In an horizontal dial, the centre of projection Z (fig. 57.) represents the zenith of the place for which Fig. 57. the dial is to be constructed; ZA the perpendicular height of the style: the angle ZPA, equal to the given latitude, determines the distance ZP of the zenith from the pole; and AP the edge of the style, which by its shadow gives the hour: the angle ZAP, equal also to the latitude, gives the distance of the equator EQ from the zenith: let EA be equal to EQ, and A will be the dividing point of the equator. Hence if the angles E a I, E a II, &c. E a XI, E a X, &c. be made equal to 15°, 30°, &c. the equator will be divided into hours.
PROJECTION OF THE SPHERE.

If the dial is either vertical, or inclined to the horizon, then the point \( Z \) will be the zenith of that place whose horizon is parallel to the plane of the dial: \( ZE \) will be that latitude of the place; and the hours on the former dial will now be changed into others, by a quantity equal to the difference of longitude between the given place and that for which the dial is to be constructed. Thus, if it is noon when the shadow of the style falls on the line \( PX \), then the difference of meridians is the angle \( E A X \), or 30°. Hence, when a dial is to be constructed upon a given plane, either perpendicular or inclined to the horizon, the declination and inclination of that place must be previously found.

In an erect direct south dial, its zenith \( Z \) is the south point of the horizon, \( ZP \) the distance of this point from the pole, and \( ZE \) its distance from the equator. If the dial is directed to the north, \( Z \) represents the north point of the horizon; \( PZ \) the distance of \( Z \) from the pole under the horizon; and \( ZE \) the elevation of the equator above the horizon.

If the dial is an erect east or west dial, the zenith \( Z \) is the east or west points of the horizon, accordingly, and the pole \( P \) is at an infinite distance, for the angle \( ZAP \) is a right angle; and therefore the line \( AP \) will not meet the meridian \( PZ \). The line \( ZA \) produced is the equator, and is divided into hours by lines perpendicular to it.

If the plane of the dial is parallel to the equator, its zenith \( Z \) coincides with one of the poles of the equator \( P \); and hence the hour lines of this dial are formed by drawing lines from the point \( Z \), containing angles equal to 15°.

In the preceding methods of projection of the sphere, equal portions of a great circle on the sphere are represented by unequal portions in the plane of projection, and this inequality increases with the distance from the centre of projection. Hence, in projections of the earth, those places towards the circumference of the projection are very much distorted. In order to avoid this inconvenience, M. de la Hire proposed, that the eye should be placed in the axis produced at the distance of the sine of 45° beyond the pole: In this case, the arcs of the sphere and their projections are very nearly equal and proportionally to each other. Hence in a map of the earth agreeable to this construction, the axis, instead of being divided into a line of semitangents, is divided equally, in like manner as the circumference. The map of the world is constructed agreeable to this method of projection.

PROLEGOMENA, in Philology, certain preparatory observations or discourses prefixed to a book, &c. containing something necessary for the reader to be apprised of, to enable him the better to understand the book, or to enter deeper into the science, &c.

PROLEPsis, a figure in Rhetoric, by which we anticipate or pretend what might be objected by the adversary. See Oratory, No. 80.

PROLEPTIC, an epithet applied to a periodical disease which anticipates, or whose paroxysm returns sooner and sooner every time; as is frequently the case in agues.

PROLIFER FLOS, (proles, "an offspring;" and fero, "to bear") a prolific flower, or a flower which from its own substance produces another; a singular degree of luxuriance, to which full flowers are chiefly incident. See Botany.

PROLIFIC, something that has the qualities necessary for generating.

The prolific powers of some individuals among mankind are very extraordinary—Instances have been found where children, to the number of six, seven, eight, nine, and sometimes sixteen, have been brought forth after one pregnancy. The wife of Emmanuel Gago, a labourer near Valladolid, was delivered, the 14th of June 1779, of five girls, the two first of whom were baptized: the other three were born in an hour after; two of them were baptized; but the last, when it came into the world, had every appearance of death. The celebrated Tarrin was brought to bed in the seventh month of her pregnancy, at Argenteuil near Paris, 19th July 1779, of three boys, each 14 inches and a half long, and of a girl 13 inches: they were all four baptized, but did not live 24 hours.

The public papers for the month of June 1779, made mention of one Maria Ruiz, of the district of Lucena in Andalusia, who was successively delivered of 16 boys, without any girls; and seven of them were still alive on the 17th of August thereafter. The following, though a recent fact, is almost incredible: In the year 1755, a Muscovite peasant, named James Kyroff, and his wife, were presented to the empress of Russia. This peasant had twice married, and was then 70 years of age. His first wife was brought to bed 21 times; namely, four times of four children each time; seven times of three, and ten times of two; making in all 57 children, who were then alive. His second wife, who accompanied him, had already been delivered seven times, once of three children, and six times of twins, which made 15 children for her share. Thus the Muscovite patriarch had already had 72 children by two marriages. We are assured that the sultan Mustapha III. had issue by his concubines 580 male children. What number of female children he had, and whether there were twins of both sexes, we are not informed. These facts suppose great fecundity; and whatever credit is given them, we must consider as entirely fabulous what is reported concerning a countess of Holland, who was delivered of 365 children, of a very small size.

PROLIXITY in discourse, the fault of entering into too minute a detail, or being too long, precise, and circumstantial, even to a degree of tediousness.

PROLOCUTOR of the convocation, the speaker or chairman of that assembly. See CONVOCATION.

PROLOGUE, in dramatic poetry, a discourse addressed to the audience before the drama or play begins. The original intention was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action, and sometimes to make an apology for the poet.

PROMETHEUS, the son of Japetus, supposed to have been the first discoverer of the art of striking fire by flint and steel; which gave rise to the fable of his stealing fire from heaven: A renowned warrior; but whose history is involved in fable. He flourished about 1697 B.C. The poetical account it, that he formed a man of clay of such exquisite workmanship, that Pallas, charmed with his ingeniosity, offered him whatever in heaven could contribute to finish his design; and for this purpose took him up with her to the celestial mansions, where he stole some fire from the chariot of the sun, which he used to animate his image. At this theft Jupiter was so enraged, that he ordered Vulcan to chain him down on Mount Caucasus, and sent an eagle or vulture to prey on his liver; which every night was renewed in proportion to the quantity eaten up in the daytime, until at last he was delivered by Hercules, who killed the vulture.

PROMETHEUS, in Ancient Astronomy, was the name of a constellation of the northern hemisphere, now called HERCULES EUGONAS. See ASTRONOMY.

PROMISE, in ordinary cases, is a declaration of some intention to be put in execution; but in morals it is a solemn assurance by which one pledges his veracity that he shall perform, or cause to be performed, the thing which he mentions.

As such a declaration excites expectations in the minds of those to whom it is made; and as to frustrate these expectations might rouse indignation, and be followed by consequences injurious to the person, the character, or interest, of him who made it—it becomes a matter of prudence in the promiser to keep his word. And farther, as a certain degree of confidence is found necessary to the very existence of civil society, and as others may have acted on the faith of his promise, it is now not a matter of prudence only to keep his word—it is a duty which he owes to all who have spent their time, their money, or their labour, in consequence of those expectations which he has warranted them to entertain.

It, then, being consonant to sound reason, necessary to the existence of civil society, and in general the interest of both the promiser and promisee, that the words of the promise should be fulfilled, it has become a maxim in morals that a man is obliged to perform his promise.

In many instances, the great difficulty concerning a promise is, how to explain it; for although the grounds of its obligation be those expectations which it has raised, a question will occur, Is the promiser bound to answer fully all the expectations to which the different constructions of his words may have given birth? Should I, for instance, desire a man to run with a letter to such a place, and engage to satisfy him upon his return; and if on his return I gave him double of the usual hire in like cases; but if he be not satisfied with less than the triple of such a sum, am I obliged to grant his demands? This will lead us to consider the rules by which a promise should be interpreted.

If a promise were always to be deemed obligatory in the sense in which the promise receives it, a man would not know what he had promised; the promisee, from a difference of views, associations, and interests, might conceive a sense of which the promiser had not ought to have dreamed; might suppose engagements which were never intended, which could not be foreseen, and, although foreseen, could not be performed. For these reasons it is natural to think that the sense of the promiser should rather direct the interpretation. He knows precisely what it is he has undertaken, and is unquestionably the best judge of what meaning he affixed to his words. His explanation should therefore be admitted, if information alone could give him a title to decide in the affair.

But something more than mere information, or a knowledge of the cause, is expected from a judge, as integrity is equally essential to his character. Doubts may arise when the words will admit of various meanings, whether the promiser will be so candid as impartially to own the precise meaning which he had actually annexed to his expressions: At any rate, if he wishes to deceive, he might purposely use an ambiguous phrasing, and perform the promise in a sense of his own, without satisfying the reasonable hopes of the promisee.

When the daughter of Tarpeius bargained with Tatius to betray the citadel for what he and his Sabines wore on their left hands, meaning their rings and their golden bracelets, Tatius probably performed his promise in the way he intended, when he caused her to be buried under their shields, which they carried also on their left hands. But who will say that here were not treachery and a dishonourable abuse of that confidence which had been reposed in him?
It must therefore be obvious, that the import of a promise, where its meaning is disputed, is not to be determined by the sense of the promiser nor by the expectations of the promisee; and if it was said that the obligation of a promise arose from those expectations which had been raised by it, the assertion now must be limited to those expectations which were intentionally raised by the promiser, or those which to his knowledge the promisee was induced to entertain in consequence of that declaration which had been made to him. Should there still be a doubt about what expectations were intentionally raised, and what should have been reasonably entertained, recourse must be had to the judgment of those who are allowed to be persons of candour, and who are acquainted with the characters of the men, and with those circumstances in which the promise was made.

The following are some of the cases in which a promise is not binding.

As the obligation to perform the promise arises from those expectations which are intentionally raised by the promiser; it is plain that no promise can be binding before acceptance, before the promise has been communicated to the promisee, and before he has entertained hopes of its performance. The case is similar where a promise is released, that is, where the performance is dispensed with by the promiser, and where he entertains no expectations on account of anything than the promiser has said to him. Should a third person entertain hopes on account of the promise, he is to cherish these hopes at his own hazard, having no encouragement from the promiser to do so: yet if this person has been warranted to hope by the promiser, the promiser has renounced his privilege of releasing the promise, and along with the promiser becomes bound for its performance.

A promise is not binding where the performance is unlawful, and the performance is unlawful where it is contrary to former promises, or to any moral or religious precept, which from the beginning to the end of time is of perpetual and unalterable obligation. Thus no man is bound by his promise to give to me what he has already promised to another; and no man is bound by his promise to blaspheme God, to commit murder, or to criminate the innocent. Such promises are unlawfully made, and cannot be otherwise than unlawfully performed.

Some have even carried their scruples so far as to doubt, whether any promise unlawfully made, can be lawfully performed. Should a man, during the lifetime of his wife, happen to promise marriage to another, such a man (they say) by the Christian religion has already committed adultery in his heart: and should he afterwards become a widower, he is not bound, and he even ought not, to fulfill his engagements, as this would be putting his criminal intention into execution. This species of reasoning, we must confess, is to us unintelligible. — As the wife is dead, what now should prevent the man from marrying the object of his affections? Why, say the canuts, he already is under a promise to marry her, and his promise was made at a time when it should not have been made. It is true, the performance, considered by itself, is opposed by no law human or divine; but then it originated in what was wrong; and however much the Supreme Being and the bulk of the creation may be out of the secret, we have discovered by the ingenious logic of casuistry, that evil can never spring out of good, nor good out of evil; but that the means and the end, the motive and the action, are always of the same complexion in morals.

When a promise is made, the particular circumstances in which it is to be deemed obligatory are some times mentioned. I promise (for instance) to lend my friend 200 pounds within three days, provided a certain creditor which I name do not make a demand on me before that time. In other cases no circumstance is foreseen by the promiser to prevent the fulfilling of his engagement; and hence we have erroneous promises, which proceed on the supposition that things are true, possible, and lawful, which are not so. An erroneous promise, which proceeds on the false representation of the promisee, is not binding.

A London gentleman lately purchased an estate in the south of England at a public sale, believing the description which he saw in the newspapers, and which likewise was given by the auctioneer, to be true; but finding afterwards that the estate was not to his purpose, he was ready to make the seller pay him for the next year's produce of his estate; but before that time Tobago fell into the hands of the French, and the West Indian found it impossible to answer the expectations of his friend in England.

An erroneous promise, whose performance is impossible, is not binding. Before the conclusion of the late war, a planter of Tobago, promised to send to his friend in England 1200 sacks of sugar from the next year's produce of his estate; but before that time Tobago fell into the hands of the French, and the West Indian found it impossible to answer the expectations of his friend in England.

An erroneous promise, whose performance is unlawful, or, to speak more precisely, whose performance is contrary to a prior promise, or to any moral or religious obligation, is not binding. A father, believing the accounts from abroad of his son's death, soon after bequeaths his fortune to his nephew: but the son, the report of whose death had been false, returns home, and the father is released from the promise to his nephew, because it was contrary to a prior promise, which he had tacitly come under to his son. This prior promise was implied in the whole of the father's conduct, and was expressed in signs as emphatic and unequivocal as those of language. It had all the effect too of the most solemn promise on the son, who, to his father's knowledge, was induced in consequence of this promise to entertain the most sanguine hopes of succeeding to his father, if he survived. The world likewise could bear testimony that these expectations were not rashly cherished. He was brought into existence by means of his father, who was thereby understood to love him affectionately, he was ushered into society as the representative of his family, and was therefore supposed to be the heir of its wealth. Religion itself supported his pretensions, pronouncing the father more than an infidel who neglects to show the attention to his children which the world naturally expects from a parent. — That the father's promise was not released from the mere circumstance that the mistake was known to his nephew the promisee, will appear plain from the following circumstance. Suppose the father a landed proprietor, that the lease of one of his farms has expired, and that he has long been expecting
The great difficulty which many have to encounter in determining when erroneous promises ought or ought not to be kept, arises from their proceeding on a principle of whose consequences they do not seem to be always aware. There is seldom, they perceive, a virtuous action that is not attended with some happy effects; and it will, perhaps, be generally allowed, that the comparative merit of similar virtues may safely be estimated by their utility: But to make utility, as some do, the criterion of virtue, and pronounce an action vicious or virtuous merely on account of those consequences which they see may flow from it, is a dangerous maxim. Evil has often sprung out of good, and good out of evil; and good and evil have frequently sprung from the same action.

In Mandeville's *Hive*,

That root of evil Avarice,
That damned ill-natur'd baneful vice,
Was slave to Prodigality,
That noble sin; whilst Luxury
Employ'd a million of the poor,
And odious Pride a million more.
Envy itself and Vanity
Were ministers of Industry:
That darling folly, Fickleness,
In diet, furniture, and dress,
That strange ridiculous vice, was made
The very wheel that turn'd the trade.

The description here is not altogether false; and these indeed may be some of the consequences that flow from avarice, luxury, pride, vanity, and envy: but these are not all. — To see at once all the consequences that spring from an action, the good and the bad, the particular and general, the immediate and remote, would require sometimes the foresight of Omniscience, and at all times a knowledge superior to what is human. In the Fable of the Bees, the author's object was to show that private vices are public benefits; and he therefore was naturally led by his argument to consider only such consequences of vice as favoured his hypothesis. He wanted candour. And that artifice which runs through his Fable happens to remind us, that while the remote and the general effects of an action may not be seen, the particular and immediate, which fall within our notice, are apt to be viewed through the medium of passion, interest, or opinion. For these reasons, it appears surprising how any person should ever imagine that the obligation to perform a promise should depend entirely upon the ideas which the promiser apprehended of its utility.

The best refutation of such an opinion are the singular conclusions to which it leads.

A late writer on political justice, who appears to have embraced it, gets into reasoning not very common: In a part of his system he looks on morals as an article of trade: virtue and vice, in his Chapter of *Promises*, are but antiquated terms for profit and loss; and right and wrong are used to express what is beneficial and what is hurtful, in his apprehension, to himself and the community. — With respect to veracity, those "rational and intelligent beings," by whom he wishes the affairs of the world to be carried on, may, while they act as rational and intelligent, break or perform their promises at pleasure. He thinks it "essential to various circumstances of human intercourse, that we should be known to bestow a steady attention upon the quantities of convenience or inconvenience, of good or evil, that might arise from others from our conduct." After this attention, the disappointment of the promise is not to be minded, though the expectations excited by these "rational and intelligent beings" may have "altered the nature of his situation, and engaged him in undertakings from which he would otherwise have abstained." What the promiser takes to be the general utility and the fitness of things is to be his guide. And a breach of promise will be attended with the following advantages: "The promisee, and all other men, will be taught to depend more upon their own exertions, and less upon the assistance of others, which rapacity may refuse or justice withhold. He and all others will be taught to acquire such merit and to engage in such pursuits, as shall oblige any honest man to come to their succour if they should stand in need of assistance. This breach of promise, with a view to the general utility, will, so far from being criminal, form a part of that resolute execution of justice which would in a thousand ways increase the independence, the energies, and the virtue of mankind."

Such are the views which determined this author to consider "the validity of promises" as "inconsistent with justice," and as "foreign to general good." From one, however, who relies with so much confidence on the promiser, it would certainly be desirable to know, whether the person, who violates his faith for the public utility, is always to be candid. Where breach of individual faith promotes his own interest, ought he alone to be no right to intrude on the validity of his promise? or where promises are broken for the general good, is he to be guided by his own visionary schemes of utility? Is he to act as the public trustee for the public without any delegated power? and shall the community submit to his decisions without so much as putting the question, Who hath made thee a ruler over us? When a writer thus deviates so far from the path of reason, it is natural to ask, what was the ignis fatuus that misled him? In the present case it is pretty obvious. Being something of opinion with the celebrated Turgot, that romances are the only books in which moral principles are treated in an impartial manner, this gentleman, in his Chapter of *Promises*, seems to have borrowed a part of his morality from...
Promises from the doggerel of Butler; and having adopted, though from different motives, the political principles of Sir Hudibras’s squire, that obedience to civil government is not due because it is promised, he has come to exactly the same conclusion with respect to the obligation of keeping one’s word. But Ralph has reasoned with more ingenuity; and has shewn not only that the public good, but the glory of the Lord, may be sometimes promoted by a breach of faith.

The saints*, whom oaths and vows oblige,
Know little of their privilege;
Farther, I mean, than carrying on
Some self-advantage of their own:
For if the devil, to serve his turn,
Can tell truth, why the saints should scorn,
When it serves theirs, to swear and lie,
I think there’s little reason why:
Else h’ has a greater pow’r than they,
Which ’ware impiety to say:
W’ are not commanded to forbear,
Indefinitely, at all to swear;
But to swear idly, and in vain,
Without self-interest and gain;
For breaking of an oath and lying
Is but a kind of self-denying,
A saint-like virtue; and from hence
Some have broke oaths by Providence:
Some, to the glory of the Lord,
Perjur’d themselves and broke their word:—
For saints may do the same thing by
The spirit, in sincerity,
Which other men are tempted to,
And at the devil’s instance do.

**Hudibras, Canto II.**

Here are new views of utility; which, were they to be considered as of any weight, would increase the difficulty of determining when an erroneous promise ought to be kept.

But should views of utility lie aside, and should it be made an invariable rule that truth is on no account to be violated, that deceit is never to be practised, and that moral obligations are not to be dissolved for the prospect of any physical advantage; those doubts which arise concerning the validity of erroneous promises will soon disappear. Disagreeable perhaps and ridiculous consequences may sometimes arise to a few individuals from an honest and conscientious adherence to their promise; but will any assert that the general good, that burden of the song, will ever be endangered by too much veracity.

So numerous inconveniences arise daily from the regular operation of those great physical laws, which are under the immediate direction of Providence, that those philosophers who have adopted the principle of utility, and are much surprised to see the universe so awkwardly planned for the ease and comfort of them and their species, have been under the necessity of imputing many events in nature to the malignity of some evil independent being; or of allowing that things have degenerated since they first came from the hands of the Creator, and that they must now be exceedingly altered from what they had been when He chose to pronounce them all very good. Thus, absurdity or impiety must always be the consequence of judging of the vice and virtue of an action by its utility, and of estimating its utility by our limited views and erroneous conceptions.

As for extorted promises, it is curious to observe how this question should always be started, whether or not they ought to be kept? and another question should seldom be thought of, whether or not they ought to be made? Fortitude was one of the cardinal virtues, extended among the ancients; and is deemed of such importance in the Christian system, that the fearful are classed with the unbelievers, and are thought unworthy of the favour of the Deity, as being incapable of supporting those trials to which heaven exposes the faithful as the truest test of Christian virtue. — If a person should want the blessing of a necessary promise to be virtuous, it will be a poor excuse for his baseness, that he has added deceit to his cowardice: and surely it is not the business of morality, when it has found him guilty of one crime, to grant him a dispensation for committing two. The laws of jurisprudence, it will readily be allowed, cannot favour the claims of the promisee; because they ought never to lend their support to oppression and violence. But their acquittal, should he violate his faith, will by no means vindicate the character of the promisee. Their acquitting a woman from the charge of adultery, goes a short way in restoring the fair reputation of her innocence.

Let jurisprudence decide as it will, the man of honour and the generous patriot can never be brought to respect the person who, struck with a panic, could betray either himself or his friends. The magnummous spirits who could die for the truth will view with contempt his pitiful deceit. Those unfortunate men who may suffer from that very distrust which the breach of his faith has begotten, will always detest him as a traitor and enemy; and heaven itself cannot be supposed towards that soldier who deserts her cause, and relinquishes the post which she has assigned him, at the sight of danger.

If we once begin to accommodate morality to the dispositions and humours of mankind, it is hard to say where this species of complaisance will end. The degrees of timidity are so various, and some tempers by nature so yielding, that required importunity or an earnest request will extort a promise.

A young lady was frequently pressed by her dying husband to grant him a promise that she would not marry after his death. For some time she was able to resist with becoming spirit his absurd request; but upon being told to his declaring oftener than once that he could not otherwise be wise die in peace, she complied and promised. Too many and too intense was the love of this young, however, for this effort of continence, she afterwards listened to the addresses of a second lover, and found her heart insensibly engaged before she adverted to the impropriety of a new attachment. But proposals of marriage could scarcely fail to remind her of her promise and awaken her scruples. These she soon communicated to her lover, with her firm resolution to remain a widow, if the contrary measure, which she greatly preferred, and on which her earthly happiness depended, were not removed by some spiritual counselor.

Upon this declaration it was agreed to take the advice of their own minister, who was an eminent dissenting clergyman.
clergyman in the diocese of Oxford: but this gentleman, unwilling to decide in a matter of such importance, proposed to refer it to Dr. Secker, who was then bishop of that see. This prelate too declined to give any judgement in the case; but, as was his way, mustered up a number of arguments on each side of the question, and committed them to a letter, which a learned gentleman of our acquaintance had some time ago an opportunity of seeing in manuscript.

If the sentiments to which the bishop was inclined could have been inferred from his statement of arguments, he seemed to think that the promise was binding. In our opinion, he ought to have given a positive decision. It was no matter whether the promise was expressed or not: the promise was made; and the question was now, whether or not was the performance lawful? That it was lawful appears evident. The lady was under a moral obligation to remain a widow; and no moral obligation, so far as we know, required her to marry.

To be fruitful and multiply, indeed, is declared in Scripture, and is found, to the woful experience of many, to be one of the general laws of our nature. But of all those laws intended by nature to regulate the conduct of inferior intelligences, the moral, which were meant to be checks and correctors of those abuses to which the physical are apt to be carried, are certainly the most sacred and obligatory. To procreate his species, a man is not then to be guilty of adultery, or of fornication, or to listen to the lewd calls of incontinency. St. Paul's observation, that it is better to marry than burn, cannot be allowed in this instance to have much weight. He has not defined what degree of amoros inflammatio constitutes burning, nor in what cases this burning would be a sufficient warrant for marrying. In the present instance he does not even consider marriage as a duty; he compares it with burning, and thinks it only the least of the two evils. Not that marriage is evil of itself; for he that marrieth doth well: but there are circumstances in which it would be inconvenient to marry, and in which he that marrieth not is said to do better. But if those inconveniences be reasons sufficient to deter from marrying, is that person to be held excusable who, in order to gratify an animal passion, somewhat refined, should violate an oath, and trample on a sacred moral obligation?

The young lady might indeed declare that her earthly happiness was at an end if she were not permitted to marry again; but what circumstance prevented her from marrying? It was not the opinion of her own pastor, or the bishop of Oxford: the truth is, it was certain scruples of her own, which being unable of herself to overcome, she had piously solicited the assistance of others. It is certainly a misfortune that a devotional and amorous turn should always be so closely connected in the females. Both, however, cannot always be indulged. Who will say, that the motive is rational which inclines one to cherish a passion which conscience disapproves? The virtue of continency might indeed have borne hard on this lady's constitution, and in her way to immortal happiness might have formed a gate so strait and narrow as it might be difficult for her to pass through: but after all, her case was not harder than that of nuns, who take the vows of perpetual chastity, and endure sufferings of a similar nature, and in some instances
this dull and blunt instrument is by no means calculated for the purposes it is to serve. The prong-hoe consists of two hooked points of five or seven inches long, and when struck into the ground will stir and remove it the same depth as the plough does, and thus answer both the ends of cutting up the weeds and opening the land. It is useful even in the horse-hoeing husbandry, because the hoe-plough can only come within three or four inches of the rows of the corn, turnips and the like; whereas this instrument may be used afterwards, and with it the land may be raised and stirred even to the very stalk of the plant. See Agriculture.

PRONOUN, Pronomen, in Grammar, a declinable part of speech, which being put instead of a noun, points out some person or thing. See Grammar.

PRONUNCIATION, in Grammar, the manner of articulating or sounding the words of a language.

Pronunciation makes the most difficult part of written grammar; in regard that a book expressing itself to the eyes, in a manner that wholly concerns the ears, seems next akin to that of teaching the blind to distinguish colours: hence it is that there is no part so defective in grammar as that of pronunciation, as the writer has frequently no term whereby to give the reader an idea of the sound he would express; for want of a proper term, therefore, he substitutes a vicious and precarious one.

To give a just idea of the pronunciation of a language, it seems necessary to fix a nearly as possible all the several sounds employed in the pronunciation of that language. Cicero tells us, that the pronunciation underwent several changes among the Romans: and indeed it is more precarious in the living languages, being, as Du Bos tells us, subservient to fashion in these. The French language is clogged with a difficulty in pronunciation from which most others are free; and it consists in this, that most of their words have two different pronunciations, the one in common prose, the other in verse.

As to the pronunciation of the English language, the ingenious Mr. Martin, in his Spelling-Book of Arts and Sciences, lays down the following rules: 1. The final (e) lengthens the sound of the foregoing vowel; as in can, cane; rob, robe; tun, tune, &c. 2. The final (e) in words ending in re, is sounded before the r like u; as massacre, massacre; lucru, lu-cru, &c. 3. The Latin diphthongs ae, e, are sounded like e; as Etta, Etta; academia, economia, &c.: but at the end of the words or sounds like o; as in toe, foe, &c. 4. The English improper diphthongs, ca, co, cu, we, sound only the e and u; as tea or te; f, coffee, or jeffe; due or du; true or true, &c. though sometimes co and ca are pronounced like e, as in people, fear, near, &c. 5. Sometimes the diphthong (ie) is pronounced like e in ceiling, like e in field, and at the end of words, always like y, as in lie, &c.; and ei is pronounced either like e or a, as in deceit, reign, &c. 6. The triphthong ear is pronounced like o, in beau and jet d'eau; and its sound sounds like u in lieu, adieu, &c. The sound of g is hard before the vowels a, o, u, in call, cold, cup, &c.; also sometimes before h, as in char, chord, &c.; and before l and r, as in clear, creep, &c. It is otherwise generally soft, as in city, cell, cryer, child, &c. 8. In French words ch is sounded like sh, as in chugreen, machine; and sometimes like gu, as in choir. The sound of g is hard before a, o, u, i, r, as in gall, go, gum, green, grope; also before u, as in guil, guil, &c.: and before h, as in ghost; sometimes before f, as in gibbous, gibberish. It is also generally hard before e, as in gel, fennel, geld, &c.; but soft in many words derived from the Greek and Latin, as in geometry, genealogy, genus, &c. Two gg are always hard, as in dogger, &c. The sound of g, when soft, is like that of j. 10. In any part of a word, ph sounds like f, as in philosophy, &c. 11. The sound of qu, at the end of French words, is like k, as in risque, &c. 12. The syllables ti and ci, if followed by a vowel, sound like si or shi; as in fiction, logician, &c. 13. When cc occurs before ı, the first is hard and the latter is soft; as in fieck, &c. 14. The letter p is not pronounced at the beginning of syllables before f and s; as in psalm, pterium, &c. As to other peculiarities regarding the pronunciation of single letters, many of them have been taken notice of at the beginning of each, in the course of this work.

But it is not enough to know the just pronunciation of single letters, but also of words: in order to which, the accented of words ought to be well understood; since nothing is more harsh and disagreeable to the ear, than to hear a person speak or read with wrong accents. And indeed in English the same word is often both a noun and a verb, distinguished only by the accent, which is on the first syllable of the noun, and on the last of the verb, as ferment and ferment; record and record, &c. We are to observe also, that in order to a just expression of words, some require only a single accent on the syllable, as in torment, &c.; but in others it should be marked double, as in animal, because it is pronounced as if the letter was wrote double, viz. animall.

Mr. Sheridan's Dictionary will be found extremely useful as a directory in acquiring the pronunciation of the English language; but care must be taken to avoid the provincial brogures, which has certainly misled him in several instances. Mr. Walker's Pronouncing Dictionary, lately published, will likewise deserve the student's attention. It is a work of great labour and merit, and is highly useful. It has indeed some faults and inaccuracies, but it is notwithstanding, in all probability, the best of the kind.

Pronunciation is also used for the fifth and last part of rhetoric, which consists in varying and regulating the voice agreeably to the matter and words, so as most effectually to persuade and touch the hearers. See Oratory, Part IV.

PROOF, in Law and Logic, is that degree of evidence which carries conviction to the mind. It differs from demonstration, which is applicable only to those truths of which the contrary is inconceivable. It differs likewise from probability, which produces for the most part nothing more than opinion, while proof produces belief. See Probability.

The proof of crimes was anciently effected among our ancestors divers ways; viz. by duel or combat, fire, water, &c. See Duel and Ordeal.

Proof of Artillery and Small Arms, is a trial whether they stand the quantity of powder allotted for that purpose. The rule of the board of ordinance is, that all guns, under 24-pounders, be loaded with powder as much as their shot weight; that is, a brass 24 pounder with 21 lb. a brass 32-pounder with 26 lb. 12 oz. and a 42-pounder with 31 lb. 8 oz.; the iron 24-pounder with 18 lb. the 32-pounder with 21 lb. 8 oz. and the 42-pounder with 25 lb.
The brass light field-pieces are proved with powder that weighs half as much as their shot, except the 24-pounder which is loaded with 10 lb. only.

Government allows 11 bullets of lead in the pound for the proof of muskets and 14, 5, or 20 in two pounds, for service; 17 in the pound for the proof of carabines, and 20 for service; 28 in the pound for the proof of pistols, and 34 for service.

When guns of a new metal, or of lighter construction, are proved; then, besides the common proof, they are fired 200 or 300 times, as quick as they can be, loaded with the common charge given in actual service. Our light 6-pounders were fired 300 times in 3 hours 27 minutes, loaded with 1 lb. 4 oz. without receiving any damage.

Proof of Powder, is in order to try its goodness and strength. See Gunpowder.

Proof of Cannon, is made to ascertain their being well cast, their having no cavities in their metal, and, in a word, their being fit to resist the effort of their charge of powder. In making this proof, the piece is laid upon the ground, supported only by a piece of wood in the middle, of about 5 or 6 inches thick, to raise the muzzle a little; and then the piece is fired against a solid butt of earth.

Tools used in the Proof of Cannon, are as follows:

Searcher, an iron socket with branches, from 4 to 8 in number, bending outward a little, with small points at their ends: to this socket is fixed a wooden handle, from 8 to 12 feet long, and 1½ inch in diameter. This searcher is introduced into the gun after each firing, and turned gently round to discover the cavities within: if any are found, they are marked on the outside with chalk; and then the

Searcher with one point is introduced: about which point a mixture of wax and tallow is put, to take the impression of the holes; and if any are found of one-fourth of an inch deep, or of any considerable length, the gun is rejected as unserviceable to the government.

Receiver, is an iron ring fixed to a handle, by means of a socket, so as to be at right angles; it serves to disengage the first searcher, when any of its points are retained in a hole, and cannot otherwise be got out. When guns are rejected by the proof-masters, they order them to be marked X thus, which the contractors generally alter WP thus; and after such alteration, dispose of them to foreign powers for Woolwich proof.

The most curious instrument for finding the principal defects in pieces of artillery, was lately invented by Lieut.-general Desaguliers, of the royal regiment of artillery. This instrument, grounded on the true mechanical principles, is no sooner introduced into the hollow cylinder of the gun, than it discovers its defects, and more particularly that of the piece not being truly bored; which is a very important one, and to which most of the disasters happening to pieces of artillery are in a great measure to be imputed; for, when a gun is not truly bored, the most expert artillerist will not be able to make a good shot.

Proof of Mortars and Howitzers, is made to ascertain their being well cast, and of strength to resist the effort of their charge. For this purpose the mortar or howitzer is placed upon the ground, with some part of their trunnions or breech sunk below the surface, and resting on wooden billets, at an elevation of about 70 degrees.

The mirror is generally the only instrument to discover the defects in mortars and howitzers. In order to use it, the sun must shine; the breech must be placed towards the sun, and the glass over-against the mouth of the piece: it illuminates the bore and chamber sufficiently to discover the flaws in it.

Proof of Foreign Brass-Artillery, 1st, The Prussians. Their battering-train and garrison artillery are proved with a quantity of powder equal to ¾ the weight of the shot, and fired 75 rounds as fast as in regular service; that is, 2 or 3 rounds in a minute. Their light field-train, from a 12-pounder upwards, are proved with a quantity of powder = 1-3d of the weight of the shot, and fired 150 rounds, at 3 or 4 rounds in a minute. From a 12-pounder downwards, are proved with a quantity of powder = 1-5th of the shot's weight, and fired 300 rounds, at 5 or 6 rounds each minute, properly sponge and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible.

2d, The Dutch prove all their artillery by firing each piece 5 times; the two first rounds with a quantity of powder = 2-3ds of the weight of the shot; and the three last rounds with a quantity of powder = ½ the weight of the shot.

3d, The French the same as the Dutch.

Proof, in brandy and other spirituous liquors, is a little white lather which appears on the top of the liquor when poured into a glass. This lather, as it diminishes, forms itself into a circle called by the French the chapelet, and by the English the bead or bubble.

Proofs of Prints, were anciently a few impressions Nichol's taken off in the course of an engraver's process. He Life of He proved a plate in different states, that he might ascertain how far his labours had been successful, and when they were complete. The excellence of such early impressions, worked with care, and under the artist's eye, occasioning them to be greedily sought after, and liberally paid for, it has been customary among our modern print-sellers to take off a number of them, amounting perhaps, to hundreds, from every plate of considerable value; and yet their want of rarity has by no means abated their price. On retouching a plate, it has been also usual, among the same conscientious fraternity, to over the inscription, which was immediately added after the first proofs were obtained, with slips of paper, that a number of secondary proofs might also be created.

Proof, in the sugar trade. See Sugar.

Proofs, in printing. See Printing.

Propagation, the act of multiplying the kind. See Generation.

Propagation of Plants. The most natural and the most universal way of propagating plants is by seeds. See Plants. But they may also be propagated by sets, pieces, or cuttings, taken from the parent plant. Willows are very easily propagated by sets: such as rise to be considerable timber trees being raised from sets seven or eight feet long, sharpened at their larger ends, which are thrust into the ground by the sides of ditches, on the banks of rivers, or in any moist soil. The sallow trees are raised from sets only three feet long. The plane tree, mint, &c. may be propagated in the same way.
Propagating

Property.

Propagating

Property.

Property, in Law, is described to be the highest right which a person has or can have to any thing.

There is nothing which so generally strikes the imagination, and engages the affections of mankind, as the right of property; or that sole and despotic dominion which one man claims and exercises over certain external things of the world, in total exclusion of the right of any other individual in the universe. And yet there are very few that will give themselves the trouble to consider the original and foundation of this right. Pleas'd us with the possession, we seem afraid to look back to the means by which it was acquired, as if fearful of some defect in our title; or at best we rest satisfied with hasty references to the length of the laws in our favour, without examining, intending the reason or authority upon which those laws have been built. We think it enough that our title is derived by the grant of the former proprietor, by descent from ancestors, or by the last will and testament of the dying owner: not caring to reflect, that (accurately and strictly speaking) there is no foundation in nature or in natural law, why a set of words upon parchement should convey the dominion of land; why the sea should have a right to exclude his fellow creatures from a determinate spot of ground, because his father had done so before him; or why the occupier of a particular field or of a jewel, when lying on his death-bed and no longer able to maintain possession, should be entitled to tell the rest of the world which of them should enjoy it after him. These inquiries, it must be owned; would be useless and even troublesome in common life. It is well if the mass of mankind will obey the laws when made, without scrutinizing too nicely into the reasons of making them. But when law is to be considered not only as a matter of practice, but also as a rational science, it cannot be improper or useless to examine more deeply the rudiments and grounds of these positive constitutions of society.

In the beginning of the world, we are informed by the holy writ, that the all-bountiful Creator gave to man "dominion over the earth; and over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth." This is the only true and solid foundation of man's dominion over external things, whatever airy metaphysical notions may have been started by fanciful writers upon this subject. The earth, therefore, and all things therein, are the general property of all mankind, exclusive of other beings, from the immediate gift of the Creator. And, while the earth continued thinly inhabited, it is reasonable to suppose, that all was in common among them, and that every one took from the public stock to his own use such things as his immediate necessities required.

These general notions of property were then sufficient to answer all the purposes of human life; and might perhaps still have answered them, had it been possible for ages of the mankind to have remained in a state of primitive simplicity: as may be collected from the manners of many American nations, which first discovered by the Europeans; and from the ancient method of living among the first Europeans themselves, if we may credit either the memorial of these preserved in the golden age of the poets, or the uniform accounts given by historians of those times.

Placed in the midst of a world avaritia communis et indigenciam nihil, veluti unum cunctis patrimonium esse. Not that this communion of goods seems ever to have been applicable, even
even in the earliest ages, to aught but the substance of the thing; nor could it be extended to the use of it. For, by the law of nature and reason, he who first began to use it, acquired therein a kind of transient property, that lasted so long as he was using it, and no longer; or, to speak with greater precision, the right of possession continued for the same time only that the act of possession lasted. Thus the ground was in common, and no part of it was the permanent property of any man in particular; yet whoever was in the occupation of any determinate spot of it, for rest, for shade, or the like, acquired for the time a sort of ownership, from which it would have been unjust, and contrary to the law of nature, to have driven him by force; but the instant that he quitted the use or occupation of it, another might seize it without injustice. Thus also a vine or other tree might be said to be in common, as all were equally entitled to its produce; and yet any private individual might gain the sole property of the fruit, which he had gathered for his own repast. A doctrine well illustrated by Cicero, who compares the world to a great theatre, which is common to the public, and yet the place which any man has taken for the time his own.

But when mankind increased in number, craft, and ambition, it became necessary to entertain conceptions of more permanent dominion; and to appropriate to individuals, not the immediate use only, but the very substance of the thing to be used: otherwise innumerable tumults must have arisen, and the good order of the world been continually broken and disturbed, while a variety of persons were striving who should get the first occupation of the same thing, or disputing which of them had actually gained it. As human life also grew more and more refined, abundance of conveniences were devised to render it more easy, commodious, and agreeable; as habitations for shelter and safety, and ramifies for warmth and decency. But no man would be at the trouble to provide either, so long as he had only an unUseful and unprofitable to them, which would increase the instant that he quitted possession;—if, as soon as he walked out of his tent, or pulled off his garment, the next stranger who came by would have a right to inhabit the one and to wear the other. In case of habitations in particular, it was natural to observe, that even the brute creation, to whom every thing else was in common, maintained a permanent property in their dwellings, especially for the protection of their young; that the birds of the air had nests, and the beasts of the field had caverns, the invasion of which they esteemed a very flagrant injustice, and would sacrifice their lives to preserve them. Hence a property was soon established in every man's house and home-stall; which seem to have been originally mere temporary huts or movable cabins, suited to the design of Providence for more speedily populating the earth, and suited to the wandering life of their owners, before any extensive property in the soil or ground was established. And there can be no doubt, but that moveables of every kind became sooner appropriated than the permanent substantial soil: partly because they were more susceptible of a long occupancy, which might be continued for months together without any sensible interruption, and at length by usage ripen into an established right; but principally because few of them could be fit for use, till improved and melliorated by the bodily labour of the occupant; which bodily labour, bestowed upon any subject which before lay in common to all men, is universally allowed to give the fairest and most reasonable title to an exclusive property therein.

The article of food was a more immediate call, and in food and therefore a more early consideration. Such as were not contented with the spontaneous product of the earth, sought for a more solid refreshment in the flesh of beasts, which they obtained by hunting. But the frequent disappointments incident to that method of provision induced them to gather together such animals as were of a more tame and sequacious nature; and to establish a permanent property in their flocks and herds, in order to sustain themselves in a less precarious manner, partly by the milk of their dams, and partly by the flesh of the young. The support of these their cattle made the article of water also a very important point. And therefore the book of Genesis (the most venerable monument of antiquity, considered merely with a view to history) will furnish us with frequent instances of violent contempts concerning wells; the exclusive property of which appears to have been established in the first digger or occupant, even in such places where the ground and berbage remained yet in common. Thus we find Abraham, who was but a sojourner, asserting his right to a well in the country of Abimelech, and exacting an oath for his security, "because he had digged that well." And Isaac, about 90 years afterwards, reclaimed this his father's property; and, after much contention with the Philistines, was suffered to enjoy it in peace.

All this while the soil and pasture of the earth remained still in common as before, and open to every occupant except perhaps in the neighbourhood of towns, where the necessity of a sole and exclusive property in lands (for the sake of agriculture) was earlier felt, and therefore more readily complied with. Otherwise, when the multitude of men and cattle had consumed every convenience on one spot of ground, it was deemed a natural right to seize upon and occupy such other lands as would more easily supply a succession. This practice is still retained among the wild and uncultivated nations that have never been formed into civil states, like the Tartars and others in the east; where the climate itself, and the boundless extent of their territory, conspire to retain them still in the same savage state of vagrant liberty, which was universal in the earliest ages, and which Tacitus informs us continued among the Germans till the decline of the Roman empire. We have also a striking example of the same kind in the history of Abraham and his nephew Lot. When their joint substance became so great, that pasture and other conveniencies grew scarce, the natural consequence was, that a strife arose between their servants; so that it was no longer practicable to dwell together. This contention Abraham endeavoured to compose: "Let there be no strife, I pray thee, between thee and me. Is not the whole land before thee? Separate thyself, I pray thee, from me: if thou wilt take the left hand, then I will go to the right; or if thou goest to the right, then I will go to the left." This plainly imports an acknowledged right, in either, to occupy whatever ground he pleased, that was not pre-occupied by other tribes. "And Lot lifted up his eyes, and beheld all the plain of Jordan, that it was well watered everywhere, even as the garden of the Lord. Then Lot chose all the plain of Jordan, and journeyed east; and Abraham dwelt in the land of Canaan."
Necessity of property and of laws respecting it.

Property acquired first by occupancy.

The only question remaining is, How this property became actually vested; or what it is, that gave a man an exclusive right to retain in a permanent manner that specific land which before belonged generally to every body, but particularly to nobody? And as we before observed, that occupancy gave the right to the temporary use of the soil; so it is agreed upon all hands, that occupancy gave also the original right to the permanent property in the substance of the earth itself, which excludes every one else but the owner from the use of it. There is indeed some difference among the writers on natural law, concerning the reason why occupancy should convey this right, and invest one with this absolute property: Grotius and Puffendorf insisting, that this right of occupancy is founded upon a tacit and implied consent of all mankind, that the first occupant should become the owner; and Barbeyrac, Titius, Mr Locke, and others, holding that there is no such implied assent, neither is it necessary that there should be; for that the very act of occupancy, alone, being a degree of bodily

labour, is from a principle of natural justice, without any consent or compact, sufficient of itself to gain a title. A dispute that savours too much of nice and scholastic refinement. However, both sides agree in this, that occupancy is the thing by which the title was in fact originally gained; every man seizing to his own continuance use such spots of ground as he found most agreeable to his own convenience, provided he found them unoccupied by any one else.

Property, both in lands and moveables, being thus originally acquired by the first taker, which taking amounts to a declaration, that he intends to appropriate the thing to his own use, it remains in him, by the principle of universal law, till such time as he does some other act which shows an intention to abandon it; for then it becomes naturally speaking, publici juris once more, and is liable to be again appropriated by the next occupant. So if one is possessed of a jewel, and casts it into the sea or a public highway, this is such an express derecliction, that a property will be vested in the first fortunate finder that shall seize it to his own use. But if he hides it privately in the earth, or other secret place, and it is discovered, the finder acquires no property therein; for the owner had not by this act declared any intention to abandon it, but rather the contrary; and if he loses or drops it by accident, it cannot be collected from thence that he designed to quit the possession; and therefore in such cases the property still remains in the loser, who may claim it again of the finder. And this, we may remember, is the doctrine of the English law with relation to Treasure-Trove.

But this method of one man's abandoning his property, and another seizing the vacant possession, however well-founded in theory, could not long subsist in fact. It was calculated merely for the rudiments of civil society, and necessarily ceased among the complicated interests and artificial refinements of polite and established governments. In these it was found, that what became inconvenient or useless to one man was highly convenient and useful to another; who was ready to give in exchange for it some equivalent that was equally desirable to the former proprietor. This mutual convenience introduced commercial traffic, and the reciprocal transfer of property by sale, grant, or conveyance: which may be considered as a continuance of the original possession which the first occupant had, or as an abandoning of the thing by the present owner, and an immediate successive occupancy of the same by the new proprietor. The voluntary delection of the owner, and delivering the possession to another individual, amount to a transfer of the property; the proprietor declaring his intention no longer to occupy the thing himself, but that his own right of occupancy shall be vested in the new acquirer. Or, taken in the other light, if I agree to part with an acre of my land to Titius, the deed of conveyance is an evidence of my intending to abandon the property; and Titius, being the only or first man acquainted with such my intention, immediately steps in and seizes the vacant possession: thus the consent expressed by the conveyance gives Titius a good right against me; and possession or occupancy confirms that right against all the world besides.

The most universal and effectual way of abandoning a property is by the death of the occupant: when, both of the actual possession and intention of keeping possess the occasion past.
The right of inheritance, or descent to the children and relations of the deceased, seems to have been allowed much earlier than the right of devising by testament. We are apt to conceive at the first view that it has nature on its side; yet we often mistake for nature what we find established by long and inveterate custom. It is certainly a wise and effectual, but clearly a political, establishment; since the permanent right of property, vested in the ancestor himself, was no natural, but merely a civil, right. It is true, that the transmission of one's possessions to posterity has an evident tendency to make a man a good citizen and a useful member of society: it sets the passions on the side of duty, and prompts a man to deserve well of the public, when he is sure that the reward of his services will not die with himself, but be transmitted to those with whom he is connected by the dearest and most tender affections. Yet, reasonable as this foundation of the right of inheritance may seem, it is probable that its immediate original arose not from speculations altogether so delicate and refined, and, if not from fortuitous circumstances, at least from a plainer and more simple principle. A man's children or nearest relations are usually about him on his death-bed, and are the earliest witnesses of his decease. They became therefore generally the next immediate occupants, till at length in process of time this frequent usage ripened into general law. And therefore also in the earliest ages, on failure of children, a man's servants born under his roof were allowed to be his heirs; being immediately on the spot when he died. For we find the old patriarch Abraham expressly declaring, that "since God had given him no seed, his steward Eliezer, one born in his house, was his heir."

While property continued only for life, testaments were useless and unknown; and when it became inhe- visible, the inheritance was long indefeasible, and the children or heirs at law were incapable of exclusion by will. Till at length it was found that so strict a rule of inheritance made heirs disobedient and headstrong, defrauded creditors of their just debts, and prevented many provident fathers from dividing or charging their estates as the exigence of their families required. This introduced pretty generally the right of disposing of one's property, or a part of it, by testament; that is, by written or oral instructions properly witnessed and authenticated, according to the pleasure of the deceased; which we therefore emphatically style his will. This was established in some countries much later than in others. In England, till modern times, a man could only dispose of one-third of his moveables from his wife and children; and in general, no will was permitted of lands till the reign of Henry VIII; and then only of a certain portion; for it was not till after the Restoration that the power of devising real property became so universal as at present.

Wills, therefore, and testaments, rights of inheritance, are created and succeed to the de facto states and municipal laws, and accordingly are in all respects regulated by them; every distinct country having different ceremonies and requisites to make a testament completely valid; neither does any thing vary more than the right of inheritance under different national establishments. In England particularly, this diversity is carried to such a length, as if it had been meant to point out the power of the laws in regulating the succession to property, and how futile every claim must be that has not its foundation in the positive rules of the state. In personal estates, the father may succeed to his children; in landed property, he never can be their immediate heir by any the remotest possibility: in general, only the eldest son, in some places only the youngest, in others all the sons together, have a right to succeed to the inheritance: In real estates, males are preferred to females, and the eldest male will usually exclude the rest; in the division of personal estates, the females of equal degree are admitted together with the males, and no right of primogeniture is allowed.

This one consideration may help to remove the scruples of many well-meaning persons, who set up a mistaken conscience in opposition to the rules of law. If a man disinherit his son, by a will duly executed, and leaves his estate to a stranger, there are many who consider this proceeding as contrary to natural justice; while others so scrupulously adhere to the supposed intention of the deed, that if a will of lands be attested by only two witnesses instead of three, which the law requires,
PRO

Property requires, they are apt to imagine that the heir is bound in conscience to relinquish his title to the devisee. But both of them certainly proceed upon very erroneous principles: as if, on the one hand, this son had by nature a right to succeed to his father's lands; or as if, on the other hand, the owner was by nature entitled to direct the succession of his property after his own decease. Whereas the law of nature suggests, that on the death of the possessor, the estate should again become common, and be open to the next occupant, unless otherwise ordered, for the sake of civil peace, by the positive law of society. The positive law of society, which is with us the municipal laws of England and Scotland, directs it to vest in such person as the last proprietor shall by will, attended with certain requisites, appoint; and, in defect of such appointment, to go to some particular person, who from the result of certain local constitutions, appears to be the heir at law. Hence it follows, that, where the appointment is regularly made, there cannot be a shadow of right in any one but the person appointed; and, where the necessary requisites are omitted, the right of the heir is equally strong, and built upon as solid a foundation, as the right of the devisee would have been, supposing such requisites were observed.

But, after all, there are some few things, which notwithstanding the general introduction and continuance of property, must still unavoidably remain in common; being such wherein nothing but an usufructuary property is capable of being bad: and therefore they still belong to the first occupant, during the time he holds possession of them, and no longer. Such (among others) are the elements of light, air, and water; which a man may occupy by means of his windows, his gardens, his mills, and other conveniences; such also are the generality of those animals which are said to be from nature, or of a wild and untamable disposition; which any man may seize upon and keep for his own use or pleasure. All these things, so long as they remain in possession, every man has a right to enjoy without disturbance; but if once they escape from his custody, or he voluntarily abandons the use of them, they return to the common stock, and any other man has an equal right to seize and enjoy them afterwards.

Again, there are other things in which a permanent property may subsist not only as to the temporary use, but also the solid substance; and which yet would be frequently found without a proprietor, had not the wisdom of the law provided a remedy to obviate this inconvenience. Such are forests and other waste grounds, which were omitted to be appropriated in the general distribution of lands: such also are wrecks, estrays, and that species of wild animals, which the arbitrary constitutions of positive law have distinguished from the rest by the well-known appellation of game. With regard to these and some others, as disturbances and quarrels would frequently arise among individuals contending about the acquisition of this species of property by first occupancy, the law has therefore wisely cut up the root of dissension, by vesting the things themselves in the sovereign of the state; or else in his representatives appointed and authorised by him, being usually the lords of manors. And thus our legislature has universally promoted the grand ends of civil society, the peace and security of individuals, by steadily pursuing that wise and orderly maxim, of assigning to every property owner that wise and orderly maxim, of assigning to every property owner that wise and orderly maxim, of assigning to every property owner

In this age of paradox and innovation, much has been said of liberty and equality; and some few have contended for an equalization of property. One of those who contended is an equalization of property altogether, has (inadvertently we suppose) given a complete confusion, not only of his own arguments, but also of the arguments of all who have written on the same side of the question. After labouring to prove that it is gross injustice in any man to retain more than is absolutely necessary to supply him with food, clothes, and shelter, this zealous reformer states an objection to his theory, arising from the well-known allurements of sloth, which, if the accumulation of property were not permitted, would banish industry from the whole world. The objection he urges fairly, and answers it thus: "It may be observed, that the equality for which we are pleading is an equality that would succeed to a state of great intellectual improvement. So bold a revolution cannot take place in human affairs, till the general mind has been highly cultivated. The present age of mankind is greatly enlightened; but it is to be feared is not yet enlightened enough. Hasty and undigested tumults may take place, under the idea of an equalization of property; but it is only a calm and clear conviction of justice, of justice mutually to be rendered and received, of happiness to be produced by the desertion of our most rooted habits, that can introduce an inviable system of this sort. Attempts without this preparation will be productive only of confusion. Their effect will be momentary, and a new and more barbarous inequality will succeed. Each man with unaltered appetite will watch his opportunity to gratify his love of power, or his love of distinction, by usurping on his inattentive neighbours."

These are just observations, and such as we have often made to ourselves on the various proposed reformation of government. The illumination which the author requires before he would introduce his abolition of property, would constitute men more than angels; for to be under the influence of no passion or appetite, and to be guided in every action by unmixed benevolence and pure intellect, is a degree of perfection which we can attribute to no being inferior to God. But it is the object of the greater part of this writer's book to prove that all men must arrive at such perfection before his ideal republic can contribute to their happiness; and therefore every one who is conscious of being at any time swayed by passion, and who feels that he is more attached to his wife or children than to strangers, will look without envy to the present inequalities of property and power, if he be an intelligent disciple of Mr Godwin.

LITRARY PROPERTY. See COPY-RIGHT.

PROPHETY is a word derived from prophecein, and in its original import signifies the prediction of future events.

As God alone can perceive with certainty the future actions of free agents, and the remote consequences of present actions; those laws of nature which he himself established, prophecy, when clearly fulfilled, affords the most convincing evidence of an intimate and supernatural connexion between

Disj.
The word prophecy in Scripture has various meanings.

The ill-founded pretensions of paganism, ancient and modern, have been exposed under various articles of this work. (See Divination, Magic, Necromancy, and Mythology.) And the claims of the Arabian impostor are examined under the articles ALCORAN and MAHOMETANISM; so that at present we have only to consider the use, intent, and truth, of the Jewish and Christian prophecies.

Prophecy is the foretelling of future events, either in an especial manner, or in a general way.

When a revelation was made of any important truth, there was some mingling of which the minds of all have not faculties always active to comprehend, that revelation, though unaccompanied by miracles, must have been so far from confirming the truth of revealed religion in general, that it could not gain credit itself, but by some extrinsic evidence that it came indeed from God. Hence we find Moses, after it was revealed to him from the burning bush that he should deliver his countrymen from Egyptian bondage, replying, “Behold, they will not believe me, nor hearken to my voice; for they will say, the Lord hath not appeared unto thee.” This revelation certainly constituted him a prophet to Israel; and there cannot be a doubt but that he perfectly knew the divine source from which he received it: but he very naturally and reasonably concluded, that the children of Israel would not believe that the Lord had appeared to him, unless he could give them some other proof of this supernatural appearance than his own simple affirmation of its reality. This proof he was immediately enabled to give, by having conferred upon him the power of working miracles in confirmation of his prophecy. Again, when Gideon was called to the deliverance of Israel, the angel of the Lord came and said unto him, “The Lord is with thee, thou mighty man of valour: go in this thy might, and thou shalt save Israel from the hand of the Midianites. Have not I sent thee?” Here was a prophecy delivered by the angel of the Lord to encourage Gideon’s undertaking: but he, being probably afraid of some illusion of sense or imagination, demanded a sign that he was really an angel who talked with him. A sign is accordingly given him, a miraculous sign, with which he is satisfied, and undertakes the work appointed him.

From these and many similar transactions recorded in the Old Testament, it appears that prophecy was never self-intimated as an evidence of an original revelation. It is no proof of the nature and origin of a revelation; because it is impossible, without some extrinsic proof of its divine origin, to know whether any prophecy be true or false, till the era arrive at which it ought to be fulfilled. When it is fulfilled, it affords complete evidence that he who uttered it spake by the spirit of God, and that the doctrines which he taught of a religious nature, were all either dictated by the same spirit, or at least are true, and calculated to direct mankind in the way of their duty.

The prophecies vouchsafed to the patriarchs in the most early periods of the world, were all intended to keep alive in their minds a sense of religion, and to direct their views to the future completion of that first religion among men. Immediately on his fall: but in order to secure credit to those prophecies themselves, they were always accompanied by some miraculous sign that they were indeed given by the God of truth, and not the delusions of fanaticism or hypocrisy. Prophecy, in the proper sense of the word, commenced with the fall; and the first instance of it is implied in the sentence denounced upon

Vol. XVII. Part II.
Prophecy.

10 Probable effects of the first prophecy on our first parents.

as some well-meaning though weak advocates for Christianity have imagined, as a prediction pointing directly to the cross of Christ.

This prophecy, though one of the most important that ever was delivered, when considered by itself, is exceedingly obscure. That Adam should have understood it, as some of his degenerate sons have pretended to do, in a literal sense, is absolutely impossible. He knew well that it was the great God of heaven and earth who was speaking, and that such a Being was incapable of trifling with the wretchedness of his fallen creature. The sentence denounced upon himself and his wife was awful and severe. The woman was doomed to sorrow in conception; the man to sorrow and travel all the days of his life. The ground was cursed for his sake; and the end of the judgment was, “Dust thou art, and to dust shalt return.”

Had our first parents been thus left, they must have looked upon themselves as rejected by their Maker, delivered up to trouble and sorrow in the world, and as having no hope in any other. With such impressions on their minds they could have retained no sense of religion; for religion, when unaccompanied by hope, is a state of frenzy and distraction: yet it is certain that they could have no hope from anything expressly recorded by Moses, except what they might draw from this sentence passed on their deceiver. Let us then endeavour to ascertain what consolation it could afford them.

At that awful juncture, they must have been sensible that their fall was the victory of the serpent, whom by experience they had found to be an enemy to God and to man. It could not therefore but be some comfort to them to hear this enemy first condemned, and to see that, however he had prevailed against them, he had gained no victory over their Maker. By this condemnation they were secured from thinking that there was any malignant being equal to the Creator in power and dominion; an opinion which, through the prevalence of evil, gained ground in after times, and was destructive of all true religion. The belief of God’s supreme dominion being thus preserved, it was still necessary to give them such hopes as might induce them to love as well as to fear him; and these they could not but conceive when they heard from the mouth of their Creator and Judge, that the serpent’s victory was not complete even over themselves; that they and their posterity should be enabled to contest his empire; and that though they were to suffer much in the struggle, they should yet finally prevail, bruise the serpent’s head, and deliver themselves from his power and dominion.

This prophecy therefore was to our first parents a light shining in a dark place. All that they could certainly conclude from it was, that their case was not desperate; that some remedy, some deliverance from the evil they were under, would in time appear; but when or where, or by what means they were to be delivered, they could not possibly understand, unless the matter was further revealed to them, as probably it was at the institution of sacrifice (see SACRIFICE). Obvious, however, as this promise or prophecy was, it served after the fall as a foundation for religion, and trust and confidence towards God in hopes of deliverance in time from the evils of disobedience: and this appears to have been the sole purpose for which it was given, and not,
Prophets, which were reserved to be the matter of another covenant, in another age, and to be revealed by him, whose province it was to "bring life and immortality to light through the gospel." But if Noah and his forefathers expected deliverance from the whole curse of the fall, the actual deliverance from one part of it was a very good pledge of a further deliverance to be expected in time. Man himself was cursed as well as the ground; he was doomed to dust: and fruitful seasons are but a small relief compared to the greatness of his loss. But when fruitful seasons came, and one part of the curse was evidently abated, it gave great assurance that the other should not last for ever, but that by some means, still unknown to them, they should be freed from the whole, and finally bruise the serpent's head, who, at the deluge, had so severely bruised man's heel.

Upon this assurance mankind rested for some generations, and practised, as we have every reason to believe, a rational worship to the one God of the universe. At last, however, idolatry was by some means or other introduced (see Polytheism), and spread so universally through the world, that true religion would in all probability have entirely failed, had not God visibly interposed to preserve such a sense of it as was necessary for the accomplishment of his great design to restore mankind. Thus he did by calling Abraham from amidst his idolatrous kindred, and renewing to him the word of prophecy: "Get thee out of thy country (said he), and from thy kindred, and from thy father's house, unto a land that I will shew thee. And I will make of thee a great nation, and I will bless thee, and make thy name great; and thou shalt be a blessing. And I will bless them that bless thee, and curse him that curseth thee; and in thee shall all the families of the earth be blessed." These magnificent promises are several times repeated to the father of the faithful, with additional circumstances of great importance, such as, "that he should be multiplied exceedingly; that he should be a father of many nations; that kings should come out of him;" and above all, that God would establish an everlasting covenant with him and his seed, to give him and them all the land of Canaan for an everlasting possession, and to be their God.

Upon such of these promises, as relate to temporal blessings, we need not dwell. They are much of the same nature with those which had been given before to Lamech, Noah, Shem, and Japheth; and all the world knows how amply and literally they have been fulfilled. There was, however, so little probability in nature of their accomplishment at the time when they were made, that we find the patriarch asking, "Whereby should he know that he should inherit such an extent of country?" And as the promises that he should inherit it were found to be a foundation for religion and confidence in God, a miraculous sign was given him that they came indeed from the spirit of truth. This removed from his mind every doubt, and made him give the fullest credit not only to them, but also to that other promise, "that in his seed should all the nations of the earth be blessed."

What distinct notion he had of this blessing, or in what manner he hoped it should be effected, we cannot pretend to say. "But that he understood it to be a promise of restoring mankind, and delivering them from the remaining curse of the fall, there can be no doubt. He knew that death had entered by sin; he knew that God had promised victory and redemption to the seed of the woman. Upon the hopes of this restoration the religion of his ancestors was founded; and when God, from whom this blessing on all men was expected, did expressly promise a blessing on all men, and in this promise founded his everlasting covenant—what could Abraham else expect but the completion in his seed of that ancient promise and prophecy concerning the victory to be obtained by the woman's seed? The curse of the ground was expiated in the flood, and the earth restored with a blessing, which was the foundation of the temporal covenant with Noah; a large share of which God expressly grants to Abraham and his posterity, particularly, together with a promise to bring by their means, a new and further blessing upon the whole race of men. If we lay these things to heart, we cannot suppose that less could be expected from the new promise or prophecy given to Abraham than a deliverance from that part of the curse still remaining on men: Dust thou art, and to dust thou shalt return. In virtue of this covenant Abraham and his posterity had reason to expect that the time would come when man should be called from his dust again. For this expectation they had his assurance who gave the covenant, that he would be their God for ever. Well might our Saviour then tell the sons of Abraham, that even Moses at the bush's Use and Intent of Prophecy, Lord the God of Abraham, and the God of Isaac, and the God of Jacob."

These promises made to Abraham were renewed to Isaac and Jacob; to the last of whom it was revealed, not only that all the nations of the earth should be blessed in his seed, but that the blessing should spring from his son Judah. It is, however, by no means evident that any one of those patriarchs knew precisely by what means (A) the curse of the fall was to be entirely removed, and all men called from their dust again. It was enough that they were convinced of the fact in general terms, since such conviction was a sufficient foundation of a rational religion; and the descendants of Abraham had no other foundation upon which to rest their

---

(A) This they certainly could not know from the promises expressed in the very general terms in which they are recorded in the book of Genesis. It is, however, not improbable that those promises, as they immediately received them, were conceived in terms more precise and particular; and, at all events, Dr Warburton has proved to the full conviction of every man who is not a determined unbeliever, that Abraham was commanded to sacrifice his son Isaac, not only as a trial of his obedience, but also that God might give him what he earnestly desired, a coenical representation of the means by which mankind were to be redeemed from death. The learned writer thinks, and his reasoning compels us to think with him, that to this transaction our Saviour alludes when he says, "Your father Abraham rejoiced to see my day, and he saw it and was glad."
Prophecy, till the giving of the law to Moses. Then indeed they were incorporated into a society with municipal laws of their own, and placed under a theocratic government; the temporal promises made to their fathers were amply fulfilled; religion was maintained among them by rewards and punishments equally distributed in this world (see Theology): and a series of prophets succeeding one another pointed out with greater and greater clearness, as the fulness of time approached, the person who was to redeem mankind from the power of death; by what means he was to work that great redemption, and at what precise period he was to make his appearance in the world. By these supernatural interpositions of divine providence, the principles of pure theism and the practice of true religion were preserved among the children of Israel, when all other nations were sunk in the grossest idolatry, and wallowed in the most abominable vices; when the far-famed Egyptians, Greeks, and Romans, fell down with adoration to stocks and stones and the vilest reptiles; and when they had no well-grounded hope of another life, and were in fact without God in the world.

We are all intended to have a sense of religion. From this short deduction, we think ourselves entitled to conclude, that the primary one and intent of prophecy, under the various dispositions of the government, was, not merely to establish the divine mission of Jesus Christ, but to keep alive in the minds of those to whom it was given, a sense of religion, and a hope of future deliverance from the curse of the fall. It was, in the expressive language of St Peter, "a light that shone in a dark place, unto which men did well to take heed until the day dawned and the day-star arose in their hearts." But though this was certainly the original intent of prophecy (for Christ, had he never been foretold, would have proved himself to be the son of God with power by his astonishing miracles, and his resurrection from the dead), yet it cannot be denied, that a long series of prophecies, given in different and far distant ages, and having all their completion in the life, death, and resurrection, of Jesus, concur very forcibly with the evidence of miracles to prove that he was the seed of the woman ordained to bruise the head of the serpent, and restore man to his forfeited inheritance. To the Jews the force of this evidence must have been equal, if not superior, to that of miracles themselves; and therefore we find the Apostles and first preachers of the gospel, in their addresses to them, constantly appealing to the law and the prophets, whilst they urged upon the Gentiles the evidence of miracles.

In order to form a right judgment of the argument for the truth of Christianity drawn from the sure word of prophecy, we must not consider the prophecies given in the Old Testament as so many predictions only independent of each other; for if we do, we shall totally lose sight of the purpose for which they were originally given, and shall never be able to satisfy ourselves when confronted by the objections of unbelievers. It is easy for men of leisure and tolerable parts to find difficulties in particular predictions, and in the application of them made by writers, who lived many hundreds of years ago, and who had many ancient books and records of the Jewish church, from which they drew many passages, and perhaps some prophecies; which books and records we have not to enable us to understand, and to justify their applications. But it is not so easy a matter to show, or to persuade the world to believe, that a chain of prophecies reaching through several thousand years, delivered at different times, yet manifestly subservient to one and the same administration of providence from beginning to end, is the effect of art and contrivance and religious fraud. In examining the several prophecies recorded in the Old Testament, we are not to suppose that each of them expressly pointed out and clearly characterized Jesus Christ. Had they done so, instead of being a support to religion in general, the purpose for which they were originally intended, they would have had a very different effect, by making those to whom they were given repose at being placed under dispensations so very inferior to that of the gospel. We are therefore to inquire only whether all the notices, which, in general and often metaphorical terms, God gave to the fathers of his intended salvation, are perfectly answered by the coming of Christ; and we shall find that nothing has been promised with respect to that subject which has not been performed in the most ample manner. If we examine the prophecies in this manner, we shall find that there is not one of them, which the Apostles have applied to the Messiah, that is not applicable in a rational and reasonable sense to something in the birth, life, preaching, death, resurrection, and ascension of Jesus of Nazareth; that as applied to him they are all consistent with each other; and that though some few of them may be applied without absurdity to persons and events under the Jewish dispensation, Christ is the only person that ever existed in whom they all meet as in a centre. In the limits prescribed us, it is impossible that we should enter upon a particular proof of this position. It has been proved by numberless writers, and, with respect to the most important prophecies, by none with greater success than Bishop Sherlock in his Use and Intent of Prophecy in the several ages of the World; a work which we recommend to our readers as one of the most valuable on the subject in our own or any other language.

But admitting that it would have been improper, for the reason already hinted at, to have given a clear and precise description of Christ, and the Christian dispensation, to men who were ordained to live under dispensations less perfect, how, it may be asked, comes it to pass that many of the prophecies applied by the writers of the gospel to our Saviour and his actions are still dark and obscure, and so far from belonging evidently to him and to him only, that it requires much learning and sagacity to show even now the connection between some prophecies and the events?

In answer to these questions, the learned prelate just referred to observes, "That the obscurity of prophecy does not arise from hence, that it is a relation or description of something future; for it is as easy to speak of things future plainly, and intelligibly, as it is of things past or present. It is not, therefore, of the nature of prophecy to be obscure; for it may easily be made, when he who gives it thinks fit, as plain as history. On the other side, a figurative and dark description of a future event will be figurative and dark still when the event happens; and consequently will have all the obscurity of a figurative and dark description as well after as before the event. The prophet Isaiah describes the peace
The peace of Christ's kingdom in the following manner: 'The wolf shall dwell with the lamb, and the leopard shall lie down with the kid, and the calf and the young lion, and the fatling, together, and a little child shall lead them.' Nobody, some modern Jews excepted, ever understood this literally; nor can it now be literally applied to the state of the gospel. It was and is capable of different interpretations: it may mean temporal peace, or that internal and spiritual peace—that tranquillity of mind, which sets man at peace with God, himself, and the world. But whatever the true meaning is, this prophecy does no more obtrude one determinate sense upon the mind since the coming of Christ than it did before. But then we say, the state of the gospel was very properly prefigured in this description, and is as properly prefigured in a hundred more of the like kind; and since they all agree in a fair application to the state of the gospel, we strongly conclude, that this state was the thing foretold under such expressions. So that the argument from prophecy for the truth of Christianity does not rest on this, that the event has necessarily limited and ascertained the particular sense and meaning of every prophecy; but in this, that every prophecy has in a proper sense been completed by the coming of Christ. It is absurd, therefore, to expect clear and evident conviction from every single prophecy applied to Christ; the evidence must arise from a view and comparison of all together. It is a most great mistake to suppose that prophecy was intended solely or chiefly for their sakes in whose time the events predicted are to happen. What great occasion is there to lay so long feminine the evidence of prophecy to convince men of things that are to happen in their own times; the truth of which they may, if they please, learn from their own senses? Yet some people are apt to talk as if they thought the truth of the events predicted depended very much on the evidence of prophecy: they speak, for instance, as if they imagined the certainty and reality of our Saviour's resurrection were much concerned in the clearness of the prophecies relating to that great and wonderful event, and seem to think that they are confuting the truth of his resurrection when they are pointing out the absurdity of the prophecies relating to it. But can any thing be more absurd? For what ground or pretense is there to inquire whether the prophecies foretelling that the Messiah should die and rise again do truly belong to Christ, unless we are first satisfied that Christ died and rose again?

The part which unbelievers ought to take in this question, if they would make any use of prophecy, should be, to show from the prophets that Christ was necessarily to rise from the dead; and then to prove that in fact Jesus never died. Here would be a plain consequence. But if they like not this method, they ought to let the prophecies alone; for if Christ did not rise, there is no harm done though the prophets have not foretold it. And if they allow the resurrection of Christ, what do they gain by discrediting the prophets? The event will be what it is, let the prophets be what they will.

These considerations show how far the gospel is necessarily concerned in prophetical evidence, and how clear the prophecies should be. Christ claims to be the person foretold in the law and the prophets; and as truth must ever be consistent with itself, this claim must be a prophecy. But so unreasonably are unbelievers, whilst some of them object to the obscurity of the prophecies, others have rejected them altogether on account of their clearness, pretending that they are histories and not predictions. The prophecies against which this objection has been chiefly urged are those of Daniel, which were first called in question by the famous Porphyry. He affirmed that they were not composed by Daniel, whose name they bear, but by some author who lived in Judea about the time of Antiochus Epiphanes; because all that time contained true history, but all the facts beyond that were manifestly false.

This method of opposing the prophecies, as a father answered, of the church rightly observes, is the strongest testimony of their truth: for they are so exactly fulfilled, that to infidels the prophet seemed not to have foretold things future, but to have related things past. To an infidel of this age, if he has the same ability and knowledge of history that Porphyry had, all the subsequent prophecies of Daniel, except those which are still fulfilling, would appear to be history and not prophecy; for it entirely overthrows the notion of their being written in the days of Antiochus Epiphanes, or of the Maccabees, and establishes the credit of Daniel as a prophet beyond contradiction, that there are several of those prophecies which have been fulfilled since that period as well as before; nay, that there are prophecies of Daniel which are fulfilling at this very time in the world.

Our limits will not permit us to enter into the objections which have been made to this prophet by the author of the Literal Scheme of Prophecy considered; nor is there occasion that we should enter into them. They have been all examined and completely answered by Bishop Chandler in his Vindication of his Defence of Christianity, by Mr. Samuel Chandler in his Vindication of the Antiquity and Authority of Daniel's Prophecies, and by Bishop Newton in his excellent Dissertations on the Prophecies. To these authors we refer the reader; and shall conclude the present article with a view of some prophecies given in very remote ages, which are in this age receiving their accomplishment.

Of these the first is that of Noah concerning the servitude of the posterity of Canaan. In the greater part of original manuscripts, and in our version of the holy scriptures, this prophecy is thus expressed: "Cursed be Canaan; a servant of servants shall he be unto his brethren:" but in the Arabic version, and in some copies of the Septuagint, it is, "Cursed be Ham the father of Canaan; a servant of servants shall he be to his brethren." Whether the curse was really pronounced upon Ham, which we think most probable, or only upon his son Canaan, we shall find the prediction remarkably
To show how fully and literally all these prophecies have been accomplished, would require more room than we have to bestow; and to the reader of history the labour would be superfluous. We shall therefore only request the unbeliever to attend to the history of the Arabs, the undoubted descendants of Ishmael; and to say how it comes to pass, that though they have been robbers by land and pirates by sea for time immemorial, though their hands have been against every man, and every man’s hand against them, they always have dwelt, and at this day dwell, in the presence of their brethren, a free and independent people. It cannot be pretended that no attempt has ever been made to conquer them; for the greatest conquerors in the world have all in their turns attempted it: but though some of them made great progress, not one was ever crowned with success. It cannot be pretended that the inaccessibleness of their country has been their protection; for their country has been often penetrated, though it never was entirely subdued. When in all human probability they have been on the brink of ruin, they were signalized and providentially delivered. Alexander was preparing an expedition against them when he was cut off in the flower of his age. Pompey was in the care of his conquests when urgent affairs called him elsewhere. Titus Gallus had penetrated far into their country, when a fatal disease destroyed great numbers of his men, and obliged him to return. Trajan besieged their capital city, but was defeated by thunder and lightning and whirlwinds. Severus besieged the same city twice, and was twice repelled from before it. The Turks, though they were able to wrest from them their foreign conquests, have been so little able to subdue the Arabs themselves, or even to restrain their depredations, that they are obliged to pay them a sort of annual tribute for the safe passage of the pilgrims who go to Mecca to pay their devotions. On these facts we shall not exclaim. He who is not struck upon comparing the simple history of this singular people with the prophecies so long ago delivered of them and their great ancestor, whose love of liberty is compared to that of the wild ass, would rise wholly unmoved from our exclamations.

A fourth prophecy of this kind, which cannot be alleged to have been uttered after the event, is the denunciation of Moses against the children of Israel in case of their disobedience; which is so literally fulfilled, that fortold even at this moment it appears rather a history of the present state of the Jews, than a remote prediction of their apostasy and punishment. "And the Lord shall scatter thee among all people from the one end of the earth even unto the other. And among these nations shalt thou find no ease, neither shall the sole of thy foot have rest; but the Lord shall give thee there a trembling heart and falling of eyes, and sorrow of mind. And thy life shall hang in doubt before thee; and thou shalt fear day and night, and shall have none assurance of thy life," (Deut. xxviii: 64, 65, 66.). "And thou shalt become an astonishment, a proverb, and a by-word, among all nations, whither the Lord shall lead thee." (Deut. xxviii: 37.)

Similar to this denunciation, but attended with some circumstances still more wonderful, is the following prediction of the prophet Hosea: "The children of Israel shall abide many days without a king, and without a prince, and without a sacrifice, and without an image,
Prophesy, and without an ephod, and without a teraphim. Afterwards the children of Israel return, and seek the Lord their God, and David their king; and shall fear the Lord and his goodness in the latter days. In this passage we find the state of the Jews for the last 1700 years clearly and distinctly described with all its circumstances. From the time that they rejected their Messiah all things began to work towards the destruction of their politics both civil and religious; and within a few years from his death, their city, temple, and government, were utterly ruined; and they themselves not carried into a gentle captivity, to enjoy their laws, and live under governors of their own, as they did in Babylon, but they were sold like beasts in that market, and became slaves in the strictest sense; and from that day to this have had neither prince nor chief among them. Nor will any one of them ever be able, after all their pretences, to prove his descent from Aaron, or to say with certainty whether he is of the tribe of Judah or of the tribe of Levi, till he shall discover that unknown country where never mankind dwelt, and where the apocryphal Ezra has placed their brethren of the ten tribes. This being the case, it is impossible they can have either an altar, or a sacrifice, or a priesthood, according to the institution of Moses, but are evidently an outcast people living under laws which cannot be fulfilled.

The cause of this deplorable condition is likewise assigned with the same perspicuity; they are scattered over the face of the earth, because they do not acknowledge Christ for the Messiah; because they do not submit to their own king, the true David. In the prophetic writings the name of David is frequently given to the Messiah, who was to descend from that prince. Thus Ezekiel, speaking of the kingdom of Christ, says, “I will set up one Shepherd over them, and he shall feed them, even my servant David; he shall feed them, and he shall be their shepherd.” And Jeremiah says, “They shall serve the Lord their God, and David their king, whom I will raise up unto them.” That in these places, as well as in the passage under consideration, the Messiah is meant, is undeniable; for David the son of Jesse was dead long before any of the three prophets was born; and by none of them it is said “afterwards David their king shall come again;” but “afterwards the children of Israel shall return to David their king,” they shall recover from their blind infatuation, and seek him whom they have not yet known. By their not receiving Jesus for their Christ, they have forfeited all claim to the divine favour, and are, of consequence, “without a king, and without a chief, and without a sacrifice, and without an altar, and without a priesthood.”

The time, however, will come, when they shall return and seek “the Lord their God and David their king;” when they shall tremble before him whom their fathers crucified, and honour the son even as they honour the father. That this part of the prophecy will in time be as completely fulfilled as the other has been, may be confidently expected from the wonderful preservation of the Jews for so many ages. Scattered as they are over the whole earth, and hated as they are by all nations, it might naturally be thought, that in process of time they would have coalesced with their conquerors, and have been ultimately absorbed and annihilated by their union, so that no trace of them should now have remained; yet the fact is, that, dispersed as they have ever since been over the whole face of the globe, they have never, in a single instance, in any country, lost their religious or natural distinctions; and they are now generally supposed to be as numerous as they were under the reigns of David and Solomon. This is contrary to all history, and all experience of the course of human affairs in similar cases; it has been boldly and justly styled a standing miracle. Within 1000 or 1200 years back, a great variety of extraordinary and important revolutions have taken place among the nations of Europe. In the southern part of this island the Britons were conquered by the Saxons, the Saxons by the Danes, and the Danes and Saxons by the Normans; but in a few centuries these opposite and hostile nations were consolidated into one indistinguishable mass. Italy, about the same time that Britain was subdued by the Saxons, was conquered by the Goths and Vandals: and it is not easy to conceive a more striking contrast than that which subsisted between the polished inhabitants of that delightful country and their savage invaders; and yet how soon did all distinction cease between them! In France, the Roman colonies gradually assimilated with the ancient Gauls; and in Spain, though the Moors continued for several ages, and till their final expulsion, a distinct people, yet after they were once reduced to a state of subjection, their numbers very sensibly diminished; and such of them as were suffered to remain after their last overthrow have been long since so blended with the Spaniards that they cannot now be distinguished. But with regard to the Jews, the wonder is, that though they do not in any country where they are settled bear any proportion to the natural inhabitants, though they are universally reduced to a state of the lowest subjection, and even exposed to hatred, contempt, and persecution; yet in no instance does there seem to be the least appearance or probability of their numbers being diminished, in no instance do they discover any decay of attachment to their religious principles. Whence then comes it that this people alone, who, having no form of government or a republic anywhere subsisting, are without the means by which other people are kept united and distinct, should still be preserved amongst so many different nations? How comes it, when they have been thus scattered into so many distant corners, like dust which cannot be perceived, that they should still so long survive the dissolution of their own state, as well as that of so many others! To these questions the answer is obvious: They are

(b) Such is our translation of this remarkable prophecy; but the Greek version of the Seventy has it, perhaps more properly, thus: “The children of Israel shall abide many days without a king, and without a chief, and without a sacrifice, and without an altar, and without a priesthood, and without prophecies. Afterwards,” &c.
are preserved, that, as a nation, "they may return and seek the Lord their God and David their king, and fear the Lord and his goodness in the latter days." "

We might here subjoin many prophecies both from the Old and the New Testament, and especially from the writings of St Paul and St John, which so clearly describe the various fortunes of the Christian church, her progress to that state of general corruption under which she was sunk three centuries ago, and her gradual restoration to her primitive purity, that they cannot be supposed to proceed from the cunning craftiness of men, or to have been written after the events of which they speak. To do justice to these, however, would require a volume, and many excellent volumes have been written upon them. The reader who wishes for satisfaction on so interesting a subject will do well to consult the writings of Mr Mede and Sir Isaac Newton, together with Bishop Newton's Dissertations, and the Sermons of Hurd, Halifax, and Bagot, preached at Warburton's lecture. We shall only observe, that one of the ablest reasoners that Great Britain ever produced, after having paid the closest attention to the predictions of the New Testament, hath been bold enough to put the truth of revealed religion into the temples of the prophetic spirit which foretold the desolation of Christ's church and kingdom by antichrist. "If (says he), in the days of St Paul and St John, there was any foot-step of such a sort of power as this in the world; or if there had been any such power in the world; or if there was then any appearance or probability that could make it enter into the heart of man to imagine that there ever could be any such kind of power in the world, much less in the temple or church of God; and if there be not now such a power actually and conspicuously exercised in the world; and if any picture of this power, drawn after the event, can now describe it more plainly and exactly than it was originally described in the words of the prophecy—then may it, with some degree of plausibility, be suggested, that the prophecies are nothing more than enthusiastic imaginations."

Upon the whole, we conclude with Bishop Sherlock, that the various prophecies recorded in the Holy Scriptures were given, not to enable man to foresee with clearness future events, but to support the several dispensations of religion under which they were respectively promulgated. The principal prophecies recorded in the Old Testament led mankind to hope for a complete deliverance from the curse of the fall; and therefore tended to fill their minds with gratitude, and to enforce a cheerful obedience to that God who in the midst of judgment remembereth mercy. The prophecies, whether in the Old or New Testament, that portray the present state of the Jews, and the various fortunes of the Christian church, as they are daily fulfilling in the presence of all men, are the strongest possible proof of the divinity of our holy religion, and supply to us in the latter-days the place of miracles, by which it was at first established.

PROPHET, in general, a person who foretells future events; but is particularly applied to such inspired persons among the Jews as were commissioned by God to declare his will and purposes to that people. Among the canonical books of the Old Testament we have the writings of 16 prophets, four of whom are denominated the greater prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length and extent of their writings, which exceed those of the others, viz. Hoses, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Zecchariah, and Malachi, who are called the lesser prophets, from the shortness of their writings. The Jews do not place Daniel among the prophets, because, they say, he lived the life of a courtier rather than that of a prophet. An account of the several writings of the prophets may be seen each under its particular head. See the article ISAIAH, &c.

SONS of the PROPHETS, in scripture history, an appellation given to young men who were educated in the schools or colleges under a proper master, who was commonly, if not always, an inspired prophet, in the knowledge of religion and in sacred music, and thus were qualified to be public preachers; which seems to have been part of the business of the prophets on the Sabbath days and festivals. It is probable that God generally chose the prophets, whom he inspired, out of these schools. See PROPHET.

PROPTITIATION, in Theology, a sacrifice offered to God to assure his wrath and render him propitious. Among the Jews this was the office of the high priest as ordinary and public sacrifices, as holocausts, &c. offered by way of thanksgiving; and extraordinary ones, offered by particular persons guilty of any crime, by way of propitiation. The Roman church believes the mass to be a sacrifice of propitiation for the living and the dead. The reformed churches allow no propitiation but that one offered by Jesus Christ on the cross. See SACRIFICE.

PROPTITATORY, any thing rendering God propitious; as we say propitiatory sacrifices, in contradistinction to sacrifices which were eucharistical. Among the Jews the propitiatory was the cover or lid of the ark of the covenant; which was lined both within and without with plates of gold, insomuch that there was no wood to be seen. This propitiatory was a type or figure of Christ, whom St Paul calls the propitiatory ordained from all ages. See ARC of the Covenant.

PROPOLIS, the name of a certain substance more tenacious than wax, with which the bees stop up all the holes or cracks in the side of their hives. See BEE, No. 12.

PROPONTIS, or SEA of MARMOA, a part of the Mediterranean, dividing Europe from Asia; it has the Hellespont or canal of the Dardanelles to the south-east, whereby it communicates with the Archipelago, and the ancient Bosphorus of Thrace, or strait of Constantinople, to the north-east, communicating with the Black or Euxine sea. It has two castles: that on the Asia side is on a cape, where formerly stood a temple of Jupiter. The castle of Europe is on an opposite cape, and had anciently a temple of Serapis. It is 120 miles long, and in some places upwards of 40 miles broad.

PROPORTION, the identity or similitude of two ratios. Hence quantities that have the same ratio between them are said to be proportional; e. g. if A be to B as C to D, or B be to A as 30 to 15; A, B, C, D, and 3, 4, 30, and 15, are said to be in proportion, or are simply called proportional. Proportion is frequently confounded with ratio; yet have the two in reality very different ideas, which ought by all means to be distinguished. Ratio is properly the relation or habitude
Proportion.

One from the quantity of two things, which determines the quantity of one of them, and thereby makes the other to be of a certain proportion to the first. Thus, if the ratio of 2 to 3 is 4:6, the ratio of 2 to 3 is also 4:6. This is because the ratio of two quantities is the same as the ratio of any other quantities obtained by multiplying or dividing both quantities by the same number.

PROPORTION

The product by the number remaining after the middle or second is subtracted from double the first; the quotient is a third harmonic proportion; thus supposing the numbers 9, 12, 16, a fourth will be found by the rule to be 24.

5. If there be four numbers disposed in order, whereof one extreme and the two middle terms are in arithmetic proportion; and the same middle terms with the other extremes are in harmonic proportion; the four are in geometrical proportion; as here 2:3::4:6, which are geometrical; whereof 2, 3, 4, are arithmetical, and 3, 4, 6, are harmonic.

6. If between any two numbers, you put an arithmetical mean, and also an harmonic one, the four will be in geometrical proportion; thus between 2 and 6 an arithmetical mean is 4, and an harmonic one 3; and the four 2:3:4:6, are geometrical.

We have this notable difference between the three kinds of proportion, arithmetical, harmonic, and geometrical; that from any given number we can raise a continued arithmetical series increasing in infinitum, but not decreasing; the harmonic is decrescent in infinitum, but not increasent; the geometrical is both.

PROPORTION or Rule of Three. See ARITHMETIC.

Reciprocal Proportion. See Reciprocal.

Proportion is also used for the relation between unequal things of the same kind, whereby their several parts correspond to each other with an equal augmentation or diminution.

Thus, in reducing a figure into little, or in enlarging it, care is taken to observe an equal diminution or enlargement through all its parts; and so that if one line, e.g. be contracted by one-third of its length, all the rest shall be contracted in the same proportion.

Proportion, in Architecture, denotes the just magnitude of the members of each part of a building, and the relation of the several parts of the whole; e.g. of the dimensions of a column, &c. with regard to the ordonnance of the whole building.

One of the greatest differences among architects, M. Perrault observes, is in the proportion of the heights of entablatures with respect to the thickness of the columns, to which they are always to be accommodated.

In effect, there is scarcely any work, either of the ancients or moderns, wherein this proportion is not different; some entablatures are even near twice as high as others;—yet it is certain this proportion ought of all others to be most regulated; none being of greater importance, as there is none in which a defect is sooner seen, nor any in which it is more shocking.

Compass of Proportion, a name by which the French, and after them some English, authors call the Sector.

Proportional, relating to proportion. Thus we say, proportional compasses, parts, scales, spirals, &c.

Proportional, in Geometry, are quantities, either linear or numerical, which bear the same ratio or relation to each other.

Proposition, in Logic, part of an argument, wherein some quality, either negative or positive, is attributed to a subject.

Proposition, in Mathematics, is either some truth advanced and shown to be such by demonstration, or some operation proposed and its solution shown. If the
Proposition be deduced from several theoretical definitions compared together, it is called a theorem; if from a praxis, or series of operations, it is called a problem. See the articles Theorem and Problem.

Proposition, in Oratory. See Oratory, No 28.

Proposition, in Poetry. The first part of a poem, wherein the author propouses briefly, and in general, what he is to say in the body of his work. It should comprehend only the matter of the poem, that is, the action and persons that act. Horace prescribes modesty and simplicity in the proposition, and would not have the poet promise too much, nor raise in the reader too great an idea of what he is going to relate.

Proprefect, among the Romans, the prefect's lieutenant, or an officer whom the prefect of the pretorium commissioned to do part of his duty in his place.

Propretor, a Roman magistrate, who, having discharged the office of pretor at home, was sent into a province to command there with his former pretorial authority. It was also an appellation given to those who, without having been pretors at Rome, were sent extraordinarily into the provinces to administer justice with the authority of pretors.

Proprietor, or Proprietary, is he who possesses any thing as his own in the utmost degree. Such monks were called proprietary as had reserved goods and effects to themselves, notwithstanding their formal renunciation of all at the time of their profession. They are frequently mentioned in the Monast. Anglic. &c. and were to be very severely dealt with; to be excommunicated, deprived of burial, &c. Monachi proprietarii excommunicentur ab abbotibus: et, si in morte proprietarius inventus fuit, ecclesiasticae careat sepultura, &c. Addit. ad Matt. Par.

Pro Rata, in commerce, a term sometimes used by merchants for in proportion; as, each person must reap the profit or sustain the loss, pro rata to his interest, that is, in proportion to his stock.

Prorogation, the act of prolonging, adjourning, or putting off, to another time. The difference between a prorogation and an adjournment of parliament is, that by prorogation the session is ended, and such bills as passed in either house, or both houses, and had not the royal assent, must at the next assembly begin again.

Proscription, a publication made in the name of the chief or leader of a party, whereby he promises a reward to any one who shall bring him the head of one of his enemies.

Sulla and Marius by turns proscribed each others adherents.—Under the triumvirate great part of the best and bravest of the Romans fell by proscription.

The term took its rise from the practice of writing down a list of the persons names, and posting it in public; from pro and scribo, "I write."

Prose, the natural language of mankind, loose and unconfined by poetical measures, rhymes, &c. In which sense it stands opposed to verse.

There is, however, a species of prose which is measured, such as that in which epistles and other inscriptions are generally written; and indeed every man who has formed for himself a style writes in uniform periods regularly recurring. It has been much disputed whether a poem can be written in prose.

The word prose comes from the Latin proser, which some will have derived from the Hebrew poras, which signifies expendit: others deduce it from the Latin prorsus, of prorsus, "going forwards." by way of opposition to versus, or "turning backwards," as is necessary in writing.

Prosecution, in the criminal law. The next step towards the punishment of offenders after commitment, is their prosecution, or the manner of their formal accusation. And this, in the English law, is either upon a previous finding of the fact by an inquest or grand jury; or without such previous finding.

The former way is either by Presentment or Indictment. See these articles.

The remaining methods of prosecution are without any previous finding by a jury, to fix the authoritative stamp of verisimilitude upon the accusation. One of these, by the common law, was in the chief was taken with the mainour, that is, with the thing stolen upon him, in manu. For he might, when so detected, flagrante delicto, be brought into court, arraigned, and tried, without indictment: as by the Danish law he might be taken and hanged upon the spot without accusation or trial. But this proceeding was taken away by several statutes in the reign of Edward III. though in Scotland a similar process remains to this day. So that the only species of proceeding at the suit of the king, without a previous indictment or presentment by a grand jury, now seems to be that of Information, which see.

These are all the methods of prosecution at the suit of the king. There yet remains another, which is merely at the suit of the subject, and is called an Appeal. See that article.

But of all the methods of prosecution, that by indictment is the most general. See Indictment.

Prosecutor, in Law, he that pursues a cause in another's name.

Proselyte, a new convert to some religion or religious sect.

Proserpinaca, a genus of plants belonging to the triandria class, and in the natural method ranking under the 15th order, Inundatae. See Botany Index.

Proserpine, in fabulous history, the daughter of Jupiter and Ceres, was carried off by Pluto as she was gathering flowers with her companions. Ceres, disconsolate for the loss of her daughter, after having long sought her, heard where she was, and intreated Jupiter to let her return from hell. This request Jupiter granted, on condition she had tasted nothing in Pluto's dominions. Ceres therefore went to fetch her; but when her daughter was preparing to return, Ascalaphus gave information that he had seen Proserpine eat some grains of a pomegranate she had gathered in Pluto's garden; on which she was sentenced to continue in Tartarus in quality of Pluto's spouse, and the queen of those gloomy regions: but to mitigate the grief of Ceres for her disappointment, Jupiter granted that her daughter should only spend six months together in hell with her husband, and the other six on earth with her mother.

Some mythologists imagine that the latter part of the fable
fable alludes to the corn, which must remain all the
winter bid in the earth, in order to sprout forth in the
spring, and produce the harvest.

PROSEUCHE, in antiquity, properly signifies prayer; but it is taken for the places of prayer of the Jews,
and was pretty near the same as their synagogues. But
the synagogues were originally in the cities, and were
covered places: whereas, for the most part, the pro-
senches were out of the cities, and on the banks of ri-
vers; having no covering except perhaps the shade of
some trees or covered galleries. The word is Greek,
Ἑρμακία, prayer.

PROSLAMBANOMENE, the name of a musical
note in the Greek system.

As the two tetrachords of the Greeks were conjunc-
tive, or, in other words, as the highest note of the first
served likewise for the lowest note of the second, it is
plain that a complete octave could not be formed. To
remedy this deficiency, therefore, one note beneath the
lowest tetrachord was added, as an octave to the high-
est of the last tetrachord. Thus, if we suppose the
first to have begun on B, the last must have ended upon
A, to which one note subjoined immediately beneath
the lowest B in the diatonic order must have formed an
octave. This note was called proslambanomene. But
it appears from authors who have scrutinized antiquity
with some diligence, and perhaps with as much success
as the data upon which they proceeded could produce,
that the names of the notes in the Greek system, which
originally signified their natural station in the scale of
ascending or descending sounds, were afterwards ap-
plied to their positions in the lyre. Higher or lower,
then, according to this application, did not signify their
degrees of acuteness or gravity, but their higher or
lower situation upon this instrument.

PROSODY, that part of grammar which treats of
the quantities and accents of syllables, and the manner
of making verses.

The English prosody turns chiefly on two things,
numbers and rhyme. See Poetry, No. 66—76, and
Part III.

PROSOPIS, in Botany, a genus of the monogynia
order, belonging to the dodecandria class of plants.
The calyx is hemispherical and quadridentate; the
stigma is simple; the legumen inflated and monosper-
mous. See Botany Index.

PROSOPOPOEIA, a figure in oratory, whereby
we raise qualities of things inanimate into persons. See
Oratory.

PROSTATÆ, in Anatomy, a gland, generally sup-
posed to be two separate bodies, though in reality but
one, situated just before the neck of the bladder, and
surrounding the beginning of the urethra. See Anato-
my Index.

PROSTYLE, in Architecture, a range of columns
in the front of a temple.

PROTAGORAS, a famous Greek philosopher, was
born at Abdera. In his youth, his poverty obliged
him to submit to the servile office of frequently car-
yrying logs of wood from the neighbouring fields to
Abdera. It happened that as he was one day going
briskly towards the city under one of these loads, he
was met by Democritus, who was particularly struck
with the neatness and regularity of the bundle. De-
iring him to stop and rest himself, Democritus exami-
ined more closely the structure of the load, and found that
it was put together with mathematical exactness; upon
which he asked the youth whether he himself had made
it up. Protagoras assured him that he had; and imme-
diately taking it to pieces, with great ease replaced
every log in the same exact order as before. Democri-
tus expressed much admiration of his ingenuity; and
said to him, "Young man, follow me, and your talents
shall be employed upon greater and better things." The
youth consented, and Democritus took him home, main-
tained him at his own expense, and taught him philo-
sophy, which qualified him for the office of legislator of
the Thurians. He was more subtle than solid in his
reasonings; however, he taught at Athens with great
reputation, but was at length banished from thence for
the impiety of his doctrines. He then travelled, and vis-
ited the islands in the Mediterranean, where it is said
that he was the first philosopher who taught for money.
He died in a voyage to Sicily, in a very advanced age.
He commonly reasoned by dilemmas, and left the mind
in suspense with respect to all the questions he was propo-
sed. His moral principles were adopted by Hobbes. (See
Moral Philosophy.) Plato wrote a dialogue against
him. He flourished 400 years B.C.

PROTASIS, in the ancient drama, the first part of
a comic or tragic piece, wherein the several persons are
shown, their characters intimated, and the subject of
the piece proposed and entered upon.

It might reach as far as our two first acts; and when
it ended the epitasis commenced. See the article En-
tasis.

PROTEA, the Silver-tree, a genus of plants, be-
longing to the tetrandria class; and in the natural me-
thod ranking under the 47th order, Stellatae. See
Botany Index.

PROTECTOR, a person who undertakes to shelter
and defend the weak, helpless and distressed.

Every Catholic nation, and every religious order, has
a protector residing at the court of Rome, who is a car-
dinal, and is called the cardinal protector.

Protector is also sometimes used for a regent of a kung-
dom, made choice of to govern it during the minority
of a prince.

Cromwell assumed the title and quality of lord pro-
tector of the commonwealth of England.

PROTESILAUS TURRIS, the sepulchre of Protes-
lius, with a temple, at which Alexander sacrificed,
(Arian); situated at the south extremity of the Helle
spont, near the Chersonesus Thracia. Proteus was
the first Greek who landed on the coast of Troy, and
the first Greek slain by the Trojans, (Homer, Ovid).
His wife Nadezia, to assuage her grief, begged the
gods for a sight of his shade; and obtaining her request,
she expired in his embraces, (Hyginus). Proteus was
also called Phylaceus, from Phylace, a town of
Thessaly.

PROTEST, in Law, is a call of witness, or an open
affirmation that a person does, either not at all, or but
conditionally, yield his consent to any act, or to the
proceeding of any judge in a court in which his juris-
diction is doubtful, or to answer upon his oath farther
than he is bound by law.

Any of the lords in parliament have a right to pro-
test their dissent to any bill passed by a majority: which
protest is entered in form. This is said to be a very

ancient
ancient privilege. The commons have no right to protest. See PARLIAMENT.

PROTEST, in Commerce, a summons written by a notary-public to a merchant, banker, or the like to accept or discharge a bill of exchange drawn on him, after his having refused either to accept or pay it. See BILL of Exchange.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529 they protested against a decree of the emperor Charles V. and the diet of Spires, declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin; and is now become a common denomination for all those of the reformed churches.

PROTEUS, in Heathen Mythology. See EGYPT, No 6.

PROTHONOTARY, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople.

Prothonotary, with us, is used for an officer in the court of king's bench and common pleas; the former of which courts has one, and the latter three. The prothonotary of the king's bench records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the common pleas enter and enrol all declarations, pleadings, assizes, judgments, and actions: they also make out all judicial writs, except writs of habeas corpus, and distingas jurator, for which there is a particular office, called the habeas corpus office; they likewise enter recognizances acknowledged, and all common recoveries; make exemplifications of records, &c.

In the court of Rome there is a college of 12 prelates, called apostolical prothonotaries, to make all informations and proceedings necessary for the canonization of saints; and all such acts as are of great consequence to the Papacy: for which purpose they have the right of admission into all consistories, whether public or half public. They also attend on the pope whenever he performs any extraordinary ceremony out of Rome.

PROTO, a Greek term, frequently used in composition of priority: thus proto-collum, in the ancient jurisprudence, signifies the first leaf of a book; proto-martyr, the first martyr; proto-plast, the first man formed, &c.

PROTOGENES, a celebrated ancient painter, was born at Caunus, a city of Caria, subject to the Rhodians, and flourished 300 years before the birth of our Saviour. He was first obliged to paint ships for his livelihood, but afterwards acquired the highest reputation for history-painting; though Apelles blamed him for finishing his pieces too highly, and not knowing when to have done. The finest of his pictures was that of Jalisus, which is mentioned by several ancient authors, though none of them give any description of it. He worked seven years on this picture; during which time he lived entirely upon lupines and water, being of opinion that this light and simple nourishment left him greater freedom of fancy. Apelles, on seeing this picture, was struck with such admiration, that he was unable to speak, or to find words sufficient to express his idea of its beauty. It was this picture that saved the city of Rhodes when besieged by Demetrius king of Macedon; for being able to attack it only on that side where Protagenes worked, which he intended to burn, he chose rather to abandon his design than to destroy so fine a piece. Pliny says, that Apelles asking him what price he had for his pictures, and Protagenes naming an inconsiderable sum, Apelles concerned at the injustice done to the beauty of his productions, gave him 50 talents, about 10,000, for one picture only, declaring publicly, that he would sell it for his own. This generosity made the Rhodians sensible of the merit of Protagenes; and they were so eager to purchase the picture Apelles had bought, that they paid him a much greater price for it than he had given.

PROTOTYPE, is the original or model after which a thing was formed; but chiefly used for the patterns of things to be engraved, cast, &c.

PROTRACTOR, an instrument for laying down and measuring angles upon paper with accuracy and dispatch; and by which the use of the line of chords is superseded. This instrument is variously formed, as semicircular, rectangular, or circular; and constructed of different materials, as brass, ivory, &c. It is necessary in laying down those surveys or other plans where angles are concerned.

The rectangular protractor is constructed in form of a right-angled parallelogram, which, when applied to a case of mathematical instruments, is substituted in place of the semicircular protractor and scale of equal parts. Fig. 1. is a representation of it: the manner of using it is exactly similar to that of the semicircular one.

The circular protractor, as its name implies, is a complete circle, and is superior by far to either of the former, both in point of accuracy and dispatch, especially when several angles are to be formed at the same point. The limb of this instrument is divided into 360 degrees, and each degree in some protractors is halved: it has a subdividing scale or vernier, by which an angle may be laid down or measured to a single minute. In the centre of the protractor is a fine mark, which, when an angle is to be protracted or measured, is to be laid upon the angular point, and the limb, upon the given line forming one side of the angle.

Fig. 2. represents a circular protractor whose limb is divided as above described, and the dividing scale on the index, which moves round the limb of the protractor on a conical centre, gives every minute of a degree. That part of the index beyond the limb has a steel point fixed at the end, in a direct line with the centre of the protractor, and whose use is to prick off the proposed angles.

Fig. 3. is another circular protractor, a little different. It is entirely constructed from the former. The central point is formed by the intersection of two lines crossing each other at right angles, which are cut on a piece of glass. The limb is divided into degrees and half degrees, having an index with a vernier graduated to count to a single minute, and is furnished with a tooth and pinion, by means of which the index is moved round by turning a small nut. It has two pointers, one at each end of the index, furnished with springs for keeping them suspended while they are bringing to any angle; and being
PROTRACTOR.

PLATE CCCCXLVIII.

Fig. 1.  Fig. 2.  Fig. 3.  Fig. 4.
Protractor

Proverb.

The Protractor

being brought, applying a finger to the top of the pointer, and pressing it down, pricks off the angle.

There is this advantage in having two pointers, that all the bearings round a circuit may be laid or pricked off, although the index traverses but one-half of the protractor.

Another circular protractor, different from either of the former, is represented at fig. 4. The centre is also formed by the intersection of two lines at right angles to each other, which are cut on glass, that all parallax may thereby be avoided. The index is moved round by a tooth and pinion. The limb is divided into degrees and half-degrees, and subdivided to every minute by the vernier. The pointer may be set at any convenient distance from the centre, as the socket which carries it moves upon the bar BC, and is fixed thereto by the nut D, at right angles to the bar BC, and moveable with it. There is another bar EF: On this bar different scales of equal parts are placed; so that by moving a square against the inner edge thereof, angles may be transferred to any distance within the limits, from the centre containing the same number of degrees marked out by the index.

It would indeed be superfluous to describe any more of these circular protractors, especially as the little alterations in them depend very much upon the fancy of the artist. Suffice it however to say, that we have seen others still differently constructed, one of which we shall briefly describe. The divisions upon the limb of this instrument are similar to those already described; but the index is a straight bar continued to some considerable distance each way beyond the limb of the instrument, and has a vernier to show minutes as usual; a mark upon one of the edges of the index, always coincides with the centre of the instrument. Instead, therefore, of pricking down the angle as in the former, part of the line containing the angle may be drawn, which, although perhaps not so accurate as a point, is more conspicuous, and the line is easily completed upon removal of the protractor. The common dimensions of the circular part of these instruments is from six to ten inches diameter; and they are made of brass.

PROTUBERANCE, in Anatomy, is any eminence, whether natural or preternatural, that projects or advances out beyond the rest.

PROVEDITOR, an officer in several parts of Italy, particularly at Venice, who has the direction of matters relating to policy.

PROVENCE, a province or government of France, bounded by Dauphiné on the north, by Piedmont on the east, by the Mediterranean on the south, and by the river Rhone, which separates it from Languedoc, on the west: it is about 100 miles long, and near as many broad.

PROVEND, or PROVENDER, originally signified a kind of vessel containing the measure of corn daily given to a horse, or other beast of labour, for his subsistence; but is now generally used to signify the food for cattle; whatever it is.

PROVERB, according to Camden, is a concise, witty, and wise speech, grounded upon experience, and for the most part containing some useful instruction.

Book of Proverbs, a canonical book of the Old Testament, containing a part of the proverbs of Solomon the son of David king of Israel. The first 24 chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his proverbs made by order of King Hezekiah; and the two last seem to have been added, though belonging to different and unknown authors, Agur the son of Jakeh, and King Lemuel.

In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, children, &c.

PROVIDENCE, the superintendence and care of which God exercises over creation.

That there exists a divine providence which attends Belief of a man to the affair of this world, and directs their course, has been a received opinion among the human race in every country and in every period of history. Every altar that is erected, every prayer and every sacrifice that is offered up, affords a proof of this belief. So fully have men been convinced of the sincerity of each other's faith upon this subject, that in one form, that of an appeal to the Divine Ruler of the world, by the solemnity of an oath, they have introduced it both into the most ordinary and the most important business of life.

This universal conviction of men of all degrees of existence, knowledge, from the most profound philosopher to the rudest barbarian, is probably to be traced to some primitive tradition, never totally effaced from every nation on earth. The truth itself, however, is susceptible of the complete proof from principles of science. If the world had a beginning, it may obviously have an end, and can be continued in existence only by the constant energy of that power by which it was at first created. He therefore who acknowledges a creation and denies a providence, involves himself in this palpable contradiction—"that a system, which of itself had not an original and momentary existence, may yet of itself have a perpetual existence; or that a being which cannot of itself exist for a second of time, may yet, of itself, exist for thousands of years." Or should we be so complaisant, as for a moment to suppose, with certain theists, ancient and modern, that the universe is self-existent and eternal, and that the power of God was exerted, not in creating substances, but in reducing the original matter from a state of chaos into that beautiful order in which we see it arranged; the constant energy of providence must still be admitted as necessary to preserve the forms and to continue the motions which were originally impressed upon the chaotic mass. From late experiments it appears extremely doubtful whether any two atoms of the most solid body be in actual contact; and that they are not all in contact is certain. (See METAPHYSICS, N. 176. and OPTICS, N° 45, p. 185). Yet it requires a very considerable degree of force to carry to a greater distance from one another the parts of a stone or of a bar of iron. By what power then are those parts kept contiguous? It cannot be by their own; because nothing can act where it is not present, and because our best philosophy has long taught us that the atoms of matter are essentially inanimate. Again, it requires a very great degree of force to bring two bodies, however small, into apparent contact (see OPTICS,ubi supra); and therefore it follows that they must be kept under by some foreign power. Every attempt to solve these phenomena by the intervention...
Providence, whatever a subtle fluid is vain; for the question recurs, what keeps the parts of the fluid itself contiguous, and yet separated from each other? The cohesion therefore of the parts of matter, and that which is called their repulsive power, demonstrate, through the whole system, the immediate energy of something which is not matter, and by which every body small and great is preserved in its proper form. It has been elsewhere shown (see Metaphysics, Part II. chap. 5. and Motion, No. 19. 20.), that the various motions which are regularly carried on through the universe, by which animals and vegetables grow and decay, and by which we have day and night, summer and winter, cannot be accounted for by any laws of mere mechanism, but necessarily imply the constant agency of something which is itself distinct from matter. But the forms of bodies are preserved, and their natural motions carried on, for purposes obviously planned by Wisdom. The power therefore which effects these things must be combined with intelligence: but power and intelligence preserving the order of the universe constitute all that is meant by a general providence; which is therefore as certainly administered as the sun daily rises and sets, or as bodies are kept solid by what is termed cohesion and repulsion.

Abstracted and metaphysical as this reasoning may appear, it is by no means peculiar to the philosophers of Europe. Its force has been felt from time immemorial by the Brahmins of Hindostan, who, as Sir William Jones informs us, "being unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of supreme goodness was left a moment to itself; imagine that the Deity is ever present to his work, not in substance, but in spirit and in energy." On this rational and sublime conception they have indeed built numberless absurd superstitions; but their holding the opinion itself, shows that they believe in the reality of providence upon philosophical principles: and what truth is there on which the mind of man has not ingrained marks of its own weakness?

Few nations, however, except the ancient Greeks, have had philosophers equally subtle with the Brahmins of India; and therefore though all mankind have in general agreed in the belief of a superintending Providence, they have in different ages and countries admitted that truth upon different kinds of evidence, and formed very different notions concerning the mode in which the Divine superintendence is exerted.

While societies are still in a rude and unpolished state, while individuals possess little security and little leisure for the exertion of their rational powers, every important or singular appearance in nature becomes an object of wonder or of terror. In this state of ignorance, men see not the universe as it is, a great collection of connected parts, all contributing to form one grand and beautiful system. Every appearance seems to stand alone; they know that it must have a cause, but what that cause is they are ignorant. The phenomena exhibited by nature are so complicated and so various, that it never occurs to them that it is possible for one Being to govern the whole. Hence arose the different systems of polytheism that have appeared in the world. Nature was divided into different regions, and a particular invisible power was assigned to each department: one conducted the flaming chariot of the sun, another wielded the terrible thunderbolt, and others were employed in diffusing providence, plenty, and introducing the useful arts among men.

Thus, although the various systems of polytheism are general acknowledged one Supreme Ruler, the father of gods and men, yet they at the same time peopled not only the regions above, the air and the heavens, but also filled the ocean and the land, every grove, and every mountain, with active but invisible natures. Having arisen from the same causes, these systems of polytheism, which are so many hypotheses concerning Divine providence, are all extremely similar; and we have a very favourable specimen of them in the elegant mythology of Greece and Rome, which gave to every region of nature a guardian genius, and taught men in the deep recesses of the forest, or in the windings of the majestic flood, to expect the presence of protecting and friendly powers. See Polytheism.

Notwithstanding this universal reception, in some The de- form or other, of the doctrine of a divine providence, it has in every age met with some opponents. The most ancient of these were Democritus and Leucippus. They denied the existence of a Deity—asserted that all things were mechanically necessary, and that thought and sense were only modifications of matter. This is atheism in the strictest sense, and the only form of it that has ever been consistently supported. Epicurus followed upon the same principles; but he rendered the system altogether absurd, by confessing the freedom of the human will. To avoid the imputation of atheism, he asserted the existence of God; but declared that he resided above the heavens, and interfered not in human affairs. One of his maxims was, that "the blessed and immortal Being neither hath any employment himself, nor troubles himself with others." Maximus Tyrius justly observes, that this is rather a description of Sardanapulus than of a Deity. And some of the moralists of antiquity remarked, that they knew as many gods ab men among themselves possessed of active and generous minds, whose characters they valued more highly than that of Epicurus's god. Some of the ancients also appear to have entertained the following strange notions: They acknowledged the existence of a Supreme and of many inferior deities; but at the same time, they supposed that there is a certain fate which rules over all, and is superior to the gods themselves. See Necessity in Mythology.

The providence exerted by the Author of nature over his works is usually divided into two branches: a general, referring to the management of the universe at large; and a particular providence, chiefly regarding particular men.

Upon the first of these, in The Religion of Nature de General

linedated, the question is stated somewhat in the follow-
Providence: understand his governing the world by such laws as these now mentioned: so that if there are such, there must be a Divine providence.

With regard to immovable objects, the case agrees precisely with the above supposition. The whole of that universe which we see around us is one magnificent and well-�regulated machine. The world that we inhabit is a large globe, which, conducted by an invisible power, flies with a rapidity of which we have no conception, through an extent of space which sets at defiance every power of fancy to embody it into any distinct image. A large flaming orb stands immovable in the heavens; around which this, and other worlds of different magnitudes, perform their perpetual revolutions. Hence arise the expected returns of day and night, and the regular diversity of seasons. Upon these great operations a thousand other circumstances depend. Hence, for example, the vapours ascend from the ocean, meet above in clouds, and after being condensed, descend in showers to cover the earth with fertility and beauty. And these appearances are permanent and regular. During every age since men have been placed upon the earth, this astonishing machine continued steadily to perform its complicated operations. Nothing is left to chance. The smallest bodies are not less regular than the largest, and observe continually the same rules of attraction, repulsion, &c. The apparent variations of nature proceed only from different circumstances and combinations of things, acting all the while under their ancient laws. We ourselves can calculate the effects of the laws of gravitation and of motion. We can render them subservient to our own purposes, with entire certainty of success if we only adhere to the rules established by nature, that is to say, by providence.

Vegetables also live and flourish according to prescribed methods. Each sort is produced from its proper seed; has the same texture of fibres, is at all times nourished by the same kind of juices, digested and prepared by the same vessels. Trees and shrubs receive annually their peculiar liversies, and bear their proper fruits: so regular are they in this last respect, that every species may be said to have its profession or trade appointed to it, by which it furnishes a certain portion of manufacture, or of food, to supply the wants of animals: being created for the purpose of consumption, all vegetables produce great quantities of seed to supply the necessary waste. Here too, there is evidently a regulation by which the several orders are preserved, and the ends of them answered according to their first establishment.

With regard to animals, they too, in structure of their form, are subject to laws similar to those which govern the vegetable world. In the sentient part of their constitution they are no less subject to rule. The lion is always fierce, the fox is crafty, and the hare is timid. Every species retains from age to age its appointed place and character in the great family of nature. The various tribes are made and placed in such a manner as to find proper means of support and defence. Beasts, birds, fishes, and insects, are all possessed of organs and faculties adapted to their respective circumstances, and opportunities of finding their proper food and prey.

Man is subject to the ordinary laws which other material and animal substances obey; but he is left more at large in the determination of his actions. Yet even here things do not fluctuate at random. Individuals do indeed rise and perish according to fixed rules, and nations themselves have only a temporary endurance. But the species advances with a steady progress to intellectual improvement. This progress is often interrupted; but it appears not to be less sure at the long-run than even the mechanical laws which govern the material part of our constitution. Amidst the convulsion of states and the ruin of empires, the useful arts, when once invented, are never lost. These, in better times, render subsistence easy, and give leisure for reflection and study to a greater number of individuals. Tyre and Sidon have passed away, Athens itself has become the prey of barbarians, and the prosperity of ancient Egypt is departed, perhaps for ever; but the ship, the plough, and the loom, remain, and have been perpetually improving. Thus every new convulsion of society does less mischief than the last; and it is hoped that by the assistance of printing the most polished arts and the most refined speculations have now become immortal.

The world is not then left in a state of confusion: it is reduced into order, and methodised for ages to come; the several species of beings having their offices and provinces assigned them. Plants, animals, men, and nations, are in a state of continual change; but successors are appointed to relieve them, and to carry on the scheme of Providence.

But the great difficulty is, how to account for that difficulty providence which is called particular: For rational beings, and free agents, are capable of doing and deserving particular praise or blame; and the safety or danger, that happiness or misery, of a man here, must depend upon many things that seem scarcely capable of being determined by Providence. Besides himself and his own conduct, he depends upon the conduct of other men; whose actions, as we naturally suppose, cannot, consistently with their free will, be controlled for the advantage of another individual. The actions of numbers of men proceeding upon their private freedom, with different degrees of ability, as they cross and impede, or directly oppose each other, must produce very different effects upon men of different characters, and thus in a strange manner embarrass and entangle the general plan. And as to the course of nature, it may justly be asked, is the force of gravitation to be suspended till a good man pass by an infirm building? (See Prayer). Add to this, that some circumstances appear absolutely irreconcilable. The wind which carries one into port drives another back to sea: and the rains that are just sufficient upon the hills may drown the inhabitants of the valleys. In short, may we expect miracles or can there be a particular Providence that foresees and prepares for the several cases of individuals, without force frequently committed upon the laws of nature and the freedom of intelligent agents?

In whatever way it is brought about, there is little doubt that something of this kind must take place. For argument as the Deity does direct, as already mentioned, the great and general progress of things in this world, he must also manage those of less importance. Nations are composed of individuals. The progress of individuals is the progress of the nation, and the greatest events usually depend upon the history and the most trifling actions.
Terrified by the gigantic bulk and mighty force of Goliath, no man would risk the unequal conflict. David, who was too young to carry arms, had been sent to the camp with provisions for his brothers, and heard the challenge. In defence of his flock he had killed some beasts of prey in the wilderness, and he was an excellent marksman with the sling. He thought it might probably be as easy to kill a man as a wild beast; at all events, he knew that a bow well directed would prove no less fatal to a giant than to a dwarf: he therefore resolved to try his skill; and he tried it with success. Here no man's free will was interrupted, and no miracle was accomplished: Yet by this train of circumstances thus brought together, a foundation was laid for the future fortunes of the son of Jesse, for the greatness of his country, and for accomplishing the purposes of Providence. According to Seneca, "Hoc dico, fulgur, non miti a Jove, sed sic omnia disposita, ut ea etiam que ab illo non fuisset, tamen sine ratione non sit; que illius est.—Nam etsi Jupiter illa nunc non facit, fecit ut herent."—I say, that the lightning comes not directly from the hand of Jove, but things are properly disposed for the indirect execution of his will; for he acts not immediately, but by the intervention of means.

3. Lastly, it is not impossible that many things may be accomplished by secret influence upon the human mind, either by the Deity himself, or by the intervention of agents possessed of powers superior to those which belong to us. "For instance, if the case should require that a particular man be delivered from some threatening ruin, or from some misfortune, which would certainly befall him if he should go such a way as at such a time, as he intended: upon this occasion some new reasons may be presented to his mind why he should not go at all, or not then, or not by that road; or he may forget to go. Or, if he is to be delivered from some dangerous enemy, either some new turn given to his thoughts may divert him from going where the enemy will be, or the enemy may be after the same manner diverted from coming where he shall be, or his resentment may be qualified; or some proper method of defence may be suggested to the person in danger. After the same manner advantages and successes may be conferred on the deserving; as, on the other side, men, by way of punishment for their crimes, may incur mischiefs and calamities. These things, and such as these (says Mr Wolston), may be. For since the motions and actions of men, which depend upon their wills, do also depend upon their judgments, as these again do upon the present sect. appearances of things in their minds; if a new prospect of things can be any way produced, the lights by which they are seen altered, new forces and directions impressed upon the spirits, passions exalted or abated, the power of judging enlivened or debilitated, or the attention taken off without any suspension or alteration of the standing laws of nature,—then, without that, new volitions, designs, measures, or a cessation of thinking, may also be produced; and thus many things prevented that otherwise would be, and many brought about that would not. That there may possibly be such inspirations of new thoughts and counsels (continues our author), may perhaps appear farther from this, that we frequently find thoughts arising in our heads, into which we are led by no discourse, nothing we read, no clue of reasoning, but they surprise and come upon us from we know not."

14 The Deity may easily foresee the actions of men; 15 and may therefore fit them for their situations in life. 16 The possibility of this exemplified.
PRO [ 465 ]

Providence, not what quarter. If they proceeded from the mobility of spirits straggling out of order, and fortuitous affections of the brain, or were they of the nature of dreams, why are they not as wild, incoherent, and extravagant as they are? Is it not much more reasonable to imagine that they come by the order and direction of an all-seeing and all-gracious God, who continually watches over us, and disposes every thing in and about us for the good of ourselves or others? not to speak of the agreeableness of this notion to the opinions of the best and wisest men in all ages (A). If this, then, be the case, as it seems to be, that men’s minds are susceptible of such insinuations and impressions, as frequently, by ways unknown, do affect them, and give them an inclination towards this or that; how many things (asks our author) may be brought to pass by these means without fixing and refining the laws of nature, any more than they are unfixed when one man alters the opinion of another by throwing in his way a book proper for that purpose? We may be affected either by the immediate interposition of God himself, or by that of beings invisible, and in nature superior to us, who act as the ministers of his providence. That there are such beings we can hardly doubt, as it is in the highest degree improbable that such imperfect beings as men are at the top of the scale of created existence. And since we ourselves, by the use of our limited powers, do often alter the course of things within our sphere from what they would be if left to the ordinary laws of motion and gravitation, without being said to alter those laws; why may not superior beings do the same as instruments of divine providence? The idea of the intervention of superior natures is beautifully illustrated by Thomson in the following passage:

These are the haunts of meditation, these
The scenes where ancient bards the’ inspiring breath,
Ecstatic, felt; and from this world retir’d,
Convers’d with angels and immortal forms,
On gracious errands bent: to save the fall
Of virtue struggling on the brink of vice;
In waking whispers, and repeated dreams,
To hint pure thought, and warn the favour’d soul
For future trials fated to prepare.

We agree, however, with Mr Wollaston, in thinking the power of these beings not so large as to alter or suspend the general laws of nature (see Miracle); for the world is not like a bungling piece of clock-work, which requires to be often set backwards or forwards. We are likewise perfectly satisfied, that they cannot change their condition, to ape us or inferior beings; and consequently we are not apt hastily to credit stories of portents, &c. such as cannot be true, unless the nature of things and their manner of existence were occasionally reversed. Yet as men may be so placed as to become,
even by the free exercise of their own powers, instruments of God’s particular providence to other men; so we may well suppose that these higher beings may be so distributed through the universe, and subject to such an economy, unknown to us, as may render them also instruments of the same providence: and that they may, in proportion to their greater abilities, be capable, consistently with the laws of nature, of influencing human affairs in proper places.

We shall next proceed to state some of the chief objections which in ancient or modern times have been brought against the opinion, that the world is governed by a Divine providence. The first of these is, that the system of nature from the contains many imperfections which it ought not to do if it be the work of a perfectly wise and good Being. To avoid the force of this objection, some modern writers have deserted the ground of supreme and absolute goodness, which the ancient theorists always occupied, and have asserted that the divine perfection consists in unlimited power and uncontrolled supremacy of will; that consequently the Deity does not always that which is best, but merely what he himself pleases; and that for no other reason but because he wills to do so. But this is no better than atheism itself. For it is of no importance to us whether the universe is governed by blind fate or chance, that is to say, by nothing at all; or whether it is governed by an arbitrary sovereign will that is directed by chance, or at least by no principle of benevolence. The true answer to this objection is, that no created system can have every perfection, because it must necessarily be destitute of self-existence and independence; and therefore if being destitute of some perfections be better than nothing, it was worthy of infinite power and perfect goodness to create such beings. In our present state, we mortals stand upon too low ground to take a commanding view of the whole frame of things. We can only reason concerning what is unknown from the little that is within our reach. In that little, we can see that wisdom and goodness reign; that nature always aims to produce perfection; that many salutary effects result even from the thunder and the storm: and we doubt not that a view of the whole structure of the universe would afford an additional triumph to the goodness and skill of its great Architect.

We see a regular ascent in the scale of beings from mere lifeless matter up to man; and the probability is, that the scale continues to ascend as far above man in perfection as created beings can possibly be raised. The sole purpose of God in creating the world must have been to produce happiness: but this would be most effectually done by creating, in the first place, as many of the most perfect class of beings as the system could contain, and afterwards other classes less and less perfect, till the whole universe should be completely full. We do not positively assert such a scheme of creation.

(A) That such was the general belief of the Greeks in the days of Homer, is plain from that poet’s constantly introducing his deities into the narrative of his poems, and telling us that Minerva, or some other god, altered the minds of his heroes. “By this,” says Plutarch, “the poet does not mean to make God destroy the will of man, but only move him to will: nor does he miraculously produce the appetites themselves in men, but only causes such imaginations as are capable of exciting them.”

Vol. XVII. Part II.
Where all must fall, or not coherent be; And all that rises, rise in due degree,
was actually in the divine Architect’s intention; but that it is possible, is sufficiently obvious. No man will pretend to say, that this earth could afford a comfortable subsistence to a greater number of the human race, were all the inferior animals annihilated, than it could at present, swarming as every element is with life.— Suppose then, that as many men had been placed at first upon the earth as it could possibly support, and that matters had been so constituted, as that the number should never have been either increased or diminished; we beg leave to ask, whether, since there would have been evidently room for inferior animals, it would have been most worthy of infinite goodness to leave the whole globe to men, or to introduce it into different orders of less perfect beings, which, while they could not incommodate this principal inhabitant, would each find pleasure in its own existence? To this question different answers cannot surely be given. Let the reader then extend his view, and consider the universe, which, however vast, cannot be positively infinite, as one system as much united as the several parts of this globe; let him suppose that there were at first created as many of the highest order of beings as it could have contained had creation there stopped; let him remember that happiness in many different degrees is valuable; and he will not surely think it any imputation on the goodness of God that there are in the universe many beings far from perfection. The most imperfect of these are by themselves better than nothing; and they all contribute to make up a system which, considered as a whole, we have every reason to believe to be as perfect as any thing not self-existent can possibly be.

2 If the world is conducted by a benevolent providence, how came evil to be introduced into it? This question has perplexed mankind in all ages. The ancient Persians resolved it, by asserting the existence of two gods, Oromades the author of good, and Arimanus the author of evil. From them the Christian heretics called Manichees borrowed their doctrine of two opposite co-eternal principles. Both the Platonists and Stoics ascribed the origin of evil to the perverseness or imperfection of matter, which they thought the Deity could not alter: and Pythagoras imagined a state of pre-existence, in which the souls of men had committed offences, for which they are here suffering the punishment. But these hypotheses are, some of them impious, and all unsatisfactory.

Taking the expression in its most extensive sense, the evils to which the human race are exposed may be reduced to pain, uneasiness, disappointment of appetites, and death; of which not one could have been wholly prevented without occasioning greater evils, inconsistent with the perfect goodness of the Creator. As long as we have solid bodies capable of motion, supported by food, subject to the influence of the atmosphere, and divisible, they must necessarily be liable to dissolution or death: But if a man could suffer death, or have his limbs broken, without feeling pain, the human race had been long ago extinct. A fever is a state of the body in which the fluids are in great disorder. Felt we no uneasiness from that disorder, we should have no inducement to pay the proper attention to our state, and should cer-

3 tainly die unawares, without suspecting ourselves to be provided in danger; whereas, under the present administration of divine providence, the pain and sickness of the disease compel us to have recourse to the remedies proper for restoring us to soundness and to health. Of the uneasiness to which we are liable, and which are not the effect of immediate pain, the greatest has been sometimes said to arise from the apprehension of death, which constantly stares us in the face, and frequently embitters all our pleasures even in the hour of perfect health—But this dread of death is implanted in our breasts for the very best of purposes. Had we no horror at the apprehension of death, we should be apt, whenever any misfortune befell us, to quit this world rashly, and rush unprepared into the presence of our Judge; but the horror which attends our reflections on our own dissolution, arising not from any apprehensions of the pain of dying, but from our anxiety concerning our future state of existence, tends strongly to make us act, while we are here, in such a manner as to ensure our happiness hereafter. Add to this, that the fear of death is the greatest support of human laws. We every day see persons breaking through all the regulations of society and good life, notwithstanding they know death to be the certain consequence, and feel all the horrors of it that are natural to man: and therefore were death divested of these horrors, how insignificant would capital punishments be as guardians of the law, and how insecure would individuals be in civil society?

With regard to the unavoidable misfortunes and anxieties of our present state, so far from being truly hurtful in themselves, they are proofs of divine benevolence. When we see men displeased with their situation, when we hear them complain of the difficulties, the miseries, and the cares of life, of the hardships which they have undergone, and the labours which still lie before them: instead of accounting them unfortunate, we ought to regard them as active beings, placed in the only situation that is fit for the improvement of their nature. That discontent, these restless wishes to improve their condition, are so many sure indications that their faculties will not languish. They who are in the least degree accustomed to observe the human character, know well the influence which pleasure and repose have in enfeebling every manly principle, and how capable they are of attaching us even to a sordid and dishonourable existence.

Happy indeed it is for the human race, that the number of those men is small whom providence has placed in situations in which personal activity is unnecessary. By far the greater number are compelled to exert themselves, to mix and contend with their equals, in the race of fortune and of honour. It is thus that our powers are called forth, and that our nature reaches its highest perfection. It is even perhaps a general truth, that they who have struggled with the greatest variety of hardships, as they always acquire the highest energy of character, so if they have retained their integrity, and have not sunk entirely in the contest, seldom fail to spend their remaining days respectable and happy, superior to passion, and secured from folly by the possession of a wisdom dearly earned.

But the benefits of physical evils have been set in a still stronger light by a great master of moral wisdom, calm of mind, to whom was himself subject to many of those evils. That moral good man
Pro. man is a moral agent, sent into this world to acquire habits of virtue and piety to fit him for a better state, is a truth to which no consistent theist will for a moment refuse his assent. But almost all the moral good which is left among us, is the apparent effect of physical evil.

"Goodness is divided by divines into soverenity, righteousness, and godliness. Let it be examined which of these duties would be practised if there were no physical evil to enforce it.

"Sobriety or temperance is nothing but the forbearance of pleasure; if pleasure was not followed by pain, who would forbear it? We see every hour those in whom the desire of present indulgence overpowers all sense of past, and all foresight of future misery. In a remission of the gout, the drunkard returns to his wine, and the glutton to his feast; and if neither disease nor poverty were felt or dreaded, every one would sink down in idle sensuality, without any care of others, or of himself. To eat and drink, and lie down to sleep, would be the whole business of mankind.

"Righteousness, or the system of social duty, may be subdivided into justice and charity. Of justice, one of the heathen sages has shown, with great acuteness, that it was impressed upon mankind only by the inconveniences which injustice had produced. In the first ages (says he) men acted without any rule but the impulse of desire; they practised injustice upon others, and suffered it from others in their turn; but in time it was discovered, that the pain of suffering wrong was greater than the pleasure of doing it; and mankind, by a general compact, submitted to the restraint of laws, and resigned the pleasure to escape the pain.

"Of charity, it is superfluous to observe, that it could have no place if there were no want; for of a virtue which could not be practised, the omission could not be culpable. Evil is not only the occasional but the efficient cause of charity; we are incited to the relief of misery by the consciousness that we have the same nature with the sufferer; that we are in danger of the same distresses, and may some time implore the same assistance.

"Godliness or piety is elevation of the mind towards the Supreme Being, and extension of the thoughts to another life. The other life is future, and the Supreme Being is invisible. None would have recourse to an invisible power, but that all other subjects had eluded their hopes. None would fix their attention upon the future, but that they are discontented with the present. If the senses were feasted with perpetual pleasure, they would always keep the mind in subjection. Reason has no authority over us but by its power to warn us against evil.

"In childhood, while our minds are yet unoccupied, religion is impressed upon them; and the first years of almost all who have been well educated are passed in a regular discharge of the duties of piety: But as we advance forward into the crowds of life, innumerable delights solicit our inclinations, and innumerable cares distract our attention. The time of youth is passed in noisy frolics; manhood is led on from hope to hope, and from project to project; the dissoluteness of pleasure, the inebriation of success, the ardour of expectation, and the vehemence of competition, chain down the mind alike to the present scene: nor is it remembered how soon this mist of trifles must be scattered, and the bubbles that float upon the rivulet of life be lost for ever in the gulf of eternity. To this consideration scarce any man is awakened but by some pressing and resistless evil; the death of those from whom he derived his pleasures, or to whom he destined his possessions, some disease which shows him the vanity of all external acquisitions, or the gloom of age which intercepts his prospects of long enjoyment, forces him to fix his hopes upon another state; and when he has contended with the tempests of life till his strength fails him, he flies at last to the shelter of religion.

"That misery does not make all virtuous, experience too certainly informs us; but it is no less certain, that of what virtue there is, misery produces far the greater part. Physical evil may be therefore endured with patience, since it is the cause of moral good; and patience itself is one virtue by which we are prepared for that state in which evil shall be no more."

The calamities and the hardships of our present state, then, are so far from being real evils, of which providence ought to be accused, that in every point of view in which we can consider them, they afford the surest proofs of the wisdom of its administration, and of its goodness to man.

The most serious difficulty lies in accounting for the objections of moral evil or guilt, in a system governed by infinite benevolence and wisdom. Those who in a consistent manner hold the doctrine of the absolute necessity of human actions in its full extent, and acknowledge all its consequences, find it easy to elude this difficulty. They very fairly deny the existence of any such thing as moral evil in the abstract; and assert, that what we call a crime, is nothing more than an action which we always regard with a painful sensation: that these apparent evils endure only for a time; and that all will at last terminate in the perfection and happiness of every intelligent being.

Upon the system of liberty, the shortest answer seems to be this: that some things are absolutely impossible, not from any weakness in the Deity, but because they infer absurdity or contradiction. Thus it is impossible for twice two to be any thing else than four; and thus it is impossible for Omnipotence itself to confer self-appropriation upon an intelligent being who has never deserved it; that is to say, it is impossible for a man of sense to be pleased with himself for having done a certain action, while he himself is conscious that he never did that action. But self-appropriation constitutes the highest, the most unmixed, and permanent felicity, of which our nature is capable. It is not in the power of Omnipotence itself, then, to bestow the highest and most permanent felicity of our nature; it must be earned and deserved before it can be obtained. In the same manner good desert, virtue or merit, cannot be conferred; they must be acquired. To enable us to acquire these, we must be exposed to difficulties, and must suffer in a certain degree. If these difficulties had no influence upon our conduct and feelings, if they exposed us to no real danger, no fabric of merit and of self-appropriation could be reared upon them. All that the Supreme Being could do for us, was to confer such an original constitution and character as would enable us to do well if we should exert our utmost powers.
Providence is not ruled by favour, but by justice. Complete felicity must be purchased. Guilt is an abuse of our freedom, a doing ill where we could have done well, and is entirely the work of man. Heaven would not avoid permitting its existence, and exposing us to danger; for temptation is necessary to virtue, and virtue is the perfection of our nature, our glory, and our happiness.

The permission of moral evil has been so ably accounted for by Simplicius, a Pagan writer, and therefore not biassed by any partiality to the Jewish or Christian Scriptures, that we cannot deny ourselves the pleasure of laying his reasoning before our readers. He asks, "Whether God may be called the author of sin, because he permits the soul to use her liberty? and answers the question thus:

"He who says that God should not permit the exercise of its freedom to the soul, must affirm one of these two things; either that the soul, though by nature capable of indifferentily choosing good or evil, should yet be constantly prevented from choosing evil; or else that it should have been made of such a nature as to have no power of choosing evil.

"The former assertion (continues he) is irrational and absurd; for what kind of liberty that would be in which there should be no freedom of choice? and what choice could there be, if the mind were constantly restrained to one side of every alternative? With respect to the second assertion, it is to be observed (says he), that no evil is in itself desirable, or can be chosen as evil. But if this power of determining itself either way in any given case must be taken from the soul, it must either be as something not good, or as some great evil. But whoever saith so, does not consider how many things there are which, though accounted good and desirable, are yet never put in competition with this freedom of will: for without it we should be on a level with the brutes; and there is no person who would rather be a brute than a man. If God then shows his goodness in giving to inferior beings such perfections as are far below this, is it incongruous to the divine nature and goodness to give man a self-determining power over his actions, and to permit him the free exercise of that power? Had God, to prevent man’s sin, taken away the liberty of his will, he would likewise have destroyed the foundation of all virtue, and the very nature of man; for there could be no virtue were there not a possibility of vice; and man’s nature, had it continued rational, would have been divine, because impeccable. Therefore (continues he), though we attribute to God, as its author, this self-determining power, which is so necessary in the order of the universe; we have no reason to attribute to him that evil which comes by the abuse of liberty: For God doth not cause that aversion from good which is in the soul when it sins; he only gave to the soul such a power as might turn itself to evil, out of which he produces much good, which, without such a power, could not have been produced by Omnipotence itself.

So consonant to the doctrine of our scriptures is the reasoning of this opponent of the writings of Moses! Fas est et ab hoste doceri.

The last objection to the belief of a divine providence arises from the apparent confusion of human affairs, that all things happen alike to all, that bad men are prosperous, and that a total want of justice appears to attend the divine administrations. Even the best men have at times been shaken by this consideration. But there are many reasons for rendering this world a mixed scene: it would become unfit for a state of trial and of education to virtue it otherwise.

It has been shown already, that physical evil is the abstract parent of moral good; and therefore it would be absurd to expect that the virtuous should be entirely exempted from that evil. For the occasional prosperity of the wicked, many reasons have been assigned even by those who, in their dispositions, were not guided by that revelation which has brought to light life and immortality. "God (says Plutarch) spares the wicked, that he may set to mankind an example of forbearance, and teach them not to revenge their injuries too hastily on each other. He spares some wicked men from early punishment, in order to make them instruments of his justice in punishing others. And he spares all for a time, that they may have leisure for repentance; for men (says the same excellent moralist) look at nothing further, in the punishments which they inflict, than to satisfy their revenge and malice, and therefore they pursue those who have offended them with the utmost rage and eagerness; whereas God, aiming at the cure of those who are not utterly incurable, gives them time to be converted." But this objection receives the best solution from the doctrine of the immortality of the human soul.

Providence-Plantation, a colony of New England, which, with Rhode island, formerly constituted a charter government. Its chief town is Newport.

Providence, one of the least of the Bahama islands in the American ocean, but the best of those planted and fortified by the English. It is seated on the east side.
PROVINCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command of annual governors sent from Rome; being commonly obliged to pay such taxes and contributions as the senate thought fit to demand.

Of these countries, that part of France next the Alps was one, and still retains the name Provence.

Niccol de Gruelle, in his work "Procul Viciendo," "living afar off;" but it is better deduced from pro and vicus, "I overcome."

PROVINCE, in Geography, a division of a kingdom or state, comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent of the civil or ecclesiastical jurisdiction.

The church distinguishes its provinces by archbishoprics; in which sense, England is divided into two provinces, Canterbury and York.

The United Provinces are seven provinces of the Netherlands, who, revolting from the Spanish dominion, made a perpetual alliance, offensive and defensive, at Utrecht, anno 1579. See United Provinces.

PROVINCIAL, something relating to a province. It also denotes, in Roman countries, a person who has the direction of the several convents of a province.

PROVISIONS, in a military sense, implies all manner of eatables, food or provender, used in an army, both for man and beast.

PROVOST, of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Paris, &c. being much the same with mayor in other places. He presides in city-courts, and together with the bailies, who are his deputies, determines in all differences that arise among citizens.

The provost of Edinburgh is called lord, and the same title is claimed by the provost of Glasgow. The former calls yearly conventions of the royal boroughs to Edinburgh by his missives, and is, ex officio, president to the convention when met.

PROVOST, or Provost-Royal, a sort of inferior judge formerly established throughout France, to take cognizance of all civil, personal, real, and mixed causes, among the people only.

Grand Provost of France, or of the Household, had jurisdiction in the king's house, and over the officers therein; looked to the policy thereof, the regulation of provisions, &c.

Grand Provost of the Constable, a judge who manages processes against the soldiers in the army who have committed any crime.

He has four lieutenants distributed throughout the army, called provosts of the army, and particular provosts in the several regiments.

Provost Marshal of an Army, is an officer appointed to seize and secure deserters, and all other criminals. He is to hinder soldiers from pillaging, to indict offenders, and see the sentence passed on them executed. He also regulates the weights and measures, and the price of provisions, &c. in the army.

For the discharge of his office, he has a lieutenant, a clerk, and a troop of marshal-men on horseback, as also an executioner.

There is also a provost-marshal in the navy, who has charge over prisoners, &c.

The French also had a provost-general of the marines, whose duty it was to prosecute the marines when guilty of any crime, and to make report thereof to the council of war; besides a marine provost in every vessel, who was a kind of gaoler, and took the prisoners into his care, and kept the vessel clean.

Provosts of the Marshals, were a kind of lieutenants of the marshals of France; of these there were 120 seats in France; their chief jurisdiction regarded highwaymen, footpads, house-breakers, &c.

Provost of the Mint, a particular judge instituted for the apprehending and prosecuting of false coiners.

Provost, or Provost, in the king's stables; his office is to attend at court, and hold the king's stirrup when he mounts his horse. There are four provosts of this kind, each of whom attends in his turn, monthly.

PROW, denotes the head or fore-part of a ship, particularly in a galley; being that which is opposite to the poop or stern.

PROXIMITY, denotes the relation of nearness, either in respect of place, blood, or alliance.

PRUDENTIUS, in ethics, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, De Officiis, lib. i. cap. 43. prudence is the knowledge of what is to be desired or avoided. Accordingly, he makes prudentia (De Legibus, lib. i.) to be a contracction of providentia, or foresight. Plato (De Legibus, lib. iii.) calls this the leading virtue; and Juvenal, Sat. x. observes,

Nullum nomen abest si sit prudentia.

The idea of prudence includes sapiens, or due consultation; that is, concerning such things as demand consultation in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and sapientia, or a faculty of discerning proper means when they occur; and to the perfection of prudence, these three things are farther required, viz. sapientia, or a natural sagacity; sapio, presence of mind, or a ready turn of thought; and sapientia, or experience. The extremities of prudence are craft or cunning on the one hand, which is the pursuit of an ill end by direct and proper though not honest means; and folly on the other, which is either a mistake, both as to the end and means, or prosecuting a good end by foreign and improper means. Groves's Moral Philosophy, vol. ii. chap. ii.

PRUDENTIUS, or Aurelius Prudentius Clemens, a famous Christian poet, under the reign of Theodosius the Great, who was born in Spain in the year 348. He first followed the profession of an advocate, was afterwards a judge, then a soldier, and at length had an honourable employment at court. We have a great number of his poems, which, from the choice of his subject, may be termed Christian poems; but the style is barbarous, and very different from the purity of the Augustan age. The most esteemed editions of Prudentius's works are that of Amsterdam, in 1667, with Heinsius's Notes, and that of Paris in 1687, in usum Delphini.

PRUNELLA, a genus of plants belonging to the didymnia class; and in the natural method ranking under
PRUNES, are plums dried in the sunshine, or in an oven.

PRUNING, in Gardening and Agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

Pruning, though an operation of very general use, is nevertheless rightly understood by few; nor is it to be learned by rote, but requires a strict observation of the different manners of growth of the several sorts of fruit-trees; the proper method of which cannot be known without carefully observing how each kind is naturally disposed to produce its fruit: for some do this on the same year's wood, as vines; others, for the most part, upon the former year's wood, as peaches, nectarines, &c.; and others upon spurs which are produced upon wood of three, four, &c. to fifteen or twenty years old, as pears, plums, cherries, &c. Therefore, in order to the right management of fruit-trees, provision should always be made to have a sufficient quantity of bearing wood in every part of the trees; and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years.

The reasons for pruning of fruit-trees, are, 1. To preserve them longer in a vigorous bearing-state; 2. To render them more beautiful; and, 3. To cause the fruit to be larger and better tasted.

The general instructions for pruning are as follow:

The greatest care ought to be taken of fruit-trees in the spring, when they are in vigorous growth; which is the only proper season for procuring a quantity of good wood in the different parts of the tree, and for displacing all useless branches as soon as they are produced, in order that the vigour of the tree may be entirely distributed to such branches only as are designed to remain. For this reason trees ought not to be neglected in April and May, when their shoots are produced; however, those branches which are intended for bearing the succeeding year should not be shortened during the time of their growth, because this would cause them to produce two lateral shoots from the eyes below the place where they were stopped, which would draw much of the strength from the buds of the first shoot: and if the two lateral shoots are not entirely cut away at the winter-pruning, they will prove injurious to the tree. This is to be chiefly understood of stone-fruit and grapes; but peaches, nectarines, apricots, cherries, and plums, are always in the greatest vigour when they are least damaged by the knife; for where large branches are taken off, they are subject to gum and decay. It is therefore the most prudent method to rub off all useless buds when they are first produced, and to pinch others, where new shoots are wanted to supply the vacancies of the wall; by which management they may be so ordered as to want but little of the knife in winter-pruning. The management of pears and apples is much the same with these trees in summer; but in winter they must be very differently pruned: for as peaches and nectarines, for the most part, produce their fruit upon the former year's wood, and must therefore have their branches shortened according to their strength, in order to produce new shoots for the succeeding year; so, on the contrary, pears, apples, plums, and cherries, producing their fruit upon spurs, which come out of the wood of five, six, and seven years old, should not be shortened, because thereby those buds which were naturally disposed to form these spurs, would produce wood branches; by which means the trees would be filled with wood, but would never produce much fruit. The branches of standard-trees should never be shortened unless where they are very luxuriant, and, by growing irregularly on one side of the trees, attract the greatest part of the sap, by which means the other parts are either unfurnished with branches, or are rendered very weak; in which case the branch should be shortened down as low as is necessary, in order to obtain more branches to fill up the hollow of the tree; but this is only to be understood of pears and apples, which will produce shoots from wood of three, four, or more years old; whereas most sorts of stone-fruit will gum and decay after such amputations; whenever this happens to stone-fruit, it should be remedied by stopping or pinching those shoots in the spring, before they have obtained too much vigour, which will cause them to push out side-branches; but this must be done with caution. You must also cut out all dead or decaying branches, which cause their heads to look ragged, and also attract noxious particles from the air; in doing this, you should cut them close down to the place where they were produced, otherwise that part of the branch which is left will also decay, and prove equally hurtful to the rest of the tree; for it seldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced, and if permitted to remain long uncut, often infects some of the other parts of the tree. If the branches cut off are large, it will be very proper, after having smoothed the cut part exactly even with a knife, chisel, or hatchet, to put on a plaster of grafting clay, which will prevent the wet from soaking into the tree at the wounded part. All such branches as run across each other, and occasion a confusion in the head of the tree, should be cut off; and as there are frequently young vigorous shoots on old trees, which rise from the old branches near the trunk, and grow upright into the head, these should be carefully cut out every year, lest, by being permitted to grow, they fill the tree too full of wood.

As to the pruning of forest-trees, if they be large, it is best not to prune them at all; yet, if there be an absolute necessity, avoid taking off large boughs as much as possible. And, 1. If the bough be small, cut it smooth, close and sloping. 2. If the branch be large, and the tree old, cut it off at three or four feet from the stem. 3. If the tree grow crooked, cut it off at the crook, sloping upward, and nurse up one of the most promising shoots for a new stem. 4. If the tree grow top-heavy, its head must be lightened, and that by thinning the boughs that grow out of the main branches. But if you would have them spring, rub off the buds, and shroud up the side-shoots. 5. If the side-bough still break out, and the top be able to sustain itself, give the boughs that put forth in spring a pruning after Midsummer, cutting them close.

It
PRU

It has been observed, that trees are subject to gum and decay, in consequence of pruning; to prevent these injurious effects, a remedy has been proposed by Mr. Bucknall, which on trial, it is said, has been successful. By this method the branches to be removed are to be cut close to the place of separation from the trunk, smoothed well with a knife, and the wound is to be smeared over with medicated tar, laid on with a painter’s brush. The following is the composition of this medicated tar. One quarter of an ounce of corrosive sublimate reduced to fine powder, by beating it with a wooden hammer, is introduced into a three pint earthen pipkin, with about a glassful of gin or other spirit. The mixture is to be well stirred till the sublimate is dissolved. The pipkin is then gradually filled with vegetable or common tar, and constantly stirred, till the mixture be blended together as intimately as possible; and this quantity will at any time be sufficient for 200 trees. To prevent danger, the corrosive sublimate must be mixed with the tar as quickly as possible after it is purchased; for being of a very poisonous nature to all animals, it should not be suffered to lie about a house, for fear of mischief to some part of the family.

By applying this composition, Mr. Bucknall can, without the least danger, use the pruning hook on all sorts of trees, much more freely than by the use of any article hitherto recommended. The following remarks by the author on pruning in general, seem worthy of notice, and we give them in his own words. "I give no attention (says he) to fruit branches, and wood branches; but beg, once for all, that no branch shall ever be shortened unless for the figure of the tree, and then constantly taken off close to the separation, by which means the wound soon heals. The more the range of the branches shoots circularly, a little inclining upwards, the more equally will the sap be distributed, and the better will the tree bear; for, from that circumstance, the sap is more evenly impelled to every part. Do not let the ranges of branches be too near each other; for, remember all the fruit and the leaves should have their full share of the sun; and where it suits, let the middle of the tree be free from wood, so that no branch shall ever cross another, but all the extreme ends point upwards."

PRUNUS, a genus of plants belonging to the icosandria class; and in the natural method ranking under the 36th order, Pomaceae. See Botany Index.

PRUSA, in Ancient Geography, a town situated at Mount Olympus in Mysia, built by Prussias, who waged war with Cressus, (Strabo); with Cyrus, (Stephanus); both contemporary princes. Now called Bursa or Prusa, capital of Bithynia, in Asia Minor. E. Long. 29° 5′ N. Lat. 39° 22′.

PRUSIAS, the name of several kings of Bithynia. PRUSIAS, a town of Bithynia, anciently called Cloe, from a cognominal river, and giving name to the Sinus Cianus of the Propontis; rebuilt by Prusias the son of Zela, after having been destroyed by Philip the son of Demetrius: it stood on the Sinus Cianus, at the foot of Mount Arganthionus. This is the Prusias who harboured Hannibal after the defeat of Antiochus.—Of this place was Asclepiades, surnamed Prusicius, the famous physician.

PRUSSIA, a modern, but deservedly celebrated kingdom of Poland and Russia, whose monarch, along with Prussia Proper, possesses also the electorate of Brandenburg, and some other territories of considerable extent. The district properly called Prussia is of great extent, and divided into the Ducal and Royal Prussia, the latter belonging to the republic of Poland till the late partition of the Polish territories. Both together are of great extent; being bounded on the north by the Baltic, on the west by Poland and the duchy of Mazovia, on the west by Pomerania, and on the east by Lithuania and Samogitia. The name is by some thought to be derived from the Borussi, a tribe of the Sarmatians, who, 87 of the migrating from the foot of the Riphean mountains, were tempted by the beauty and fertility of the country to settle there. Others think that the name of this country is properly Porussia; for in the language of the natives signifying near, and Porussia signifying near Russia. To the latter etymology we find the king of Prussia himself assenting in the treatise intitled Memoirs of the House of Brandenburg. However, it must be owned, that these or any other etymologies of the word are very uncertain, and we find nothing like it mentioned by historians before the tenth century.

The ancient state of Prussia is almost entirely unknown. However, the people are said to have been very savage and barbarous; living upon raw flesh, and drinking the blood of horses at their feasts, according to Stella, even to intoxication (A). Nay, so extreme an expense were this people, that they were even unacquainted with the method of constructing huts, and took up their dwelling in caves and cavities of rocks and trees, where they protected themselves and children from the inclemencies of the weather. Among such a people it is vain to expect that any transactions would be recorded, or indeed that any thing worthy of being recorded would be transmitted. We shall therefore begin our history of Prussia with the time when the Teutonic knights first got footing in the country. (See Teutonic Knights.)

On the expulsion of the Christians from the Holy Land by Saladin, a settlement was given to the Teutonic knights in Prussia by Conrade duke of Mazovia, first elector of Brandenburg. Their first residence in this country was Culm; to which they afterwards removed, as the condition of the country they were confined by the conditions of the donation, excepting what they could conquer from their pagan neighbours, all which the emperor granted to them in perpetuity.

Encouraged by this grant, the knights conquered the greatest
greatest part of the country which now goes by the name of Prussia; and, not content with this, became very troublesome to Poland, insomuch that the monarchs of that kingdom were sometimes obliged to carry on dangerous and bloody wars with them; for an account of which we refer to the article Poland, No. 61, 67, &c.

The Teutonic order continued in Prussia till the year 1531. Their last grand-master was Albert marquis of Brandenburg, and nephew to Sigismund I. king of Poland. He was preferred to this dignity, in hopes that his affinity to Sigismund might procure a restitution of some of the places which had been taken from the order during the former unsuccessful wars with Poland; but in this the fraternity were disappointed. Albert, however, was so far from Endeavouring to obtain any favour from his uncle by fair means, that he refused to do homage to him, and immediately began to make preparations for throwing off his dependence altogether, and recovering the whole of Prussia and Pomerania by force of arms. In this he was so far from succeeding, that, being foiled in every attempt, he was forced to resign the dignity of grand-master; in recompense for which, his uncle bestowed on him that part of Prussia now called Ducal, in quality of a secular duke. It was now the interest of the house of Brandenburg to assist in the expulsion of the fraternity; and accordingly, being at last driven out of Prussia and Pomerania, they transferred their chapter to Mariendal in Franconia; but in that and other provinces of the empire where they settled, little more than the name of the order, once so famous, now remains.

The other most considerable part of his Prussian majesty's dominions is the electorate of Brandenburg. Like other parts of Germany, it was anciently possessed by barbarians, of whom no history can be given. These were subdued by Charlemagne, as is related under the article France; but being on every occasion ready to revolt, in 927 Henry the Fowler established margraves, or governors of the frontiers, to keep the barbarians in awe. The first margrave of Brandenburg was Sigebrzy, brother-in-law to the above-mentioned emperor; under whose administration the bishoprics of Brandenburg and Havelberg were established by Otho I. From this Sigebrzy, to the succession of the house of Hohenzollern, from whom the present elector is descended, there are reckoned eight different families, who have been margraves of Brandenburg; namely, the family of the Saxons, of Walbeck, Staden, Plenck, Anhalt, Bavaria, Luxemburg, and Misnia. The margraves of the four first races had continual wars with the Vandals and other barbarous people; nor could their ravages be stopped till the reign of Albert surnamed the Bear, the first prince of the house of Anhalt. He was made margrave by the emperor Conrad III. and afterwards raised to the dignity of elector by Frederic Barbarossa, about the year 1100. Some years afterwards the king of the Vandals dying without issue, left the Middle Marche by his last will to the elector, who was besides possessed of the Old March, Upper Saxony, the country of Anhalt, and part of Lusace. In 1532 this line became extinct, and the electorate devolved to the empire. It was then given by the emperor Louis of Bavaria to his son Louis, who was the first of the sixth race. Louis the Roman succeeded his brother; and as he also died without children, he was succeeded by Otho, his third brother, who sold the electorate to the emperor Charles IV. of the house of Luxemburg, for 200,000 florins of gold. Charles IV. gave the Marche to his son Wenceslaus, to whom Sigismund succeeded. This elector, being embarrassed in his circumstances, sold the New Marche to the knights of the Teutonic order. Josse succeeded Sigismund; but aspiring to the empire, sold the electorate to William duke of Misnia; who, after he had possessed it for one year, sold it again to the emperor Sigismund. In 1417, Frederic VI. burggrave of Nuremberg, received the investiture of the country of Brandenburg at the diet of Constance from the hands of the emperor Sigismund; who, two years before, had conferred upon him the dignity of elector, and arch-chamberlain of the Holy Roman empire.

This prince, the first of the family of Hohenzollern, found himself possessed of the Old and Middle Marche, but the dukes of Pomerania had usurped the Marche Ukraine. Against them, therefore, the elector immediately declared war, and soon recovered the province. As the New Marche still continued in the hands of the Teutonic knights, to whom it had been sold, as we have already mentioned, the elector, to make up for this, took possession of Saxony, which at that time happened to be vacant by the death of Albert the last elector of the Anhalt line. But the emperor, not approving of this step, gave the investiture of Saxony to the duke of Misnia; upon which Frederic voluntarily desisted from his acquisitions. This elector made a division of his possessions by will. His eldest son was deprived of his right on account of his having too closely applied himself to search for the philosopher's stone; so he left him only Voigland. The electorate was given to his second son Frederic; Albert, surnamed Achilles, had the duchies of Franconia; and Frederic, surnamed the Fat, had the Old Marche; but by his death it returned to the electorate of Brandenburg.

Frederic I. was succeeded by his son, called also Frederic, and surnamed Iron-tooth on account of his strength. He might with as great reason have been surnamed the Magnanimous, since he refused two crowns, viz. that of Bohemia, which was offered him by the pope, and the kingdom of Poland to which he was invited by the people; but Frederic declared he would not accept of it unless Casimir brother to Ladislaus the late king refused it. These instances of magnanimity had such an effect on the neighbouring people, that the states of Lower Lusatia made a voluntary surrender of their country to him. But as Lusatia was a field of Bohemia, the king of that country immediately made war on the elector, in order to recover it. However, he was so far from being successful, that, by a treaty of peace concluded in 1462, he was obliged to yield the perpetual sovereignty of Corbus, Peita, Sommefeld, and some other places, to the elector. Frederic then, having redeemed the New Marche from the Teutonic order for the sum of 100,000 florins, and still further enlarged his dominions, resigned the sovereignty in 1489 to his brother Albert, surnamed Achilles.

Albert was 57 years old when his brother resigned.
the electorate to him. Most of his exploits, for which
he had the surname of Achilles, had been performed
while he was burggrave of Nuremberg. He declared
war against Lewis duke of Bavaria, and defeated
and took him prisoner. He gained eight battles against
the Nuremberges, who had rebelled and contested
his rights to the burggrave. In one of these he fought
singly against 16 men, till his people came up to his
assistance. He made himself master of the town of
Grefissenburg in the same manner that Alexander the
Great took the capital of the Oxydraco, by leaping
from the top of the walls into the town, where he de-
defended himself singly against the inhabitants till his
men forced the gates and rescued him. The confidence
which the emperor Frederic Ill. placed in him, gained
him the direction of almost the whole empire. He
commanded the Imperial armies against Lewis the
Rich duke of Bavaria; and against Charles the Bold
duke of Burgundy, who had laid siege to Nuis, but
concluded a peace at the interposition of Albert. He
gained the prize at 17 tournaments, and was never dis-
mounted.

All these exploits, however, had been performed be-
fore Albert obtained the electorate. From that time
we meet with no very important transactions till the
year 1594, when John Sigismund of Brandenburg,
having married Anne the only daughter of Albert duke of
Prussia, this united that duchy to the electorate, to which
it has continued to be united ever since; and obtained
pretensions to the countrys of Juliers, Berg, Cleves,
March, Ravensburg, and Ravenstein, to the succession
of which Anne was heiress.

Sigismund died in 1619, and was succeeded by his
son George William; during whose government the electorate suffered the most miserable calamities. At
this time it was that the war commenced between the
Protestants and Catholics, which lasted 30 years. The
former, although leagued together, were on the point
of being utterly destroyed by the Imperialists under
the command of Count Tilly and Wallenstein, when
Gustavus Adolphus of Sweden turned the scale in their
favour, and threatened the Catholic party with utter
destruction. But by his death at the battle of Lut-
zen, the fortune of war was once more changed. At
last, however, peace was concluded with the empe-
ror; and, in 1640, the elector died, leaving his do-
minions to his son Frederic William, surnamed the
Great.

This young prince, though only 20 years of age
at the time of his accession, applied himself with the
utmost diligence to repair the losses and devastations
occasioned by the dreadful wars which had preceded.
He received the investiture of Prussia personally from
the king of Poland, on condition of paying 100,000
florins annually, and not making truce or peace with
the enemies of that crown. His envoy likewise recei-
ved the investiture of the electorate from the emperor
Ferdinand III. The elector then thought of recovering
his provinces from those who had usurped them.
He concluded a truce for 20 years with the Swedes,
who evacuated the greatest part of his estates. He
likewise paid 140,000 crowns to the Swedish garri-
sions, which still possessed some of his towns; and he
concluded a treaty with the Hessians, who delivered up
VOL XVII. Part II.
a part of the duchy of Cleves; and obtained of the Hol-
danders the evacuation of some other cities.

In the mean time, the powers of Europe began to
be weary of a war which had continued for such a
length of time with such unrelenting fury. The cities
of Osnabruck and Munster being chosen as the most
proper places for negotiation, the conferences were
opened in the year 1645; but, by reason of the mul-
tiplicity of business, they were not concluded till two
years after. France, which had espoused the interests
of Sweden, demanded that Pomerania should be ceded
to that kingdom as an indemnification for the expences
which the war had cost Gustavus Adolphus and his
successors. Although the empire and the elector refused
to give up Pomerania, it was at last agreed to give
up to the Swedes Hither Pomerania, with the isles of
Rügen and Wollin, also some cities; in return for
which cession, the bishops of Halberstadt, Minden,
and Camin, were secularized in favour of the elector,
of which he was put in possession, together with the
lordships of Hochenstein and Richenstein, with the
reversion of the archbishopric of Magdeburg. Thus was
the Treaty of the treaty of Westphalia concluded in 1648, and which Westphali-
relieves as a basis to all the possessions and rights of the
German princes. The elector then concluded a new
treaty with the Swedes, for the regulation of limits, and
for the acquittal of some debts, of which Sweden would
only pay a fourth; and next year the electorate, Pome-
rania, and the duchies of Cleves, were evacuated by the
Swedes.

Notwithstanding all these treaties, however, the
Swedes soon after invaded Pomerania, but were en-
tirely defeated by the elector near the town of Peh-
bellin. Three thousand were left dead on the spot,
against the among whom were a great number of officers; and
a great many were taken prisoners. The elector then
pursued his victory, gained many advantages over the
Swedes, and deprived them of the cities of Stralsund
and Grieswald. On this the Swedes, hoping to
oblige the elector to evacuate Pomerania, which he
had almost totally subdued, invaded Prussia, from Li-
vonia, with 16,000 men; and advancing into the
country, they burned the suburbs of Memel, and took
the cities of Tilsit and Insterburg. The elector, to
oppose the invaders, left Berlin on the 10th of Ja-

uary 1679, at the head of 9000 men. The Swedes
retired at his approach, and were greatly harassed by
the troops on their march. So successful indeed was
the elector on this occasion, that the Swedes lost al-
most one half of their army killed or taken prisoners.
At last, having crossed the bay of Frisch-haff and
Courland on the ice, he arrived on the 19th of January,
with his infantry, within three miles of Tilsit, where
the Swedes had their head-quarters. The same day,
his general, Trenfeldt, defeated two regiments of
the enemy near Splitter; and the Swedes who were
in Tilsit abandoned that place, and retired towards
Courland. They were pursued by General Gortz,
and entirely defeated with such slaughter, that some
3000 of them returned to Livonia. Yet, notwithstanding
all these victories, the elector, being pressed on to
conclude the other side by the victorious generals of France, a treaty of
peace with
them.

PRU

Prussia, that the treaty of Westphalia should serve for a basis to the peace; that the elector should have the property of the customs in all the ports of the former Pomerania, with the cities of Camin, Gartz, Griebenbourg, and Wildenbruck: on his part, he consented to give up to the Swedes all that he had conquered from them, and to give no assistance to the king of Denmark, upon condition that France delivered up to him his provinces in Westphalia, and paid him 300,000 ducats, as an indemnification for the damages done by the French to his states. This treaty was styled the peace of St Germain.

With the treaty of St Germain terminated the military exploits of Frederic William, who passed the last years of his administration in peace. His great qualities had rendered him respected by all Europe, and had even been heard of in Tartary. He received an ambassador from Murad Geray, cham of the Tartars, courting his friendship. The barbarian ambassador appeared in such tattered clothes as scarce covered his nakedness, so that they were obliged to furnish him with other clothes before he could appear at court. His interpreter had a wooden nose and no ears. In 1684, Frederic received into his dominions great numbers of Protestants who fled out of France from the persecutions of Louis XIV, after he had revoked the edict of Nantes. Twenty thousand of them are said to have settled at this time in the electorate, where they introduced new arts and manufactures, that were of the utmost benefit to the country. By this, however, he disobliged Louis XIV, for which reason he concluded an alliance with the emperor; and having furnished him with 8000 troops against the Turks in Hungary, the emperor yielded to him the circle of Schwibus in Silesia, as an equivalent for all his rights in that province.

In 1688, the elector Frederic William died, and was succeeded by his son Frederic III. This prince was remarkably fond of shows and ceremony, which, during the course of his government, involved him in much expense. The regal dignity seemed to be the greatest object of his ambition. To obtain this, he joined with the emperor in the alliance against France, in which he was engaged by William III, king of Britain. He also yielded up the circle of Schwibus, which had been given to his predecessor; and, in 1700, obtained from the emperor that dignity which he had so earnestly desired. The terms on which it was obtained were: 1. That Frederic should never separate from the empire those provinces of his dominions which depended on it. 2. That he should not, in the emperor’s presence, demand any other marks of honour than those which he had hitherto enjoyed. 3. That his Imperial majesty, when he wrote to him, should only give him the title of Royal Dictation. 4. That nevertheless the ministers which he had at Vienna should be treated like those of other crowned heads. 5. That the elector should maintain 6000 men in Italy at his own expense, in case the emperor should be obliged to make war on account of the succession of the house of Bourbon to the crown of Spain. 6. That those troops should continue there as long as the war lasted.

Thus was the kingdom of Prussia established through the friendship of the emperor, with whom Frederic I, so called as being the first king of Prussia, continued all his life in strict alliance. Indeed he was a pacific prince; and though contemptible in his person, and Prussia incapable of achieving great things, had this merit, that he always preserved his dominions in peace, and thus consulted the true interest of his subjects much more than those monarchs who have dazzled the eyes of the world by their military exploits. He was indeed vain, and fond of show, as we have already observed; but had a good heart, and is said never to have violated his conjugal vow; though it does not appear that he was greatly beloved by his royal consorts (of whom he had three) on that or any other account.

Frederic I. died in the beginning of 1713, and was succeeded by Frederic William. He was in almost every thing the reverse of his father. His dispositions were altogether martial; so that he applied himself entirely to the augmentation of his army, and perfecting them in their exercise, by which means they became the most expert soldiers in Europe. His foible was an ambition of having his army composed of men above the ordinary size; but as these could not be procured, he composed a regiment of the tallest men he could find; and as his officers made no scruple of picking up such men wherever they could find them for his majesty’s use, the neighbouring states were frequently offended, and a war was often likely to ensue even from this ridiculous cause. However, his Prussian majesty was never engaged in any martial enterprise of consequence: but having put his army on the most respectable footing of any in the world, and filled his coffers, for he was of a very saving disposition, he put it in the power of his son to perform those exploits which have been matter of astonishment to all Europe.

It was in this king’s reign that Prussia first perceived Enemy to her natural enemy and rival to be the house of Austria, and not France as had been formerly supposed. Hence frequent bickerings took place between these two powers, for which the persecution of the Protestants by some of the Catholic states of the empire afforded a pretence; and though a war never actually took place, yet it was easy to see that both were mortal enemies to each other. But when Frederic William died in 1740, this enmity broke out in full force. The empress queen was then left in a very disagreeable situation, as has been observ-
ed under the article BRITAIN, No. 410, &c. Of this Frederic III. took the advantage to do himself justice, as seems Silesia, of which his ancestors had been unjustly deprived. This province he seized at that time: but it cost him dear; for the empress having at last overcome all difficulties, formed against him the most terrible combination that ever was known in Europe.

The treaty was hardly concluded with the king of Prussia, by which she reluctantly yielded up the province of Silesia, and with it an annual revenue of 800,000l. a year, before she entered into another with the court of Petersburg, which was concluded May 22, 1746. This treaty, so far as it was made public, was only of a defensive nature; but six secret and separate articles were added to it. By one of these it was provided, that in case his Prussian majesty should attack the empress queen, or the emperor of Russia, or even the republic of Poland, it should be considered as a breach of the treaty of Dresden, by which Silesia was given up. It was also stipulated, that, notwithstanding that treaty (which indeed had been dictated by the king of Prussia himself), the
the right of the empress-queen to Silesia still conti-
ued, and for the recovery of that province the con-
tracting powers should mutually furnish an army of
65,000 men. To this treaty, called the treaty of Pe-
tersburg, the king of Poland was invited to accede;
but he, being in a manner in the power of the king of
Prussia, did not think proper to sign it: however,
he verbally acceded to it in such a manner, that the
other parties were fully convinced of his design to co-
operate with all their measures; and in consideration
of this intention, it was agreed that he should have
a share in the partition of the king of Prussia's do-
inions, in case of a successful event of their enter-
pises.

In consequence of these machinations, every art was
used to render the king of Prussia personally odious
to the empress of Russia; the queen of Hungary made
vast preparations in Bohemia and Moravia; and the
king of Poland, under pretence of a military amusement,
drew together 16,000 men, with whom he occupied a
strong post at Pirna. The queen of Hungary, still
further to strengthen herself, concluded a treaty with
the court of France at Versailles, dated May 1. 1756.
But in the mean time, the king of Prussia having un-
derstood by his emissaries what was going forward, re-
solved to be beforehand with his enemies, and at least
to keep the war out of his own country; and therefore
entered Saxony with a considerable army. At first he
affected only to demand a free passage for his troops,
and an observance of the neutrality professed by the
king of Poland; but, having good reasons to doubt
this neutrality, he demanded, as a preliminary, that
these Saxon troops should immediately quit the strong
post they occupied, and disperse themselves. This de-
mand was refused; on which his Prussian majesty
blockaded the Saxon camp at Pirna, reducing to none
it by famine, since its strong situation rendered
an attack very dangerous. At that time there were in
Bohemia two Saxon armies, one under the command of
M. Brown, and the other under M. Ficolomini. To
keep these in awe, the king had sent M. Schwerin
with an army into Bohemia from the country of
Glatz, and M. Keith had penetrated into the same
kingdom on the side of Misisia. But still the king of
Prussia did not entirely confide in these dispositions;
and therefore fearing lest M. Brown might afford some
assistance to the Saxons, he joined his forces under
Keith, and on December 1. attacked and defeated the
Austrian general, so that the latter found it impossible
to relieve the Saxons, who, after a vain attempt to re-
tire from their post, were all taken prisoners. The
king of Poland quitted his dominions in Germany,
and the Prussians took up their winter quarters in
Saxony. Here they seized on the revenues, levied ex-
orbitant contributions, and obliged the country to fur-
nish them with recuits. The king of Prussia at this
time made himself master of the archives of Dresden,
by which means he procured the originals of those
pieces above mentioned, which, when produced to the
world, gave a full proof of the combination that had
been formed against him, and consequently justified the
measures he had taken for his own defence.

No sooner had the king entered Saxony, in the man-
ner already related, than a process was commenced
against him in the emperor's Aulic council, and before
the diet of the empire, where he was soon condemned
for contumacy, and put to the ban of the empire.

The various circles of the empire were ordered to fur-
nish their contingents of men and money to put this
sentence in execution; but these came in so slowly,
that, had it not been for the assistance of the French
under the prince de Soubise, the army would pro-
hably have never been in a condition to act. The
prodigious Austrians, in the mean time, made great preparations,
and raised 100,000 men in Bohemia, whom they com-
mitted to the care of Prince Charles of Lorraine, assist-
ed by M. Brown. The czarina sent a body of 60,000
men under M. Apraxin, to invade the Duchy of Prussia;
whilst a strong fleet was equipped in the Baltic, in
order to co-operate with that army. The king of
Sweden also acceded to the confederacy, in hopes of
recovering the possessions in Pomerania which his an-
cestors had enjoyed; and the duke of Mecklenburg
took the same party, promising to join the Swedes
with 6000 men as soon as it should be ne-
necessary. On the king of Prussia's side appeared no-
one excepting an army of between 30,000 and 45,000
Hanoverians commanded by the duke of Cumberland;
and these were outnumbered and forced to yield to
a superior army of French commanded by M. d'Etresse.

In the mean time, his Prussian majesty, finding he
invades

it must depend for assistance solely on his own
abilities, resolved to make the best use of his time.
Accordingly, in the spring 1757, his armies poured in
Bohemia from two different quarters, while the army
himself prepared to enter it from a third. M. Schwerin
entered from Silesia; the prince of Bevern from
Lusatia, where he defeated an army of 28,000
Austrians that opposed his passage. As the intentions
of the king himself were not known, the Austrians de-
tached a body of 20,000 men from their main army to
observe his motions. This was no sooner done than
the king cut off all communication between the detach-
ment and the main body: and having joined his two
generals with incredible celerity, he engaged the
Austrians near Prague, totally defeated them, took their
camp, military chest, and cannon; but lost the brave
General Schwerin, who was killed at the age of 82,
with a colonel's standard in his hand. On the Au-
strian side, M. Brown was wounded, and died in a
short time, though it is supposed more from the chag-
rin he suffered, than from the dangerous nature of the
wound itself.

About 40,000 of the Austrian army took refuge in
Besiges

Prague, while the rest fled different ways. The city
was instantly invested by the king, and all succours
were cut off. The great number of troops which it contain-
ed rendered an attack unadvisable, but seemed to render
the reduction of it by famine inevitable; however, the
king, to accomplish his purpose the more speedily, pre-
pared to bombard the town. On the 29th of May,
after a most dreadful storm of thunder and lightning,
four batteries began to play on the city. These
were thrown, every 24 hours, 288 bombs, besides a vast
number of red-hot balls, so that it was soon on fire in
every quarter. The garrison made a vigorous defence,
and one well-conducted sally; but had the misfortune
to be repulsed with great loss. The magistrates, burgh-
ers, and clergy, seeing their city on the point of being

Count Daun takes the command of the Austrian army.

Thus the affairs of the empress queen seemed verging to destruction, when Leopold count Daun took upon him the command of the remains of M. Brown's army. This general had arrived within a few miles of Prague the day after the great battle. He immediately collected the scattered fugitives with the greatest diligence, and retired with them to a strong post in the neighbourhood, from whence he gave the troops in Prague hopes of a speedy relief. It was now the king of Prussia's business, either to have attempted to make himself master of the city by one desperate effort, or entirely to have abandoned the enterprise, and driven Count Daun from his post before his troops had recovered from the terror of their late defeat; but, by attempting to do both, he rendered himself incapable of doing either. Though the army of Count Daun already amounted to 63,000 men, and though they were strongly entrenched, and defended by a vast train of artillery, his majesty thought proper to send no more than 32,000 men. This body made the arduous attempt on the 18th of June; but though they did all that human courage and conduct could do, and though the king himself at last charged at the head of his cavalry, the Prussians were driven out of the field with great loss. This engagement was named the battle of Colin.

26

Defeats the Prussians at Colina.

The first consequence of the battle of Colina was, that the king of Prussia was obliged to raise the siege of Prague; soon after which, he was obliged to quit Bohemia, and take refuge in Saxony. The Austrians harassed him as much as possible; but, notwithstanding their great superiority, their armies were not in a condition to make any decisive attempt upon him, as the frontiers of Saxony abounded with situations easily defended. In the mean time the Russians, who had hitherto been very dilatory in their motions, began to exert themselves, and entered Ducal Prussia, under M. Apraxin and Fermor, where they committed innumerable cruelties and excesses. A large body of Austrians entered Silesia, and penetrated as far as Breslau. Then they made a turn backwards, and besieged Schweidnitz. Another body entered Lusatia, and made themselves masters of Zittau. An army of 22,000 Swedes entered Prussian Pomerania, took the towns of Anclam and Demmin, and laid the whole country under contribution. The French, too, being freed from all restraint by the capitulation of the dukedom of Cumberland at Closter Seven, made their way into Halberstadt and the Old March of Brandenburg, first exacting contributions, and then plundering the towns. The army of the empire, being reinforced by that of the prince de Soubise, after many delays, was on full march to enter Saxony, which left the Austrians at liberty to exert the greatest part of their force in the reduction of Silesia. General Haddick penetrated through Lusatia, passed by the Prussian armies, and suddenly appeared before the gates of Berlin, which city he lay under contribution. He retired on the approach of a body of Prussians; yet he still found means to keep such a post as interrupted the king's communication with Silesia. The destruction of the king of Prussia therefore now seemed inevitable.

27

Siege of Prague raised.

Every exertion which he had made, though brave and well-conducted, had been unsuccessful. His general Lehwald, who opposed the Russians, had orders to attack them at all events. He obeyed his orders; and with 30,000 men attacked 60,000 of the enemy strongly entrenched at a place called Norkitten. The Lehwald of the Prussians behaved with the greatest valour; but after having killed five times more of the enemy than they themselves lost, they were obliged to retire, though the Russians were more formidable after their defeat than the Russians were after their victory. The king, in the mean time, exerted himself on every side, and his enemies fled everywhere before him; but whilst he pursued one body, another gained upon him in some other part, and the winter came on fast, while his strength decayed, and that of his adversaries seemed to increase on every quarter.

The Prussian monarch, however, though distressed, did not abandon himself to despair, or lose that wonderful presence of mind which has so eminently distinguished him in all his military enterprises. He immediately delayed a decisive action till the approach of the winter; but at last, after various movements, on November 5, 1757, he met at Rosbach with the united army of his enemies commanded by the prince of Saxe-Hildburghausen and the prince de Soubise. The allied army amounted to 30,000 men complete; but most of the troops of the Circles were now raised, and many of them not well affected to the cause. The Prussians did not exceed 25,000 men; but they were superior to any troops in the world, and were inspired, by the presence of their king, with the most enthusiastic valor. The Austrians were defeated with the loss of 3000 killed, eight generals, 250 officers of different ranks, and 6000 private soldiers, taken prisoners, while night alone prevented the total destruction of the army.

By this battle the king was set free on one side; but this only gave him an opportunity of renewing his labours on another. The Austrians had a great force, and now began to make a proportionable progress in Silesia. After a siege of 16 days, they had reduced the strong fortress of Schweidnitz, and obliged Schwindnitz to surrender prisoners of war. Hearing then of the victory at Rosbach, and that the king of Prussia was in full march to relieve Silesia, they resolved to attack the prince of Bevern in his strong camp under the walls of Breslau. They attacked the prince's army on November 22d; but their attack was sustained with the greatest resolution. The slaughter of the Austrians was prodigious. A great part of the enemy had retired from the field of battle, and the rest were preparing to retire, when all at once the Russian general took the same resolution. Their army had suffered much in the engagement, and they became apprehensive of a total defeat in case their intrenchments should be forced in any part; for which reason they quitted their strong post, and retired behind the Oder. Two days after, the prince of Bevern, going to reconnoitre without escort, attended only by a groom, was taken prisoner by an advanced party of Croats, a small body of whom had crossed the Oder.
On this the town of Breslau immediately surrendered; where, as well as at Schweidnitz, the Austrians found great quantities of provisions, ammunition, and money. All Silesia was on the point of falling into their hands, and the Prussian affairs were going into the utmost distraction, when the king himself by a most rapid march passed through Thuringia, Misnia, and Lusatia, in spite of the utmost efforts of the generals Haddick and Marshal, who were placed there to oppose him; and, entering Silesia on the 2d of December, joined the prince of Bevern's corps, who repossessed the Oder to meet him. The garrison of Schweidnitz, who, as we have already observed, had been made prisoners of war, also joined the king's army unexpectedly; and their presence contributed not a little, notwithstanding the smallness of their number, to raise the spirits of the whole army. They had submitted to the capitulation with the greatest reluctance; but as the Austrians were conducting them to prison, they happened to receive intelligence of the victory at Rossbach; on which they immediately rose on the escort that conducted them, and entirely dispersed it; and afterwards marched in such a direction as they thought might most readily lead them to their king, they accidentally fell in with his army.

His Prussian majesty now approached Breslau; on which the Austrians, confiding in their superiority, (for they exceeded 70,000, while the Prussians scarce amounted to 36,000), abandoned their strong camp, the same which the prince of Bevern had formerly occupied, and advanced to give him battle. The king did not intend by any means to disappoint them, but advanced on his part with the greatest celerity. The two armies met on December 5th, near the village of Leuthen. Count Daun made the best dispositions possible. The ground occupied by his army was a plain, with small eminences in some parts. These eminences they surrounded with artillery; and as the ground was also interspersed with thickets, they sought to turn these likewise to their advantage. On their right and left were hills, on which they planted batteries of cannon. The ground in their front was intersected by many causeways; and to make the whole more impracticable, the Austrians had felled a great number of trees, and scattered them in the way. It was almost impossible at the beginning of the engagement for the Prussian cavalry to act, on account of these impediments; but, by a judicious disposition made by the king himself, all difficulties were overcome. His majesty had placed four battalions behind the cavalry of his right wing; foreseeing that General Nadasti, who was placed on the enemy's left with a corps de reserve, designed to attack him in flank. It happened as he had foreseen: that general's cavalry attacked the Prussian right wing with great fury; but he was received with such a severe fire from the four battalions, that he was obliged to retire in disorder. The king's flank then, well covered and supported, was enabled to act with such order and vigour as repulsed the enemy. The Austrian artillery was also silenced by that of the Prussians; however, the Austrians continued to make a gallant resistance during the whole battle. After having been once thrown into disorder, they rallied all their forces about Leuthen, which was defended on every side by entrenchments and redoubts. The Prussians attacked them with the utmost impetuosity, and at last became masters of the post; on which the enemy fled on all sides, and a total rout ensued. In this battle the Austrians lost 6000 killed on the spot, 15,000 taken prisoners, and upwards of 200 pieces of cannon.

The consequences of this victory were very great. Breslau was immediately invested, and surrendered on the 12th of December; the garrison, amounting to 13,000 men, were made prisoners of war. The blockade of Schweidnitz was formed as closely as the season of the year would permit; while detached Prussian parties overran the whole country of Silesia, and reduced every place of less importance. The Russians, who had ravaged and destroyed the country in such a manner that they could not subsist in it, thought proper to retire out of the Prussian dominions altogether. Thus the Swedes and Pomerania. General Lehwald was left at liberty to act against the enemy. The Swedes and Pomerania, the whole of which country he not only possessed, but also some part of Swedish Pomerania. Thus the duchy of Mecklenburg being left quite exposed, the king took ample vengeance on it by exacting the most severe punishments of men and money. To complete this monarch's good fortune also, the French, who had retired after the battle of Rossbach, were now opposed by the Hanoverians under Prince Ferdinand, who kept them so well employed, that, during the rest of the war, the king of Prussia had no more trouble from them. See BRITAIN, N° 442.

The beginning of the year 1758 was favourable to the arms of his Prussian majesty. On the 3d of April be commenced his operations against Schweidnitz, and pushed the siege so vigorously, that the place surrendered in 13 days. He then disposed his forces in such a manner as might best guard his dominions against his numerous enemies. For this purpose Count Dohna commanded a body of troops on the side of Pomerania; another considerable body was posted between Wohland and Glogau, in order to cover Silesia from the Russians, in case they should make their inroad that way. An army, in a little time after, was formed in Saxony, commanded by the king's brother Prince Henry. This army consisted of 30 battalions and 45 squadrons, and was designed to make head against the army of the empire; which, by great efforts made during the winter, and the junction of a large body of Austrians, was again in a condition to act. Between all these armies a ready communication was kept up by a proper choice of posts. After the reduction of Schweidnitz, the king having made a show of invading Bohemia, suddenly burst into Moravia, where in a short time he made himself master of the whole country, and on the 27th of May laid siege to Olmutz the capital. Of this M. Daun was no sooner informed, than he took his route to Moravia through Bohemia: and though he was not in a condition to risk a battle, nor indeed would have done so unless he had had a very considerable advantage; yet, by placing himself in a strong situation where he could not be attacked, by harassing the king's troops and cutting off their convoys, he at last obliged him to abandon the enterprise. The king, however, who frequently owed a good part of his success to the impenetrable secrecy with which he covered all his designs, gave not the least hint of his intention to raise the siege of Olmutz.
On the contrary, the very day before the siege was raised, the firing continued as brisk as ever; but in the night (July 1) the whole army took the road to Bohemia in two columns, and gained an entire march upon the Austrians. Thus, notwithstanding the utmost efforts of his enemies, the Russian army reached Bohemia with very little molestation. Here he seized upon a large magazine at Lietomisessel; defeated some corps of Austrians who had attempted to interrupt his progress; and arrived at Königgrätz, of which he took possession, after driving from it 7000 Austrians who were intrenched there. This city and several other districts he laid under contribution; but soon after entered Silesia, and marched with the utmost rapidity to encounter the Russians, who had at that time united their forces under generals Brown and Fermor, entered the New Marche of Brandenburg, and laid siege to Custrin.

But are defeated at Zorndorf.

The king arrived at this city at a very critical period. The Russians had laid siege to it on the 15th of August; and though they were not well skilled in managing artillery, yet, by furious and unremittting discharges at random, they threw in such a number of bombs and red-hot balls, that the town was soon on fire in every quarter. Some of the wretched inhabitants were burned; others buried in the ruins of their houses, or killed by the balls which fell like hail in the streets; while many of the survivors abandoned their habitations, and fled out of the town on that side where it was not invested. The governor did every thing for the defence of the place; but as the walls were built after the old manner, it was impossible that the town could have made a defence for any length of time, especially as the principal magazine of the besieged had been blown up. The avenger of all these injuries, however, was now at hand. The king came in sight of the Russians on the 25th of August, after a march of 66 days, and beheld the country everywhere desolated, and the villages in the hands of the depredators of his cruel enemy, who had raised the siege at his approach, and retired towards a neighbouring village named Zorndorf. At nine o’clock in the morning, a most terrible fire of cannon and mortars poured destruction on the right wing of the Russian army for two hours without intermission. The slaughter might have been expected; but the Russians kept their ground with astonishing resolution, new regiments still pressing forward to supply the places of those that fell. When the first line had fired away all their charges, they rushed forward on the Prussians with their bayonets; and all at once these brave troops, though encouraged by the presence of their king, gave way and fled before an enemy already half defeated. The Russian generals ought now to have attacked with their cavalry the disordered infantry of their enemies, which would have completed the defeat, and in all probability given the finishing stroke to the king of Prussia’s affairs. This opportunity, however, they lost: but the king was not so negligent; for, by a very rapid and masterly motion, he brought all the cavalry of his right wing to the centre, and falling on the Russian foot uncovered by their horse, and even disorderly by their own success, they pushed them back with most miserable slaughter, at the same time that the repulsed battalions of infantry, returning from the charge, and exasperated at their late disgrace, rendered the victory no longer doubtful. The Russians were now thrown into the most dreadful confusion. The wind blew the dust and smoke into their faces, so that they could not distinguish friends from foes; they fired on each other, plundered their own baggage which stood between the lines, and intoxicated themselves with brandy: the ranks fell in upon one another; and, being thus crammed together into a narrow space, the fire of the Prussians had a full and dreadful effect, while their enemies kept up only a scattered and ineffectual fire, generally quite over their heads. Yet even in this dismal situation the Russians did not fly; but suffered themselves to be slaughtered till seven at night, when their generals having caused an attack to be made on the Prussian right wing, the attention of the enemy was drawn to that quarter, and they had time to retire a little from the field of battle to recover their order.

In this engagement, which was called the battle of Zorndorf, the Russians lost 21,529 men, while that of the Prussians did not exceed 4000. A vast train of artillery was taken, together with the military chest, and many officers of high rank. The consequence was, that the Russian army retreated as far as Landsberg on the frontiers of Poland, and the king was left at liberty to march with his usual expedition to the relief of Prince Henry in Saxony.

The prince was at this time sorely pressed by M. Ostermann Daun. As soon as the king had left Bohemia in the manner already related, M. Daun, considering that it would have been to no purpose to follow him, resolved to turn his arms towards Saxony. Towards that country, therefore, he took his route through Lusatia, by Zittau, Gorlitz, and Bautzen. On the 3d of September he invested the strong fortress of Sonnestein; which unaccountably surrendered, after a single day’s resistance, to one of his generals named Marguere. He then began to favour the operations of General Laudon, who had advanced through the Lower Lusatia to the confines of Brandenburg; and, by drawing the attention of the Prussian forces which were left in Silesia to the northward of that duchy, he facilitated the progress of the generals Harsch and De Ville in the southern parts. He then proposed that Prince Henry should be attacked by the army of the empire, while that of the Austrians should pass the Elbe, and falling at the same time on the Prussians, second the attack of the Imperialists, and cut off the retreat of their enemies from Dresden. The sudden appearance of the king of Prussia, however, put an end to his plan; General Laudon abandoned all his conquests in Lower Lusatia, and retired towards M. Daun, while that general himself retired from the neighbourhood of Dresden as far as Zittau. The army of the empire only kept its ground; possessing itself of the strong post at Pirna, formerly mentioned, but did not undertake any thing. As for the Swedes, who had directed their motions by those of the Russians, they no sooner heard of the victory of Zorndorf, than they retreated with much more expedition than they had advanced.

Thus the king of Prussia’s affairs seemed to be pretty well retrieved, when by one fatal piece of negligence his army of
of the empire. On the other hand, the king of Prussia, having taken possession of an important post at Bautzen, extended his right wing to the village of Hochkirchen, by which he preserved a communication with his brother Prince Henry, protected Brandenburg, and was better situated than he could be anywhere else for throwing succours into Silesia. The two armies kept a watchful eye on the motions of each other; and as the principal aim of M. Daun was to cut off the king's communication with Silesia, and of the king to cut off M. Daun's communication with Bohemia, a battle seemed inevitable, though great danger seemed to await that party who should begin the attack.

In this critical posture of affairs, the Austrian general formed a design of attacking the Prussian camp in the night. In what manner he came to surprise such a vigilant enemy has never been accounted for; but that such a surprise was actually accomplished on the 14th of October, is certain. In the dead of the preceding night, the Austrian army began to march in three columns towards the camp of the king of Prussia; and though the night was exceedingly dark, and they had a considerable way to go, they all arrived at the same time, in safety, without being discovered, and without the least confusion; and at five in the morning began a regular and well-conducted attack. The Prussians were in a moment thrown into confusion; Marshal Keith, one of their best generals, received two musket-balls, and fell dead on the spot. Prince Francis of Brunswick had his head shot off by a cannon-ball as he was mounting his horse; and every thing seemed to announce the total destruction of the army. Still, however, the king preserved his wonderful presence of mind, which indeed he never appears to have lost on any occasion. He ordered some detachments from his left to support his right wing; but the moment that these orders were received, the left itself was furiously attacked. General Ketzow, who commanded in that quarter, repulsed the Austrians with difficulty, and was not able to afford any considerable assistance to the right; which alone was obliged to sustain the weight of the grand attack. The Austrians, in the beginning of the engagement, had driven the Prussians out of the village of Hochkirchen; and as the fate of the day depended on the possession of that post, the hottest dispute was there. The Prussians made three bloody and unsuccessful attacks on the village; on the fourth they carried it; but the Austrians continually pouring in fresh troops, at last drove them out with prodigious slaughter on all sides. The king then ordered a retreat, which was conducted in good order, without being pursued; however, this bloody action cost him 7000 men, together with a great number of cannon. The Austrians computed their own loss at 5000.

His Prussian majesty, having thus happily escaped such imminent danger, took every possible measure to prevent the enemy from gaining any considerable advantage from his defeat. Perceiving that the only advantage they wished to derive from it was to cover the operations of their armies in Silesia, and that he had now nothing to fear on the side of Saxony, he largely reinforced his own army from that of Prince Henry, and hastened into Silesia, in order to raise the siege of Neisse, which had been completely invested on the 4th of October. On the 24th of that month, therefore, he quitted his camp, and making a great compass to avoid obstructions from the enemy, arrived in the plains of Gorlitz. A body of the Austrians had in vain attempted to secure this post before him, and some who arrived after him were defeated with the loss of 800 men. From this place the king pursued his march with the utmost diligence; but was followed by General Laudohn, at the head of 24,000 men, who constantly hung on his rear, and harassed his army. The king, however, knowing the importance of his expedition, continued his march without interruption, and suffered his antagonist to obtain many little advantages without molestation. Daun, however, not content with the opposition given by Laudohn, sent a large body of horse and foot by another route to reinforce the generals Karsch and De Ville, who had formed the siege of Neisse and the blockade of Cösel, while he himself passed the Elbe, and advanced towards Dresden.

All these precautions, however, were of little avail. The generals Karsch and De Ville, notwithstanding their reinforcement, no sooner heard of the king of Prussia's approach, than they raised the siege of both places, and retired, leaving behind them a considerable quantity of military stores. The end of the Prussian monarch's march being thus accomplished, he instantly returned by the same way he came, and hastened to the relief of Saxony, the capital of which (Dresden) was in great danger from Marshal Daun. The place was but indifferently fortified, and garrisoned only by 12,000 men; so that it could not promise to hold out long against a numerous and well-appointed army. It was besides commanded by a large suburb, of which, if once the enemy got possession, all defence of the city must then be vain. For this reason M. Schmettau, the Prussian governor, determined to set these suburbs on fire, which was actually done November 10th, with an incredible loss to the inhabitants, as in the suburbs were carried on most of those valuable manufactures which render the city of Dresden remarkable. This disappointed the designs of M. Daun; but, though the action was agreeable to the laws of war, and had been executed with all the caution and humanity of which such an action was capable, yet the Austrians exclaimed against it as a piece of the most unprovoked and wanton cruelty recorded in history.

After the king of Prussia had approached Dresden, all the Austrian armies retired into Bohemia, where they took up their winter-quarters, as the king of Prussia did in Saxony. This unhappy country he said he would now consider as his own by right of conquest. But instead of treating the conquered people as his lawful subjects, he oppressed them in all possible ways, by levying the most severe and exorbitant contributions, surrounding the exchange with soldiers, and confining the merchants in narrow lodgings on straw-beds, till they drew upon their correspondents for such sums as he wanted.

In 1759, as early as the 23rd of February, the Prussians commenced their military operations. General Wobersow marched with a body of troops into Poland, where he destroyed several very large magazines belonging to the Russians, and returned into Silesia without any loss on the 18th of April. In the mean time, by some movements of the king of Prussia himself, the greatest part of the Austrian troops had been drawn
drawn towards the frontiers of Silesia. Prince Henry immediately took advantage of this opening, and on the 15th of April entered Bohemia with his army divided into two columns. One, commanded by himself, marched towards Peterswade; the other, under General Hulsen, passed by the towns of Pasberg and Commmottau. That command by Prince Henry himself penetrated as far as Loboschutz and Lettmoritz; the enemy flying everywhere before them, and burying or abandoning the vast magazines which they had amassed in these parts. The body under General Hulsen had a more active employment. A strong pass at Pasberg was defended by a considerable body of Austrians. General Hulsen, having conducted his cavalry by another way in such a manner as to fall directly on their rear, attacked them in front with his infantry, drove them out of their intrenchments, and totally defeated them with the loss of a great number killed, and 2,000 taken prisoners, while that of the Prussians did not exceed 70 in killed and wounded. After this exploit they returned into Saxony, with hostages for the contributions which they had largely exacted during the course of their expedition.

Some other successes obtained by Prince Henry cleared the country of Franconia of his enemies; but now the approach of the Russians seemed once more to bring the affairs of the king of Prussia to a crisis. Notwithstanding the destruction of their magazines, they had continued to advance into Silesia, where they were opposed by Count Dohna; but as the troops he had with him were very far inferior to his enemies, he found it impossible to do more, or, at least, with any appearance of success, than to observe their motions and harass them on their march. But this was so displeasing to the king, that he disgraced his general, and appointed Wedel to succeed him, with orders to attack the Russians at all events. To enable him, however, in some measure to comply with this desperate order, he sent him some reinforcements, which brought his army up to near 30,000. With these, on the 23rd of July 1759, General Wedel attacked 70,000 Russians posted in the most advantageous manner at Zulichau, and defended by a numerous artillery. Though the Prussians marched on to certain destruction and disgrace, they sustained the attack for a long time with unparalleled resolution. At last, however, they gave way, and were obliged to retire with the loss of 4700 killed or taken prisoners, and 3000 wounded.

The consequences of this victory were, that the Russians penetrated into the king’s territories, and took possession of the towns of Crosen and Frankfurt on the Oder, which made it absolutely necessary for the king to come in person to oppose them. Accordingly, on the 4th of August, he joined Wedel with a considerable body of forces, having left the greatest part of his army in Saxony under Prince Henry. But as Marshal Daun had sent a body of 12,000 horse and 8000 foot under General Landohn to the assistance of the Russians, the king still found himself unable to fight them; as, with this and some other reinforcements, their army now amounted to upwards of 90,000. He therefore recalled General Finck, whom he had sent into Saxony with 9000 men; but with all his reinforcements, it was found impossible to augment his army to 50,000 complete. His situation, however, was now so critical that a battle was unavoidable; and therefore, on the 12th of August, with this inferiority of number, the king attacked his enemies strongly intrenched, and defended by a prodigious number of cannon. In this action, his principal effort was against the left wing of the Russian army. He began the attack, according to custom, with a heavy cannonade; which having produced the desired effect, he attacked that wing with several battalions disposed in columns. The Russian intrenchments were forced with great slaughter, and 72 pieces of cannon were taken. But still there was a defea to be passed, and several redoubts which covered the village of Cunnersdorf to be mastered. These were attacked with the same resolution, and taken one after another. The enemy made another stand at the village, and endeavored to preserve their ground there by pushing forward several battalions of horse and foot; but this also proved unsuccessful; they were driven from post to post quite to the last redoubt. For upwards of six hours the Prussians were successful, and everywhere broke the enemy with prodigious slaughter; drove them from almost all the ground they had occupied before the battle, took more than half their artillery, and scarce any thing seemed wanting to make the victory complete. In these circumstances, the king wrote the following billet to the queen: "Madam, we have beaten the Russians from their intrenchments. In two hours expect to hear of a glorious victory." Of this victory, however, he deprived himself, by an excessive eagerness for conquest. The enemy, defeated almost in every quarter, found their left wing, shattered as it was, to be more entire than any other part of their army. Count Soltikoff, the Russian general, therefore, assembled the remains of his right wing, and, gathering as many as he could from his centre, reinforced the left, and made a stand at a redoubt which had been erected on an advantageous eminence in a place called the Jews burying-ground. All the king’s generals are said to have been of opinion that he ought to allow the Russians the peaceable possession of this post. Their army had already suffered so much, that it would have been impossible for them to have attempted any enterprise of consequence after the battle; but their artillery was still numerous, the post very strong, and the Prussian troops greatly fatigued. These reasons for a few moments had some weight with the king; but the natural impetuousity of his temper getting the better of his reason, he led on his wearied troops again and again; till at last, when their strength was in a manner totally exhausted, they were attacked and utterly routed by the Austrian and Russian cavalry, the former of which had hitherto remained quite inactive, and were therefore quite fresh, and irresistible by the enfeebled Prussians. The night, and the prudent use of some eminences, prevented the total destruction of the army; however, their loss amounted to 20,000 men killed and wounded. The king, when he found the victory totally lost, sent another billet to the queen, expressed in the following manner: "Remove from Berlin with the royal family; let the archives be carried to Potsdam; the town may make conditions with the enemy."

Immediately after this defeat, the king set himself about repairing his losses with the utmost diligence. In a few days every thing was again put in order in his camp.
Prussia. [481]

Prussia. General Kliëst with 5000 men from Pomerania; detached 6000 from his own army to the defence of Saxony; and with the remainder put himself between the Russians and Great Glogau, covering that city which had been the chief object of their designs; and in short, notwithstanding their victory, obliged them to return to Poland without accomplishing anything but the carnage at Cunnersdorf.

The misfortunes of the Prussian monarch, however, were not at an end. Prince Henry, indeed, by a most extraordinary and well-conducted march, entered Saxony, which was now totally overrun by the armies of the enemy. At the same time, strong detachments having been sent into that country under generals Finck and Wunsch, the whole was in a short time recovered except Dresden. Towards this place Marshal Daun retired, and in all probability would soon have been obliged to leave Saxony entirely. But the king's impatience could not be satisfied without cutting off his retreat, and forcing him to a battle; for which purpose he sent General Finck with upwards of 12,000 men according to the Prussian account, but 20,000 according to the Austrians, to seize some passes through which M. Daun could only take his route towards Bohemia. This commission was executed with great exactness; but the Prussian general, having probably advanced too far into these defiles, and neglected to preserve a communication with the main army, gave his enemy an opportunity of surrounding him, and at last forcing him and his whole army to surrender prisoners of war. This disaster was soon after followed by another. General Durecke was posted at the right of the Elbe, opposite to Messen; but on the approach of a large body of Austrians, they prepared to retreat over the river into a place where they hoped to be more secure. But having been obliged by an hard frost to withdraw their bridge of boats, a thaw supervened, when they attempted to lay a bridge of pontoons, so that they were again obliged to have recourse to their boats. In this situation, their rear-guard was attacked with great fury by the Austrians, and all the soldiers who composed it killed or taken. The loss of the Prussians on this occasion was computed at 3000 men.

The year 1760 showed the Prussian monarch in a more dangerous situation than he had ever yet experienced. Indeed his affairs now seemed to be altogether desperate. His losses were not to be measured by the number of the killed or prisoners, but by armies destroyed or taken. Forty generals had died or been killed in his service since the beginning of October 1756, exclusive of those who were wounded or taken prisoners. This of itself would have been an irreparable loss, had not the very wars which destroyed these furnished others equally capable of filling their places. But another deficiency, which could not be remedied, still remained. The king had, by his indefatigable industry and exertions, supplied all the deficiencies of men in his armies, but they were not the same men as before. The hardy veterans, with whom he had originally taken the field, were now no more, and their places were supplied by others who had neither the same experience nor discipline; so that now he was obliged to supply this deficiency by his own genius and heroism.

But whatever abilities the Prussian monarch might possess, and though he undoubtedly exerted them to the utmost, it seemed only to be contending against fate, and his enemies gained still greater and greater advantages. General Landou, with whom none but the Prussians seem to have been able to cope, by a re-adopted art of skilful movements, drove into a disadvantageous situation M. Fouquet, one of the Prussian generals, with a strong body of forces. Perceiving it impossible for them to escape, Landou then made a violent attack on their entrenchments in the dead of the night of June 23d. The Prussians made a gallant defence, but at last were all killed or taken prisoners except about 300. Of the Prussians were killed 4000, and 7000 taken prisoners; 50 pieces of cannon, and a great number of colours, were also lost. The victory, however, was dear bought; for the Austrians lost above 12,000 men in killed and wounded; whom, however, they could better spare than the Prussians, on account of their numbers.—This action was called the battle of Landshut.

Baron Landou failed not to improve this victory. Glatz is to the utmost. He instantly turned back from Landshut by the Austrians. Duschten, and fell upon the city of Glatz, which he took in a very short time, with the garrison who defended it, consisting of 2000 men. In this place were found 101 pieces of brass cannon, with immense quantities of provisions and military stores. From thence he marched against Breslau, and immediately invested it. But, in the mean time, the king of Prussia, whose motions had been all this time counteracted by M. Daun in Saxony, marched with his usual rapidity towards Silesia. By this means he drew M. Daun out of Saxony; and indeed the Austrian general used such expedition, that he gained two full days on the king. This was no sooner known to his Prussian majesty, than he returned with the same expedition that he had advanced, and sat down before Dresden. Of Dresden being besieged, this M. Daun soon received intelligence, and returned without delay. In the mean time, however, the buildings of success, by the city were terribly shivered by the king's cannon, the city was set on fire, and bombs which continually played on it. His utmost depositions, however, proved ineffectual to reduce it before the arrival of M. Daun. The siege had begun on the 13th of July, and on the 19th M. Daun appeared within a league of Dresden. The Prussians then redoubled their efforts. They had that day received reinforcements of heavy cannon and mortars, with which they battered the place incessantly. The cathedral church, New Square, several principal streets and some palaces, and the noble manufactories of porcelain, were entirely destroyed. The siege was continued till the 22d; but, on the night of the 21st, M. Daun had thrown 16 battalions into the city; which rendered it impossible for the king to continue longer with it any prospect of success. He therefore raised the siege, and retired without molestation, though there were three considerable armies of the enemy in the neighbourhood. Breslau was fiercely bombarded by Landou, but the approach of Prince Henry obliged him to desist from his enterprise on the 11th of August.

But, in the mean time, the fortune of the king seemed likely to be terminated by one fatal stroke. Finding it impossible for him to carry on a defensive war, he marched towards Silesia with such astonishing rapidity,

Three Austrian generals join their forces against him.

pity, that before the middle of August he had advanced 200 miles, leaving Marshal Daun with his army far behind him. This expedition he undertook in order to engage General Laudohn before he could have time to effect a junction with Daun and Lacy, another Austrian general; which triple union seemed to threaten him with unavoidable destruction at once. This, however, he found impossible to prevent: and the three armies, when joined, formed a most tremendous line of encampments, extending no less than 30 English miles; at the same time that every one of their posts was strong, and the communication between them easy. The king was strongly encamped at Lignitz; and for several days employed all his military skill in attempting to induce one of the bodies to detach itself from the rest, or to attack them at some disadvantage; but without effect. At last, the Austrian generals, having maturely weighed all circumstances, resolved to attack the king’s camp itself, strong as it was; and Marshal Daun, remembering the advantage he had gained at Hochkirchen by an attack in the night-time, resolved to follow the same plan now. The plan therefore was laid in the following manner. The whole army, as soon as it should begin to grow dark, was to march from their several posts to such situations as were marked out for each corps: they were to strike their tents, but yet to keep up the fires in their camps, and to have the drums beat the tattoo as usual, by which means they had a probability of surprising the enemy; or if not, they judged it absolutely impossible for him to escape them, though he should be ever so much on his guard. In what manner the king of Prussia became acquainted with this plan, is not known. His friends attributed it to his own penetration and knowledge of the stratagems of war; the Austrians, to intelligence given him by deserters. But, in whatever way he became acquainted with this design, it is certain that he took the most effectual methods of preventing it. As the Austrian plan was to surround his camp, and this could not be done without the division of their army which he had so long desired, he resolved to intercept one of the parties; and if that should be disabled from acting, he could then more easily deal with the other two. Therefore, in the very evening calculated for the decisive attack on his camp, he quitted it with the utmost privacy, and took an advantageous post on the road through which General Laudohn was to pass. The nature of this post was such, that at the same time that it stopped the progress of Laudohn in front, Daun would lie under great difficulties if he should attempt his rear; at the same time that, for his further security, the king strengthened the rear with several batteries. As soon as his army was drawn up, he divided it; leaving his right on the ground where it had been formed, to observe Marshal Daun, and to maintain that post; whilst with his left he turned in order to fall on the corps under General Laudohn. In the mean time, that commander, ignorant of the fate which was awaiting him, advanced with the utmost expedition towards the place which had been assigned him, in order to share in the glory of destroying the Prussian monarch; when, at three in the morning, on the 15th of August, a thick fog which covered the ground, suddenly clearing up, discovered, like the opening of a great scene, the dreadful front of the Prussian army regularly embattled, and advantageously posted. La-

dohn, though surprised, made the best dispositions that circumstances would admit of, and an obstinate engagement ensued; in which, however, he was at last obliged to yield to the superior skill of his adversary, with the loss of 10,000 killed, wounded, and prisoners, 82 pieces of cannon, and 23 pair of colours.

The victory, though complete, gave but a partial relief to the King of Prussia. The most essential service it did was the preventing of the Russians from joining those enemies which he already had. Count Czerni- chew had been advancing with 24,000 men, and had even passed the Oder; but was so intimidated by this news, that he instantly repassed that river on the same bridges which he had lately built, even though M. Daun sent him a strong body of troops in order to encourage him to advance. Soon after this battle, the king joined his brother Prince Henry at New Marche, and marched against Daun, who had begun to form the blockade of Schweidnitz; fell upon a corps under General Beck, made two battalions of Croats prisoners, and dispersed the rest, which obliged the enemy to abandon the enterprise they had just undertaken. About the same time, General Hulsen gained a considerable advantage over the Imperial army in Saxony, with very trifling loss on his part, by which he effectually prevented them from cutting off his communication with the city of Tor- gau.

By these successes the affairs of his Prussian majesty seemed to revive: but there was no end of his enemies. The late manoeuvres had drawn him so far into Silesia, that his communication with Brandenburg was almost wholly cut off. The Russian army, which after it had repassed the Oder began to move out of Silesia, sent forward a powerful detachment under Count Czerni- chew towards the march of Brandenburg. A body of 15,000 Austrians, under the generals Lacy and Brentano, and the whole united body of Austrians and Imperialists which acted in Saxony, began their march in concert with the Russians, and proposed to unite at the gates of Berlin. These armies amounted to 40,000 men. To oppose this formidable power, General Hulsen called to his assistance General Werner, who had been sent with a body of troops into Pomerania; but, after being joined by him, their united forces were found not to exceed 15,000 or 16,000 men. To attempt a defence of the capital with this force would have been little short of madness: and therefore these commanders were obliged to leave Berlin to its fate; Berlin be- longed to the Austrians; and the animosity of the Austrians, seemed to be a dreadful one. However, by the powerful mediation of several foreign ministers, the town obtained terms which were not altogether intolerable; but the maga- zines, arsenals, and foundries were destroyed, and an immense quantity of military stores seized, with a number of cannon and other arms. The city was first obliged to pay 800,000 guilders, after which a contribution of 1,900,000 crowns was laid on; yet notwithstanding this, many violences were committed, and the king’s palace was plundered and the furniture abused in a scandalous army.

The combined armies stayed in Berlin only four days, dreading the severe vengeance of the king of Prussia, who.
who they heard was advancing towards that place with great expedition. But so great were the embarrassments which now attended that monarch, that it seemed almost beyond human power to retrieve his affairs. The Imperialists, on their return from Berlin, having no army to oppose them, made themselves masters of Leipsic, Torgau, Meissen, and Wirttemberg; in which last city they found the grand magazine of the Prussians; immensely stored with provisions, ammunition &c. M. Stainville also, with a detachment from Bregio the French general's army, laid the city and duchy of Halberstadt under contribution. In Eastern Pomerania, the Russians had besieged Colberg by sea and land. In the Western Pomerania, the Swedes advanced with great celerity, hoping to share in the plunder of Berlin. In Silesia, the king no sooner began his march to the northward, than Laudobn advanced, and laid siege to the important fortress of Cosel; and, to complete this distress and embarrassment, the king himself was attended at every step by Count Daun with a superior army well prepared to take every advantage.

In this desperate situation the king, being joined by his generals Hulsen and Prince Eugene of Wirtemberg with the corps under their command, advanced up the Elbe, while M. Daun fell back to cover Leipsic and Torgau, but the latter finding that the Prussians directed their march towards the Elbe, encamped within reach of Torgau; one part of his army extending to the Elbe, by which he was covered on that side, whilst on the other he was covered by hills and woods, so that it was impossible to choose a more advantageous situation. The Prussian army did not amount to 50,000 men, whilst that of the Austrians exceeded 86,000: yet such were the unfortunate circumstances of the king, that he was obliged to fight under all these disadvantages; and therefore he caused his army to be informed, that he was now to lead them to a most desperate attempt, that his affairs required it, and that he was determined to conquer or die. His soldiers unanimously declared that they would die with him.

The 3d of November 1760 was the day on which this important affair was decided. The king divided his forces into three columns. General Hulsen was to take post with one in a wood that lay on the left of the Austrian army, and had orders not to move until he found the rest of the Prussians engaged. General Zieten was to charge on the right; and the great attack in front was to be conducted by the king in person. His forces were disposed in such a manner that, either his right or left must take the enemy in rear and close them in, so as to disable them from undertaking any thing against the part where he intended to effect his principal attack. On the other hand, M. Daun perceiving the king to be serious in his design of fighting, to prevent confusion, sent all his baggage over the Elbe, across which he threw three bridges in case a retreat should be necessary. At the same time he caused Torgau to be evacuated; and then, extending his first line to a village called Zimne on the left, he stretched it to another called Crowsitz on the right; supporting the right of his second line upon the Elbe. In this disposition he was found, when, about two o'clock in the afternoon, the king began his attack. He was received by the fire of 200 pieces of cannon, which, were disposed along the Austrian front. The Prussians were thrice led on to the attack; but were every time repulsed and broken with terrible slaughter. The king at length commanded a fresh body of cavalry to advance, which at first compelled the Austrians to retire; but new reinforcements continually coming in, this cavalry was in its turn obliged to fall back, and the Prussians maintained themselves with extreme difficulty, until General Zieten, with the right wing, attacked the enemy in the rear, repulsed them, and possessed himself of some eminences which commanded the whole Austrian army. Encouraged by this success, the Prussian infantry once more advanced, mastered several of the enemy's intrenchments, and made way for a new attack of their cavalry, which broke in with irresistible fury on the Austrians, and threw several bodies of them into irreparable disorder. It was now about 9 o'clock, and of consequence both armies were involved in thick darkness; yet the fire continued without intermission, and the battalions with a blind rage discharged at one another without distinguishing friend from foe. M. Daun received a dangerous wound in the thigh, and was carried from the field, which probably hastened the defeat of his troops. The command then devolved on Count O'Donnel; who, finding the greatest part of his troops in disorder, the night advanced, and the enemy possessed of some eminences which commanded his camp, and from which it was in vain to think of driving them, ordered a retreat, which was conducted with wonderful order and exactness; none were lost in passing the bridges, and by far the greater part of their artillery was preserved. The loss of the Prussians was estimated at 10,000 killed and wounded, and 3000 taken prisoners. That of the Austrians in killed and wounded is not known; but 8000 were taken prisoners, with 216 officers, among whom were four generals.

The consequence of the victory of Torgau was, that all Saxony was recovered; all Saxony except Dresden; and in the mean time General Werner having marched into Pomerania, the Russians raised the siege of Colberg, and retired into Poland, without having effected any thing further than wasting the open country. Werner then flew to the assistance of Western Pomerania, where he defeated a body of Swedes, and at last drove them totally out of the country. General Laudohn too abruptly raised the blockade of Covel; and after, abandoning Landshut, he retired into the Austrian Silesia, leaving the Prussian part entirely in quiet. M. Daun placed one part of his army in Dresden, and the other in some strong posts which lie to the south and west of it, by which he commanded the Elbe, and preserved his communication with Bohemia. The army of the empire retired into Franconia, and placed its headquarters at Bamberg.

Though these successes had, to appearance, retrieved the king's affairs in some measure, yet his strength seemed now to be wholly exhausted; and in the campaign of 1761, he made no such vigorous efforts as he had formerly done. The Russians, dividing themselves into two bodies, invaded Silesia and Pomerania. In the former country they laid siege to Breslau, and in the latter to Colberg. Tottleben also, who had commanded the Russian armies, was now removed on a suspicion that he had corresponded with the king of Prussia, and General Remanzow put in his place; by which it was.
expected that the Russian operations would be more brisk this year than formerly.

The king continued strongly encamped near Schweidnitz; where he was so closely watched by generals Daun and Laudohn, that he could attempt nothing. However, he defeated the designs of the Russians against Breclaw, by sending General Platen to destroy their magazines; which he accomplished with great success, at the same time cutting off a body of 4000 of their troops. But this only brought the more sure destruction upon Colberg; to which place that body of Russians immediately marched, cruelly wasting the country as they went along. The king of Prussia could do nothing but send detachments of small parties, which, though they could not oppose their enemies in the field, yet he hoped, by cutting off the convoys of the enemy, might distress them to such a degree as to oblige them to abandon the siege, or at least protract it till the severity of the winter should render it impossible for them to carry on their operations. Thus he weakened his own army so much, that it was found requisite to draw 10000 men out of Schweidnitz in order to reinforce it; and no sooner was this done, than General Laudohn suddenly attacked and took that fortress by a coup de main. Colberg made a brave defence; but the troops sent to its relief being totally unable to cope with the Russian army, consisting of 52,000 men, it was obliged to surrender on the 3d of December; and thus the fate of the Prussian monarch seemed to be decided, and almost every part of his dominions lay open to the invaders.

In the midst of these gloomy appearances the empress of Russia, the king's most inveterate and inflexible enemy, died on the 2d of January 1762. Her successor, Peter III, instead of being the king's enemy, was his most sanguine friend. As early as the 23d of February, in a memorial delivered to the ministers of the allied courts, he declared, that, "in order to the establishment of peace, he was ready to sacrifice all the conquests made in this war by the arms of Russia, in hopes that the allied courts will on their parts equally prefer the restoration of peace and tranquillity, to the advantages which they might expect from the continuance of the war, but which they cannot obtain but by a continuance of the effusion of human blood."—This address was not so well relished by the allies: however, they were very willing to make peace, provided it was for their own interest; but they recommended to his attention fidelity to treaties, which constitutes a no less valuable part of the royal character, than humanity and disinterestedness. This answer made no impression on the czar; a suspension of hostilities took place on the 16th of March, which was followed by a treaty of alliance on the 5th May. In this treaty the czar stipulated nothing in favour of his former confederates; on the contrary, he agreed to join his troops to those of the king of Prussia, in order to act against them. Sweden, which had for a long time acted under the direction of Russian counsels, now followed the example of her mistress, and concluded a peace with Prussia on the 22d of May. It is not to be supposed that the king of Prussia would remain long inactive after such an unexpected turn in his favour. His arms were now everywhere attended with success. Prince Henry drove the Imperialists from some important posts in Saxony, by which he secured all that part which the Prussians possessed; and though the Austrians frequently attempted to recover these posts, they were constantly repulsed with great slaughter. The king was not joined by his new troops till the latter end of June; after which he drove M. Daun before him to the extremity of Silesia, leaving the town of Schweidnitz entirely uncovered, and which the king immediately prepared to invest. In the mean time, different detachments of Prussians, some on the side of Saxony, and others on that of Silesia, penetrated deep into Bohemia, laid many parts of the country under contribution, and spread an universal alarm. A considerable body of Russian irregulars also made an irruption into Bohemia, where they practised on the Austrians the same cruelties which they had long been accustomed to practise on the Prussians.

But while the king was thus making the best use of his time, he was all at once threatened with a fatal reverse of fortune by a new revolution in Russia. The emperor was deposed, and his deposition was soon after followed by his death. The empress, who succeeded him, suspected that her husband had been misled by the counsels of his Prussian majesty, against whom, therefore, she entertained a mortal enmity. She could not, however, in the very beginning of her reign, undertake again a war of so much importance as that which had been just concluded. She therefore declared her intention of observing the peace concluded by the late emperor; but, at the same time, of recalling her armies from Silesia, Prussia, and Pomerania; which indeed the unsettled state of the kingdom now made in some degree necessary. At the same time a discovery was made with regard to the king of Prussia himself, which turned the scale greatly in his favour. The Russian senate, flaming with resentment against this monarch, and against their late unfortunate sovereign; and the empress, full of suspicion, that the conduct of the latter might have been influenced by the counsels of the former, searched eagerly amongst the papers of the late emperor for an elucidation or proofs of this point. They found indeed many letters from the Prussian monarch, but in a strain absolutely different from what they had expected. The king had, as far as prudence would permit, kept a reserve and distance with regard to the too rash advances of this unhappy ally; and, in particular, counselled him to undertake nothing against the empress his consort. The bearing of these letters read is said to have had such an effect upon the empress, that she burst into tears, and expressed her gratitude towards the Prussian monarch in the warmest terms. Still, however, the Russian army was ordered to separate from the Prussians; but all the important places which the former had taken during the whole war were faithfully restored.

The king, finding that the Russians were no more to take an active part in his favour, resolved to profit by their appearance in his camp; and, therefore, the very day after the order for their return had arrived, he attacked the Austrian army, and drove their right wing from some eminences and villages where they were advantageously posted; by which means he entirely cut off their communication with Schweidnitz, so that nothing could be attempted for its relief. Prince Henry kept them in continual alarms for Bohemia; and a great
great part of their attention, and no small part of their forces, were engaged on that side. Marshal Daun, now finding himself rendered almost incapable of undertaking any thing, detached General Laudon, with a force very much superior, to attack the prince of Bevern, and drive him from the advantageous post he occupied. But the prince defended himself with such resolution, that all the efforts of Laudon could not succeed before the king had time to come to his assistance. The Austrians, being then put between two fires, were routed and pursued with terrible slaughter; after which, the king marched without more disturbance in his preparations for the siege, and the trenches were opened on the 18th of July. Marshal Daun made no attempts to relieve the place; but the garrison being very strong, it held out for near two months from the opening of the trenches. It is said that the attack was conducted, and the defence made, by two engineers who had written on the subject of the attack and defence of fortified places; and they were now practically engaged to prove the superiority of their systems. At last, however, the garrison, to the number of 8000 men, surrendered prisoners of war; and the whole body, except nine, were soon after drowned at the mouth of the Oder, on their passage to their intended confinement in Königsberg.

The king of Prussia, now become master of Schieidenitz, turned his attention towards Saxony, where he considerably reinforced his brother's army, and made preparations for laying siege to Dresden. In this country the Austrians had lately met with some success, and driven Prince Henry as far back as Freyberg; but on the 29th of October, they were attacked by the Prussian army thus reinforced, and totally routed. Great numbers were slain, and near 6000 taken prisoners. This victory proved decisive; and the empress-queen, finding herself deserted by all her allies, was glad to conclude a treaty, the substance of which was, that a mutual restitution and oblivion should take place, and both parties sit down at the end of the war in the same situation in which they began it. This treaty is called the peace of Hubertusburg.

The war was no sooner concluded than the king of Prussia turned his attention to domestic policy, and the recovery of his dominions from those innumerable calamities which had befallen them during the war. He immediately distributed lands to his disowned soldiers, and gave them the horses of his artillery to assist them in their cultivation. By his wise and prudent management, the horrors of war were soon forgotten; and the country was quickly in as flourishing a state as ever. Notwithstanding this pacific disposition, however, the king never slackened his endeavours for the defence of his country, by keeping a respectable army on foot; which might be able to act on the least emergency.

In the year 1778, a new difference with the house of Austria took place, concerning the duchy of Bavaria. But though the most enormous warlike preparations were made on both sides, and immense armies brought into the field, nothing of consequence was effected. What little advantage there was, seems to have been on the Prussian side, since they made themselves masters of several towns, and kept the war in the enemy's country. However, the emperor acted with so much caution, and showed so much skill in a defensive war, that all the manoeuvres of his Prussian majesty could gain no material advantage; as, on the other hand, his adversary was too wise to venture an engagement. A peace therefore was very soon concluded, and since that time the history of Prussia, during the remainder of the great Frederick's reign, affords no remarkable event which we have not mentioned in the life of that hero, and the article Poland. He left his crown to his nephew, whose character was not then much developed; and it was easily seen that a new kingdom, which had risen suddenly to such unexampled power and greatness as to excite the jealousy or apprehension of all its neighbours, would require great abilities to preserve it from dismemberment.

The late king had indeed bequeathed the most effectual securities to his successor for the preservation of his dominions, that human wisdom could provide or devise; by leaving him a full treasury, the finest army in the world, and a people enthusiastically attached to his memory and government. The new monarch, with these advantages, was not wanting to himself. The late king's predilection for the French language and French literature were not grateful to his subjects. The present sovereign began his reign with declaring in council, "Germans we are, and Germans I mean we shall continue;" giving directions, at the same time, that their native language should resume its natural rank and station, from which for near half a century it had been degraded by the French. This was a very popular measure, and it was followed by another still more so. Observing that he had marked with great concern the progress of impiety and profaneness on the one hand, and of enthusiasm on the other, he declared, that he would not have his subjects corrupted either by fanatics or atheists, and strictly prohibited all publications tending to excite a contempt or indifferency for religion.

Such, on his immediate accession to the throne, was the pacific conduct of the monarch, which endeared him to his subjects, and commanded the approbation of all good men. An opportunity soon occurred, in the state of the stadholder against the states of Holland, which he thought to have displayed such talents in negotiation and in military arrangements, as proclaimed him in every respect a worthy successor of his uncle. The states of Holland, who had long been jealous of the power of the stadholder, and inclined to a republican government without any permanent chief, had gained such an ascendency in the states general, that in 1786 and 1787 they in effect divested the Prince of Orange of all his prerogatives, (see United Provinces). They proceeded even to the seizure and imprisonment of the princess, sister to the king of Prussia; and depending upon support from France, treated with insolence every power connected with them in Europe. The court of Berlin did not witness these proceedings without indignation; and the king formed his plan for restoring the power of the stadholder; and so secrecy and prudence, that perhaps nothing could surpass it but the bravery and military skill of the duke of Brunswick, by whom it was carried into execution. In the short space of one month, that accomplished general led 18,000 Prussians to Amsterdam, and restored the just prerogatives of the prince of Orange.

The affairs of Prussia during the early period of the French revolution, and the active but unsuccessful part which that monarch took against it, are interwoven with the
the historical details of that period under the articles France and Britain, to which we refer our readers.

For a number of years he acted the prudent part of standing clear of hostilities as much as possible; and when he did act at all inter esse, we find little in his conduct which is intitled to the praise either of consistency or honour. Indeed it may perhaps be admitted, that on many occasions he acted rather from necessity than choice; and finding that a contest with France was both absurd and ruinous, he chose to sacrifice a less evil to a greater good. Whether by consent or compulsion is not certainly known, the king of Prussia ceded to France the duchies of Cleves and Berg, March 1806, which were to be governed by Prince Murat, the brother-in-law of Bonaparte, under the title of Joachim, duke of Cleves and Berg.

The king of Prussia likewise took possession of the Hanoverian states 30th October 1806, at the time when Great Britain had no reason to apprehend any such mysterious conduct from that quarter. He entered into a secret treaty with France for the purpose of shutting the northern ports; a measure which gave such offence to this country, that the British minister thought proper to take his leave of Berlin. At one period he came to a final determination to make no separate treaty with the French government, and proposed a treaty of peace and alliance between his court and that of Britain. To give this as much effect as possible, the Prussian princes of the blood began to raise volunteer regiments in Poland and Silesia, the loyalty of the peasantry in these countries far exceeding the most sanguine expectations.

So low, however, were the king of Prussia's finances at the time of Lord Hutchinson's arrival at Memel, March 1807, that his lordship found it necessary to advance 80,000l. for the support of his family and domestic household. This being intimated to the British ministers, his majesty recommended it to parliament to enable him to implement the agreement. Yet not long after this period he actually entered into a treaty of peace with the emperor of France, by virtue of which his territories were so dreadfully mutilated, as to leave him little more of a sovereign than the name. He was required to renounce the whole of his dominions situated between the Rhine and the Elbe; the circle of Cotbus in Lower Lusatia; nearly all the provinces which formerly constituted part of the kingdom of Poland; the city of Danzig; and he was laid under the necessity of shutting all the ports and harbours of his whole dominions against the trade and navigation of Great Britain. Not above 18 months prior to this treaty, the king of Prussia might have been said to hold the fate of Europe in his hands; but by means of it he was reduced to the very lowest rank among the powers of Europe. Had he taken a decided part against France before the battle of Austerlitz, he might have been able to secure the independence of Europe; but, having suffered this auspicious moment to pass unimproved, the consequences were exactly such as might have been predicted, without any pretensions to uncommon sagacity.

The king of Prussia being thus degraded by means of his own imprudence and want of sound policy, endeavoured to ease the burdens of his remaining subjects by reducing his civil and military establishments. The army was reduced to 24,000 men, and General Knobledorf was sent to Paris to procure a diminution of the contributions exacted from him, or to crave that payments might be accepted by instalments; and, in the mean time, the troops belonging to France were not to be withdrawn from the impoverished kingdom of Prussia. Every decree issued in Holland against the commerce of Great Britain, this humbled monarch was obliged to adopt, and to order the publication of them in every part of his mutilated dominions.

In this state of degradation the Prussian monarchy continued till the extraordinary events of 1812. When Bonaparte made his irruption into Russia, Prussia was compelled to furnish a body of troops for the service, who formed part of the army under MacDonald. After the disastrous retreat of the French, the king made his escape from Potsdam, and retired to Silesia. He immediately called on his subjects to rise in arms for the defence of their country, without at first disclosing against whom he was to act. Great numbers of all ages joyfully obeyed the call. On the 22d February 1813, he entered into a treaty of alliance with Russia. The battle of Lutzen, however, on the 2d, and of Bautzen on the 20th May, threw discouragement on the rising hopes of the allies. But in August they were strengthened by the junction of Austria. The battle of Dresden was lost on the 26th of August; but from this time their affairs began to improve, and the victory of Leipzig, on the 16th October, turned the scale entirely in their favour. Prussia was now delivered entirely from French oppression; and her armies took a part in all the events that followed, to the peace of Paris in May 1814. When the war broke out again on Bonaparte's return, the Prussian armies performed essential services. The advance of Blucher in the afternoon gave a decisive turn to the battle of Waterloo.

By these successes Prussia not only recovered her former losses, but gained large additions of territory and population. She recovered the province of Posen in Poland, all her territories between the Elbe and the Rhine; and obtained besides, about one half of the king of Saxony's territories, and extensive districts on the south side of the Rhine. She acquired also Swedish Pomerania; and ceded East Friesland with some other districts to Hanover, and Anspach and Bayreuth to Bavaria. After these acquisitions and cessions, Prussia contained in 1819, 156,000 square English miles, and 10,065,000 inhabitants.

The air of Prussia is wholesome, and the soil fruitful in grain; affording, besides, plenty of pitch and other fuel. The rivers and lakes are well stored with fish; and amber is found on its coast towards the Baltic.

The principal rivers are the Vistula, Bregel, Memel, the Passarge, and the Elbe; all of which frequently do damage by their inundations.

Since the year 1719 it is computed that about 34,000 colonists have removed to Prussia from France, Switzerland, and Germany; of which number one half were Saltzburgers. These emigrants have built 400 small villages, 11 towns, 50 new churches, and founded 1000 village-schools. The manners of the people differ but little from those of the Germans. The established religions are those of Luther and Calvin, but chiefly the former; though almost all other sects are tolerated.

The late king of Prussia, by the assistance of an excellent police, brought the commerce and manufactures of factories.
of this country to a very flourishing state, which during his life were daily improving. The manufactures of Prussia consist in glass, iron-work, paper, gunpowder, copper and brass-mills, manufactures of cloth, camblet, linen, silk, gold and silver lace, stockings, and other articles. The inhabitants export variety of naval stores, amber, lint-seed and hemp-seed, oat-meal, fish, meal, tallow, and caviar; and it is said that 500 ships are loaded with those commodities every year, chiefly from Königsberg.

His Prussian majesty is absolute through all his dominions; but the late king was too wise to oppress his subjects, though he availed himself to the full of his power. The government of this kingdom is by a regency of four chancellors of state, viz. 1. The great-master; 2. The great-burgrave; 3. The great-chancellor; and, 4. The great-marshall. There are also some other councils, and 37 bailiwickes. The states consist, 1. Of counsellors of state; 2. Of deputies from the nobility; and, 3. From the commons. Besides these institutions, the late king erected a board for commerce and navigation.

His Prussian majesty, by means of the happy situation of his country, its inland navigation, and the excellent regulations of his predecessor, derives an amazing revenue from this country, which, about a century and a half ago, was the seat of boors and barbarism. It is said, that amber alone brings him in 26,000 dollars annually. His other revenues arise from his demesnes, his duties of customs and tolls, and the subsidies yearly granted by the several states. In 1815 the whole revenues of Prussia were estimated at seven millions sterling. See Europe, Supplement.

The military regulations introduced by the late king had a wonderfully quick operation in forming his troops and recruiting his armies. Every regiment has a particular district assigned it, where the young men proper for bearing arms are registered; and when occasion offers, they join their regiment, and being incorporated with veterans they soon become well disciplined troops. The Prussian army, in the time of peace, consists of 250,000 of the best disciplined troops in the world; and during the last war, that force was augmented to 300,000 men.

The royal arms of Prussia are argent, an eagle displayed sable, crowned, or, for Prussia: azure, the Imperial sceptre, or, for Courland: argent, an eagle displayed, gules, with semicircular wreaths, for the marquisate of Brandenburg: to these are added the respective arms of the several provinces subject to the Prussian crown.

There are two orders of knighthood: the first, that of the Black Eagle, instituted by Frederic I. on the day of his coronation at Königsberg, with this motto, Suum cuique. The sovereign is always grand-master; and the number of knights, exclusive of the royal family, is limited to 30. Next to this is the order of Merit, instituted by his late majesty; the motto is, Four le vert.

PRUSSIAN BLUE. See Chemistry Index.

PRUSSIC ACID. See Chemistry Index.

PRYNE, William, an English lawyer, much distinguished in the civil commotions under Charles I. was born at Swaineswick in Somersetshire in 1600. His Histrionomastix, written against stage-plays in 1632, containing some reflections that offended the court, he was sentenced by the star-chamber to pay a fine of 5000l. to stand in the pillory, to lose his ears, and to perpetual imprisonment. During his confinement, he wrote several more books; particularly, in 1637, one entitled News from Ipswich, which reflecting severely on the bishops, he was again sentenced by the star-chamber to another fine of 5000l. to lose the remainder of his ears in the pillory, to be branded on both cheeks with S. L. for seditious libeller, and to be perpetually imprisoned in Caernarvon castle. Nothing but cutting off his hands could have prevented Pryne from writing: he wrote still; and in 1640, being set at liberty by the house of commons, he entered London in a kind of triumph, was elected into parliament for Newport in Cornwal, and opposed the bishops with great vigour, being the chief manager of Archbishop Laud's trial. In the long parliament he was zealous in the Presbyterian cause; but when the Independents gained the ascendency, he opposed them warmly, and promoted an agreement with the king. When the army garnished the house and refused him entrance, he became a bitter enemy to them and their leader Cromwell, and attacked them with his pen so severely, that he was again imprisoned: but he pleaded the liberty of the subject so successfully, that he was enlarged, to write more controversial books. Being restored to his seat after Cromwell's death, with the other secluded members, he assisted in promoting the restoration, and was appointed keeper of the Tower records: a place excellently well calculated for him, and where he was very useful by the collections he published from them. He presented 40 volumes of his works, in folio and 4to, to Lincoln's-inn library, of which society he was a member; and, dying in 1669, was buried under the chapeal.

PRYTANES, in Grecian antiquity, were the presidents of the senate, whose authority consisted chiefly in assembling the senate; which, for the most part, was done once every day.

The senate consisted of 500, 50 senators being elected out of each tribe: after which, lots were cast to determine in what order the senators of each tribe should preside; which they did by turns, and during their presidship were called prytaenes. However, all the 50 prytanes of the tribes did not govern at once, but one at a time, viz. for seven days; and after 35 days, another tribe came into play, and presided for other five weeks; and so of the rest.

PSALM, a divine song or hymn; but chiefly appropriated to the 150 Psalms of David, a canonical book of the Old Testament.

Most of the psalms have a particular title, signifying either the name of the author, the person who was to set it to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined that David was the sole author of the Book of Psalms; but the titles of many of them prove the contrary, as psalm xix, which appears to have been written by Moses. Many of the psalms are inscribed with the names Korah, Jeduthun, &c. from the persons who were to sing them.

PSALMANAZAR, George, the fictitious name of a pretended Formosan, a person of learning and ingenuity. He was born in France, and educated in
the sceptics triumphed. Some absurdities were discov-
ered in his history, of such a nature as to discredit
the whole narration, and saved him the trouble of an
open declaration of his imposture; which however he
owned at length to his private friends. For the remain-
der of his life, his learning and ingenuity enabled him to
procure a comfortable support by his pen: he was con-
cerned in several works of credit, particularly The Uni-
versal History. He lived irreproachably for many years,
and died in 1763.

PSALMIST, in the church of Rome, one of the
lesser ecclesiastical orders; the same with what among
us is called clerk, preacher, or singer.

PSALMODY, the art or act of singing psalms.
See Psalm.

Psalmody was always esteemed a considerable part
of devotion, and usually performed in the standing posture;
and as to the manner of pronunciation, the plain song
was sometimes used, being a gentle inflexion of the voice,
not much different from reading, like the chant in cather-
als; at other times more artificial compositions were
used, like our anthems.

As to the persons concerned in singing, sometimes a
single person sung alone; sometimes the whole assem-
bly joined together, which was the most ancient and
general practice. At other times the psalms were sung al-
ternately, the congregation dividing themselves into two
parts, and singing verse about, in their turns. There
was also a fourth way of singing, pretty common in the
fourth century, which was, when a single person began
the verse, and the people joined with him in the close:
this was often used for variety, in the same service with
alternate psalmody.

The use of musical instruments in the singing of
psalms, seem to be as ancient as psalmody itself; the
first psalm we read of being sung to the timbrel, viz.
that of Moses and Miriam, after the deliverance of the
Israelites from Egypt; and afterwards, musical instru-
ments were in constant use in the temple of Jerusalem.
See Organ.

PSALTER, the same with the book of psalms. See
the article Psalm.

Among the religious in the Popish countries, the
term psalter is also given to a large chaplet or rosary,
consisting of 150 beads, according to the number of
psalms in the psalter.

PSALTERY, a musical instrument, much in use
among the ancient Hebrews, who called it nebhel.
We know little or nothing of the precise form of the
ancient psaltery. That now in use is a flat instrument,
in form of a trapezium or triangle truncated at top; it
is strung with 13 wire-chords, set to unison or octave,
and mounted on two bridges, on the two sides: it is
struck with a plectrum, or little iron rod, and sometimes
with a crooked stick. Its chest or body resembles that
of a spinet.

PSAMMETICUS, or PSAMMITICHUS, a renown-
ed conqueror, who subduing 11 other petty kings of
Egypt, became the founder of the kingdom of Egypt,
about 670 B. C. He is memorable likewise for taking
the city of Azot, after a siege of 20 years; and for
discovering the sources of the river Nile. See EGYPT,
N° 10.

PSATYRIANS, a sect of Arians, who, in the
council of Antioch, held in the year 360, maintained
that
PSE The bees, who are a match for most other creatures by means of their stings, would easily destroy these weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter. The first, which immediately covers the body, is of a kind of silk of their own spinning; and the outer covering over this is of the bees-wax: this is laid considerably thick; and the creature, just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their stings. He never forsakes his covering, but lengthens and enlarges it as he goes; and gnawing down the sides of the cells in his march, without stopping to eat them one by one, the havoc and destruction he occasions are scarcely to be conceived. When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymph state; whence, after a proper time, it comes forth in form of a moth, with granulated horns and a crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form; and as this is a weak and defenceless state, they attack and destroy all the moths of this species they meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren. All the flies of the moth kind lay a vast number of eggs, and this is behind hand with none of them in that particular: the young ones produced from the eggs of one surviving female of this species are sufficient to destroy many honey-combs; nay, many hives of them. The moth produced by this caterpillar flies but little; yet it is very nimble in avoiding danger, by running, which it does with great swiftness.

There is a species of these pseudo-tineens, or wax-eating caterpillars, which infest the subterraneous hives of wasps and other creatures which make wax: the manner of living, feeding, and defending themselves from their enemies, is the same in all the species. These last, if they are at any time distressed for food, will eat their own dung; the wax having passed almost unaltered through their bodies, and being still wax, and capable of affording them more nourishment on a second digestion. These species, though they naturally live on this soft food, yet if by any accident they meet with harder only, they know how to live upon it; and can eat a way into the covers and leaves of books, and make themselves cases and coverings of the fragments of these substances. The accurate author of these observations describes all this to a kind of pseudo-tineum which feeds on wool, and another that eats leather; both making themselves houses also of the materials they feed on.

There is also another kind very destructive to corn: these make themselves a covering by fastening together a great number of the grains, and there live and eating in secret. All these creatures, whatever be their food or habitation, finally become phalene, or moths; and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a proboscis, or trunk, more or less incurvated.

PSEUDONYMOUS, among critics, an author who publishes a book under a false or signified name; as cyp...
Pseudonymity is given to him who publishes one under a disguised name, and anonymous to him who publishes without any name at all.

Psildium, the Guava; a genus of plants belonging to the ixocandria class, and in the natural method ranking under the 19th order, Hesperidicea. See Botany Index.

A decoction of the roots of guava is employed with success in dysenteries: a bath of the decoction of the leaves is said to cure the itch and other cutaneous eruptions. Guayava, or guava, is distinguished from the colour of the pulp into two species, the white and the red; and, from the figure of the fruit, into the round and the pear-fashioned or perfumed guava. The latter has a thicker rind and a more delicate taste than the other. The fruit is about the bigness of a large tennis ball; the rind or skin generally of a russet stained with red. The pulp within the thick rind is of an agreeable flavour, and interspersed with a number of small white seeds. The rind, when stewed, is eaten with milk, and preferred to any other stewed fruit. From the same part is made marmalade; and from the whole fruit is prepared the finest jelly in the world. The fruit is very astrigent, and nearly of the same quality with the pomegranate. The seeds are so hard as to resist the effects of the stomach of animals; so that, when voided with the excrements, they take root, germinate, and produce thriving trees. Whole meadows in the West Indies are covered with guavas, which have been propagated in this manner.

Psittacus, or Parrot, a genus of birds, belonging to the order of Picea. See Ornithology Index.

Psosas, in Anatomy. See there, Table of the Muscles.

Psophia, a genus of birds belonging to the order of Gallinace. See Ornithology Index.

Psoralea, a genus of plants belonging to the diadelphus, and in the natural method ranking under the 32d order, Papilionaceae. See Botany Index.

Psychotria, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 47th order, Stellatea. See Botany Index.

Psylli, (Strabo, Plutemy): a people in the south of Cyrenaica, were called from King Psyllus, (Agatharidges, quoted by Pliny): a people almost overwhelmed by sand driven by a south wind (Herodotus). They had something in their bodies fatal to serpents, and their very smell proved a charm against them, according to Pliny, Lucan, &c.

Though we may justly look upon it as fabulous, that these people had any thing in their bodies different from others; it is, however, certain that there are in Egypt at this day some persons who have a method of handling the most poisonous serpents without any hurt. Of these Mr. Hasselquist gives the following account:

"They take the most poisonous vipers with their bare hands, play with them, put them in their bosoms, and use a great many more tricks with them, as I have often seen. I have frequently seen them handle those that were three or four feet long, and of the most horrid sort. I inquired and examined whether they had cut out the vipers poisonous teeth; but I have with my own eyes seen they do not. We may therefore conclude, that there are to this day Psylli in Egypt; but what art they use is not easily known. Some people are very superstitious, and the generality believe this to be done by some supernatural art which they obtain from invisible beings. I do not know whether their power is to be ascribed to good or evil; but I am persuaded that those who undertake it use many superstitious.

"The art of fascinating serpents is a secret amongst the Egyptians. It is worthy the endeavours of all naturalists, and the attention of every traveller, to learn something decisive as to this affair. How ancient this art is among the Africans, may be concluded from the ancient Marii and Psylli, who were from Africa, and daily showed proofs of it at Rome. It is very remarkable that this should be kept a secret for more than 2000 years, being known only to a few, when we have seen how many other secrets have within that time been revealed. The circumstances relating to the fascination of serpents in Egypt, related to me, were principally, 1. That the art is only known to certain families, who propagate it to their offspring. 2. The person who knows how to fascinate serpents, never meddles with other poisonous animals, such as scorpions, lizards, &c. There are different persons who know how to fascinate these animals; and they again never meddle with serpents. 3. Those that fascinate serpents, eat them both raw and boiled, and even make broth of them, which they eat very commonly amongst them; but in particular, they eat such a dish when they go out to catch them. I have been told, that serpents fried or boiled are frequently eaten by the Arabians both in Egypt and Arabia, though they know not how to fascinate them, but catch them either alive or dead. After they have eaten their soup, they procure a blessing from their sheik (priest or lawyer), who uses some superstitious ceremonies, and amongst others, spits on them several times with certain gestures. This manner of getting a blessing from the priest is pure superstition, and certainly cannot in the least help to fascinate serpents; but they believe, or, at least, persuade others, that the power of fascinating serpents depends upon this circumstance."

Notwithstanding this testimony of Hasselquist, the story of the incantation of serpents, though frequently referred to in Scripture, has been generally treated as a fable. It is, however, affirmed as a certain truth, both by Mr. Bruce and M. Savary. "There is no doubt (says the former of these travellers) of its reality. The Scriptures are full of it. All that have been in Egypt have seen as many different instances as they chose. Some have doubted that it was a trick; and that the animals thus handled had been first trained, and then deprived of their power of hurting; and fond of the discovery, they have rested themselves upon it, without experiment, in the face of all antiquity. But I will not hesitate to aver, that I have seen at Cairo (and this may be seen daily without any trouble or expense), a man who came from the catacombs, where the pits of the mummy-birds are kept, who has taken a cerasates with his naked hand from a number of others lying at the bottom of a tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast, and tied it about his neck like a necklace; after which it has been applied to a hen, and bit it, which died in a few minutes; and
and, to complete the experiment, the man has taken it by the neck, and beginning at his tail, has ate it as one would a carrot or stock of celery, without any seeming repugnance.

"We know from history, that where any country has been remarkably infested with serpents, there the people have been screened by this secret.

"To leave ancient history, I can myself vouch, that all the black people in the kingdom of Sennaar, whether Funge or Nuba, are perfectly armed against the bite of either scorpion or vipers. They take the cerastes in their hands at all times, put them in their bosoms, and throw them to one another as children do apples or balls, without having irritated them by this usage so much as to bite. The Arabs have not this secret naturally, but from their infancy they acquire an exemption from the mortal consequences attending the bite of these animals, by chewing a certain root, and washing themselves (it is not anointing) with an infusion of certain plants in water."

From this account we should be apt to think, that these vipers really would not bite any who were thus armed against their poison; especially as he adds, that he "constantly observed, that the viper, however lively before, upon being seized by any of these barbarians, seemed as if taken with sickness and feebleness, frequently shut his eyes, and never turned his mouth towards the arm of the person who held him." Yet in another place, speaking of the activity of the cerastes, he says, "I saw one of them at Cairo, in the house of Julian and Rossa, crawl up the side of a box in which there were many, and there lie still, as if hiding himself, till one of the people who brought them to us came near him; and though in a very disadvantageous posture, sticking as it were perpendicularly to the side of the box, he leaped near the distance of three feet, and fastened between the man's fore-finger and thumb, so as to bring the blood. The fellow showed no signs of either pain or fear, and even kept him with us full four hours, without his applying any sort of remedy, or seeming inclined to do so."

It is of interest to see how these two accounts can be reconciled. If those who catch vipers are in danger of being bit by them after they are caught, certainly they must be so before, and then the whole relation becomes contradictory. Our author tells us, that these feats were performed for a season, by those who were artificially armed against the viper's poison, as well as those who had the exemption naturally; but though put in possession of the drugs, he never had the courage to make the experiment. That he should have made such a dreadful experiment on himself; no person in his senses would expect; but it is indeed very surprising, that he did not attempt by means of these medicines to arm some of the brute creatures, of the lives of which he was sufficiently prodigal, against the effects of that deadly poison by which so many of them perished. As surprising it is, that he did not try what effect the root or its decoction would have upon the serpents themselves; or that, though he says he had a small quantity of this extraordinary root by him, he gave neither drawing nor description of it.

Though it is impossible to reconcile the particulars of this account to one another, the general fact of the incantation is confirmed by the testimony of M. Savary.

This writer tells us, that he saw at the feast of Sidi Ibrahim, a troop of people, seemingly possessed, with naked arms and a fierce look, holding in their hands enormous serpents, which twined round their body, and endeavoured to escape. These Psylli, grasping them strongly by the neck, avoided the bite; and notwithstanding their hissing, tore them with their teeth, and ate them alive, while the blood streamed from their mouth.

PTARMIGAN. See Tetrao, Ornithology Index.

PETLEA, Shrubs-Trefoil; a genus of plants belonging to the tetrandria class; and in the natural method ranking with those of which the order is doubtful. See Botany Index.

PETRIS, a genus of plants belonging to the order of Siliceae, and to the Cryptogamia class. See Botany Index. The fructifications are in lines under the margin. There are 19 species; the most remarkable is the aquinilla, or common female fern. The root of this is viscid, nauseous, and bitterish; and like all the rest of the fern tribe, has a salt, maculaceous taste. It creeps under the ground in some rich soils to the depth of five or six feet, and is very difficult to be destroyed. Frequent mowing in pasture grounds, plentiful dunging in arable lands, but, above all, pouring urine upon it, are the most approved methods of killing it. It has, however, many good qualities to counterbalance the few bad ones. Fern cut while green, and left to rot upon the ground, is a good improver of land; for its ashes, if burnt, will yield the double quantity of salt that most other vegetables will. Fern is also an excellent manure for potatoes; for if buried beneath their roots, it never fails to produce a good crop.—Its astringency is so great, that it is used in many places abroad in dressing and preparing kid and chamois leather. In several places in the north, the inhabitants mow it green, and, burning it to ashes, make those ashes up into balls, with a little water, which they dry in the sun, and make use of them to wash their linen with instead of soap. In many of the Western Isles the people gain a very considerable profit from the sale of the ashes to soap and glass makers. In Clenenig in Inverness-shire, and other places, the people thatch their houses with the stalks of this fern, and fasten them down with ropes made either of birch-bark or heath. Sometimes they use the whole plant for the same purpose, but that does not make so durable a covering. Swine are fond of the roots, especially if boiled in their wash. In some parts of Normandy we read that the poor have been reduced to the miserable necessity of mixing them with their bread. And in Siberia, and some other northern countries, the inhabitants brew them in their ale, mixing one-third of the roots to two-thirds of malt. The ancients used the root of this fern, and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds, arising from obstructions of the viscera and the spleen. Some of the moderns have given it a high character in the same intentions, but it is rarely used in the present practice. The country people, however, still continue to retain some of its ancient uses; for they give the powder of it to destroy worms, and look upon a bed of the green plant as a sovereign cure for the rickets in children.

PTEROCAIPUS, a genus of plants belonging to...
the diademphila class; and in the natural method ranking under the 32d order, Papilionaceae. See Botany Index. There are four species, viz. 1. Draca; 2. Ecostaphyllum; 3. Lunatus; and, 4. Santalium. This last is by some referred to the genus Santalum. It is called red saunders; and the wood is brought from the East Indies, in large billets, of a compact texture, a dull red, almost blackish colour on the outside, and a deep brighter red within. This wood has no manifest smell, and little or no taste. It has been commended as a mild astringent, and a corroboration of the nervous system; but these are qualities that belong only to the yellow sort.

The principal use of red saunders is as a colouring drug; with which intention it is employed in some formulae, particularly in the tinctura lavandulae composita. It communicates a deep red to rectified spirit, but gives no tinge to aqueous liquors; a small quantity of the resin, extracted by means of spirit, produces a large one of fresh spirit of an elegant blood-red. There is scarcely any oil, that of lavender excepted, to which it communicates its colour. Geoffrey and others take notice, that the Brazil woods are sometimes substituted for red saunders; and the college of Brussels are in doubt whether all that is sold among them for saunders be not really a wood of that kind. According to the account which they have given, their saunders is certainly the Brazil wood; the distinguishing character of which is, that it imparts its colour to water.

PTEROCEOCEUS, a species of plant belonging to the genus Calligonum. See Calligonum, Botany Index.

PTERONIA, a genus of plants belonging to the monodelphia class; and in the natural method ranking under the 37th order, Cistuminae. See Botany Index.

PTINUS, a genus of insects belonging to the order of coleoptera. See Entomology Index.

PTISAM, in properly barley decorticated, or deprived of its hulls, by beating in a mortar, as was the ancient practice; though the cooling of the liquor is obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice-root, is what at present goes by the name of pitaan; and to render it laxative, some add a little seeds or other ingredient of the same intention.

PTOLEMAIC System of Astronomy, is that invented by Claudius Ptolemaeus. See Ptolemy, Claudius.

PTOLEMAIS, in Ancient Geography; the port of Arisinoe, situated on the west branch of the Nile, which conveys to form the island called Nomos Heracleotes, to the south of the vertex of the Delta.

PTOLEMAIS, (Strabo); the largest and most considerable town of the Thebais, or Higher Egypt, and in nothing short of Memphis; governed in the manner of a Greek republic; situated on the west side of the Nile, almost opposite to Coptos. This town, which was built by Ptolemy Philadelphia, is now known by the name of Ptolemais. The walls and gates are still entire, and there are a vast number of Greek inscriptions, but only a few columns of the portico remain. There is likewise an Ionic temple done in the most ancient manner of executing that order, of which Mr Bruce took a drawing, which is preserved in the king's collection.

Another, of Cyrenaica, anciently called Barca. A Ptolemaic of the Trogodytis, surnamed Epithera, from the chase of wild beasts, as elephants; lying in the same parallel with Meroe (Staba); on the Arabian gulf (Pliny); 4820 stadia to the south of Berenice. A fourth, of Galilee, anciently called Aca, or Acon; made a Roman colony under the emperor Claudius (Pliny). A fifth of Phrygia; situated near the river Mara, on the borders of Cilicia Aspera.

PTOLEMY Soter, or Lagus, king of Egypt, a renowned warrior, and an excellent prince; he established an academy at Alexandria, and was himself a man of letters. Died 284 B.C. aged 92.

PTOLEMY Philadelphia, his second son, succeeded him to the exclusion of Ptolemy Ceraunus. He was renowned as a conqueror, but more revered for his great virtues and political abilities. He established and augmented the famous Alexandrian library, which had been begun by his father. He greatly increased the commerce of Egypt, and granted considerable privileges to the Jews, from whom he obtained a copy of the Old Testament, which he caused to be translated into Greek, and deposited in his library. This is supposed to have been the version called the Septuagint. He died 246 years B.C. aged 64.

PTOLEMY Ceraunus, the elder brother, fled to Seleucus king of Macedon, who received him hospitably; in return for which he assassinated him, and usurped his crown. He then invited Arsinoe, who was his widow and his own sister, to share the government with him; but as soon as he got her in his power, he murdered her and her children. He was at length defeated, killed, and torn limb from limb by the Gauls, 279 B.C.

PTOLEMY, Claudius, a celebrated mathematician and astrologer, was born at Pelusium, and surnamed by the Greeks Most Divine and Most Wise. He flourished at Alexandria in the second century, under the reigns of Adrian and Marcus Aurelius, about the 138th year of the Christian era. There are still extant his Geography, and several learned works on astronomy. The principal of which are, 1. De Astronomia: 2. De Indiciis Astronomicis: 3. Planisphaerium. His system of the world was for many years adopted by the philosophers and astronomers; but the learned have rejected it for the system of Copernicus. See Astronomy, No. 16.

PTIALISM, in Medicine, a salivation, or frequent and copious discharge of saliva. The word is Greek, formed from πτιαλοι, "to spit."

PUBERTY, denotes the age at which the person is capable of procreating or begetting children. See Man.

PUBERTY, in Law, is fixed at the age of 12 in females, and 14 in males; after which they are reckoned to be fit for marriage. But as to crimes and punishments, the age of puberty is fixed at 14 in both sexes.

PUBES, in Anatomy, denotes the middle part of the hypogastric region in men or women, lying between the two inguina or groins.

Section of the Pubes. See Midwifery and Stomatian Operations.

Pubes, in Botany, the hair or down on the leaves of some plants. See Hair.

PUBLICAN, among the Romans, one who farmed the taxes and public revenues.

PUBLICATION,
PUBLICATION, the art of making a thing known to the world; the same with promulgation.

PUBLIUS SYRUS, a Syrian mimic poet, who flourished about 44 years before Christ. He was originally a slave sold to a Roman patrician, called Domitius, who brought him up with great attention, and gave him his freedom when of age. He gained the esteem of the most powerful men at Rome, and reckoned Julius Cæsar among his patrons. He soon eclipsed the poet Laberius, whose burlesque compositions were in general esteem. There remains of Publius a collection of moral sentences, written in iambics, and placed in alphabetical order.

OAK ProcERON, a name given by naturalists to a very remarkable species of animal of the pucerons kind. They bury themselves in the crevices of the oak and some other trees, and getting into the crevices, where the bark is a little separated from the wood, they live at ease, and feed on their fill, without being exposed to their common enemies. They are larger than the other pucerons, the winged ones being nearly as large as a common house fly, and those without wings are also larger than any other species of the same genus. The winged ones are black, and the others of a coffee colour. Their trunk is twice the length of their bodies, and, when walking, it is carried straight along the belly, trailing behind it with the point up. When the creature has a mind to suck a part of the tree that is just before it, it draws up and shortens the trunk, till it brings it to a proper length and direction; but when it sucks in the common way, it crawls upon the inner surface of the bark, and the turned up end of the trunk, which resembles a tail, fixes itself against the wood that is behind it, or contiguous to its back, and sucks there. The extremity of this trunk holds so fast by the wood, that when it is pulled away, it frequently brings a small piece of the wood away with it.

The ants are as fond of these as of the other species of pucerons, and that for the same reason, not feeding upon them, but on their dung, which is a liquid matter of a sweet taste, and is the natural juice of the tree, very little altered. These creatures are the surest guides where to find this species of puceron; for if we at any time see a number of these crawling up an oak to a certain part, and there creeping into the crevices of the bark, we may be assured that in that place there are quantities of these oak pucerons. The ants are so extremely fond of the juices of the tree, when prepared for them by passing through the body of this animal, that when the puceron has a drop not yet evacuated, but hanging only in part out at the passage, an ant will often seize on it there.

PUCERONS, Vine-fretters, or Plant-lice. See APHIS.

PuDenDa, the parts of generation in both sexes.

See Anatomy, No. 107 and 108.

PUERILITY, in discourse, is defined by Longinus to be a thought which, by being too far fetched, becomes flat and insipid. Puerility, he adds, is the common fault of those who affect to say nothing but what is brilliant and extraordinary.

Puffsendorf, Samuel de, was born in 1631 at Flech, a little village in Mâine, a province in Upper Saxony; and was son of Elias Puffendorf, minister of that place. After having made great progress in the sciences at Leipzig, he turned his thoughts to the study of the public law, which in Germany consists of the knowledge of the rights of the empire over the princes and states of which it is composed, and those of the princes and states with respect to each other. But though he used his utmost efforts to distinguish himself, he despised those pompous titles which are so much sought for at universities, and never would take the degree of doctor. He accepted the place of governor to the son of M. Coyet, a Swedish nobleman, who was then ambassador from Sweden to the court of Denmark. For this purpose he went to Copenhagen, but continued not long at ease there; for the war being renewed some time after between Denmark and Sweden, he was seized with the whole family of the ambassador. During his confinement, which lasted eight months, as he had no books, and was allowed to see no person, he amused himself by meditating on what he read in Grotius's treatise De Jure Belli et Pacis, and the political writings of Mr. Hobbes. Out of these he drew up a short system, in which he added some thoughts of his own, and published it at the Hague in 1660, under the title of DEnUenta Jurisprudentiae Universalis. This recommended him to the elector Palatine, who invited him to the University of Heidelberg, where he founded in his favour a professorship of the law of nature and nations, which was the first of that kind established in Germany. Puffendorf remained at Heidelberg till 1673, when Charles XI. of Sweden gave him an invitation to be professor of the law of nature and nations at Lund; which place the elector Palatine reluctantly allowed him to accept. He went thither the same year; and after that time his reputation greatly increased. Some years after, the king of Sweden sent for him to Stockholm, and made him his historiographer, and one of his counsellors. In 1688, the elector of Brandenburg obtained the consent of his Swedish majesty, that he should come to Berlin, in order to write the history of the elector William the Great; and in 1694 made him a baron. But he died that same year of an inflammation in his feet, occasioned by cutting his nails; having attained his grand climacteric. Of his works, which are numerous, the following are the principal: 1. A Treatise on the Law of Nature and Nations, written in German; of which there is an English translation with Barbyear's Notes. 2. An Introduction to the History of the Principal States which at present subsist in Europe; written in German; which has been also translated into English. 3. The History of Sweden, from Gustavus Adolphus's expedition into Germany to the abdication of Queen Christina. 4. The History of Charles Gustavus, two volumes folio, &c.

Puffin. See ALCA, ORNITHOLOGY Index.

Puget, Peter Paul, one of the greatest painters and sculptors France ever produced, though but little noticed by their own writers, was born at Marseilles in 1623. In his youth he was the disciple of Roman, an able sculptor; and then went to Italy, where he studied painting and architecture. In painting he so well imitated the manner of Peter de Cortona, that this painter desired to see him, and entered into a friendship with him. In 1657, a dangerous disorder obliged him to renounce the pencil, and devote himself to sculpture; and his reputation causing him to be invited to Paris, he enjoyed a pension of 1200 crowns, as sculptor and director of the works relating to vessels and galleys.
galleys. He died at Marseilles in 1695, and has left a number of admirable statues behind him both in France and Italy.

PUGIL, in *Materia Medica*, such a quantity of flowers, seeds, or the like, as may be taken up between the thumb and two fore-fingers. It is reckoned the eighth part of the manipulus or handful.

PULEGICUM, or *Penny-Royal*. See *Mentha*, *Botany Index*.

PULEX, the *Flea*, in *Zoology*, a genus of insects belonging to the order of aptera. See *Entomology Index*.

By keeping fleas in a glass tube corked up at both ends, but so as to admit fresh air, their actions and manners may be observed. They are thus seen to lay their eggs, not all at once, but ten or twelve in a day, for several days successively; which eggs will be afterwards found to hatch successively in the same order. The flea may easily be dissected in a drop of water; and by this means the stomach and bowels, with their peristaltic motion, may be discovered very plainly, as also their testes and penis, with the veins and arteries, though minute beyond all conception. Mr. Leuenenboek affirms also, that he has seen innumerable animalcula, shaped like serpents, in the semen masculinum of a flea. This blood-thirsty insect, which fattens at the expense of the human species, prefers the more delicate skin of women; but prays neither upon epileptic persons, nor upon the dead or dying. It loves to nestle in the fur of dogs, cats, and rats. The nests of river-swallows are sometimes plentifully stored with them.

Fleas are apterous; walk but little, but leap to a height equal to 200 times that of their own body. This amazing motion is performed by means of the elasticity of their feet, the articulations of which are so many springs. Thus it eludes, with surprising agility, the pursuit of the person on whom it rests. Among the memorabilis of fleas, one, they say, has been seen to draw a small silver piece of ordnance to which it was fastened, the firing of the gun nowise daunting its intrepidity. The owner carried it about in a little box lined with velvet, every now and then placing it on her arm to let it feed; but winter put an end to the being of this martial flea. Another flea that became slave to an Englishman, had, for its daily and easy task, to drag its golden chain and padlock, of the weight of one grain. A third flea served as a thill-horse to an English artist, who had made an ivory coach and six, that carried a coachman and his dog between his legs, a po-stillion, two footmen, and four inside riders. At Strat fleas, bugs, and other voracious vermin, are in so great a venation, that they have an hospital endowed, where every night a poor fellow, for hire, suffers himself to be preyed upon. He is fastened naked on a bed, when the feast begins at his expence. In Turkey there is a similar foundation for decayed dogs; an institution less ridiculous than the other. Mercurial ointment bismuth, a fumigation with the leaves of penmyroyal, or fresh-gathered leaves of that plant sewed up in a bag, and laid in the bed, are remedies pointed out as destructive of fleas.

*Pulex Arboris*, in *Natural History*, the name given by Mr. Reasmar to a very large genus of small animals. They are a kind of half-winged creatures: they have granulated antennae; and some of them, in their most perfect state, have complete wings. These are distinguished from the others by the name of *musca-pulex,* or the winged *pulex*. See *Coccus*, *Entomology Index*.

*Pulex Aquaticus erectus* (monocolus pulex of Linnæus) is a species of the genus *Monoculus*; which see, under *Entomology Index*.

*Pulex-Eaters*, a name given by naturalists to a sort of worms frequently found on the leaves of trees, where they devour the animals called *pulex arboris*.

Of these there are several species, which owe their origin to the eggs of different creatures; for there are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, these are of different form and structure. Some are hexapodes, or ended with six feet; these belong to the beetle-tribe, and finally change into beetles like the parent animal from whose eggs they sprung. Others have no legs, and are produced from the eggs of flies of various kinds. And, finally, others are genuine caterpillars, though small; but these are the most rare of all.

The two general kinds are the hexapodes, or beetle-worms; and the apodes, or fly-worms. The fly which gives origin to the last of these is a four-winged one; and takes care always to deposit her eggs in a place where there are plenty of the pulices, usually on the stalk or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenseless. The stalks of the elder and woodbine are frequently found covered over with these pulices; and among them there may usually be found one or more of these destroyers feeding at will, sucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged fly, there is one of a two-winged wasp-fly, very destructive of these animals.

PULLEY, in *Mechanics*, one of the five mechanical powers. See *Mechanics*.

PULMO, the *Lungs*, in *Anatomy*. See *Anatomy Index*.

PULMONARIA, LUNGWORT, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 41st order, *Asperifolias*. See *Botany Index*.

PULO, the name of several Asiatic islands, in the Indian ocean, the principal of which only, it is said, is inhabited. It is denominated

*Pulo-Condore*, an island about 13 miles long and three broad, which was visited by Lord Macartney on his way to China. It has convenient anchoring places during either monsoon. Here his lordship's squadron came to anchor on the 17th of May. The bay is formed by four small islands approaching so near to each other, as to exhibit the appearance of meeting together in different points. They all seem to be the rude fragments of primitive mountains, which have been detached from the great continent in the lapse of ages. Condore lies in 8° 40' North Lat. and 105° 55' E. Long.

The English at one period had a settlement here, but being driven from it by some Malay soldiers in their pay, probably for some unjustifiable treatment, no Europeans, it is said, have resided in it ever since. When a party went on shore from Lord Macartney's squadron, they...
they were welcomed by the natives with much urbanity of manners, and conducted to the house of their chief. Their dress consisted chiefly of blue cotton garments hanging loosely about them; and their flat faces and noses seemed to denote that they were descended from the Chinese. A missionary being of the party, could not understand their language as they spoke it; but as soon as committed to writing it was perfectly intelligible to him. This led to the conclusion, that the inhabitants of Pulo-Condore were originally Cochín Chinese, who fled from their own country in consequence of their attachment to one of its sovereigns who had been dethroned by a number of his own subjects.

Here the squadron was to purchase provisions, and the people promised to have the proposed quantity in readiness, if possible, at the appointed time. Next morning, a party of pleasure went from the Hindostan to a small island near Pulo-Condore; but being apprehensive of an approaching storm, they made towards the ship with all convenient speed. The weather again becoming favourable, they set off for the island again, and were astonished, on their arrival, to find it wholly abandoned. In the principal cabin a letter was found, written in the Chinese language, expressing their terror at the arrival of such great ships and powerful persons; not being able to satisfy their demands as to cattle and other provisions, the poor inhabitants of Pulo-Condore having scarcely any to supply, they therefore fled to preserve their lives; declared themselves to be few in number, and very poor, but honest; and concluded with requesting the great people to have pity on them, as they had left their all behind, and earnestly implored them not to burn their cabins.

The generous English left them an intimation that they called merely for refreshment on fair and equitable terms, without harbouring against them any evil designs. They claimed a connection to a civilized nation, acted up to principles of humanity, by which they were prohibited from plundering or doing injury to others, who might have the misfortune to be fewer or weaker than themselves. No doubt the poor terrified inhabitants would be agreeably surprised to find, on their return, not only that all their tents were in perfect safety, but that nothing was either disturbed or removed, and a small present left to their chief in the principal dwelling.

PULO-Lingen, another island of the cluster mentioned above, is of some extent, though inferior in size to Pulo-Condore. It is chiefly remarkable for a mountain in its centre, terminating in a fork like Parnassus, but denominated by mariners the assæ ears. The people of Lord Macartney's squadron were constantly discovering new islands, many of which were clothed with verdure; some had lofty trees growing upon them; others were nothing but naked rocks, the resort of innumerable birds, and whitened with their dung.

PULU PENANG. See Prince of Wales's Island.

PULP, in Pharmacy, the fleshy and succulent parts of fruits extracted by infusion or boiling, and passed through a sieve.

PULPIT, an elevated place in a church, whence sermons are delivered. The French give the same name to a reading desk.

PULPITUM, in the Grecian and Roman theatres, was a place where the players performed their parts. It was lower than the scaenæ, and higher than the orchestra. It nearly answered to what we call the stage, as distinguished from the pit and galleries. Pulpitum was also a moveable desk or pulpit, from which disputants pronounced their dissertations, and authors recited their works.

PULSE, in the animal economy, denotes the beating or throbbing of the heart and arteries.

No doctrine has been involved in more difficulties than that of pulses; since, in giving a physiological account of them, physicians have espoused quite opposite sentiments; whilst some doubt whether the pulse is owing to the systole or diastole; as also, whether the motion of the heart and arteries is one and the same, for a moment of time.

With regard to motion, the pulses are reckoned only four; great and little, quick and slow. When quickness and greatness are joined together, it becomes violent; and when it is little and slow it is called a weak pulse. They are also said to be frequent and rare, equal and unequal; but these are not the essential affections of motion. Frequency and quickness are often confounded with each other. A pulse is said to be hard or soft, with regard to the artery, according as it is tense, renient, and hard, or flaccid, soft, and lax: for the disposition of the arteries contributes greatly to the change of the pulse; wherefore it sometimes happens, that the pulse in both arms is not alike, which is very common in a hemiplegia. Add to these a convulsive pulse, which does not proceed from the blood, but from the state of the artery; and is known by a tremulous subsultory motion, and the artery seems to be drawn upwards: this, in acute fevers, is the sign of death; and is said to be the pulse in dying persons, which is likewise generally unequal and intermitting. A great pulse shows a more copious influx of the blood to the heart, and from thence into the arteries: a little pulse the contrary.

The pulses of persons differ according to the largeness of the heart and vessels, the quantity and temperature of the blood, the elastic force of the canals; as also with regard to the sex, age, season, air, motion, food, sleep, watchings, and passions of the mind. The pulse is larger and more quick in men than in women; in the bilious and sanguineo-bilious, than in the phlegmatic and melancholic. Those who are lean, with tense fibres, and large vessels, have a greater and a stronger pulse, than those that are obese, with lax fibres and small vessels; whence they are more healthy, robust, and apt for labour. In children, the pulse is quick and soft; in adults greater and more violent. In the old, it is commonly great, hard, and slow. Labour, motion, and exercise of the body, increase the circulation of the blood, the excretions, and particularly respiration; rest renders the circulation slow and weak; intense speaking increases the circulation, and consequently renders the pulse large and quick. In watching, the pulse is more evident; in sleep, more slow and languid. After drinking hot things, such as coffee and tea, or hot bath-waters, as well as after meals, the pulse vibrates more quick. But nothing produces a greater change in the pulse than affections of the mind: in terror, it is unequal, small, and contracted: in joy, frequent and great; in anger, quick and hard; in sadness, slow, small, deep, and weak; and in intense study, languid and weak. With regard to the air, when, after the predominancy
predominance of a west or south wind, it becomes north or east, the pulse is stronger and larger; as also when the quicksilver rises in the barometer. But when the atmosphere is dense, humid, rainy, with a long south wind; as also where the life is sedentary, the sleep long, and the season autumnal, the pulse is languid and small, and the perspiration decreased. In May it is great, and sometimes violent; in the middle of summer, quick but weak; in the autumn, slow, soft, and weak; in the winter, hard and great. A drastic purge and an emetic render the pulse hard, quick, and weak, with loss of strength; chalybeates, and the bark, render it great and robust; and the complexon lively; volatiles amplify and increase the pulse; acids and nitrous remedies refrigerate the body, and appease the pulse; opiates and the like render it small and weak, and decrease the elasticity of the solids; and poisons render it small, contracted, and hard. When the quantity of the blood is too great, bleeding raises the pulse.

Pulse, is also used for the stroke with which any medium is affected by the motion of light, sound, &c. through it.

Sir Isaac Newton demonstrates, that the velocities of the pulses in an elastic fluid medium (whose elasticity is proportionable to its density) are in a ratio compounded of half the ratio of the elastic force directly, and half the ratio of the density inversely; so that in a medium whose elasticity is equal to its density, all pulses will be equally swift.

Pulse, in Botany, a term applied to all those grains or seeds which are gathered with the hand; in contradistinction to corn, &c. which are reaped, or mowed; or, it is the seed of the leguminous kind of plants, as beans, vetches, &c.; but is by some used for artichokes, asparagus, &c.

PULTENY, WILLIAM, the famous opponent of Sir Robert Walpole in parliament, and afterward earl of Bath, was descended from one of the most ancient families in the kingdom, and was born in 1682. Being well qualified in fortune, he early procured a seat in the house of commons, and distinguished himself as a warm partisan against Queen Anne's ministry; whose errors he had sagacity to detect, and spirited eloquence to expose. When King George I. came to the throne, Mr. Pulteney was made secretary at war, and soon after cofferer to the king's household; but the good understanding between this gentleman and Sir Robert Walpole, who then acted as prime minister, was interrupted in 1725, on a suspicion that Walpole was desirous of extending the limits of prerogative, and of promoting the interests of Hanover, to the prejudice of those of Britain. His opposition to Sir Robert was indeed carried to such indiscriminate lengths, that some have been of opinion he often acted against measures beneficial to the public, merely from personal motives. It would be impracticable here to trace his parliamentary conduct: so it must suffice to observe in general, that he became so obnoxious to the crown, that in 1731 the king called for the council-book, and with his own hand struck out his name from the list of privy-counsellors; a proceeding that only served to inflame his resentment and increase his popularity. Thus he still continued to attack the minister with a severity of eloquence and sarcasm that worsted every antagonist; so that Sir Robert was heard to declare, he dreaded that man's tongue more than another man's sword. At length, when Walpole found the place of prime minister no longer tenable, and resigned in 1741, among other promotions Mr Pulteney resumed his place in the privy-council, and was created earl of Bath; a title purchased at the expense of that popularity which afterward he naturally enough affected to contemplate. In 1763, toward the close of the war, he published A Letter to two Great Men, recommending proper articles to be insisted on in a treaty of peace; which, though the writer was then unknown, was greatly applauded, and went through several impressions. He died in 1764; and as his only son died before him, the title became extinct.

PULVERIZATION, the art of pulverizing, or reducing a dry body into a fine powder; which is performed in friable bodies by pounding or beating them in a mortar, &c.; but to pulverize malleable ones, other methods must be taken. To pulverize lead, or tin, the method is this: Rub a round wooden box all over the inside with chalk; pour a little of the melted metal nimbly into the box; when shutting the lid, and shaking the box briskly, the metal will be reduced to powder.

PUMEX, the Pumice-stone. See Mineralogy Index.

Pumice-stone is used in some mechanical arts; as for rubbing and smoothing the surface of metals, wood, pasteboard, and stone; for which it is well fitted by reason of its harsh and brittle texture; thus scouring and carrying off the little inequalities from the surfaces just mentioned.

PUMICE-stone. See Mineralogy Index.

PUMP, an hydraulic machine for raising water by means of the pressure of the atmosphere. It would be an entertaining and not an uninteresting piece of information to learn the progressive steps by which the ingenuity of man has invented the various methods of raising water. A pump must be considered as the last step of this progress. Common as it is, and overlooked even by the curious, it is a very abstruse and refined invention. Nothing like it has been found in any of the rude nations whom the restless spirit of the Europeans has discovered, either in the new continent of America, or the islands of the Pacific ocean. Nay, it was unknown in the cultivated empire of China at the time of our arrival there by sea; and it is still a rarity everywhere in Asia, in places unfrequented by the Europeans. It does not appear to have been known to the Greeks and Romans in early times; and perhaps it came from Alexandria, where physical and mathematical science was much cultivated by the Greek school under the protection of the Ptolemies. The performances of Ctesibius and Hero are spoken of by Pliny and Vitruvius as curious novelties (A). It is perhaps not difficult to trace the steps by which those mechanicians were led to

(A) In the early Greek writings, it does not appear that the words ἕλπλοσ, ἕλπλος, ἑπλαμ, &c. were used to express anything like what we call a pump. In all these passages the words either express generally the drawing of water,
to the invention. The Egyptian wheel was a common machine all over Asia, and is still in use in the remotest corners, and was brought by the Saracens into Spain, where it is still very common under its ancient name noria. The Danish missionaries found in a remote village in the kingdom of Siam the immediate off-spring of the noria (Lettres Édifiantes et Curieuses). It was a wheel turned by an ass, and carrying round, not a string of earthen pots, but a string of wisps of hay, which it drew through a wooden trunk. This rude chain-pump was in frequent use for watering the rice fields. It is highly probable that it is of great antiquity, although we have no record of its being mentioned by any of the Greek or Roman writers. The Arabs and Indians were nothing less than innovators; and we may suppose with great safety, that what arts we now find among them they possessed in very remote periods. Now the step from this to the pump is but small, though it is nice and refined; and the forcing pump of Ctesibius is the easiest and most natural.

Let AB (fig. 1.) be the surface of the water in the well, and D the height where it is to be delivered. Let DC be a long wooden trunk, reaching as deep under water as possible. Let the rope EE be fitted with its knot of hay F. When it is drawn up through the trunk, it will bring up along with it all the water lying between C and A, which will begin to run out by the spout D as soon as the knot gets to G, as far below D as G is below A. All this is very obvious: and it required but little reflection to be assured, that if F was let down again, or pushed down, by a rod instead of a rope, it would again perform the same office. Here is a very simple pump. And if it was ever put in practice, it behoved to show the supporting power of the atmosphere, because the water would not only be lifted by the knot, but would even follow it. The imperfection of this pump behaved to appear at first sight, and to suggest its remedy. By pushing down the knot F, which we shall henceforth call the piston, all the force expended in lifting up the water between A and G is thrown away, because it is again let down. A valve G, at the bottom would prevent this. But then there must be a passage made for the water by a lateral tube KBD (fig. 2.) And if this be also furnished with a valve H, to prevent its losing the water, we have the pump of Ctesibius, as sketched in fig. 2. The valve is the great refinement: but perhaps even this had made its appearance before in the noria. For, in the more perfect kinds of these machines, the pots have a stop or valve in their bottom, which hangs open while the pot descends with its mouth downwards, and then allows it to fill readily in the cistern: whereas, without the valve, it would occasion a double load to the wheel. If we suppose that the valve had made its appearance so early, it is not improbable that the common pump sketched in fig. 3. was as old as that of Ctesibius. In this place we shall first give a short description of the chief varieties of these engines, considering them in their simplest form, and we shall explain in very general terms their mode of operation. We shall then give a concise and popular theory of their operation, furnishing principles to direct us in their construction; and we shall conclude with the description of a few peculiarities which may contribute to their improvement or perfection.

There are but two sorts of pumps which essentially differ; and all the varieties that we see are only modifications of these. One of these original pumps has a solid piston; the other has a piston with a perforation and a valve. We usually call the first a FORCING PUMP, and the second a LIFTING OF SUCKING PUMP.

Fig. 2. is a sketch of the forcing pump in its most forcing simple form and situation. It consists of a hollow cylinder, the cylinder AD (fig. 3.) called the WORKING BARREL, open at both ends, and having a valve G at the bottom, opening upwards. This cylinder is filled by a solid piston EF, covered externally with leather or tow, by which means it fits the box of the cylinder exactly, and allows no water to escape by its sides. There is a pipe KHD, which communicates laterally with this cylinder, and has a valve at some convenient place H, as near as possible to its junction with the cylinder. This valve also opens upwards. This pipe, usually called the rising pipe, or main, terminates at the place D, where the water must be delivered.

Now suppose this apparatus set into the water, so its mode of that the upper end of the cylinder may be under or even operated, with the surface of the water AB; the water will open the valve G, and after filling the barrel and lateral pipe, will also open the valve H, and at last stand at an equal height within and without. Now let the piston be put in at the top of the working barrel, and thrust down to K. It will push the water before it. This will shut the valve G, and the water will make its way through the valve H, and fill a part B of the rising pipe, equal to the internal capacity of the working barrel. When this downward motion of the piston ceases, the valve H will fall down by its own weight and shut this passage. Now let the piston be drawn up again: The valve H hinders the water in the rising pipe from returning into the working barrel. But now the valve G is opened by the pressure of the external water, and the water enters and fills the cylinder as the piston rises. When the piston has got to the top, let it be thrust down again: The valve G will again be shut, and the water will be forced through the passage at H, and rise along the main, pushing before it the water already there, and will now have its surface at L. Repeating this operation, the water must at last arrive at D, however

"Plate xcvii.

Fig. 3.

Ctesibius's Pump.

Fig. 3.

Ctesibius's Pump.
ever remote, and the next stroke would raise it to $e$; so that during the next rise of the piston the water in $e D$ will be running off by the spout.

The effect is the same whatever be the position of the working barrel, provided only that it be under water. It may lie horizontally or sloping, or it may be with its mouth and piston rod undermost. It is still the same forcing pump, and operates in the same manner and by the same means, viz., the pressure of the surrounding water.

The external force which must be applied to produce this effect is opposed by the pressure exerted by the water on the opposite face of the piston. It is evident, from the common laws of hydrostatics, that this opposing pressure is equal to the weight of a pillar of water, having the face of the piston for its base, and the perpendicular height $d A$ of the place of delivery above the surface of the water $A B$ in the cistern for its height.

The form and dimensions of the rising pipe are indifferent in this respect, because heavy fluids press only in the proportion of their perpendicular height. Observe that it is not $d F$, but $d A$, which measures this pressure, which the moving force must balance and surmount. The whole pressure on the under surface $F / F$ of the piston is indeed equal to the weight of the pillar $d F / 3$; but part of this is balanced by the water $A F / a$. If indeed the water does not get into the upper part of the working barrel, this compensation does not obtain. While we draw up the piston, this pressure is removed, because all communication is cut off by the valve $H$, which now bears the whole pressure of the water in the main. Now, the ascent of the piston is even assisted by the pressure of the surrounding water. It is only during the descent of the piston that the external force is necessary.

Observe that the measure now given of the external force is only what is necessary for balancing the pressure of the water in the rising pipe. But in order that the pump may perform work, it must surmount this pressure, and cause the water to issue at $D$ with such a velocity that the required quantity of water may be delivered in a given time. This requires force, even although there were no opposing pressure; which would be the case if the main were horizontal. The water fills it, but it is at rest. In order that a gallon, for instance, may be delivered in a second, the whole water in the horizontal main must be put in motion with a certain velocity. This requires force. We must therefore always distinguish between the state of equilibrium and the state of actual working. It is the equilibrium only that we consider at present; and no more is necessary for understanding the operation of the different species of pumps. The other force is of much more intricate investigation, and will be considered by itself.

The simplest form and situation of the lifting pump is represented by the sketch fig. 3. The pump is immersed in the cistern till both the valve $G$ and piston $F$ are under the surface $A B$ of the surrounding water. By this means the water enters the pump, opening both valves, and finally stands on a level within and without.

Now draw up the piston to the surface $A$. It must lift up the water which is above it (because the valve in the piston remains shut by its own weight); so that its surface will now be at $e$, $A D$ being made equal to $A F$. In the mean time, the pressure of the surrounding water forces it into the working barrel, through the valve $G$; and the barrel is now filled with water. Now, let the piston be pushed down again; the valve $G$ immediately shuts by its own weight, and in opposition to the endeavours which the water in the barrel makes to escape this way. This attempt to compress the water in the barrel causes it to open the valve $F$ in the piston; or rather, this valve yields to our endeavour to push the piston down through the water in the working barrel. By this means we get the piston to the bottom of the barrel; and it has now above it the whole pillar of water reaching to the height $a$. Drawing up the piston to the surface $A$ a second time, must lift this double column along with it, and its surface now will be at $b$.

The piston may again be thrust down through the water in the barrel, and again drawn up to the surface, which will raise the water to $c$. Another repetition will raise it to $d$; and it will now show itself at the intended place of delivery. Another repetition will raise it to $e$; and while the piston is now descending to make another stroke, the water in $e d$ will be running off through the spout $D$; and thus a stream will be produced, in some degree continual, but very unequal. This is inconvenient in many cases: thus, in a pump for domestic uses, such a hobbling stream would make it very troublesome to fill a bucket. It is therefore usual to terminate the main by a cistern $L M N O$, and to make the spout small.

By this means the water brought up by the successive strokes of the piston rises to such a height in this cistern, as to produce an efflux by the spout nearly equable. The smaller we make the spout $D$ the more equable will be the stream; for when the piston brings up more water than can be discharged during its descent, some of it remains in the cistern. This, added to the supply of next stroke, makes the water rise higher in the cistern than it did by the preceding stroke. This will cause the efflux to be quicker during the descent of the piston, but perhaps not yet sufficiently quick to discharge the whole supply. It therefore rises higher next stroke; and at last it rises so high, that the increased velocity of efflux makes the discharge precisely balance the supply. Now, the quantity supplied in each stroke is the same, and occupies the same room in the cistern at top; and the surface will sink the same number of inches during the descent of the piston, whether that surface has been high or low at the beginning. But because the velocities of the efflux are as the square roots of the heights of the water above the spout, it is evident that a sink of two or three inches will make a smaller change in the velocity of efflux when this height and velocity are great. This seems but a trifling observation; but it serves to illustrate a thing to be considered afterwards, which is important and abstruse, but perfectly similar to this.

It is evident, that the force necessary for this operation must be equal to the weight of the pillar of water $d A a D$, if the pipe be perpendicular. If the pump be standing aslape, the pressure which is to be balanced is still equal to the weight of a pillar of water of this perpendicular height, and having the surface of the piston for its base.

Such is the simplest, and, we may add, by far the best, form of the forcing and lifting pumps; but it is not the most usual. Circumstances of convenience, economy, and more frequently of fancy and habit, have caused the pump-makers to deviate greatly from this form. It is not usual to have the working barrel in the
the water; this, especially in deep wells, makes it of
difficult access for repairs, and requires long piston rods.
This would not do in a forcing pump, because they would
bend.

We have supposed, in our account of the lifting pump,
that the rise of the piston always terminated at the sur-
face of the water in the cistern. This we did in order
that the barrel might always be filled by the pressure of
the surrounding water. But let us suppose that the rise
of the piston does not end here, and that it is gradually
drawn up to the very top: it is plain that the pressure
of the atmosphere is by this means taken off from the
water in the pipe (see PNEUMATICS), while it remains
pressing on the water of the cistern. It will therefore
cause the water to follow the piston as it rises through
the pipe, and it will raise it in this way 33 feet at a me-
median. If, therefore, the spout D is not more than 33
feet above the surface of the water in the cistern, the
pipe will be full of water when the piston is at D. Let
it be pushed down to the bottom; the water will remain
in the pipe, because the valve G will shut: and thus
we may give the piston a stroke of any length not ex-
ceeding 33 feet. If we raise it higher than this, the
water will not follow; but it will remain in the pipe,
to be lifted by the piston, after it has been pushed down
through it to the bottom.

It may be conceived better perhaps in this way.
When the piston was under the surface of the water in
the cistern, it was equally pressed on both sides, both
by the water and atmosphere. The atmosphere exerted its
pressure on it by the intervention of the water; which
being, to all sense, a perfect fluid, propagates every
external pressure undiminished. When the piston is drawn
up above the surface of the pit-water, the atmosphere
continues to press on its upper surface with its whole
weight, through the intervention of the water which
lies above it; and its pressure must therefore be added
to that of the incumbent water. It also continues to
press on the under surface of the piston by the inter-
vention of the water; that is, it presses this water to the
piston. But, in doing this, it carries the weight of
this water which it is pressing on the piston. The pres-
sure on the piston therefore is only the excess of the
whole pressure of the atmosphere above the weight of
the column of water which it is supporting. There-
fore the difference of atmospheric pressure on the upper
and under surfaces of the piston is precisely equal to the
weight of the column of water supported in the pipe by
the air. It is not, however, the individual weight of
this column that loads the piston; it is the part of the
pressure of the atmosphere on its upper surface; which
is not balanced by its pressure on its under surface.

In attempting, therefore, to draw up the piston, we
have to surmount this unbalanced part of the pressure
of the atmosphere, and also the weight of the water
which lies above the piston, and must be lifted by it:
and thus the whole opposing pressure is the same as
before, namely, the weight of the whole vertical pillar
reaching from the surface of the water in the cistern to
the place of delivery. Part of this weight is immedi-
ately carried by the pressure of the atmosphere; but, in
lieu of it, there is an equal part of this pressure of the
atmosphere abstracted from the under surface of the
piston, while its upper surface sustains its whole pressure.

So far, then, these two states of the pump agree. Other cir-
stances and the same circumstances not very obvious which to at-
2
must be attended to, in order that the pump may deliv-
per any water at the spout D. This requires, therefore,
a serious examination.

Let the fixed valve G (fig. 4) be supposed at the Fig.
surface of the cistern water. Let Mm be the lowest,
and Nn the highest, positions of the piston, and let
HA = a be the height of a column of water equiponde-
ent with the atmosphere.

When the pump is filled, not with water, but with
air, and the piston is in its lowest position, and all in
equilibrium, the internal air has the same density and

elasticity
Pump elasticity with the external. The space \( MA am \), therefore, contains air of the common density and elasticity. These may be measured by \( h \), or the weight of a column of water whose height is \( h \). Now, let the piston be drawn up to \( N n \). The air which occupied the space \( MA am \) now occupies the space \( NA an \), and its density is now \( NA an \). Its elasticity is now diminished, being proportional to its density (see *Pneumatics*), and no longer balances the pressure of the atmosphere. The valve \( G \) will therefore be forced up by the water, which will rise to some height \( SA \). Now let the piston again descend to \( MM \). It cannot do this with its valve shut; for when it comes down so far as to reduce the air again to its common density, it is not yet at \( M \), because the space below it has been diminished by the water which got into the pipe, and is retained there by the valve \( G \). The piston valve, therefore, opens by the air which we thus attempt to compress, and the superfluous air escapes. When the piston has got to \( M \), the air is again of the common density, and occupies the space \( MS sm \). Now draw the piston up to \( N \). The air will expand into the space \( NS sn \), and its density will be reduced to \( MS sm \), and its elasticity will no longer balance the pressure of the atmosphere, and more water will enter, and it will rise higher. This will go on continually. But it may happen that the water will never rise so high as to reach the piston, even though not 33 feet above the water in the cistern: For the successive diminutions of density and elasticity are a series of quantities that decrease geometrically, and therefore will have a limit. Let us see what determines this limit.

At whatever height the water stands in the lower part of the pipe, the weight of the column of water \( SA as \), together with the remaining elasticity of the air above it, exactly balances the pressure of the atmosphere (see *Pneumatics*, No 108). Now the elasticity of the air in the space \( NS sn \) is equal to \( h \times NS sn \). Therefore, in the case where the limit obtains, and the water rises no farther, we must have \( h = AS + h - AS = HS \), and \( NS sn \).

Because the column is of the same diameter throughout,

\[ h = AS + h - AS = HS \]

Then \( MS = HA : HS \), and \( NS - MS : NS = HA - HS \), \( HA \), or \( NM = NS \times AS \), \( AH \), and \( NM \times HA = NS \times AS \). Therefore, if \( AN \), the distance of the piston in its highest position from the water in the cistern, and \( NM \) the length of its stroke, be given, there is a certain determined height \( AS \) to which the water can be raised by the pressure of the air: For \( AH \) is a constant quantity; and therefore when \( MN \) is given, the rectangle \( AS \times SN \) is given. If this height \( AS \) be less than that of the piston in its lowest position, the pump will raise no water, although \( AN \) may be less than \( AH \). Yet the same pump will raise water very effectually, if it be first of all filled with water; and we have seen professional engineers much puzzled by this capricious failure of their pumps. A little knowledge of the principles would have prevented their disappointment.

To insure the delivery of water by the pump, the stroke must be such that the rectangle \( MN \times AH \) may be greater than any rectangle that can be made of the parts of \( AN \), that is, greater than the square of half \( AN \). Or, if the length of the stroke be already fixed by other circumstances, which is a common case, we must make \( AN \) so short that the square of its half, measured in feet, shall be less than 33 times the stroke of the piston.

Suppose that the fixed valve, instead of being at the surface of the water in the cistern, is at \( S \), or anywhere between \( S \) and \( A \), the performance of the pump will be the same as before: But if it be placed anywhere above \( S \), it will be very different. Let the fixed valve be at \( T \). It is plain that when the piston is pushed down from \( N \) to \( M \), the valve at \( T \) prevents any air from getting down; and therefore, when the piston is drawn up again, the air contained in the space \( MT tm \) will expand into the space \( NT tn \), and its density will be \( MS \), which expresses the density of the air which was left in the space \( TS st \) by the former operations.—The air, therefore, in \( TS st \) will also expand, will open the valve, and now the water will rise above \( S \). The proportion of \( SN \) to \( NT \) may be evidently such that the water will even get above the valve \( T \). This diminishes the space \( NT tn \); and therefore, when the piston has been pushed down to \( M \), and again drawn up to \( N \), the air will be still more rarefied, and the water will rise still higher. The foregoing reasoning, however, is sufficient to show that there may still be a height which the water will not pass, and that this height depends on the proportion between the stroke of the piston and its distance from the water in the cistern. We need not give the determination, because it will come afterwards in combination with other circumstances. It is enough that the reader sees the physical causes of this limitation: And, lastly, we see plainly that the utmost security will be given for the performance of the pump, when the fixed valve is so placed that the piston, when in its lowest position, shall come into contact with it. In this case, the rarefaction of the air will be the complete, and it will be possible; and, if there were no space left between the piston and valve, and all were perfectly air-tight, the rarefaction would be complete, and the valve might be anything less than 33 feet from the surface of the water in the cistern.

But this perfect contact and tightness is unattainable; and though the pump may be full of water, its continual downward pressure causes it to filtrate slowly through every crevice, and the air enters through every pore, and even disengages itself from the water, with which a considerable portion had been chemically combined. The pump by this means loses water, and it requires several strokes of brisk working to fill it again: and if the leathers have become dry, so much admission may be given to the air, that the pump will not fill itself with water by any working. It is then necessary to pour water into it, which shuts up these passages, and sets all to rights again. For these reasons it is always prudent to place the fixed valve as low as other circumstances will permit, and to make the piston rod of such a length, that when it is at the bottom of its stroke it shall be almost in contact with the valve. When
we are not limited by other circumstances, it is evident
that the best possible form is to have both the piston and
the fixed valve under the surface of the water of the cistern.
In this situation they are always wet and air-tight.
The chief objection is, that by this disposition they
were not easily come at when needing repair. This
is a material objection in deep mines. In such situations,
therefore, we must make the best compensation of different
circumstances that we can. It is usual to place the
fixed valve at a moderate distance from the surface of
the water, and to have a hole in the side of the pipe, by
which it may be got out. This is carefully shut up by
a plate firmly screwed on, with leather or cement be-
 tween the parts. This is called the clock door.
It would, in every case, be very proper to have a fixed
valve in the lower end of the pipe. This would com-
bine all advantages. Being always tight, the pipe would
retain the water, and it would leave to the valve above
its full effect of increasing the rarefaction. A similar
hole is made in the working barrel, a little above the
highest position of the piston. When this needs repair,
it can be got at through this hole, without the immense
trouble of drawing up the whole rods.

Thus we have conducted the reader step by step,
from the simplest form of the pump to that which long expe-
rience has at last selected as the most generally conve-
nient. This we shall now describe in some detail.
The sucking pump consists of two pipes D, D, D, and
B, B (fig. 5); of which the former is called the Bar-
rel, or the Working barrel, and the other is called the
suction-pipe, and is commonly of a smaller diameter.
These are joined by means of flanges E, F, pierced
with holes to receive screwed bolts. A ring of lea-
thier, or of lead, covered with a proper cement, is put
between them; which, being strongly compressed by
the screw-bolts, renders the joint perfectly air-tight.
The lower end A of the suction-pipe is commonly spread
out a little to facilitate the entry of the water, and fre-
quently has a grating across at AA to keep out filth or
gravel. This isimmered in the standing water YZ.
The working barrel is cylindrical, as evenly and smooth-
ly bored as possible, that the piston may fill it exactly
through its whole length, and move along it with as
little friction as may be consistent with air-tightness.
The piston is a sort of truncated cone OPL, gen-
erally made of wood not made to slip, such as elm or
beech. The small end of it is cut off at the sides, so
as to form a sort of arch OQP, by which it is fasten-
ed to the iron rod or spear. It is exhibited in differ-
ent positions in figures 6, 7, which will give a more dis-
 tinct notion of its shape in my description. The two ends
of the conical part may be hooped with brass. This
cone has its larger end surrounded with a ring or band
of strong leather fastened with nails, or by a copper
loop, which is driven on at the smaller end. This
band should reach to some distance beyond the base of
the cone: the farther the better: and the whole must
be of uniform thickness all round, so as to suffer equal
compression between the cone and the working barrel.

The seam or joint of the two ends of this band must
be made very close, but not sewed or stitched togeth-
er. This would occasion bumps or inequalities, which would
spoil its tightness; and no harm can result from the want
of it, because the two edges will be squeezed close to-
gether by the compression in the barrel. It is by no
means necessary that this compression be great. This
is a very detrimental error of the pump-makers. It
occasions enormous friction, and destroys the very pur-
pose which they have in view, viz. rendering the piston
air-tight; for it causes the leather to wear through very
soon at the edge of the cone, and it also wears the
working barrel. This very soon becomes wide in that
part which is continually passed over by the piston, while
the mouth remains of its original diameter, and it be-
comes impossible to thrust in a piston which shall com-
pletely fill the worn part. Now, a very moderate pres-
sure is sufficient for rendering the pump perfectly tight, and
a piece of glove leather would be sufficient for this
purpose, if loose or detached from the solid cone; for
pumps suppose such a loose and flexible, but impervious, band
of leather put round the piston, and put into the barrel;
and let it even be supposed that the cone does not com-
press it in the smallest degree to its internal surface.—
Pour a little water carefully into the inside of this sort
of cup or dish; it will cause it to swell out a little,
and apply itself close to the barrel all round, and even
adjust itself to all its inequalities. Let us suppose it to
touch the barrel in a ring of the inch bread all round.
We can easily compute the force with which it is pres-
sed. It is half the weight of a ring of water an inch
deep and an inch broad. This is a trifle, and the fric-
tion occasioned by it is not worth regarding; yet, this
trilling pressure is sufficient to make the passage per-
fectly impervious, even by the most enormous, Where
of a high column of incumbent water: for let this
pressure be ever so great, the pressure by which the lea-
thier adheres to the barrel always exceeds it, because
the incumbent fluid has no preponderating power by which
it can force its way between them, and it must insinu-
ate itself precisely so far, that its pressure on the inside
of the leather shall still exceed, and only exceed, the
pressure by which it endeavours to insinuate itself; and
thus the piston becomes perfectly tight with the smallest-pos-
sible friction. This reasoning is perhaps too refined
for the un instructed artist, and probably will not persuade
him. To such we would recommend an examination be prac-
ticd of the pistons and valves contrived and executed by that cable from
artist, whose skill far surpasses our highest conceptions, the human
all-wise Creator of this world. The valves which
shut up the passages of the veins, and this in places
where an extravasation would be followed by instant
death, are cups of thin membrane which adhere to
the sides of the channel about half way round, and
are detached in the rest of their circumference. When
the blood comes in the opposite direction, it pushes
the membrane aside, and has a passage perfectly free. But
a stagnation of motion allows the tone of the muscular
perhaps membrane, to restore its natural shape, and
the least motion in the opposite direction causes it instantly
to clasp close to the sides of the vein, and then no
pressure whatever can force a passage. We shall recur
to this again, when describing the various contrivances
Best form
of a pin-
to this again, when describing the various contrivances
rawing of valves, &c. What we have said is enough for sup-
porting our directions for constructing a tight piston.
But we recommended thick and strong leather, while
our present reasoning seems to render thin leather pre-
ferable. If the leather be thin, and the solid piston in
any part does not press it gently to the barrel, there
will be in this part an unbalanced pressure of the incum-
Y
Pump. A strong leather bag; but when the solid piston, covered with leather, exactly fills the barrel, and is even pressed a little to it, there is no such risk; and now that part of the leather band which reaches beyond the solid piston performs its office in the completest manner. We do not hesitate, therefore, to recommend this form of a piston, which is the most common and simple of all, as preferable, when well executed, to any of those more artificial, and frequently very ingenious, constructions, which we have met with in the works of the first engineers. To proceed, then, with our description of the sucking-pump.

Further description of the sucking-pump.

At the joining of the working barrel with the suction-pipe there is a hole H, covered with a valve opening upwards. This hole H is either made in a plate which makes a part of the suction-pipe, being cast along with it, or it is made in a separate plate. This last is the most convenient, being easily removed and replaced.

Different views are given of this valve in figs. 8, 9, 10. The diameter EF (fig. 10.) of this plate is the same with that of the flanges, and it has holes corresponding to them, through which their bolts pass which keep all together. A ring of thick leather NKL is applied to this plate, having a part cut out between N and L, to make room for another piece of strong leather NR (fig. 9.) which composes the valve. The circular part of this valve is broader than the hole in the middle of the suction-pipe, but not quite so broad as to fill up the inside of the ring of leather QOP of this figure, which is the same with GKI of fig. 10. The middle of this leather valve is strengthened by two brass (not iron) plates, the uppermost of which is seen at R of fig. 9: the one on its underside is a little smaller than the hole in the valve-plate, that it may go freely in; and the upper plate B is larger than this hole, that it may compress the leather to its brim all round. It is evident, that when this plate with its leathers is put between the joint flanges, and all is screwed together, the tail of leather N of fig. 9 will be compressed between the plates, and form a hinge, on which the valve can turn, rising and falling. There is a similar valve fastened to the upper side, or broadest base of the piston. This description serves for both valves, and in general for most valves which are to be found in any parts of a pump.

The reader will now understand, without any repetition, the process of the whole operation of a sucking-pump. The piston rarifies the air in the working barrel, and that in the suction-pipe expands through the valve into the barrel; and, being no longer a balance for the atmospheric pressure, the water rises into the suction-pipe; another stroke of the piston produces a similar effect, and the water rises farther, but by a smaller step than by the preceding stroke: by repeating the strokes of the piston, the water gets into the barrel; and when the piston is now pushed down through it, it gets above the piston, and must now be lifted up to any height. The suction-pipe is commonly of smaller size than the working barrel, for the sake of economy. It is not necessary that it be so wide; but it may be, and is, made too small. It should be of such a size, that the pressure of the atmosphere may be able to fill the barrel with water as fast as the piston rises. If a void is left below the piston, it is evident that the piston must be carrying the whole weight of the atmosphere, besides the water which is lying above it. Nay, if the pipe be only so wide, that the barrel shall fill precisely as fast as the piston rises, it must sustain all this pressure. The suction-pipe should be wider than this, that all the pressure of the atmosphere which exceeds the weight of the pillar in the suction-pipe may be employed in pressing it on the under surface of the piston, and thus diminishes the load. It cannot be made too wide; and too strict an economy in this respect may very sensibly diminish the performance of the pump, and more than defeat its own purpose. This is most likely when the suction-pipe is long, because there the length of the pillar of water nearly balances the air's pressure, and leaves very little accelerating force; so that water will rise but slowly even in the widest pipe. All these things will be made the subjects of computation afterwards.

It is plain that there will be limitations to the rise of the water in the suction-pipe, similar to what we found when the whole pump was an uniform cylinder. Let \( a \) be the height of the fixed valve above the water in the cistern: let \( B \) and \( b \) be the spaces in cubic measure between this valve and the piston in its highest and lowest positions, and therefore express the bulk of the air which may occupy these spaces: let \( y \) be the distance between the fixed valve and the water in the suction-pipe, when it has attained its greatest height by the rarefaction of the air above it: let \( h \) be the height of a column of water in equilibrio, with the whole pressure of the atmosphere, and therefore having its weight in equilibrio with the elasticity of common air; and let \( x \) be the height of the column whose weight balances the elasticity of the air in the suction-pipe, when rarefied as much as it can be by the action of the piston, the water standing at the height \( a \) = \( y \).

Then, because this elasticity, together with the column \( a \) = \( y \) in the suction-pipe, must balance the whole pressure of the atmosphere, (see Pneumatics, \( \text{No} \ 108), \) we must have \( h = x + a = y, \) and \( y = a + x - h. \)

When the piston was in its lowest position, the bulk of the air between it and the fixed valve was \( b \). Suppose the valve kept shut, and the piston raised to its highest position, the bulk will be \( B \), and its density \( b^\text{, and its elasticity, or the height of the column whose weight will balance it, will be } \frac{b}{B}. \) If the air in the suction-pipe be denser than this, and consequently more elastic, it will lift the valve, and some will come in; therefore, when the pump has rarefied the air as much as it can, so that none does, in fact, come in, the elasticity of the air in the suction-pipe must be the same.

Therefore \( x = h \frac{b}{B}. \)

We had \( y = a + x = h. \) Therefore \( y = a + h \frac{b}{B} \)

\( -h = a + \frac{b}{B} \cdot h = \frac{a}{B} + \frac{b}{B} \cdot h. \)

Therefore when \( \frac{b}{B} \cdot h \) is less than \( a, \) the water will stop before it reaches the fixed valve. But when \( a \) is less than \( \frac{b}{B} \cdot h, \) the water will get above the fixed valve, \( y \) becoming negative.
The operation of this pump is abundantly simple. When the piston is thrust into the pump, it pushes the air before it through the valve S, for the valve R remains shut by its own weight. When it has reached near the bottom, and is drawn up again, the air which filled the small space between the piston and the valve S now expands into the barrel; for as soon as the air begins to expand, it ceases to balance the pressure of the atmosphere, which therefore shuts the valve S. By the expansion of the air in the barrel, the equilibrium at the valve R is destroyed, and the air in the suction-pipe lifts the valve, and expands into the barrel; consequently it ceases to be a balance for the pressure of the atmosphere, and the water is forced into the suction-pipe. Pushing the piston down again forces the air in the barrel through the valve S, the valve R in the mean time shutting. When the piston is again drawn up, S shuts, R opens, the air in the suction-pipe dilates anew, and the water rises higher in it. Repeating these operations, the water gets at last into the working barrel, and is forced into the main by pushing down the piston, and is pushed along to the place of delivery.

The operation of this pump is therefore two-fold: sucking and forcing. In the first operation, the same force must be employed as in the sucking-pump, namely, a force equal to the weight of a column of water having the section of the piston for its base, and the height of the piston above the water in the cistern for its height. It is for the sake of this part of the operation that the upper cone is added to the piston. The air and water would pass by the side of the lower cone while the piston is drawn up; but the leather of the upper cone applies to the surface of the barrel, and prevents this. The space contained between the barrel and the valve S is a great obstruction to this part of the operation, because this air cannot be rarefied to a very great degree. For this reason, the suction-pipe of a forcing-pump must not be made long. It is not indeed necessary; for by placing the pump a few feet lower, the water will rise into it without difficulty, and the labour of suction is as much diminished as that of impulsion is increased. However, an intelligent artist will always endeavour to make this space between the valve S and the lowest place of the piston as small as possible.

The power employed in forcing must evidently surmount the pressure of the whole water in the rising pipe, and (independent of what is necessary for giving the water the required velocity, so that the proper quantity per hour may be delivered), the piston has to withstand a force equal to the weight of a column of water having the section of the piston for its base, and the perpendicular altitude of the place of delivery above the lower surface of the piston for its height. It is quite indifferent in this respect what is the diameter of the rising pipe; because the pressure on the piston depends on the altitude of the water only, independent of its quantity. We shall even see that a small rising pipe will require a greater force to convey the water along it to any given height or distance.

When we would employ a pump to raise water in a crooked pipe, or in any pipe of moderate dimensions, this form of pump, or something equivalent, must be used. In bringing up great quantities of water from mines, the common sucking-pump is generally employed.
Pump—ed, as really the best of them all; but it is the most expensive, because it requires the pipe to be perpendicular, straight, and of great dimensions, that it may contain the piston rods. But this is impracticable when the pipe is crooked.

If the forcing pump, constructed in the manner now described, be employed, we cannot use forceps with long rods. These would bend when pushed down by their further extremity. In this case, it is usual to employ only a short and stiff rod, and to hang it by a chain, and load it with a weight superior to the weight of water to be raised by it. The machinery therefore is employed, not in forcing the water along the rising-pipe, but in raising the weight which is to produce this effect by its subsequent descent.

In this case, it would be much better to employ the lifting-pump of fig. 11. For as the load on the forceps must be greater than the resistances which it must surmount, the force exerted by the machine must in like manner be greater than this load. This double excess would be avoided by using the lifting-pump.

It will readily occur to the reader that the quantity of water delivered by any pump will be in the joint proportion of the surface or base of the piston and its velocity: for this measures the capacity of the part of the working barrel which the piston passes over. The velocity of the water in the conduit pipe, and in its passage through every valve, will be greater or less than the velocity of the piston, in the same proportion that the area of the piston or working barrel is greater or less than the area of the conduit or valve. For whatever quantity of water passes through any section of the working barrel in a second, the same quantity must go through any one of these passages. This enables us to modify the velocity of the water as we please: we can increase it to any degree at the place of delivery by diminishing the aperture through which it passes, provided we apply sufficient force to the piston.

It is evident that the operation of a pump is by starts, and that the water in the main remains at rest, pressing on the valve during the time that the piston is withdrawn from the bottom of the working barrel. It is in most cases desirable to have this motion equable, and in some cases it is absolutely necessary. Thus, in the engine for extinguishing fires, the spout of water going by jerks could never be directed with a certain aim, and half of the water would be lost by the way; because a body at rest cannot in an instant be put in rapid motion, and the first portion of every jerk of water would have but a small velocity. A very ingenious contrivance has been fallen upon for obviating this inconvenience, and procuring a stream nearly equable. We have not been able to discover the author. At any convenient part of the rising-pipe beyond the valve there is annexed a capacious vessel \( VZ \) (fig. 13. No. 1. and 2.) close a-top, and of great strength. When the water is forced along this pipe, part of it gets into this vessel, keeping the air confined above it, and it fills it to such a height \( V \), that the elasticity of the confined air balances a column reaching to \( T \), we shall suppose, in the rising-pipe. The next stroke of the piston sends forward more water, which would fill the rising-pipe to some height above \( V \). But the pressure of this additional column causes some more of it to go into the air vessel, and compress its air so much more that its elasticity now balances a longer column. Every succeeding stroke of the piston produces a like effect. The water rises higher in the main pipe, but some more of it goes into the air vessel. At last the water appears at the place of delivery; and the air in the air vessel is now so much compressed that its elasticity balances the pressure of the whole column. The next stroke of the piston sends forward some more water. If the diameter of the orifice of the main be sufficient to let the water flow out with a velocity equal to that of the piston, it will so flow out, rising no higher, and producing no sensible addition to the compression in the air vessel. But if the orifice of the main be contract ed to half its dimensions, the water sent forward by the piston cannot flow out in the time of the stroke without a greater velocity, and therefore a greater force. Part of it, therefore, goes into the air vessel, and increases the compression. When the piston has ended its stroke, and no more water comes forward, the compression of the air in the main vessel being greater than what was sufficient to balance the pressure of the water in the main pipe, now forces out some of the water which is lying below it. This cannot return towards the pump, because the valve \( S \) is now shut. It therefore goes forward along the main, and produces an efflux during the time of the piston's rising in order to make another stroke. In order that this efflux may be very equable, the air vessel must be very large. If it be small, the quantity of water that is discharged by it during the return of the piston makes so great a portion of its capacity, that the elasticity of the confined air is too much diminished by this enlargement of its bulk, and the rate of efflux must diminish accordingly. The capacity of the air vessel should be so great that the change of bulk of the compressed air during the int raction of the piston may be inconsiderable. It must therefore be very strong.

It is pretty indifferent in what way this air vessel is connected with the rising-pipe. It may join it laterally, as in fig. 13. No. 1. and the main pipe go on without interruption; or it may be made to surround an interruption of the main pipe, as in fig. 13. No. 2. It may also be in any part of the main pipe. If the sole effect intended by it is to produce an equable jet, as in ornamental water-works, it may be near the end of the main. This will require much less strength, because there remains but a short column of water to compress the air in it. But it is, on the whole, more advantageous to place it as nearly the pump as possible, that it may produce an equable motion in the whole main pipe. This is of considerable advantage: when a column of water several hundred feet long is at rest in the main pipe, and the piston at one end of it put at once into motion, even with a moderate velocity, the strain on the pipe would be very great. Indeed if it were possible to put the piston instantaneously into motion with a finite velocity, the strain on the pipe, tending to burst it, would be next to infinite. But this seems impossible in the natural nature; all changes of motion which we observe are gradually, because all impelling bodies have some elasticity or softness by which they yield to compression. And, in the way in which pistons are commonly moved, viz. by cranks or something analogous to them, the motion is very sensibly gradual. But still the air vessel tends to make the motion along the main pipe less desolatory, and therefore diminishes those strains which would really take place.
PUMP

Pump. place in the main-pipe. It acts like the springs of a travelling-carriage, whose jolts are incomparably less than those of a cart; and by this means really enables a given force to propel a greater quantity of water in the same time.

Corrected.

We may here by the way observe, that the attempts of mechanicians to correct this unequal motion of the piston-rod are misplaced, and if it could be done, would greatly hurt a pump. One of the best methods of producing this effect is to make the piston-rod consist of two parallel bars, having teeth in the sides which front each other. Let a toothed wheel be placed between them, having about half of its circumference furnished with teeth. It is evident, without any farther description, that if this wheel be turned uniformly round its axis, the piston-rod will be moved uniformly up and down without intermission. This has often been put in practice; but the machine always went by jolts, and seldom lasted a few days. Unskilled mechanicians attributed this to defect in the execution: but the fault is essential, and lies in the principle.

The machine could not perform one stroke, if the first mover did not slacken a little, or the different parts of the machine did not yield by bending or by compression; and no strength of materials could withstand the violence of the strains at every reciprocation of the motion. This is chiefly experienced in great works which are put in motion by a water-wheel, or some other equal power exerted on the mass of matter of which the machine consists. The water-wheel being of great weight, moves with considerable steadiness or uniformity; and when an additional resistance is opposed to it by the beginning of a new stroke of the piston, its great quantity of motion is but little affected by this addition, and it proceeds very little retarded; and the machine must either yield a little by bending and compression, or go to pieces, which is the common event. Cranks are free from this inconvenience, because they accelerate the piston gradually, and bring it gradually to rest, while the water-wheel moves round with almost perfect uniformity. The only inconvenience (and it may be considerable) attending this slow motion of the piston at the beginning of its stroke is, that the valves do not shut with rapidity, so that some water gets back through them. But when they are properly formed and loaded, this is but trifling.

We must not imagine, that because the stream produced by the assistance of an air-barrel is almost perfectly circular, and because as much water runs out during the returning of the piston as during its active stroke, it therefore doubles the quantity of water. No more water can run out than what is sent forward by the piston during its effective stroke. The continued stream is produced only by preventing the whole of this water from being discharged during this time, and by providing a propelling force to act during the piston's return. Nor does it enable the moving force of the piston to produce a double effect: for the compression which is produced in the air-vessel, more than what is necessary for merely balancing the quiescent column of water, reacts on the piston, resisting its compression just as much as the column of water would do which produces a velocity equal to that of the efflux. Thus if the water is made to spout with the velocity of eight feet per second, this would require an additional column of four feet high, and this would just balance the compression in the air-vessel, which maintains this velocity during the non-action of the piston. It is, however, a matter of fact, that a pump furnished with an air-vessel delivers a little more water than it would do without it. But the difference depends on the combination of many very dissimilar circumstances, which it is extremely difficult to bring into calculation. Some of these will be mentioned afterwards.

To describe, or even to enumerate, the immense variety of combinations of these three simple pumps would fill a volume. We shall select a few, which are more deserving of notice.

I. The common sucking-pump may, by a small addition, be converted into a lifting pump, fitted for propelling the water to any distance, and with any velocity. Fig. 14, is a sucking-pump, whose working-barrel ACDB has a lateral pipe AEHF connected with it close to the top. This terminates in a main or rising pipe 1K, furnished or not with a valve L. The top of the barrel is shut up by a strong plate MN, having a hollow neck terminating in a small flang. The piston rod QR passes through this neck, and is nicely turned and polished. A number of rings of leather are put over the rod, and strongly compressed round it by another flang and several screwed bolts, as is represented at OP. By this contrivance the rod is closely grasped by the leathers, but may be easily drawn up and down, while all passage of air or water is effectually prevented.

The piston S is perforated, and furnished with a valve opening upwards. There is also a valve T on the top of the suction-pipe YY; and it will be of advantage, though not absolutely necessary, to put a valve at the bottom of the rising pipe. Now suppose the piston at the bottom of the working-barrel. When it is drawn up, it tends to compress the air above it, and the valve in the piston remains shut by its own weight. The air therefore is driven through the valve into the rising pipe, and escapes. In the mean time, the air which occupied the small space between the piston and the valve T expands into the upper part of the working-barrel; and its elasticity is so much diminished thereby, that the atmosphere presses the water of the cistern into the suction-pipe, where it will rise till an equilibrium is again produced. The next downward stroke of the piston allows the air, which had come from the suction-pipe into the barrel during the ascent of the piston, to get through its valve. Upon drawing up this piston, the air is also drawn off through the rising pipe. Repeating this process brings the water at last into the working-barrel, and it is then driven along the rising-pipe by the piston.

This is one of the best forms of a pump. The resistance of the water may be very perfect, because the piston can be brought so near to the bottom of the working-barrel; and, for forcing water in opposition to great pressures, it appears preferable to the common forcing-pump; because in that the piston rods are compressed and exposed to bending, which greatly hurts the pump by wearing the piston and barrel on one side. This soon renders it less tight, and much water squirts out by the sides of the piston. But in this pump the piston rod is always drawn or pulled, which keeps it straight; and...
Suppose the piston close to the entry of the lateral pipe \( m \), and that it is drawn up; it compresses the air above it, and drives it through the valve \( G \), where it escapes along the rising pipe; at the same time it rares the air in the space below it. Therefore the weight of the atmosphere shuts the valve \( E \), and causes the water of the cistern to rise through the valve \( D \), and fill the lower part of the pump. When the piston is pushed down again, this water is first driven through the valve \( E \), because \( D \) immediately shuts; and then most of the air which was in this part of the pump at the beginning goes up through it, some of the water coming back in its stead. In the mean time, the air which remained in the upper part of the pump after the ascent of the piston is rared by its descent; because the valve \( G \) shuts as soon as the piston begins to descend, the valve \( F \) opens, the air in this suction pipe \( F \) expands into the barrel, and the water rises into the pipes by the pressure of the atmosphere. The next rise of the piston must bring more water into the lower part of the barrel, and must drive a little more air through the valve \( G \), namely, part of that which had come out of the suction-pipe \( F \); and the next descent of the piston must drive more water into the rising pipe \( H \), and along with it most if not all of the air which remained below the piston, and must rarely still more the air remaining above the piston; and more water will come in through the pipe \( F \), and get into the barrel. It is evident, that a few repetitions will at last fill the barrel on both sides of the piston with water. When this is accomplished, there is no difficulty in perceiving how, at every rise of the piston, the water of the cistern will come in by the valve \( D \), and the water in the upper part of the barrel will be driven through the valve \( G \); and, in every descent of the piston, the water of the cistern will come into the barrel by the valve \( F \), and the water below the piston will be driven through the valve \( E \); and thus there will be a continual influx into the barrel through the valves \( D \) and \( F \), and continual drain along the rising pipe \( L \) through the valves \( E \) and \( G \).

This machine is, to be sure, equivalent to two foren pump pumps, although it has but one barrel and one piston; but it has no sort of superiority. It is not even more economical in most cases; because we apprehend the additional workmanship will fully compensate for the barrel and piston that is saved. There is indeed a saving in the rest of the machinery, because one lever produces both motions. We cannot therefore say that it is inferior to two pumps; and we acknowledge that there is some ingenuity in the contrivance.

We recommend to our readers the perusal of Belidor's *Architecture Hydraulique*, where is to be found a great variety of combinations and forms of the simple pumps; but we must caution them with respect to his theories, which in this article are extremely defective. Also in Leibnitz's *Theatrum Machinarum Hydraulicae*, there is a prodigious variety of all kinds of pumps, many of them very singular and ingenious, and many which have particular advantages, which may suit local circumstances, and give them a preference. But it would be improper to dwell a work of this kind with so many peculiarities; and a person who makes himself master of the principles delivered here in sufficient detail, can be at no loss to suit a pump to his particular

---

"Pump..."
The forcing pump is sometimes of a very different form from that already described. Instead of a piston, which applies itself to the inside of the barrel, and slides up and down in it, there is a long cylinder POQ (fig. 16). nicely turned and polished on the outside, and of a diameter somewhat less than the inside of the barrel. This cylinder (called a plunger) slides through a collar of leathers on the top of the working-barrel, and is constructed as follows. The top of the barrel terminates in a flanch ab, pierced with four holes for receiving screw-bolts. There are two rings of metal, cd, ef, of the same diameter, and having holes corresponding to those in the flanch. Four rings of soft leather, of the same size, and similarly pierced with holes, are well soaked in a mixture of oil, tallow, and a little rosin. Two of these leather rings are laid on the pump flanch, and one of the metal rings above them. The plunger is then thrust down through them, by which it turns their inner edges downwards. The other two rings are then slipped on at the top of the plunger, and the second metal ring is put over them, and then the whole are slid down to the metal ring. By this the inner edges of the last leather rings are turned upwards. The three metal rings are now forced together by the screwed bolts; and thus the leathern rings are strongly compressed between them, and made to grasp the plunger so closely that no pressure can force the water through between them. The upper metal ring just allows the plunger to pass through it, but without any play; so that the turned-up edges of the leather rings do not come up between the plunger and the upper metal ring, but are lodged in the collar taper, which is given to the inner edge of the upper plate, its hole being wider below than above. It is on this trifling circumstance that the great tightness of the collar depends. To prevent the leathers from shrinking by drought, there is usually a little cistern formed round the head of the pump, and kept full of water. The plunger is either forced down by a rod from a working beam, or by a set of metal weights laid on it, as is represented in the figure.

It is hardly necessary to be particular in explaining the operation of this pump. When the plunger is at the bottom of the barrel, touching the fixed valve M with its lower extremity, it almost completely fills it. That it may do it completely, there is sometimes a small pipe RSZ branching out from the top of the barrel, and fitted with a cock at S. Water is admitted till the barrel is completely filled, and the cock is then shut. Now when the plunger is drawn up, the valve N in the rising pipe is also shut. The water remains in the atmosphere, and a void must be made in the barrel. Therefore the valve M on the top of the suction-pipe must be opened by the elasticity of the air in this pipe, and the air must expand into the barrel; and being no longer a balance for the atmosphere, the water in the cistern must be forced into the suction-pipe, and rise in it to a certain height. When the plunger descends, it must drive the water through the valve N (for the valve M will immediately shut), and along with it most of the air which had come into the barrel. And as this air occupied the upper part of the barrel, part of it will remain when the plunger has reached the bottom; but a stroke or two will expel it all, and then every succeeding stroke of the descending piston will drive the water along the rising pipe, and every ascent of the plunger will be followed by the water from the cistern.

The advantage proposed by this form of piston is that it may be more accurately made and polished than the inside of a working barrel, and it is of much easier repair. Yet we do not find that it is much used, although an invention of the 17th century (we think by Sir Samuel Morland), and much praised by the writers on these subjects.

It is easy to see that the sucking-pump may be varied in the same way. Suppose this plunger to be open both at top and bottom, but the bottom filled with a diaphragm valve opening upward. When this is pushed to the bottom of the barrel, the air which it tends to compress lifts the valve (the lateral pipe FIK being taken away and the passage shut up), and escapes through the plunger. When it is drawn up, it makes the same rarefaction as the solid plunger, because the valve at O shuts, and the water will come up from the cistern as in the former case. If the plunger be now thrust down again, the valve M shuts, the valve O is forced open, and the plunger is filled with water. This will be lifted by it during its next ascent; and when it is pushed down again, the water which filled it must now be pushed out, and will flow over its sides into the cistern at the head of the barrel. Instead of making the valve at the bottom of the piston, it may be made at the top; but this disposition is much inferior, because it cannot rarely the air in the barrel one half. This is evident; for the capacity of the barrel and plunger together cannot be twice the capacity of the barrel.

Another form of the sucking-pump comes up through a cistern KMNLC deeper or longer than the intended stroke of the piston, and has a valve C at top. The piston, or what acts in lieu of it, is a tube AHGB, open at both ends, and of a diameter somewhat larger than that of the suction-pipe. The interval between them is filled up at HG by a ring or belt of soft leather, which is fastened to the outer tube, and moves up and down with it, sliding along the smoothly polished surface of the suction-pipe with very little friction. There is a valve I on the top of this piston, opening upwards. Water is poured into the outer cistern.

The outer cylinder or piston being drawn up from its bottom, there is a great rarefaction of the air which was between them, and the atmosphere presses the water up through the suction-pipe to a certain height; for the valve I keeps shut by the pressure of the atmosphere and its own weight. Pushing down the piston causes the air, which had expanded from the suction-pipe into the piston, to escape through the valve I; drawing it up a second time, allows the atmosphere to press more water into the suction-pipe, to fill it, and also part of the piston. When this is pushed down again, the water which had come through the valve C is now forced out through the valve I into the cistern KMNLC, and now the whole is full of water. When, therefore, the piston is drawn up, the water follows, and fills it, if
not 33 feet above the water in the cistern; and when it
is pushed down again, the water which filled the piston
is all thrown out into the cistern; and after this it deli-
ers its full contents of water every stroke. The water
in the cistern KMNL, effectually prevents the entry of
any air between the two pipes; so that a very moderate
compression of the belt of soft leather at the mouth of
the piston cylinder is sufficient to make all perfectly
tight.

The piston cylinder differently formed.

It might be made differently. The ring of leather
might be fastened round the top of the inner cylinder
at DE, and slid on the inside of the piston cylinder;
but the first form is most easily executed. Muschen-
broeck has given a figure of this pump in his large
system of natural philosophy, and speaks very highly of
its performance. But we do not see any advantage
which it possesses over the common sucking-pump. He
indeed says that it is without friction, and makes no
mention of the ring of leather between the two cy-
linders. Such a pump will raise water extremely well
to a small height, and it seems to have been a model
only which he had examined: But if the suction-pipe is
long, it will by no means do without the leather; for
on drawing up the piston, the water of the upper cistern
will rise between the pipes, and fill the piston, and none
will come up through the suction pipe.

We may take this opportunity of observing, that the
many ingenious contrivances of pumps without friction
are of little importance in great works; because the
friction which is completely sufficient to prevent all
escape of water in a well-constructed pump is but a
very trifling part of the whole force. In the great
pumps which are used in mines, and are worked by
a steam-engine, it is very usual to make the pistons and
valves without any leather whatever. The working bar-
rel is bored truly cylindrical, and the piston is made of
metal of a size that will just pass along it without stick-
ing. When this is drawn up with the velocity com-
petent to a properly loaded machine, the quantity of
water which escapes round the piston is insignificant.
The piston is made without leather, not to avoid fric-
tion, which is also insignificant in such works; but to
avoid the necessity of frequently drawing it up for re-
pairs through such a length of pipes.

V. If a pump absolutely without friction be wanted,
the following seems preferable for simplicity and per-
formance to any we have seen, when made use of in
proper situations. Let NO (Fig. 18.) be the surface
of the water in the pit, and K the place of delivery.
The pit must be as deep in water as from K to NO.

ABCD is a wooden trunk, round or square, open at
both ends, and having a valve P at the bottom. The
top of this trunk must be on a level with K, and has a
small cistern EADF. It also communicates laterally
with a rising pipe GHK, furnished with a valve at H
opening upwards. LM is a beam of timber so fitted
to the trunk as to fill it without sticking, and is of at
least equal length. It hangs by a chain from a work-
ning beam, and is loaded on the top with weights ex-
ceeding that of the column of water which it displaces.

Now suppose this beam allowed to descend from the
position in which it is drawn in the figure; the wa-
ter must rise all around it, in the crevice which is be-
tween it and the trunk, and also in the rising pipe; be-
cause the valve P shuts, and H opens; so that when the
plunger has got to the bottom, the water will stand at
K: When the plunger is again drawn up to the top by the action of the moving power, the wa-
ter sinks again in the trunk, but not in the rising pipe,
because it is stopped by the valve H. Then allowing
the plunger to descend again, the water must once more
sink in the trunk to the level of K, and it must now flow
out at K; and the quantity discharged will be equal to
the part of the beam below the surface of the pit
water, deducting the quantity which fills the small space
between the beam and the trunk. This quantity may
be reduced almost to nothing; but if the inside of the
trunk and the outside of the beam be made tapering,
the beam may be let down till they exactly fit; and as
this may be done in square work, a good workman can
make it exceedingly accurate. But in this case, the
lower half of the beam and trunk must not taper: and
this part of the trunk must be of sufficient width round
the beam to allow free passage into the rising pipe.
Or, which is better, the rising pipe must branch off
from the bottom of the trunk. A discharge may be
made from the cistern EADF, so that as little water as
possible may descend along the trunk when the piston
is raised.

One great excellence of this pump is, that it is per-
fected free from all the deficiencies which in common
pumps result from want of being air-tight. Another
is, that the quantity of water raised is precisely equal
to the power expended; for any want of accuracy in
the work, while it occasions a diminution of the quan-
tity of water discharged, makes an equal diminution in
the weight which is necessary for pushing down the
plunger. We have seen a machine consisting of two
such pumps suspended from the arms of a long beam,
the upper side of which was formed into a walk with
a rail on each side. A man stood on one end till it
got to the bottom, and then walked soberly up to
the other end, the inclination being about twenty-
five degrees at first, but gradually diminished as he went
along, and changed the load of the beam. By this
means he made the other end go to the bottom, and so
on alternately, with the easiest of all exertions, and
what we are most fitted for by our structure. With
this machine, a very feeble old man, weighing 110 pounds,
raised 7 cubic feet of water 114 feet high in a minute,
and continued working 8 or 10 hours every day. A
stout young man, weighing nearly 135 pounds, raised
8½ to the same height, and when he carried 30 pounds,
conveniently slung about him, he raised 9½ feet to this
height, working 10 hours a day without fatigueing
himself. This exceeds Desagulier's maximum of a
hogshead of water 10 feet high in a minute, in the pro-
portion of 9 to 7 nearly. It is limited to very modera-
rate heights; but in such situations it is very effectual.
It was the contrivance of an untutored labouring man,
possessed of uncommon mechanical genius. We shall
have occasion to mention, with respect, some other con-
trivances of the same person, in the article Water-
Works.

VI. The most ingenious contrivance of a pump with-
out friction is that of Mr Haskins, described by Desagu-
liers, and called by him the Quicksilver Pump. Its
construction and mode of operations are pretty compli-
cated; but the following preliminary observations will,
we hope, render it abundantly plain.

Let
Let \( \text{ilmk (fig. 19.)} \) be a cylindrical iron pipe, about six feet long, open at top. Let \( egh \) be another cylinder, connected with it at the bottom, and of smaller diameter. It may either be solid, or, if hollow, it must be close at top. Let \( abc \) be a third iron cylinder, of an intermediate diameter, so that it may move up and down between the other two without touching either, but with as little interval as possible. Let this middle cylinder communicate, by means of the pipe \( AB \), with the upright pipe \( FE \), having both \( C \) and \( F \) open, and open at the top, and communicating to the pipe of communication. Suppose the outer cylinder suspended by chains from the end of a working beam, and let mercury be poured into the interval between the three cylinders till it fills the space to \( op \), about \( \frac{1}{3} \) of their height. Also suppose that the lower end of the pipe \( FE \) is immersed into a cistern of water, and that the valve \( D \) is less than 33 feet above the surface of this water.

Now suppose a perforation made somewhere in the pipe \( AB \), and a communication made with an air-pump. When the air-pump is worked, the air contained in \( CE \), in \( AB \), and in the space between the inner and middle cylinders, is rarefied, and is abstracted by the air-pump; for the valve \( D \) immediately shuts. The pressure of the atmosphere will cause the water to rise in the pipe \( CE \), and will cause the mercury to rise between the inner and middle cylinders, and sink between the outer and middle cylinders. Let us suppose mercury 12 times heavier than water: Then for every foot that the water rises in \( EC \), the level between the outside and inside mercury will vary an inch; and if we suppose \( DE \) to be 30 feet, then if we can rarefy the air so as to raise the water to \( D \), the outside mercury will be depressed to \( qr \), and the inside mercury will have risen to \( s \), \( t \), \( s \) and \( t \), being about 30 inches. In this state of things, the water will run over by the pipe \( BA \), and every thing will remain nearly in this position. The columns of water and mercury balance each other, and balance the pressure of the atmosphere.

While things are in this state of equilibrium, if we allow the cylinders to descend a little, the water will rise in the pipe \( FE \), which we may now consider as a suction-pipe; for by this motion the capacity of the whole is enlarged, and therefore the pressure of the atmosphere will still keep it full, and the situation of the mercury will again be such that all shall be in equilibrium. It will be a little lower in the inside space and higher in the outside.

Taking this view of things, we see clearly how the water is supported by the atmosphere at a very considerable height. The apparatus is analogous to a siphon which has one leg filled with water and the other with mercury. But it was not necessary to employ an air-pump to fill it. Suppose it again empty, and all the valves shut by their own weight. Let the cylinders descend a little. The capacity of the spaces below the valve \( D \) is enlarged, and therefore the included air is rarefied, and some of the air in the pipe \( CE \) must diffuse itself into the space quitted by the inner cylinder. Therefore the atmosphere will press some water up the pipe \( FE \), and some mercury into the inner space between the cylinders. When the cylinders are raised again, the air which came from the pipe \( CE \) would return into it again, but is prevented by the valve \( C \).

Raising the cylinders to their former height would compress this air; it therefore lifts the valve \( D \), and escapes. Another depression of the cylinders will have a similar effect. The water will rise higher in \( FC \), and the mercury in the inner space; and then, after repeated strokes, the water will pass the valve \( C \), and fill the whole apparatus, as the air-pump had caused it to do before.

The position of the cylinders, when things are in this situation, is represented in fig. 20. The outer and inner cylinders in their lowest position having descended about 30 inches. The mercury in the inner space has risen at \( qr \), a little above the middle of the cylinders, and the mercury in the inner space is near the top \( te \) of the inner cylinder. Now let the cylinders be drawn up. The water above the mercury cannot get back again through the valve \( C \), which shuts by its own weight. We therefore attempt to compress it; but the mercury yields, and descends in the inner space, and rises in the outer, till both are quickly on a level, about the height \( uv \). If we continue to raise the cylinders, the compression forces out more mercury, and it now stands lower in the inner than in the outer space. But that there may be something to balance this inequality of the mercurial columns, the water goes through the valve \( D \), and the equilibrium is restored when the height of the water in the pipe \( ED \) above the surface of the internal mercury is 12 times the difference of the mercurial columns (on the former supposition of specific gravity). If the quantity of water is such as to rise two feet in the pipe \( ED \), the mercury in the outer space will be two inches higher than that in the inner space. Another depression of the cylinders will again enlarge the space within the apparatus, the mercury will take the position of fig. 19, and more water will come in. Raising the cylinders will send this water four feet up the pipe \( ED \), and the mercury will be four inches higher in the inner than in the outer space. Repeating this operation, the water will be raised still higher in \( DE \); and this will go on till the mercury in the outer space reaches the top of the cylinder; and this is the limit of the performance. The dimensions with which we set out will enable the machine to raise the water about 30 feet in the pipe \( ED \); which, added to the 30 feet of \( CF \), makes the whole height above the pit-water 60 feet. By making the cylinders longer, we increase the height of \( ID \). This machine must be worked with great attention, and but slowly; for at the beginning of the forcing stroke the mercury very rapidly sinks in the inner space and rises in the outer, and will dash out and be lost. To prevent this as much as possible, the outer cylinder terminates in a sort of cup or dish, and the inner cylinder should be tapered a-top.

The machine is exceedingly ingenious and refined; ingenuity and there is no doubt but that its performance will exceed the convenience of that of any other pump which raises the water to great height, because friction is completely avoided, and there can be no want of tightness of the piston.—But this is all its advantage; and from what has been but the observed, it is but trifling. The expense would be enormous; for whatever care the cylinders are made, the interval between the inner and outer cylinders must contain a very great quantity of mercury. The middle cylinder must be made of iron plate, and must be without a seam, for the mercury would dissolve every solder.
PUM [ 510 ]

such reasons, it has never come into general use. But it would have been unpardonable to have omitted the description of an invention which is so original and ingenious; and there are some occasions where it may be of great use, as in nice experiments for illustrating the theory of hydraulics, it would give the finest pistons for measuring the pressures of water in pipes, &c. It is on precisely the same principle that the cylinder belows, described in the article Pneumatics, are constructed.

Description of another pump without friction.

We beg leave to conclude this part of the subject with the description of a pump without friction, which may be constructed in a variety of ways by any common carpenter, without the assistance of the pump-maker or plumber, and will be very effective for raising a great quantity of water to small heights, as in draining marshes, marl-pits, quarries, &c. or even for the service of a house.

VII. ABCD (fig. 21.) is a square trunk of carpenter's work, open at both ends, and having a little ci-stern and spout at top. Near the bottom there is a pair of tongs made of board, barrel-tin, or wrought iron, and covered with a clack. \( f \) \( f \) \( f \) \( f \) represents a long cylindrical bag or pudding, made of leather or of double canvas, with a fold of thin leather such as sheep skin between the canvas bags. This is firmly nailed to the board E with leather between. The upper end of this bag is fixed on a round board, having a hole and valve F. This board may be turned in the lathe with a groove round its edge, and the bag fastened to it by a cord bound tight round it. The fork of the piston-rod EG is firmly fixed into this board; the bag is kept distended by a number of wooden hoops or rings of strong wire \( f \) \( f \) \( f \) \( f \) \( f \) \( f \), &c. put into it at a few inches distance from each other. It will be proper to connect these hoops before putting them in, by three or four cords from top to bottom, which will keep them at their proper distances. Thus will the bag have the form of a barber's bellows powder-puff. The distance between the hoops should be about twice the breadth of the rim of the lock to which the upper valve and piston-rod are fixed.

Now let this trunk be immersed in water. It is evident that if the bag be stretched from the compressed form which its own weight will give it by drawing up the piston-rod, its capacity will be enlarged, the valve F will be shut by its own weight, the air in the bag will be rarefied, and the atmosphere will press the water into the bag. When the rod is thrust down again, this water will come out by the valve F, and fill part of the trunk. A repetition of the operation will have a similar effect; the trunk will be filled, and the water will at last be discharged by the spout.

Here is a pump without friction, and perfectly tight. For the leather between the folds of canvas renders the bag impervious both to air and water. And the canvas has very considerable strength. We know from experience that a bag of six inches diameter, made of sail-cloth No. 3, with a sheep skin between, will bear a column of two hundred feet of water, and stand six hours work per day for a month without failure, and that the pump is considerably superior in effect to a common pump of the same dimensions. We must only observe, that the length of the bag must be three times the intended length of the stroke; so that when the piston-rod is in its highest position, the angles or ridges of the bag may be pretty acute. If the bag be not extended farther than this, the force which must be exerted by the labourer becomes much greater than the weight of the column of water which he is raising. If the pump be laid aslant, which is very usual in these occasional and hasty drawings, it is necessary to make a guide for the piston-rod within the trunk, that the bag may play up and down without rubbing on the sides, which would quickly wear it out.

The experienced reader will see that this pump is very like that of Gosset and De la Deneille, described by Belidor, vol. ii. p. 120, and most writers on hydraulics. It would be still more like it, if the bag were on the under side of the partition E, and a valve placed farther down the trunk. But we think that our form is greatly preferable in point of strength. When in the other situation, the column of water lifted by the piston tends to burst the bag, and this with a great force, as the intelligent reader well knows. But in the form recommended here, the bag is compressed, and the strain on each part may be made much less than that which tends to burst a bag of six inches diameter. The nearer the rings are placed to each other, the smaller will the strain be.

The same bag-piston may be employed for a forcing pump, by placing it below the partition, and inverting the valve; and it will then be equally strong, because the resistance in this case too will act by compression.

We now come naturally to the consideration of the different forms which may be given to the pistons and valves of a pump. A good deal of what we have been describing already is reducible to this head; but, having a more general appearance, changing as it were the whole form and structure of the pump, it was not improper to keep these things together.

The great desideratum in a piston is, that it be as tight as possible, and have as little friction as is consistent with this indispensable quality. We have already said that the common form, when carefully executed, has a much less friction than common form. Accordingly this form has kept its ground amidst all the improvements which ingenious artists have made. Mr Belidor, an author of the first reputation, has given the description of a piston which he highly extols, and is undoubtedly a very good one, constructed from principle, and extremely well composed.

It consists of a hollow cylinder of metal \( g \) \( a \) (fig. 22.) pierced with a number of holes, and having at top a flange \( A B \), whose diameter is nearly equal to that of the working-barrel of the pump. This flange has a groove round it. There is another flange \( I K \) below, by which this hollow cylinder is fastened with bolts to the lower end of the piston, represented in fig. 23. This consists of a plate \( C D \), with a grooved edge similar to \( A B \), and an intermediate plate which forms the seat of the valve. The composition of this part is better understood by inspecting the figure than by any description. The piston-rod \( H L \) is fixed to the upper plate by bolts through its different branches at \( C, C \). This metal body is then covered with a cylindrical bag of leather fastened on it by cords bound round it, filling up the grooves in the upper and lower plates. The operation of the piston is as follows.

A little water is poured into the pump, which gets past
past the sides of the piston, and lodges below in the fixed valve. The piston being pushed down dips into this water, and it gets into it by the valve. But as the piston in descending compresses the air below it, this compressed air also gets into the inside of the piston, swells out the bag which surrounds it, and compresses it to the sides of the working-barrel. When the piston is drawn up again, it must remain tight, because the valve will shut and keep in the air in its most compressed state; therefore the piston must perform well during the suction. It must act equally well when pushed down again, and acting as a forcer; for however great the resistance may be, it will affect the air within the piston to the same degree, and keep the leather close applied to the barrel. There can be no doubt therefore of the piston's performing both its offices completely; but we imagine that the adhesion to the barrel will be greater than necessary: it will extend over the whole surface of the piston, and be equally great in every part of its surface; and we suspect that the friction will therefore be very great. We have very high authority for supposing that the adhesion of a piston of the common form, carefully made, will be such as will make it perfectly tight; and it is evident that the adhesion of Belidor's piston will be much greater, and it will be productive of worse consequences. If the leather bag be worn through in any one place, the air escapes, and the piston ceases to be compressed altogether; whereas in the common piston there will very little harm result from the leather being worn through in one place, especially if it project a good way beyond the base of the cone. We still think the common piston preferable. Belidor's piston would do much better inverted as the piston of a sucking pump; and in this situation it would be equal, but not superior to the common.

Belidor describes another forcing piston, which he had executed with success, and prefers to the common wooden forcer. It consists of a metal cylinder or cone, having a broad flanch uniting it to one end, and a similar flanch which is screwed on the other end. Between these two plates are a number of rings of leather strongly compressed by the two flanches, and then turned in a lathe like a block of wood, till the whole fits tight, when dry, into the barrel. It will swell, says he, and soften with the water, and withstand the greatest pressures. We cannot help thinking this but an indifferent piston. When it wears, there is nothing to squeeze it to the barrel. It may indeed be taken out and another ring or two of leather put in, or the flanches may be more strongly screwed together; but all this may be done with any kind of piston; and this has therefore no peculiar merit.

The following will, we presume, appear vastly preferable. ABCD (fig. 24), is the solid wooden block of the piston; EF is a metal plate, which is turned hollow or dish-like below, so as to receive within it the solid block. The piston rod goes through the whole, and has a shoulder above the plate EF, and a nut H below. Four screw-bolts, such as i, k, l, m, also go through the whole, have their heads k, m sunk into the block, and nuts above at i, l. The packing or stuffing, as it is termed by the workmen, is represented at NO. This is made as solid as possible, and generally consists of soft hennep twine well soaked in a mixture of oil, tallow, and resin. The plate EF is gently screwed down, and the whole is then put into the barrel, fitting it as tight as may be thought proper. When it wears loose, it may be tightened at any time by screwing down the nuts i, l, which cause the edges of the dish to squeeze out the packing, and compress it against the barrel to any degree.

The greatest difficulty in the construction of a piston in constructing pistons is to give a sufficient passage through it for the water, and yet allow a firm support for the valve, and fixture for the piston rod. We shall see presently that it occasions a considerable expense of the moving power to force a piston with a narrow perforation through the water lodged in the working barrel. When we are raising water to a small height, such as to or 20 feet, the power so expended amounts to a fourth part of the whole, if the water-way in the piston is less than one-half of the section of the barrel, and the velocity of the piston two feet per second, which is very moderate. There can be no doubt, therefore, that metal pistons are preferable, because their greater strength allows much wider apertures.

The following piston, described and recommended by Belidor, seems as perfect in these respects as the nature of things will allow. We shall therefore describe it in the author's own words as a model, which may be adopted with confidence in the greatest works. The body of the piston is a truncated metal cone (fig. 25), having a small fillet at the greater end. Fig. 26 shows the profile, and fig. 27 the plan of its upper base; where appears a cross bar DD, pierced with an oblong mortise E for receiving the tail of the piston-rod. A band of thick and uniform leather AA (fig. 26. and 28.) is put round this cone, and secured by a brass hoop BB firmly driven on its smaller end, where it is previously made thinner to give room for the hoop.

This piston is covered with a leather valve fortified with metal plates GG (fig. 29.). These plates are wider than the hole of the piston, so as to rest on its rim. There are similar plates below the leather of a smaller size, that they may go into the hollow of the piston; and the leather is firmly held between the metal plates by screws H, H, which go through all. This is represented by the dotted circle IK. Thus the pressure of the incumbent column of water is supported by the plates GG, whose circular edges rest on the rim of the water-way, and their straight edges rest on the cross bar DD of fig. 26. and 27. This valve is laid on the top of the conical box in such a manner that its middle FF rests on the cross bar. To bind all together, the end of the piston-rod is formed like a cross, and the arms MN (fig. 30.) are made to rest on the diameter FF of the valve, the tail EP going through the hole E in the middle of the leather, and through the mortise E of the cross bar of the box; and also through another bar QR (fig. 28. and 29.) which is notched into the lower rim of the box. A key V is then driven into the hole T in the piston-rod; and this wedges all fast. The bar QR is made strong; and its extremities project a little, so as to support the brass hoop BB which binds the leather band to the piston-box. The adjoining scale gives the dimensions of all the parts, as they were executed for a steam-engine near Coulon, where the piston gave complete satisfaction.

This piston has every advantage of strength, tightness, and
PUM [ 512 ]

the form of the valve (which has given it the name of the butterfly-valve) is extremely favourable to the passage of the water; and as it has but half the motion of a complete circular valve, less water goes back while it is shuttling.

The following piston is also ingenious, and has a great deal of merit. OPPO (fig. 32) is the box of the piston, having a perforation Q, covered above with a flat valve K, which rests in a metal plate that forms the top of the box. ABCBA is a stirrup of iron to which the box is fixed by screws a, a, a, a, whose heads are sunk in the wood. This stirrup is perforated at C, to receive the end of the piston-rod, and a nut H is screwed on below to keep it fast. DEFED is another stirrup, whose lower part at DD forms a loop like the sole of a stirrup, which embraces a small part of the top of the wooden box. The lower end of the piston-rod is screwed; and before it is put into the holes of the two stirrups (through which holes it slides freely) a broad nut G is screwed on it. It is then put into the holes, and the nut H firmly screwed up. The packing RR is then wound about the piston as tight as possible, till it completely fills the working barrel of the pump. When long use has rendered it in any degree loose, it may be tightened again by screwing down the nut G. This causes the ring DD to compress the packing between it and the projecting shoulder of the box at PP, and thus cause it to swell out, and apply itself closely to the barrel.

We shall add only another form of a perforated piston; which being on a principle different from all the preceding, will suggest many others; each of which will have its peculiar advantages. OO in fig. 32, represents the box of this piston, fitted to the working barrel in any of the preceding ways as may be thought best. AB is a cross bar of four arms, which is fixed to the top of the box. CF is the piston-rod going through a hole in the middle of AB, and reaching a little way beyond the bottom of the box. It has a shoulder D, which prevents its going too far through. On the lower end there is a thick metal plate, turned conical on its upper side, so as to fit a conical seat PP in the bottom of the piston-box.

When the piston-rod is pushed down, the friction on the barrel prevents the box from immediately yielding. The rod therefore slips through the hole of the cross bar AB. The plate E, therefore, detaches itself from the box. When the shoulder D presses on the bar AB, the box must yield, and be pushed down the barrel, and the water gets up through the perforation. When the piston-rod is drawn up again, the box does not move till the plate E lodges in the seat PP, and thus shuts the water-way; and then the piston lifts the water which is above it, and acts as the piston of a sucking pump.

This is a very simple and effective construction, and makes a very tight valve. It has been much recommended by engineers of the first reputation, and is frequently used; and from its simplicity, and the great solidity of which it is capable, it seems very fit for great works. But it is evident that the water-way is limited to less than one-half of the area of the working-barrel. For if the perforation of the piston be one-half of the area, the diameter of the plate or ball EF must be greater; and therefore less than half the area will be left for the passage of the water by its sides.

We come now to consider the forms which may be given to the valves of a hydraulic engine.

The requisites of a valve are, that it shall be tight of sufficient strength to resist the great pressures to which it is exposed, that it afford sufficient passage for the water, and that it do not allow much to go back while it is shuttling.

We have not much to add to what has been said about ready on this subject. The valves which accompany the pump of fig. 5, are called clock valves, and are of all the most obvious and common; and the construction described on that occasion is as perfect as any. We only add, that as the leather is at last destroyed at the hinge by such incessant motion, and it is troublesome, especially in deep mines, and under water, to undo the joint of the pump in order to put in a new valve, it is frequently annexed to a box like that of a piston, made a little conical on the outside, so as to fit a conical seat made for it in the pipe, as represented in fig. 33; and it has an iron handle like that of a basket, by which it can be laid hold of by means of a long grappling-hook let down from above. Thus it is drawn up; and being very gentle tapered on the sides, it sticks very fast in its place.

The only defect of this valve is, that by opening it very wide when pushed up by the stream of water, it allows a good deal to go back during its shuttling again. In some great machines which are worked by a slow turning crank, the return of the piston is so very slow, that a sensible loss is incurred by this; but it is nothing like what Dr Desaguliers says, one-half of a cylinder whose height is equal to the diameter of the valve.

For in such machines, the last part of the upward stroke is equally slow, and the velocity of the water through the valve exceedingly small, so that the valve is at this time almost shut.

The butterfly-valve represented in figures 29, &c., is Utility of free from most of these inconveniences, and seems the better most perfect of the clock valves. Some engineers make allowable; their great valves of a pyramidal form, consisting of four clacks, whose hinges are in the circumference of the water-way, and which meet with their points in the middle, and are supported by four ribs which rise up from the sides and unite in the middle. This is an excellent form, affording the most spacious water-way, and shutting very readily. It seems to be the best possible for a piston. The rod of the piston is branched out on four sides, and the branches go through the piston-box, and are fastened below with screws. These branches form the support for the four clacks. We have seen a valve of this form in a pump of six feet diameter, which discharged 20 bogsheads of water every stroke, and made 12 strokes in a minute, raising the water above 22 feet.

There is another form of valve, called the button or turned conical, so as exactly to fit the conical cavity of its box. A tail CD projects from the under side, which passes through a cross bar EF in the bottom of the box, and has a little knob at the end, to hinder the valve from rising too high.

This valve, when nicely made, is unexceptionable.
It has great strength, and is therefore proper for all severe strains, and it may be made perfectly tight by grinding. Accordingly it is used in all cases where this is of indispensable consequence. It is most durable, and the only kind that will do for passages where steam or hot water is to go through. Its only imperfectness is a small water-way; which, from what has been said, cannot exceed, or indeed equal, one half of the area of the pipe.

If we endeavour to enlarge the water-way, by giving the cone very little taper, the valve frequently sticks so fast in the seat that no force can detach them.—And this sometimes happens during the working of the machine; and the jolts and blows given to the machine in taking it to pieces, in order to discover what has been the reason that it has discharged no water, frequently detach the valve, and we find it quite loose, and cannot tell what has deranged the pump. When this is guarded against, and the diminution of the water-way is not of very great consequence, this is the best form of a valve.

Analogous to this is the simplest of all valves, represented in fig. 35. It is nothing more than a sphere of metal A, to which is fitted a seat with a small portion BC of a spherical cavity. Nothing can be more effectual than this valve; it always falls into its proper place, and in every position it fits exactly. Its only imperfectness is the great diminution of the water-way. If the diameter of the sphere does not considerably exceed that of the hole, the touching parts have very little taper, and it is very apt to stick fast. It opposes much less resistance to the passage of the water than the flat under-surface of the button-valve. N. B. It would be an improvement of that valve to give it a taper-shape below like a boy's top. The spherical valve must not be made too light, otherwise it will be hurried up by the water, and much may go back while it is returning to its place.

Belidor describes with great minuteness (vol. ii. p. 221, &c.) a valve which unites every requisite. But it is of such nice and delicate construction, and its defects are so great when this exactness is not attained, or is impaired by use, that we think it hazardous to introduce it into a machine in a situation where an intelligent and accurate artist is not at hand. For this reason we have omitted the description, which cannot be given in few words, nor without many figures; and desire our curious readers to consult that author, or peruse Dr Desaguliers's translation of this passage. Its principle is precisely the same with the following rude contrivance, with which we shall conclude the descriptive part of this article.

Suppose ABCD (fig. 36.) to be a square wooden trunk. EF is a piece of oak board, exactly fitted to the trunk in an oblique position, and supported by an iron pin which goes through it at I, one-third of its length from its lower extremity at E. The two ends of this board are bevelled, so as to apply exactly to the sides of the trunk. It is evident, that if a stream of water come in the direction BA, its pressure on the part IF of this board will be greater than that upon EI. It will therefore force it up and rush through, making it stand almost parallel to the sides of the trunk. To prevent its rising so far, a pin must be put in its way. When this current of water changes its direc-

tion, the pressure on the upper side of the board being again greatest on the portion IF, it is forced back again to its former situation; and its two extremities rising on the opposite sides of the trunk, the passage is completely stopped. This board therefore performs the office of a valve; and this valve is the most perfect that can be, because it offers the freest passage to the water, and it allows very little to get back while it is shutting; for the part IE brings up half as much water as IF allows to go down. It may be made extremity tight, by fixing two thin fillets H and G to the sides of the trunk, and covering those parts of the board with leather which applies to them; and in this state it perfectly resembles Belidor's fine valve.

And this construction of the valve suggests, by the Description way, a form of an occasional pump, which may be of an occasional pump essentially constructed. Let abcde (fig. 36.) be a square box made to slide along this wooden trunk without shake, having two of its sides projecting wards, terminating like the gable-ends of a house. A piece of wood e is mortised into these two sides, and to this the piston-rod is fixed. This box being furnished with a valve similar to the one below, will perform the office of a piston. If this pump be immersed so deep in the water that the piston shall also be under water, we scruple not to say that its performance will be equal to any. The piston may be made abundantly tight by covering its outside neatly with soft leather. And as no pipe can be bored with greater accuracy than a very ordinary workman can make a square trunk, we presume that this pump will not be very deficient even for a considerable suction.

We now proceed to the last part of the subject, to consider the motion of water in pumps, in reference to the force which must be employed. What we have hitherto said with respect to the force which must be applied to a piston, related only to the sustaining the water at a certain height; but in actual service we must not only do this, but we must discharge it at the place of delivery in a certain quantity; and this must require a force superadded to which is necessary for its mere support at this height.

This is an extremely intricate and difficult subject, an intricate and very imperfectly understood even by professed engineers. The principles on which this knowledge must be founded are of a much more abstruse nature than the ordinary laws of hydraulics; and all the genius of Newton was employed in laying the foundation of this part of physical science. It has been much cultivated in the course of this century by the first mathematicians of Europe. Daniel and John Bernoulli have written very elaborate treatises on the subject, under the very apposite name of Hydrodynamics; in which, although they have added little or nothing to the fundamental denominations established in some sort by Newton, and the Hydrodynamics,
any case, and in many are inadmissible: and it remains to this hour a wonder or puzzle how these propositions and their results correspond with the phenomena which we observe.

But fortunately this correspondence does obtain to a certain extent. And it seems to be this correspondence chiefly which has given these authors, with Newton at their head, the confidence which they place in their respective principles and methods: for there are considerable differences among them in those respects; and each seems convinced that the others are in error. Messieurs d'Alembert and De la Grange have greatly corrected the theories of their predecessors, and have proceeded on postulates which come much nearer to the real state of the case. But their investigations involve us in such an inextricable maze of analytical investigation, that even when we are again conducted to the light of day by the clue which they have given us, we can make no use of what we there discovered.

But his theory, imperfect as it is, is of great service. It generalizes our observations and experiments, and enables us to compose a practical doctrine from a heap of facts which otherwise must have remained solitary and unconnected, and as cumbersome in their application as the characters of the Chinese writing.

The fundamental proposition of this practical hydrodynamics is, that water or any fluid contained in an open vessel of indefinite magnitude, and impelled by its weight only, will flow through a small orifice with the velocity which a heavy body would acquire by falling from the horizontal surface of the fluid. Thus, if the orifice is 16 feet under the surface of the water, it will issue with the velocity of 32 feet in a second.

Its velocity corresponding to any other depth of the orifice under the surface, will be had by this easy proportion: \( \sqrt{h} = \sqrt{16} \times \sqrt{\frac{h}{4}} \), where \( h \) is the height in feet, and \( v \) is the velocity required.

On the other hand, it frequently occurs, that we want to discover the depth under the surface which will produce a known velocity \( v \). Therefore, \( \sqrt{h} = \frac{v}{\sqrt{8}} \)

and \( h = \frac{v^2}{64} \) : that is, divide the square of the velocity by 64, and the quotient is the depth wanted in feet.

This proposition is sufficient for all our purposes. For since water is nearly a perfect fluid, and propagates all impressions undiminished, we can, in place of any pressure of a piston or other cause, substitute a perpendicular column of water whose weight is equal to this pressure, and will therefore produce the same efflux. Thus, if the surface of a piston is half a square foot, and it be pressed down with the weight of 500 pounds, and we would wish to know with what velocity it would cause the water to flow through a small hole, we know that a column of water of this weight, and of half a foot base, would be 16 feet high. And this proposition teaches us, that a vessel of this depth will have a velocity of efflux equal to 32 feet in a second.

If therefore our pressing power be of such a kind that it can continue to press forward the piston with the force of 500 pounds, the water will flow with this velocity, whatever be the size of the hole. All that remains is, to determine what change of actual pressure on the piston results from the motion of the piston itself, and to change the velocity of efflux in the sub-duplicate ratio of the change of actual pressure.

But before we can apply this knowledge to the circumstances which take place in the motion of water in pumps, we must take notice of an important modification of the fundamental proposition, which is but very obscurely pointed out by any good theory, but is established on the most regular and unexceptionable observation.

If the efflux is made through a hole in a thin plate, and the velocity is computed as above, we shall discover the quantity of water which issues in a second by observing, that it is a prism or cylinder of the length indicated by the velocity, and having its transverse section equal to that of the orifice. Thus, in the example already given, suppose the hole to be a square inch, the solid contents of this prism, or the quantity of water issuing in a second, is \( 1 \times 32 \times 12 \) cubic inches, or \( 384 \) cubic inches. This we can easily measure by receiving it in a vessel of known dimensions. Taking this method, we uniformly find a deficiency of nearly 38 parts in 100; that is, if we should obtain 100 gallons in any number of seconds, we shall in fact get only 62. This is a most regular fact, whether the velocities are great or small, and whatever be the size and form of the orifice.

The deficiency increases indeed in a very minute degree with the velocities. If, for instance, the depth of the orifice be one foot, the discharge is \( \frac{4}{3} \); if it be 15 feet, the discharge is \( \frac{1}{20} \).

This deficiency is not owing to a diminution of velocity; for the velocity may be easily and accurately measured by the distance to which the jet will go, if directed horizontally. This is found to correspond very nearly with the proposition, making a very small allowance for friction at the border of the hole, and for the resistance of the air. Sir Isaac Newton ascribed the deficiency with great justice to this, that the lateral columns of water, surrounding the column which is incaustic on the orifice, press towards the orifice, and contribute to the expence equally with that column. These lateral filaments, therefore, issue obliquely, crossing the motion of the central stream, and produce a contraction of the jet; and the whole stream does not acquire a parallel motion and its ultimate velocity till it has got to some distance from the orifice. Careful observation showed him that this was really the case. But even his genius could not enable him to ascertain the motion of the lateral filaments by theory, and he was obliged to measure every thing as he saw it. He found the diameter of the jet at the place of the greatest contraction to be precisely such as accounted for the deficiency. His explanation has been unanimously acquiesced in; and experiments have been multiplied to ascertain all those circumstances which our theory cannot determine a priori.

The most complete set of experiments are those of Michellotti, made at Turin at the expense of the prince of Piedmont.
Piedmont. Here jets were made of 1, 2, 3, and 4 inches diameter; and the water received into cisterns most accurately formed of brick, and lined with stucco. It is the result of these experiments which we have taken for a measure of the deficiency.

We may therefore consider the water as flowing through a hole of this contracted dimension, or substitute this for the real orifice in all calculations. For it is evident that if a mouth-piece (so to call it) were made, whose internal shape precisely tallied with the form which the jet assumes, and if this mouth-piece be applied to the orifice, the water will flow out without any obstruction. The vessel may therefore be considered as really having this mouth-piece.

Nay, from this we derive a very important observation, that if, instead of allowing the water to flow through a hole of an inch area made in a thin plate, we make it flow through a hole in a thick plank, so formed that the external orifice shall have an inch area, but be widened internally, agreeably to the shape which nature forms, both the velocity and quantity will be that which the fundamental proposition determines. Michelotti measured with great care the form of the great jets of three and four inches diameter, and found that the bounding curve was an elongated trochoid. He then made a mouth-piece of this form for his jet of one inch, and found the discharges to be \( \frac{2}{5} \) and \( \frac{3}{5} \); and he, with justice, ascribed the trifling deficiency which still remained, partly to friction and partly to bis not having exactly suited his mouth-piece to the natural form. We imagine that this last circumstance was the sole cause: For, in the first place, the water in his experiments, before getting at his jet-holes, had to pass along a tube of eight inches diameter. Now a jet of four inches bears too great a proportion to this pipe; and its narrowness undoubtedly hindered the lateral columns from contributing to the efflux in their due proportion, and therefore rendered the jet less convergent. And, in the next place, there can be no doubt (and the observations of Daniel Bernoulli confirm it) but that this convergence begins within the vessel, and perhaps at a very considerable distance from the orifice. And we imagine, that if accurate observations could be made on the motion of the remote lateral particles within the vessel, and an internal mouth-piece were shaped according to the curve which is described by the remotest particle that we can observe, the efflux of water would almost perfectly tally with the theory. But indeed the coincidence is already sufficiently near for giving us very valuable information.

We learn that the quantity of water which flows through a hole, in consequence of its own weight, or by the action of any force, may be increased one half by properly shaping the passage to this hole; for we see that it may be increased from 62 to near 99.

But there is another modification of the efflux, which we confess our total incapacity to explain. If the water issues through a hole made in a plate whose thickness is about twice the diameter of the hole, or, to express it better, if it issues through a pipe whose length is about twice its diameter, the quantity discharged is nearly \( \frac{2}{5} \) of what results from the proposition. If the pipe be longer than this, the quantity is diminished by friction, which increases as the length of the pipe increases. If the pipe be shorter, the water will not fill it, but detaches itself at the very entry of the pipe, and flows with a contracted jet. When the pipe is of this length, and the extremity is stopped with the finger, so that it begins to flow with a full mouth, no subsequent contraction is observed; but merely striking on the pipe with a key or the knuckle is generally sufficient to detach the water in an instant from the sides of the pipe, and reduce the efflux to \( \frac{2}{5} \).

This effect is most unaccountable. It certainly arises from the mutual adhesion or attraction between the water and the sides of the pipe; but how this, acting at right angles to the motion, should produce an increase from 62 to 82, nearly \( \frac{2}{5} \), we cannot explain. It shows, however, the prodigious force of this attraction, which in the space of two or three inches is able to communicate a great velocity to a very great body of water. Indeed the experiments on capillary tubes show that the mutual attraction of the parts of water is some thousands of times greater than their weight.

We have only further to add, that every increase of pipe beyond two diameters is accompanied with a diminution of the discharge; but in what ratio this is diminished it is very difficult to determine. We shall only observe at present that the diminution is very great.

A pipe of 2 inches diameter and 30 feet long has its discharge only \( \frac{1}{6} \) of what it would be if only 4 inches long. If its length be 60 feet, its discharge is only more than \( \frac{1}{8} \). A pipe of 1 inch diameter would have a discharge of \( \frac{1}{6} \), and \( \frac{1}{3} \) in the same situation. Hence we may conclude that the discharge of a 4 inch pipe of 30 feet long will not exceed \( \frac{1}{3} \) of what it would be if only 8 inches long. This will suffice for our present purposes; and the determination of the velocities and discharges in long conduits from pump machines must be referred to the article *Water-Works*. At present we shall confine our attention to the pump itself, and to what will contribute to its improvement.

Before we can proceed to apply this fundamental proposition to our purpose, we must anticipate in a loose way a proposition of continual use in the construction of *water-works*.

Let water be supposed stagnant in a vessel EFGH (fig. 37.), and let it be allowed to flow out by a cylindrical pipe HIKL, divided by any number of partitions B, C, D, &c. Whatever be the areas B, C, D, of these orifices, the velocity in the intermediate parts of the pipe will be the same; for as much passes through any one orifice in a second as passes through any other in the same time, or through any section of the intervening pipe. Let this velocity in the pipe be \( V \), and let the area of the pipe be \( A \). The velocity in the orifices B, C, D, must be \( \frac{VA}{B} \), \( \frac{VA}{C} \), \( \frac{VA}{D} \), &c. Let \( g \) be the velocity acquired in a second by a heavy body. Then, by the general proposition, the height of water in the vessel which will produce the velocity \( \frac{VA}{B} \) in the first orifice alone, is \( \frac{VA}{2g} \). After this passage the velocity is again reduced to \( V \) in the middle of the space between the first and second orifices. In the second orifice this velocity is changed to \( \frac{VA}{C} \). This
Pump alone would have required a height of water \( \frac{V^2 A^2}{2g C^2} \) but the water is already moving with the velocity \( V \), which would have resulted from a height of water in the vessel (which we shall, in the language of the art, call the head of water) equal to \( \frac{V}{2g} \). Therefore there is only required a head of water \( \frac{V^2 A^2}{2g C^2} \) or \( V^2 \frac{A^2}{2g C^2} - 1 \). Therefore the whole height necessary for producing the efflux through both orifices, so as still to preserve the velocity \( V \) in the intervening pipe, is \( \frac{V^2 A^2}{2g B^2 + C^2} \). In like manner the third orifice \( D \) would alone require a head of water \( \frac{V^2 A^2}{2g B^2} - 1 \); and all the three would require a head \( \frac{V^2 A^2}{2g B^2 + C^2 + D^2} \).

By this induction may easily be seen what head is necessary for producing the efflux through any number of orifices.

Let the expence or quantity of water discharged in an unit of time (suppose a second) be expressed by the symbol \( Q \). This is measured by the product of the velocity by the area of the orifice, and is therefore \( \frac{V A^2}{B} \), \( \frac{V A}{C} \), \( \frac{V A^2}{C} \), &c. and \( V^2 = \frac{Q^2}{A^2} \). Therefore we may compute the head of water (which we shall express by \( H \)) in reference to the quantity of water discharged, because this is generally the interesting circumstance. In this view we have \( H = \frac{Q^2}{2gA B^2 + C^2 + D^2} \); which shows that the head of water necessary for producing the discharge increases in the proportion of the square of the quantity of water which is discharged.

These things being premised, it is an easy matter to determine the motion of water in a pump, and the quantity discharged, resulting from the action of any force on the piston, or the force which must be applied to the piston in order to produce any required motion or quantity discharged. We have only to suppose that the force employed is the pressure of a column of water of the diameter of the working barrel; and this is over and above the force which is necessary for merely supporting the water at the height of the place of delivery. The motion of the water will be the same in both cases.

Let us, first of all, consider a sucking-pump. The motion here depends on the pressure of the air, and will be the same as if the pump were lying horizontally, and communicated with a reservoir, in which is a head of water sufficient to overcome all the obstructions to the motion, and produce a velocity of efflux such as we desire. And here it must be noted that there is a limit. No velocity of the piston can make the water rise in the suction-pipe with a greater velocity than what would be produced by the pressure of a column of water 33 feet high; that is, about 46 feet per second.

Let the velocity of the piston be \( V \), and the area of the working barrel \( A \). Then the water fills the barrel as fast as the piston is drawn up; the discharge during the rise of the piston, or the number of cubic feet of water per second, must be \( V \times A \). This is always supposed, and we have already ascertained the circumstances which ensure this to happen. If, therefore, the water arrived with perfect freedom to the piston, the force necessary for giving it this velocity, or for discharging the quantity \( V \times A \) in a second, would be equal to the weight of the pillar of water whose height is \( \frac{V^2}{2g} \) and base \( A \).

It does not appear at first sight that the force necessary for producing this discharge has any thing to do with the obstructions to the ascent of the water into the pump, because this is produced by the pressure of the atmosphere, and it is the action of this pressure which is measured by the head of water necessary for producing the internal motion in the pump. But we must always recollect that the piston, before bringing up any water, and supporting it at a certain height, was pressed on both sides by the atmosphere. While the air supports the column below the piston, all the pressure expended in this support is abstracted from its pressure on the under part of the piston, while its upper part still supports the whole pressure. The atmosphere continues to press on the under surface of the piston, through the intermedium of the water in the suction-pipe, with the difference of these two forces. Now, while the piston is drawn up with the velocity \( V \), more of the atmospheric pressure must be expended in causing the water to follow the piston; and it is only with the remainder of its whole pressure that it continues to press on the under surface of the piston. Therefore, in order that the piston may be raised with the velocity \( V \), a force must be applied to it, over and above the force necessary for merely supporting the column of water, equal to that part of the atmospheric pressure thus employed; that is, equal to the weight of the head of water necessary for foreing the water up through the suction-pipe, and producing the velocity \( V \) in the working barrel.

Therefore let \( B \) be the area of the mouth of the suction-pipe, and \( C \) the area of the fixed valve, and let the suction-pipe be of equal diameter with the working barrel. The head necessary for producing the velocity \( V \) on the working barrel is \( \frac{V^2 A^2}{2g B^2 + C^2} \). If \( d \) express the density of water; that is, if \( d \) be the number of pounds in a cubic foot of water, then \( \frac{AV^2}{2g (B^2 + C^2)} \) will express the weight of a column whose base is \( A \), and height \( \frac{V^2}{2g} \), all being reckoned in feet. Therefore the force which must be applied, when estimated in pounds, will be \( -\frac{d AV^2 (A^2 + A^2)}{2g (B^2 + C^2)} \).

The first general observation to be made on what has been said is, that the power which must be employed to produce the necessary motion, in opposition to all the obstacles, is in the proportion of the square of the velocity.
city which we would produce, or the square of the quantity of water we would discharge.

We have hitherto proceeded on the supposition, that there is no contraction of the jet in passing through these two orifices. This we know would be very far from the truth. We must therefore accommodate things to these circumstances, by diminishing B and C in the ratio of the contraction, and calling the diminished areas b and c; then we have

\[ p = \frac{A d V^2 \left( \frac{A^2}{b^2} + \frac{A^2}{c^2} - 1 \right)}{2g}. \]

What this diminution may be, depends on the form of the parts. If the fixed valve, and the entry into the pump, are simply holes in thin plates, then \( a = \frac{2g}{A^2} \) B and \( c = \frac{2g}{C^2} \). The entry is commonly widened or trumpet-shaped, which diminishes greatly the contraction; but there are other obstacles in the way, arising from the strainer usually put round it to keep out filth. The valve may have its contraction greatly diminished also by its box being made bell-shaped internally; may, even giving it a cylindrical box, in the manner of fig. 33, better than no box at all, as in fig. 5; for such a cylindrical box will have the unaccountable effect of the short tube, and make \( b = \frac{2g}{B^2} \) B, instead of \( \frac{2g}{C^2} \). Thus we see that circumstances seemingly very trifling may produce great effects in the performance of a pump.

We should have observed that the valve itself presents an obstacle which diminishes the motion, and requires an increase of power; and it would seem that in this respect the clack or butterfly valve is preferable to the button valve.

**Example.** Suppose the velocity of the piston to be 2 feet or 24 inches per second, and that the two contracted areas are each \( \frac{1}{8} \) of the area of the pump, which is not much less than what obtains in ordinary pumps.

We have

\[ \frac{V^2}{2g} \left( \frac{A^2}{b^2} + \frac{A^2}{c^2} - 1 \right) = \frac{4}{9} \left( 25 + 25 - 1 \right) = 36.75 \text{ inches} \]

and the force which we must add to what will merely support the column is the weight of a pillar of water incumbent on the piston, and something more than three feet high. This would be a sensible portion of the whole force in raising water to small heights.

We have supposed the suction-pipe to be of the same diameter with the working barrel; but it is usual to make it of smaller diameter, generally equal to the water way of the fixed valve. This makes a considerable change in the force necessary to be applied to the piston. Let a be the area of the suction-pipe, the area of the entry being still B; and the equivalent entry without contraction being still b, we have the velocity at the entrance \( \frac{AV}{b^2} \), and the producing head of water \( \frac{A^2 V^2}{2g b^4} \). After this the velocity is changed to \( \frac{AV}{a} \) in the suction-pipe, with which the water arrives at the valve, where it is again changed to \( \frac{AV}{c} \), and requires for this change a head of water equal to \( \frac{A^2 V^2}{2g c^2} \). But the velocity retained in the suction-pipe is equivalent to the effect of a head of water \( \frac{A^2 V^2}{2g b^2} \). Therefore the head necessary for producing such a current through the fixed valve, that the water may follow the piston with the velocity \( V \), is \( \frac{A^2 V^2}{2g b^2} + \frac{A^2 V^2}{2g c^2} - \frac{A^2 V^2}{2g b^2} \), or \( V^2 \left( \frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{b^2} \right) \). This is evidently less than before, because \( a \) is less than \( A \), and therefore \( a \) is greater than unity, which was the last term of the former formula. There is some advantage, therefore, derived from making the diameter of the suction-pipe less than that of the working barrel: but this is only because the passage of the fixed valve is smaller, and the inspection of the formula plainly points out that the area of the suction-pipe should be equal to that of the fixed valve. When it is larger, the water must be accelerated in its passage through the valve; which is an useless expenditure of force, because this velocity is to be immediately reduced to \( V \) in the working-barrel. If the foregoing example be computed with \( a \) equal to \( \frac{1}{2} \) of \( A \), we shall find the head \( H \) equal to 29 inches instead of 37.

But this advantage of a smaller suction-pipe is in all cases very moderate; and the pump is always inferior to one of uniform dimensions throughout, having the orifice at the fixed valve of the same area. And as these orifices are considerably diminished in any proportion, the head necessary for overcoming the obstacles, so that the required velocity \( V \) may still be produced in the working barrel, is greatly increased. If we suppose the area \( a \) of \( A \), which is frequently done in house pumps, where the diameter of the suction-pipe does seldom exceed \( \frac{1}{4} \) of that of the working-barrel; and suppose every thing made in proportion to this, which is also usual, because the unskilled pump-makers study a symmetry which satisfies the eye; we shall find that the pump taken as an example will require a head of water \( = 13 \) feet and upwards. Besides, it must be observed that the friction of the suction-pipe itself has not been taken into the account. This alone is greater, in most cases, than all the obstructions we have been speaking of; for if this pipe is three inches diameter, and that of the working-barrel is six, which is reckoned a liberal allowance for a suction-pipe, and if the fixed valve is 25 feet above the surface of the water-pit; the friction of this pipe will amount to one-third of the whole propelling force.

Thus we have enabled the reader to ascertain the force necessary for producing any required discharge of water from a pump of known dimensions: and the converse of this determination gives us the discharge which will be produced by any given force. For making \( \frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{b^2} \) (which is a known quantity, resulting from the dimensions of the pump) \( = M \), we have \( H = \frac{V^2}{2g M} \), and \( V^2 = \frac{2g H}{M} \), and \( V = \sqrt{2g H} \). Now \( H \) is that part of the natural power which we have at command which exceeds what is necessary for merely suppressing the column of water. Thus, if we have a pump whose piston has an area of \( \frac{1}{4} \) of a square foot, its diameter being \( 6\frac{1}{2} \) inches; and we have to raise the water 32 feet, and can apply a power of 525 pounds to the piston; we wish to know at what rate the piston will be moved, and the quantity of water discharged?
Merely to support the column of water of this height and diameter, requires 500 pounds. Therefore the remaining power, which is to produce the motion, is 25 pounds. This is the weight of a column 1 foot 4 inches high, and $H = 1,333$ feet. Let us suppose the diameter of the suction-pipe $\frac{3}{4}$ of that of the working-barrel, so that $\frac{A}{B} = 4$. We may suppose it executed in the best manner, having its lower extremity trumpet-shaped, formed by the revolution of the proper trochoid. The contraction at the entry may therefore be considered as nothing, and $\frac{A}{b} = 4$, and $\frac{A^2}{b^2} = 16$. We may also suppose the orifice of the fixed valve equal to the area of the suction-pipe, so that $\frac{A^3}{c^3}$ is also $= 16$, and there is no contraction here; and therefore $\frac{A^3}{c^3}$ is also 16. And lastly, $\frac{A^3}{b^3}$ is also 16. Therefore $\frac{A^3}{b^3} + \frac{A^3}{c^3} - \frac{A^3}{a^3} = 16 + 16 - 16 = 16$.

We have also $2g = 64$. Now $N = \sqrt{\frac{2gH}{M}} = \sqrt{\frac{64 \times 1,333}{16}} = 2,309$ feet, and the piston will move with the velocity of 2 feet 4 inches nearly. Its velocity will be less than this, on account of both of the friction of the piston and the friction of the water in the suction-pipe. These two circumstances will probably reduce it to one foot eight inches; and it can hardly be less than this.

We have taken no notice of the friction of the water in the working-barrel, or in the space above the piston; because it is in all cases quite insignificant. The longest pipes employed in our deep mines do not require more than a few inches of head to overcome it.

But there is another circumstance which must not be omitted. This is the resistance given to the piston in its descent. The pistons of an engine for drawing water from deep mines must descend again by their own weight in order to repeat their stroke. This must require a preponderance on that end of the working-beam to which they are attached, and this must be overcome by the moving power during the effective stroke. It makes, therefore, part of the whole work to be done, and must be added to the weight of the column of water which must be raised.

This is very easily ascertained. Let the velocity of the piston in its descent be $V$, the area of the pump-barrel $A$, and the area of the piston-valve $a$. It is evident, that while the piston descends with the velocity $V$, the water which is displaced by the piston in a second is $(A - a) V$. This must pass through the hole of the piston, in order to occupy the space above, which is left by the piston. If there were no contraction, the water would go through with the velocity $\frac{A - a}{a} V$; but as there will always be some contraction, let the diminished area of the hole (to be discovered by experiment) be $b$, the velocity therefore will be $\frac{V}{A - a} \frac{A - a}{b}$. This requires for its production a head of water $\frac{V^2}{A - a} \frac{A - a}{b} \times \frac{2g}{b}$. This is the height of a column of water whose base is not $A$ but $A - a$. Calling the density of water $d$, we have for the weight of this column, and the force $p$ in $d \times \frac{A - a}{b} + \left(\frac{4}{b} - \frac{A - a}{b}\right) \times \frac{V^2}{2g}$, $\frac{dV^2(A - a)^3}{2g b^3}$. This, we see again, is proportional to the square of the velocity of the piston in its descent, and has no relation to the height to which the water is raised.

If the piston has a button valve, its surface is at least equal to $a$; and therefore the pressure is exerted on the water by the whole surface of the piston. In this case we shall have $p = \frac{dV^2 A^2}{2g b^2}$ considerably greater than before. We cannot ascertain this value with great precision, because it is extremely difficult, if possible, to determine the resistance in so complicated a case. But the formula is exact, if $b$ can be given exactly; and we know within very moderate limits what it may amount to. In a pump of the very best construction, with a button valve, $b$ cannot exceed one-half of $A$; and therefore $\frac{A^3}{b^3}$ cannot be less than 8. In this case, $\frac{V^2 A^3}{8}$ will be $\frac{V^2}{2g}$. In a good steam-engine pump $V$ is about three feet per second, and $\frac{V^2}{8}$ is about $\frac{1}{2}$ feet, which is but a small matter.

We have hitherto been considering the sucking-pump and the alcohol: but the forcing pump is of more importance, forcing- and apparently more difficult of investigation. Here, we have to overcome the obstructions in long pipes, with many bends, contractions, and other obstructions. But the consideration of what relates merely to the pump is abundantly simple. In most cases we have only to force the water into an air-vessel, in opposition to the elasticity of the air compressed in it, and to send it thither with a certain velocity, regulated by the quantity of water discharged in a given time. The elasticity of the air in the air-vessel propels it along the Main. We are not now speaking of the force necessary for counterbalancing this pressure of the air in the air-vessel, which is equivalent to all the subsequent obstructions, but only of the force necessary for propelling the water out of the pump with the proper velocity.

We have in a manner determined this already. The piston is solid, and the water which it forces has to pass through a valve in the lateral pipe, and then to move in the direction of the main. The change of direction requires an addition of force to what is necessary for merely impelling the water through the valve. Its quantity is not easily determined by any theory, and it varies according to the abruptness of the turn. It appears from experiment, that when a pipe is bent to a right angle, without any curvature or rounding, the velocity is diminished about $\frac{1}{2}$ of $V$. This would augment the head of water about $\frac{2}{3}$. This may be added to the contraction of the valve hole. Let $c$ be its natural area, and whatever is the contraction competent to its form, increase it $\frac{1}{2}$, and call the contracted area $c$. Then this will require a head of water $\frac{V^2 A^3}{2g c^3}$. This
This must be added to the head \( \frac{V^2}{2g} \), necessary for merely giving the velocity \( V \) to the water. Therefore the whole is \( \frac{(A^2)}{(c^2 + 1)} \); and the power \( p \) necessary for this purpose is \( \frac{dA^2V^2}{2g} \left( \frac{A^2}{c^2 + 1} \right) \).

It cannot escape the observation of the reader, that in all these formulæ, expressing the height of the column of water which would produce the velocity \( V \) in the working barrel of the pump, the quantity which multiplies the constant factor \( \frac{dA^2V^2}{2g} \) depends on the contracted passages which are in different parts of the pump, and increases in the duplicate proportion of the sum of those contractions. It is therefore of the utmost consequence to avoid all such, and to make the main which leads from the forcing-pump equal to the working barrel. If it be only half of the diameter, it has but one-fourth of the area, the velocity in the main is four times greater than that of the piston, and the force necessary for discharging the same quantity of water is 16 times greater.

It is not, however, possible to avoid these contractions altogether, without making the main pipe wider than the barrel. For if only as wide, with an entry of the same size, the valve makes a considerable obstruction. Unskilful engineers endeavour to obviate this by making an enlargement in that part of the main which contains the valve. This is seen in fig. 14, at the valve I. If this be not done with great judgment, it will increase the obstructions. For if this enlargement is full of water, the water must move in the direction of its axis with a diminished velocity; and when it comes into the main, it must again be accelerated. In short, any abrupt enlargement which is to be afterwards contracted, does as much harm as a contraction, unless it be so short that the water in the axis keeps its velocity till it reaches the contraction. Nothing would do more service to an artist, who is not well founded in the theory of hydrodynamics, than to make a few simple and cheap experiments with a vessel like that of fig. 37. Let the horizontal pipe be about three inches diameter, and made in joints which can be added to each other. Let the joints be about six inches long, and the holes from one fourth to a whole inch in diameter. Fill the vessel with water, and observe the time of its sinking three or four inches. Each joint should have a small hole in its upper side to let out the air; and when the water runs out by it, let it be stopped by a peg. He will see that the larger the pipe is in proportion to the orifices made in the partitions, the efflux is more diminished. We believe that no person would suspect this who has not considered the subject minutely.

All angular enlargements, all boxes, into which the pipes from different working barrels, unite their water before it goes into a main, must therefore be avoided by an artist who would execute a good machine; and the different contractions which are unavoidable at the seats of valves and the perforations of pistons, &c. should be diminished by giving the parts a trumpet-shape.

In the air-vessels represented in fig. 13, this is of very great consequence. The throat \( O \), through which the water is forced by the expansion of the confined air, should always be formed in this manner. For it is this which produces the motion during the returning part of the stroke in the pump constructed like fig. 13, \#1, and during the whole stroke in \#2. Neglecting this seemingly trifling circumstance, will diminish the performance at least one-fifth. The construction of \#1, is the best, for it is hardly possible to make the passage of the other so free from the effects of contraction. The motion of the water during the returning stroke is very much contorted.

There is one circumstance that we have not taken any notice of, viz. the gradual acceleration of the motion of the water in pumps. When a force is applied to the piston, it does not in an instant communicate all the velocity which it acquires. It acts as gravity acts on heavy bodies; and if the resistances remained the same, it would produce, like gravity, an uniformly accelerated motion. But we have seen that the resistances (which are always measured by the force which just overcomes them) increase as the square of the velocity increases. They therefore quickly balance the action of the moving power, and the motion becomes uniform, in a time so short that we commit no error of any consequence by supposing it uniform from the beginning. It would have prodigiously embarrassed our investigations to have introduced this circumstance; and it is a matter of mere speculative curiosity: for most of our moving powers are unequal in their exertions, and these exertions are regulated by other laws. The pressure on a piston moved by a crank is as variable as its velocity, and in most cases is nearly in the inverse proportion of its velocity, as any mechanic will readily discover. The only case in which we could consider this matter with any degree of comprehensibility is that of a steam-engine, or of a piston which forces by means of a weight lying on it. In both, the velocity becomes uniform in a very small fraction of a second.

We have been very minute on this subject. For although it is the only view of a pump which is of any importance, it is hardly ever understood even by professional engineers. And this is not peculiar to hydraulics, but is seen in all the branches of practical mechanics. The elementary knowledge to be met with in such books as are generally perused by them, goes no farther than to state the forces which are in equilibrio by the intervention of a machine, or the proportion of the parts of a machine which will set two known forces in equilibrio. But when this equilibrio is destroyed by the superiority of one of the forces, the machine must move; and the only interesting question is, what will be the motion? Till this is answered with some precision, we have learned nothing of any importance. Few engineers are able to answer this question even in the simplest cases; and they cannot, from any confined science, say what will be the performance of an untried machine. They guess at it with a success proportioned to the multiplicity of their experience and their own sagacity. Yet this part of mechanics is as susceptible of accurate computation as the cases of equilibrio.—We therefore thought it our duty to point out the manner of proceeding so circumstantially, that every step should be plain and easy, and that conviction should always accompany our progress. This we think it has been in our power to do, by the very simple method of substituting a column.
PUN

Pump

Puncheon.

PUN, or PUNN, an expression where a word has at once different meanings. The practice of punning is the miserable refuge of those who wish to pass for wits, without having a grain of wit in their composition. James the I. of England delighted in punning; and the taste of the sovereign was studied by the courtiers, and even by the clergy. Hence the sermons of that age abound with this species of false wit. It continued to be more or less fashionable till the reign of Queen Anne, when Addison, Swift, Pope, and Arbuthnot, with the other real wits of that classical age, united their efforts to banish punning from polite composition. It is still admitted sparingly in conversation; and no one will deny that a happy pun, when it comes unsought, contributes to excite mirth in a company. A professed punster, however, who is always pouring forth his senseless quibbles, as Sancho Panza poured forth his proverbs, is such an intolerable nuisance in society, that we do not wonder at Pope or Swift having written a pamphlet with the title of God’s Revenge against Punning.

PUNCH, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and take away the piece. The punch is a principal instrument of the metal-button makers, shoemakers, &c.

PUNCH is also a name for a sort of compound drink, much used here, and in many parts abroad, particularly in Jamaica, and several other parts of the West Indies.

Its basis is spring-water; which being rendered cooler, brisker, and more acid, with lemon or lime juice, and sweetened again to the palate with fine sugar, makes what they call sherbet; to which a proper quantity of spirituous liquor, as brandy, rum, or arrack, being added, the liquor becomes punch.

PUNCHEON, PUNCHIN, or Puchion, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraved either in creux or reliëvo, impressions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraved. There are various kinds of these punchcens used in the mechanical arts; such, for instance, are those of the goldsmiths, cutters, pewterers, &c.

The punchen, in coining, is a piece of iron steeled, whereon the engraver has cut in reliëvo the several figures, arms, effigy, inscription, &c. that there are to be in the matrices, wherewith the species are to be marked. Minters distinguish three kinds of punchcens, according to the three kinds of matrices to be made; that of the effigy, that of the cross or arms, and that of the legend or inscription. The first includes the whole portrait in reliëvo; the second are small, such only containing a piece of the cross or arms; for instance, a fleur-de-lis, an harp, a cornet, &c. by the assemblage of all which the entire matrix is formed. The punchcens of the legened only contain each one letter, and serve equally for the legend on the effigy side and the cross side. See the article COINAGE.

For the punchcens used in stamping the matrices wherein the types of printing characters are cast, see LETTER-FOUNDRY.

PUNCHEON is also used for several iron tools, of various sizes and figures, used by the engravers en creux on metals. Seal-engravers particularly use a great number for the several pieces of arms, &c. to be engraved, and many stamp the whole seal from a single punchen.

PUNCHEON is also a common name for all those iron instruments used by stone-cutters, sculptors, blacksmith, &c. for the cutting, incising, or piercing their several matters.

Those of sculptors and statuaries serve for the repairing of statues when taken out of the moulds. The locksmiths use the greatest variety of punchcens; some for piercing hot, others for piercing cold; some flat, some square, some round, others oval, each to pierce holes of its respective figure in the several parts of locks.

PUNCHEON, in Carpentry, is a piece of timber placed upright between two posts, whose bearing is too great; serving, together with them, to sustain some large weights.

This term is also used for a piece of timber raised upright, under the ridge of a building, wherein the legs of a couple, &c. are jointed.

PUNCHEON, is also the name of a measure for liquids. Rum is brought from the colonies in punchcens, which are large casks containing about 130 gallons.

PUNCTUATION, in Grammar, the art of point- ing, or of dividing a discourse into periods, by points expressing the pauses to be made therein.

The points used are four, viz. the period, colon, semicolon, and comma. See the particular use of each under its proper article, COMMA, COLON, PERIOD, and SEMICOLON.

In general, we shall only here observe, that the comma is to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together. The semi-colon serves to suspend and sustain the period when too long: the colon, to add some new supernumerary reason, or consequence, to what is already said: and the period to close up the sense and construction, and release the voice. It has been asserted, that punctuation is a modern art, and that the ancients were entirely unacquainted with the use of our commas, colons, &c. and wrote not only without any distinction of numbers and periods, but also without distinction of words: which custom, Lipsius observes, continued till the hundred and fourth Olympiad;
lypiad; during which time the sense alone divided the discourse.

What within our own knowledge at this day puts this beyond dispute, is the Alexandrian manuscript, which is at present in the king’s library, at the British Museum. Whoever examines this, will find that the whole is written continuo ductu, without distinction of words or sentences. How the ancients read their works written in this manner, it is not easy to conceive.

After the practice of joining words together ceased, notes of distinction were placed at the end of every word. In all the editions of the Fasti Capitolini these points occur. The same are to be seen on the Columna Rotata. For want of these, we find much confusion in the Chronicon Marmoreum, and the connexion between the Smyrneans and Magnesians, which are both now at Oxford. In Salmasius’s edition of Dedicatio status rigilae Herodis, the like confusion occurs, where we find DEEPIIT and oms. Of these marks of distinction, the Walcot inscription found near Bath may serve as a specimen; IVLIUS VITALIS IS FABR I CESIUS LEGVXXV V V V STIPENDIORUM &c.

After every word here, except at the end of a line, we see this mark v. There is an inscription in Montfaucon, which has a capital letter laid in a horizontal position, by way of interstitial mark, which makes one apt to think that this way of pointing was sometimes according to the fancy of the graver.

P. FERRARIVS HERMES CAECINIAE Δ DIGNAE CONIVCIJ Δ KARISSIMAE NVMERIAE Δ &c.

He we observe after the words a T laid horizontally, but not after each word, which proves this to be of a much later age than the former.

As the improvement of stops appears not to have taken place while manuscripts and monumental inscriptions were the only known methods to convey knowledge, it is conjectured that it was introduced with the art of printing. The 14th century, to which we are supposed to be indebted for this invention, did not, however, bestow those appendages we call stops: whoever will be at the pains of examining the first printed books, will discover no stops of any kind; but arbitrary marks here and there, according to the humour of the printer.

In the 16th century, we observe their first appearance. We find, from the books of this age, that they were not all produced at the same time; those we meet with there in use, being only the comma, the parenthesis, the interrogation, and the full point. To prove this, we need but look into Bale’s Acts of English Worthies, black letter, printed 1550. Indeed, in the dedication of this book, which is to Edward VI. we discover a colon: but, as this is the only one of the kind throughout the work, it is plain this stop was not established at this time, and so warmly put in by the printer; or if it was, that it was not in common use. Thirty years after this time, in that sensible and judicious performance of Sir Thomas Elyot, entitled The Governor, imprinted 1580, we see the colon as frequently introduced as any other stop; but the semicolon and the admiration were

VOL. XVII. Part II. still wanting, neither of these being visible in this book.

In Hakluyt’s Voyages, printed 1590, we see the semicolon; and, as if the editors did not fully apprehend the propriety of its general admission, it is but sparingly introduced. It has been said, indeed, that the semicolon was brought into use at a much earlier period; but it appears that it was only for the purpose of an abbreviation, as in (namq;) (neq;) for namque, neque, and not in the sense in which it is now employed, Month. Mag. v. 411.

The semicolon, indeed, as well as all the ordinary points, is used in a work entitled “Imagines Deorum,” printed at Leyden, in the year 1581, in Roman characters. We likewise meet with them in the translation of a justly celebrated book, written in French by that wise and good man, Philip Mornay, lord of Plessis; in the “Schoolmaster” of Roger Ascham, printed in 1570, with the exception of the semicolon; and in the “Trewnesse of the Christian Religion,” by Sir Philip Sidney, published in 1587, in which we find the asterisk, brackets, the interrogation, the comma and the semicolon, all as we now use them; and the colon and period are square dots.

In an alchemical manuscript of the date of 1572, the semicolon is said to be met with, as well as the other three points which are in common use. The colon and period are abundant in a work entitled “Dionisius de Situ Orbis,” printed at Venice in 1498, but none of the other stops or points. The single point (.) appears to be the most ancient. Since the year 1485 the colon was introduced; the comma is first seen about the year 1521; and the more refined semicolon was brought into use about the year 1570.

The invention of the semicolon is most probably due to the English; for from the Leyden edition of Pliny, 1553, it is evident that the Dutch printers were not then in the practice of using it; and if in 1570, they were, Roger Ascham would probably have employed it; for the Dutch were the principal classical printers in his time; but we find that some English books were marked with it at that period.

The admiration was the last stop that was invented, and seems to have been added to the rest in a period not so far distant from our own time.

Thus we see that these notes of distinction came into use as learning was gradually advanced and improved; one invention indeed, but enlarged by several additions.

But notwithstanding what has been said relative to the use of stops as being a modern invention, we shall find reason to be satisfied that the ancients were not acquainted with the method of making pauses in speaking and writing, if we attend to the following elaborate investigation of Mr Warburton, which we shall lay before our readers in the words of the author.

“Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols.

“Suidas says, that the period and the colon were Δ De Thras discovered and explained by Thrasymachus, about 380 c.a. 380 years before the Christian era. Cicero† says, that Thrasymachus was the first who studied oratorical num- bers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle, that punctuation was known in his time. The 1 Rhet. learned lib. II. c. 5.
PUN

Punctuation.

* Born. Or. bis erud. Literat. 1 ed. 1639.

learned Dr Edward Bernard refers the knowledge of pointing to the time of that philosopher, and says, that it consisted in the different position of one single point.

At the bottom of a letter; thus, (A.) it was equivalent to a comma; in the middle (A-) it was equal to a colon; at the top (A') it denoted a period, or the conclusion of a sentence.

"This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the ninth century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. Unius literas Hodierne usus dictium eas in extantia codicibus, quis praecum formam servavit, ac solute sunt, nec multis colligante. Hujusmodi literae unicus observatur in libris omnibus ad nonum usque seculum. Montf. Palaeogr. Recens. p. xii.

"According to Cicero, the ancient Romans as well as the Greeks made use of points. He mentions them under the appellation of libratorum notae; and in several parts of his works he speaks of 'interpunctae clausulae in orationibus,' "clausula atque interpunctae verborum," of interpunctiones verborum, &c."

"Seneca, who died A.D. 65, expressly says, that Latin writers in his time, had been used to punctuation. 'Nos 4. cum scribimus interpungere consequemur,' Marcius and Lipsius imagined that these words alluded to the insertion of a point after each word; but they certainly were mistaken, for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these words occur, Seneca is speaking of one Q. Haterius, who made no pause in his orations.

"According to Suetonius in his Illust. Gram. Valerius Probus procured copies of many old books, and employed himself in correcting, pointing and illustrating them; devoting his time to this and no other part of grammar. Multa exemplaria contracta emendare, ac distinguere et adnotare curaverit; soli haec, nec ullo praeterea, grammatici partis delibat.

"It appears from hence that in the time of Probus, or about the year 68, Latin manuscripts had not been extensively copied; and that grammarians made it their business to supply this deficiency.

"Quintillian, who wrote his celebrated treatise on Oratory about the year 88, speaks of commas, colons, and periods; but it must be observed that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation."

§ Quint. lib. ix. c. iv. "Elemus Donatus published a treatise on Grammar A.D. 340, in the fourth century, in which he explains the distinctio, the media distinctio, and the subsidio: that is, the use of a single point in the various positions already mentioned.

Jerome, who had been the pupil of Donatus, in his Latin version of the scriptures, made use of certain distinctions or divisions, which he calls cola and comota. It has however been thought probable, that those divisions were not made by the addition of any points or stops; but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. Those divisions were called stygi or symple; and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant which are written in this manner."
PURCHASE, in Law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

PURCHASE, in the sea-language, is the same as draw in: thus, when they say, the capstan purchases a-pace, they only mean it draws in the cable a-pace.

PURE, something free from any admixture of foreign or heterogeneous matters.

PURPLE, a term in heraldry, expressing ermine, peans, or any of the furs, when they compose a bordure round a coat of arms: thus they say, He hereth gules, a bordure, purfle, valer; meaning, that the bordure is furred.

PURGATION, the art of purging, scouring, or purifying a thing, by separating, or carrying off any impurities found therein. Thus:

In pharmacy, purgation is the cleansing of a medicine by retrenching its superfluities. In chemistry, it is used for the several preparations of metals and minerals intended to clear them of their impurities, more usually called purification and refining.

In medicine, purgation is an excretory motion arising from a quick and orderly contraction of the fleshy fibres of the stomach and intestines, whereby the chyle, corrupted humours, and excrements lodged therein, are protruded further and further, and at length quite excluded the body by stool. See MATERIA MEDICA.

PURGATION, in Law, signifies the clearing a person's self of a crime of which he is suspected and accused before a judge. This purgation is either canonical or vulgar. Canonical purgation is prescribed by the canon law, and the form thereof in the spiritual court is usually thus: The person suspected takes his oath that he is innocent of the crime charged against him; and at the same time brings some of his neighbours to make oath that they believe he swears truly. Vulgar purgation was anciently by fire or water, or else by combat, and was practised here till abolished by our canons. See BATEL, in law; ORDEAL, &c.

PURGATIVE or PURGING Medicines, medicaments, which evacuate the impurities of the body by stool, called also cathartics.

PURGATORY, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation. Broughton has endeavoured to prove, that this notion has been held by Pagans, Jews, and Mahometans, as well as by Christians; and that in the days of the Maccabees the Jews believed that sin might be expiated by sacrifice after the death of the sinner, cannot be questioned.

Much abuse has been poured upon the church of Rome for her doctrine of purgatory, and many false representations have been made of the doctrine itself. The following view of it is taken from a work which is considered as a standard by the British Catholics. 1. Every sin, how slight soever, though no more than an idle word, as it is an offence to God, deserves punishment from him, and will be punished by him hereafter, if not cancelled by repentance here. 2. Such small sins do not deserve eternal punishment. 3. Few depart this life so pure as to be totally exempt from spots of this nature, and from every kind of debt due to God's justice. 4. Therefore few will escape without suffering something from his justice for such debts as they have carried with them out of this world; according to that rule of divine justice, by which he treats every soul hereafter according to its works, and according to the state in which he finds it in death. From these propositions, which the Papist considers as so many self-evident truths, he infers that there must be some third place of punishment; for, since the infinite goodness of God can admit nothing into heaven which is not clean and pure from all sin both great and small; and his infinite justice can permit none to receive the reward of bliss, who
who as yet are not out of debt, but have something in justice to suffer; there must of necessity be some place or state, where souls, departing this life, pardoned as to the eternal guilt or pain, yet obnoxious to some temporal penalty, or with the guilt of some venial faults, are purged and purified before their admissitio in heaven. And this is what he is taught concerning purgatory. Which, though he knows not where it is, of what nature the pains are, or how long each soul is detained there; yet he believes, that those that are in this place, being the living members of Jesus Christ, are relieved by the prayers of their fellow members here on earth, as also by alms and masses offered up to God for their souls. And as for such as have no relations or friends to pray for them, or give alms, or procure masses for their relief; they are not neglected by the church, which makes a general commemoration of all the faithful departed in every mass, and in every one of the canonical hours of the divine office.

Such is the Popish doctrine of purgatory, which is built chiefly upon 2 Macc. xii. 43, 44, 45; St Matth. xii. 31, 32; and 1 Cor. iii. 15. By Protestants the books of Maccabees are not acknowledged to be inspired scripture; but if they were, the texts referred to would rather prove that there is no such place as purgatory, since Judas did not expect the souls departed to reap any benefit from his sin-offering till the resurrection. Our Saviour, in St Luke, speaks of remission in this world, and in the world to come; but surely neither of these is purgatory. The world to come is the state after the resurrection, and the remission spoken of is the sentence of absolution to be pronounced on the penitent from the seat of general judgment. In the obscure verse referred to in the epistle to the Corinthians, the apostle is, by the best interpreters, thought to speak of the difficulty with which Christians should be saved from the destruction of Jerusalem. Of the state of souls departed he cannot well be supposed to speak, as upon disembodied spirits fire could make no impression. We cannot help, therefore, thinking with the church of England, that “the Romish doctrine of purgatory is a fond thing, vainly invented, and grounded on no warranty of scripture;” but we must confess at the same time, that it appears to us to be a very harmless error, neither hostile to virtue nor dangerous to society. See Resurrection.

Purification, in matters of religion, a ceremony which consists in cleansing any thing from a supposed pollution or defilement.

The Pagans, before they sacrificed, usually bathed or washed themselves in water; and they were particularly careful to wash their hands, because with these they were to touch the victims consecrated to the gods. It was also customary to wash the vessel with which they made their libations. The Mahometans also use purifications previous to the duty of prayer; which are also of two kinds, either bathing, or only washing the face, hands and feet. The first is required only in extraordinary cases, as after having lain with a woman, touched a dead body, &c. But lest so necessary a preparation for their devotions should be omitted, either where water cannot be had, or when it may be of prejudice to a person’s health, they are allowed in such cases to make use of fine sand, or dust, instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male child, she was esteemed impure for 40 days; and when of a female, for 60: at the end of which time she carried a lamb to the door of the temple to be offered for a burnt-offering, and a young pigeon or turtle for a sin offering; and by this ceremony she was cleansed or purified.

Purim, or The Feast of Lots, a solemn festival of the Jews, instituted in memory of the deliverance they received, by means of Mordecai and Esther, from Haman’s wicked attempt to destroy them.

Puritan, a name formerly given in derision to the dissenters from the church of England, on account of the profession to follow the pure word of God, in opposition to all traditions and human constitutions. It was likewise given in the primitive church to the Novatian schismatics, because they would never admit to communion any one who from dread of death had apostatized from the faith.

Purity, the freedom of any thing from foreign admixture.

Purify of Style. See Oratory, p. 411, &c.

Purlieu, signifies all that ground near any forest, which being made forest by King Henry II. Richard I. and King John, was afterwards by perambulations and grants of Henry III. severed again from the same, and made purlieu; that is to say, pure and free from the laws of the forest.—The word is derived from the French pur, “pure,” and lieu, “place.”

Purlins, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

By the act of parliament for rebuilding London, it is provided, that all purlins from 15 feet 6 inches to 18 feet 6 inches long, be in their square 9 inches and 8 inches; and all in length from 18 feet 6 inches to 21 feet 6 inches, be in their square 12 inches and 9 inches.

Purple, a colour composed of a mixture of red and blue. See Colour-Making, No 29, and Dyeing Index.

Purpura, in Natural History. See Murex, Conchology Index. The Tyrian method of dyeing purple was with a liquid extracted from this fish. It has been affirmed, however, that no such method was ever practised. “At Tyre (says Mr Bruce) I engaged two fishermen, at the expense of their nets, to drag in those places where they said shell-fish might be caught, in hopes to have brought out one of the famous purple-fish. I did not succeed; but in this I was, I believe, as lucky as the old fishermen had ever been. The purple-fish at Tyre seems to have been only a concealment of their knowledge of cochineal; as, had they depended upon the fish for their dye, if the whole city of Tyre applied to nothing else but fishing, they would not have coloured 20 yards of cloth in a year.”

Purpure, in Heraldry. The colour so called, which signifies purple, is in engraving represented by diagonal lines, from the left to the right. See Heraldry.
PURSE, or PERKIN. See Agriculture Index.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it be well stowed, and keeps an account of what he every day delivers to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out; and that the paymaster or treasurer of the navy may issue out the debursements, and pay off the men, according to his book.

PURSLAIN. See Portulaca, Botany Index.

PURVIEW, a term used by some lawyers for the body of an act of parliament, or that part which begins with "Be it enacted, \\&c." as contradistinguished from the preamble.

PURULENT, in Medicine, something mixed with, or partaking of, pus or matter.

PUS, in Medicine, a white or yellowish matter designed by nature for the healing and cementing of wounds and sores.

The origin and formation of pus is as much unknown as that of any other animal fluid. In an inaugural dissertation published at Edinburgh by Dr Hendy, the author supposes pus to be a secreted fluid. It has been thought by many, that pus is either a sediment from serum when beginning to putrefy, or that it is the same fluid insipiently by the heat of the body. But both these opinions are refuted by some experiments of our author, which show, that pus is much less inclined to putrefaction than serum, and that the putrefaction of both is hastened by an addition of some of the red part of the blood. Some other experiments were made in order to try whether pus could be artificially produced. A thin piece of lamb's flesh, applied to an ulcer discharging hæmorrhage, was covered over with lead, did not assume the appearance of pus, but became fetid, and was much lessened. Serum, in its inflammatory and in its ordinary state, and lymph in different states, were applied to the same ulcer, which still discharged good pus; but none of these were converted into pus; on the contrary, they became very putrid.

In opposition to these arguments of our author, however, it may be alleged, that if pus was a secreted fluid, the vessels by which it was secreted would certainly be visible; but no such thing has ever been observed: on the contrary, it is certain that pus cannot be formed unless the air is excluded from the wound. These disputes, however, are of no great consequence: but in some cases it becomes a matter of real importance to distinguish pus from mucus; as thus we may be enabled to know whether a cough is consumptive, or merely catarrhal. See Mucous. Mr Hunter, in a dissertation on the properties of pus, in which he avails himself of the experiments of Mr Hunter, as delivered in his Physiological Lectures, says, "that the characteristic of pus is its being composed of globules; and he thinks that the presence of globules seems to depend upon the pus being in a perfect state. It differs from the blood in the colour of the globules; in their not being soluble in water, which those of the blood are; and from the fluid in which they swim being coagulable by a solution of sal ammoniac, which serum is not. Rising the formation of pus, our author adopts the idea suggested by Mr Hunter, that the vessels of the part assume the nature of a gland, and secrete a fluid which becomes pus. Mr Horne ascertains, by experiment, that pus, at its formation, is not globular, but a transparent fluid, of a consistence, in some sort, resembling jelly; and that the globules are formed while lying upon the surface of the sore; requiring, in some instances, while the influence of the external air is excluded, fifteen minutes for that purpose.

PUSTULE, a pimple, or small eruption on the skin full of pus; such as the eruptions of the smallpox.

PUTAMINE, Ec. (from putamen, "a shell," the name of the 25th order of Linnaeus's fragments of a natural method; consisting of a few genera of plants allied in habit, whose fleshy seed-vessel or fruit is frequently covered with a hard woody shell. See Botany.

PUTEOLI, (Livy, Strabo): a town of Campania; Sura, so called either from its wells, there being many hot and burnt cold springs thereabouts; or from its stench, putor, from the Latin putor, putor, "cause of sulphureous exhalations, (Varro, Strabo), \\&c."

It is now called Pozzuoli, and is pleasantly and advantageously situated for trade. In a very remote age, the Romans made it their arsenal and dockyard; and to this naval establishment gave the sublime appellation of Dicerosca or Just Power.

The Romans were well aware of the utility of this port, and took great pains to improve its natural advantages. Nothing remains of its works but a line of piers, built to break the force of a rolling sea: they are vulgarly called the bridge of Cogens, because that madman is said to have marched in triumph from Pozzuoli to Baiae on a bridge; but he was a bridge of boats.

The ruins of its ancient edifices are widely spread along the adjacent hills and shores. An amphitheatre still exists entire in most of its parts, and the temple of Serapis offers many curious subjects of observation; half of its buildings are still buried under the earth thrown upon it by volcanical commotions, or accumulated by the crumblings of the hill; the inclosure is square, environed with buildings for priests and baths for votaries; in the centre remains a circular platform, with four flights of steps up to it, vases for fire, a central altar, rings for victims, and other appendages of sacrifice, entire and not displaced; but the columns that held its roof have been removed to the new palace of Caserta (see Caserta). Behind this round place of worship stand three pillars without capitals, part of the pronaos of a large temple, they are of cipoline marble, and at the middle of their height are full of holes eaten in them by the file-fish.

The present city contains near 10,000 inhabitants, a Plate, and occupies a small peninsula; the cathedral was a Pa. DuCtius, a pagan temple, dedicated to the divinities that presided over commerce and navigation. E. Long. 14. 40. N. Lat. 41. 15.
In the neighbourhood of Puteoli are many relics of ancient grandeur, of which none deserve more attention than the Campanian Way, part of which is paved with stones, and passed on each side with venerable towers, the repositories of the dead, which are richly adorned with stucco in the inside. This road was made in a most solid expensive manner by order of Domitian, and is frequently the subject of encomium in the poems of Statius.

Puti carali, in Botany, is a genus of Indian plants, of which the characters, as given by Sir William Jones in the Asiatic Researches, vol. ii. p. 351. are these. The calyx is five-cleft, the corolla has five equal petals, the pericarpium a thorny legumen and two seeds, the leaves oval and pinnated, and the stem armed. "The seeds (says the learned president) are very bitter, and perhaps toxic; since one of them, bruised and given in two dozes, will, as the Hinduos assert, cure an intermittent fever."

Putorius. See Mustela, Mamalia Index.

Putrefaction is the natural process by which organized bodies are dissolved, and reduced to what may be called original elements.

Putrefaction differs from chemical solution; because in the latter, the dissolved bodies are kept in their state of solution by being combined with a certain agent from which they cannot easily be separated; but in putrefaction, the agent which dissolves the body appears not to combine with it in any manner of way, but merely to separate the parts from each other. It differs also from the resolution of bodies by distillation with violent fire; because, in distillation, new and permanent compounds are formed, but by putrefaction everything seems to be resolved into substances much more simple and indestructible than those which are the result of any chemical process.

The bodies most liable to putrefaction are those of animals and vegetables, especially when full of juices. Stones, though by the action of the weather they will moulder into dust, yet seem not to be subject to any thing like a real putrefaction, as they are not resolved into any other substance than sand, or small dust, which still preserves its lapidaceous nature. In like manner, vegetables of any kind, when deprived of their juices by drying, may be preserved for many ages without being subjected to any thing like a putrefactive process. The same holds good with respect to animals; the parts of which, by simple drying, may be preserved in a sound state for a much longer time than they could without the previous exhalation of their juices.

Putrefaction is generally allowed to be a kind of fermentation, or rather to be the last stage of that process; which beginning with the vinous fermentation, goes on through the aceto, to the stage of putridity, where it stops. It is argued, however, and seemingly not without a great deal of reason, that if putrefaction be a fermentation, it must necessarily be a kind distinct from either the vinous or acetous; since we frequently observe that it takes place where neither the vinous nor the aceto stages have gone before; of consequence, it must be, in some cases at least, entirely independent of and unconnected with them. In several other respects it differs so much from these processes, that it seems to some degree doubtful whether it can with propriety be called a fermentation or not. Both the vinous and acetous fermentations are attended with a considerable degree of heat; but in the putrefaction of animal matters especially, the heat is for the most part so small, that we cannot be certain whether there is any degree of it or not produced by the process. In some cases, indeed, where the quantity of corrupting animal matter is very great, some heat may be perceived; and accordingly Dr. Monro tells us, that he was sensible of heat on thrusting his hand into the flesh of a dead and corrupting whale. But the most remarkable difference between the putrefactive fermentation and that of the vinous and acetous kinds is, that the end of both these processes is to produce a new and permanent compound; but that of the putrefactive process is not to produce any new form, but to destroy, and resolve one which already exists into the original principles from which all things seem to proceed. Thus the vinous fermentation produces ardent spirits; the acetous, vinegar: but putrefaction produces nothing but earth, and some effluvia, which, though most disagreeable, and even poisonous to the human body, yet, being imbied by the earth and vegetable creation, give life to a new race of beings. It is commonly supposed, indeed, that volatile alkali is a production of the putrefactive process; but this seems liable to dispute. The vapour of pure volatile alkali is not burtiful to the human frame, but that of putrefying substances is exceedingly so; and, excepting in the case of urine, the generation of volatile alkali in putrid substances is very equivocal. This substance, which produces more alkali than any other, is much less offensive by its putrid fetor than others; and all animal substances produce a volatile alkali on being exposed to the action of fire, of quicklime, or of alkaline salts. In these cases the volatile alkali is not supposed to be produced by the quicklime or fixed salt, but only to be extricated from a kind of ammoniacal salt pre-existing in the animal matters; the probability is the same in the other case, viz. that volatile alkali is not produced, but only extricated, from these substances by putrefaction.

The only thing in which the putrefactive fermentation agrees with the other kinds is, that in all the three there is an extrication of fixed air. In the putrefactive process, it has been thought that this escape of the fixed air deprives the body of its cohesion; and Dr. Macbride has written a treatise, in which he endeavours to prove that fixed air is the very power of cohesion itself, and that all bodies when deprived of their fixed air entirely lose their cohesion. According to this hypothesis, the cause of putrefaction is the escape of fixed air; but it is impossible to give a reason why fixed air, after having so long remained in a body, and preserved its cohesion, should of a sudden begin to fly off without being acted upon by something else. To a similar objection the hypothesis of those is liable, who suppose putrefaction to be occasioned by the escape of phlogiston; for phlogiston is now known to be a chimera: and though it were a reality, it would not fly off without something to carry it off, any more than fixed air. Animalcules have been thought to be the cause of putrefaction: but if animal substances are covered so as to exclude the access of flies or other insects, no such animalcules are to be discovered though putrefaction has taken place; and indeed it requires little proof to convince us, that animals are produced in corrupted bodies only because such substances prove a proper nidus for the eggs of the parent insects.
To understand the true cause of putrefaction, we must take notice of the circumstances in which the process goes on most rapidly. These are, heat, a little moisture, and confined air. Extreme cold prevents putrefaction, as well as perfect dryness; and a free circulation of air carries off the putrid effluvia; a stagnation of which seems to be necessary for carrying on the process. It seems also to hold pretty generally, that putrefying bodies swell and become specifically lighter; for which reason the carcasses of dead animals, after having sunk in water, rise to the top and float. This last phenomenon, as has been observed under the article Blood, No. 29, shows that these bodies have received a certain quantity of an elastic principle from the air, which thus swells them up to such a size. It may be said indeed, that this increase of size in putrefying bodies is owing only to the extrication of air within themselves; but this amounts to the same thing; for the air which exists internally in the body of any animal, is entirely divested of elasticity while it remains there, and only shows its elastic properties upon being extricated. The elastic principle which combines with the air fixed in the animal substance, therefore, must come from the external atmosphere; and consequently the agent in putrefaction must be the elastic principle of the atmosphere itself, probably the same with elementary fire.

But, granting this to be true, it is difficult to show why putrefaction should not take place in a living body as well as in a dead one; seeing the one is as much exposed to the action of the air as the other. This difficulty, however, is not peculiar to the present hypothesis; but will equally occur, whenever we may suppose the cause of putrefaction to be. The difficulty seems to be a little cleared up by Dr. Priestley, who shows, that, by means of respiration, the body is freed from many noxious effluvia which would undoubtedly destroy it; and by the retention of which, he thinks, a living body would putrefy as soon as a dead one. The way in which respiration prevents the putrefaction of the body, is evidently the same with that in which the wind prevents fish or flesh hung up in it from becoming putrid. The constant inspiration of the air is like a stream of that element continually blown upon the body, and that not only upon its surface, but into it; by which means putrefaction is prevented in those parts that are most liable to become putrid. On the other hand, the elastic principle received from the air by the blood, by invigorating the powers of life, quickening the circulation, and increasing perspiration, enables the body to expel noxious particles from other parts of the body which cannot conveniently be expelled by the lungs.

This leads us, to consider the reason why a free exposure to the air prevents the coming on of putrefaction, or why the confining of the putrid effluvia should be so necessary to this process. Here it will be proper to recollect, that putrefaction is a simple resolution of the body into earth, air, &c. of which it seems originally to have been composed. This resolution is evidently performed by an expansive power seemingly situated in every part of the body. In consequence of this principle, the body first swells, then bursts; fire off in vapour, and its particles fall asunder from each other. The action of the putrefactive process, then, is analogous to that of fire, since these are the very properties of fire, and the very effects which follow the action of fire upon any combustible body. It is therefore exceedingly probable, that the agent in the air, which we have all along considered as the cause of putrefaction, is no other than fire itself; that is, the ethereal fluid expanding itself everywhere, as from a centre to a circumference.

The force of the fluid, indeed, is much less in putrefaction than in actual ignition; and therefore the effects also take place in a much smaller degree, and require a much longer time; nevertheless, the same circumstances that are necessary for keeping up the action of fire, are also necessary for keeping up the putrefactive process. One of these is a free access of air, yet without too violent a blast; for as fire cannot burn without air, neither can it endure too much of it; thus a candle goes out if put under a receiver, and the air exhausted; and it will do the same if we blow violently upon it. In like manner, putrefaction requires a certain quantity of air, much less indeed than fire: and as it requires less to support it, so it can also endure much less air than fire; for a stream of air which would not put out a fire, will effectually prevent putrefaction. The cause of this is both the same. Fire cannot burn because the vapour is carried off too fast; and thus the latent heat, which ought to support the flame, is entirely dissipated. In like manner putrefaction is as certainly attended with an emission of azotic gas as fire is with an emission of flame. These gases contain a great quantity of latent heat, or of the expansive principle already mentioned; and if these are carried off with greater rapidity than the heat of the atmosphere can produce them, the consequence must be, that an opposite principle to that which produces putrefaction, namely, a principle of cold, or condensation, instead of expansion, must take place, and the body cannot putrefy. That this must be the case, is evident from the property which all evaporations have of producing cold; and it is well known that a brisk current of air promotes evaporation to a great degree.

Please also the reason is evident why bodies are preserved uncorrupted by cold; for thus the action of the expansive principle is totally overcome and suspended, so that none of its effects can be perceived.

Thus we may say, that one reason why an animal body does not putrefy while alive, is its ventilation, as we may call it, by respiration; and another is, the continual accession of new particles, less disposed to putrefy than itself, by the food and drink which is constantly taken in. But if either of these ways of preventing the commencement of this process are omitted, then putrefaction will take place as well in a living as in a dead body. Of the truth of this last fact we have innumerable instances. When air is infected with the putrid effluvia of marshes, and thus the natural effluvia are not carried off from the human body, but, on the contrary, some enter into it which are not natural to it, the most putrid diseases are produced. The same thing happens from the putrid effluvia of dead bodies. Of this we have a remarkable instance in the fever which took place in Germany in the war of 1755: one reason of which is said to have been an infection of the air by the vast numbers of people killed in battle, to which was added a calm in the atmosphere for a long time; the putrid effluvia being by this prevented from flying off. When Mr. Holwell with 145 others were imprisoned in the black-holes at Calcutta, after passing through the disease, No. 157.
Putrefaction — a night in that distal habituation, he found himself in a high putrid fever. When sailors in long voyages are obliged to feed upon putrid aliments; when, through stormy weather, they are much exposed to wet; in the one case the putrescent effluvia being kept from flying off, and in the other a greater quantity being thrown into the body than what it naturally contains, the scurvy, malignant fevers, &c. make their appearance (A). Neither can these diseases be removed without removing every one of the causes just now mentioned: for as putrid diseases will be the consequence of confined air, nastiness, &c. though the provisions be ever so good; so on the other hand, if the provisions be bad, the best air, and most exact cleanliness, nay, the best medicines in the world, will be of no service; as hath been often observed in the scurvy.

From this account of the nature, cause, and method of preventing putrefaction by means of a current of air, we may easily see the reason why it does not take place in some other cases also. Bodies will not putrefy in vacuo, because there the atmosphere has not access to impart its elastic principle; and though in the vacuum itself the principle we speak of does undoubtedly exist, yet its action there is by far too weak to decompose the structure of an animal body. In extreme cold, the reason why putrefaction does not take place, has been already shown. If the heat is extremely great, the process of ignition or burning takes place instead of putrefaction. If the body is very dry, putrefaction cannot take place, because the texture is too firm to be decomposed by the weak action of the elastic principle. Putrefaction may also be prevented by the addition of certain substances; but they are all of them such as either harden the texture of the body, and thus render it proof against the action of the elastic fluid, or, by dissolving its texture entirely, bring it into a state similar to what it would be brought by the utmost power of putrefaction, so that the process cannot then take place. Thus various kinds of salts and acids harden the texture of animal substances, and are thus successfully used as antiseptics. The same thing may be said of ardent spirits; while oils and gums of various kinds prove antiseptic by a total exclusion of air, which is necessary in some degree for carrying on the process of putrefaction. Many vegetable fluids, by the astringent qualities they possess, harden the texture of animal substances, and thus prove powerfully antiseptic; while, on the other hand, fixed alkaline salts, quicklime, and caustic volatile alkali, though they prevent putrefaction, yet do it by dissolving the substances in such a manner that putrefaction could do no more though it had exerted its utmost force. There is only one other antiseptic substance whose effects deserve to be considered, and that is sugar. This, though neither acid nor alkaline, is yet one of the most effectual means of preventing putrefaction: and this seems to be owing to its great tendency to run into the vinous fermentation, which is totally inconsistent with that of putrefaction; and this tendency is so great, that it can scarce be contested, by the tendency of animal substances to putrefy in any circumstances whatever.

Some kinds of air are remarkably antiseptic, though this subject has not been so fully inquired into as could be wished. The most powerful of them in this respect is the nitrous air; next to it, is fixed air; but the powers of the other airs are not so well known. It is probable that the antiseptic properties of fixed and nitrous air, are owing to their quality of extinguishing fire, or at least that the principle is the same; but till the nature of these two kinds of air are better known, little can be said with certainty on the subject.

Sir John Pringle has made experiments to determine the powers of certain substances to promote or to prevent putrefaction. From these experiments he has formed the following Table, showing the relative antiseptic powers of the saline substances mentioned. Having found that two drams of beef put in a phial with two ounces of water, and placed in a heat equal to 90° of Fahrenheit's

(A) This seriform fluid, which is exhaled from animal bodies in a state of putrefaction, acts at certain times more powerfully than at others, and is indeed in one stage of the process infinitely more noxious than any other elastic fluid yet discovered. In the Gentleman's Magazine for August 1788, Dr St John informs us, that he knew a gentleman who, by slightly touching the intestines of a human body beginning to liberate this corrosive gas, was affected with a violent inflammation, which in a very short space of time extended up almost the entire length of his arm, producing an extensive ulcer of the most foul and frightful appearance, which continued for several months, and reduced him to a miserable state of emaciation. The same writer mentions a celebrated professor who was attacked with a violent inflammation of the nerves and fauces, from which he with difficulty recovered, merely by stooping for an instant over a body which was beginning to give forth this deleterious fluid. Hence he infers, that the same gas modified or mixed, or united with others, may be the occasion of the plague, which has so often threatened to annihale the human species. It is happy, however, for mankind that this particular stage of putrefaction continues but for a few hours; and what may appear very remarkable, this destructive gas is not very disagreeable in smell, and has nothing of that abominable and loathsom fetor produced by dead bodies in a less dangerous state of corruption; but has a certain smell totally peculiar to itself, by which it may be instantly discovered by any one that ever smelled it before. This is an object very worthy the attention of physicians: it is both extremely interesting, and very little known; but at the same time it is a study in the highest degree unpleasant, from the detestable smell and nastiness which attend the putrefaction of animal bodies; and! man must be armed with uncommon philantropy and resolution to attempt it.

Dr St John thinks it probable that there is a rapid fixation of the basis of vital air in dead bodies at a certain state of putrefaction, on account of the luminous appearance which they sometimes make, and which exists but for a few hours: but whether this luminous appearance takes place in every body, or whether it precedes or follows the exhalations of the corrosive gas above mentioned, he had not, when he wrote his paper, been able to discover.
Fahrenheit's thermometer, became putrid in 14 hours, and that 60 grains of sea-salt preserved a similar mixture of beef and water more than 30 hours, he made the antiseptic power of the sea-salt a standard, to which he compared the powers of the other salts. The algebraic character + signifies, that the substance to which it is annexed had a greater antiseptic power than is expressed by the numbers:

Sea-salt, or the standard - - - 1
Sal-gem - - - 1+
Vitirotiated tartar - - - 2
Spiritus Mindereri - - - 2
Soluble tartar - - - 2+
Sal diucreticlus - - - 2
Crude sal ammoniac - - - 3
Saline mixture - - - 3
Nitre - - - 4+
Salt of hartshorn - - - 4+
Salt of wormwood - - - 4+
Borax - - - 12
Salt of amber - - - 20
Alum - - - 30

N.B. The quantities of spiritus Mindereri and of the saline mixture were such, that each of them contained as much alkaline salt as the other neutral salts.

Myrrh, aloes, assufetida, and terra Japonica were found to have an antiseptic power 30 times greater than the standard. Gum ammoniacum and sagapenum showed little antiseptic power.

Of all resinous substances, camphor was found to resist putrefaction most powerfully. Sir John Pringle believes that its antiseptic power is 300 times greater than that of sea-salt.

Chamomile flowers, Virginian snake-root, pepper, ginger, saffron, contrayerba root, and galls, were found to be 12 times more antiseptic than sea-salt.

Infusions of large quantities of mint, angelica, ground-ivy, green tea, red-roses, common wormwood, mustard, and horse-radish, and also decoctions of poppy-heads, were more antiseptic than sea-salt.

Decoctions of wheat, barley, and other farinaceous grains, checked the putrefaction by becoming sour.

Chalks and other absorbent powders, accelerated the putrefaction, and resolved meat into a perfect mucus.

The same powders prevented an infusion of farinaceous grains, from becoming mucilaginous and sour.

One dram of sea-salt was found to preserve two drams of fresh beef in two ounces of water, above 30 hours, uncorrupted, in a heat equal to that of the human body, or above 20 hours longer than meat is preserved in water without salt: but half a dram of salt did not preserve it more than two hours longer than pure water. Twenty-five grains of salt had little or no antiseptic quality. Twenty grains, 15 grains, but especially 10 grains only of sea-salt, were found to accelerate and heighten the putrefaction of two drams of flesh. These small quantities of sea-salt did also soften the flesh more than pure water.

The same learned and ingenious physician made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being beat to the consistence of pap, and exposed to 90° of heat according to Fahrenheit's thermometer, began to ferment in a few hours, and continued in fermentation during two days. When it began to ferment and swell, the putrefaction had begun; and in a few hours afterwards, the smell was offensive. Next day the putrid smell ceased, and an acid taste and smell succeeded. Fresh alimentary vegetables, as spinach, asparagus, sourney-grass, produced similar effects as bread on flesh, but in a weaker degree. From several other experiments he found, that animal substances excite the fermentation of vegetable substances, and that the latter substances correct the putrescency of the former.

By adding saliva to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no saliva was used.

By added an oily substance to the common mixture of flesh, bread, and water, a stronger fermentation was produced, which could not be moderated by the quantity of saliva used in the following experiment, till some fixed alkaline salt was added; which salt was found, without saliva, to stop suddenly very high fermentations.

He did not find that small quantities of the following salts, sal ammoniac, nitre, vitriolated tartar, sal diucreticus, salt of hartshorn, salt of wormwood, were septic, as small quantities of sea-salt were.

Sugar was found to resist putrefaction at first, as other salts do, and also to check the putrefaction after it had begun by its own fermentative quality, like bread and other fermentative vegetables.

Lime-water made some small resistance to putrefaction.

Port-wine, small-beer, infusions of bitter vegetables, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an unstrained decoction of bark considerably increased that fermentation.

Crab-eyes accelerated and increased the fermentation of a mixture of flesh and bread.

Lime-water neither retarded nor hastened the fermentation of such a mixture: but when the fermentation ceased, the liquor was neither putrid nor acid, but smelt agreeably.

Flesh pounded in a mortar was found to ferment sooner than that which had not been bruised.

The tough inflammatory crust of blood was found to be most putrescent; next to which the crassamentum, or red coagulated mass; and lastly the serum.

Dr Macbride's experiments confirm many of those above related, especially those which show that the fermentation of vegetable substances is increased by a mixture of animal or putrescent matter; that the putrescence of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances were accelerated by additions of absorbent earths and of Peruvian bark. He also found, that although unburnt calcarious earths were septic, quicklime and lime-water prevented putrefaction, but that they destroyed or dissolved the texture of flesh.

The experiments of the author of the Essai pour servir à l'Histoire de la Putrefaction, show that metallic salts,
salty, resins, powders, extracts of bark, and opium, are very powerfully antiseptic, and that salts with earthy bases are less antiseptic than any other salts.

**PUTTOCK-SHROUDS.** See **PUTTOCK-SHROUDS**.

PUTTY, in its popular sense, is a kind of paste compounded of whiting and linseed oil, beaten together to the consistence of a thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PUTTY sometimes also denotes the powder of calcined tin, used in polishing and giving the first gloss to works of iron and steel.

**PUY DE DOME**, a department in the south of France, forming part of the ancient province of Auvergne. The soil is mountainous, but fertile in all kinds of grain, vines, and fruits; and contains mines of iron, lead, coal, and many mineral springs. There are manufactures of cloth of various kinds, lace, serges, ribbons, &c. The territorial extent of the department is 794,370 hectares, and the population in 1817 was 528,834. The contributions for 1822 amounted to 3,855,547 francs. Clermont is the chief town.

**TERRA PUZZULANA**, or **PUZZULANA**, is a grayish kind of earth used in Italy for building under water. The best is found about Puteoli, Baiae, and Cumae, in the kingdom of Naples, from the first of which places it derives its name. It is a volcanic product, composed of heterogeneous substances, thrown out from the burning mouths of volcanoes in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance. In the year 79 of the common era, the cities of Herculanenum, Pompeii, and Stabia, although at the distance of many miles from Vesuvius, were, nevertheless, buried under the matters of these dreadful eruptions; as Bergman relates in his Treatise of the Volcanic Products. This volcanic earth is of a gray, brown, or blackish colour; of a loose granular, or dusty and rough, porous or spongy texture, resembling a clay hardened by fire, and then reduced to a coarse powdered. It contains various heterogeneous substances mixed with it. Its specific gravity is from 2500 to 2800; and it is, in some degree, magnetic: it scarcely effervesces with acids, though partially soluble in them. It easily melts per se; but its most distinguishing property is, that it hardens very suddenly when mixed with 1/3 of its weight of lime and water; and forms a cement which is more durable in water than any other.

According to Bergman's Analysis, 100 parts of it contain from 55 to 60 of siliceous earth, 20 of argillaceous, five or six of calcareous, and from 15 to 20 of iron. Its effects, however, in cement may perhaps depend only on the iron it contains.

It is evidently a martial argillaceous marl, that has suffered a moderate heat. Its hardening power arises from the dry state of the half-baked argillaceous particles, which makes them imbibe water rapidly, and thus accelerates the desiccation of the calcareous part; and also from the quantity and peculiar state of the iron and manganese which it contains; on which metals its properties chiefly depend. It is found not only in Italy but in France, and also in England and elsewhere.

**PUZZOLI.** See **PUTTOCK-SHROUDS**.

**PYANEPSIA**, in antiquity, an Athenian festival celebrated on the seventh day of the month Pyanepeis; which, according to the generality of critics, was the same with our September.

Plutarch refers the institution of this feast to Theseus, who, after the funeral of his father, on this day paid his vows to Apollo, because the youth who returned with him safe from Crete then made their entry into the city. On this occasion, these young men putting all that was left of their provisions into one kettle, feasted together on it, and made great rejoicing. Hence it was derived the custom of boilingpulse on this festival. The Athenians likewise carried about an olive branch, bound about with wood, and crowned with all sorts of first-fruits, to signify that scarcity and barrenness were ceased, singing in procession a song. And when the solemnity was over, it was usual to erect the olive branch before their doors, as a preservative against scarcity and want.

**PYCNOSTYLE**, in the ancient architecture, is a building where the columns stand very close to each other: one only diameter and a half of the column being allowed for the intercolumniations.

According to Mr Evelyn, the pycnostyle chiefly belonged to the Composite order, and was used in the most magnificent buildings; as at present in the persityle at St Peter's at Rome, which consists of near 300 columns; and in such as yet remain of the ancients, among the ruins of Palmyra.

**PYGARGUS**, a species of falco. See **ORNITHOLOGY INDEX**.

**PYGMALION**, in fabulous history, a king of Cyprus, who, being disgusted at the dissolute lives of the women of his island, resolved to live in perpetual celibacy; and making a statue of ivory, he fell so passionately in love with it, that the high festival of Venus being come, he fell down before the altar of that goddess, and besought her to give him a wife like the statue he loved. At his return home, he embraced, as usual, his ivory form, when he perceived that it became sensible by degrees, and that last a living maid, who found herself in her lover's arms the moment she saw the light. Venus blessed their union; and, at the end of nine months, she was delivered of a boy, who was named **PAPHOS**.

**PYGMY**, a person not exceeding a cubit in height. This appellation was given by the ancients to a fabulous nation inhabiting the Thracian: which brought forth young at five years of age, and were old at eight: these were famous for the bloody war they waged with the cranes. As to this story, and for the natural history of the true pygmy, see **SIMIA, MAMMALIA INDEX**.

**PYKAR**, a broker in India, inferior to those called rattle, who transacts the business at first hand with the manufacturer, and sometimes carries goods about for sale.

**PYKE**, a watchman in India, employed as a guard at night. Likewise a footman or runner on business. They are generally armed with a spear.

**PYLADES**, a son of Strophius, king of Phocis, by one of the sisters of Agamemnon. He was educated together with his cousin Orestes, with whom he formed the most inviolable friendship, and whom he assisted to revenge the murder of Agamemnon, by assassinating Clytemnestra and Aegisthus. He also accompanied him to Taurica Chersonesus; and for his services...
Orestes rewarded him, by giving him his sister
Electra in marriage. Pylades had by her two sons,
Medon and Strophius. The friendship of Orestes and
Pylades became proverbial.

PYLORUS, in Anatomy, the under orifice of the
stomach. See Anatomy, No 91.

PYLUS, in Ancient Geography, a town of Elis; its
ruins to be seen on the road from Olympia to Elis, (Pau-
sanias); situated between the mouths of the Cenusus and
Selles, near Mount Scollis, (Strabo). Built by Pylaus
of Megara, and destroyed by Heroles, (Pausanias).
Another Pylus in Triphilia, (Strabo); by which the
Alphes runs (Pausanias); on the confines of Arcadia,
and not in Arcadia itself, (id.). A third in Messenia,
(Strabo, Ptolemy); situated at the foot of Mount Æge-
uleus on the sea coast, over-against the island Sphagea
or Sphaxeria; built by Pylus, and settled by a colony
of Leleges from Megara; but thence expelled by
Leleges and the Pelasgi, and therefore called Nelca, (Ho-
er.) A sandy territory. The royal residence of Nel-
eges, and of Nestor his son: the more ancient and more
excellent Pylus; whence the proverb Pylus ante Pylum
(Aristophanes, Plutarch), used when we want to re-
press the arrogance and pride of any one: said to be
afterwards called Corephaxium. It made a figure in the
Peloponnesian war; for being rebuilt by the Athenians.
It proved of great benefit to them for the space of 15
years, and of much annoyance to the Lacedaemonians,
(Thucydides). All the three Pylai were subject to Ne-
stor, (Strabo).

PYRAMID, in Geometry, a solid standing on a tri-
gle, square, or polygonal basis, and terminating in
a point on the top; or, in the language of Euclid, it is a
solid figure, consisting of several triangles, whose bases
are all in the same plane, and have one common vertex.

Pyramids are sometimes used to preserve the memory
of singular events, and sometimes to transmit to post-
erity the glory and magnificence of princes. But as
they are esteemed a symbol of immortality, they are
most commonly used as funeral monuments and temples
to the gods. Such is that of Cestius at Rome; the
pyramids of Dashur drawn by Pococke; and those other
celebrated ones of Egypt, as famous for the enormity
of their size as their antiquity. Of these the largest are
the pyramids of Gaza, so called from a village of that
name on the banks of the Nile, distant from them about
11 miles. The three which most attract the attention of
travellers stand near one another on the west side of
the river, almost opposite to Grand Cairo, and not far
from the place where the ancient Memphis stood. They
were visited by M. Savary, of whose description of them
we shall here give an abstract. He took his journey in the night time, in order to
gain up to the top of the great one by sunrise. Having
got within sight of the two great ones, while the full
moon shone upon them, he informs us, that they ap-
teated, at the distance of three leagues, like two points
of rock crowned by the clouds.

It is in the rich territory which surrounds them that
fable has placed the Elysian fields. The canals which
intersect them are the Styx and Lethe.

The aspects of the pyramids, varied according to
the circuits he made in the plain, and the position of
the clouds, displayed themselves more and more to view.

### Number of layers of stone which form it.

- Greaves: 207
- Maillet: 208
- Albert Liewenstein: 260
- Pococke: 212
- Belon: 250
- Thevenot: 208

---

"It appears that Messrs Greaves and Niebuhr have prodigiously deceived themselves in measuring the perpendicular height of the great pyramid. All the travellers allow that it has at least 200 layers of stone. These layers are from two to four feet high. According to Pococke, they are from four feet and a half to four feet high, being not so high at the top as at the base. Prosper Alpinus informs us, that the elevation of the first layer is five feet, but it diminishes insensibly in proportion as one mounts. Thevenot mentions 208 steps of large stones, the thickness of which makes the height of them about two feet and a half one with another. He measured some of them more than three feet high. I have measured several of them which were more than three feet high, and I found none less than two; the least height of them we can take as a medium therefore is two feet and a half, which, even according to Mr Greaves's calculation, who reckons 207 layers, would make 517 feet 6 inches perpendicular height. Messrs Greaves, Maillet, Thevenot, and Pococke, who only differ in the number of the layers from 207 to 212, all mounted by the north-east angle, as the least injured. I followed the same route, and counted only 208 steps. But if we reflect that the pyramid has been open on the side next the desert, that the stones on that side have been thrown down, that the sand which covers them has formed a considerable hill, we shall not be astonished that Albert Liewenstein, Belon, and Prosper Alpinus, who must have mounted by the south-east or south-west angle, which are less exposed to the sands of Libya, should have found a greater number of steps: so that the calculation of these travellers, agreeing with that of Diodorus Siculus and Strabo, appears to be nearest the true height of the pyramid taken at its natural base; whence we may conclude with reason that it is at least 600 feet high. Indeed this is authenticated by a passage of Strabo. These are his words: 'Towards the middle of the height of one of the sides is a stone that may be raised up. It shuts an oblique passage which leads to a coffin placed in the centre of the pyramid.' This passage, open in our days, and which in the time of Strabo was towards the middle of one face of the pyramid, at present only 100 feet from the base. So that the ruins of the covering of the pyramid, and of the stones brought from within, buried by the sand, have formed a hill in this place 200 feet high. Pliny confirms this opinion. The great sphynx was in his time upwards of 62 feet above the surface of the ground. Its whole body is at present buried under the sand. Nothing more appears of it than the neck and head, which are 27 feet high. If even the sphynx, though defended by the pyramids against the northerly winds, which bring torrents of sand from Libya, be covered as high as 38 feet, what an immense quantity must have been heaped up to the northward of an edifice whose base is upwards of 700 feet long? It is to this we must attribute the prodigious difference between the accounts of the historians who have measured the great pyramid at distant periods, and at opposite angles. Herodotus, who saw it in the age nearest to its foundation, when its base was still uncovered, marked it 600 feet square. The opinion appears very probable. Pliny also says that it covered the space of eight acres.

"Messrs Shaw, Thevenot, and the other travellers who pretend that this pyramid was never finished, because it is open and without coating, are in an error. It is only necessary to observe the remains of the morter, with the splinters of white marble which are to be found in many parts of the steps, to see that it has been coated. After reading attentively the description given of it by the ancients, every doubt vanishes, and the truth is as clear as day-light. Herodotus tells us, 'The great pyramid was covered with polished stones, perfectly jointed, the smallest of which was 30 feet long. It was built in the form of steps, on each of which were placed wooden machines to raise the stones from one another.' According to Diodorus, 'The great pyramid is built of stones, very difficult of workmanship, but of an eternal duration. It is preserved to our day (towards the middle of the Augustan age) without being in the least injured. This marble was brought from the quarries of Arabia.' This historian thought that the whole building was composed of stones, similar to those of the coating, which were of very hard marble. Had there been some pieces torn off, he would have perceived under that covering a calcareous stone rather soft. Pliny says that it 'is formed of stones brought from the quarries of Arabia. It is not far from the village of Busiris (which still exists under the name of Bousir), where those persons reside who are so skilful as to climb up the top.'

"This passage shows that Pliny, deceived by the appearance, was in the same error with Diodorus Siculus. It demonstrates also that it was covered: for what difficulty would there have been for the inhabitants of Busiris to scale a building raised by steps? but it was really a prodigy for them to get it up when it formed a mountain, the four inclined planes of which presented a surface covered with polished marble. It is indeed, an incontestable fact, that the great pyramid was coated. It is as certain too that it has been shot, as Strabo gives us to understand; and that by removing a stone placed in the middle of one of the sides, one found a passage which led to the tomb of the king. But I shall leave Mr Maillet, who visited it 40 times with all imaginable
imaginable attention, the honour of relating the means employed to open it. I have examined the inside of it in two different journeys: twice I have mounted it: and I cannot help admiring the sagacity with which that author has developed the mechanism of that astonishing edifice.

Our author next proceeds to give a particular description of the methods by which it is most probable that the pyramids were closed, and the immense labour requisite to open them. We must remark, that the final outlet to the workmen he supposes to have been the well at the entrance formerly mentioned. This well descends towards the bottom of the pyramid by a line not quite perpendicular to the horizon, but slanting a little, in such a manner as to resemble the figure of the Hebrew letter Lamed. About 60 feet from the aperture there is a square window in this passage, from whence we enter a small grotto hewn out of the mountain; which in this place is not a solid stone, but a kind of gravel conglomerate. This grotto was 5 feet from east to west, where there is another groove hollowed likewise, but almost perpendicular. It is two feet four inches wide by two and a half in height. It descends through a space of 123 feet, after which we meet with nothing but sand and stones. M. Savary is convinced that the only use of this passage was to serve as a retreat for the labourers who constructed the pyramid; and of this he looks upon the slope of the conduit, its winding road, its smallness, and its depth, to be certain proofs. The way out of it he supposes to have been formed by a passage over which hung a row of stones, which they had discovered the secret of suspending, and which falling down into the passage by the means of some spring they set in motion, shut up the entrance for ever, as soon as the workmen were withdrawn from the pyramid.

It is not known in Europe when the pyramids were built; but we have reason to expect a history of them soon from Shascrat records examined by Mr Wilford himself. It is little known at what time, or from what motive, the great pyramid was opened. Some think it was done by one of the khalefs about the beginning of the eighth century, in expectation of finding a great treasure; but all believe he met with the king's body, with some golden idols which had been buried along with it. By others, it is supposed to have been done by the celebrated Harun Al Raschid khalif of Bagdad; but all are agreed that this pyramid was opened in the time of the Arabs. The second pyramid has likewise been opened; and an attempt was made not long ago upon the third by one of the Beys of Cairo: but after removing a number of stones at a considerable expense, he thought proper to desist from the enterprise. Mr Bryant is of opinion that the pyramids, at least the three great ones, are not artificial structures of stone and mortar, but solid rocks cut into a pyramidal shape, and afterwards cased with stone; and to this we find that Mr Bruce likewise assents. The reason given for this opinion is, that the passages within it seem rather to answer to the natural cavities and rents in rocks than to the artificial ones in buildings. The opinion, however, we think sufficiently confuted by Savary and Maillet: and, as an acute critic observes, it is in itself as improbable, as that the caverns inhabited by the Troglodytes were dug by the hands of man. See Troglodytes.

On the east side of the second pyramid is the sphynx, an enormous mass of one solid stone, but so buried in the sand that only the top of the back is visible, which is 100 feet long. Its head rises, as we have seen, 27 feet above the sand; and its face has been disfigured by the Arabs, who hold all representations of men and living animals in detestation. This figure was more completely exposed by digging round it in 1816.

In the desert of Saccara there is a great number of pyramids, which, in Mr Bruce's opinion, are composed of clay. They terminate in what the inhabitants call a dagbour or false pyramid, about two miles from the Nile, between Suf and Woodan. This is no other than a hill cut into the shape of a pyramid, or naturally so formed, for a considerable height; on the top of which is a pyramidal building of brick terminating in a point, that hugging its basis so exactly as to the top of the hill, that at a distance the difference is not perceived; especially as the face of the stones resembles very nearly the clay of which the pyramids of the Saccara are composed.

But a very different opinion concerning the purposes to which the great pyramid was originally destined, and the period in which that extraordinary edifice was erected, is held by Mr Gabb, who has not long since published an elaborate treatise on this subject. According to this author not only the great pyramid, but also the smaller pyramids are of antediluvian origin; the immense accumulation of sand around those stupendous structures took place at the time of the deluge; the height of this sand, when the waters subsided, probably reached the summit of the pyramid, and the apex of the great pyramid was torn off by the violent agitation of the waters.

But the most curious part of this author's disquisition concerning the pyramid relates to the purpose for which this marvellous fabric was raised; and here he is decided in opinion, that it was originally intended as a standard of measure, and not as has been more generally supposed as a sepulchral monument; and farther that the excavation of the celebrated granite chest in the interior of the pyramid was intended not for the repository of a corpse, but for a standard measure of capacity, as its length was for linear measure. This is also the opinion of the French scavans who accompanied the army of Bonaparte to Egypt, and very successfully ascertained the dimensions of that remarkable building. The plan of the pyramid is a geometrical square, the side of which is equal to 400 cubits of Cairo, or the great Egyptian stadium. The length of the granite chest in the upper chamber of the pyramid is exactly four cubits, which is precisely one hundredth part of the base of the side of the pyramid. The commensurability of the component parts of the pyramid now mentioned, as well as of others discussed by the author, is undoubtedly a curious circumstance.

These wondrous structures still excite the curiosity of ingenious and enterprising men. In 1816 some researches were made by Mr Caviglia, who discovered a chamber in the pyramid of Cheops which had not been visited by any modern traveller. But the most interesting discovery was made by Mr Belzoni in March 1818.
1818. Long investigations among the monuments of Egypt have enabled this traveller to detect certain relations in their construction, from which he divined that an entrance existed into the interior of the pyramid of Cepheus, and that this entrance was to be sought in a particular part of the north side, though no outward marks of it appeared, and though preceding travellers had acquiesced in the opinion that no chambers were to be found in it. With incredible labour, and after many discouragements, he was so fortunate as to find a passage which first led downward, at an angle of 26 degrees, and then horizontally to the centre of the pyramid. Here he entered a chamber 46 feet 3 inches long, 16 feet 3 inches wide, and 23 feet 6 inches high, for the most part cut out of the solid rock, except that part of the roof towards the western end. In the midst was a sarcophagus of granite, partly buried in the ground to the level of the floor, 8 feet long, 3 feet six inches wide, and 2 feet 3 inches deep inside, surrounded by large blocks of granite, being placed apparently to guard it from being taken away. The lid of it had been opened. He found in it only a few bones, supposed to be those of a human skeleton, but which it is said have since been found to belong to the skeleton of a bull. On the wall of the western side of the chamber is an Arabic inscription, a translation of which was said to be sent to the British Museum, but has not yet been published. It testifies that this pyramid was opened by Mahomet El Aghar, and Otman, and that it was inspected in presence of the sultan Ali Mahomet the first, Ugoch (a Tartaric title). There were several other inscriptions on the walls, supposed to be Coptic. Another chamber was found nearer the exterior of the pyramid on the north side, but sunk farther into the rock. It was smaller in size, and contained some inscriptions, but no sarcophagus was observed.

In the various exterior passages opened, it has been remarked that they have nearly all the same degree of declivity, forming an angle of about 26 degrees with the horizon. There is reason to suppose that this coincidence is not accidental, but that it was connected with some internal purpose. It may have been intended to observe the passage over the meridian of a particular star. The dip gives a line of direction not very different from that point in the heavens where the north pole star now crosses the meridian below the pole.

These researches tend to confirm the opinions of Strabo and Diodorus Siculus, that the pyramids are sepulchral monuments. Some of them were probably destined to receive the bodies of their deities, and others those of their kings. But the cells discovered yet in the interior of these immense structures, occupy so small a part of their solid contents, that it is probable many more remain to be laid open. It is probable some will yet be found which have never been entered by the Arabs, or any of the other conquerors whose lust for hidden treasures made them ransack these mysterious depositories; and when some of these unviolated chambers are found, we will have a better idea of the original destination and use of these singular monuments. See Fawkes's Travels, and Quarterly Review, No. 37 and 38.

PYRAMIDALES, in Anatomy, one of the muscles of the abdomen. See Anatomy, Table of the Muscles.
PYROMANCY, a kind of divination by means of fire. See Divination, No. 6.

PYROMETER, an instrument for measuring the expansion of bodies by heat. See Chemistry Index. Myschenbroeck, who was the original inventor of this machine, has given a table of the expansion of the different metals in the same degree of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at 32 degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the 44\textsuperscript{th} part of an inch.

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments, it appears at first view that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames placed together, cause a greater rarefaction than when they have a sensible interval between them; iron in the former case, being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious.

By comparing the expansions of the same metal produced by one, two, three, or more flames, it appears that two flames do not cause double the expansion of one, nor three flames three times that expansion, but always less; and these expansions differ so much the more from the ratio of the numbers of flames as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more some less. Thus tin began to run when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

Mr Elliot found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow:

Gold, Silver, Brass, Copper, Iron, Steel, Lead, 73 103 95 89 69 56 149

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat. See Pendulum.

Mr Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Mr Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw.

The following table shows how much a foot in length of each metal grows longer by an increase of heat, corresponding to 18\textdegree of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expressed in such parts of which the unit is equal to the 10,000th part of an inch.

We shall close this article with a brief description of a pyrometer invented by M. De Luc, in consequence of a hint suggested to him by Mr Ramsden. The basis of this instrument is a rectangular piece of deal-board two feet and a half long, 15 inches broad, and one inch and a half thick; and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long and an
PYROTECHNY,

Definition. 

Literally signifies the art of fire, and is derived from ἐφέ, "fire," and ἔφη, "art." The term is now, however, generally confined to denote the art of making artificial fire-works, which has become a particular trade.

As this art depends chiefly on chemical principles, and all the objects about which it is employed afford some of the most gratifying occasions on occasions of public rejoicing, we have not considered it unworthy of a place in our Encyclopedia; and we shall endeavor to give such an account of the operations and principles of the art as may satisfy those who wish to practise it by way of rational amusement.

Of the origin of artificial fire-works nothing certain appears to be recorded. We know that in Europe their invention is of a recent date, and appears due to the Italians. The use of fire-works in China seems to have been very general long before their invention in Europe, and that ingenious people have carried these exhibitions to a degree of perfection which European artists have yet scarcely attained. The following description of a Chinese display of fire-works by one of the gentlemen who accompanied Lord Macartney's embassy to Pekin, will give our readers some idea of the state of the art among those people.

Description of Chinese fire-works.

"The fire-works in some particulars, exceeded any thing of the kind I had ever seen. In grandeur, magnificence, and variety, they were, I own, inferior to the Chinese fire-works we had seen at Batavia, but infinitely superior in point of novelty, neatness, and ingenuity of contrivance. One piece of machinery I greatly admired; a green chest of five feet square was hoisted up by a pulley to the height of 50 or 60 feet from the ground; the bottom was so constructed as then suddenly to fall out, and make way for 20 or 30 strings of lanterns enclosed in the box to descend from it, unfolding themselves from one another by degrees, so as at last to form a collection of at least 100, each having a light of a beautifully coloured flame burning brightly within it. This deviation and development of lanterns (which appeared to me to be composed of gauze and paper) were several times repeated, and every time exhibited a difference of colour and figure. On each side was correspondence of smaller boxes, which opened in like manner as the others, and let down an immense net-work of fire, with divisions and compartments of various forms and dimensions, round and square, hexagons, octagons, and lozenges, which shone like the brightest burnished copper, and flashed like prismatic lightning, with every impulse of the wind. The diversity of colours indeed with which the Chinese have the secret of clothing fire seems one of the chief merits of their pyrotechny. The whole concluded with a volcano, or general explosion and discharge of suns and stars, squibs, bouchers, crackers, rockets, and grenades, which involved the garden for above an hour after in a cloud of intolerable smoke."

Till of late the French and Italian makers of fire-works...
works much excelled our British artists, and even now, though the practice of the art is well understood among us, its principles are almost entirely unknown; and no English work of any respectability has appeared on the subject. In France, the art has been more fortunate, and several men of eminent literary abilities have condescended to make it an object of their attention. It will be sufficient, in proof of this, to mention the names of Ozanam and Montucu. The following works are recommended by the latter, as containing the best account of this amusing art; viz.

Traité des Feux d'Artifice (Treatise on Artificial Fire-works), by M. Frezier, a new edition of which appeared in 1745.

Traité des Feux d'Artifice pour le Spectacle et pour la Guerre, (Treatise on Artificial Fire-Works, employed in Exhibitions and in War), by M. Perrinot d'Orval.

Indeed most of the written information which we possess on the making of fire-works, is derived from the French; and many of these productions still retain French names, such as gerbes, ballons, maroons, tourbillons, saucissons, &c.

We shall divide this article into two chapters; in the first of which we shall consider the apparatus required for forming the cases or shells of artificial fire-works, and the materials employed in their construction; and in the second we shall describe the different kinds of fire-works and the most approved methods of constructing them.

CHAP. I. Of the Apparatus and Materials employed in making Fire-Works.

SECT. I. Of Apparatus.

The apparatus used in making fire-works consists chiefly of solid wooden cylinders, called formers, for rolling the cases on; similar cylinders either of wood or metal for ramming down the composition; moulds for holding the cases while filling, a machine for chocking or contracting the cavity of the cases, another for grinding the materials, and a particular apparatus for boring some cases after they are filled.

We shall begin with describing the moulds, as on the size of these depends that of the formers and rammers.

As the performance of rockets depend much on their moulds, it is requisite to give a description of them and their proportions: They are made and proportioned by the diameter of their orifice, which is divided into equal parts. Fig. 1. represents a mould made by its diameter $AB$: its height from $C$ to $D$ is six diameters and two-thirds; from $D$ to $E$ is the height of the foot, which is one diameter and two-thirds; $F$ the chock or cylinder, whose height is one diameter and one third; it must be made out of the same piece as the foot, and fit tight in the mould; $G$ is an iron pin that goes through the cylinder to keep the foot fast; $H$ the nipple, which is half a diameter high, and two-thirds thick, and of the same piece of metal as the piercer $I$, whose height is three diameters and a half, and at the bottom it is one-third of the diameter thick.

N. B. The diameter of the nipple must always be equal to that of the former.

We shall now show the method of finding the diameters or calibres of rockets, according to their weight; but we must first observe, that a pound rocket, is that 3 just
Pyrotechny.

Apparatus, just capable of admitting a leaden bullet of a pound weight, and so of the rest. The calibre for the different sizes may be found in the two following tables, one of which is calculated for rockets of a pound weight and under; and the other for those from a pound to 50 pounds.

The use of this table will be understood merely by inspection; for it is evident that the mould for a rocket of 12 ounces ought to be 17 lines in diameter; one of eight ounces, 15 lines; one of 10 drams, 14 lines; and so of the rest.

On the other hand, if the diameter of the rocket be given, it will be easy to find the weight of the ball corresponding to that calibre. For example, if the diameter be 13 lines, it will be immediately seen, by looking for that number in the column of lines, that it corresponds to a ball of five ounces.

The use of this second table is as follows: If the weight of the ball be given, which we shall suppose to be 24 pounds, seek for that number in the column of pounds, and opposite to it, in the column of calibres, will be found the number 288. Then, say, as 100 is to 19½, so is 288 to a fourth term, which will be the number of lines of the calibre required; or multiply the number found, that is 288, by 19½, and from the product divide 3616, cut off the two last figures; the required calibre, therefore, will be 56½, or 36 lines, or four inches and eight lines.

On the other hand, the calibre being given in lines, the weight of the ball may be found with equal ease. If the calibre, for example, be 28 lines, say as 19½ is to 28, so is 100 to a fourth term, which will be 143½, or nearly 144. But in the above table, opposite to 144 in the second column, will be found the number 3 in the first; which shows that a rocket, the diameter or calibre of which is 28 lines, is a rocket of a three pounds ball.

Fig. 7. represents a mould, in which the cases are fig. 7., driven solid; L the nipple, with a brass point at top (flat at top, and of the same length as the neck of the case), which, when the case is filling, serves to stop the nozzle, and prevent the composition from falling out of the cases, without this point it would; and, in consequence, the air would get into the vacancy in the charge, and at the time of firing cause the case to burst. These moulds are made of any length or diameter, according as the cases are required; but the diameter of the rollers must be equal to half the bore, and the rammer made quite solid. The nipple and cylinders must bear the same proportion as those for rockets.

The rolling and forming of cases is so intimately connected with the construction of moulds and formers, that we shall introduce what we have to say on that subject into the same section.

Sky-rockets cases are to be made 62 of their exterior diameter long; and all other cases that are to be filled in moulds must be as long as the moulds, within half its interior diameter.

Rocket cases from the smallest to four or six pounds, are generally made of the strongest sort of cartridge paper, and rolled dry; but the large sort are made of pasted pasteboard. As it is very difficult to roll the ends of the cases quite even, the best way will be to keep a pattern of the paper for the different sorts of cases; which pattern should be somewhat longer than the case it is designed for, and on it marked the number of sheets required, which will prevent any paper being cut to waste. Having cut the papers of a proper size, and the last sheet for each case with a slope at one end, so that when the cases are rolled it may form a spiral line round the outside, and that this side may always be the same, let the pattern be so cut as a guide. Before you begin to roll, fold down one end of the first sheet, so far that the fold will go two or three times round the former: then, on the double edge, lay the former with its handle off the table; and when you have rolled on the paper within two or three turns, lay the next sheet on that part which is loose, and roll it all on.

Having thus done, you must have a smooth board, about 20 inches long, and equal in breadth to the length of the case. In the middle of this board must be a handle placed lengthwise. Under this board lay the case, and let one end of the board lie on the table, then press hard on it, and push it forwards, which will roll the paper very tight; do this three or four times before you roll on any more paper. This must be repeated with every other sheet of paper, till the case is thick enough;

...
enough; but if the rolling board be drawn backwards, it will loosen the paper: you are to observe when you roll on the last sheet, that the point of the slope be placed at the small end of the roller. Having rolled your case to the mould, push in the small end of the former F, about one diameter from the end of the case, and put in the end-piece within a little distance of the former; then give the pinching cord one turn round the case, between the former and the end-piece; at first pull gently, and keep moving the case, which will make the neck smooth, and without large wrinkles. When the case is hard, take a sheet of paper (except the first and last, in that part where the neck is formed) be a little moistened with water; immediately after you have struck the concave stroke, bind the neck of the case round with small twine, which must not be tied in a knot, but fastened with two or three bitches. Having thus pinched and tied the case, so not to give way, put it into the mould without its foot, and with a mallet drive the former hard on the end-piece, which will force the neck close and smooth. This done, cut the case to its proper length, allowing from the neck to the edge of the mouth half a diameter, which is equal to the height of the nipple; then take out the former, and drive the case over the piercer with the long rammer, and the vent will be of a proper size. Wheel-cases must be driven on a nipple with a point to close the neck, and make the vent of the size required; which, in most cases, is generally one fourth of their interior diameter. As it is very often difficult, when the cases are rolled, to draw the roller out, you may make a hole through the base, and insert in it a small pin, by which you may easily turn the former round and pull it out. Fig. 3 shows the method of pinching cases; P a trellis, which, when pressed hard with the foot will draw the cord tight, and force the neck as close as you please; Q a small wheel or pulley, with a groove round it for the cord to run in.

Cases for wheels and fixed pieces are commonly rolled wet; and when they are required to contain a great length of charge, the method of making those cases is this: The paper must be cut as usual, only the last sheet must not be cut with a slope: Having the paper ready, paste each sheet on one side; then fold down the first sheet as before directed: but be careful that the paste does not touch the upper part of the fold; for if the roller be wetted, it will tear the paper in drawing it out. In pasting the last sheet, observe not to wet the last turn or two in that part where it is to be pinched; for if that part be damp, the pinching cord will stick to it, and tear the paper: therefore when you choke those cases, roll a bit of dry paper once round the case before you put on the pinching cord; but this bit of paper must be taken off after the case is chocked. The rolling board, and all other methods, according to the former directions for the rolling and pinching of cases, must be used to these as well as all other cases.

Tourbillon cases are generally made about eight diameters long; but if very large, seven will be sufficient: tourbillons will answer very well from four ounces to two pounds; but when larger there is no certainty. The cases are best rolled wet with paste, and the last sheet must have a straight edge, so that the case may be all of a thickness: when the cases have been rolled in the manner of wheel cases, pinch them at one end quite close; then with the rammer drive the ends down flat. Apparatus, and afterwards ram in about one-third of a diameter of dried clay. The diameter of the former for these cases must be the same as that for sky-rockets.

N. B. Tourbillons are to be rammed in moulds without a nipple, or in a mould without its foot.

For balloons, first prepare an oval former turned of Balloon case-smooth wood; over which pasting a quantity of brown sea, or paper or cartridge paper, let it lie till the paste has quite soaked through; this done, rub the former with soap or grease, to prevent the paper from sticking to it; then lay the paper on in small slips till you have made it one-third of the thickness of the intended shell. This being done, set it to dry; and when dry, cut it round the middle, and the two halves will easily come off; but observe, when you cut, to leave about one inch uncut, which will make the halves join much better than if they had been quite separated. When there are some ready to join, place the halves evenly together, paste a slip of paper round the opening to hold them together, and let that dry; then lay on paper all over as before, everywhere equal, excepting that end which goes downwards in the mortar, which may be a little thicker than the rest; for that part which receives the impulse from the powder in the chamber of the mortar requires the greatest strength. When the shell is thoroughly dry, burn a round hole at top, with square iron, large enough for the fuzes: this method will do for balloons from four inches two-fifths, to eight inches diameter; but if they are larger, or required to be thrown a great height, let the first shell be turned of elm, instead of being made of paper.

For a balloon of four inches two-fifths, let the former be three inches one-eighth diameter, and five inches and a half long. For a balloon of five inches and a half, the diameter of the former must be four inches, and eight inches long. For a balloon of eight inches, let the diameter of the former be five inches and 1½-16ths, and 11 inches seven-eighths long. For a 10-inch balloon, let the former be seven inches three-sixteenths diameter, and 14 inches and a half long. The thickness of a shell for a balloon of four inches two-fifths, must be one-half inch. For a balloon of five inches and a half, let the thickness of the paper be five-eighths of an inch. For an eight-inch balloon, seven-eighths of an inch. And for a 10-inch balloon, let the shell be one inch one-eighth thick.

Shells that are designed for stars only, may be made quite round, and the thinner they are at the opening, the better; for if they are too strong, the stars are apt to burst at the bursting of the shell: when making the shell, use a pair of calibre compasses, or a round gage, so that the paper may not be laid thicker in one place than another; and also to know when the shell is of a proper thickness. Balloons must always be made to go easy into the mortars.

Port-fire cases must be made very thin, and rolled on Cases for formers, from two inches to ⅓ of an inch diameter, and port-fires from two to six inches long: they are pinched close at one end, and left open at the other. When they are to be filled, put in but little composition at a time, and ram it lightly, so as not to break the case: three or four rounds of paper, with the last round pasted, will be strong enough for these cases.

Common port-fires are intended for the purpose of fir-
PYROTECHNY.

Apparatus, the works, their fire being very slow, and the heat of the flame so intense, that, if applied to rockets, leaders, &c. it will fire them immediately. Portfuses may be made of any length, but are seldom made more than 11 inches long: the interior diameter of portfuse moulds should be 10-16ths of an inch, and the diameter of the former half an inch. The cases must be rolled wet with paste, and one end pinched, or folded down. The moulds should be made of brass, and such as will take in two pieces lengthwise; when the case is in the two sides, they are held together by brass rings, or hoops, which are made to fit over the outside. The bore of the mould must not be made quite through, so that there will be no occasion for a foot. These portfuses, when used, are held in copper sockets, fixed on the end of a long stick; these sockets are made like port crayons, only with a screw instead of a ring.

Method of grinding the ingredients.

There have been many methods contrived for grinding the ingredients for fire-works to a powder, such as large mortars and pestles made of ebony and other hard wood, and horizontal mills with brass barrels; but none have proved so effectual and speedy, as that of the meal-ting-table, represented in fig. 9, made of elm, with a rim round its edge four or five inches high; and at the narrow end A, furnished with a slider that runs in a groove, and forms part of the rim: so that when you have taken out of the table as much powder as you can with the copper shovel (fig. 10.), sweep all clean out at the slider A. When about to meal a quantity of powder, observe not to put too much in the table at once; but when you have put in a good proportion, take the muller (fig. 11.) and rub it till all the grains are broken; then sift it in a large sieve that is made quite through, so that it can be used by the apothecaries, and that which does not pass through the sieve, must be returned again to the table, and ground till it is fine enough to go through the sieve. Sulphur and charcoal are ground in the same manner, only the muller must be made of ebony: for these ingredients being harder than powder, would stick in the grain of elm, and be difficult to grind. As sulphur is apt to stick and clog to the table, it will best to keep one for that purpose, by which means you will always have your brimstone clean and well ground.

Apparatus for boring rockets that are rammed so.

Fig. 12. represents the plan of an apparatus, or lathe, for boring rockets. A large wheel, which turns the small one B, that works the rammer C: these rammers are of different sizes according to the rockets; they must be of the same diameter as the top of the intended bore, and continue that thickness a little longer than the depth of the bore required, and their points must be like that of an auger: the thick end of each rammer must be made square, and all of the same size, so as to fit into one socket, into which they are fastened by a screw D. E is guide for the rammer, which is made to move backwards and forwards; so that, after the rammer has been marked three diameters and a half of the rocket from the point, set the guide, allowing for the thickness of the fronts of the rocket boxes, and the neck and mouth of the rocket; so that when the front of the large box is close to the guide, the rammer may not go too far up the charge. F boxes for holding the rockets, which are made so as to fit one within the other, and their sides must be equal in thickness to the difference of the diameters of the rockets, and their interior diameters equal to the exterior diameters of the rockets. To prevent the rocket from turning round while boring, a piece of wood must be placed against the end of the box inside, and pressed against the tail of the rocket. This will also hinder the rammer from forcing the rocket backwards. G, a rocket in the box. H, a box that slides under the rocket boxes to receive the boring for the rockets, which fall through holes made on purpose in the boxes; these holes must be just under the mouth of the rocket, one in each box, and all to correspond with each other.

Fig. 13. is a front view of the large rocket-box. I is an iron plate, in which are holes of different sizes, through which the rammer passes; this plate is fastened with a screw in the centre, so that when the rammer is changed the plate is turned round, but the holes you are going to use must always be at the bottom: the fronts of the other boxes must have holes in them to correspond with those in the plate. K, the lower part of the large box, which is made to fit the inside of the lathe, that all the boxes may move quite steadily.

Fig. 14. is a perspective view of the lathe. L is the guide for the rammer, which is set by the screw at bottom.

Fig. 15. A view of the front of the guide facing the rammer. M is an iron plate, of the same dimensions as that on the front of the box, and placed in the same direction, and also to turn on a screw in the centre. N, the rocket-box which slides backwards and forwards when a rocket is fixed in the box, it is to be pushed forwards against the rammer; and when the scoop of the rammer appears to be full, draw the box back and knock out the composition: this must be done till the rocket is bored, or it will be in danger of taking fire; and if the boring be done in a hurry, wet the end of the rammer now and then with oil to keep it cool.

Having bored a number of rockets, you must have taps of different sorts according to the rockets. These taps are a little longer than the bore: but when used they must be marked 3½ diameters from the point, allowing for the thickness of the rocket's neck; then, holding the rocket in one hand, tap it with the other. One of these taps is represented by fig. 16. They are made in the same proportion as the fixed piercers, and are hollowed their whole length.

There are hand machines for boring, which answer very well, though not so expeditious as the lathes. But these they are not so expensive, and they may be worked by one man, whereas the lathe will require three. Fig. 17. Fig. 15. represents the machine. O, the rocket boxes, which are to be fixed, and not to slide as those in the lathe. PQ are guides for the rammer, that are made to slide together, as the rammer moves forward; the rammer for these machines must be made of a proper length, allowing for the thickness of the front of the boxes, and the length of the mouth and neck of the case; on the square end of these rammers must be a round shoulder of iron, to turn against the outside of the guide Q, by which means the guides are forced forwards. R, the stock which turns the rammer, and which while turning, must be pressed towards the rocket by the body of the man who works it; all the rammers are to be made to fit one stock.

Sect.
The charges or compositions with which the cases that we have described are to be filled, consist chiefly of gunpowder, or of a powder composed of the same materials in various proportions, and some other combustible substances, intended either to give the composition a stronger impelling force, or to increase the beauty and splendour of the exhibition. As the nature and composition of gunpowder have been fully explained under the article Gunpowder, it is unnecessary to consider them in this place; but as the makers of fire-works commonly employ considerable quantities of the substances of which gunpowder is composed, it is proper to give some directions for obtaining these in the greatest purity. We may also notice, that gunpowder, in its ordinary state, is called corn-powder; while, when ground down, as directed in No. 15, it is denominated meal-powder.

Nitre.
The ingredient on which the force of the compositions chiefly depends, is nitre or saltpetre; but as this substance, in its usual state, is very impure, being much contaminated with earthy matter, and as pure nitre is now become very expensive, it is of consequence to know how the nitre of commerce may be purified.

Nitre, like most other saline bodies, is much more soluble in boiling water, than in water of the ordinary temperature. If, therefore, the nitre of commerce be dissolved in a small quantity of boiling water, and the solution be properly strained, the liquor, when cold, will afford crystals that are very pure. The following is the most convenient method of proceeding. Dissolve the nitre in boiling water, in the proportion of about an English quart, or Scotch chopin, to each pound of nitre; and that the solution may be more easily effected, let the nitre be reduced to powder, and let the vessel containing the nitre and water be kept at the boiling heat till all the salt is dissolved. Then strain the liquor while hot through thick blotting paper, placed in a clean funnel, and set by the filtered liquor in a shallow vessel, in some cold place, till crystals are formed. These must be removed from the liquor, and dried with a gentle heat; and if the remaining liquor be slowly evaporated over the fire, in an earthen unglassed vessel, till a film appears on the top, and then set by to crystallize as before, an additional quantity of pure nitre will be procured; and thus, by repeated evaporation and crystallizations, the whole of the salt will be obtained.

Nitre may be obtained in great purity from damaged gunpowder, which may often be bought at a cheap rate. The damaged powder must be ground with a small quantity of hot water, in a large wooden or stone mortar, or it may be boiled over a gentle fire, with as much water as will cover it. When the water seems to have dissolved as much of the nitre as it will retain, it is to be poured off from the sediment, and filtered or strained through a flannel bag, then heated again, and, while hot, filtered through blotting paper, and set by to crystallize, as in the former case. Fresh quantities of hot water are to be successively added to the sediment, and strained as before, till the whole of the nitre is obtained.

Charcoal may, in general, be procured at the shops of founders and hardware dealers; but when this is not the case, it may easily be prepared by putting a quantity of small pieces of wood into a large earthen crucible or iron pot, and covering them with sand, and placing the crucible or the pot in the middle of a strong fire, where it must be kept red hot for an hour or two, in proportion to the quantity of wood. Charcoal should be chosen soft and light, and such as may easily be reduced to powder. It should be kept in a dry place, but is always best when fresh burned.

Several other ingredients are employed in the composition of fire-works, such as camphor, antimony (sulphuret of antimony), rasping of ivory, yellow amber, sal ammoniac, verdigris, common pitch, and Greek pitch, all of which are used on different occasions, to produce a change of colour in the fire; filings of iron and copper, for giving a sparkling appearance to the flame, and salt of bismuthic acid to produce an agreeable odour.

Iron filings answer very well for ordinary fire-works; Method of but they do not produce such a brilliant appearance as powdering powdered cast-iron. The introduction of this latter is an improvement of the Chinese, and its use is now very general.

Cast-iron being of so hard a nature as not to be cut by a file, we are obliged to reduce it into grains, though this is rather difficult to perform; but if we consider what beautiful sparks this iron yields, no pains should be spared to granulate such an essential material: to do this, procure at an iron-foundery some thin pieces of iron, such as generally run over the mould at the time of casting: then have a square block made of cast-iron, and an iron square hammer about four lb. weight; then, having covered the floor with cloth or something to catch the beatings, lay the thin pieces of iron on the block, and beat them with the hammer till reduced into small grains; which afterwards sift with a very fine sieve, to separate the fine dust, which is sometimes used in small case of brilliant fire, instead of steel dust; and when you have got out all the dust, sift what remains with a sieve.

The other composition is called spur-fire, because the sparks yielded by it have a starry appearance like the rowel of a spur.

Spur-fire.—This fire is the most beautiful and curious of any yet known; and was invented by the Chinese, but now is in greater perfection in England than in China. As it requires great trouble to make it to perfection, it will be necessary that beginners should have full instructions; and it is to be taken that all the ingredients are of the best, that the lamp-black is not damp and cloddled, that the saltpetre and brimstone are thoroughly refined. This composition is generally rammed in one or two ounce cases about five or six inches long, but not above very hard; and the cases must have their concave stroke struck very smooth, and the choak or vent not quite so large as the usual proportion: this charge, when driven and kept a few months, will be much better than when rammed; and will not spoil, if kept dry, in many years.

As the beauty of this composition cannot be seen at so great a distance as brilliant fire, it has a better effect in a room than in the open air, and may be fired in a chamber without any danger: it is of so innocent a nature, that, though with an improper phrase, it may be called a cold fire; and so extraordinary is the fire produced from this composition, that, if well made, the sparks will not burn a handkerchief when held in the midst of them; you may hold them in your hand while burning, with as much safety as a candle, and if you put your hand within a foot of the mouth of the case, you will feel the sparks like drops of rain.—When any of these spur-fires are fired singly, they are called artificial flower-pots; but some of them placed round a transparent pyramid of paper, and fired in a large room, make a very pretty appearance.

The composition consists of saltpetre, four pounds eight ounces; sulphur two pounds, and lamp-black one pound eight ounces; or, saltpetre one pound, sulphur half a pound, and lamp-black four quarts.—This composition is very difficult to mix. The saltpetre and brimstone must be first sifted together, and then put into a marble mortar, and the lamp-black with them, which you work down by degrees with a wooden pestle, till all the ingredients appear of one colour, which will be something grayish, but very near black: then drive a little into a case for trial, and fire it in a dark place; and if the sparks which are called stars, or pinks, come out in clusters, and afterwards spread well without any other sparks, it is a sign of its being good, otherwise not; for if any drossy sparks appear, and the stars not full, it is then not mixed enough; but if the pinks are very small, and soon break, it is a sign that it has been rubbed too much.

PYROTECHNY.

Wheel-cases from two ounces to four pounds.—I. Meal-powder 2 lb. saltpetre 4 oz. iron-fillings 7. II. Meal-powder 2 lb. saltpetre 12 oz. sulphur 4, steel-dust 3. III. Meal-powder 4 lb. saltpetre 1 lb. brimstone 8 oz. charcoal \(\frac{3}{4}\). IV. Meal-powder 8 oz. saltpetre 4, sawdust \(\frac{1}{4}\), sea-coal \(\frac{1}{4}\). V. Meal-powder 1 lb. 4 oz. For wheels, brimstone 4 oz. 10 dr. salt petre 8 oz. glass-dust \(\frac{3}{4}\). VI. Meal-powder 1 oz. charcoal 1, sawdust \(\frac{3}{4}\). VII. Saltpetre 1 lb. 9 oz. brimstone 4 oz. charcoal \(\frac{3}{4}\). VIII. Meal-powder 2 lb. saltpetre 1, brimstone 1, and sea-coal 2 oz. X. Meal-powder 1 lb. saltpetre 2 oz. and steel-dust \(\frac{3}{4}\). XI. Meal-powder 2 lb. and steel-dust 2 and a half oz. with 2 and a half of the fine dust of beat iron. XII. Saltpetre 2 lb. 13 oz. brimstone 8 oz. and charcoal.

Slow fire for wheels.—I. Saltpetre 4 oz. brimstone 2, and meal-powder 1 and a half. II. Saltpetre 4 oz. brimstone 1, and antimony 1 oz. 6 dr. III. Saltpetre 4 oz. and a half, brimstone 1 oz. and meal-powder 1 and a half.

Dead fire for wheels.—I. Saltpetre \(\frac{3}{4}\) oz. brimstone \(\frac{1}{4}\), laps-calaminaris \(\frac{1}{2}\), and antimony 2 dr.

I. Meal-powder 4 lb. saltpetre 2, brimstone and charcoal for fixed or coal 1. II. Meal-powder 2 lb. saltpetre 1, and steel-stand ing dust 8 oz. III. Meal-powder 1 lb. 4 oz. and charcoal 4 oz. IV. Meal-powder 1 lb. and steel-dust 4 oz. V. Meal-powder \(\frac{3}{4}\) lb. brimstone 4 oz. and sea-coal 6. VI. Meal-powder 3 lb. charcoal 5 oz. and saw-dust 1 and a half.

I. Meal-powder 8 oz. saltpetre 1 lb. 2 oz. steel-dust for sun 2 lb. 10 oz. brimstone 4. II. Meal-powder 3 lb. saltpetre 6 oz. and steel-dust 7 oz.

I. Meal-powder 11 lb. saltpetre 1, brimstone 4 oz. steel for a brilliant dust 1 lb. and a half. II. Meal-powder 6 lb. and beat-iron 2 lb. 1 oz. and a half. III. Meal-powder 2 lb. iron 1 oz. and charcoal 4 oz. and a half. IV. Eight ounce Tourbillons.—Meal-powder 2 lb. and billons charcoal \(\frac{3}{4}\) oz.

Large Tourbillons.—Meal-powder 2 lb. saltpetre 1, brimstone 8 oz. and beat iron 8.

N. B. Tourbillons may be made very large, and of different-colored fires: only you are to observe, that the larger they are, the weaker must be the charge; and, on the contrary, the smaller, the stronger their charge.

I. Saltpetre 4 lb. brimstone 2, meal-powder 2, anti-for water mony 4 oz. saw dust 4, and glass-dust 1 and a fourth. II. Saltpetre 9 lb. brimstone 3 lb. meal-powder 6 lb. rosin 12 oz. and antimony 8 oz. III. Meal-powder 1 lb. and charcoal 1 lb. II. Meal-powder for water powder 1 lb. and charcoal 9 oz.

I. Meal-powder 1 lb. and charcoal 1 oz. II. Meal-powder 9 oz. charcoal 1 oz.

I. Meal-powder 1 lb. and charcoal 1 oz. II. Meal-powder for firing rockets, &c.—I. Saltpetre 12 oz. brimstone 4 oz. and meal-powder 2 oz. II. Saltpetre 8 oz. For fire, brimstone 4 oz. and meal-powder 2 oz. III. Saltpetre 1 lb. 2 oz. meal-powder 1 lb. and a half, and brimstone 10 oz. This composition must be moistened with one gill of linseed oil. IV. Meal-powder 6 oz. saltpetre 2 lb. 2 oz. and brimstone 10 oz. V. Saltpetre 1 lb. 4 oz. meal-powder 4 oz. brimstone 5 oz. saw dust 8 oz. VI. Saltpetre 8 oz. brimstone 2 oz. and meal-powder 2 oz.

For illuminations.—Saltpetre 1 lb. brimstone 8 oz. and meal-powder 6 oz.

Sulphur.
PYROTECHNY.

Apparatus, Saltpetre 1 lb. and a half, brimstone 6 oz. meal-pow-der 14 oz. and glass-dust 14 oz.

Material, Saltpetre 6 oz. brimstone 2 lb. antimony 4 oz. and camphor 2 oz.

Coarse or spiral wheels.

1. Saltpetre 1 lb. 10 oz. brimstone 8 oz. and meal-powder 1 lb. 6 oz. II. Saltpetre 1 lb. and a half, brimstone 8 oz. and meal-powder 1 lb. 8 oz.

Meal-powder 1 lb. 8 oz. saltpetre 12 oz. and charcoal 2 oz.

Crowns or globes.

1. Saltpetre 5 lb. brimstone 1 lb. meal-powder 1 lb. and a half, and glass-dust 1 lb. II. Saltpetre 5 lb. 8 oz. brimstone 2 lb. meal-powder 1 lb. 8 oz. and glass-dust 1 lb. 8 oz.

Air balloon or fuses.

1. Saltpetre 2 lb. brimstone 3 lb. antimony 1 lb. II. Saltpetre 3 lb. sulphur 2 lb. meal-powder 1 lb. antimony half a lb. glass-dust 4 oz. brass-dust 1 oz.

N. B. These compositions, driven 6 inch in a 1 oz. case, will burn one minute, which is much longer time than an equal quantity of any composition yet known will last.

Meal-powder 9 oz. amber 3 oz. This charge may be droved in small cases, for illuminations.

Saltpetre 3 lb. brimstone 1 lb. meal-powder 1 lb. antimony 10 oz. All these must be mixed with the oil of spike.

A red fire.

1. Meal-powder 3 lb. charcoal 12 oz. and saw-dust 8 oz.

2. Saltpetre 3 lb. charcoal 10 oz. and brimstone 2 oz.

3. Meal-powder 4 oz. saltpetre 2 oz. brimstone 2 oz. steel-dust 1 oz. and a half, and camphor, white amber, antimony, and mercury-sulphate, of each ½ oz. II. Rochet-petre 10 oz. brimstone, charcoal, antimony, meal-powder, and camphor, of each ½ oz. moistened with oil of turpentine. These compositions are made into stars, by being worked to a paste with aqua vitae, in which has been dissolved some gum-tragacanth; and after you have rolled them in powder, make a hole through the middle of each, and sting them on quick-match, leaving about 2 inches between each. III. Saltpetre 8 oz. brimstone 2 oz. yellow amber 1 oz. antimony 1 oz. and powder 3 oz. IV. Brimstone 2½ oz. saltpetre 6 oz. obidanum or frankincense in drops 4 oz.; mastick, and mercury-sulphate, of each 4 oz. meal-powder 5 oz. white amber, yellow amber, and camphor, of each ½ oz. antimony and ornament half an oz. each. V. Saltpetre 1 lb. brimstone half a lb. and meal-powder 8 oz. moistened with petrolio oil. VI. Powder half a lb. brimstone and saltpetre, of each 4 oz. VII. Saltpetre 4 oz. brimstone 2 oz. and meal-powder 1 oz.

Stars that carry tails of sparks.—I. Brimstone 6 oz. crude antimony 2 oz. saltpetre, 4 oz. and rosin 4 oz. II. Saltpetre, rosin, and charcoal, of each 2 oz. brimstone 1 oz. and pitch 1 oz.

These compositions are sometimes melted in an earthen pan, and mixed with chopped cotton-match, before they are rolled into stars; but will do as well if wetted, and worked up in the usual manner.

Stars that yield some sparks.—I. Camphor 2 oz. saltpetre 1 oz. meal-powder 1 oz. II. Saltpetre 1 oz. ditto melted half an oz. and camphor 2 oz.

When you would make stars of either of these compositions, you must wet them with gum-water, or weak spirits, in which has been dissolved some gum-arabic, or gum-tragacanth, that the whole may have the consistence of a pretty thick liquid; having thus done, take 1 oz. of lint, and stir it about in the composition till it becomes dry enough to roll into stars.

Stars of a yellowish colour.—Take 4 oz. of gum-tragacanth or gum-arabic, pounded and sifted through a fine sieve, camphor dissolved in brandy 2 oz. saltpetre 1 lb. sulphur half a lb. coarse powder of glass 4 oz. white amber 1 oz. and a half, ornament 2 oz. Being well incorporated, make them into stars after the common method.

Stars of another kind.—Take 4 oz. of camphor, es- melt it in a pint of spirit of wine over a slow fire, then add to it ½ lb. of gum-arabic that has been dissolved with this liquor mixed with saltpetre, 6 oz. of sulphur, and 5 oz. of meal-powder; and after you have strowed them well together, roll them into stars proportionate to the rockets for which you intend them.

As variety of fires adds greatly to a collection of works, it is necessary that every artist should know the different effect of each ingredient. For which reason, we shall here explain the colours they produce of them-selves; and likewise how to make them retain the same when mixed with other bodies: as for example, sulphur gives a blue, camphor a white or pale colour, saltpetre a clear white-yellow, amber a colour inclining to yellow, sal-ammoniac a green, antimony a reddish, ros-in a copper colour, and Greek pitch a kind of bronze, or between red and yellow. All these ingredients are such as show themselves in a flame, viz.

White flame.—Saltpetre, sulphur, meal-powder, and camphor; the saltpetre must be the chief part.

Blue flame.—Meal-powder, saltpetre, and sulphurium; sulphur must be the chief; or meal-powder, saltpetre, camphor and wine, and oil of spike; but if the powder be the principal part.

Flame inclining to red.—Saltpetre, sulphur, antimony, and Greek-pitch; saltpetre the chief.

By the above method may be made various colours of fire, as the practitioner pleases; for, by making a few trials, he may cause any ingredient to be predominant in colour.

The set colours of fire produced by sparks are div-ided into four sorts, viz. the black, while, gray, and red. The black charges are composed of two ingredients, which are meal-powder and charcoal; the white of three; viz. saltpetre, sulphur, and charcoal; the gray of four, viz. meal-powder, saltpetre, brimstone, and charcoal; and the red of three; viz. meal-powder, charcoal, and saw-dust.

There are, besides these four regular or set charges, two others, which are distinguished by the names of compound and brilliant charges; the compound being made of many ingredients, such as meal-powder, saltpetre, brimstone, charcoal, saw-dust, sea-coal, antimony, glass-dust, brass-dust, steel-bling, cast-iron, tannin's dust, &c. or any thing that will yield sparks; all which must be managed with discretion. The brilliant fires are composed of meal-powder, saltpetre, brimstone, and steel-dust; or with meal-powder and steel-bling only.

The beauty of fire-works depends much on the compo-sitions being well mixed; therefore great care must be taken in this part of the work, particularly for the composition for sky-rockets. When there are four or five pounds of ingredients to be mixed, which is a sufficient quantity at a time (for a larger proportion will not do
PYROTECHNY.

mals and other objects in fire. To prepare this paste, take sulphur reduced to a very fine powder, or flowers of sulphur, and having formed it into a paste with starch, &c. of Fire-Works, cover with it the figure you are desirous of representing on fire: it is here to be observed, that the figure must first be coated over with clay, to prevent it from being burnt.

When the figure has been covered with this paste, besprinkle it while still moist with pulverized gunpowder; and when the whole is perfectly dry, arrange some small matches on the principal parts of it, that the fire may be speedily communicated to it on all sides.

The same paste may be employed on figures of clay, to form devices and various designs. Thus, for example, festoons, garlands, and other ornaments, the flowers of which might be imitated by fire of different colours, could be formed on the frieze of a piece of architecture covered with plaster. The Chinese imitate grapes exceedingly well, by mixing pounded sulphur with the pulp of the jujube, instead of flour paste.

It is usual to paint the frames or stands of large fire-works of works some dark colour, but this renders them very preserving combustible. It would be better to wash them with the fire-works following composition, which will both give them a proper colour, and render them less combustible. Take by equal parts of brick-dust, coal-ashes, and iron-flings, and mix them with a double size while hot. With this wash over the frames, &c. and when dry repeat the washing.

CHAP. II. Of the principal varieties of Fire-Works, and the most approved Methods of constructing them.

ARTIFICIAL fire-works differ from each other very Division of much in point of simplicity of construction. Some require very little dexterity in the preparation; and are either employed as appendages to works of greater importance, or if used by themselves, are confined to the sports of schoolboys. Of this nature are squibs, serpents, crackers, stars, sparks, morrows, saucisons, pin wheels, leaders, and jetoes or Roman candles. Others are very complex in their structure, require considerable address and ingenuity, and form the amusement of fashionable circles on occasion of public rejoicings or private festivity: Such are rockets, of various kinds, wheels, suns, globes, balloons, pyramids, &c. We shall first describe the more simple kinds, and then give an account of the method of constructing those of a more complex nature.

SECT. I. Of Simple Fire-Works.

As in the subsequent directions for fire-works, we shall have frequent occasion to mention pipes of communication commonly called leaders, by which the several parts of a compound fire-work are connected with each other, it will be proper to show how these are constructed. Leaders consist of small tubes of paper of different lengths, according to the distance to which they must extend; and these tubes are filled with a combustible composition that will not burn too fast.

The best paper for leaders is that called elephant; which is cut into long slips 2 or 3 inches broad, so that they may go 3 or 4 times round the former, but not more: when they are very thick, they are too strong

We are indebted to the Chinese for the contrivance of a paste which may be employed for representing ani-
PYROTECHNY.

Chap. II.

Varieties for the paper which fastens them to the works, and will sometimes fly off without leading the fire. The forms for these leaders are made from 2 to 6-16ths of an inch diameter; but 4-16ths is the size generally used. The forms are made of smooth brass wire: when used, rub them over with grease, or keep them wet with paste, to prevent their sticking to the paper, which must be pasted all over. In rolling pipes, make use of a rolling-board, but use it lightly: having rolled a pipe, draw out the former with one hand, holding the pipe as light as possible with the other; for if it press against the former, it will stick and tear the paper.

N. B. Make the leaders of different lengths, or in clothing works many will be wasted. Leaders for marron batteries must be made of strong cartridge paper.

Joining and placing leaders is a very essential part of fire-works, as it is on the leaders that the performance of all complex works depends; for which reason the method of conducting pipes of communication shall be here explained in as plain a manner as possible. Your works being ready to be clothed, proceed thus: Cut your pipes of a sufficient length to reach from one case to the other; then put in the quick-match, which must always be made to go in very easy; when the match is in, cut it off within about an inch of the end of the pipe, and let it project as much at the other end: then fasten the pipe to the mouth of each case with a pin, and put the loose ends of the match into the mouths of the cases, with a little meal-powder: this done to all the cases, paste over the mouth of each two or three bits of paper. The preceding method is used for large cases, and the following for small, and for illuminations: First thread a long pipe; then lay it on the tops of the cases, and cut a bit off the under side, over the mouth of each case, so that the match may appear; then pin the pipe to every other case; but before you put on the pipes, put a little meal-powder in the mouth of each case. If the cases thus clothed are port-fires or illuminated works, cover the mouth of each case with a single paper; but if they are chocked cases, situated so that a number of sparks from other works may fall on them before they are fired, secure them with three or four papers, which must be pasted on very smooth, that there may be no creases for the sparks to lodge in, which often set fire to the works before their time. Avoid as much as possible placing the leaders too near, or one across the other so as to touch, as it may happen that the flash of one will fire the other; therefore if your works should be so formed that the leaders must cross or touch, be sure to make them very strong, and secure at the joints, and at every opening.

When a great length of pipe is required, it must be made by joining several pipes in this manner: Having put on one length of match as many pipes as it will hold, paste paper over every joint; but, if a still greater length is required, more pipes must be joined, by cutting about an inch off one side of each pipe near the end, and laying the quick-match together, and tying them fast with small twine; after which, cover the joint with pasted paper.

One of the simplest fire-works is what is called a serpentine, which consists of a cylindrical paper case, about 4 or 5 inches long, and not made very thick. AC, fig. 19, represents the usual form of the serpentine, except that in general they have not the contraction in the middle, represented in this figure. The name serpentine has been given to this fire-work, either from the hissing noise which it makes when fired, or from the zigzag or undulating direction in which it moves, when properly constructed. The case or cartridge is rolled round a cylindrical stick, rather larger than a goose quill, and provided at one end with a narrow appendage, such as that used for rockets, fig. 3, by means of which it is chocked at one end. This case is filled about half way with some of the compositions described for making small rockets, see No 30, rammed moderately hard in the proper mould, and then it is either chocked in the middle, or some obstructing body, such as a small piece of paper, is introduced, and the remainder of the case is filled with ground or corn powder. Lastly, this other extremity is well secured with twine, and commonly dipt into melted pitch; a little moistened meal powder is introduced into the extremity next the chock, and a piece of touch-paper being properly fastened on this end, the serpentine is complete.

Crackers are composed of a pretty long paper case, filled with the proper composition, as will be described immediately, and folded up in such a manner as, when fired, to make successive rows at different intervals. To construct these crackers, cut some cartridge paper into pieces 3 1/2 inches broad, and one foot long; one edge of each fold down lengthwise about 1/8 of an inch broad; then fold the double edge down 1/2 of an inch, and turn the single edge back half over the double fold; then open it and lay all along the channel, which is formed by the folding of the paper, some meal-powder; then fold it over and over till all the paper is doubled up, rubbing it down every turn; this done, bend it backwards and forwards, 2 inches and a half, or thereabouts, at a time, as oft as the paper will allow; then hold all these folds flat and close, and with a small pinching cord give one turn round the middle of the cracker, and pinch it close; then bind it with a packthread as tight as possible; then in the place where it was pinched, prime one end of it, and cap it with touch-paper. When these crackers are fired, they will give a report at every turn of the paper: if you would have a great number of reports, the paper must be cut longer, or join them after they are made; but if they are made very long before they are pinched, you must have a piece of wood with a groove in it, deep enough to let in half the cracker; this will hold it straight while it is pinching. Fig. 20, represents a cracker complete.

Stars are small balls, prepared of a composition which emits a brilliant, radiating light, and are much employed in the construction of rockets, Roman candles, and similar fire-works. They are made of various sizes, but generally about as large as a musket bullet. Compositions for stars have been described in No 31, and 54. The ingredients must be thoroughly incorporated, and in forming the ball, unless the paste is sufficiently glutinous, it must be wrapped up in a piece of paper, or linen rag, tied closely round with pack thread, and a hole must be pierced through its middle for the insertion of a piece of match. These stars, when lighted, will exhibit a most beautiful appearance; for the fire, as it issues from the two ends of the hole in the middle, will extend to
a great distance, and thus make the fiery ball appear much larger.

Strung stars. First take some thin paper, and cut it into pieces of one inch and a half square, or thereabouts; then on each piece lay as much dry star-composition as the paper will easily contain; then twist up the paper as tight as possible; when done, rub some paste on the hands, and roll the stars between these, then set them to dry: the stars, being thus made, get some flax or fine tow, and roll a little of it over each star; then paste the hand and roll the stars as before, and set them again to dry; when they are quite dry, with a piercer make a hole through the middle of each, into which run a cotton quick-match, long enough to hold 10 or 12 stars at 3 or 4 inches distance: but any number of stars may be strung together by joining the match.

Tailed stars. These are called tailed stars, because there are a great number of sparks issuing from them, which represent a tail like that of a comet. Of these there are two sorts; which are rolled, and driven: when rolled, they must be moistened with a liquor made of half a pint of spirit of wine and half a gill of thin size, of this as much as will wet the composition enough to make it roll easy; when they are rolled, sift meal powder over them, and set them to dry.

When tailed stars are driven, the composition must be moistened with spirit of wine only, and not made wet as for rolling: and 2 oz. cases, rolled dry, are best for this purpose: and when they are filled, unroll the case within 3 or 4 rounds of the charge, and all that are unrolled cut off; then paste down the loose edge: 2 or 3 days after the cases are filled, cut them in pieces 5 or 6 8ths of an inch in length: then melt some wax, and dip one end of each piece into it, so as to cover the composition: the other end must be rubbed with meal powder wetted with spirit of wine.

Driven stars. Cases for driven stars are rolled with paste, but are made of paper very thin. Before they are filled, damp the composition with spirit of wine that has had some campbror dissolved in it: ram them indifferently hard, so that the case be not broken or sacked; to prevent which, they should fit tight in the mould. They are driven in cases of several sizes, from 8 drams to 4 oz. When they are filled in half ounce cases, cut them in pieces of three fourths of an inch long: if 1 oz. cases, cut them in pieces of 1 inch; if 2 oz. cases, cut them in pieces of 1 and one fourth inch long; and if 4 oz. cases, cut them in pieces of 1 inch and a half long: having cut the stars of a proper size, prime both ends with wet meal-powder. These stars are seldom put in rockets, they being chiefly intended for air-balloons, and driven in cases, to prevent the composition from being broken by the force of the blowing powder in the shell.

Rolling stars are commonly made about the size of a musket ball; though they are rolled of several sizes, from the bigness of a pistol ball to 1 inch diameter; and sometimes very small, but are then called sparks. Great care must be taken in making stars, first, that the several ingredients are reduced to a fine powder; secondly, that the composition may be well worked and mixed. Before beginning to roll, take about a pound of composition, and wet it with the following liquid, enough to make it stick together and roll easy: Spirit of wine 1 quart, in which dissolve one fourth of an ounce of isinglass. If a great quantity of composition be wetted at once, the spirit will evaporate, and leave it dry, before it is rolled into stars: having rolled up one proportion, shake the stars in meal-powder, and set them to dry, which they will do in 3 or 4 days; but if they should be wanted for immediate use, dry them in an earthen pan over a slow heat, or in an oven, it being necessary to make the composition of an equal size when the composition is taken up purposefully with the fingers; but by the following method they may be made very exactly. When the mixture is moistened properly, roll it on a flat smooth stone and cut it into square pieces, making each square large enough for the stars intended. There is another method used by some to make stars, which is by rolling the composition in long pieces, and then cutting off the star, so that each star will be of a cylindrical form: but this method is not so good as the former; for, to make the composition roll this way, it must be made very wet, which makes the stars heavy, as well as weakens them. All stars must be kept as much from air as possible, otherwise they will grow weak and bad.

Sparks differ from stars, only in their size and burn. Sparks, as they are made smaller than stars, and are sooner extinguished. The following is the most approved method of making them. Having put into an earthen vessel an ounce of mealed gunpowder, 3 oz. of powdered saltpetre, and 4 oz. of campbror, reduced to powder by rubbing it in a mortar with a little spirit of wine; pour over this mixture some weak gum water, or some weak brandy, in which some gum dragant has been dissolved, till the composition acquires the consistence of thick soup. Then take some lint or caddice, which has been boiled in brandy, vinegar, or with saltpetre, and afterwards dried and unravelled, and throw into the composition as much of it as is necessary to absorb the whole, taking care to stir it well. This matter is to be formed into small balls of about the size of a pea, which being dried in the air, are to be sprinkled with meal gunpowder, that they may more readily take fire.

Another method of making sparks is, to take some saw dust of any wood that burns readily, such as fir, and boil it in water that has been saturated with saltpetre. When it has been boiled for some time, the vessel is to be removed from the fire, and the solution of nitre poured off, so as to leave the saw dust at the bottom. The saw dust thus impregnated with nitre, is then to be poured on a table, and, while moist, to be sprinkled with powdered sulphur, to which a little bruised gunpowder has been added; and when the whole is well mixed, and of a proper consistence, sparks are to be made of it as before.

Marroons are small boxes made either of paper or pasteboard, and of a roundish or cubical form, so prepared as when fired to make a loud and sudden report. They are usually employed either as appendages to other fire-works, or a great many of them are so arranged, as to explode successively at certain intervals.

Formers for marroons are from three fourths of an inch to one and a half diameter; but the paper for the cases twice the diameter of the former broad, and long enough to go three times round. When you have rolled a case, paste down the edge and tie one end close; then with the former drive it down to take away the wra-
Having filled some pipes, have some small circular blocks made about one inch diameter and half an inch thick: round one of these blocks wind and paste a pipe, and to the end of this pipe join another; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other with a little paste: in this manner join four or five pipes, winding them one upon the other so as to form a spiral line. Having wound on your pipes, paste two slips of paper across them to hold them together; besides these slips of paper, the pipes must be pasted together.

There is another method of making these wheels, viz. by winding on the pipes without paste, and sticking them together with sealing-wax at every half turn; so that when they are fired, the end will fall loose every time the fire passes the wax, by which means the circle of fire will be considerably increased. The formers for these pipes are made from one and a half to 4 16ths of an inch diameter; and the composition for them is as follows: Meal-powder 8 oz. salt pier 2 oz. and sulphur 1; among these ingredients may be mixed a little steel filings or the dust of cast iron: this composition should be very dry, and not made too fine, or it will stick in the funnel. These wheels may be fired on a large pin, and held in the hand with safety.

There is a pleasing decoration frequently added to shower of rockets, called a shower of fire, rain, or rain fall, and it is fire or rain. It is called gold or silver rain, according as its colour is more or less intense. It consists of several small cases filled with a brilliant composition, such as the following variety of Chinese fire, viz. meal powder 1 pound, flower of sulphur 2 oz. and iron sand of the first order, 5 oz.

Gold and silver rain compositions are rammed in cases that are pinched quite close at one end; if rolled dry, 4 or 5 rounds of paper will be strong enough; but if they are pasted, 3 rounds will do; and the thin sort of cartridge paper is best. These small cases are rolled which you must not turn down the inside edge as in other cases, for a double edge would be too thick for so small a bore. The moulds for rain falls should be made of brass, and turned very smooth inside; or the cases, which are so very thin, would tear in coming out; for the charge must be rammed in tight; and the better the case fits the mould, the more driving it will bear. These moulds have no nipple, but instead of it they are made flat. As it would be very tedious and troublesome to shake the composition out of such small ladies as are used for these cases, it will be necessary to have a funnel made of thin tin, to fit on the top of the case, by the help of which they may be filled very fast.

For single rain-falls for 4 oz. rockets, let the diameter of the former be 2-16ths of an inch, and the length of the case 2 inches; for 8 oz. rockets, 2-16ths and 2 diameters of the rocket long; for 1 lb. rockets, 4-16ths, and 2 diameters of the rocket long; for 2 lb. rockets, 5-16ths, and 3 inches and a half long; for 4 lb. rockets, 6-16ths, and 4 inches and a half long; and for 6-pounders, 7-16ths diameter, and 5 inches long.

Of double rain-falls there are two sorts. For example, some appear first like a star, and then the rain; and some appear first like rain, and then like a star. When you would have stars first, you must fill the cases, within half an inch of the top, with rain-composition, and the remainder with star-composition; but when you intend
PYROTECHNY.

N. B. Gerbes are made by their diameters, and their cases at bottom one-fourth thick. The method of finding the interior diameter of a gerbe is this: Supposing the exterior diameter of the case, when made, to be five inches, then, by taking two-fourths for the sides of the case, there will remain 2\( \frac{1}{2} \) inches for the bore, which will be a very good size. These gerbes should be rammed very hard.

Small Gerbes, or white Fountains.

May be made of four ounces, eight ounces, or one pound cases, pasted and made very strong, of any length: but before they are filled, drive in clay one diameter of their orifice high; and when the case is filled, bore a vent through the centre of the clay to the composition: the common proportion will do for the vent, which must be primed with a slow charge. These cases, without the clay, may be filled with Chinese fire.

SECT. II. Of Compound Fire-works.

Among the most pleasing compound fire-works are Rockets, which are of various kinds. Some are made to ascend to a great height in the air, where they burst, and throw out the contents of the head with which they are provided. These are called sky-rockets. Others are so constructed as to run with great velocity along a line, and are called line-rockets. Some are arranged at the extremities of the spokes of a wheel, and are denominated wheel-rockets, while a fourth variety have their cases made water tight, and are filled with a very strong composition, so as to admit of their burning below water. These last are called water-rockets. Sky rockets are tied to a stick, which rends their ascent into the air more equable and steady.

Fig. 25. represents a rocket complete without its Sky-rock-stick. Its length from the neck is five diameters one-sixth: the cases should always be cut to this length after Fig. 25. they are filled. M is the head, which is two diameters high, and one diameter one-sixth and a half in breadth; N the cone or cap, whose perpendicular height must be one diameter one-third; Fig. 26. the collar to which the head is fixed: this is turned out of fir or any light wood, and its exterior diameter must be equal to the interior diameter of the head; one-sixth will be sufficient for its thickness, and round the outside edge must be a groove; the interior diameter of the collar must not be quite so wide as the exterior diameter of the rocket: this is to be glued on the rocket, two or three rounds of paper must be cut off the case, which will make a shoulder for it to rest upon. Fig. 27. a former Fig. 27. for the head: two or three rounds of paper well pasted will be enough for the head, which, when rolled, put the collar on that part of the former marked O, which must fit the inside of it; then, with the pinching cord, pinch the bottom of the head into the groove, and tie it with small twine. Fig. 28. a former for the cone. Fig. 28. To make the caps, cut the paper in round pieces, equal in diameter to twice the length of the cone to be made; which pieces being cut into halves, will make two caps each, without wasting any paper; having formed the caps, paste over each of them a thin white paper, which must be a little longer than the cone, so as to project about half an inch below the bottom: this projection of paper, being notched and pasted, serves to fasten the cap to the head.

When

Chap. II.

Varieties of Construction.

When you load the heads of the rockets with stars, rains, serpents, crackers, or any thing else, according to fancy, remember always to put one ladleful of meal-powder into each head, which will be enough to burst the head, and disperse the stars, or whatever it contains: when the heads are loaded with any cases, let their mouths be turned downwards; and after the heads are filled, paste on the top of them a piece of paper before putting on the caps. As the size of the stars often differs, it would be needless to give an exact number for each rocket; but this rule may be observed, that the heads may be nearly filled with whatever they are to contain.

Fig. 25. The last column on the right, in the above table, expresses the distance from the top of the cone, where the stick, when tied on, should balance the rocket, so as to stand in an equilibrium on one's finger, or the edge of a knife. The best wood for the sticks is dry fir, and they are thus made: When you have cut and planned the stick, according to the dimensions given in the table, cut, on one of the flat sides at the top, a groove the length of the rocket, and as broad as the stick will allow; then on the other side, cut two notches for the cord, which ties on the rocket, to lie in; one of these notches must be near the top of the stick, and the other facing the neck of the rockets; the distance between these notches may easily be known, for the top of the stick should always touch the head of the rocket. When the rockets are stuck, lay the rockets in the grooves in the sticks and tie them on. Those who, merely for curiosity, may choose to make rockets of different sizes from those expressed in the table of dimensions, may find the length of their sticks, by making them for rockets, from half an ounce to one pound, 20 diameters of the rocket long; and for rockets above one pound 50 or 60 diameters will be a good length; their thickness at top may be about half a diameter, and their breadth a little more; their square at bottom is generally equal to half the thickness at top. But although the dimensions of the sticks be very nicely observed, we can depend only on their balance; for, without a proper counterpoise, the rockets, instead of mounting perpendicularly, will take an oblique direction, and fall to the ground before they are burnt out.

Rockets rammed over a piercer must not have so much composition put into them at a time as when rammed solid; for the piercer, taking up great part of the bore of the case, would cause the rammer to rise too high, so that the pressure of it would not be so great on the composition, nor would it be rammed everywhere equal. To prevent this, observe the following rule: Ramming that for those rockets which are rammed over a piercer, rockets let the ladle hold as much composition as, when drove, will raise the drift one-half the interior diameter of the case, and for those rammed solid to contain as much as will raise it one-half the exterior diameter of the case; ladles are generally made to go easy in the case, and the length of the scoop about one and a half of its own diameter.

The charge of rockets must always be rammed one diameter above the piercer, and on it must be rammed one-third of a diameter of clay; through the middle of which bore a small hole to the composition, that, when the charge is burnt to the top, it may communicate its fire, through the hole, to the stars in the head. Great care must be taken to strike with the mallet, and with an equal force, the same number of strokes to each ladleful of charge; otherwise the rockets will not rise with an uniform motion, nor will the composition burn equally and regularly: for which reason they cannot carry a proper tail: for it will break before the rocket has got half way up, instead of reaching from the ground to the top, where the rocket breaks and disperses the stars, rains, or whatever is contained in the head. When ramming, keep the drift constantly turning or moving; and when you use the hollow rammer, knock out of them the composition now and then, or the piercer will split them. To a rocket of four ounces, give to each ladleful of charge, 16 strokes; to a rocket of one pound, 28; to a two pounder, 36; to a four pounder, 42; and to a six pounder, 56; but rockets of a larger sort cannot be rammed well by hand, but must be rammed with a machine made in the same manner as those for driving piles.

The method of ramming wheel cases, or any other sort, in which the charge is rammed solid, is much the same as in sky-rockets; for the same proportion may be observed in the ladle, and the same number of strokes given, according to their diameters, all cases being distinguished by their diameters. In this manner, a case, whose bore is equal to a rocket of four ounces, is called a four ounce case, and that which is equal to an eight ounce rocket an eight ounce case, and so on, according to the different rockets.

Having taught the method of ramming cases in moulds, we shall here say something concerning those filled without moulds; which method, for strong pasted cases, will do extremely well, and save the expense of making so many moulds. The reader must here observe, when filling any cases, to place the mould on a perpendicular block of wood, and not on any place that is hollow; for we have found by experience, that when cases were rammed on driving benches, which were formerly used, the works frequently miscarried, on account of the hollow resistance of the benches, which often jarred and loosened the charge in the cases; but this accident never happens when the driving blocks are used.

When cases are to be filled without moulds, proceed thus: Have some nipples made of brass or iron,
of several sizes, in proportion to the cases, and to screw
or fix in the top of the driving block; when you have
fixed in a nipple, make, at about one inch and a half
from it, a square hole in the block, six inches deep and
one inch diameter; then have a piece of wood, six inches
longer than the case intended to be filled, and two
inches square; on one side of it cut a groove almost
the length of the case, whose breadth and depth must be
sufficient to cover near one-half of the case; then cut
the other end to fit the hole in the block, but take care
to cut it so that the groove may be at a proper distance
from the nipple; this half mould being made and fixed
tight in the block, cut, in another piece of wood
nearly of the same length as the case, a groove of the
same dimensions as that in the fixed piece; then put
the case on the nipple, and with a cord tie it and the two
half moulds together, and the case will be ready for fil-
ing.

The dimensions of the above-described half-moulds
are proportionable for cases of eight ounces, but notice
must be taken, that they differ in size in proportion to
the cases they are to fill.

The best wood for mallets is dry beech. If a person
uses a mallet of a moderate size, in proportion to the
rocket, according to his judgment, and if the rocket
succeeds, he may depend on the rest, by using the same
mallet; yet it will be necessary that cases of different
sorts be driven with mallets of different sizes.

The following proportion of the mallets for rockets
of any size, from one oz. to six lb. may be observed; but
as rockets are seldom made less than one oz. or larger
than six lb. we shall leave the management of them to
the curious; but all cases under one oz. may be rammed
with an ounce rocket mallet. The mallets will strike
more solid, by having their handles turned out of the
same piece with the head, and made in a cylindrical form.
Let their dimensions be worked by the diameters of the
rockets: for example; let the thickness of the head be
three diameters, and its length four, and the length of the
handle five diameters, whose thickness must be in propor-
tion to the handle.

As the case which occasions the ascent of a rocket
into the air is the same as that which makes a musket
recoil when fired, it will be proper, before explaining
the ascent of rockets, to show how the recoil of fire-arms
is produced. When the powder is suddenly inflamed in
the chamber, or at the bottom of the barrel, it neces-
sarily exercises an action two ways at the same time;
that is to say, against the breech of the piece, and against
the bullet or wadding, which is placed above it. Be-
sides this, it acts also against the sides of the chamber
which it occupies; and as they oppose a resistance al-
most insurmountable, the whole effort of the elastic fluid,
produced by the inflammation, is exerted in the two de-
tructions above mentioned. But the resistance opposed by
the bullet, being much less than that opposed by the mass
of the barrel or cannon, the bullet is forced out with
great velocity. It is impossible, however, that the body
of the piece itself should not experience a movement
backwards; for if a spring is suddenly let loose, between
two movable obstacles, it will impel them both, and
communicate to them velocities in the inverse ratio of
their masses; the piece, therefore, must acquire a velo-
city backwards nearly in the inverse ratio of its mass to
that of the bullet. We make use of the term nearly,
because there are various circumstances which give to
this ratio certain modifications; but it is always true
that the body of the piece is driven backwards, and that
if it weighs with its carriage 1000 times more than
the bullet, it acquires a velocity which is 1000 times
less, and which is soon annihilated by the friction of the
wheels against the ground, &c.

The cause of the ascent of a rocket is nearly the same.
At the moment when the powder begins to inflame, its
expansion produces a torrent of elastic fluid, which acts
in every direction; that is, against the air which op-
poses its escape from the cartridge, and against the up-
per part of the rocket; but the resistance of the air is
more considerable than the weight of the rocket, on ac-
count of the extreme rapidity with which the elastic
fluid issues through the neck of the rocket to throw it-
self downwards, and therefore the rocket ascends by the
excess of the one of these forces above the other.

This however would not be the case, unless the rocket
were pierced to a certain depth. A sufficient quantity
of elastic fluid would not be produced for the com-
position would inflame only in circular costs of a diameter
equal to that of the rocket; and experience shows that
this is not sufficient. Recourse then is had to the very in-
genious idea of piercing the rocket with a conical hole,
which makes the composition burn in conical strata which
have much greater surface, and therefore produce a much
greater quantity of inflamed matter and fluid. This ex-
pedition was certainly not the work of a moment.

When sky-rockets are fixed one on the top of an-
to fix one
other, they are called towering rockets, on account of rocket on
their mounting so very high. Towering rockets are
made after this manner: Fix on a pound-rocket a head
without a collar; then take a four ounce rocket, which
may be headed or bounced, and rub the mouth of it with
meal-powder wetted with spirit of wine: this done, put
in the head of the large rocket with its mouth down-
wards; but before it is put in, stick a bit of quick-match
in the hole of the clay of the pound-rocket, which match
should be long enough to go a little way up the bore of
the small rocket, to fire it when the large rocket is burst
out. As the four ounce rocket is too small to fill the head
of the other, roll round it as much as will make it
stand upright in the centre of the head: the rocket being
thus fixed, paste a single paper round the opening of the
top of the head of the large rocket. The large rocket
must have only half a diameter of charge rammed above
the piercer; for, if filled to the usual height, it would
turn before the small one takes fire, and entirely destroy
the intended effect: when one rocket is headed with
another, there will be no occasion for any blowing pow-
der; for the force with which it goes off will be suffi-
cient to disengage it from the head of the first fired
rocket. The sticks for these rockets must be a little
longer than for those headed with stars, rains, &c.

Caduceus rockets are such as, in rising, form two spi-
ral lines, by reason of their being placed obliquely, one
opposite to the other; and their counterpoise in their
centre, which causes them to rise in a vertical direction.
Rockets for this purpose must have their ends chocked
close, without either head or bounce, for a weight at
top would be a great obstruction to their mounting.
No caduceus rockets ascend so high as single, because of
their
their serpentine motion, and likewise the resistance of air, which is much greater than two rockets of the same size would meet with if fired singly.

Fig. 32. shews the method of fixing these rockets: the sticks for this purpose must have all their sides equal, and the sides should be equal to the breadth of a stick proper for a sky-rocket of the same weight as those you intend to use, and made to taper downwards as usual, long enough to balance them, one length of a rocket from the cross stick; which must be placed from the large stick six diameters of one of the rockets, and its length seven diameters; so that each rocket, when tied on, may form with the large stick an angle of 60 degrees. In tying on the rockets, place their heads on the opposite sides of the cross stick, and their ends on the opposite sides of the long stick; then carry a leader from the mouth of one into that of the other. When these rockets are to be fired, suspend them between two hooks or nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of one lb. are a good size for this use.

Honorary rockets. Honorary rockets are the same as sky-roquets, except that they carry no head nor report, but are closed at top, on which is fixed a cone: then on the case, close to the top of the stick is tied on a two ounce case, about five or six inches long, filled with a strong charge, and pinched close at both ends; then in the reverse sides, at each end, bore a hole in the same manner as in tubbils, to be presently described; from each hole carry a leader into the top of the rocket. When the rocket is fired, it will rise to its proper height, it will give fire to the case at top; which will cause both rocket and stick to spin very fast in their return, and represent a werm of fire descending to the ground.

There is another method of placing the small case, which is by letting the stick rise a little above the top of the rocket, and tying the case to it, so as to rest on the rocket: these rockets have no conic.

A third method by which they are managed is this: In the top of a rocket fix a piece of wood, in which drive a small iron spindle; then make a hole in the middle of the small case, through which put the spindle: then fix on the top of it a nut, to keep the case from falling off; when this is done, the case will turn very fast, without the rocket: but this method does not answer so well as either of the former.

Fig. 31. is the honorary rocket complete. The best sized rockets for this purpose are those of one lb.

To make a rocket form an arch in rising.

Having some rockets made, and headed according to fancy, and tied on their sticks; get some sheet tin, and cut it into round pieces about three or four inches diameter; then on the stick of each rocket, under the mouth of the case, fix one of these pieces of tin 16 inches from the rocket's neck, and support it by a wooden bracket, as strong as possible: the use of this is, that when the rocket is ascending the fire may play with great force on the tim, which will divide the tail in such a manner that it will form an arch as it mounts, and will have a very good effect when well managed: if there is a short piece of port-fire, of a strong charge, tied to the end of the stick, it will make a great addition; but this must be lighted before the rocket is fired.

Take six, or any number of sky-roquets, of any size; then cut some strong packthread into pieces of three or four yards long, and tie each end of these pieces to a rocket in this manner; Having tied one end of the packthread round the body of one rocket, and the other end to another, take a second piece of packthread, and make one end of it fast to one of the rockets already tied, and the other end to a third rocket, so that all the rockets, except the two on the outside, will be fastened to two pieces of packthread: the length of thread from one rocket to the other may be what the maker pleases; but the rockets must be all of a size, and their heads filled with the same weight of stars, rains, &c.

Having thus done, fix in the mouth of each rocket a leader of the same length; and when about to fire them, hang them almost close; then tie the ends of the leaders together, and prime them: this prime being fired, all the rockets will mount at the same time, and divide as far as the strings will allow; and this division they will keep, provided they are all rammed alike, and well made. They are sometimes called chained rockets.

Signal rockets are made of several kinds, according to the different signals intended to be given; but in artificial fire-works, two sorts are only used, which are one with reports and the other without; but those for the use of the navy and army are headed with stars, serpents, &c.—Rockets which are to be bounced must have their cases made one and a half or two diameters longer than the common proportion; and after they are filled, drive in a double quantity of clay, then bounce and pinch them after the usual manner, and fix on each a cap.

Signal sky-roquets without bounces, are only sky-roquets closed and capped: these are very light, therefore do not require such heavy sticks as those with loaded heads; for which reason the rocket may be cut from the stick, or else be made thinner.

Signal rockets with reports are fired in small flights; and often both these, and those without reports, are used for a signal to begin firing a collection of works.

Two, three, or six sky-roquets, fixed on one stick, and fired together, make a grand and beautiful appearance; for the tails of all will seem but as one of an immense size, and the breaking of so many heads at once will resemble the bursting of an air-balloons. The management of this device requires a skilful hand; but if the following instructions be well observed, even by those who have not made a great progress in this art, there will be no doubt of the rockets having the desired effect.

Rockets for this purpose must be made with the greatest exactness, all rammed by the same hand, in the same mould, and filled with the same proportion of composition; and after they are filled and headed, must all be of the same weight. The stick must also be well made (and proportioned) to the following directions: first, supposing the rockets to be half pounders, whose sticks are six feet six inches long, then if two, three, or six of these are to be fixed on one stick, let the length of it be nine feet nine inches: then cut the top of it into as many sides as there are rockets, and let the length of each side be equal to the length of one of the rockets without its head; and in each side cut a groove (as usual); then from the grooves plane it round, down to the bottom, where its thickness must be equal to half the top of the round part. As their thickness cannot be exactly ascertained, we shall give a rule which generally answers for
for any number of rockets above two: the rule is this; that the stick at top must be thick enough, when the grooves are cut, for all the rockets to lie, without pressing each other, though as near as possible.

When only two rockets are to be fixed on one stick, let the length of the stick be the last given proportion, but shaped after the common method, and the breadth and thickness double the usual dimensions. The point of poise must be in the usual place (let the number of rockets be what they will): if sticks made by the above directions should be too heavy, plane them thinner; and if too light, make them thicker; but always make them of the same length.

When more than two rockets are tied on one stick, there will be some danger of their flying up without the stick, unless the following precaution is taken: For cases being placed on all sides, there can be no notches for the cord which ties on the rockets to lie in; therefore, instead of notches, drive a small nail in each side of the stick, between the necks of the cases; and let the cord, which goes round their necks, be brought close under the nails; by this means the rockets will be as secure as when tied on singly. The rockets being thus fixed, carry a quick-match, without a pipe, from the mouth of one rocket to the other; this match being lighted will give fire at all once.

Though the directions already given may be sufficient for these rockets, we shall here add an improvement on a very essential part of this device, which is, that of hanging the rockets to be fired; for before the following method was contrived, many attempts proved unsuccessful. Instead, therefore, of the old and common manner of hanging them on nails or hooks, make use of the following contrivance: Have a ring made of strong iron wire large enough for the stick to go in as far as the mouths of the rockets; then have another ring supported by a small iron, at some distance from the post or stand to which it is fixed: then have another ring fit to receive and guide the small end of the stick. Rockets thus suspended will have nothing to obstruct their fire; but when they are hung on nails or hooks, in such a manner that some of their mouths are against or upon a nail, there can be no certainty of their rising in a vertical direction.

To fire rockets without sticks, you must have a stand, of a block of wood, a foot diameter, and make the bottom flat, so that it may stand steady: in the centre of the top of this block draw a circle two inches and a half diameter, and divide the circumference of it into three equal parts; then take three pieces of thick iron wire, each about three feet long, and drive them into the block, one at each point made on the circle; when these wires are driven in deep enough to hold them fast and upright, so that the distance from one to the other is the same at top as at bottom, the stand is complete.

The stand being thus made, prepare the rockets thus: Take some common sky-rockets of any size, and head them as you please; then get some balls of lead, and tie to each a small wire two or two feet and a half long, and the other end of each wire tie to the neck of a rocket. These balls answer the purpose of sticks when made of a proper weight, which is about two-thirds the weight of the rocket; but when they are of a proper size, they will balance the rocket in the same manner as a stick, at the usual point of poise. To fire these, hang them, one at a time, between the tops of the wires, letting their heads rest on the point of the wires, and the balls hang down between them: if the wires should be too wide for the rockets, press them together till they fit; and if too close, force them open; the wires for this purpose must be softened, so as not to have any spring, or they will not keep their position when pressed close or opened.

Cases for scrolls should be made four or five inches in scroll for length, and their interior diameters three eighths of an inch: one end of these cases must be pinched quite close before beginning to fill; and when filled, close the other end: then in the opposite sides make a small hole at each end, to the composition, as in tourbillons; and prime them with wet meal powder. You may put in the head of a rocket as many of these cases as it will contain: being fired they turn very quick in the air, and form a scroll or spiral line. They are generally filled with a strong charge, as that of serpents or brilliant fire.

Rockets that pass under the denomination of swarmers are, those from two ounces downwards. These rockets are fired sometimes in flights, and in large waterworks, &c. Swarmers of one and two ounces are bored, and made in the same manner as large rockets, except that, when headed, their heads must be put on without a collar: the number of strokes for driving one ounce must be eight, and for two ounces twelve.

All rockets under one ounce are not bored, but must be filled to the usual height with composition, which generally consists of fine meal-powder four ounces, and charcoal or steel dust two drams: the number of strokes for ramming these small swarmers is not material, provided they are rammed truly, and moderately hard. The necks of unbored rockets must be in the same proportion as in common cases.

Care must be taken, in placing the rockets, when stands for them are to be fixed, to give them a vertical direction. At their first setting out; which may be managed thus: Have two rails of wood, of any length, supported at each end by a perpendicular leg, so that the rails may be horizontal, and let the distance from one to the other be almost equal to the length of the sticks of the rockets intended to be fired; then in the front of the top rail drive square holes at eight inches distance, with their points turning sidewise, so that when the rockets are hung on them, the points will be before the sticks and keep them from falling or being blown off by the wind; in the front of the rail at bottom must be staples, driven perpendicular under the hooks at top; through these staples put the small ends of the rocket sticks. Rockets are fired by applying a lighted port-fire to their mouths.

N. B. When sky-rockets are made to perfection, and fired, they will stand two or three seconds on the hook before they rise, and then mount up briskly, with a steady motion, carrying a large tail from the ground all the way up, and just as they turn, break, and disperse the stars.

Girandole chests are generally composed of four sides of equal dimensions; but may be made of any diameter, according to the number of rockets designed to be fired; their height must be in proportion to the rockets, but must always be a little higher than the rockets with their sticks. When the sides are joined, fix in the top...
to strike against, or its force will cut the line. Let the line be well soaped, and the hole in the swivel very smooth.

To line rockets may be fixed a great variety of different figures, as flying dragons, Mercury's ships, &c.; or they may be made to run on the line like a wheel; which is done in this manner. Have a flat swivel made very exactly, and on it tie two rockets obliquely one on each side, which will make it turn round as it goes, and form a circle of fire; the charge for these rockets should be a little weaker than common. If you would show two dragons fighting, get two swivels made square, and on each tie three rockets together on the under side; then have two flying dragons made of tin, and fix one of them on the top of each swivel, so as to stand upright; in the mouth of each dragon put a small case of common fire, and another at the end of the tail; put two or three port-fires, of a strong charge, on one side of their bodies, to show them. This done, put them on the line, one at each end; but let there be a swivel in the middle of the line to keep the dragons from striking together: before firing the rockets, light the cases on the dragons; and if care be taken in firing both at the same time, they will meet in the middle of the line, and seem to fight. Then they will run back and return with great violence, which will have a very pleasing effect. The line for these rockets must be very long, or they will strike too hard together.

Cases for Chinese flyers may be made of different sizes, from one to eight ounces; they must be made thick Chinese of paper, and eight interior diameters long; they are rolled in the same manner as tourbillons, with a straight pasted edge, and pinched close at one end. The method of filling them is, the case being put in a mould, whose cylinder, or foot, must be flat at top without a nipple; fill it within half a diameter of the middle; then ram in half a diameter of clay, on that as much composition as before, on which drive half a diameter of clay; then pinch the case close, and drive it down flat: after this is done, bore a hole exactly through the centre of the clay in the middle; then in the opposite sides, at both ends, make a vent; and in that side intended to be fired first make a small hole to the composition near the clay in the middle, from which carry a quick-match, covered with a single paper, to the vent at the other end; then, when the charge is burnt on one side, it will, by means of the quick-match, communicate to the charge on the other (which may be of a different sort). The flyers being thus made, put an iron pin, that must be fixed in the work on which they are to be fired, and on which they are to run, through the hole in the middle; on the end of this pin must be a nut to keep the fire from running off. If they are to turn back again after they are burnt, make both the vents at the ends on the same side, which will alter its course the contrary way.

Table rockets are designed merely to show the truth of driving, and the judgment of a fire-worker; they having no other effect, when fired, than spinning round in the same place where they begin, till they are burnt out, and showing nothing more than an horizontal circle or arc.

The method of making these rockets is,—Have a cone turned out of hard wood two inches and a half in diameter, and as much high; round the base of it drive a line;
PYROTECHNY.

line; on this line fix four spokes, each two inches long, so as to stand one opposite the other; then fill four nine-inch, one pound cases with any strong composition, within two inches of the top; these cases are made like tourbillons, and must be rammed with the greatest exactness.

The rockets being filled, fix their open ends on the short spokes; then in the side of each case bore a hole near the clay; all these holes, or vents, must be so made that the fire of each case may act the same way; from these vents carry leaders to the top of the cone, and tie them together. When the rockets are to be fired, set them on a smooth table, and light the leaders in the middle, and all the cases will fire together (see fig. 32.) and spin on the point of the cone.

These rockets may be made to rise like tourbillons, by making the cases shorter, and boring four holes in the under side of each at equal distances: this being done they are called double tourbillons.

Note: All the vents in the under side of the cases must be lighted at once; and the sharp point of the cone cut off, at which place make it spherical.

Fireworks called aerial globes or bombs consist of a spherical case made of strong paper, or of wood, prepared as will be immediately described, and thrown from a mortar commonly made of pasteboard, with a copper chamber to contain the charge, such as AB, fig. 33. This small mortar must be made of light wood, or of paper pasted together, and rolled up in the form of a cylinder, or truncated cone, the bottom excepted; which, as already said, must be of wood. The chamber for the powder AC must be pierced obliquely, with a small gimlet, as seen at BC; so that the aperture B corresponding to the aperture of the metal mortar, in which this paper mortar must be placed when the globe is fired, the fire applied to the latter may be communicated to the powder which is at the bottom of the chamber AC, immediately below the globe. By these means the globe will catch fire and make an agreeable noise as it rises into the air; but it would not succeed so well if any vacuity were left between the powder and globe.

A profile or perpendicular section of such a globe is represented by the right-angled parallelogram ABCD, fig. 34.; the breadth of which AB is nearly equal to the height AD. The thickness of the wood towards the two sides L, M, is equal to about the twentieth part of the diameter of the globe; and the thickness E, F, of the cover, is double the preceding, or equal to a sixth part of the diameter. The height GK, or HI of the chamber GHIK, where the match is applied, and which is terminated by the semicircle LGKM, is equal to the fourth part of the breadth AB, and its breadth GH is equal to the sixth part of AB.

We must here observe, that it is dangerous to put wooden covers, such as EF, on aerial balloons or globes, for these covers may be so heavy as to wound those on whom they happen to fall. It will be sufficient to place turf or hay above the globe, in order that the powder may experience some resistance.

The globe must be filled with several pieces of cane or common reed, equal in length to the interior height of the globe, and charged with a slow composition, made of three ounces of pounded gunpowder, an ounce of sulphur moistened with a small quantity of petroleum oil, and two ounces of charcoal; and in order that these reeds or canes may catch fire sooner, and with more facility, they must be charged at the lower ends, which rest on the bottom of the globe, with pulverized gunpowder moistened in the same manner with petroleum oil, or well besprinkled with brandy, and then dried.

The bottom of the globe ought to be covered with a little gunpowder half pulverized and half grained; which, when set on fire by means of a match applied to the end of the chamber GH, will set fire to the lower part of the reed. But care must have been taken to fill the chamber with a composition similar to that in the reeds, or with another slow composition made of eight ounces of gunpowder, four ounces of saltpetre, two ounces of sulphur, and one ounce of charcoal; the whole must be well pounded and mixed.

Instead of reeds, the globe may be charged with running rockets, or paper petards, and a quantity of fiery stars or sparks mixed with the pulverized gunpowder, placed without any order above these petards, which must be choked at unequal heights, that they may perform their effect at different times.

These globes may be constructed in various other ways, which it would be tedious here to enumerate. We shall only observe, that when loaded they must be well covered at the top; they must be wrapped up in a piece of cloth dipped in glue, and a piece of woollen cloth must be tied round them, so as to cover the hole which contains the match.

Fuzes for air balloons are sometimes turned out of dry beech, with a cup at top to hold the quick-match, or other firing material; but if made with pasted paper, they will do as well: the diameter of the former for fuzes for coehorn balloons must be half an inch; for a royal fuze, five-eighths of an inch; for an eight inch fuze, three-fourths of an inch; and for a ten inch fuze, seven-eighths of an inch. Having rolled the cases, pinch and tie them almost close at one end: then drive them down, and let them dry. Before beginning to fill them, mark on the outside of the case the length of the charge required, allowing for the thickness of the bottom; and when the composition is rammed in, take two pieces of quick-match about six inches long, and lay one end of each on the charge, and then a little meal-powder, which ram down hard; the loose ends of the match double up into the top of the fuze, and cover it with a paper cap to keep it dry. When the shells are put into the mortars, uncap the fuzes, and pull out the loose ends of the match, and let them hang on the sides of the balloons. The use of the match is, to receive the fire from the powder in the chamber of the mortar, in order to light the fuze: the shell being put in the mortar with the fuze uppermost, and exactly in the centre, sprinkle over it a little meal-powder, and it will be ready to be fired. Fuzes made of wood must be longer than those of paper, and not bored quite through, but left solid about half an inch at bottom; and when used saw them off to a proper length, measuring the charge from the cut at top.

To make Tourbillons.—Having filled some cases with Tourbillons, in about one diameter and a half, drive in a ladleful of loose clay; then pinch the ends close, and drive them down with a mallet. When done, find the centre of gravity of each case: where the nail and stick are tied, which should
should be half an inch broad at the middle, and run a little narrower to the ends: these sticks must have their ends turned upwards, so that the cases may turn horizontally on their centres: at the opposite sides of the cases, at each end, bore a hole close to the clay with a gimlet, the size of the neck of a common case of the same nature: from these holes draw a line round the cases, and at the under part of the case bore a hole with the same gimlet, within a half a diameter of each line towards the centre; then from one hole to the other draw a right line. Divide this line into three equal parts; and at X and Y (fig. 35.) bore a hole; then from these holes to the other two lead a quick-match, over which paste a thin paper. Fig. 36. represents a tourbillon as it should lie to be fired, with a leader from one side hole A to the other B. When tourbillons are fired lay them on a smooth table, with their sticks downwards, and burn the leader through the middle with a portfire. They should spin three or four seconds on the table before they rise, which is about the time the composition will be burning from the side holes to those at bottom.

To tourbillons may be fixed reports in this manner: In the centre of the case at top make a small hole, and in the middle of the report make another; then place them together, and tie on the report, and with a single paper secure it from fire: this done, the tourbillon is completed. By this method you may fix on tourbillons small cones of stars, rains, &c. but be careful not to load them too much. One eighth of an inch will be enough for the thickness of the sticks, and their length equal to that of the cases.

Mortars to throw aigrettes are generally made of pasteboard, of the same thickness as balloon mortars, and two diameters and a half long in the inside from the top of the foot: the foot must be made of elm without a chamber, but flat at top, and in the same proportion as those for balloon mortars; these mortars must also be bound round with a chord: sometimes eight or nine of these mortars, of about three or four inches diameter, are bound all together, so as to appear but one: but when they are made for this purpose, the bottom of the foot must be of the same diameter as the mortars, and only half a diameter high. The mortars being bound well together, fix them on a heavy solid block of wood. To load these mortars, first put on the inside bottom of each a piece of paper, and on it spread one ounce and a half of meal and corn powder mixed; then tie the serpents up in parcels with quickmatch, and put them in the mortar with their mouths downwards; but take care the parcels do not fit too tight in the mortars, and that all the serpents have been well primed with powder wetted with spirit of wine. On the top of the serpents in each mortar lay some paper or tow; then carry a leader from one mortar to the other all round, and then from all the outside mortars into that in the middle: these leaders must be put between the cases and the sides of the mortar, down to the powder at bottom: in the centre of the middle mortar fix a fire pump, or brilliant fountain, which must be open at bottom, and long enough to project out of the mouth of the mortar; then paste paper on the tops of all the mortars.

Mortars thus prepared are called a nest of serpents, as represented by fig. 37. When these mortars are to be fired, light the fire pump C, which when consumed will communicate to all the mortars at once by means of the leaders. For mortars of 8, 9, or 10 inches diameter, the serpents should be made in one and two ounce cases, six or seven inches long, and fired by a leader brought out of the mouth of the mortar, and turned down the outside, and the end of it covered with paper, to prevent the sparks of the other works from setting it on fire. For a six-inch mortar, let the quantity of powder for firing be two ounces; for an eight-inch, two ounces and three quarters; and for a ten-inch, three ounces and three quarters. Care must be taken in these, as well as small mortars, not to put the serpents in too tight for fear of bursting the mortars. These mortars may be loaded with stars, crackers, &c.

If the mortars, when loaded, are sent to any distance, or liable to be much moved, the firing powder should be secured from getting amongst the serpents, which would endanger the mortars, as well as hurt their performance. To prevent this, load the mortars thus: First put in the firing powder, and spread it equally about; then cut a round piece of blue touch-paper, equal to the exterior diameter of the mortar, and draw on it a circle equal to the interior diameter of the mortar, and notch it all round as far as that circle; then paste that part which is notched, and put it down the mortar close to the powder, and stick the pasted edge to the mortar; this will keep the powder always smooth at bottom, so that it may be moved or carried anywhere without receiving damage. The large single mortars are called pots des aigrettes.

Pots des Brins are formed of pasteboard, and must be Pots des rolled pretty thick. They are usually made three or four inches diameter, and four diameters long; and pinched with a neck at one end, like common cases. A number of these are placed on a plank thus: Having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg; through all the holes run a quickmatch, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that when lighted at one end it may discharge the whole almost instantaneously: in all the pots put about one ounce of meal and corn powder; then in some put stars, and in others rains, snakes, serpents, crackers, &c.: when they are all loaded, paste paper over their mouths. Two or three hundred of these pots being fired together make a very pretty show, by affording so great a variety of fires. Fig. 38, is a range of pots des brins, with a leader A, by which they are fired.

Pots des Sauccions are generally fired out of large Pots des mortars without chambers, the same as those for aigrettes. A pot, only somewhat stronger. Sauccions are made of one and two ounce cases, five or six inches long, and choked in the same manner as serpents. Half the number which the mortar contains must be driven one diameter and a half with composition, and the other half two diameters, so that when fired they may give two volleys of reports. But if the mortars are very strong, and will bear a sufficient charge to throw the sauccions very high, you may make three volleys of reports, by dividing the number of cases into three parts, and making a difference
PYROTECHNY.

Chap. II.

Varieties of Construction.

The difference in the height of the charge. After they are filled, pinch and tie them at top of the charge almost close; only leaving a small vent to communicate the fire to the upper part of the case, which must be filled with corn-powder very near the top; then pinch the end quite close, and tie it: after this is done, bind the case very tight with waxed packthread, from the choke at top of the composition to the end of the case; this will make the case very strong in that part, and cause the report to be very loud. Scarcious should be rolled a little thicker of paper than the common proportion. When they are to be put in the mortar, they must be primed in their mouths, and fired by a case of brilliant fire fixed in their centre.

The charge for these mortars should be one-sixth or one-eighth more than for pots des aigrettes of the same diameter.

Single vertical wheels.

There are different sorts of vertical wheels; some having their fells of a circular form, others of an hexagonal, octagonal, or decagonal form, or of any number of sides, according to the length of the cases you design for the wheel: the spokes being fixed in the nave, nail slips of tin, with their edges turned up so as to form grooves for the cases to lie in, from the end of one spoke to that of another; then tie the cases in the grooves head to tail, in the same manner as those on the horizontal water-wheel, so that the cases successively taking fire from one another, will keep the wheel in an equal rotation. Two of these wheels are very often fired together, one on each side of a building; and both lighted at the same time, and all the cases piled alike, to make them keep time together; as they will, if made by the following directions: In all the cases of both wheels, except the first, on each wheel drive two or three ladesful of slow fire, in any part of the cases; but be careful to ram the same quantity in each case, and in the end of one of the cases, on each wheel, you may ram one ladesful of dead-fire composition, which must be very lightly driven; you may also make many changes of fire by this method.

Let the hole in the nave of the wheel be lined with brass, and made to turn on a smooth iron spindle. On the end of this spindle let there be a nut, to screw on and off; when you have put the wheel on the spindle, screw on the nut, which will keep the wheel from flying off. Let the mouth of the first case be a little raised. See fig. 39. Vertical wheels are made from ten inches to three feet diameter, and the size of the cases must differ accordingly; four-ounces cases will do for wheels of 14 or 16 inches diameter, which is the proportion generally used. The best wood for wheels of all sorts is a light and dry beech.

Horizontal wheels.

Horizontal wheels are best when their fells are made circular; in the middle of the top of the nave must be a pindle, turned out of the same piece as the nave, two inches long, and equal in diameter to the bore of one of the cases of the wheel: there must be a hole bored up the centre of the nave, within half an inch of the top of the pindle. The wheel being made, nail at the end of each spoke (of which there should be six or eight) a piece of wood, with a groove cut in it to receive the case. Fix these pieces in such a manner that half the cases may incline upwards and half downwards, and that, when they are tied on, their heads and tails may come very nearly together; from the tail of one case to the mouth of the other carry a leader, which should be secured with pasted paper. Besides these pipes, it will be necessary to put a little meal-powder within the pasted paper, to blow off the pipe, that there may be no obstruction to the fire from the cases. By means of these pipes the cases will successively take fire, burning one upwards and the other downwards. On the pindle fix a case of the same sort as those on the wheel; this case must be fired by a leader from the mouth of the last case on the wheel, which case must play downwards: instead of a common case in the middle, you may put a case of Chinese fire, long enough to burn as long as two or three of the cases on the wheel.

Horizontal wheels are often fired two at a time, and made to keep time like vertical wheels, only they are made without any slow or dead fire; 10 or 12 inches will be enough for the diameter of wheels with six spokes. Fig. 40. represents a wheel on fire, with the first case burning.

Spiral wheels, are only double horizontal wheels, and made thus: The nave must be about six inches long, and rather thicker than the single sort; instead of the pindle at top, make a hole for the case to be fixed in, and two sets of spokes, one set near the top of the nave, and the other near the bottom. At the end of each spoke cut a groove wherein you tie the cases, there being no fall; the spokes should not be more than two inches and a half long from the naves, so that the wheel may not be more than eight or nine inches diameter; the cases are placed in such a manner, that those at top play down, and those at bottom play up, but let the third or fourth case play horizontally. The case in the middle may begin with any of the others: six spokes will be enough for each set, so that the wheel may consist of 12 cases, besides that on the top: the cases six inches each.

Plural wheels are made to turn horizontally, and to consist of three sets of spokes, placed six at top, six at wheels. bottom, and four in the middle, which last must be a little shorter than the rest: let the diameter of the wheel be 10 inches; the cases must be tied on the ends of the spokes in grooves cut on purpose, or in pieces of wood nailed on the end of the spokes, with grooves cut in them as usual: in clothing these wheels, make the upper set of cases play obliquely downwards, the bottom set obliquely upwards, and the middle set horizontally.

In placing the leaders, they must be managed so that the cases may burn thus, viz. first up, then down, then horizontal, and so on with the rest. But another change may be made, by driving in the end of the eighth case two or three ladesful of slow fire, to burn till the wheel has stopped its course; then let the other cases be fixed the contrary way, which will make the wheel run back again: for the case at top you may put a small gerbe; and let the cases on the spokes be short, and filled with a strong brilliant charge.

Illuminated spiral wheels.—First have a circular horizontal wheel made two feet diameter, with a hole quite spiral through the nave; then take three thin pieces of deal, wheels three feet long each, and three-fourths of an inch broad each: one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular to that in the block of the wheel, but not so large. The wheel being thus made, have
PYROTECHNY.

have a hoop planed down very thin and flat; then nail one end of it into the fell of the wheel, and wind it around the three sticks in a spiral line from the wheel to the block at top: on the top of this block fix a case of Chinese fire; on the wheel you may place any number of cases, which must incline downwards, and burn two at a time. If the wheel should consist of ten cases, you may let the illuminations and Chinese fire begin with the second cases. The spindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper block is to turn, and the whole weight of the wheel to rest. See fig. 47.

Double spiral wheel.—For this wheel the block, or nave, must be as long as the height of the worms, or spiral lines, but must be made very thin, and as light as possible. In this block must be fixed several spokes, which must diminish in length, from the top to the top, so as not to exceed the surface of a cone of the same height. To the ends of these spokes nail the worms, which must cross each other several times: clothe these worms with illuminations, the same as those on the single wheels; but the horizontal wheel you may clothe as you like. At top of the worm place a case of spur-fire, or an amber light, see fig. 42. This figure is shown without leaders, to prevent a confusion of lines.

Balloon wheels are made to turn horizontally: they must be made two feet diameter, without any spokes; and very strong, with any number of sides. On the top of a wheel range and fix in pots, three inches diameter and seven inches high each, as many of these as there are cases on the wheel: near the bottom of each pot make a small vent; into each of these vents carry a leader from the tail of each case; load some of the pots with stars, and some with serpents, crackers, &c. As the wheels turn, the pots will successively be fired, and throw into the air a great variety of fires.

For fruition wheels first have a nave made nine inches long and three in diameter: near the bottom of this nave fix eight spokes, with a hole in the end of each, large enough to receive a two or four ounce case: each of these spokes may be 14 inches long from the block. Near the top of this block fix eight more of the same spokes, exactly over the others, but not so long by two inches. As this wheel is to run horizontally, all the cases in the spokes must play obliquely upwards, and all those in the spokes at bottom obliquely downwards. This being done, have a small horizontal wheel made with eight spokes, each five inches long from the block: on the top of this wheel place a case of brilliant fire: all the cases on this wheel must play in an oblique direction downwards, and burn two at a time, and those on the large wheel four at a time; that is, two of those in the top set of spokes, and two of those in the bottom set of spokes.

The four first cases on the large wheel, and the two first on the small, must be fixed at the same time, and the brilliant fire at top at the beginning of the last cases. The cases of the wheels may be filled with a gray charge. When these wheels are completed, you must have a strong iron spindle, made four feet six inches long, and fixed perpendicularly on the top of a stand: on this put the large wheel, whose nave must have a hole quite through from the bottom to the top. This hole must be large enough to turn easily round the bottom of the spindle, at which place there must be a shoulder, to keep the wheel from touching the stand: at the top of the spindle put the small wheel, and join it to a large one with a leader, in order that they may be fired both together.

Cascades of fire are made of any size; but one made according to the dimensions of that shown in fig. 43, will be large enough for eight-ounce cases. Let the distance from A to B be three feet; from B to C two feet six inches; and from C to D two feet; and let the cross piece at A be four feet long: then from each end of this piece draw a line to D; then make the other cross pieces so long as to come within those lines. The top piece D may be of any length, so as to hold the cases, at a little distance from each other; all the cross pieces are fixed horizontally, and supported by brackets; the bottom cross piece should be about one foot six inches broad in the middle, the second one foot, the third nine inches, and the top piece four inches: the cases may be made of any length, but must be filled with a brilliant charge. On the edges of the cross pieces must be nailed bits of wood, with a groove cut in each piece, large enough for a case to lie in. These bits of wood are fixed so as to incline downwards, and that the fire from one tier of cases may play over that of the other. All the cases being tied fast on, carry leaders from one to the other; and let there be a pipe hung from the mouth of one of the cases, covered at the end with a single paper, which you burn to fire the cascade.

The Fire Tree.—To make a fire tree, as shown by fig. 44. you must first have a piece of wood six feet long, and three inches square; then at E, nine inches from the top, make a hole in the front, and in each side; or, instead of holes, you may fix short pegs, to fit the inside of the cases. At F, nine inches from E, fix three more pegs; at G, one foot nine inches from F, fix three pegs; at H, nine inches from G, fix three pegs; at I, nine inches from H, fix three pegs, inclining downwards; but all the other pegs must incline upwards, that the cases may have the same inclination as is seen in the figure: then at top place a four-inch mortar, loaded with stars, rains, or crackers. In the middle of this mortar place a case filled with any sort of charge, but let it be fired with the other cases; a brilliant charge will do for all the cases; but the mortar may be made of any diameter, and the tree of any size; and on it any number of cases, provided they are placed in the manner described.

Chinese Fountains.—To make a Chinese fountain, you must have a perpendicular piece of wood seven feet long and two inches and a half square. Sixteen inches from the top, fix on the front a cross piece one inch thick, and two and a half broad, with the broad side upwards; below this, fix three more pieces of the same width and thickness, at sixteen inches from each other; let the bottom rail be five feet long, and the others of such a length as to allow the fire-pumps to stand in the middle of the intervals of each other. The pyramid being thus made, fix in the holes made in the bottom rail five fire pumps, at equal distances; on the second rail, place four pumps; on the third, three; on the fourth, two; and on the top of the post, one; but place them all to incline a little forwards, that, when they throw out the stars, they may not strike against the
Chap. II.

PYROTECHNY.

Varieties of Construction.

112 Illuminated globes with horizontal wheels.

The cross rails. Having fixed your fire-pumps, clothe them with leaders, so that they may all be fired together. See fig. 45.

Of illuminated Globes with horizontal Wheels.—The hoops for these globes may be made of wood, tin, or iron wire, about two feet in diameter. For a single globe, take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave six inches long; the top of which the globe is fixed, so as to stand three or four inches from the wheel: on this wheel you may put any number of cases, filled with what charge you please; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will stand within two inches and a half of each other: fasten these on the hoops with small iron binding wire; and when they are all on, put the pipes of communication, which must be so managed as to light them all with the second or third case on the wheel. The spindle on which the globe is to run must go through the block of the wheel, up to the inside of the top of the globe; where must be fixed a bit of brass, or iron, with a hole in it to receive the point of the spindle, on which the whole weight of the wheel is to bear, as in fig. 46, which represents a globe on its spindle. By this method may be made a crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are managed so as to stand still, and the wheel only to turn round; but when you would have the globe or crown to stand still, and the wheel to run by itself, the block of the wheel must not be so long, nor the spindle any longer than just to raise the globe a little above the wheels; and the wheel cases and illumination must begin together.

The Dodecahedron.—So called because it nearly represents a twelve-sided figure, is made thus: First have a ball turned out of some hard wood, 14 inches diameter: divide its surface into 14 equal parts, from which bore holes one inch and a half diameter, perpendicular to the centre, so that they may all meet in the middle: then let there be turned in the inside of each hole a female screw; and to all the holes but one must be made a round spoke five feet long, with four inches of the screw at one end to fit the holes; then in the screw-end of all the spokes bore a hole, five inches up, which must be bored slanting, so as to come out at one side, a little above the screw; from which cut a small groove along the spoke, within six inches of the other end, where make another hole through to the other side of the spoke. In this end fix a spindle, on which put a small wheel of three or four sides, each side six or seven inches long; these sides must have grooves cut in them, large enough to receive a two or four ounce case. When these wheels are clothed, put them on the spindles, and at the end of each spindle put a nut to keep the wheel from falling off. The wheels being thus fixed, carry a pipe from the mouth of the first case on each wheel, through the hole in the side of the spoke, from thence along the groove, and through the other hole, so as to hang out at the screw-end about an inch. The spokes being all prepared in this manner, you must have a post, on which you intend to fire the work, with an iron screw in the top of it, to fit one of the holes in the ball: on the screw fix the ball; then in the top hole of the ball put a little meal-powder, and some loose quick-match: then screw in all the spokes; and in one side of the ball bore a hole, in which put a leader, and secure it at the end; and the work will be ready to be fired. By the leader the powder and match in the centre is fired, which will light the match of the ends of the spokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A gray charge will be proper for the wheel cases.

The Yew Tree of Brilliant Fire is represented by a few trees as it appears when burning. First, let A be an upright piece of wood, four feet long, two inches broad, and one thick: at top of the piece, on the flat side, fix a hoop 14 inches diameter; and round its edge and front place illuminations, and in the centre a five-pointed star; then at E, which is one foot and a half from the edge of the hoop, place two cases of brilliant fire, one on each side; these cases should be one foot long each: below these fix two more cases of the same size, and at such a distance that their mouths may almost meet them at top: then close to the ends of these fix two more of the same cases; they must stand parallel to them at E. The cases being thus fixed, clothe them with leaders; so that they, with the illuminations and stars at top, may all take fire together.

Stars with Points for regulated Pieces, &c.—These Stars with points are made of different sizes, according to the work. For which they are intended: they are made with cases from one ounce to one pound, but in general with four-ounce cases, four or five inches long; the case must be rolled with paste, and twice as thick as that of a rocket of the same bore. Having rolled a case, pinch one end of it quite close: then drive in half a diameter of clay; and when the case is dry, fill it with composition, two or three inches to the length of the cases with which it is to burn: at top of the charge drive some clay; as the ends of these cases are seldom pinched, they would be liable to take fire. Having filled a case, divide the circumference of it at the pinched end close to the clay into five equal parts; then bore five holes with a gimlet about the size of the neck of a common four-ounce case, into the composition: from one hole to the other carry a quick-match, and secure it with paper: this paper must be put on in the manner of that on the end of wheel-cases, so that the hollow part, which projects from the end of the case, may serve to receive a leader from any other work, to give fire to the points of the stars. These stars may be made with any number of points.

Fixed Sun with a transparent Face.—To make a sun fixed sun of the best kind, there should be two rows of cases, as in fig. 48, which will show a double glory, and make the rays strong and full. The frame or sun-wheel, must be made thus: Have a circular flat nave made very strong, 12 inches diameter: to this fix six strong flat spokes, A, B, C, D, E, F. On the front of these fix a circular fell, five feet diameter; within which fix another fell, the length of one of the sun-cases less in diameter; within this fix a third fell, whose diameter must be less than the second by the length of one case and one-third. The wheel being made, divide the fells into so many equal parts.
PYROTECHNY.

Varities of Con.,
structure.

parts as there are to be cases (which may be done from 24 to 44): at each division fix a flat iron staple; these staples must be made to fit the cases, to hold them fast on the wheel; let the staples be so placed, that one row of cases may lie in the middle of the intervals of the other.

In the centre of the block of the sun drive a spindle, on which put a small hexagonal wheel, whose cases must be filled with the same charge as the cases of the sun: two cases of this wheel must burn at a time, and begin with them on the fells. Having fixed on all the cases, carry pipes of communication from one to the other, as you see in the figure, and from one side of the sun to the wheel in the middle, and from thence to the other side of the sun. These leaders will hold the wheel steady while the sun is fixing up, and will also be a sure method of lighting both cases of the wheel together. A sun thus made is called a brilliant sun, because the wood work is entirely covered with fire from the wheel in the middle, so that there appears nothing but sparks of brilliant fire: but if you would have a transparent face in the centre, you must have one made of pasteboard of any size. The method of making a face is, by cutting out the eyes, nose, and mouth for the sparks of the wheel to appear through; but instead of this face, you may have one painted on oiled paper, or Persian silk, strained tight on a hoop; which hoop must be supported by three or four pieces of wire at six inches distance from the wheel in the centre, so that the light of it may illuminate the face. By this method may be shown in the front of a sun, Vivat Rex, cut in pasteboard, or Apollo painted on silk; but, for a small collection, a sun with a single glory, and a wheel in front, will be most suitable. Half pound cases, filled ten inches with composition, will be a good size for a sun of five feet diameter; but if larger, the cases must be greater in proportion.

Three Vertical Wheels illuminated, which turn on their own Naves upon a horizontal Table.—A plan of this is shown by fig. 49. Let D be a fir table three feet in diameter; this table must be fixed horizontally on the top of a post; on this post must be a perpendicular iron spindle, which must come through the centre of the table; then let A, B, C, be three spokes joined to a triangular flat piece of wood, in the middle of which make a hole to fit easily over the spindle: let E, F, G, be pieces of wood, four or five inches long each, and two inches square, fixed on the under sides of the spokes; in these pieces make holes lengthwise to receive the thin part of the blocks of the wheels, which, when in, are prevented from coming out by a small iron pin being run through the end of each. K, L, M, are three vertical octagonal wheels, 18 inches diameter each: the blocks of these wheels must be long enough for three or four inches to rest on the table; round which part drive a number of sharp points of wire, which must not project out of the blocks more than 1/16th of an inch: the use of these points is, that, when the blocks run round, they will stick in the table, and help the wheels forward: if the naves are made of strong wood, one inch will be enough for the diameter of the thin part, which should be made to turn easily in the holes of the pieces E, F, G. On the front of the wheels make four or five circles of strong wire, or flat hoops, and tie on them as many illuminations as they will hold at two inches distant from each other; instead of circles, you may make spiral lines, clothes with illuminations, at the same distance from each other as those on the hoops. When illuminations are fixed on a spiral line in the front of a wheel, they must be placed a little on the slant, the contrary way from that in which the wheel runs; the cases for these wheels may be filled with any coloured charge, but must burn only one at a time.

The wheels being thus prepared, you must have a globe, crown, or spiral wheel, to put on the spindle in the middle of the table: this spindle should be just long enough to raise the wheel of the globe, crown, or spiral wheel, so high that its fire may play over the three vertical wheels: by this means their fires will not be confused, nor will the wheels receive any damage from the fire of each other. In clothing this work, let the leaders be so managed, that all the wheels may light together, and the illuminations after two cases of each wheel are burned.

Illuminated works are much admired by the Italians, and indeed are a great addition to a collection of works: in a grand exhibition an illuminated piece should be fired after every two or three wheels, or fixed pieces of common and brilliant fires; and likewise illuminated works may be made cheap, quick, and easy.

To make an illuminated chandelier, you must first have one made of thin wood (see fig. 50). The chandelier being made, bore in the front of the branches, and in the body, and also in the crown at top, as many holes for illuminations as they will contain at three inches distance from each other: in these holes put illuminations filled with white, blue, or brilliant charge. Having fixed in the port-fires, clothe them with leaders, so that the chandelier and crown may light together. The small circles on this figure represent the mouths of the illuminations, which must project straight from the front.

To make a flaming star with brilliant wheels, you must first have made a circular piece of strong wood about one inch thick and two feet diameter; round this block fix eight points, two feet six inches long each; four of these points must be straight and four flaming: these points being joined on very strong, and even with the surface of the block, nail tin or pasteboard on their edges, from the block to the end of each, where they must be joined; this tin must project in front eight inches, and be joined where they meet at the block; round the front of the block fix four pieces of thick iron wire, eight inches long each, equally distant from each other: this being done, cut a piece of pasteboard round, two feet diameter, and draw on it a star, as may be seen in fig. 51. Cut out this star, and on the back of it paste oiled paper; then paint each point half red and half yellow, lengthwise; but the body of the star must be left open, where in must run a brilliant wheel, made thus: Have a light block turned nine inches long: at each end of it fix six spokes; at the end of each spoke put a two ounce case of brilliant fire: the length of these cases must be in proportion to the wheel, and the diameter of the wheel when the cases are on must be a little less than the diameter of the body of the small star: the cases on the spokes in front must have their mouths incline outwards, and those on the inside spokes must be placed so as to form a vertical circle of fire. When you place the leaders, carry the first pipe from the tail of one of the
Cases in front to the mouth of one of the inside cases, and from the tail of that to another in front, and so on to all the cases. The wheel being made, put it on a
spindle, in the centre of the star; this spindle must have a shoulder at bottom, to keep the wheel at a little distance from the block. The wheel must be kept on the spindle by a nut at the end; having fixed on the wheel, fasten the transparent star to the four pieces of wire:
when you fire it, you will only see a common horizontal wheel; but when the first case is burnt out, it will fire one of the vertical cases, which will show the transparent star, and fill the large flames and points with fire; then it will again appear like a common wheel, and so on for 12 charges.

A regulated piece, if well executed, is as curious as any in fire-works; it consists of fixed and moveable pieces on one spindle, representing various figures, which take fire successively one from another, without any assistance after lighting the first mutation. See fig. 53.

I. Names of the mutations, with the colour of fire and size of the case belonging to each.

First mutation is a hexagon vertical wheel, illuminated in front with small portfires tied on the spokes; this wheel must be clothed with two ounce cases, filled with black charge; the length of these cases is determined by the size of the wheel, but must burn singly.

Second mutation is a fixed piece, called a golden glory, by reason of the cases being filled with spur-fire. The cases must stand perpendicular to the block on which they are fixed, so that, when burning, they may represent a glory of fire. This mutation is generally composed of five or seven ounce cases.

Third mutation is moveable; and is only an octagon vertical wheel, clothed with four ounce cases, filled with brilliant charge; two of these cases must burn at a time. In this wheel you may make changes of fire.

Fourth mutation is a fixed sun of brilliant fire, consisting of 12 four ounce cases; the necks of these cases must be a little larger than those of four ounce wheel-cases. In this mutation may be made a change of fire, by filling the cases half with brilliant charge, and half with gray.

Fifth mutation is a fixed piece, called the porcupine's quills. This piece consists of 12 spokes, standing perpendicular to the block on which they are fixed; on each of those spokes, near the end, must be placed a four ounce case of brilliant fire. All these cases must incline either to the right or left, so that they may all play in one way.

Sixth mutation is a standing piece, called the cross-fire. This mutation consists of eight spokes fixed in a block; near the end of each of those spokes must be tied two four ounce cases of white charge, one across the other, so that the fires from the cases on one spoke may intersect the fire from the cases on the other.

Seventh mutation is a fixed wheel, with two circular fells, on which are placed 16 eight ounce cases of brilliant fire, in the form of a star. This piece is called a fixed star of wild fire.

Eighth mutation.—This is a beautiful piece, called a brilliant star-piece. It consists of six spokes, which are strengthened by two fells of a hexagon form, at some distance from each other; at the end of each spoke, in the front, is fixed a brilliant star of five points; and on each side of every star is placed a four ounce case of black or gray charge; these cases must be placed with their mouths sideways, so that their fires may cross each other.

Ninth mutation is a wheel-piece. This is composed of six long spokes, with a hexagon vertical wheel at the end of each; these wheels run on spindles in the front of the spokes; all the wheels are lighted together; two ounce cases will do for these wheels, and may be filled with any coloured charge.

II. Proportions of the mutations, with the method of conveying the fire from one to the other, and the distance at which they stand one from the other on the spindle.

First mutation must be a hexagon vertical wheel, 14 inches diameter; on one side of the block, whose diameter is two inches and a quarter, is fixed a tin barrel A (see fig. 53. No. 1). This barrel must be a little less in diameter than the nave; let the length of the barrel and block be six inches. Having fixed the cases on the wheel, carry a leader from the tail of the last case into the tin barrel through a hole made on purpose, two inches from the block; at the end of this leader, let there be about one inch or two of loose match, but take care to secure well the hole wherein the pipe is put, to prevent any sparks falling in, which would light the second mutation before its time, and confuse the whole.

Second mutation is thus made: Have a nave turned two inches and a half diameter, and three long; then let half an inch of that end which faces the first wheel be turned so as to fit easy into the tin barrel of the first mutation, which must turn round it without touching. On the other end of the block fix a tin barrel B, No. 2. This barrel must be six inches long, and only half an inch of it to fit on the block. Round the nave fix five spokes, one inch and a half long each; the diameter of the spokes must be equal to a two ounce former. On these spokes put five seven inch two ounce cases of spur-fire, and carry leaders from the mouth of one to the other, that they may all light together. Then from the mouth of one of these cases carry a leader through a hole bored slantwise in the nave, from between the spokes, to the front of the block near the spindle hole; the end of this leader must project out of the hole into the barrel of the first mutation, so that when the pipe which comes from the end of the last case on the first wheel flashes, it may take fire, and light the second mutation. To communicate the fire to the third mutation, bore a hole near the bottom of one of the five cases to the composition, and from thence carry a leader into a hole made in the middle of the barrel B: this hole must be covered with pasted paper.

Third mutation may be either an octagon or hexagon wheel, 20 inches diameter; let the nave be three inches and a quarter diameter, and three and a half in length; one inch and a half of the front of the nave must be made to fit in the barrel B. On the other end of the block fix a tin barrel C, No. 3. This barrel must be six inches and a half in length, one inch of which must fit over the block. The cases of this wheel must burn two at a time; and from the mouths of the first two cases carry a leader, through holes in the nave, into the barrel of the second mutation, after the usual manner: but besides these leaders let a pipe go across the wheel from the first case to the other; then from the tail of one of the
the last cases carry a pipe into a hole in the middle of the barrel C: at the end of this pipe let there be some loose quick-match.

Fourth and fifth mutations.—These may be described under one head, as their naves are made of one piece, which from E to F is 14 inches; E, a block four inches diameter, with 10 or 12 short spokes, on which are fixed 11 inch eight ounce cases: let the front of this block be made to fit easily in the barrel C, and clothe the cases so that they may all light together; and let a pipe be carried through a hole in the block into the barrel C, in order to receive the fire from the leader brought from the last case on the wheel. G is the nave of the 5th mutation; whose diameter must be four inches and a half: in this nave fix 10 or 12 spokes, one foot and a half in length each; these spokes must stand seven inches distant from the spokes of the 4th mutation; and at the end of each spoke tie a four ounce case, as in No. 4. All these cases are to be lighted together, by a leader brought from the end of one of the cases on No. 4. Let F and H be of the same piece of wood as E and G, but as much thinner as possible, to make the work light.

Sixth and seventh mutations.—The blocks of these two mutations are turned out of one piece of wood, whose length from F to P is 15 inches. L, a block five inches diameter, in which are fixed eight spokes, each two feet four inches long; at the end of each spoke tie two four ounce cases, as in No. 6. All these cases must be fixed at the same time, by a pipe brought from the end of one of the cases on the 5th mutation. Let the distance between the spokes at L, and those in the 5th mutation, be seven inches. M, the nave of the 7th mutation, whose diameter must be five inches and a half: in this nave fix eight spokes, and on the front of them two circular fells, one of four feet eight inches diameter, and one of three feet 11 inches diameter; on these fells tie 16 eight ounce or pound cases, as in No. 7, and carry leaders from one to the other, so that they may all be fired together. This mutation must be fired by a leader brought from the tail of one of the cases on the 6th mutation.

Eighth and ninth mutations.—The blocks of these may be turned out of one piece, whose length from P to D must be 12 inches. O, the block of the 8th mutation, which must be six inches diameter; and in it must be fixed six spokes, each three feet in length, strengthened by a hexagon fell within three or four inches of the ends of the spokes: close to the end of each spoke, in the front, fix a five-pointed brilliant star; then seven inches below each star tie two 10 inch eight ounce cases, so that the upper ends of the cases may rest on the fells, and their ends on the spokes. Each of these cases must be placed parallel to the opposite fell (see No. 8.) NNN, &c. are the cases, and kkk, &c. the stars.

The 9th mutation is thus made: Let D be a block seven inches diameter. In this block must be screwed six spokes, six feet long each, with holes and grooves for leaders, as those in the dodecahedron; at the end of each spoke, in the front, fix a spindle for a hexagon vertical wheel, 10 inches diameter, as in No. 9. When these wheels are on, carry a leader from each into the block, so that they may all meet; then lead a pipe from the end of one of the cases of the 8th mutation, through a hole bored in the block D, to meet the leaders from the vertical wheels, so that they may all be fired together.

The spindles for larger pieces are required to be made very strong, and exact as possible: for a piece of nine mutations, let the spindle be at the large end one inch diameter, and continue that thickness as far as the 7th mutation; and thence to the 5th, let its diameter be three-fourths of an inch; from the 5th to the 4th, five-eighths of an inch; from the 4th to the second half an inch; and from the second to the end three eighths of an inch. At the small end must be a not to keep on the first wheel, and at the thick end must be a large nut, as shown by the figure; so that the screw part of the spindles being put through a post, and a nut screwed on tight, the spindle will be held fast and steady: but you are to observe, that that part of the spindle on which the movable pieces are to run, be made long enough for the wheels to run easy without sticking; the fixed pieces being made on different blocks, the leaders must be joined after they are fixed on the spindle. The best method of preventing the fixed mutations from moving on the spindle, is to make that part of the spindle which goes through them square; but as it would be difficult to make square holes through such long blocks as are sometimes required, it will be best to make them thus: Bore a hole a little larger than the diameter of the spindle; and at each end of the block, over the hole, fasten a piece of brass with a square hole in it to fit the spindle.

To make a horizontal wheel change to a vertical wheel with a sun in front.—The sudden change of this piece from one to another is very pleasing; and gives great surprise to those who are not acquainted with the contrivance. A wheel for this purpose should be about three feet diameter, and its fell circular: on which tie 16 half pound cases filled with brilliant charge: two of these cases must burn at a time: and on each end of the nave must be a tin barrel of the same construction as those on the regulated piece. The wheel being completed, prepare the post or stand thus: First have a stand made of any height, about three or four inches square; then saw off from the top a piece two feet long; this piece join again at the place where it was cut with a hinge on one side, so that it may lift up and down in the front of the stand; then fix on the top of the bottom part of the stand, on each side, a bracket; and these brackets must project at right angles with the stand, one foot from the front, for the short piece to rest on. These brackets must be placed a little above the joint of the post, so that when the upper stand falls, it may lie between them at right angles with the bottom stand; which may be done by fixing a piece of wood, one foot long, between the brackets, and even with the top of the bottom stand; then, as the brackets rise above the bottom stand, they will form a channel for the short post to lie, and keep it steady without straining the hinge. On the side of the short post, opposite the hinge, nail a piece of wood, of such a length, that, when the post is perpendicular, it may reach about one foot and one half down the long post: to which being tied, it will hold the short stand upright. The stand being thus prepared, in the top of it fix a spindle 10 inches long: on this spindle put the wheel: then fix on a brilliant sun with a single glory; the diameter of this sun must be six inches less than that of the wheel. When you fire this piece, light the wheel first, and let it run horizontally till four cases are consumed; then from the end of the fourth case carry a leader into the tin barrel that turns over the end of the stand: this leader must be met by another brought through the top
of the post, from a case filled with a strong port-fire charge, and tied to the bottom post, with its mouth facing the packthread which holds up the stand; so that when this case is lighted, it will burn the packthread, and let the wheel fall forward, by which means it will become vertical: then from the last case of the wheel, carry a leader into the barrel next the sun, which will begin as soon as the wheel is burnt out.

Grand volute illuminated with a projected wheel in front.—First have two hoops made of strong iron wire, one of six feet diameter, and one of four feet two inches; these hoops must be joined to scrolls A, A, A, &c. as in fig. 54. These scrolls must be made of the same sort of wire as the hoops; on these scrolls lie, with iron binding wire, as many illuminating port-fires as they will hold, at two inches distance; these port-fires with leaders, so that they may all take fire together.

Then let C be a circular wheel of four spokes, three feet six inches diameter; and on its fell tie as many four ounce cases, head to tail, as will complete the circle, only allowing a sufficient distance between the cases, that the fire may pass free; which may be done by cutting the upper part of the end of each case a little shelving: on each spoke fix a four ounce case, about three inches from the fell of the wheel: these cases are to burn one at a time, and the first of them to begin with those on the fell, of which four are to burn at a time; so that the wheel will last no longer than one-fourth of the cases on the fell, which in number should be 16 or 20. On the front of the wheel form a spiral line with strong wire, on which tie port-fires, placing them on a slant, with their mouths to face the same way as the cases on the wheel: all these port-fires must be fired with the second cases of the wheel. Let D, D, D, &c. be spokes of wood, all made to screw into a block in the centre; each of these spokes may be in length about four feet six inches; in the top of each fix a spindle, and on each spindle put a spiral wheel of eight spokes, such as E, E, E, &c. The blocks of these wheels must have a hole at top for the centre case, and the spindle must have nuts screwed on their ends; which nuts should fit in the holes at top of the blocks, so that all the wheels must be put on before you fix in the centre cases: as some of these wheels, from their situation, will not bear on the nut, it will be necessary to have smooth shoulders made on the spindles for the blocks to run on. The cases of these wheels are to burn double; and the method of firing them, is by carrying a leader from each down the spokes into the block in the centre, as in the dodecahedron, but the centre case of each wheel must begin with the two last cases as usual. It is to be observed, that the large circular wheel in front must have a tin barrel on its block, into which a pipe must be carried from one of the second cases on the wheel; this pipe being met by another from the large block, in which the eight spokes are of screwed, will fire all the spiral wheels and the illuminating port-fires at the same time. The cases of the projected wheel may be filled with a white charge, and those of the spiral wheels with a gray charge.

Let fig. 55. be a smooth circular board six feet diameter; out of the middle of it cut a circular piece 12 or 14 inches diameter; and over the vacancy put white Persian silk, on which paint a moon's face: then let I, I, I, &c. be stars, each four or five inches diameter, cut out with five points, and covered with oiled silk; on the front of the large circular board draw a seven pointed star as large as the circle will allow; then on the lines which form this star bore holes, wherein fix pointed stars. When this case is to be fired, it must be fixed upon the front of a post, on a spindle, with a wheel of brilliant fire behind the face of the moon; so that while the wheel burns, the moon and stars will appear transparent: and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of pointed stars, will begin, being lighted by a pipe of communication from the last case of the vertical wheel, behind the moon; this pipe must be managed in the same manner as those in regulated pieces.

Double cone-wheel illuminated.—This piece is represented by fig. 56. Let A be a strong decagonal or ten sided wheel, two feet six inches diameter; then on each side of it fix a cone B and C: these cones are to consist of a number of hoops, supported by three or four pieces of wood, in the manner of the spiral wheels. Let the height of each cone be three feet six inches; and on all the hoops tie port-fires horizontally, with their mouths outwards, and clothe the wheel with eight-ounce cases, all to play horizontally, two at a time: the cones may be fired with the first or second cases. The spindle for this piece must go through both the cones, and rise three feet above the point of the cone at top; so that its length will be 13 feet four inches from the top of the post H, in which it is fixed, allowing four inches for the thickness of the block of the wheel. The whole weight of the wheel and cones must bear on a shoulder in the spindle, on which the block of the wheel must turn.

Near the top of the spindle must be a hole in the front, into which screw a small spindle, after the cones are on: then on this small spindle fix a sun D, composed of sixteen nine inch four-ounce cases of brilliant fire; which cases must not be placed on a fall, but only stuck into a block of six inches diameter: then in the front of this sun must be a circular vertical wheel, 16 inches diameter; on the front of this wheel form with iron wire a spiral line, and clothe it with illuminations after the usual method. As this wheel is not to be fired till the cones are burnt out, the method of firing it is this: Let the hole in the block, at the top of the uppermost cone, be a little larger than the spindle which passes through it. Then, from the first case of the vertical wheel before the sun, carry a leader down the side of the spindle to the top of the block of the horizontal wheel, on which must be a tin barrel: then this leader being met by another brought from the end of the last case of the horizontal wheel, will give fire to the vertical wheel as soon as the cones are extinguished: but the sun D must not be fired till the vertical wheel is quite burnt out.

Cases for fire pumps are made as those for tourbillons; only they are pasted, instead of being rolled dry. Having rolled and dried the cases, fill them: first put in a little meal-powder, and then a star; on which pour in lightly a ladleful or two of composition; then a little meal-powder, and on that a star, then again composition; and so on till the cases are filled. Stars for fire pumps should not be round; but must be made either square, or flat and circular, with a hole through the middle: the quantity of powder for throwing the stars must increase near the top of the case; for, if much powder be put at the bottom, it will burst the case. The stars must differ in size in this manner: Let the star which is 4 B 2 put
PYROTECHNY.

A vertical scroll wheel may be made of any diameter, but must be constructed as in fig. 57, to do which proceed thus: Have a block made of a moderate size, in which fix four flat spoked, and on them fix a flat circular fall of wood; round the front of this fell place portfires; then on the front of the spokes form a scroll, either with a hoop or strong iron wire; on this scroll tie cases of brilliant fire, in proportion to the wheel, head to tail, as in the figure. When you fire this wheel, light the first case near the fell; then, as the cases fire successively, the circle of fire will gradually diminish; but whether the illuminations on the fell begin with the scroll or not, is immaterial.

N. B. This wheel may be put in the front of a regulated piece, or fired by itself, occasionally.

There are two sorts of fire-globes: one with projected cases, the other with the cases concealed. For the latter have a globe made of wood, of any diameter, and divide the surface of it into 14 equal parts, and at each division bore a hole perpendicular to the centre: these holes must be in proportion to the cases intended to be used: in every hole, except one, put a case filled with brilliant or any other charge, and let the mouths of the cases be even with the surface of the globe; then cut in the globe a groove, from the mouth of one case to the other, for leaders which must be carried from case to case, so that they may all be fired together; this done, cover the globe with a single paper, and paint it. These globes may be used to ornament a building.

Fire-globes with projected cases are made thus: the globe being made with 14 holes bored in it as usual, fix in every hole except one, a case, and let each case project from the globe two-thirds of its length; then clothe all the cases with leaders, so that they may all take fire at the same time. Fire-globes are supported by a pindle, made to fit the hole in which there is no case.

Nothing adds more to the appearance of fire-works than placing them properly; though this chiefly depends on the judgment of the maker. The following are the rules generally observed, whether the works are to be fired on a building or on stands: if they are a double set, place one wheel of a sort on each side of the building; and next to each of them, towards the centre, place a fixed piece, then wheels, and so on; leaving a sufficient distance between them for the fire to play from one without burning the other. Having fixed some of the works thus in front, place the rest behind them, in the centre of their intervals: The largest piece, which is generally a regulated or transparent piece, must be placed in the centre of the building, and behind it a sun, which must always stand above all the other works. A little before the building, or stands, place the large gerbes; and at the back of the works six maroon batteries, pots des aigrettes, pots des brins, pots des saucissons, air-balloons, and flights of rockets: the rocket stands may be fixed behind, or anywhere else, so as not to be in the way of the works.

Single collections are fixed on stands; which are made in the same manner as theodolite stands, only the top part must be long or short occasionally: these stands may be fixed up very soon without much trouble.

The following order of firing will serve as a specimen of the Plan to be pursued in an exhibition of Fire-works.

1. Two signal rockets
2. Six sky rockets
3. Two honorary vertical wheels illuminated
4. Four caduceus transparent stars
5. Two air balloons illuminated
6. Two Chinese fountains
7. Regulating pieces of four mutations each
8. Three large geese
9. Four tourbillons
10. Horizontal wheels
11. Two air-balloons of serpents and two compound tourbillons
12. Two balloon wheels
13. Two cascades of brilliant fire
14. Twelve sky rockets
15. Illuminated yew trees
16. A flight of rockets
17. Two fruiloni wheels
18. Illuminated globes with horizontal wheels
19. One pot des saucissons
20. Two plural wheels
21. Maroon battery
22. Two chandeliers illuminated
23. Range of pots des brins
24. Twelve sky-rockets
25. Two yeu-trees of fire
26. Nest of serpents
27. Two double cones illuminated
28. Regulating piece of seven mutations, vts.
29. Vertical wheel illuminated
30. Golden glory
31. Octagon vertical wheel
32. Porcupine’s quilla
33. Cross fires
34. Star-piece with brilliant rays
35. Seven vertical wheels
36. Brilliant sun
37. Large flight of rockets.

When water-works are to be exhibited, divide them into several sets, and fire one set after every fifth or sixth change of land and air-works. Observe this rule in firing a double set of works: Always begin with sky-rockets, then two moveable pieces, then two fixed pieces, and so on; ending with a large flight of rockets, or a maroon battery: if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works.
Fig. 58. represents a fountain of 30 rockets. Let A be a perpendicular post, 16 feet high from the ground, and 4 inches square. Let the rail, or cross piece C, be one foot six inches long, three inches broad, and one inch thick. The rail D, at which it must be six feet long, two sides which serve to supply the rails D, E, H, I, C: these sides are one foot broad at bottom, and cut in the front with a regular slope, to three inches at top; but their back edges must be parallel with the front of the pots A. The breadth of the rails E, H, I will be determined by the breadth of the sides: all the rails must be fixed at two feet distance from each other, and at right angles with the pots. Having placed the rails thus, bore in the bottom rail 10 holes, at equal distances, large enough to receive the stick of a pound rocket: in the back edge of this rail cut a groove from one end to the other, fit to contain a quick-match; then cut a groove in the top of the rail, from the edge of each hole, into the groove in the back: in the same manner cut in the second rail, E, eight holes and grooves; in the third rail, H, six holes and grooves; in the fourth rail, I, four holes and grooves; and in the top rail, two holes and grooves. B, a rail with holes in it to guide the ends of the rocket sticks; this rail must be fixed six feet from the rail D. The fountain frame being thus made, prepare the rockets thus: Tie round the mouth of each piece of thin paper, large enough to go twice round, and to project about an inch and a half from the mouth of the rocket, which must be rubbed with wet meal-powder; in the mouth of each rocket put a leader, which secure well with the paper that projects from the mouth of the case: these leaders must be carried into the grooves in the back of the rails, in which lay a quick-match from one end to the other, and cover it with pasted paper: holes must be made in the rail D, to receive the ends of the sticks of the rockets in the rail E, and so on to the fourth rail; so that the sticks of the rockets at top may go through all the rails. The rockets being so prepared, fix a gerbe, or white flower-pot, on each rail, before the post, with its mouth inclining a little forwards: these gerbes must be lighted all at once. Behind or before each gerbe, fix a case of brilliant or slow fire: these cases must be filled so that they may burn out one after the other, to regulate the fountain; which may be done by carrying a leader from the end of each slow or brilliant fire, into the groove in the back of each rail. Different fixed rockets may be used in these fountains; but it will be best to fill the heads of the rockets on each rail with different sorts of things, in this manner: those at top with crackers, the next with raisins, the third with serpents, the fourth with tailed stars, and the last flight with common or brilliant stars.

The piece called a palm tree, though made of common fires, and of a simple construction, has a very pleasing effect; from the fires intersecting so often, that they resemble the branches of trees. Let A (fig. 59.) be a perpendiclar post, of any thickness, so that it be sufficiently strong to hold the cases; let the distance from B to C be two feet six inches, and from C to D two feet six inches, and let the length of each cross-piece be two feet; on each end of each fix a five-pointed star: then fix, on pegs made for the purpose, twelve inch half-pound cases of brilliant fire, as in the figure.

All the cases and stars must be fired at once. This piece should be fixed high from the ground.

An illuminated pyramid, with Archimedean screws, a globe, and vertical sun, may be of any size. One made according to the dimensions of fig. 60. will be of a good proportion, whose height is 21 feet; from C to D, six feet; from E to F, nine feet: the space between the rails must be six inches, and the rails as thin as possible; in all the rails stick portières at four inches distance. The Archimedean screws, G, K, are nothing more than double spiral wheels, with the cases placed on their wheels horizontally instead of obliquely. The vertical sun, I, need not consist of more than 12 rays, to form a single glory. The globe at top must be made in proportion to the pyramid; which being prepared according to the preceding directions, place the leaders so that all the illuminating portières, screws, globe, and sun, may take fire together. The pyramid must be supported by the two sides, and by a support brought from a pole, which must be placed two feet from the back of the pyramid, that the wheels may run freely.

A rose-piece may be used for a modification of a regular luted piece, or fired by itself: it makes the best appearance when made large; if its exterior diameter be six feet, it will be of a good size. Fig. 61. shows the manner in which it appears before it is fired. Let the outer fell be made of wood, and supported by four wooden spokes: all the other parts, on which the illuminations are fixed, must be made of strong iron wire: on the outer fell place as many half-pound cases of brilliant charge as you think proper, but the more the better; for the nearer the cases are placed, the stronger will be the rays; the illuminations should be placed within three inches of each other: they must all be fired together, and burn some time before the sun is lighted: which may be done by carrying a leader from the middle of one of the illuminations, to the mouth of one of the sun cases.

Fig. 62. represents an illuminated star. Let the diameter from A to B be two feet, and from C to D seven feet. First make a strong circular back or body of the star, two feet diameter, to which fix the illuminated rays: in the centre of the front of the body fix a spindle, on which put a double triangular wheel, six inches diameter, clothed with two ounce cases of brilliant charge: the cases on this wheel must burn out one at a time. Round the edge of the body, nail a hoop made of thin wood or tin: this hoop must project in front six or seven inches; in this hoop out three or four holes to let out the smoke from the wheel. The star and garter may be cut out of strong pasteboard or tin, made in this manner: Cut a round piece of pasteboard or tin, two feet diameter, on which draw a star, and cut it out; then over the vacancy paste Persian silk; paint the letters yellow, four of the rays yellow, and four red; the cross in the middle may be painted half red and half yellow, or yellow and blue. This transparent star must be fastened to the wooden hoop by a screw, made so as to take off and on; the illuminated rays are made of thin wood, with tin sockets fixed on their sides within four inches of each other; in these sockets stick illuminating portières: behind the point of each ray fix a half-pound case of gray, black, or Chinese fire.

N. B. The illuminated rays are to be lighted at the
same time as the triangular wheel, or after it is burnt out; which may be done by a tin barrel being fixed to the wheel, after the manner of those in the regulated pieces. Into this barrel carry a leader from the illuminated rays, through the back of the star; and this leader must be met by another, brought from the tail of the last case on the wheel.

Fig. 63. represents a table star, whose diameter from E to F, is 12 feet; and from E to L, four feet. This observation, preserved on each side, will make the centre frame four feet square: in this square fix a transparent star, as in the figure. This star may be painted blue, and its rays made as those of the flaming stars described before. The wheel for this star may be composed of different coloured fires, with a charge or two of slow fire; the wheels a, a, a, a, may be clothed with any number of cases, so that the star-wheel consist of the same: the illuminating portfires, which must be placed very near each other on the frames, must be so managed as to burn as long as the wheels, and lighted at the same time.

The regulated illuminated spiral piece, with a projected star-wheel illuminated, is represented by fig. 64. and is thus made. Have a block made eight inches diameter; in this block screw six iron spokes, which must serve for spindles for the spiral wheels: these wheels are made as usual, each one foot and a half diameter, and three feet in height: the spindles must be long enough to keep the wheels four or five inches from one another: at the end of each spindle must be a screw-nut, on which the wheels that hang downwards will run; and on the spindles which stand upwards must be a shoulder, for the blocks of the wheels to run on.

The projected star-wheel must turn on the same spindle on which the large block is fixed; this spindle must be long enough to allow the star-wheel to project a little before the spiral wheels: the exterior diameter of the star-wheel must be three feet five inches. On this wheel fix three circles of iron wire, and on them portfires; on the block place a transparent star, or a large five-pointed brilliant star. The cases on this wheel may burn four at once, as it will contain nearly twice the number of one of the spiral wheels: the cases on the spiral wheels must be placed parallel to their falls, and burn two at a time.

A figure piece illuminated with five-pointed stars.—The construction of this piece is very easy, as shown by fig. 65. whose diameter from B to C is eight feet, and from D to F two feet: the vertical wheel in the centre must be one foot diameter, and consist of six four-ounce cases of different coloured charge, which cases must burn double: on the frames fix five-pointed brilliant or blue stars, rammed four inches with composition: let the space between each star be eight inches; at each point fix a gerbe, or case of Chinese fire. When to be fired, let the gerbe, stars, and wheel, be lighted at the same time.

The star-wheel illuminated, is shown by fig. 66. Its exterior fell is made of wood, three feet six inches or four feet diameter; within this fell, form with iron wire three circles, one less than the other, so that the diameter of the least may be about 10 inches: place the portfires on these falls with their mouths inclining outwards, and the portfires on the points of the star with their mouths projecting in front; let the exterior fell be clothed with four-ounce cases of gray charge: these cases must burn four at a time, and be lighted at the same time as the illuminations.

Pyramid of flower-pots is represented at fig. 67; and is made thus. Let the distance from A to B be six feet, and from one rail to the other, two: on the bottom nine, fix five paper mortars, each three inches and a half diameter; these mortars load with serpents, crackers, stars, &c.

In the centre of each mortar fix a case of spar-fire on the second rail fix mortars, so as to stand exactly in the middle of the intervals of those on the bottom rail; on the third rail place three mortars; on the fourth, two; and on the top of the posts, t; the bottom rail must be six feet long: all the mortars must incline a little forwards, that they may be easily discharged; and the spur-fires rammed exactly alike, that the mortars may all be fired at the same time. Having prepared the pyramid according to the preceding directions, carry pipes of communication from one spur-fire to the other.

Fig. 68. represents one half of the illuminated revolving piece.—A, A, A, A, are flat wooden spokes, two five feet long; at the end of each place a vertical wheel 10 inches diameter, clothed with six four-ounce cases of brilliant fire: these cases must burn but one at a time: with the bottom two of the spokes of each wheel place two portfires, which must be lighted with the first case of the wheel on each spoke A, A, &c. behind the wheels, place six cases of the same size with those on the wheels: these cases must be tied across the spokes with their mouths in one way, and be made to take fire successively one after the other, so that they may assist the whole piece to turn round.

The diameter of the large wheel must be two feet and a half; and its fell made of wood, which must be fixed to the large spokes: on this wheel place 24 cases of the same size with those on the small wheels; these cases must burn four at a time: in this wheel make three circles with iron wire, and on them place illuminating portfires, as in the figure: the star-points of the large spokes may be made of thin ash-hoops; the diameter of these points close to the centre-wheel must be 11 inches: on these points place portfires, at three inches, and a half distance one from the other.

Fig. 69. represents the blocks of this piece. The diameters of these blocks, at A and B, must be eight inches; and C and D, four inches and a half: the length of each of those blocks must be six inches: at the small ends of these blocks fix an iron wheel, five inches diameter, and these wheels must have teeth to turn the wheel C: this wheel is fixed on a small spindle, rammed into the large spindle, which goes through the two blocks, and on which they run.

Supposing fig. 68. to be on the block A, in fig. 69; and to turn to the right, and another piece of the same construction on the block B, with its fires placed so as to turn it to the left; you will find them move very true and fast, by the help of the three iron wheels, which serve to regulate their motions, as well as to assist them in turning: let the iron circles in the front of the great wheels be of different diameters, so that when fired there may appear six circles. When this piece is fired all the wheels and illuminations must be lighted at one time.
Works that sport in the water are much esteemed by most admirers of fire-works, particularly water-rockets; and as they seem of a very extraordinary nature to those who are unacquainted with this art, they merit a particular explanation.

Water-rockets may be made from four ounces to two pounds. If larger, they are too heavy, so that it will be difficult to make them keep above water without a cork float, which must be tied to the neck of the case; but the rockets will not dive so well with as without floats.

Cases for these are made in the same manner and proportion as sky-rockets, only a little thicker of paper. When you fill those which are driven solid, put in first one ladleful of slow fire, then two of the proper charge, and on that one or two ladles of sinking charge, then the proper charge, then the sinking charge again, and so on, till you have filled the case within three diameters; then drive on the composition one ladleful of clay; through which make a small hole to the charge; then fill the case, within half a diameter, with corn-powder, on which turn two or three rounds of the case in the inside; then pinch and tie the end very tight; having filled the rockets (according to the above directions), dip their ends in melted rosin or sealing-wax, or else secure them well with grease. When you fire these rockets, throw in six or eight at a time; but, if you would have them all sink, or swim, at the same time, you must fill them with an equal quantity of composition and fire them altogether.

Pipes of communication, which may be used under water, must be a little thicker in the paper than those for land. Having rolled a sufficient number of pipes, and kept them till dry, wash them over with drying oil, and set them to dry; but when you oil them, leave about an inch and a half at each end dry, for joints; as if they were oiled all over, when you come to join them, the paste would not stick where the paper is green; after the leaders are joined, and the paste dry, oil the joints. These pipes will lie many hours under water, without receiving any damage.

To make horizontal wheels for the water, first get a large wooden bowl without a handle; then have an eight-sided wheel made of a flat board 18 inches diameter, so that the length of each side may be near seven inches; in all the sides cut a groove for the cases to lie in. This wheel being made, nail it on the top of the bowl; then take four eight-ounce cases, filled with a proper charge, each about six inches in length. Now, to clothe the wheel with these cases, get some white-brown paper, and cut into slips four or five inches broad and seven or eight long; these slips being pasted all over on one side, take one of the cases, and roll one of the slips of paper about an inch and a half on its end, so that there will remain about two inches and a half of the paper hollow from the end of the case: tie this case on one of the sides of the wheel, near the corners of which must be holes bored, through which put the pack-thread to tie the cases: having tied on the first case at the neck and end, put a little meal powder in the hollow paper; then paste a slip of paper on the end of another case, the head of which put into the hollow paper on the first, allowing a sufficient distance from the tail of one to the head of the other for the pasted paper to bend without tearing; tie on the second case as you did the first: and so on with the rest, except the last, which must be closed at the end, unless it is to communicate to any thing on the top of the wheel, such as fire-pumps or brilliant fires, fixed in holes cut in the wheel, and fired by the last or second case, as the fancy directs; six, eight, or any number, may be placed on the top of the wheel, provided they be not too heavy for the bowl.

Before tying on the cases, cut the upper part of all their ends, except the last, a little shelving, that the fire from one may play over the other, without being obstructed by the case. Wheel cases have no clay drove in their ends, nor pinched, but are always left open, only the last, or those which are not to lead fire, which must be well secured.

For water mines you must have a bowl with a wheel on it, made in the same manner as the water-wheel; only in its middle there must be a hole, of the same diameter as that of the intended mine. These mines are tin pots, with strong bottoms, and a little more than two diameters in length: the mine must be fixed in the hole in the wheel, with its bottom resting on the bowl; then loaded with serpents, crackers, stars, small water-rockets, &c. in the same manner as pots of aigrettes; but in their centre fix a case of Chinese fire, or a small gerbe, which must be lighted at the beginning of the last case on the wheel. These wheels are to be clothed as usual.

Bowls for water-globes must be very large, and the Fire-globes wheels on them of ten sides; on each side nail a piece for the wood four inches long; and on the outside of each piece cut a groove, wide enough to receive about onefourth of the thickness of a four-ounce case: these pieces of wood must be nailed in the middle of each face of the wheel, and fixed in an oblique direction, so that the fire from the cases may incline upwards: the wheel being thus prepared, tie in each groove a four-ounce case filled with a gray charge; then carry a leader from the tail of one case to the mouth of the other.

Globes for these wheels are made of two tin hoops, with their edges outwards, fixed one within the other, at right angles. The diameter of these hoops must be rather less than that of the wheel. Having made the globe, drive in the centre of a wheel an iron spindle, which must stand perpendicular, and its length four or six inches more than the diameter of the globe.

The spindle serves for an axis, on which is fixed the globe, which must stand four or six inches from the wheel: round one side of each hoop must be soldered little bits of tin, two inches and a half distance from each other; which pieces must be two inches in length each, and only fastened at one end, the other ends being left loose, to turn round the small portfires, and hold them on: these portfires must be made of such a length as will last out the cases on the wheel. There need not be any portfires at the bottom of the globe within four inches of the spindle; as they would have no effect, but to burn the wheel: all the portfires must be placed perpendicularly from the centre of the globe, with their mouths outwards; and must be clothed with leaders so as all to take fire with the second case of the wheel; and the cases must burn two at a time, one opposite the other. When two cases of a wheel begin together, two will...
will end together; therefore the two opposite end cases must have their ends pinched and secured from fire. The method of firing such wheels is, by carrying a leader from the mouth of one of the first cases to that of the other; and the leader being burnt through the middle, will give fire to both at the same time.

Odoriferous water balloons are made in the same manner as air balloons, but very thin of paper, and in diameter one inch and three-fourths, with a vent of half an inch diameter. The shells being made, and quite dry, fill them with any of the following compositions, which must be rammed in tight: these balloons must be fired at the vent, and put into a bowl of water. Odoriferous works are generally fired in rooms.

Composition I. Saltpetre two ounces, flour of sulphur one ounce, camphor half an ounce, yellow amber half an ounce, charcoal dust three-fourths of an ounce, salt of benjamin half an ounce, all powdered very fine and well mixed.

II. Saltpetre 12 ounces, meal-powder three ounces, frankincense one ounce, myrrh half an ounce, camphor half an ounce, charcoal three ounces, all moistened with the oil of spike.

III. Saltpetre two ounces, sulphur half an ounce, antimony half an ounce, amber half an ounce, cedar raspings one-fourth of an ounce, all mixed with the oil of roses and a few drops of bergamot.

IV. Saltpetre four ounces, sulphur one ounce, saw-dust of juniper half an ounce, saw-dust of cypress one ounce, camphor one-fourth of an ounce, myrrh two drams, dried rosemary one-fourth of an ounce, all moistened a little with the oil of roses.

N. B. Water-rockets may be made with any of the above compositions, with a little alteration, to make them weaker or stronger, according to the size of the cases.

Having procured four or five small ships, of two or three feet in length, make a number of small reports, which are to serve for guns. Of these range as many as you please on each side of the upper decks; then at the head and stern of each ship fix a two-ounce case, eight inches long, filled with a slow portfire composition; but take care to place it in such a manner that the fire may fall in the water, and not burn the rigging: in these cases bore holes at unequal distances from one another, but make as many in each case as half the number of reports, so that one case may fire the guns on one side, and the other those on the opposite. The method of firing the guns is, by carrying a leader from the holes in the cases to the reports on the decks; you must make these leaders very small, and be careful in calculating the burning of the slow fire in the regulating cases, that more than two guns be not fired at a time. When you would have a broadside given, let a leader be carried to a cracker, placed on the outside of the ship; which cracker must be tied loose, or the reports will be too slow: in all the ships put artificial guns at the ports holes (A).

Having filled and bored holes in two portfires for regulating the guns in one ship, make all the rest exactly the same; then, when you begin the engagement, light one ship first, and set it a sailing, and so on with the rest, sending them out singly, which will make them fire regularly, at different times, without confusion; for the time between the firing of each gun will be equal to that of lighting the slow fires.

The fire-ship may be of any size; and need not be very good, for it is always lost in the action. To prepare a ship for this purpose, make a portfire equal in size with those in the other ships, and place it at the stern; and in every part place a large portfire, filled with a very strong composition, and painted in imitation of a gun, and let them all be fired at once by a leader from the slow fire, within two or three diameters of its bottom; all along both sides, on the top of the upper deck, lay star-composition about half an inch thick and one broad, which must be wetted with thin size, then primed with meal-powder, and secured from fire by pasting paper over it; in the place where you lay this composition, drive some little tacks with flat heads, to hold it fast to the deck: this must be fired just after the shams guns, and when burning will show a flame all round the ship: at the head take up the decks, and put in a tin mortar loaded with crackers, which mortar must be fired by a pipe from the end of the slow fire; the firing of this mortar will sink the ship, and make a pretty conclusion. The regulating portfire of this ship must be lighted at the same time with the first fighting ship.

Having prepared all the ships for fighting, we shall next proceed with the management of them when on the water. At one end of the pond, just under the surface of the water, fix two running blocks, at what distance you choose the ships should fight; and at the other end of the pond, opposite to each of these blocks, under the water, fix a double block; then on the land, by each of the double blocks, place two small windlasses; round one of them turn one end of a small cord, and put the other end through one of the blocks; then carry it through the single one at the opposite end of the pond, and bring it back through the double block again, and round the other windlass: to this cord, near the double block, tie as many small strings as half the number of the ships, at any distance; but these strings must not be more than two feet long each: make fast the loose end of each to a ship, just under her bowprit; for if tied to the keel, or too near the water, it will overset the ship. Half the ships being thus prepared, near the other double block fix two more windlasses, to which fasten a cord, and to it tie the other half of the ships as before: when you fire the ships, pull in the cord with one of the windlasses, to get all the ships together; and when you have set fire to the first, turn that windlass which draws them out, and so on with the rest, till they are all out in the middle of the pond; then, by turning the other windlass, you will draw them back again; by which method you may make them change sides, and tack about backwards and forwards at pleasure. For the fire ship fix the blocks and windlasses between the others.

(A) Reports for these and similar occasions are made, by filling small cartridges with grained powder; pinching them close at each end, and, when used, boring a hole in the side, to which is placed a match or leader for firing them.
PYROTECHNY.

PLATE CCCCLIII.
ch. ii. pyrotechny.

on floats: then in the places where their eyes should be, bore holes two inches deep, inclining downwards, and wide enough to receive a small portfire; the portfire cases for this purpose must be made of brass, two inches long, and filled with a slow bright charge. In the middle of one of these cases make a little hole; then put the portfire in the eye-hole of the swan, leaving about half an inch to project out; and in the other eye put another portfire, with a hole made in it: then in the neck of the swan, within two inches of one of the eyes, bore a hole slantwise, to meet that in the portfire; in this hole put a leader, and carry it to a water-rocket, that must be fixed under the tail with its mouth upwards. On the top of the head place two one-ounce cases, four inches long each, drove with brilliant fire; one of these cases must incline forwards, and the other backwards: these must be lighted at the same time as the water-rocket; to do which, bore a hole between them in the top of the swan’s head, down to the hole in the portfire, to which carry a leader: if the swan is filled with rockets, they must be fired by a pipe from the end of the water-rocket under the tail. When you set the swan a swimming, light the two eyes.

To make a fire-fountain for the water, first have a water float made of wood, three feet diameter; then in the fountain, middle fix a round perpendicular post, four feet high, and two inches diameter; round this post fix three circular wheels made of thin wood, without any spokes. The largest of these wheels must be placed within two or three inches of the float, and must be nearly of the same diameter. The second wheel must be two feet two inches diameter, and fixed at two feet distance from the first. The third wheel must be one foot four inches diameter, and fixed within six inches of the top of the post: the wheels being fixed, take 18 four or eight-ounce cases of brilliant fire, and place them round the first wheel with their mouths outwards, and inclining downwards; on the second wheel place 13 cases of the same, and in the same manner as those on the first; on the third, place eight more of these cases, in the same manner as before, and on the top of the post fix a gerbe; then clothe all the cases with leaders, so that both they and the gerbe may take fire at the same time. Before firing this work, try it in the water to see whether the float is properly made, so as to keep the fountain upright.

As the artificial fire-works which we have described require considerable caution in their preparation and management, and are attended with great expense, at fire-works attempts have been made to imitate some of the more simple kinds by optical delusion, and to give to the objects represented the appearance of moving fire, though they be really fixed, and no fire be employed. These attempts have been tolerably successful; and by means of this invention, a spectacle of artificial fire-works may be apparently exhibited at a trifling expense; and if the pieces employed are constructed with ingenuity, and with a proper attention to the rules of perspective, while in viewing them we employ glasses which magnify the objects, and prevent them from being too distinctly seen, a very agreeable illusion will be produced.

The artificial fire-works imitated with most success by this invention, are fixed sumis, gerbes, and jets of fire, cascades, globes, pyramids, and columns, moveable around their axes. To represent a gerbe of fire, take
PYROTECHNY.

Paper blackened on both sides, and very opaque; and having delineated on a piece of white paper the figure of a grue of fire, apply it to the black paper, and with the point of a very sharp penknife make several slashes (Plate CCCLVII. fig. 71.) in it, as 3, 5, or 7, proceeding from the origin of the grue: these lines must not be continued, but cut through at unequal intervals. Pierce these intervals with unequal holes made with a piercing iron, in order to represent the sparks of such a grue. In short, you must endeavour to paint by these lines and holes, the well known effect of the fire of inflamed gunpowder, when it issues through a small aperture.

According to the same principles, you may delineate the cascades (fig. 72.) and jets of fire which you are desirous of introducing into this exhibition, which is purely optical; and those jets of fire which proceed from the radii of suns, either fixed or moveable. It may easily be conceived, that in this operation taste must be the guide.

If you are desirous of representing globes, pyramids, or revolving columns, draw the outlines of them on paper, and then cut them out in a helical form; that is, cut out spirals with the point of a penknife, and of a size proportioned to that of the piece.

It is to be observed also, that as these different pieces have different colours, they may be easily imitated by pasting on the back of the paper, cut as here described, very fine silk paper coloured in the proper manner. As jets, for example, when loaded with Chinese fire, give a reddish light, you must paste to the back of these jets transparent paper, slightly tinged with red; and proceed in the same manner in regard to the other colours by which the different fire-works are distinguished.

When these preparations have been made, the next thing is to give motion, or the appearance of motion, to this fire, which may be done two ways, according to circumstances.

If a jet of fire, for example, is to be represented, prick unequal holes, and at unequal distances from each other, in a band of paper, fig. 73. and then move this band, making it ascend between a light and the above jet; the rays of light which escape through the holes of the moveable paper will exhibit the appearance of sparks rising into the air. It is to be observed that one part of the paper must be white; that another must be pierced with holes thinly scattered; that in another place they must be very close, and then moderately so: by these means it will represent those sudden jets of fire observed in fire-works.

To represent a cascade, the paper pierced with holes, instead of moving upwards, must be made to descend.

This motion may be easily produced by means of two rollers, on one of which the paper is rolled up, while it is unrolled from the other.

Suns are attended with some more difficulty; because in these it is necessary to represent fire, proceeding from the centre to the circumference. The artifice for this purpose is as follows.

On strong paper describe a circle, equal in diameter to the sun which you are desirous to exhibit, or even somewhat larger; then trace out on this circle two spirals, at the distance of a line or half a line from each other, and open the interval between them with a penknife, in such a manner, that the paper may be cut from the circumference, decreasing in breadth to a certain distance from the centre, fig. 74: cut the remainder of the circle into spirals of the same kind, open and close alternately; then cement the paper circle to a small iron hoop, supported by two pieces of iron, crossing each other in its centre, and adjust the whole to a small machine, which will suffer it to revolve round its centre. If this moveable paper circle, cut in this manner, be placed before the representation of your sun, with a light behind it, as soon as it is made to move towards that side to which the convexity of the spirals is turned, the luminous spirals, or those which afford a passage to the light, will give, on the image of the radii or jets of fire of your sun, the appearance of fire in continual motion, as if undulating from the centre to the circumference.

The appearance of motion may be given to columns, pyramids, and globes, cut through in the manner above described, by moving in a vertical direction a band of paper cut through into apertures, inclined at an angle rather different from that of the spirals. By these means the spectators will suppose that they see fire continually circulating and ascending along the spirals; and thus will be produced an optical illusion, in consequence of which the columns or pyramids will seem to revolve.

We have thus briefly explained the principle on which artificial fire-works may be imitated; and as the taste of the artist may suggest to him many circumstances which may improve the representation, and render the illusion stronger, we shall not enlarge further on the subject, but shall conclude this article with a few observations on illuminated prints and drawings, which are sometimes introduced as accompaniments in these imitations of artificial fire-works.

The mode of preparing these illuminations is thus described in Hutton's translation of Montucla's Recreations. Take some prints representing a castle, or palace, &c.; and having coloured them properly, cement paper to the back of them, in such a manner that they shall be only semitransparent; then, with piercing irons of different sizes, prick small holes in the places and on the lines where the lamps are generally placed, as along the sides of the windows, on the cornices or balustrades, &c. But care must be taken to make these holes smaller and closer, according to the perspective diminution of the figure. With other irons of a larger size, cut out, in other places, some stronger lights, so as to represent fire-pots, &c. Cut out also the panes in some of the windows, and cement to the back of them transparent paper of a green or red colour, to represent curtains drawn before them, and concealing an illuminated apartment.

When the print is cut in this manner, place it in the front of a sort of small theatre, strongly illuminated from the back part, and look at it through a convex glass of a pretty long focus, like that used in those small machines called optical boxes. If the rules of perspective have been properly observed in the prints, and if the lights and shades have been distributed with taste, this spectacle will be highly agreeable.

Before dismissing this subject, it may not be improper to point out the most effectual means of relieving those areas of the burn, to which fire-workers are so much exposed.

When the burn is first received, and before blisters arise, the best applications are oil of turpentine, strong spirits,
PYROTECHNY.

spirits, rectified spirit of wine, or camphorated spirit, with which linen rags must be wetted and kept moist on the part till the pain abates. If no other remedy can be procured, immersing the part for a long time in cold water will often afford great relief. When these means have been neglected, and blisters arise, if these are small, they should not be opened; but if large, the water must be let out, and the sore covered with rags spread with a mixture of linseed oil and lime water, in the proportion of one part of the former to three of the latter. We must remark, however, that in all cases of extensive burns, or where some very delicate part is injured, speedy recourse should be had to medical assistance.

PYR.

PYROTICS, in Medicine, caustics, or remedies either actually or potentially hot; and which accordingly will burn the flesh, and raise an eschar. See CAUSTICITY.

PYRRHICA, in antiquity, a kind of exercise on horseback, or a feigned combat, for the exercise of the cavalry.

It was thus called from its inventor Pyrrhichus, or Pyrrhus of Cydonia, who first taught the Cretans to march in measure and cadence to battle, and to observe the pace of the Pyrrhic foot. Others derive the name from Pyrrhus the son of Achilles, who instituted this exercise at the bequest of his father. Aristotle says, that it was Achilles himself who invented it.

The Romans also called it ludus Trojanus, "the Trojan game," and Aulus Gellius decursus. It is doubtless this exercise that we see represented on medals by two cavaliers in front running with lances, and the word decursio in the exergum.

PYRRIFICHIUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short;—as, Deos. Among the ancients this foot is also called periambus; by others bogomana.

PYRROH, a Greek philosopher, born at Elis in Peloponnesus, flourished about 300 B.C. He was the disciple of Anaxarchus, whom he accompanied as far as India, where he conversed with the Brahmins and Gymnosophists. He had made painting his profession before he devoted himself to the study of philosophy. He established a sect whose fundamental principle was, That there is nothing true or false, right or wrong, honest or dishonest, just or unjust; or that there is no standard of anything beyond law or custom, and that uncertainty and doubt belong to everything. From this continual seeking after truth and never finding it, the sect obtained the name of Sceptics or Pyrrhonians, from the founder, who is said to have acted upon his own principles, and to have carried his scepticism to such a ridiculous extreme, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. If this was true, it was not without reason that he was ranked among those whose intellects were disturbed by intense study. But it is treated by a modern writer as a mere calumny invented by the dogmatists; and we are strongly inclined to believe of his opinion, (see SCEPTICS.) Pyrrho died about the 40th year of his age, when his memory was honoured with a statue at Athens, and a monument erected to him in his own country.

PYTHAGORAS, a celebrated philosopher of anti-
quity, respecting the time and place of whose birth the learned are much divided. Eratosthenes asserts, that in the 48th Olympiad*, when he was very young, he was a victor at the Olympic games. Hence M. L. Ch. 5. 55.

Bentley † determines the date of his birth to be the 4th year of the 43d Olympiad; whilst Lloyd ‡, who denies that the Olympic victor was the same person with the phi-

philosopher places it about the 3d year of the 48th O-

chron. of lympid. Mr. Dodwell § differs from both, and wishes Pythago-

Two Diss. on the age Chez le tom. x. p. 81. &c. and from a review of the of Priene and Py-

thagoras.

The arguments of these learned writers, Le Clerc has given a summary in the Bibliothèque on the age

In the year of the 43d Olympiad, or later than the 4th year of the 52d Olympiad. Of the arguments of these learned writers, Le Clerc has given a summary in the Bibliothèque of the age

of Pythagoras, who is thought by some to have been a lapidea-

lary, and by others a merchant of Tyre, appears to have cap.

been a man of some distinction, and to have bestowed upon his son the best education.

Jambicetus † relates a number of wonderful stories re-

Py-

pecting Pythagoras's descent from Jupiter, his birth, and early life; and represents him even in his youth as a prodigy of wisdom and manly seriousness. But most of these idle tales confute themselves, afford nothing of importance to be depended upon, and only prove the credulity, carelessness, and prejudice of their author. Of his childhood and early education we know nothing, except that he was first instructed in his own country by Creophilus, and afterwards in Sicily by Thales (see Thales.) According to the custom of the times he was made acquainted with poetry and music; eloquence and astronomy became his private studies, and in gymnastic exercises he often bore the palm for strength and dexterity. He first distinguished himself in Greece at the Olympic games, where, beside gaining the prize, he is said to have excelled the highest admiration by the elegance and dignity of his person, and the brilliancy of his understanding.

4 C 2
Soon after his appearance at these games, Pythagoras commenced his travels in quest of knowledge. He first visited Egypt, where, through the interest of Polycrates tyrant of Samos, he obtained the patronage of Amasis king of Egypt, by whose influence, combined with his own assiduity, patience, and perseverance, he at length gained the confidence of the priests; from whom he received their sacred mysteries, the alphabet, and the whole system of symbolical learning. In Egypt, too, he became acquainted with geometry and the true solar system; and, before he left that country, made himself master of all the learning for which it was so famed among the nations of antiquity.

He afterwards visited Persia and Chaldæa, where from the Magi he learnt divination, the interpreting of dreams, and astronomy. He is likewise said to have travelled into India, to have conversed with the Gymnosophists, and to have acquired from them a knowledge of the philosophy and literature of the east; and such was his ardour in the pursuit of science, that in quest of it he crossed many seas, and travelled on foot through many barbarous nations.

After Pythagoras had spent many years in gathering information on every subject, especially respecting the nature of the gods, the rites of religion, and the immortality of the human soul, he returned to his native island, and attempted to make his knowledge useful by instituting a school for the instruction of his countrymen. Failing of success in this laudable undertaking, he repaired to Delos, where he pretended to receive moral dogmas from the priestess of Apollo. He also visited Crete, where he was initiated into the most sacred mysteries of Greece. He went likewise to Sparta and Elisa, and again assisted at the Olympic games; where in the public assembly he was saluted with the title of sophist or wise man, which he declined for one more humble. See PHILOGY, No. 1. and PHILOSOPHY, No. 1.

He returned to Samos enriched with mythological learning and mysterious rites, and again instituted a school. His mysterious symbols and oracular precepts made this attempt more successful than the former had been; but meeting with some opposition, or being detected in some pious frauds, he suddenly left Samos, retired to Magna Grecia, and settled at Crotona.

Here he founded the Italic sect (see PHILOSOPHY, No. 20.) and his mental and personal accomplishments, the fame of his distant travels, and his Olympic crown, soon procured him numerous pupils. His bold and manly eloquence and graceful delivery attracted the most dissolute, and produced a remarkable change in the morals of the people of Crotona. His influence was increased by the regularity of his own example, and its conformity to his precepts. He punctually attended the temples of the gods, and paid his devotions at an early hour; he lived upon the purest and most innocent food, clothed himself like the priests of Egypt, and by his continual purifications and regular offerings appeared to be superior in sanctity to the rest of mankind. He endeavoured to assuage the passions of his scholars with verses and numbers, and made a practice of composing his own mind every morning, by playing on his harp, and singing along with it the poems of Thales. To avoid the temptations of ease and the seductions of idleness, bodily exercises also made a considerable part of his discipline.

At Crotona he had a public school for the general benefit of the people, in which he taught them their duty, praising virtue and condemning vice; and particularly instructing them in the duties of social life. Besides this, he had a college in his own house, which he denominated academus, in which there were two classes of students, viz. egereus, who were also called conantians, and sororitans. The former of these were probationers, and were kept under a long examen. Silence of five years was imposed upon them; which Apuleius thinks was intended to teach them modesty and attention; but Clemens Alexandrinus thinks it was for the purpose of abstracting their minds from sensible objects, and inuring them to the pure contemplation of the Deity. The latter class of scholars were called genuini, perfecti, mathematici, and, by way of eminence, Pythagoreans. They alone were admitted to the knowledge of the arcana and depths of Pythagoric discipline, and were taught the use of ciphers and hieroglyphic writings.

Clemens observes, that these orders corresponded very exactly to those among the Hebrews: for in the schools of the prophets, there were two classes, viz. the sons of the prophets, who were the scholars, and the doctors or masters, who were also called perfecti; and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the proselytes there were two orders; eexteriores, or proselytes of the 4th; and intrinseci or perfecti, proselytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a proselyte of the gate, if not of the covenant. Gale endeavours to prove that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers and ancient authors, and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras’s doctrine. But we believe the learned author was misled by the Christian Platonists.

The authority of Pythagoras among his pupils was so great, that it was even deemed a crime to dispute his word; and their arguments were considered as infallibly convincing, if they could enforce them by adding, that “the master said so;” an expression which afterwards became proverbial in jurare in verba magistri. This influence over his school was soon extended to the world, and even his pupils themselves divided the applause and approbation of the people with their masters; and the rulers and legislators of all the principal towns of Greece, Sicily, and Italy, boasted of being the disciples of Pythagoras. To give more weight to his exhortations, as some writers mention, Pythagoras retired into a subterraneous cave, where his mother sent him intelligence of every thing which happened during his absence. After a certain number of months he again re-appeared on the earth with a grim and ghastly countenance, and declared in the assembly of the people that he was returned from hell. From similar exaggerations it has been asserted that he appeared at the Olympic games with a golden thigh, and that he could write in letters of blood whatever he pleased on a looking-glass; and that by setting it opposite to the moon, when full, all the characters which were on the glass
Pythagoras became legible on the moon's disc. They also relate, that by some magical words he tamed a bear, stopped the flight of an eagle, and appeared on the same day and at the same instant in the cities of Crotona and Metapontum, &c.

At length his singular doctrines, and perhaps his strenuously asserting the rights of the people against their tyrannical governors, excited a spirit of jealousy, and raised a powerful party against him; which soon became so outrageous as to oblige him to fly for his life. His friends fled to Rhegium; and he himself, after being refused protection by the Locrians, fled to Metapontum, where he was obliged to take refuge in the temple of the muses, and where it is said he died of hunger about 497 years before Christ. Respecting the time, place, and manner of his death, however, there are various opinions, and many think it uncertain when, where, or in what manner he ended his days. After his death his followers paid the same respect to him as was paid to the immortal gods; they erected statues in honour of him, converted his house at Crotona into a temple to Ceres, appealed to him as a deity, and swore by his name.

Pythagoras married Theano of Crotona, or, according to others, of Crotz, by whom he had two sons, Te- lauges and Menarchus, who, after his death, took care of his school. He is said also to have had a daughter called Deamon.

Whether he left any writings behind him is disputed. It seems probable, however, that he left none, and that such as went under his name were written by some of his followers. The golden verses which Hierocles illustrated with a commentary, have been ascribed to Epiphanus or Empedocles, and contain a brief summary of his popular doctrines. From this circumstance, and from the mysterious secrecy with which he taught, our information concerning his doctrine and philosophy is very uncertain, and cannot always be depended on.

The purpose of philosophy, according to the system of Pythagoras, is to free the mind from incumbrances, and to raise it to the contemplation of immutuble truth and the knowledge of divine and spiritual objects. To bring the mind to this state of perfection is a work of some difficulty, and requires a variety of intermediate steps. Mathematical science was with him the first step to wisdom, because it inures the mind to contemplation, and takes a middle course between corporeal and incorporeal beings. The whole science he divided into two parts, numbers and magnitude; and each of these he subdivided into two others, the former into arithmetic and music, and the latter into magnitude at rest and in motion; the former of which comprehends geometry, and the latter astronomy. Arithmetic he considered as the noblest science, and an acquaintance with numbers as the highest good. He considered numbers as the principles of every thing; and divided them into scientific and intelligible. Scientific number is the production of the powers involved in unity, and its return to the same; number is not infinite, but is the source of that infinite divisibility into equal parts which is the property of all bodies. Intelligible numbers are those which existed in the divine mind before all things. They are the model or archetype of the world, and the cause of the essence of beings. Of the Monad, Duad, Triad, Tetrad, and Decad, various explanations have been given by various authors; but nothing certain or important is known of them. In all probability, numbers were used by Pythagoras as symbolical representations of the first principles and forms of nature, and especially of those eternal and immutable essences which Plato denominated ideas; and in this case the Monad was the simple root from which he conceived numbers to proceed, and as such, analogous to the simple essence of deity; from whence, according to his system, the various properties of nature proceed.

Music followed numbers, and was useful in raising the mind above the dominion of the passions. Pythagoras considered it as a science to be reduced to mathematical principles and proportions, and is said to have discovered the musical chords from the circumstance of several men successively striking with hammers a piece of heated iron upon an anvil. This story Dr. Burney's History discredits; but allows, from the uniform testimony of Music, writers ancient and modern, that he invented the monical canon or monochord, (see Monochord). The music of the spheres, of which every one has heard, was a most fanciful doctrine of Pythagoras. It was produced, he imagined, by the planets striking on the ether through which in their motion they passed; and he considered their musical proportions as exact, and their harmony perfect.

Pythagoras, as we have already seen, learned geometry in Egypt; but by investigating many new theorems, and by digesting its principles, he reduced it to a more regular science. A geometrical point, which he defines to be a monad, or unity with position, he says corresponds to unity in arithmetic, a line to two, a superficies to three, and a solid to four. He discovered several of the propositions of Euclid; and on discovering the 47th of book 1st, he is said to have offered a heca-tomb to the gods; but as he was averse to animal sacrifices, this assertion is surely false. His great progress in astronomical science has been mentioned elsewhere. See Astronomy, No 11, 22, and Philosophy, No 15, 16.

Wisdom, according to Pythagoras, is conversant with those objects which are naturally immutable, eternal, and incorruptible; and its end is to assimilate the human mind to the divine, and to qualify us to join the assembly of the gods. Active and moral philosophy prescribes rules and precepts for the conduct of life, and leads us to the practice of public and private virtue.—On these heads many of his precepts were excellent, and some of them were whimsical and useless. Theoretical philosophy treats of nature and its origin, and is, according to Pythagoras, the highest object of study. It included all the profound mysteries which he taught, of which but little is now known. God he considers as the universal mind, diffused through all things, and the self-moving principle of all things, and of whom every human soul is a portion. It is very probable, that he conceived of the Deity as the inanimate, eternal, active, and intelligent; which is not inconsistent with the idea of incorporeality, as the ancients understood that term. This Deity was primarily combined with the chaotic mass of passive matter, but he had the power of separating himself, and since the separation he has remained distinct. The learned Codworth
Pythagoras, worth contends, that Pythagoras maintained a trinity of hypostases in the divine nature, similar to the Platonic triad (see PLATONISM). We cannot say that his arguments appear to have much force; but we think the conclusion which he wishes to establish extremely probable, as Plato certainly drew his doctrine from some of the countries which Pythagoras had visited before him.

Subordinate to the Deity there were in the Pythagorean creed three orders of intelligences, gods, demons, and heroes, of different degrees of excellence and dignity. These, together with the human soul, were considered as emanations from the Deity, the particles of subtle ether assuming a grosser clothing the farther they receded from the fountain. Hierocles defines a hero to be a rational mind united with a luminous body. God himself was represented under the notion of monad, and the subordinate intelligences as numbers derived from and included in unity. Man is considered as consisting of an elementary nature and a divine or rational soul. His soul, a self-moving principle, is composed of two parts; the rational, seated in the brain; and the irrational, including the passions, in the heart. In both respects he participates with the brutes, whom the temperament of their body, &c. allows not to act rationally. The sensitive soul perishes; the other assumes an ethereal vehicle, and passes to the region of the dead, till sent back to the earth to inhabit some other body, brutal or human. See METEMPSYCHOSIS. It was unquestionably this notion which led Pythagoras and his followers to deny themselves the use of flesh, and to be so peculiarly merciful to animals of every description. Some authors, however, say, that flesh and beans, the use of which he also forbade, were prohibited, because he supposed them to have been produced from the same putrefied matter, from which, at the creation of the world, man was formed.

Of the symbols of Pythagoras little is known. They have been religiously concealed; and though they have awakened much curiosity, and occasioned many ingenious conjectures, they still appear to us dark and trifling. As a specimen we give the following: "Adore the sound of the whispering wind. Stir not the fire with a sword. Turn aside from an edged tool. Pass not over a balance. Setting out on a journey, turn not back, for the furies will return with you. Breed nothing that hath crooked talons. Receive not a swallow into your house. Look not in a mirror by the light of a candle. At a sacrifice pare not your nails. Eat not the heart or brain. Taste not that which hath fallen from the table. Break not bread. Sleep not at noon. When it thunders touch the earth. Pluck not a crown. Roast not that which has been boiled. Sail not on the ground. Plant not a palm. Breed a cock, but do not sacrifice it, for it is sacred to the sun and moon. Plant mallows in thy garden, but eat them not. Abstain from beans."

The following precepts are more important: "Disown not of Pythagorean doctrines without light. Above all things govern your tongue. Engrave not the image of God in a ring. Quit not your station with the command of your general. Remember that the paths of virtue and of vice resemble the letter Y. To this symbol Persius refers, when he says,

Pythagoras did not write his speculations in a book, but his philosophy was transmitted through oral communication and musical notation. His system was grounded in mathematics and geometry, and he believed that the Universe could be understood through numbers. His pupils, the Pythagoreans, continued his work and spread his teachings throughout the ancient world.
Q or q, the 16th letter and 12th consonant of our alphabet; but is not to be found either in the Greek, old Latin, or Saxon alphabets; and indeed some would entirely exclude it, pretending that it ought to be used wherever this occurs. However, as it is formed in the voice in a different manner, it is undoubtedly a distinct letter: for, in expressing this sound, the cheeks are contracted, and the lips, particularly the under one, are put into a canular form, for the passage of the breath.

The q is never sounded alone, but in conjunction with u, as in quality, question, quite, quote, &c. and never ends any English word.

As a numeral, Q stands for 900; and with a dash over it, thus Q, for 900,000.

Used as an abbreviation q signifies quantity, or quantum. Thus, among physicians, q. pl. is quantum placet; i.e. "as much as you please" of a thing; and q.s. is quantum sufficit, i.e. "as much as is necessary." Q. E. D. among mathematicians, is quod erat demonstrandum, i.e. "which was to be demonstrated:" and Q. E. F. is quod erat faciendum, i.e. "which was to be done." Q. D. among grammarians is quasi dictum, i.e. "as if it were said:" or, "as who should say." In the notes of the ancients, Q stands for Quintus, or Quintus; Q. B. V. for quod bene vertit; Q. S. S. for quae sunt super scripta; Q. M. for Quintus Mutius; Qumodo; Q. Q. for Quintilius; and Ques. for quas est.

QUAB, in Ichthyology, the name of a Russian fish, which is said to be at first a tadpole, then a frog, and at last a fish. Dr. Mounsey, who made many inquiries concerning these pretended changes, considers all of them as fabulous. He had opportunity of seeing the fish itself, and found that they spawned like other fishes, and grew in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in standing lakes, or in rivers passing through marshes or mossy grounds, where frogs most of all.

QUABES, are a free people of Africa, inhabiting the southern banks of the river Sestos, and between that and Sierra Leone. They are under the protection of the emperor of Manow.

QUACHA, or Quagga. See Equus, Mammalia Index.

QUACHILTO, in Ornithology, is the name of a very beautiful Brazilian bird, called also porciznto and porphyrio Americanus. It is of a fine blackish-purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its basis, resembling in some sort the coot; its legs are of a yellowish green; it lives about the waters, and feeds on fish, yet is a very well tasted bird. It imitates the crowing of a common cock, and makes its music early in the morning.

QUACK, among physicians, the same with empiric. See Empric.

QUADI, (Tacitus): a people of Germany, situated to the south-east of the mountains of Bohemia, on the banks of the Danube, and extending as far as the river Marus, or March, running by Moravia, which country they occupied.

QUADAGESIMA, a denomination given to lent, from its consisting of 40 days. See LENT.

QUADRAGEMENTE, in Geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the a., or pound.

QUADRANS, in English money, the fourth part of a penny. Before the reign of Edward I. the smallest coin was a sterlining, or penny, marked with a cross; by the guidance of which a penny might be cut into halves for a halfpenny, or into quarters or four parts for farthings; till, to avoid the fraud of unequal cuttings, that king coined halfpence and farthings in distinct round pieces.

QUADANT, in Geometry, the arch of a circle, containing 90°, or the fourth part of the entire periphery.

Sometimes also the space or area, included between this arch and two radii drawn from the centre to each extremity thereof, is called a quadrant, or, more properly, a quadrantal space, as being a quarter of an entire circle.

QUADANT, also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also for taking angles in surveying, &c.

This instrument is variously contriv'd, and furnished with different apparatus, according to the various uses it is intended for; but they all have this in common, that they consist of a quarter of a circle, whose limb is divided into 90°. Some have a plummet suspended from the centre, and are furnished with sights to look through.

The principal and most useful quadrants are the common surveying quadrant, astronomical quadrant, Adams's quadrant, Cole's quadrant, Gunter's quadrant, Hadley's quadrant, horoditical quadrant, Sutton's or Collins's quadrant, and the sinical quadrant, &c. Of each of which in order.

1. The common surveying quadrant, is made of brass, wood, or any other solid substance; the limb of which is divided into 90°, and each of these farther divided into as many equal parts as the space will allow, either diagonally or otherwise. On one of the semidiameters are fitted two movable sights; and to the centre is sometimes also fixed a label, or moveable index, bearing two other sights; but in lieu of these last sights there is sometimes fitted a telescope: also from the centre there is hung a thread with a plummet; and on the under side or face of the instrument is fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from
Quadrant. from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. But besides the parts already described, there is frequently added to the face, near the centre, a kind of compartment, called the quadrant, or geometrical square. See Quadrant.

This quadrant may be used in different situations: for observing heights or depths, its plane must be disposed perpendicularly to the horizon; but to take horizontal distances, its plane is disposed parallel thereto. Again, heights and distances may be taken two ways, viz. by means of the fixed sights and plummet, or by the label: As to which, and the manner of measuring angles, see Geometry and Mensuration.

2. The astronomical quadrant is a large one, usually made of brass, or wooden bars faced with iron plates; having its limb nicely divided, either diagonally or otherwise, into degrees, minutes, and seconds; and furnished with two telescopics, one fixed on the side of the quadrant, and the other movable about the centre, by means of the screw. There are also dented wheels which serve to direct the instrument to any object or phenomenon. The use of this curious instrument, in taking observations of the sun, planets, and fixed stars, is obvious; for being turned horizontally upon its axis, by means of the telescopics, till the object is seen through the movable telescopics, then the degrees, &c. cut by the index give the altitude required. See Astronomical Index.

3. Cole’s quadrant is a very useful instrument invented by Mr Benjamin Cole. It consists of six parts, viz. the staff AB (fig. 1); the quadrantal arch DE; three vanes A, B, C; and the vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is also of wood; and is divided into degrees, and third parts of a degree, to a radius of about nine inches; to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, round which it easily moves. The sight-vane A is a thin piece of brass, about two inches in height and one broad, placed perpendicularly on the end of the staff A, by the help of two screws passing through its foot. Through the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizon vane B is about an inch broad, and two inches and a half high, having a slit cut through it of near an inch long and a quarter of an inch broad; this vane is fixed in the centre-pin of the instrument, in a perpendicular position, by the help of two screws passing through its foot, whereby its position with respect to the sight-vane is always the same, their angles of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one, which serves as an arm, is about four inches and a half long, and three quarters of an inch broad, being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin: the other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate, at about half an inch distance from that end next the arch; this vane may be used either by its shade or by the solar spot cast by a convex lens placed therein. And, because the wood-work is often apt to warp or twist, therefore this vane may be rectified by the help of a screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner:—Set the line G on a vernier against a degree on the upper limb of the quadrant, and turn a screw on the backside of the limb forward or backward, till the hole in the sight-vane, the centre of the glass, and the sunk spot in the horizon-vane lie in a right line.

To find the sun’s altitude by this instrument. Turn your back to the sun, holding the instrument by the staff with your right hand, so that it be in a vertical plane passing through the sun; apply your eye to the sight-vane, looking through that and the horizon-vane till you see the horizon; with the left hand slide the quadrantal arch upwards, until the solar spot or shade, cast by the shade-vane, fall directly on the spot or slit in the horizon-vane; then will that part of the quadrantal arch, which is raised above G or S (according as the observation respects either the solar spot or shade) show the altitude of the sun at that time. But if the meridian altitude be required, the observation must be continued; and as the sun approaches the meridian, the sea will appear through the horizon-vane, and then is the observation finished; and the degrees and minutes, counted as before, will give the sun’s meridian altitude: or the degrees counted from the lower limb upwards will give the zenith-distance.

4. Adams’s quadrant differs only from Cole’s quadrant in having an horizontal vane, with the upper part of the limb lengthened; so that the glass, which casts the solar spot on the horizon-vane, is at the same distance from the horizon-vane as the sight-vane at the end of the index.

5. Gunter’s quadrant, so called from its inventor Edmund Gunter, besides the usual apparatus of other quadrants, has a stereographical projection of the sphere on the plane of the equinoctial. It has also a calendar of the months, next to the divisions of the limb.

Use of Gunter’s quadrant. 1. To find the sun’s meridian altitude for any given day, or the day of the month for any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; and the degree it cuts in the limb is the sun’s meridian altitude. Thus the thread, being laid on the 15th of May, cuts 59° 30’, the altitude sought; and, contrariwise, the thread, being set to the meridian altitude, shows the day of the month. 2. To find the hour of the day. Having put the head, which slides on the thread, to the sun’s place in the ecliptic, observe the sun’s altitude by the quadrant; then, if the thread be laid over the same in the limb, the head will fall upon the hour required. Thus suppose on the 10th of April, the sun being then in the beginning of Taurus, I observe the sun’s altitude by the quadrant to be 36°; I place the head to the beginning of Taurus in the ecliptic, and lay the thread over 36° of the limb; and find the head to fall on the hour-line marked three and nine; accordingly the hour is either nine in the morning or three in the afternoon. Again, laying the head on the hour given, having first rectified or put it to the sun’s place, the degree cut by the thread on the limb gives the altitude. Note, the head may be rectified otherwise, by bringing
forming a kind of cross, without touching the circle, Quadrant, he showed him that there was not an error of a single second in the 52 degrees; and that the difference was occasioned by a mural quadrant of Bird, in which the arc of 52 degrees was too great by several seconds, and which had never been rectified by so nice a method as that of Mr Ramsden.

But the quadrant is not the instrument which stands highest in Mr Ramsden's opinion; it is the complete circle: and he has demonstrated to M. de la Lande, that the former must be laid aside, if we would arrive at the utmost exactness of which an observation is capable. His principal reasons are: 1. The least variation in the centre is perceived by the two diametrically opposite points. 2. The circle being worked on the turn, the surface is always of the greatest accuracy, which it is impossible to obtain in the quadrant. 3. We may always have two measures of the same arc, which will serve for the verification of each other. 4. The first point of the division may be verified every day with the utmost facility. 5. The dilatation of the metal is uniform, and cannot produce any error. 6. This instrument is a meridian glass at the same time. 7. It also becomes a moveable azimuth circle by adding a horizontal circle beneath its axis, and then gives the refractions independent of the mensuration of time.

6. Hadley's quadrant is an instrument of vast utility both in navigation and practical astronomy. It derives its name from Mr Hadley, who first published an account of it, though the first thought originated with the celebrated Dr Hooke, and was completed by Sir Isaac Newton (see Astronomy, N° 22. and also N° 17. and 22.). The utility of this quadrant arises from the accuracy and precision with which it enables us to determine the latitude and longitude; and to it is navigation much indebted for the very great and rapid advances it has made of late years. It is easy to manage, and of extensive use, requiring no peculiar steadiness of hand, nor any such fixed basis as is necessary to other astronomical instruments. It is used as an instrument for taking angles in maritime surveying, and with equal facility at the mast head as upon the deck, by which its sphere of observation is much extended; for supposing many islands to be visible from the mast head, and only one from deck, no useful observation can be made by any other instrument. But by this, angles may be taken at the mast head from the one visible object with great exactness, and further taking angles from heights, as hills, or a ship's mast's head, is almost the only way of describing exactly the figure and extent of shoals.

It has been objected to the use of this instrument for surveying, that it does not measure the horizontal angles, by which alone a plan can be laid down. This objection, however true in theory, may be reduced in practice by a little caution; and Mr Adams has given very good directions for doing so.

Notwithstanding, however, the manifest superiority of this instrument over those that were in use at the time of its publication, it was many years before the sailors could be persuaded to adopt it, and lay aside their imperfect and inaccurate instruments, so great is the difficulty to remove prejudice, and emancipate the mind from the slavery of opinion. No instrument has undergone, since the original invention, more changes than
Quadrant, than the quadrant of Hadley; of the various alterations, many had no better foundation than the caprice of the makers, who by these attempts have often rendered the instrument more complicated in construction, and more difficult in use, than it was in its original state.

It is an essential property of this instrument, derived from the laws of reflection, that half degrees on the arc answer to whole ones in the angles measured: hence an octant, or the eighth part of a circle, or 45 degrees on the arch, serves to measure 90 degrees; and sextants will measure an angular distance of 120 degrees, though the arch of the instrument is no more than 60 degrees. It is from this property that foreigners term that instrument an octant, which we usually call a quadrant, and which in effect it is. This property reduces indeed considerably the bulk of the instrument: but at the same time it calls for the utmost accuracy in the divisions, as every error on the arch is doubled in the observation.

Another essential, and indeed an invaluable, property of this instrument, whereby it is rendered peculiarly advantageous in marine observations, is, that it is not liable to be disturbed by the ship's motion; for provided the mariner can see distinctly the two objects in the field of his instrument, no motion nor vibration of the ship will injure his observation.

Thirdly, the errors to which it is liable are readily discovered and easily rectified, while the application and use of it is facile and plain.

To find whether the two surfaces of any one of the reflecting glasses be parallel, apply your eye at one end of it, and observe the image of some object reflected very obliquely from it; if that image appear single, and well-defined about the edges, it is a proof that the surfaces are parallel: on the contrary, if the edge of the reflected images appear misted, as if it threw a shadow from it, or separated like two edges, it is a proof that the two surfaces of the glass are inclined to each other: if the images in the spectulum, particularly if that image be the sun, be viewed through a small telescope, the examination will be more perfect.

To find whether the surface of a reflecting glass be plane. Choose two distant objects, nearly on a level with each other: hold the instrument in an horizontal position, view the left-hand object directly through the transparent part of the horizon-glass, and move the index till the reflected image of the other is seen below it in the silvered part; make the two images unite just at the line of separation, then turn the instrument round slowly on its own plane, so as to make the united images move along the line of separation of the horizon-glass: if the images continue united without receding from each other, or varying their respective position, the reflecting surface is a good plane.

To find if the two surfaces of a red or darkening glass are parallel and perfectly plane. This must be done by means of the sun when it is near the meridian, in the following manner: hold the sextant vertically, and direct the sight to some object in the horizon, or between you and the sky, under the sun; turn down the red glass and move the index till the reflected image of the sun is in contact with the object seen directly; fix then the index, and turn the red glass round in its square frame; view the sun's image and object immediately, and if the sun's image is neither raised nor depressed, but continues in contact with the object below, as before, then the surfaces of the darkening glass are true.

For a more particular description of Hadley’s quadrant, and the mode of using it, see Navigation, Book II. chap. i.

This instrument has undergone several improvements since its first invention, and among these improvements must be ranked Mr. Ramsden. He found that the essential parts of the quadrant had not a sufficient degree of solidity; the friction at the centre was too great, and in general the alidade might be moved several minutes without any change in the position of the mirror; the divisions were commonly very inaccurate, and Mr. Ramsden found that Abbé de la Caille did not exceed the truth in estimating at five minutes the error to which an observer was liable in taking the distance between the moon and a star; an error capable of producing a mistake of 50 leagues in the longitude. On this account Mr. Ramsden changed the principle of construction of the centre, and made the instrument in such a manner as never to give an error of more than half a minute; and he has now brought them to such a degree of perfection as to warrant it not more than six seconds in a quadrant of fifteen inches. Since the time of having improved them, Mr. Ramsden has constructed an immense number; and in several which have been carried to the East Indies and America, the deficiency has been found no greater at their return than it had been determined by examinations before their being taken out. Mr. Ramsden has made them from 3½ inches to an inch and a half, in the latter of which the minutes are easily distinguishable; but he prefers for general use those of ½ inches, as being more easily handled than the greater, and at the same time capable of equal accuracy. See Sextant.

A great improvement was also made in the construction of this quadrant by Mr. Peter Dollond, famous for his invention of achromatic telescopes. The glasses of the quadrants should be perfect planes, and have their surfaces perfectly parallel to one another. By a practice of several years, Mr. Dollond found out methods of grinding them of this form to great exactness; but the advantage which should have arisen from the goodness of the glasses was often defeated by the index-glass being bent by the frame which contains it. To prevent this, Mr. Dollond contrived the frame so that the glass lies on three points, and the part that presses on the front of the glass has also three points opposite to the former. These points are made to confine the glass by three screws at the back, acting directly opposite to the points between which the glass is placed. The principal improvements, however, are in the methods of adjusting the glasses, particularly for the back-observation. The method formerly practised for adjusting that part of the instrument by means of the opposite horizons at sea, was attended with so many difficulties that it was scarcely ever used: for so little dependence could be placed on the observations taken this way, that the best Hadley's sextants, made for the purpose of observing the distances of the moon from the sun or fixed stars, have been always made without the horizon-glass for the back-observation; for want of which, many valuable observations of the sun and moon have been lost, when their distance exceeded 20 degrees.
Quadrant. gueses. To make the adjustment of the back-observation easy and exact, he applied an index to the back horizon-glass, by which it may be moved in a parallel position to the index-glass, in order to give it the two adjustments in the same manner as the fore horizon-glass is adjusted. Then, by moving the index to which the back horizon-glass is fixed exactly 90 degrees (which is known by the divisions made for that purpose), the glass will thereby be set at right angles to the index-glass, and will be properly adjusted for use; and the observations may be made with the same accuracy by this as by the fore-observer. To take the horizon-glasses in the perpendicular position to the plane of the instrument, he contrived to move each of them by a single screw, which goes though the frame of the quadrant, and is turned by means of a milled head at the back; which may be done by the observer while he is looking at the object. To these improvements also he added a method invented by Dr Maskelyne, of placing darkening-glasses behind the horizon-glasses. These, which serve for darkening the object seen by direct vision, in adjusting the instrument by the sun or moon, he placed in such a manner as to be turned behind the fore horizon-glass, or behind the back horizon-glass: there are three of these glasses of different degrees of darkness.

We have been the more particular in our description and use of Hadley's quadrant, as it is undoubtedly the best hitherto invented.

7. Horological quadrant, a very commodious instrument, so called from its use in telling the hour of the day.—Its construction is this: From the centre of the quadrant, C, fig. 3, whose limb AB is divided into 90°, describe seven concentric circles at intervals at pleasure; and to these add the signs of the zodiac, in the order represented in the figure. Then applying a ruler to the centre C and the limb AB, mark upon the several parallels the degrees corresponding to the altitude of the sun when therein, for the given hours; connect the points belonging to the same hour with a curve line, to which add the number of the hour. To the radius CA fit a couple of sights, and to the centre of the quadrant C tie a thread with a plummet, and upon the thread a bead to slide. If now the thread be brought to the parallel wherein the sun is, and the quadrant directed to the sun, till a visual ray pass through the sights, the bead will show the hour; for the plummet, in this situation, cuts all the parallels in the degrees corresponding to the sun's altitude. Since the bead is in the parallel which the sun describes, and through the degrees of altitude to which the sun is elevated every hour there pass hour lines, the bead must show the present hour. Some represent the hour-lines by arches of circles, or even by straight lines, and that without any sensible error.

8. Sutton's or Collins's quadrant (fig. 4.) is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole: it is fitted to the latitude of London. The lines running from the right hand to the left are parallels of altitude; and those crossing them are azimuths. The lesser of the two circles bounding the projection, is one-fourth of the tropic of Capricorn; the greater is one-fourth of that of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and, by having the sun's altitude, the hour of the day may be found here to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the sun's declination. On the projection are placed several of the most noted fixed stars between the tropics; and the next below the projection is the quadrant and line of shadows. To find the time of the sun's rising or setting, its amplitude, his azimuth, hour of the day, &c. by this quadrant: lay the thread over the day and the month, and bring the bead to the proper axis, either of summer or winter, according to the season, which is called rectifying; then, moving the thread, bring the bead to the horizon, in which case the thread will cut the limb in the time of the sun's rising or setting before or after six; and at the same time the bead will cut the horizon in the degrees of the sun's amplitude.—Again, observing the sun's altitude with the quadrant, and supposing it found 45° on the fifth of May, lay the thread over the fifth of May, bring the bead to the summer axis, and carry it to the parallel of altitude 45°; in which case the thread will cut the limb at 5° 15', and the hour will be seen among the hour-lines to be either 41° past nine in the morning, or 19° past two in the afternoon.—Lastly, the bead among the azimuths shows the sun's distance from the south 50° 41'. But note, that if the sun's altitude be less than what it is at six o'clock, the operation must be performed among those parallels above the upper horizon, the bead being rectified to the winter axis.

9. Sinical quadrant (fig. 5.) consists of several con-

Fig. 3.

centric quadrantal arches, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles. Now any one of the arches, as BC, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then BC be taken for a quadrant of the horizon, either of the sides, as AB, may represent the meridian; and the other side, AC, will represent a parallel, or line of east and west; and all the other lines, parallel to AB, will be also meridians; and all those parallel to AC, east and west lines, or parallels.—Again, the eight spaces into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11° 15'. The arch BC is likewise divided into 90°, and each degree subdivid-
ed into 12, diagonal-wise. To the centre is fixed a thread, which, being laid over any degree of the quadrant, serves to divide the horizon.

If the sinical quadrant be taken for a fourth part of the meridian, one side thereof, AB, may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degrees of the circumference, BC, will represent degrees of latitude; and the parallels to the side AB, assumed from every point of latitude to the axis AC, will be radii of the parallels of latitude, as likewise the sine of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lesser leagues in the parallel of 48°; lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues on
Quadrant. AB, beginning at A; this will terminate in H, allowing every small interval four leagues. Then tracing out the parallel HE, from the point H to the thread; the part AE of the thread shows that 125 greater or equinocntial leagues make 65° 15'; and therefore that the 83 lesser leagues AH, which make the difference of longitude of the course, and are equal to the radius of the parallel HE, make 65° 15' of the said parallel.

If the ship sails an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westerly, to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional parallel between them. To find this, we have on the instrument a scale of cross latitudes. Suppose then it were required to find a mean parallel between the parallels of 40° and 60°; with your compasses take the middle between the 40th and 60th degree on this scale; the middle point will terminate against the 51st degree, which is the mean parallel required.

The principal use of the sinical quadrant is to form triangles upon, similar to those made by a ship's way with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants and the lines N and S, E and W; and every fifth line and arch is made deeper than the rest. Now, suppose a ship to have sailed 150 leagues north-east, one-fourth north, which is the third point, and makes an angle of 33° 44' with the north part of the meridian: here are given the course and distance sailed, by which a triangle may be formed on the instrument similar to that made by the ship's course; and hence the unknown parts of the triangle may be found. Thus, supposing the centre A to represent the place of departure, count, by means of the concentric circles along the point the ship sailed on, viz. AD, 150 leagues: then in the triangle AED, similar to that of the ship's course, find AE=difference of latitude, and DE=difference of longitude, which must be reduced according to the parallel of latitude come to.

Fig. 6. 10. Gunner's quadrant (fig. 6.), sometimes called gunner's square, is that used for elevating and pointing cannon mortars, &c. and consists of two branches either of brass or wood, between which is a quadrantal arch divided into 90 degrees, beginning from the shorter branch, and furnished with a thread and plummet, as represented in the figure. The use of the gunner's quadrant is extremely easy; for if the longest branch be placed in the mouth of the piece, and it be elevated till the plummet cut the degree necessary to hit a proposed object, the thing is done. Sometimes on one of the surfaces of the long branch are noted the division of diameters and weights of iron bullets, as also the bores of pieces.

Quadrant of Altitude, is an appendage of the artificial globe, consisting of a lamina, or slip of brass, the length of a quadrant of one of the great circles of the globe, and graduated. At the end, where the division terminates, is a nut riveted on, and furnished with a screw, by means whereof the instrument is fitted on the meridian, and moveable round upon the rivet to all points of the horizon.—Its use is to serve as a scale in measuring altitudes, amplitudes, azimuths, &c. See Quadrant Astronomo.

QUADRANTAL, in Antiquity, the name of a vessel in use among the Romans for the measuring of liquids. It was at first called amphora; and afterwards quadrantal, from its form, which was square every way like a die. Its capacity was 80 librae, or pounds of water, which made 36 sextaries, two urens, or eight congi.

QUADRAT, a mathematical instrument, called also a Geometrical Square, and Line of Shadows: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrants.

Quadrat, in Printing, a piece of metal used to fill up the void spaces between words, &c. There are quadrats of different sizes; as n-quadrats, m-quadrats, &c., which are respectively of the dimensions of these letters, only lower, that they may not receive the ink.

QUADRATIC EQUATIONS, in Algebra, those wherein the unknown quantity is of two dimensions, or raised to the second power. See Algebra.

QUADRATRIX, in Geometry, a mechanical line, by means whereof we can find right lines equal to the circumference of circles, or other curves, and their several parts.

QUADRATURE, in Geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c. The quadrature, especially among the ancient mathematicians, was a great postulatum. The quadrature of rectilinear figures is easily found, for it is merely the finding their areas or surfaces, i.e. their squares; for the squares of equal areas are easily found by only extracting the roots of the areas thus found. The quadrature of curvilinear spaces is of more difficult investigation; and in this respect extremely little was done by the ancients, except the quadrature of the parabola by Archimedes. In 1657, Sir Paul Neil, Lord Brouncker, and Sir Christopher Wren, geometrically demonstrated the equality of some curvilinear spaces to rectilinear spaces; and soon after the like was proved both at home and abroad of other curves, and it was afterwards brought under an analytical calculus; the first specimen of which was given to the public in 1688 by Mercator, in a demonstration of Lord Brouncker's quadrature of the hyperbola, by Dr Wallis's reduction of a fraction into an infinite series by division. Sir Isaac Newton, however, had before discovered a method of attaining the quantity of all quadruple curves analytically by his flexions before 1668. It is disputed between Sir Christopher Wren and Mr Huygens which of them first discovered the quadrature of any determinate cycloidal space. Mr Leibnitz afterwards found that of another space; and in 1669 Bernoulli discovered the quadrature of an infinity of cycloidal spaces both segments and sectors, &c. See Squaring the Circle.

Quadrature, in Astronomy, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters. See Astronomy Index.

QUADRATUS, in Anatomy, a name given to several muscles on account of their square figure. See Anatomy. Table of the Muscles.

QUADREL, in Building, a kind of artificial stone, so-called from its being perfectly square. The quadrals are made of a chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

QUADRIGA, in Antiquity, a car or chariot drawn by four horses. On the reverses of medals, we frequently see the emperor or Victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called nummi quadrigati, and victoriai.

QUADRILATERAL, in Geometry, a figure whose perimeter consists of four sides and four angles; whence it is also called a quadrangular figure.

QUADRILLE, a little troop or company of cavaliers, pompously dressed, and mounted for the performance of carousals, justs, tournaments, runnings at the ring, and other gallant diversions.

QUADRILLE, a game played by four persons, with 40 cards; which are the remains of a pack after the four tens, nine, and eights are discarded; these are dealt three and three, and one round four, to the right-hand player; and the trump is made by him that plays with or without calling, by naming spades, clubs, diamonds, or hearts, and the suit named is trumps. If the person who names the trump should mistake, and say spades instead of clubs, or if he name two suits, the first named is the trump.

In this game, the order of the cards, according to their natural value, is as follows: of hearts and diamonds, king, queen, knave, ace, deuce, three, four, five, six, seven, in all 10: of spades and clubs, king, queen, knave, seven, six, five, four, three, deuce; in all 10. The reason why the ace of spades and ace of clubs are not mentioned, is, because they are always trumps in whatever suit that is played. The ace of spades being always the first, and the ace of clubs the third trump, for the cards ranked according to their value when trumps stand in the following order.

Hearts and diamonds, spadill, or the ace of spades; manill, the seventh of the two red suits; basto, the ace of clubs; ponto, the ace of hearts and diamonds; king, queen, knave, seven, six, five, four, three; in all 12. Spades and clubs, spadill, the ace of spades, manill, the deuce of spades and clubs, basto the ace of clubs, king, queen, knave, seven, six, five, four, three; in all 11.

It is here to be observed, that the card which is manill and the second trump, is always the lowest in its suit when not trumps; and that the ace of hearts or diamonds, which when trump is above the king, is below the knave when not trump.

There are three matadores; spadill, manill, and basto; the privilege of which is, that when the player has no other trumps but them, and trumps are led, he is not obliged to play them, but may play what card he thinks proper, provided, however, that the trump led is of an inferior rank; but if spadill should be led, he that has manill or basto only is obliged to play it; Quedrille, it is the same of manill basto, with respect to the superior matador always forcing the inferior. Though there are properly but three matadores, nevertheless all those trumps which follow the three first without interruption, are likewise called matadores; but the three first only enjoy the privilege above mentioned.

Each person is to play as he judges most convenient for his own game. He is not to encourage his friend to play; but each person ought to know what to do when it is his turn to play. The stakes consist of equal mils or contracts, as they are sometimes called, comprising the ten counters and fishes, which are given to each player. A mil is equal to ten fish, and each fish to ten counters; the value of the fish is according to the players agreement, as also the number of tours, which are generally fixed at ten, and marked by turning the corners of a card.

If the cards should happen not to be dealt right, or that there should be two cards of the same sort, as two deuces of spades, for example, there must be a new deal; provided it is discovered before the cards are all played. The cards must likewise be dealt over again in case a card is turned in dealing, as it might be of prejudice to him who should have it, and of course if there should be several cards turned. There is no penalty for dealing wrong, he who does so must only deal again.

When each player has got his ten cards, he that is on the right hand of the dealer, after examining his game, and finding his hand fit to play, asks if they play; or if he has not a good hand, he passes, and so the second, third, and fourth. All the four may pass; but he that has spadill, after having shown or named it, is obliged to play by calling a king. Whether the deal is played in this manner, or that one of the players has asked leave, nobody choosing to play without calling, the eldest hand must begin the play, first naming the suit, and the king which he calls; he who wins the trick plays another card, and so of the rest till the game is finished. The tricks then are counted; and if the ombre, that is, he who stands the game, has together with him who is the king called, six tricks, they have won and are paid the game, the consolation, and the matadores, if they have them, and divide what is upon the game, and the beasts if there are any. But if they make only five tricks, it is a remise, and they are beasted, what goes upon the game, paying to the other players the consolation and the matadores.

If the tricks are equally divided betwixt them, they are likewise beasted; and if they make only four tricks between them, it is a remise; if they make less they lose codill (A), and in that case they pay to their adversaries what should have received if they had won; that is, the game, the consolation, and the matadores, if they have them, and are beasted what is upon the game: they who win codill, divide the stakes. The beast and every thing else that is paid, is paid equally betwixt the two lesse; one half by him that calls, and the other half by him that is called, as well in case of codill as a remise.

(A) Codill is when those who defend the pool make more tricks than they who stand the game; which is called winning the codill.
Quadrille, mise; unless the ombre does not make three tricks, in which case he that is called is not only exempted from paying half the beast, but also the game, the consolation, and the matadores if there are any, which the ombre in that case pays alone; and as well in case of a codill as a remise. This is done in order to oblige players not to play games that are unreasonable. There is nevertheless, one case in which if the ombre makes only one trick, he is not beasted alone, and that is, when not having a good hand he passes, and all the other players have passed likewise; he having spadill is obliged to play. Here it would be unjust to oblige him to make three or four tricks; in this case, therefore, he that is called pays one half of the losings. For which reason he that has spadill with a bad hand, should pass, that if he is afterwards obliged to play by calling a king (which is called forced spadill), he may not be beasted alone. He that has once passed cannot be obliged to play; and he that has asked leave cannot refuse to play, unless any one should offer to play without calling.

If he that has four kings, may call a queen to one of his kings, except that which is trump. He that wants one or more kings, may call one of those kings; but in that case, he must make six tricks alone, and consequently he wins or loses alone. The king of that suit in which he plays cannot be called. No one should play out of his turn, although he is not beasted for so doing. If he who is not the eldest hand has the king called, and plays spadill, manill, or baso, or even the king called in order to show that he is the friend, having other kings that he fears the ombre should trump, he is not to be allowed to go for the vole; he is even beasted, if it appears to be done with that intent. It is not permitted to show a hand though codill may already be won; that it may be seen whether the ombre is beasted alone. If the ombre or his friend shows their cards before they have made six tricks, thinking that they have made them, and there appears a possibility of preventing their making them, the other players can oblige them to play their cards as they think proper.

A player need only name his suit when he plays, without calling a king. He who plays without calling must make six tricks alone to win; for all the other players are united against him, and they are to do what they can to prevent his winning. He who plays without calling, is admitted to play in preference to him who would play with calling; however, if he that has asked leave will play without calling, he has the preference of the other who would force him. These are the two methods of play without calling that are called forced.

As he who plays without calling does not divide the winnings with any person, he consequently, when he loses, pays all by himself: if he loses by remise he is beasted, and pays each of the other players the consolation, the sans appeller (which is commonly, but improperly, called the sans prendre), and the matadores if there are any; if he loses codill he is likewise beasted and pays to each player what he would have received from each if he had won. They who win codill divide what there is; and if there are any counters remaining, they belong to him of the three who shall have spadill or the highest trump the next deal. It is the same with regard to him who calls one of his own quadrille kings; he wins alone or loses alone as in the other case, except the sans appeller, which he does not pay if he loses, or receive if he wins, although he plays alone.

If he plays sans appeller, though he may have a sure game, he is obliged to name his suit; which if he neglects to do, and shows his cards, and says "I play sans appeller," in that case neither of the other players can oblige him to play in what suit he pleases, although he should not have one trump in that suit.

He who has asked leave is not permitted to play sans appeller, unless he is forced; in which case, as was said before, he has the preference of the other that forces him.

A player is not obliged to trump when he has none of the suit led, nor play a higher card in that suit if he has it, being at his option although he is the last player, and the trick should belong to the ombre; but he is obliged to play in the suit led if he can, otherwise he renounces. If he separates a card from his game and shows it, he is obliged to play it, if by not doing it the game may be prejudiced, or if he can give any intelligence to his friend; but especially if it should be a matador. He that plays sans appeller, or by calling himself, is not subject to this law. He may turn the tricks made by the other players, and count what has been played as often as it is his turn to play, but not otherwise. If instead of turning a player's tricks, he turns and see his game, or shows it to the other players, he is beasted, together with him whose cards he turned; and each of them must pay one half of the beast.

If any one renounces, he is beasted as often as he has renounced and it is detected; but a renonce is not made till the trick is turned. If the renonce is discovered before the deal is finished, and has been detrimental to the game, the cards must be taken up again, and the game replayed from that trick where the renonce was made; but if the cards are all played, the beast is still made, and the cards must not be replayed; except there should be several renonces in the same deal: then they are to be played again, unless the cards should be mixed. If several beasts are made in the same deal, they all go together, unless it is otherwise agreed at the beginning of the party; and when there are several beasts, the greatest always goes first.

A great advantage accrues from being eldest hand at quadrille, which often renders it very disagreeable to the rest of the players, being obliged to pass with a good hand unless they choose to play alone; and when it happens that the eldest hand having asked leave, the second player has three matadores, several trumps in back, and all small cards, he cannot then even play alone; and having no chance of being called, he must pass with this good hand. On account of which, this method has been thought expedient to remedy this defect of the game; each player having an opportunity of availling himself of the goodness of his game, by adding to the usual method of playing the game that of the mediateur, and the favourite suit.

The first thing to be observed is that of drawing for places, which is done in this manner: One of the players takes four cards; a king, a queen, a knave, and an ace; each player draws one of these cards; and commonly he who comes in last, draws first. The per-
entered, who draws the king sits where he pleases, the queen at his right hand, the knave next the queen, and the ace on the left of the king. The king draws the favourite suit. The number of cards and persons is the same at this game as the other, and is played in the same manner.

The favourite suit is determined by drawing a card out of the pack, and is of the same suit, during the whole party, of the card so drawn. A king is the mediator, which is demanded of the others by one of the players, who has a hand he expects to make five tricks of; and through the assistance of this king he can play alone and make six tricks.

In return for the king received, he gives what card he thinks proper with a fish; but must give two fish if it is in the favourite suit. He who asks by calling in the favourite suit, has the preference to him who asks by calling in another; he who asks with the mediator, has the preference to him who asks by calling in the favourite suit, and by playing alone is obliged to make six tricks to win. He who asks with the mediator in the favourite suit, has the preference to him who asks with the mediator in any other suit, and is obliged to play alone, and to make six tricks.

If sans prendre is played in any other suit than the favourite, he who plays it has the preference to him who asks only, or with the mediator, or even he who plays in the favourite suit with the mediator; and the sans prendre in the favourite suit has the preference to all other players whatever.

The only difference between this method of playing the game and the other is, that when one of the players demands the mediator he is obliged to play alone, and to make six tricks, as if he played sans prendre. In this case he should judge from the strength of his hand, whether the aid of the king will enable him to play alone or not.

With the mediator and without the favourite suit it is played in this manner. The game is marked and played the same as in common quadrille. The beasts are also the same as the common game. The last game is generally played double, and is called postand for those who choose to play a higher game, they may play the double colour, which is called the Turk, and is double of the favourite suit. There is also a higher game than this, called the audite, which is paying whatever is agreed to him who happens to hold the two aces in his hand.

We have omitted many things respecting the mode of marking the game, and playing the vole, because these are different in different cases, and are to be learned only by practice. The game itself is a very inferior one; but he who wishes to know more of it, may consult Hoyle’s games improved by James Beaufort, Esq. from which we have, with very little alteration, taken this article.

QUADRIPARTITION, the dividing by four, or into four equal parts. Hence comes the term quadrupartite, the fourth part, or something divided into four.

QUADRUPLE, four-fold, or something taken four times, or multiplied by four, on which account it is the converse of quadrupartition.

QUÆSTOR, see QUESTOR.

QUAGGA, or QUACHA. See EQUUS, MAMMALIA. Index.

QUAIL. See TETRAO, ORNITHOLOGIA INDEX.

Quails are to be taken by means of the call during their whole wintering time, which lasts from April to August. The proper times for using the call are at sunrise, at nine o’clock in the morning, at three in the afternoon, and at sunset; for these are the natural times of the quail’s calling. The notes of the cock and hen quail are very different; and the sportsman who expects to succeed in the taking them must be expert in both: for when the cock calls, the answer is to be made in the hen’s note; and when the hen calls, the answer is to be made in the cock’s. By this means they will come up to the person, so that he may, with great ease, throw the net over them and take them. If a cock-call be single, on hearing the hen’s note he will immediately come; but if he have a hen already with him, he will not forsake her. Sometimes, though only one quail answers to the call, there will three or four come up; and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings, they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top; and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; that is to be stuffed half-full of horse-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit’s leg, or some other such bone: this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the purse; the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax; then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a sort of shake. This is the most useful call; for it imitates the note of the hen quail; and seldom fails to bring a cock to the net if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must
QUAKERS, a religious society, which took its rise in England about the middle of the 17th century, and rapidly found its way into other countries in Europe, and into the English settlements in North America. The members of this society, we believe, called themselves at first seekers, from their seeking the truth; but after the society was formed, they assumed the appellation of friends. The name of quakers was given to them by their enemies; and though an epithet of reproach, seems to be stamped upon them indelibly. Their founder is generally believed to have been George Fox, an illiterate shoemaker (see George Fox), but this opinion has been lately controverted. An ingenious writer having found, or fancied, a similarity of sentiments among the ancient Druids and modern Quakers, seems to think that Fox must have been nothing more than a tool employed by certain deists to pave the way for their system of natural religion, by allegorizing the distinguishing article of the Christian faith.

It must be confessed, for experience will not allow it to be denied, that extremes in religion are very apt to beget each other; and if the deists alluded to reasoned from this fact, they could not have pitched upon a tool fitter for their purpose than George Fox. From his works still extant he appears to have been one of the most extravagant and absurd enthusiasts that ever lived, and to have fancied himself, in his apostolic character, something infinitely superior to man. In a book called *News coming out of the North*, (p. 15), he says of himself, “I am the Door that ever was, the same Christ yesterday, to-day, and for ever.” And in the introduction to his *Battle-door for Teachers and Professors*, he says, “All languages are to me no more than dust, who was before languages were.” But one of the most extraordinary and blasphemous things that he ever wrote, is an answer to the Protector, who had required him to promise not to disturb his government as then established. It is as follows:

“I who am of the world called G: F: doth deny the carrying or drawing any carnal sword against any, or against thee O: C: or any man, in the presence of the Lord I declare it, God is my witness, by whom I am moved to give this forth for the truth’s sake, from him whom the world calls G: Fox, who is the son of God, who is sent to stand a witness against all violence and against the works of darkness, and to turn the people from darkness to light, and to bring them from the occasion of the war and from the occasion of the magistrate’s sword, which is a terror to the evil doer, which acts contrary to the light of the Lord Jesus Christ; which is a praise to them that do well; which is a protestation to them that do well, and not the evil; and such soldiers as are put in place so false accusers must be, no violence must do, but be content with their wages: and that magistrate bears not the sword in vain, from under the occasion of that sword do I seek to bring people: my weapons are not carnal but spiritual, and my kingdom is not of this world; therefore with carnal weapon I do not fight, but am from those things dead, from him who is not of this world, called of the world by the name of G: F: and this I am ready to seal with my blood; this I am moved to give forth for the truth’s sake, who a witness stands against all unrighteousness, and all ungodliness, who a sufferer is for the righteous seed’s sake, waiting for the redemption of it, who a crown that is mortal seeks not, for that fadeth away; but in the light dwells which comprehends that crown, which light is the condemnation of all such, in which light I witness the crown that is immortal, which fades not away from him who to all your souls is a friend, for establishing of righteousness, and clearing the land of evil doers, and a witness against all the wicked inventions of man, and murderer’s plots, which answer shall be with the light in all your consciences, which makes no covenant with death; to which light in you all I speak, and am clear, G: F: who a new name hath, which the world knows not (A).”

The Quakers, however, did not long entrust the defence of their principles to such senseless enthusiasts as George Fox: They were joined by a number of learned, ingenious, and pious men, who new-modelled their creed; and though they did not bring it to what is generally deemed the Christian standard, they so reformed it as that its tenets do not shock common sense, nor the duties prescribed scandalize a man of piety. The chief of these reformers were George Keith, the celebrated Penn, and our countryman Barclay. Keith was indeed excommunicated for the liberties which he took with the great apostle; but we have not a doubt but his writings contributed to the moderation of Penn, and the elegant and masterly apology of Barclay. From that apology we selected the summary of their opinions which was given in the former edition of this work; but they have lately published such a summary themselves, of which the reader will be pleased with the following abstract:

They tell us, that about the beginning of the 17th century a number of men, dissatisfied with all the modes of religious worship then known in the world, withdrew from the communion of every visible church to seek the Lord in retirement. Among these was their honourable elder George Fox, who being quickened by the immediate touches of divine love, could not satisfy his apprehensions of duty to God without directing the people where to find the like consolation and instruction. In the course of his

(A) We have transcribed this letter from the theological works of Mr Leslie, where it is preserved in its original form. The Quakers, after the death of their apostle, expunged from their edition of it the words which we have printed in italics; ashamed, as we hope, of the blasphemy imputed to them: but that Mr Leslie’s copy is authentic, is thus attested by two of the friends, who saw Fox deliver it to the protector’s messenger: “We are witnesses of this testimony, whose names in the flesh are,

*Tho. Adam.*

*Rob. Croswen.*"
Quakers, his travels, he met with many seeking persons in circumstances similar to his own, and these readily received his testimony. They then give us a short account of their sufferings and different settlements; and with a degree of candour which does them infinite credit, they vindicate Charles II. from the character of a persecutor; acknowledging, that though they suffered much during his reign, he gave as little countenance as he could to the severities of the legislature. They even tell us, that he exerted his influence to rescue their friends from the unprovoked and cruel persecutions of the New England fanatics; and they speak with becoming gratitude of the different acts passed in their favour during the reigns of William and Mary, and George I. They then proceed to give us the following account of their doctrine:

"We agree with other professors of the Christian name, in the belief in one eternal God, the Creator and Preserver of the universe; and in Jesus Christ his Son, the Messiah, and Mediator of the new covenant (Heb. xii. 24.)."

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour Jesus Christ, and the grace and power of God unto salvation, (1 Cor. i. 24.),

"To Christ alone we give the title of the Word of God (John i. 1.), and not to the Scriptures; although we highly esteem these sacred writings, in subordination to the Spirit (2 Pet. i. 21.), from which they were given forth; and we hold, with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus (2 Tim. iii. 15.)."

"We reverence those most excellent precepts which are recorded in Scripture to have been delivered by our great Lord, and we firmly believe that they are practicable, and binding on every Christian; and that in the life to come every man will be rewarded according to his works (Mat. xxv. 29.). And further, it is our belief, that in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the unregenerate will of man (John i. 9.), every man coming into the world is endowed with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, within the reach of temptation; but this divine grace, which comes from Him who hath overcome the world (John xvi. 33.), is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation; whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God.

"Being thus persuaded that man, without the Spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable, even the worship of the Father of lights and of spirits, in spirit and in truth; therefore we consider as obstructions to pure worship, all forms which divert the attention of the mind from the secret influence of this union from the Holy One (1 John ii. 20, 27.). Yet, although true worship is not confined to time and place; we think it incumbent on Christians to meet often together (Heb. x. 25.) in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength: nevertheless, in the performance of worship, we dare not depend for our acceptance with Him, on a formal repetition of the words and experiences of others; but we believe it to be our duty to cease from the activity of the imagination, and to wait in silence to have a true sight of our condition bestowed upon us: believing even a single sigh (Rom. viii. 26.) arising from such a sense of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man.

"From what has been said respecting worship, it follows, that the ministry we approve must have its origin from the same source; for that which is needful for a man's own direction, and for his acceptance with God (Jer. xxiii. 30, 32.), must be eminently so to enable him to be helpful to others. Accordingly, we believe the renewed assistance of the light and power of Christ to be indispensably necessary for all true ministry: and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to his chosen and devoted servants. From hence arises our testimony against preaching for hire, and in contradiction to Christ's positive command, "Freely ye have received, freely give" (Mat. x. 8.); and hence our conscientious refusal to support such ministry by tithes or other means.

"As we dare not encourage any ministry but that which we believe to spring from the influence of the Holy Spirit, so neither dare we attempt to restrain this influence to persons of any condition in life, or to the male sex alone; but, as male and female are one in Christ, we allow such of the female sex as we believe to be endowed with a right qualification for the ministry, to exercise their gifts for the general edification of the church: and this liberty we esteem to be a peculiar mark of the gospel dispensation, as foretold by the prophet Joel (Joel ii. 28, 29.), and noticed by the apostle Peter (Acts ii. 16, 17.).

"There are two ceremonies in use amongst most professors of the Christian name; Water-baptism, and what is termed the Lord's Supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter of maintaining communion with him. But as we have been convinced, that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin, by this power alone we believe salvation to be effected. We hold that as there is one Lord and one faith (Eph. iv. 5.), so his baptism is one in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, admi
Quakers ministered by his fore-runner John, belonged, as the latter confessed, to an inferior and decreasing dispensation (John iii. 30.).

With respect to the other rite, we believe that communion between Christ and his church is not maintained by that nor any other external performance, but only by a real participation of his divine nature (2 Pet. i. 4.) through faith; that this is the supper alluded to in the Revelation (Rev. iii. 20.). "Behold I stand at the door and knock, if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me;" and that where the substance is attained, it is unnecessary to attend to the shadow, which doth not confer grace, and concerning which opinions so different, and animosities so violent, have arisen.

"Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation, we cannot admit that it is conferred on a few only, whilst others are left without it; nor, thus, asserting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthier notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to assist the obedient to experience a total surrender of the natural will to the guidance of the pure unerring Spirit; through whose renewed assistance they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank (Mat. v. 48.; Eph. iv. 13.; Col. iv. 12.)."

"There are not many of our tenets more generally known than our testimony against oaths and against war. With respect to the former of these, we abide literally by Christ's positive injunction, delivered in his sermon on the mount, "Swear not at all" (Mat. v. 34.). From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself (Mat. chap. v. 39, 44.; &c. ch. xxvi. 52, 53.; Luke xxii. 51.; John xviii. 11.), and from the correspondent convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the Gospel, which still breathes peace and goodwill to men. We are also clearly of the judgment, that total subjection of the natural will to the guidance of the Spirit in the minds of men, it would effectually prevent them from oppressed, much more from enslaving, their brethren, (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan the victims of their avarice, and of their false ideas of pleasure.

"Some of our tenets have in former times, as hath been shown, subjected our friends to much suffering from government, though to the salutary purposes of government our principles are a security. They inculcate submission to the laws in all cases wherein conscience is not violated. But we hold, that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion; but to maintain the external peace and good order of the community. We therefore think persecution, even in the smallest degree, unwarrantable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

"It is well known that the society, from its first appearance, has disused those names of the months and days which, having been given in honour of the heroes or false gods of the heathens, originated in their flattery or superstition; and the custom of speaking to a single person in the plural number (b), as having arisen also from motives of adulation. Compliments, superfluity of apparel and furniture, outward shows of rejoicing and mourning, and observation of days and times, we esteem to be incompatible with the simplicity and sincerity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time which is given us for nobler purposes, and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance." To conclude, although we have exhibited the several tenets which distinguish our religious society, as one of our belief, yet we are sensible that true and living faith is not produced in the mind of man by his own effort; but is the free gift of God (Eph. ii. 8.) in Christ Jesus, nourished and increased by the progressive operation of his Spirit in our hearts, and our proportionate obedience (John vii. 17.). Therefore, although, for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as the condition of membership, or to qualify for the service of the church. We prefer the judging of men by their fruits, in a dependence on the aid of Him who, by his prophet, hath promised to be "a spirit of judgment to him that sitteth in judgment" (Isaiah xxviii. 6.). Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual shepdrd, whereof our blessed Lord declared himself to be but the door and the shepherd (John x. 7, 11.), that is, such as know his voice, and follow him in the paths of obedience.

Such are the doctrines of this people as we find them stated in a small pamphlet lately presented by themselves to the public; and in the same tract they give the following account of their discipline.

"In the practice of discipline, we think it indispensable that the order recommended by Christ himself be invariably observed: (Matth. xviii. 15. to 17.). "If thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses every word may be

(a) Speaking of this custom, Fox says; "When the Lord sent me into the world, he forbade me to put off my hat to any; and I was required to thee and thou, all men and women." Journal, p. 24.
be established; and if he shall neglect to hear them, tell it unto the church.'

'To effect the salutary purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being held, were called quarterly meetings. It was afterwards found expedient to divide the districts of those meetings, and to meet more often; whence arose monthly meetings, subordinate to those held quarterly. At length, in 1669, a yearly meeting was established, to superintend, assist, and provide, rules for the whole; previous to which, general meetings had been occasionally held.

'A monthly meeting is usually composed of several particular congregations, situated within a convenient distance of each other. Its business is to provide for the subsistence of their poor, and for the education of their offspring; to judge of the sincerity and fitness of persons appearing to be convinced of the religious principles of the society; and desiring to be admitted into membership; to excite due attention to the discharge of religious and moral duty; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct; without which they cannot gain membership in such meetings. Each monthly meeting is required to appoint certain persons under the name of overseers, who are to take care that the rules of our discipline be put in practice; and when any case of complaint or disorderly conduct comes to their knowledge, to see that private admonition, agreeable to the gospel rule before mentioned, be given previously to its being laid before the monthly meeting.

'When a case is introduced, it is usual for a small committee to be appointed to visit the offender, to endeavour to convince him of his error, and to induce him to forsake and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence; if not, he is disowned as a member of the society.

'In disputes between individuals, it has long been the decided judgment of the society that its members should not sue each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeable to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly meeting that such be disowned.

'To monthly meetings also belongs the allowing of marriages; for our society hath always scrupled to acknowledge the exclusive authority of the priests in the solemnization of marriage. Those who intend to marry, appear together and propose their intention to the monthly meeting; and if not attended by their parents or guardians, produce a written certificate of their consent, signed in the presence of witnesses. The meeting then appoints a committee to enquire whether they are clear of other engagements respecting marriage; and if at a subsequent meeting, to which the parties also come and declare the continuance of their intention, no objections are reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship; towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations and others as witnesses. Of such certificates the monthly meeting keeps a record; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of one of these last-mentioned records; and an order for the interment, countersigned by the grave-maker, of the other. The naming of children is without ceremony. Burials are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave, a pause is generally made; on which occasion it frequently falls out that one or more friends present have somewhat to express for the edification of those who attend; but no religious rite is considered as an essential part of burial.

'Several monthly meetings compose a quarterly meeting. At the quarterly meeting are produced written answers from the monthly meetings, to certain queries respecting the conduct of their members, and the meeting's care over them. The accounts thus received are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly meeting. —Appeals from the judgment of monthly meetings are brought to the quarterly meetings; whose business also is it to assist in any difficult case, or where remissness appears in the care of the monthly-meetings over the individuals who compose them.

'The yearly meeting has the general superintendence of the society in the country in which it is established (c); and therefore, as the accounts which it receives discover the state of inferior meetings, as particular exigencies require, or as the meeting is impressed with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made; and sometimes appoints committees to visit those quarterly meetings which appear to be in need of immediate help. Appeals from the judgment of quarterly meetings are here finally determined; and a brotherly correspondence, by epistles, is maintained with other yearly meetings.

'In this place it is proper to add, that as we believe women may be rightly called to the work of the ministry, we also think, that to them belongs a share in the support of our Christian discipline; and that some parts of it, wherein their own sex is concerned, devolve on them with peculiar propriety. Accordingly they have monthly, quarterly, and yearly meetings of their own sex, held at the same time and in the same place with those of the men; but separately, and without the power

---

(c) There are seven yearly meetings, 1st, London, to which come representatives from Ireland; 2d, New-England; 3d, New-York; 4th, Pennsylvania and New-Jersey; 5th, Maryland; 6th, Virginia; 7th, the Carolinas and Georgia.
of making rules: and it may be remarked, that during the persecution, which in the last century occasioned the imprisonment of so many of the men, the care of the poor often fell on the women, and was by them satisfactorily administered.

"In order that those who are in the situation of ministers may have the tender sympathy and counsel of those of either sex, who, by their experience in the work of religion, are qualified for that service; the monthly meetings are advised to select such, under the denomination of elders. These, and ministers approved by their monthly meetings (d), have meetings peculiar to themselves, called meetings of ministers and elders; in which they have an opportunity of exciting each other to a discharge of their several duties, and of extending advice to those who may appear weak, without any needless exposure. These meetings are generally held in the compass of each monthly, quarterly, and yearly meeting. They are conducted by rules prescribed by the yearly meeting, and have no authority to make any alteration or addition to them. The members of them unite with their brethren in the meetings for discipline, and are equally accountable to the latter for their conduct.

"It is to a meeting of this kind held in London, called the second-day-morning-meeting, that the revival of manuscripts concerning our principles, previously to publication, is intrusted by the yearly meeting held in London; and also the granting, in the intervals of the yearly meeting, certificates of approbation to such ministers as are considered to travel in the work of the ministry in foreign parts. When a visit of this kind doth not extend beyond Great Britain, a certificate from the monthly meeting of which the minister is a member is sufficient; if to Ireland, the concurrence of the quarterly meeting is also required. Regulations of similar tendency obtain in other yearly meetings.

"The yearly meeting held in London, in the year 1675, appointed a meeting to be held in that city, for the purpose of advising and assuring in cases of suffering for conscience sake, which hath continued with great use to the society to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on emergency. The names of all these correspondents, previous to their being recorded as such, are submitted to the approbation of the yearly meeting. Those of the men who are approved ministers are also members of this meeting, which is called the meeting for sufferings; a name arising from its original purpose, which is not yet become entirely obsolete.

"The yearly meeting has intrusted the meeting for sufferings with the care of printing and distributing books, and with the management of its stock; and considered as a standing committee of the yearly meeting, it hath a general care of whatever may arise, during the intervals of that meeting, affecting the society, and requiring immediate attention: particularly of those circumstances which may occasion an application to government.

"There is not in any of the meetings which have been mentioned any president, as we believe that Divine Wisdom alone ought to preside; nor hath any member a right to claim pre-eminence over the rest. The office of clerk, with a few exceptions, is undertaken voluntarily by some member; as is also the keeping of the records. Where these are very voluminous, and require a house for their deposit (as is the case in London, where the general records of the society in Great Britain are kept), a clerk is hired to have the care of them; but except a few clerks of this kind, and persons who have the care of meeting-houses, none receive any stipend or gratuity for their services in our religious society."

It is remarkable, that all the settlements of the Europeans in America, except the Quaker settlement of Pennsylvania, were made by force of arms, with very little regard to any prior title in the natives. The kings of Spain, Portugal, France, and Britain, together with the states of Holland, then the only maritime powers, gave grants of such parts of America as their people could lay hold on, studying only to avoid interference with their European neighbours. But Mr Penn, being a Quaker, did not think his power from King Chas. I. a sufficient title to the country since called Pennsylvania: He therefore assembled the sachems or princes then in that country, and purchased from them the extent of land that he wanted. The government of this province is mostly in the hands of the Quakers, who never have any quarrel with the natives. When they desire to extend their settlements, they purchase new lands of the sachems, never taking anything from them by force. How unlike is this conduct to that of the Spaniards, who murdered millions of the natives of Mexico, Terra Firma, Peru, Chili, &c.

QUALITY is a word which, as used in philosophic disquisitions, cannot be explained by any periphrasis, circumscribed by any adverb, or illustrated by any example. That which is expressed by it must be brought into the immediate view of the senses or intellect, and the name properly applied, or he who is a stranger to the word will never be made to comprehend its meaning. Aristotle, who treated it as a general conception, second in order among the ten predicaments or categories (see category), gives several characters of it; but though they are all in some respects just, no man could from them, without other assistance, learn what quality is. Thus he tells us, 'εν παντι ψευδονιμως και ακτο το παντο, κακως τον ρατον το μεταλλευσαι τον την τον. Αλλα γαρ, 'ομοια την καινην και της παλαιης ουκ επιτελεως ουκ ες ουκ εκ το νεον ου εις τινα καλεται ακτον και αδελφον και λοιπον, καν τα τα τα παλαια τα περιτελον.'

(d) "Those who believe themselves required to speak in meetings for worship, are not immediately acknowledged as ministers by their monthly meetings; but time is taken for judgment, that the meeting may be satisfied of their call and qualification. It will sometimes happen, that such as are not approved, will obtrude themselves as ministers, to the grief of their brethren; but much forbearance is used towards these, before the disapprobation of the meeting is publicly testified.
Quality.

When a man comprehends, by means of his senses and intellect, what it is which the word quality denotes, he will indeed perceive that the first of these characters is applicable to some qualities and not to others; that the second is more applicable to quantity than to quality; and that it is only the third which can with propriety be considered as the general characteristic of this predicament. Thus, when we have learned by our sense of sight that whiteness is a quality of snow, and blackness of coal; and by means of observation and reflection, that wisdom is a quality of one man and folly of another—we must admit that the sensible quality of the snow is contrary to that of the coal; and the intellectual quality of wisdom contrary to that of folly. There is, however, no contrariety between wisdom and whiteness or blackness, nor between hardness or softness and any particular colour; for sensible and intellectual qualities can never be compared; and it is not easy, if possible, to make a comparison between qualities perceptible only by different senses. Nay, among qualities perceptible by the same sense, we often meet with a difference where there is no contrariety; for though the figure of a cube is different from that of a sphere, and the figure of a square from that of a circle, the sphere is not contrary to the cube, nor the circle to the square.

His second characteristic of this genus is still less proper than the first. It is indeed true that some qualities admit of intensification and remission; for snow is whiter than paper, and one woman is handsomer than another; but of the species of quality called figure we cannot predicate either more or less. A crown-piece may have as much of the circular quality in it as the plane of the equator, and a musket-ball as much of the spherical quality as the orb of the sun. It is indeed a property of all quantity to admit of intensification and remission; and therefore this ought to have been given as the character not of the second but of the third category. See Quantities.

That it is only from a comparison of their qualities that things are distinguished like or unlike, or that one thing cannot resemble another, but in some quality, is indeed a just observation. We know nothing directly but qualities sensible and intellectual (see Metaphysics, Nos. 149, 150, 151, and 227); and as these have no resemblance to each other, we conclude that body or matter, the subject of the former, is a being unlike mind, the subject of the latter. Even of bodies themselves we can say, that one is like or unlike another only by virtue of their qualities. A ball of ivory resembles a ball of snow in its figure and colour, but not in its coldness or hardness; a ball of lead may resemble a ball of snow in its figure and coldness, but not in its colour; and a cube of ivory resembles a ball of lead in its figure, but a ball of lead in its colour, or coldness. The mind of a brute resembles that of a man in its powers of sensation and perception, but does not resemble it in the powers of volition and reason; or at least the resemblance, in this latter instance, is very slight. All bodies resemble one another in being solid and extended, and all minds in being more or less active. Likeness or unlikeness therefore is the universal characteristic of the category quality.

Aristotle has other speculations respecting quality, which are worthy of notice. He distinguishes between qualities which are essential and those which are accidental; between qualities which are natural and those which are acquired; and he speaks of the qualities of capacity and those of completion. Extension and figure in general are qualities essential to all bodies: but a particular extension, such as an inch or an ell, and a particular figure, such as a cube or a sphere, are qualities accidental to bodies. Among the natural qualities of glass it is one to transmit objects of vision; but to enlarge these objects is an adventitious or acquired quality. The same quality may be natural in one substance, as attraction in the magnet; and acquired in another, as the same attraction in the magnetic bar. Docility may be called a quality natural to the mind of man, science an acquired one. To understand what he means by qualities of capacity and completion, it may be sufficient to observe that every piece of iron has the qualities of a razor in capacity, because it may be converted into steel, and forced into a razor: when it is so formed, it has, in the language of this sage, the quality of a razor in completion. Among the qualities of capacity and completion, the most important, and what may lead to interesting speculations, is the reasoning faculty of man. A capacity of reasoning is essential to the human mind; but the completion of this capacity or actual reasoning is not, otherwise infants and persons aslep would be excluded from the human species.

Mr. Locke has puzzled his readers, and perhaps himself, with a question respecting the species of an idiot by Locke, or changeling, whom he pronounces to be something between a man and a brute. It is not often that we feel ourselves inclined to regret Locke’s ignorance of Aristotle’s distinctions: but we cannot help thinking, that had the British philo-sopher attended to the Stoic-rée’s account of qualities in capacity and qualities in completion, this perplexing question would never have been started. It is justly observed in the Essay on Human Understanding, that of real essences we know nothing; but that every man selects a certain number of qualities which he has always perceived united in certain beings; and forming these into one complex conception, gives to this conception a specific name, which he applies to every being in which he finds those qualities united. This is undoubtedly the process of the mind in forming genera and species; and as the excellent author conscientiously refrains the name of man to the changeling, it is obvious that this complex conception, to which he gives that name, must imply rationality and the actual exercise of reason. But this limitation will exclude many beings from the species man, whom Mr. Locke certainly considered as men and women. Not to mention infants and persons in sound sleep, how shall we class those who, after having lived 30 or 40 years in the full exercise of reason, have been suddenly or by degrees deprived of it by some disorder in the brain?

From Marlborough’s eyes the streams of dotage flow; And Swift expires a drivel and a show. Johnson.

But were the hero and the wit in those deplorable circumstances excluded from the human species, and classed between men and brutes? No surely; they were both acknowledged to be men, because they were known to have the quality of reason in what Aristotle would have called capacity. Their dotage and drivelling originated from some disorder in their bodies, probably in the region of the brain; and Locke himself contends that no defect in body is sufficient to degrade a person from the rank
QUA [ 592 ]

It appears, therefore, that the actual exercise of reason, but reason in capacity, ought to be included in the complex conception to which we give the specific name of man, as some of the greatest men have lived only during parts of their lives, deprived of the power of actual reasoning. This, however, it will be said, does not remove the difficulty; for the occasional exercise of reason in lunatics, and the great exertions of it in such men as Swift and Marlborough, show that they had it in capacity at all times; whereas we have no evidence that changelings have even a capacity of reasoning at any time, since they never do a rational action, nor ever utter a sentence to the purpose. That we have no direct and positive evidence of the minds of changelings being capable of reasoning, were they supplied with proper organs, must be granted; but the probabilities of their being so are many and great. We know by experience that the actual exercise of reason may be interrupted by an occasional and accidental pressure on the brain: and therefore we cannot doubt but that if this pressure were rendered permanent by any wrong configuration of the skull given to it in the womb, or in the act of being born into the world, an infant, with a mind capable of reasoning by means of proper organs, would by this accident be rendered, through the whole of life, an idiot or changeling. That idiotism is caused by such accidents, and is not the quality of an inferior mind occasionally given to a human body, will at least seem probable from the following considerations.

It does not appear that an animal body can live and move but while it is actuated by some mind. Whence then does the unborn infant derive its mind? It must be either immediately from God, or ex traduce from its parents; but if the mind of man be immaterial, it cannot be ex traduce. Now, as idiots are very few in number when compared with the rational part of the human species, and as God in the government of this world acts not by partial but by general laws; we must conclude that the law which he has established respecting the union of mind and matter, is, that human bodies shall be animated with minds endowed with a capacity of reasoning, and that those who never exert this capacity are prevented by some such accident as we have assigned.

For a further account of qualities, they are supposed to inhere in some subject, together with the usual distinction between the primary and secondary qualities of matter, see Metaphysics, Part II. chap. i.

Chemical Qualities, those qualities principally introduced by means of chemical experiments, as fumigation, amalgamation, cupellation, volatilization, precipitation, &c.

Quality, is also used for a kind of title given to certain persons, in regard of their territories, signiories, or other pretensions.

QUANGA. See Capra.

QUANG-PING-fou, a city in China, is situated in the northern part of the province of Pe-tcheli, between the provinces of Chang-tong and Ho-nan, and has nine cities of the third class dependent on it; all its plains are well watered by rivers. Among its temples, there is one dedicated to those men who, as these Chinese pretend, discovered the secret of rendering themselves immortal.

QUANGSI, a province of China, bounded on the north by Koe-Teheau and Ho-Quang; on the east, by Yunnan and Quantong; on the south, by the same and Tonquin; and on the west, by Yunnan. It produces great plenty of rice, being watered by several large rivers, and contains 10,000,000 of inhabitants. The southern part is a flat country, and well cultivated; but the northern is full of mountains covered with trees. It contains mines of all sorts; and there is a gold mine lately opened. The capital town is Quie-ling.

A very singular tree, says Grosier, grows in this province; instead of pith, it contains a soft pulp, which yields a kind of flour: the bread made of it is said to be exceedingly good. Besides parqueets, hedgehogs, porcupines, and rhinoceroses, a prodigious number of wild animals, curious birds, and uncommon insects, are found here. This province contains 12 cities of the first class, and 86 of the second and third. See China, Supplement.

QUANG-TONG, a province of China, bounded on the east by Kiang-si and Fukien; on the south, by the ocean; and on the west, by Tonquin. This province is diversified by valleys and mountains; and yields two crops of corn in a year. It abounds in gold, jewels, silk, porcelain, tin, quicksilver, sugar, brass, iron, steel, saltpetre, ebony, and several sorts of odoriferous wood; besides fruits of all sorts proper to the climate. They have a prodigious number of ducks, whose eggs they hatch in ovens; and a tree, whose wood is remarkably hard and heavy, and thence called iron-wood. The mountains are covered with a sort of osiers which creep along the ground, and of which they make baskets, hurdles, matting, and ropes.

Although the climate of this province is warm, the air is pure, and the people are robust and healthy. They are very industrious; and it must be allowed that they possess in an eminent degree the talent of imitation: if they are only shown any of our European works, they execute others like them with the most surprising exactness. This province suffered much during the civil wars; but at present it is one of the most flourishing in the empire; and, as it is at a great distance from court, its government is one of the most important. This province is divided into ten districts, which contain ten cities of the first class, and 84 of the second and third. Canton is the capital town.

QUANTITY, as explained by the great English lexicographer, is that property of any thing which may be increased or diminished. This interpretation of the word is certainly just, and for the purposes of common conversation it is sufficiently determinate; but the man of science may expect to find in a work like ours a definition of the thing signified. This, however, cannot be given him. A logical definition consists of the genus under which the thing defined is ranked, and the specific difference (see Logic, No. 20, &c.); but quantity is ranked under no genus. In that school where such definitions were most valued, it was considered as one of the ten categories, or general conceptions, under which all the objects of human apprehension were mastered, like soldiers in an army (see Categorium and Philosophy, No. 22). On this account, even Aristotle himself,
which it has performed, have procured it a most respectable place in the circle of the sciences. Ingenious men have availed themselves of this pre-eminence of mathematics, and have endeavoured to procure respect for their disquisitions on other subjects, by presenting them to the public as branches of mathematical science, and therefore susceptible of that accuracy and certainty which is peculiar to it. Our moral affections, our sensations, our intellectual powers, are all susceptible of augmentation and diminution, are conceivable as greater and less when stated together, and are familiarly spoken of as admitting of degrees of comparison. We are perfectly well understood when we say that one pain, heat, grief, kindness, is greater than another; and as this is the distinguishing characteristic of quantity, and as quantity is the subject of mathematical discussion, we suppose that these subjects may be treated mathematically. Accordingly, a very celebrated and excellent philosopher has said, among many things of the same kind, that the greatness of a favour is in the direct compound ratio of the service performed and the dignity of the performer, and in the inverse ratio of the merit and rank of the receiver; that the value of a character is in the compound ratio of the talents and virtues, &c.; and he has delivered a number of formal propositions on the most interesting questions in morals, couched in this mathematical language, and even expressed by algebraic formulæ. But this is merely play, and contains no instruction. We understand the words; they contain no absurdity; and in as far as they have a sense, we believe the propositions to be true. But they give no greater precision to our sentiments than the more usual expressions would do. If we attend closely to the meaning of any one of such propositions, we shall find that it only expresses some vague and indistinct notions of degrees of those emotions, sentiments, or qualities, which would be just as well conceived by means of the expressions of ordinary language; and that it is only by a sort of analogy or resemblance that this mathematical language conveys any notions whatever of the subjects.

The object of contemplation to the mathematician is not whatever is susceptible of greater and less, but what the mathematician can measure; and mathematics is not the science of indefinitely small quantities, but of magnitude which can be measured. It is indeed the science of measure, and whatever is treated in the way of measurement is treated mathematically. Now, in the discourse of ordinary life and ordinary men, many things are called quantities which we cannot or do not measure. This is the case in the instances already given of the affections of the mind, pleasure, pain, beauty, wisdom, honour, &c. We do not say that they are incapable of measure; but we have not yet been able to measure them, nor do we think of measuring them when we speak rationally and usefully about them. We therefore do not consider them mathematically; nor can we introduce mathematical precision into our discussions of these subjects till we can, and actually do, measure them. Persons who are precise in their expression will even avoid such phrases on these subjects as suppose, or strictly express, such measurement. We should be much embarrassed how to answer the question, How much pain does the toothache give you just now? and how much is it easier since yesterday?
Quantity. yesterday? Yet the answer (if we had a measure) would be as easy as to the question, How many guineas did you win at cards? or how much land have you bought? Nay, though we say familiarly, “I know well how much such a misfortune would affect you,” and are understood when we say it, it would be awkward language to say, “I know well the quantity of your grief.” It is in vain, therefore, to expect mathematical precision in our discourse or conceptions of quantities in the most abstracted sense. Such precision is confined to quantity which may be and is measured (A). It is only trifling with the imagination when we employ mathematical language on subjects which have not this property. It will therefore be of some service in science to discriminate quantities in this view; to point out what are susceptible of measure, and what are not.

What is measuring? It is one of these two things: It is either finding out some known magnitude of the thing measured, which we can demonstrate to be equal to it; or to find a known magnitude of it, which being taken so many times shall be equal to it. The geometer measures the contents of a parabolic space when he exhibits a parallelogram of known dimensions, and demonstrates that this parallelogram is equal to the parabolic space. In like manner, he measures the solid contents of an infinitely extended hyperbolic spindle, when he exhibits a cone of known dimensions, and demonstrates that three of these cones are equal to the spindle.

In this process it will be found that he actually subdivides the quantity to be measured into parts of which it consists, and states these parts as actually making up the quantity, specifying each, and assigning its boundaries. He goes on with it, piece by piece, demonstrating the respective equalities as he goes along, till he has exhausted the figure, or considered all its parts. When he measures by means of a subsurface, as when he shows the surface of a sphere to be equal to four of its great circles, he stops, after having demonstrated the equality of one of these circles to one part of the surface: then he demonstrates that there are other three parts, each of which is precisely equal to the one he has minutely considered. In this part of the process he expressly assigns the whole surface into its distinct portions, of which he demonstrates the equality.

But there is another kind of geometrical measurement which proceeds on a very different principle. The geometer conceives a certain individual portion of his figure, whether line, angle, surface, or solid, as known in respect to its dimensions. He conceives this to be lifted from its place, and again laid down on the adjoining part of the figure, and that it is equal to the part which it now covers; and therefore that this part together with the first is double of the first: he lifts it again, and lays it down on the next adjoining part, and affirms that this, added to the two former, make up a quantity triple of the first. He goes on in this way, making similar inferences, till he can demonstrate that he has in this manner covered the whole figure by twenty applications, and that his moveable figure will cover no more; and he affirms that the figure is twenty times the part employed.

This mode is precisely similar to the manner of practical measurement in common life: we apply a foot-rule successively to two lines, and find that 30 applications exhaust the one, while it requires 35 to exhaust the other. We say therefore, that the one line is 30 and 

(A) To talk intelligibly of the quantity of a pain, we should have some standard by which to measure it; some known degree of it so well ascertained, that all men, when talking of it, should mean the same thing. And we should be able to compare other degrees of pain with this, so as to perceive distinctly, not only whether they exceed or fall short of it, but also how much, or in what proportion; whether by an half, or a fifth, or a tenth. Reid.
the triangle is not the subject, but an adjunct, a quality. And when we suppose the application made, we are not in fact supposing two abstract triangles to coincide. This we cannot do with any thing like distinctness; for our distinct conception now is, not that of two triangles coinciding, but of one triangle being now exactly occupied by that moveable thing which formerly occupied the other. In short, it is a vulgar measurement, restricted by suppositions which are inadmissible in all actual measurements in the present universe, in which no moveable material thing is known to be permanent, either in shape or magnitude.

This is an undeniable consequence of the principle of universal gravitation, and the compressibility of every kind of tangible matter with which we are acquainted. Remove the brass rule but one inch from its place; its gravitation to the earth and to the rest of the universe is immediately changed, and its dimensions change of consequence. A change of temperature will produce a similar effect; and this is attended to and considered in all nice mensurations. We do the best we can to assure ourselves that our rule always occupies a sensibly equal space; and we must be contented with chances of error which we can neither perceive nor remove.

We might (were this a proper place) take notice of some other logical defects in the reasoning of this celebrated proposition: but they are beside our present purpose of explaining the different modes of mathematical measurement, with the view of discovering that circumstance in which they all agree, and which (if the only one) must therefore be the characteristic of mensuration.

We think that the only circumstance in which all modes of mensuration agree, or the only notion that is found in them all, is, that the quantity is conceived as consisting of parts, distinguishable from each other, and separated by assignable boundaries; so that they are at once conceived separately and jointly. We venture to assert that no quantity is directly measured which we cannot conceive in this way, and that such quantities only are the immediate objects of mathematical contemplation, and should be distinguished by a generic name. Let them be called MATHEMATICAL QUANTITIES, EXTENSION, DURATION, NUMBER, and PROPORTION, have this characteristic, and they are the only quantities which have it. Any person will be convinced of the first assertion by attending to his own thoughts when contemplating these notions. He will find that he conceives every one of them as made up of its own parts, which are distinguishable from each other, and have assignable boundaries, and that it is only in consequence of involving this conception that they can be added to or subtracted from each other; that they can be multiplied, divided, and conceived in any proportion to each other.

He may perhaps find considerable difficulty in acquiring perfectly distinct notions of the measurable, and the accuracy of the modes of mensuration. He will find that the way in which he measures duration is very similar to that in which he measures space or extension. He does not know, or does not attend to, any thing which hinders the brass foot-rule in his hand from continuing to occupy equal spaces during his use of it, in measuring the distance of two bodies. In like manner he selects an event which nature or art can repeat continually, and in which the circumstances which contribute to its accomplishment are invariably the same, or their variations and their effects are insensible. He concludes that it will always occupy an equal portion of time for its accomplishment, or always last an equal time. Then, observing that, during the event whose duration he wishes to measure, this standard event is accomplished 3654 times, and that it is repeated 3652 times during the accomplishment of another event, he affirms that the durations of these are in the ratio of 3654 to 3652. It is thus (and with the same logical defect as in the measuring a line by a brass rod) that the astronomer measures the celestial revolutions by means of the rotation of the earth round its axis, or by the vibrations of a pendulum.

We are indebted for most of the preceding observations to Dr Reid, the celebrated author of the Inquiry into the Human Mind on the Principles of Common Sense, and of the Essays on the Intellectual and Active Powers of Man. He has published a dissertation on this subject in the 43th volume of the Philosophical Transactions, No 489, which we recommend to our philosophical readers as a performance eminent for precision and acuteness. If we presume to differ from him in any trivial circumstance, it is with that deference and respect which is due to his talents and his worth.

Dr Reid justly observes, that as nothing has proportion which has not either extension, duration, or number, the characters of mathematical quantity may be restricted to these three. He calls them PROPER QUANTITIES, and all others he calls IMPROPER. We believe that, in the utmost precision of the English language, this denomination is very apposite, and that the word QUANTITY derived from QUANTUM, always supposes measurement: but the word is frequently used in cases where its original is not kept in view, and we use other quantities words as synonymous with it, when all mensuration, that can be considered measurement, there seems to be no impropriety in giving this name, in our language at least, to whatever can be conceived as great or little. There is no impropriety in saying that the pain occasioned by the stone is greater than that of the toothache; and when we search for the category to which the assertion may be referred, we cannot find any other than quantity. We may be allowed therefore to say, with almost all our scientific countrymen, that every thing is conceivable in respect of quantity which we can think or speak of as greater and less; and that this notion is the characteristic of quantity as a genus, while measureableness is the characteristic of mathematical quantity as a species.

But do we not measure many quantities, and consider them mathematically, which have not this characteristic of being made up of their own distinguishable parts? What else is the employment of the mechanician, when speaking of velocities, forces, attractions, repulsions, magnetic influence, chemical affinity, &c. &c.? Are not these mathematical sciences? And if the precision and certainty of mathematics arise from the nature of their specific object, are not all the claims of the mechanician and physical astronomer ill-founded pretensions? These questions require and deserve a serious answer.

It is most certain that we consider the notions which are expressed by these terms velocity, force, density, and
Some of these terms are nothing but names for relations of measurable quantity, and only require a little reflection to show themselves such. **Velocity** is one of these. It is only a name expressing a relation between the space described by a moving body and the time which elapses during its description. Certain moderate rates of motion are familiar to us. What greatly exceeds this, such as the flight of a bird when compared with our walking, excites our attention, and this excess gets a name. A motion not so rapid as we are familiar with, or as we wish, also gets a name; because in this the excess or defect may interest us. We wish for the flight of the hawk; we chide the tardy pace of our messenger: but it is scientific curiosity which first considers this relation as a separate object of contemplation, and the philosopher must have a name for it. He has not formed a new one, but makes use of a word of common language, whose natural meaning is the combination of a great space with a short time. Having once appropriated it, in his scientific vocabulary, to this very general use, it loses with him its true signification. Tardity would have done just as well, though its true meaning is diametrically opposite; and there is no greater impropriety in saying the tardity of a cannon bullet than in saying the velocity of the hour-hand of a watch. Velocity is a quality or affection of motion, the notion of which includes the notions of space and duration (two mathematical quantities), and no other. It does not therefore express a mathematical quantity itself, but a relation, a combination of two mathematical quantities of different kinds; and as it is measurable in the quantities so combined, its measure must be a unit of its own kind, that is, an unit of space as combined with an unit of time.

**Density** is another word of the same kind, expressing a combination of space with number. Densae arborae means trees standing at a small distance from each other; and the word is used in the same sense when we say that quicksilver is denser than water. The expression always suggests to the reflecting mind the notions of particles and their distances. We are indeed so habituated to complicated views of things, that we can see remote connections with astonishing rapidity; and a very few circumstances are sufficient for leading forward the mind in a train of investigation. Common discourse is a most wonderful instance of this. It is in this way that we say, that we found by weighing them that inflammable air had not the sixth part of the density of common air. Supposing all matter to consist of equal atoms equally heavy, and knowing that the weight of a bladder of air is the sum of the weights of all the atoms, and also knowing that the virchinity of the atoms is in a certain proportion of the number contained in a given bulk, we affirm that common air is more than six times denser than inflammable air; but this rapid decision is entirely the effect of habit, which makes us familiar with certain groups of conceptions, and which instantaneously distinguishes them from others, and thus think and discourse rationally. The Latin language employs the word *frequens* to express both the combination of space and number, and that of time and number.

There are perhaps a few more words which express combinations of mathematical quantities of different kinds; and the corresponding ideas or notions are there-fore proper and immediate subjects of mathematical discussion: But there are many words which are expressive of things, or at least of notions, to which this way of considering them will not apply. All those affections or qualities of external bodies, by which they are conceived to act on each other, are of this kind: Impulsive force, weight, centrifugal and centripetal force, magnetic and electrical, chemical attractions and repulsions; in short, all that we consider as the immediate causes of natural phenomena. These we familiarly measure, and consider mathematically.

What was said on this subject in the article Physics of the Phenomena will give us clear conceptions of this process of the mind. These forces or causes are not immediate objects of contemplation, and are known only by and in the phenomena which we consider as their effects. The phenomenon is not only the indication of the agency of any cause, and the characteristic of its kind, but the measure of its degree. The necessary circumstances in this train of human thought are, 1st, The notion of the force as something susceptible of augmentation and diminution. 2d, The notion of an inseparable connection of the force with the effect produced, and of every degree of the one with a corresponding degree of the other. From these is formed the notion that the phenomenon or effect is the proper measure of the force or cause. All this is strictly logical.

But when we are considering these subjects mathematically, the immediate objects of our contemplation are not the forces which we are thus treating. It is not their relations which we perceive, and which we combine with such complication of circumstances and certainty of inference as are known in all other sciences: by no means; they are the phenomena only, which are subjects of purely mathematical discussion. They are motions, which involve only the notions of space and time; and when we have finished an accurate mathematical investigation, and make our affirmation concerning the forces, we are certain of its truth, because we suppose the forces to have the proportions and relations, and no other, which we observe in the phenomena. Thus, after having demonstrated, by the geometrical comparison of the lines and angles and surfaces of an ellipse, that the momentary deflection of the moon from the tangent of her orbit is the 3650th part of the simultaneous deflection of a stone from the tangent of its parabolic path; Newton affirms, that the force by which a particle of the moon is retained in her orbit is the 3650th part of the weight of a particle of the stone; and having further shown, from fact and observation, that these momentary deflections are inversely as the squares of the distances from the centre of the earth, he affirms, that all this is produced by a force which varies its intensity in this manner.

Now all this investigation proceeds on the two suppositions mentioned above, and the measures of the forces are in fact the measures of the phenomena. The whole of physical astronomy, and indeed the whole of mechanical philosophy, might be taught and understood, without ever introducing the word force, or the notion which it is supposed to express: for our mathematical reasons are really about the phenomena, which are subjects purely mathematical.

The precision, therefore, that we presume to affirm to attend these investigations, arises entirely from the measurable
measurable nature of the quantities which are the real objects of our contemplation, and the suitableness and propriety of the measures which we adopt in our comparisons.

Since, then, the phenomena are the immediate subjects of our discussion, and the operating powers are only inferences from the phenomena considered as effects, the quantity ascribed to them must also be an inference from the quantity of the effect, or of some circumstance in the effect. The measure, therefore, of the cause, or natural power or force, cannot be one of its own parts; for the whole and the part are equally unperceived by us. Our measure, therefore, must be a measure of some interesting part, or of the only interesting part of the phenomenon. It is therefore in a manner arbitrary, and depends chiefly on the interest we take in the phenomenon. It must, however, be settled with precision, so that all men in using it may mean the same thing. It must be settled, therefore, by the description of that part or circumstance of the phenomenon which is characteristic of the natural power. This description is the definition of the measure.

Thus Newton assumes as his measure of the centripetal force, the momentary deviation from uniform rectilinear motion. Others, and sometimes Newton himself, assume the momentary change of velocity, which again is measured by twice this deviation. These measures, being thus selected, are always proper in a mathematical sense; and if strictly adhered to, can never lead us into any paradigism. They may, however, be physically wrong: there may not be that indissoluble connection between the phenomenon and the supposed cause. But this is no mathematical error, nor does it invalidate any of our mathematical inferences: it only makes them useless for explaining the phenomenon by the principle which we adopted; but it prepares a modification of the phenomenon for some more fortunate application of physical principles.

All that can be desired in the definitions or descriptions of these measures is, that they may not deviate from the ordinary use of the terms, because this would always create confusion, and occasion mistakes. Dr Reid has given an example of an impropriety of this kind, which has been the subject of much debate among the writers on natural philosophy. We mean the measure of the force inherent in a body in motion. Descartes, and all the writers of his time, assumed the velocity produced in a body as the measure of the force which produces it; and observing that a body, in consequence of its being in motion, produces changes in the state or motion of other bodies, and that these changes are in the proportion of the velocity of the changing body, they asserted that there is in a moving body a vis ininita, an inherent force, and that this is proportional to its velocity; saying that its force is twice or thrice as great, when it moves twice or thrice as fast at one time as at another. But Leibnitz observed, that a body which moves twice as fast, rises four times as high, against the uniform action of gravity; that it penetrates four times as deep into a piece of uniform clay; that it bends four times as many springs, or a spring four times as strong, to the same degree; and produces a great many effects which are four times greater than those produced by a body which has half the initial velocity. If the velocity be triple, quadruplet, &c. the effects are nine times, 16 times, &c. greater; and, in short, are proportional, not to the velocity, but to its square. This observation had been made before by Dr Hooke, who has enumerated a prodigious variety of important cases in which this proportion of effect is observed. Leibnitz, therefore, affirmed, that the force inherent in a moving body is proportional to the square of the velocity.

It is evident that a body, moving with the same velocity, has the same inherent force, whether this be employed to move another body, to bend springs, to rise in opposition to gravity, or to penetrate a mass of soft matter. Therefore these measures, which are so widely different, while each is agreeable to a numerous class of facts, are not measures of this something inherent in the moving body which we call its force, but are the measures of its exertions when modified according to the circumstances of the case; or, to speak still more cautiously and securely, they are the measures of certain classes of phenomena consequent on the action of a moving body. It is in vain, therefore, to attempt to support either of them by a demonstration. The measure itself is nothing but a definition. The Cartesian calls that a double force which produces a double velocity in the body on which it acts. The Leibnitzian calls that a quadruple force which makes a quadruple penetration. The reasonings of both in the demonstration of a proposition in dynamics may be the same, as also the result, though expressed in different numbers.

But the two measures are far from being equally proper: for the Leibnitzian measure obliges us to do continual violence to the common use of words. When two bodies moving in opposite directions meet, strike each other, and stop, all men will say that their forces are equal, because they have the best test of equality which we can devise. Or when two bodies in motion strike the parts of a machine, such as the opposite arms of a lever, and are thus brought completely to rest, we and all men will pronounce their mutual energies by the intervention of the machine to be equal. Now, in all these cases, it is well known that a perfect equality is found in the products of the quantities of matter and velocity. Thus a ball of two pounds, moving with the velocity of four feet in a second, will stop a ball of eight pounds moving with the velocity of one foot per second. But the followers of Leibnitz say, that the force of the first ball is four times that of the second.

All parties are agreed in calling gravity a uniform or invariable accelerating force; and the definition which they give of such a force is, that it always produces the same acceleration, that is, equal accelerations in equal times, and therefore produces augmentations of velocity proportionable to the times in which they are produced. The only effect ascribed to this force, and consequently the only thing which indicates, characterizes, and measures it, is the augmentation of velocity. What is this velocity, considered not merely as a mathematical term, but as a phenomenon, as an event, a production by the operation of a natural cause? It cannot be conceived any other way than as a determination to move on for ever at a certain rate, if nothing shall change it. We cannot conceive this very clearly. We feel ourselves forced to animate, as it were, the body, and give it not only a will and intention to move in this manner, but a real exertion of some faculty in consequence
QUA [ 596 ]

Quantity. consequence of this determination of mind. We are
conscious of such a train of operations in ourselves; and
the last step of this train is the exertion or energy of
some natural faculty, which we, in the utmost propriety
of language, call force. By such analogical conception,
we suppose something, an energy, inherent in the mov-
ing body; and its only office is the production and
continuation of this motion, as in our own case. Scien-
tific curiosity was among our latest wants, and lan-
guage was formed long before its appearance: as we
formed analogical conceptions, we contended ourselves
with the words already familiar to us, and to this some-
thing we gave the name FORCE, which expressed that
energy in ourselves which bears some resemblance (in
office at least) to the determination of a body to move
on at a certain rate. This sort of allegory pervades the
whole of our conceptions of natural operations, and we
can hardly think or speak of any operation without a
language, which supposes the animation of matter. And,
in the present case, there are so many points of resem-
blance between the effects of our exertions and the op-
erations of nature, that the language is most expressive,
and has the strongest appearance of propriety. By ex-
erting our forces, we not only move and keep in motion,
but we move other bodies. Just as a ball not only moves,
but puts other bodies in motion, or penetrates them,
&c.—This is the origin of that conception which so
forcibly obtrudes itself into our thoughts, that there
is inherent in a moving body a force by which it produces
changes in other bodies. No such thing appears in the
same body if it be not in motion. We therefore con-
clude, that it is the production of the moving force,
whatever that has been. If so, it must be conceived
as proportional to its producing cause. Now this force,
thus produced or exerted in the moving body, is only
another way of conceiving that determination which we
call velocity, when it is conceived as a natural event.
We can form no other notion of it. TheVIS INSITA, the
determination to move at a certain rate, and the ve-
locity, are one and the same thing, considered in different
relations.

Vis Insita. Therefore the VIS INSITA CORPORI MOVENTI, the determi-
nation to move at a certain rate, and the velocity, should
have one and the same measure, or any one of them may
be taken for the measure of the other. The velocity
being an object of perception, is therefore a proper
measure of the inherent force; and the propriety is
more evident by the perfect agreement of this use of
the words with common language. For we conceive and
express the action of gravity as uniform, when we think
and say that its effects are proportional to the times
of its action. Now all agree, that the velocity produced
by gravity is proportional to the time of its action. And
thus the measure of force, in reference to its producing
cause, perfectly agrees with its measure, independent of
this consideration.

But this agreement is totally lost in the Leibnitzian
document; for the body which has fallen four times as
far, and has sustained the action of gravity twice as long,
is said to have four times the force.

The quaintness and continued paradox of expression
which this measure of inherent force leads us into,
would have quickly exploded it, had it not been that
its chief abettors were leagued in a keen and acrimo-
nious warfare with the British mathematicians who sup-
ported the claim of Sir Isaac Newton to the invention
of fluxions. They rejoiced to find in the elegant writ-
ings of Huygens a physical principle of great extent,
such as this is, which could be set in comparison with
some of the wonderful discoveries in Newton’s Princi-
pia. The fact, that in the mutual action of bodies on
each other the product of the masses and the squares
of the velocities remain always the same (which they
call the conservatio virium vivorum) is of almost uni-
versal extent; and the knowledge of it enabled them to
give ready and elegant solutions of the most abstruse
and intricate problems, by which they acquired a great and
deserved celebrity. Dr. Robert Hooke, whose observa-
hardly any thing escaped, was the first (long before
Huygens) who remarked, that in all the cases of the
gradual production and extinction of motion, the sensible
phenomenon is proportional to the square of the produ-
ced or extinguished velocity.

John Bernoulli brought all these facts together, and
systematized them according to the principle advanced
by Huygens in his treatise on the centre of oscillation.
He and Daniel Bernoulli gave most beautiful specimen
of the prodigious use of this principle for the solution
of difficult physical problems in their dissertations
on the motion and impulse of fluids, and on the commu-
nication of motion. It was however very early objected
to them (we think by Marquis Poleni), that in the colli-
sion of bodies perfectly hard there was no such conscrv-
atio virium vivorum; and that, in this case, the forces
must be acknowledged to be proportional to the ve-
celocities. The objections were unanswerable.—But John
Bernoulli evaded their force, by affirming that there
were and could be no bodies perfectly hard. This was
the origin of another celebrated doctrine, on which
Leibnitz greatly plumed himself, the LAW OF CON-
tinuity, viz. that nothing is observed to change ab-
ruptly, or per saltum. But no one will pretend to say
that a perfectly hard body is an inconceivable thing; on
the contrary, all will allow that softness and compris-
sibility are adjunct ideas, and not in the least necessary
to the conception of a particle of matter, nay totally
incompatible with our notion of an ultimate atom.

Sir Isaac Newton never could be provoked to en-
gage in this dispute. He always considered it as a wil-
ful abuse of words, and unworthy of his attention. He
guarded against all possibility of cavi, by giving the
most precise and perspicuous definitions of those measure
of forces, and all other quantities which he had occasion
to consider, and by carefully adhering to them. And Great ap-
in one proposition of about 20 lines, viz. the 39th of
Newton.

of the 1st book of the Principia, he explained every
phenomenon adduced in support of the Leibnitzian
doctrine, showing them to be immediate consequences
of the action of a force measured by the velocity which
it produces or extinguishes. There it appears that the
heights to which bodies will rise in opposition to the
uniform action of gravity are as the squares of the initial
velocities: So are the depths to which they will pene-
trate uniformly resisting matter: So is the number of
equal springs which they will bend to the same degree,
&c. &c. &c. We have had frequent occasion to men-
tion this proposition as the most extensively useful of all
Newton's discoveries. It is this which gives the imme-
diate application of mechanical principles to the expla-
nation of natural phenomena. It is incessantly employed
escaping, also officers appointed to see quarantine performed, deserting their office, neglecting their duty, or giving a false certificate, suffer death as felons.

Goods from Turkey, or the Levant, may not be landed without license from the king, or certificate that they have been landed and aired at some foreign port. See PLACUX.

QUARLES, FRANCIS, the son of James Quarales clerk to the board of green cloth, and purveyor to Queen Elizabeth, was born in 1592. He was educated at Cambridge; became a member of Lincoln's Inn; and was for some time cup-bearer to the queen of Bohemia, and chronicler to the city of London. It was probably on the ruin of her affairs that he went to Ireland as secretary to Archbishop Usher; but the troubles in that kingdom forcing him to return, and not finding affairs more at peace in England, some disquiet he met with were thought to have hastened his death, which happened in 1644. His works both in prose and verse are numerous, and were formerly in great esteem, particularly his Divine Emblems: but the obsole West quaintness of his style has caused them to fall into neglect, excepting among particular classes of readers. "The memory of Quarales, says a late author, has been branded with more than common abuse, and he seems to have been censured merely from the want of being read. If his poetry failed to gain him friends and readers, his piety should at least have secured him peace and goodwill. He too often, no doubt, mistook the enthusiasm of devotion for the inspiration of fancy: to mix the waters of Jordan and Helicon in the same cup, was reserved for the bard of Milton; and for him, and him only, to find the bays of Mount Olivet equally verdant with those of Parnassus. Yet, as the effusions of a real poetical mind, however thwarted by wantonness of subject, will be seldom rendered totally abortive, we find in Quarles original imagery, striking sentiment, fertility of expression, and happy combinations; together with a compression of style that merits the observation of the writers of verse. Gross deficiencies of judgment, and the infelicity of his subjects, concurred in ruining him. Perhaps no circumstance whatever can give a more complete idea of Quarles's degradation than a late edition of his Emblems; the following passage is extracted from the preface: 'Mr Francis Quarles, the author of the Emblems that go under his name, was a man of the most exemplary piety, and had a deep insight into the mysteries of our holy religion. But, for all that, the book itself is written in so old a language, that many parts of it are scarcely intelligible in the present age; many of his phrases are so affected, that no person who has any taste for reading can peruse them with the least degree of pleasure; many of his expressions are harsh, and sometimes whole lines are included in a parenthesis, by which the mind of the reader is diverted from the principal object. His Latin mottoes under each cut can be of no service to an ordinary reader, because he cannot understand them. In order, therefore, to accommodate the public with an edition of Quarles's Emblems properly modernised, this work was undertaken.' Such an exhibition of Quarles is chaining Columbus to an oar, or making John Duke of Marlborough a train-band corporal."

QUARRIES, a name commonly given to an extraordinary cavern under the city of Paris, the existence
There were formerly several openings into the quarries, but the two I have mentioned, viz. the Observatory and the Val de Grâce, are, I believe, the only ones left; and these the inspectors keep constantly locked, and rarely open them, except to strangers particularly introduced, and to workmen who are always employed in some part by the king. The police thought it a necessary precaution to secure all the entrances into this cavern, from its having been formerly inhabited by a famous gang of robbers, who infested the country for many miles round the city of Paris.

As to the origin of this quarry, I could not, on the strictest inquiry, learn any thing satisfactory; and the only account I know published is the following contained in the *Tableaux de Paris, nouvelle édition, tome premier, chapitre 5me, page 12me.*

For the first building of Paris it was necessary to get the stone in the environs; and the consumption of it was very considerable. As Paris was enlarged, the suburbs were insensibly built on the ancient quarries, so that all that you see without is essentially wanting in the earth for the foundation of the city: hence proceed the frightful cavities which are at this time found under the houses in several quarters. They stand upon abysses. It would not require a very violent shock to throw back the stones to the place from whence they have been raised with so much difficulty. Eight men being swallowed up in a gulf of 150 feet deep, and some other less known accidents, excited at length the vigilance of the police and the government, and, in fact, the buildings of several quarters have been privately propped up; and by this means a support given to these obscure subterraneous places which they before wanted.

"All the suburbs of St James's, Harp-street, and even the street of Tournon, stand upon the ancient quarries; and pillars have been erected to support the weight of the houses. What a subject for reflections, in considering this great city formed and supported by means absolutely contrary! These towers, these steeples, the arched roofs of these temples, are so many signs to tell the eye that what we now see in the air is wanting under our feet."

**QUARRY,** a place under ground, out of which are got marble, freestone, slate, limestone, or other matters proper for building. See SHALE.

Some limestone quarries in Fife are highly worthy the attention of the curious, on account of an amazing mixture of organized marine productions found in them. One of this kind was opened about the year 1759, at a farm called *Endertall,* in the neighbourhood of Kirkaldy, belonging to General St Clair.

The flakes of the stone, which are of unequal thickness, most of them from eight to ten inches, lie horizontally, dipping towards the sea. Each of these flakes, when broken, presents to our view an amazing collection of petrified sea bodies, as the bones of fishes, stalks of sea-weed, vast quantities of shells, such as are commonly found on those coasts, besides several others of very uncommon figures. In some places the shells are so numerous, that little else is to be seen but prodigious clusters or concretions of them. In the uppermost stratum the shells are so entire, that the outer crust or plate may be scraped off with the finger; and the stalks of the sea-weed have a darkish colour, not that glossy whiteness which they have in the heart of.
of the quarry. The smallest rays or veins of the shells are deeply indented on the stone, like the impression of a seal upon wax. In short, no spot at the bottom of the ocean could exhibit a greater quantity of sea-bodies than are to be found in this said rock; for we have the skeletons of several fishes, the antenna or feelers of lobsters, the roots and stalks of sea-weeds, with the very capsule which contain the seed. The place where all these curiosities are found is on an eminence about an English mile from the sea; and as the ground is pretty steep the whole way, it may be 200 feet higher at least.

There are two or three things to be remarked here.
1. That among all the bodies we have mentioned, there are none but what are specifically heavier than water. This holds so constantly true, that the sea-weed, which floats in water when the plant is entire, has been stripped of the broad leaves, which make it buoyant, before it has been lodged here. 2. The shells have been all empty; for the double ones, as those of the flat kind, are always found single, or with one side only. 3. The rock seems to have been gradually deserted by the sea, and for a long time, washed with the tides; for the upper surface is all eaten, and hollowed in many places like an honey-comb, just as we observe in flat rocks exposed every tide to the access and recess of the waters. See the article Sea.

Quarry, or Quarrel, among glaziers, a pane of glass cut in a diamond form.

Quarries are of two kinds, square and long; each of which are of different sizes, expressed by the number of the pieces that make a foot of glass, viz. eights, tenths, eighteenths, and twentieths: but all the sizes are cut to the same angles, the acute angle in the square quarrels being 79° 19', and 67° 21' in the long ones.

Quarry, among hunters, is sometimes used for a part of the entrails of the beast taken, given by way of reward to the hounds.

Quarry, in falconry, is the game which the hawk is in pursuit of, or has killed.

QUART, a measure of capacity, being the fourth part of some other measure. The English quart is the fourth part of the gallon, and contains two pints. The quart of the Romans was the fourth part of their congus. The French have various quarts, besides their quart or pot consisting of two pints, and are distinguished by the whole of which they are quarters; as quart de muid, and quart de boisseau.

Quartan, a measure containing the fourth part of some other measure.

Quartan, a species of intermittent fever. See Medicine Index.

Quartation, is an operation by which the quantity of one thing is made equal to a fourth part of the quantity of another thing. Thus when gold alloyed with silver is to be parted, we are obliged to facilitate the action of the aquafortis, by reducing the quantity of the former of these metals to one fourth part of the whole mass; which is done by sufficiently increasing the quantity of the silver, if it be necessary. This operation is called quartation, and is preparatory to the parting; and even many authors extend this name to the operation of parting. See Ones, Analysis of.
Quarter. of the lower deck; a the gun-ports of the upper and quarter-deck. I the after-part of the mizzen channel. K the wing transom. LG the lower counter. LB the station of the deck transom. LQ the after-part of the main-wale. DR the after-part of the channel-wale, parallel to the main-wale. SU the sheer-rail, parallel to both wales. T t the rudder. A t F the rakes of the stern. F f the drift-rails. T U the after-part of the lead water-line; k k l the curve of the several decks corresponding to those represented in the head. See the article HEAD.

As the marks, by which vessels of different constructions are distinguished from each other, are generally more conspicuous on the stern or quarter than any other part, we have represented some of the quarters, which assume the most different shapes, and form the greatest contrast with each other. Fig. 2 shows the stern and quarter of a Dutch galleon. Fig. 3. the stern and quarter of a cat. Fig. 4. is the stern and quarter of a common galley. Fig. 5. exhibits the quarter of a first-rate galley, otherwise called a gallassa. Fig. 6. the quarter of a Dutch dogger, or galliot. Fig. 7. represents the stern and quarter of a sloop of war.

The quarters of all other ships have a near affinity to those above exhibited. Thus all ships of the line, and East-Indiamen, are formed with a quarter little differing from the principal figure in this plate. Xebecs have quarters nearly resembling those of gallasses, only somewhat higher. Hougahots and pinks approach the figure of cats, the former being a little broader in the stern, and the latter a little narrower; and the sterns and quarters of cats seem to be derived from those of xebets. The sterns of Dutch doggers and galliots are indeed singular, and like those of no other modern vessel: they have nevertheless a great resemblance to the ships of the ancient Grecians, as represented in medallis and other monuments of antiquity.

On the Quarter, may be defined an arch of the horizon, contained between the line prolonged from the ship's stern and any distant object, as land, ships, &c. Thus if the ship's keel lies on an east and west line, the stern being westward, any distant object perceived on the north-west or south-west, is said to be on the larboard or starboard quarter.

Quarter-Book, a roll, or list, containing the different stations, to which all the officers and crew of the ship are quartered in the time of battle, and the names of all the persons appointed to those stations. See Quarters.

Quarter-Master, an officer, generally a lieuten-ant, whose principal business is to look after the quarters of the soldiers, their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horse one, who are only warrant-officers, except in the Blues.

Quarter-Master-General, is a considerable officer in the army; and should be a man of great judgment and experience, and well skilled in geography. His duty is to mark the marches and encampments of an army: he should know the country perfectly well, with its rivers, plains, marches, woods, mountains, defiles, passages, &c. even to the smallest brook. Prior to a march, he receives the order and route from the commanding general, and appoints a place for the quarter-masters of the army to meet him next morning, with whom he marches to the next camp; where being come, and having viewed the ground, he marks out to the regimental quarter-masters the ground allowed each regiment for their camp: he chooses the head-quarters, and appoints the villages for the generals of the army's quarters; he appoints a proper place for the encampment of the train of artillery: he conducts foraging parties, as likewise the troops to cover them against assaults, and has a share in regulating the winter-quarters and cantonments.

Quarter-Netting, a sort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork, or old sails; but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in battle.

Quarter-Sessions, a general court held quarterly by Blackett. Common Council appointed by stat. 2 Hen. V. c. 4. to be in the first week after Michaelmas-day; the first week after the Epiphany; the first week after the close of Easter; and in the week after the translation of Saint Thomas à Becket, or the 7th of July. The court is held before two or more justices of the peace, one of whom must be of the quorum. The jurisdiction of this court by 34 Ed. III. c. 1. extends to the trying and determining of all felonies and trespasses whatsoever, though they seldom, if ever, try any greater offence than small felonies within the benefit of clergy, their commission providing, that if any case of difficulty arises, they shall not proceed to judgment, but in the presence of one of the justices of the court of king's bench or common pleas, or one of the judges of assize. And therefore murderers and other capital felonies are usually remitted for a more solemn trial to the assizes. They cannot also try any new created offence, without express power given them by the statute which creates it. But there are many offences, and particularly matters, which by particular statutes belong properly to this jurisdiction, and ought to be prosecuted in this court; as, the smaller misdemeanors against the public or commonwealth, not amounting to felony, and especially offences relating to the game, highways, alehouses, bastard children, the settlement and provision for the poor, vagrants, servants wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment, and others in a summary way by motion and order thereupon; which order may, for the most part, unless guarded against by particular statutes, be removed into the court of king's bench, by writ of certiorari facias, and be there either quashed or confirmed. The records or rolls of the sessions are committed to the custody of a special officer, denominated the custos roturum. In most corporation towns there are quarter-sessions kept before justices of their own, within their respective limits, which have exactly the same authority as the general quarter-sessions of the county, except in very few instances: one of the most considerable of which is the matter of appeals from orders of removal of the poor, which, though they be from the orders of corporation justices, must be to the sessions of the county, by 8 and 9 Will. III. c. 30. In both corporations
rations and countries at large, there is sometimes kept a special or petty session, by a few justices, for dispatching smaller business in the neighbourhood between the times of the general sessions, as for licensing alehouses, passing the accounts of parish-officers, and the like.

**Quarter-Staff**, a long staff borne by foresters, park-keepers, &c. as a badge of their office, and occasionally used as a weapon.

**Quarters**, a name given at sea to the several stations where the officers and crew of a ship of war are posted in action. See War, Part II.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are, in general, as follows, when the ship is well manned, so as to fight both sides at once occasionally:

<table>
<thead>
<tr>
<th>Pounder</th>
<th>No. of men</th>
<th>Pounder</th>
<th>No. of men</th>

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the sails. The boatswain, and a sufficient number of men, are stationed to repair the damaged rigging; and the gunner and carpenter, wherever necessary, according to their respective offices.

The marines are generally quartered on the poop and forecastle, or gang-way, under the directions of their officers; although, on some occasions, they assist at the great guns, particularly in distant cannonading.

**Quarters**, at a siege, the encampment upon one of the principal passages round a place besieged, to prevent relief and convey.

**Head Quarters of an Army**, the place where the commander in chief has his quarters. The quarters of generals of horse are, if possible, in villages behind the right and left wings, and the generals of foot are often in the same place; but the commander in chief should be near the centre of the army.

**Quarters of Refreshment**, the place or places where Vol. XVII. Part II.

- troops that have been much harassed are put to recover themselves during some part of the campaign.

- **Intrenched Quarters**, a place fortified with a ditch and parapet to secure a body of troops.

- **Winter Quarters**, sometimes means the space of time included between leaving the camp and taking the field; but more properly the places where the troops are quartered during the winter.

The first business, after the army is in winter-quarters, is to form the chain of troops to cover the quarters well: which is done either behind a river, under cover of a range of strong posts, or under the protection of fortified towns. Hussars are very useful on this service.

It should be observed, as an invariable maxim, in winter quarters, that your regiments be disposed in brigades, to be always under the eye of a general officer; and, if possible, let the regiments be so distributed, as to be each under the command of its own chief.

**Quartile**, an aspect of the planets when they are at the distance of 90° from each other, and it is denoted by the character ☐.

**Quartering**, in Heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

**Quarto-decimans**, an ancient sect in the Christian church, who taught that Easter should always be celebrated according to the custom of the Jews, on the fourteenth day of the month in the month of March, whenever that day fell out. And hence they derived their name †quarto-decimans, †q. d. Fourteenthers. The Asieties were mightily attached to this opinion, pretending that it was built on the authority of St John, who was their apostle; and Pope Victor could never bring them to obedience in this article, though he was upon the point of excommunicating them: but it is more probable he contented himself with menaces. See Easter.

**Quartz**, a mineral composed chiefly of siliceous earths. See Mineralogy Index.

**Quashing**, in Law, the overthrowing and annulling a thing.

**Quasi-contract**, in the civil law, an act without the strict form of a contract, but yet having the force thereof. In a contract there must be the mutual consent of both parties, but in a quasi-contract one party may be bound or obliged to the other, without having given his consent to the act whereby he is obliged. For example: I have done your business, in your absence, without your procuration, and it has succeeded to your advantage. I have then an action against you for the recovery of what I have disbursed, and you an action against me to make me give an account of my administration, which amounts to a quasi-contract.

**Quasi-Crime**, or Quasi-delict, in the civil law, the action of a person who does damage, or evil, involuntarily. The reparation of quasi-crimes consists in making good the damages, with interest.

**Quass**, a fermented liquor drunk in Russia. See Pissant.

**Quassia**, a genus of plants, belonging to the deciduous class; and in the natural method ranking under the 14th order, Grainales. See Botany Index.
QUE<br>QUE<br>QUATUORVIR, in antiquity, formerly written IIII. VÍR, a Roman magistrate, who had three colleagues joined with him in the same administration, and had the care of conducting and settling the colonies sent into the provinces. There were also quatuorviri appointed to inspect and take care of repairs, &c.

QUAVER, in Music, a measure of time equal to half a crotchet, or an eighth part of a semibreve.

QUAY. See KEY.

QUEBEC, a hard-wood large town of North America, and capital of Canada. The first place taken notice of when landing here is a square of an irregular figure, with well-built houses on each side; on the back of which is a rock; on the left it is bounded by a small church; and on the right are two rows of houses, parallel to each other. There is another between the church and the harbour; as also another long row on the side of the bay. This may be looked upon as a kind of suburb; and between this and the great street is a very steep ascent, in which they have made steps for the foot passengers to go up. This may be called the Upper Town, wherein is the bishop's palace; and between these two large squares is a fort where the governor lodges. The Reolets have handsome houses over against it, and on the right is the cathedral church; over against this is the Jesuits college, and between them are well-built houses; from the fort run two streets, which are crossed by a third, and between these are a church and a convent. In the second square are two descents to the river of St Charles. The Hotel Dieu is in the midway; and from thence are small houses, which reach to the house of the intendent. On the other side of the Jesuits college, where the church stands, is a pretty long street in which is a nunnery. Almost all the houses are built of stone, and there are about 15,000 inhabitants; the fort is a handsome building, but not quite finished. Quebec is not regularly fortified; but it cannot be easily taken; for the harbour is flanked with two bastions, which at high tides are almost level with the water. A little above one of the bastions is a demi-bastion, partly taken out of the rock; and above it, on the side of the gallery of the fort, is a battery of 23 pieces of cannon: still above this is a square fort called the citadel; and the ways from one fortification to another are difficult to pass. To the left of the harbour, on the side of the road, there are large batteries of cannon, and some mortars; besides these, there are several other fortifications not very easy to be described. In 1711 the British fitted out a fleet with a design to conquer Canada, which failed on account of the rashness of the admiral; who, contrary to the advice of his pilot, went too near the Seven isles, and so lost his largest ships, and 3000 of his best soldiers. It is about 300 miles north-west of Boston in New-England. On October 18, 1759, it was taken by the British under the command of General Wolfe, who lost his life in the battle, after he had the satisfaction to know that our troops were victorious. Admiral Saunders commanded a squadron of men of war, and did immense service in reducing this place; there being not a man in the navy but what was active on this occasion, not excepting the sailors belonging to the transport vessels. After this valuable acquisition, all Canada came under the jurisdiction of the crown of Great Britain.

W. Long. 69. 48. N. Lat. 46. 55.

QUEDA, a kingdom of Asia, in the peninsula beyond the Ganges, and near the straits of Malacca. The king is tributary to Siam. The principal town is of the same name, and said to contain about 8000 inhabitants. It has a harbour, and is 300 miles north of Malacca. E. Long. 100. 5. N. Lat. 7. 5.

QUEDLINGBURG, a town of Germany, in the circle of Upper Saxony, now belonging to Prussia. Here is a famous abbey, whose abbes was a princess of the empire, and sent deputies to the diets. Her contingent was one horseman and ten footmen. The inhabitants of the town live by brewing, husbandry, and feeding of cattle. It is 10 miles south-east of Halberstadt, and 32 west of Berburg. E. Long. 11. 34. N. Lat. 52. 1.

QUEEN, a woman who holds a crown singly.

The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort; the former being termed queen-regent. The widow of a king is also called queen, but with the addition of dowager. See Royal Family.

QUEEN Charlotte's Sound is situated at the northern extremity of the southern island of New Zealand, near Cook's Strait, lying in 41. 6. of south latitude, and 174. 19. of east longitude. The climate of this sound is much more mild than at Dusky Bay; and though there is not such plenty of wild fowl and fish, the defect is sufficiently compensated by the abundance of excellent vegetables. The hills about the sound consist mostly of an argillaceous stone of a greenish gray, or bluish or yellowish brown colour. A green talkous or nephritic (by the jewellers called jade) is likewise very common, together with hornstone, shingle, several sorts of flinty stones and pebbles, some loose pieces of basalt, strata of a compact mica or glimmer, with particles of quartz. Hence, Mr Forrester thinks, there is reason to believe that this part of New Zealand contains iron-ore, and perhaps several other metallic substances. The country is not so steep as at Dusky Bay, and the hills near the sea are generally inferior in height, but covered with forests equally intricate and impenetrable. Captain Cook sowed the seeds of many vegetables in this place, that have useful and nutritive roots. He sowed also corn of several sorts, beans, kidney-beans, and peas. The dogs here are of the long-haired sort, with prickled ears, and resemble the common shepherd's cur, but they are very stupid animals. They are fed with fish, and even dogs flesh, and perhaps human flesh, which the natives also eat. Captains Cook and Furneaux left on these islands a boar and two hogs, with a pair of goats, male and female, with some geese, in order to benefit the natives and future generations of navigators. They left likewise among them a number of brass medals gilt, on one side of which was the head of his present Majesty, with the inscription "George III. King of Great Britain, France, and Ireland," &c. On the reverse, a representation of two men of war, with the names Resolution and Adventure over them; and on the exergue, "Sailed from England March mcccclxxi."

QUEEN-Gold, is a royal duty or revenue belonging to
QUEENSBERRY, a division of the province of Leinster in Ireland; so called from the popish Queen Mary, in whose reign it was first made a county by the earl of Sussex, then lord-deputy. It is bounded on the south by Kilkenny and Waterford; by King's county on the north and west; part of Kildare and Carlow on the east; and part of Tipperary on the west. Its greatest length from north to south is 35 miles, and its breadth near as much; but it is unequal both ways. This country was anciently full of bogs and woods, though now pretty well enclosed and cultivated. The number of inhabitants amounts to 82,000; and it sends two members to the imperial parliament.

QUEENBREE. See BREE, N° 3, &c.

QUEENBOROUGH, a town of the isle of Sheppey in Kent, which sends two members to parliament, though consisting only of about 100 low brick houses, and scarce 350 inhabitants. The chief employment of the people here is oyster-dredging; oysters being very plentiful, and of a fine flavour. E. Long. 0. 45 N. Lat. 51. 25.

QUEENSFERRY, which is sometimes denominated South Queensferry, is a royal borough in the shire of Linlithgow, on the coast of the frith of Forth, about 9 miles to the westward of Edinburgh. It obtained the name from Margaret, queen of Malcolm Canmore, who was in the habit of frequenting the passage of the frith at this place, and was the principal patroness of the town. It is a small place, consisting of no more than one irregular street, the houses of which are small, and chiefly inhabited by people who lead a seafaring life. The principal manufacture is that of soap, begun in the year 1770, which from 1783 to 1789 was a trade of considerable extent, the works being then four in number, and paying about 10,000L. annually of excise duty.

The shipping of the port has considerably declined; and at present the chief consequence of the place may be regarded as arising from the ferry over the frith of Forth, which is very much frequented. The river here is about two miles broad, and on each side has convenient landing places. The passage is both safe and expeditious, and with the exception of a very few cases, may be bad at all times. It is one of five boroughs that send a member to the British or Imperial parliament; the other four being Stirling, Dunfermline, Inverkeithing, and Culross. The parish is of very small extent, being confined to the borough. It is an erection in the parish of Dalmeny, which took place in the year 1036. The inhabitants were 589 in the year 1811.

QUEENSFERRY, NORTH, a village in Fifeshire, situated on the Forth, directly opposite to the borough of Queensferry, between which there are regular passage boats. It lies in the parish of Dunfermline, but is annexed, quaes dat sacro, to the parish of Inverkeithing. The inhabitants in 1793 were 312.

QUEILING-FOUL, the capital of the province of Quel ling-fou, in China, has its name from a flower called qui, which grows on a tree resembling a laurel; it exudes so sweet and agreeable an odour, that the whole country around is perfumed with it. It is situated on the bank of a river, which flows into the Tsieho; but it flows with such rapidity, and amidst so narrow valleys, that it is neither navigable nor of any utility to commerce. This city is large, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to the greater part of the capitals of the other provinces. A great number of birds are found in the territories belonging to it, the colours of which are so bright and variegated, that the artists of this country, in order to add to the lustre of their silks, interweave with them some of their feathers, which have a splendour and beauty that cannot be imitated. quilin has under its jurisdiction two cities of the second class and seven of the third.

QUEZI, in Natural History, is a name given by the Chinese to a peculiar earth found in many parts of the east. It is of the nature of an indurated clay, and in some degree approaches to the steatites and the galactites. It is very white and abestive, used by the women of China to take off spots from the skin, and render it soft and smooth, as the Italian ladies use talk of Venice. They sometimes use the fine powder of this stone dry, rubbing it on the hands and face after washing; sometimes they mix it in pomatum.

QUELPAERT, an island in the mouth of the channel of Japan, subject to the king of Corea. Before the last voyage of the unfortunate La Perouse, this island was only known to the Europeans by the wreck of the Dutch ship Sparrow-hawk, in the year 1635. Some of the crew of this ship were kept prisoners for about 13 years, during which period they were often severely treated; but having found means to escape to Japan, and thence to Batavia, they at last arrived in safety at Amsterdam. La Perouse discovered the island on the 21st of May 1787, the south point of which is in N. Lat. 33° 14', and E. Long. 124° 15' from Paris. The land has a gradual slope towards the sea, which makes the habitations assume the appearance of an amphitheatre. The soil appeared to be highly cultivated, and the divisions of fields were perceived by the assistance of glasses, which afforded a convincing proof of an extensive population. It is unfortunately inhabited by a people who are prohibited from all intercourse with strangers, and who make slaves of all those who have the misfortune to suffer shipwreck on their coasts.

QUEZI, a province of Guienne in France; bounded on the north by Limousin, on the east by Rouergue and Auvergne, on the south by Upper Languedoc, on the west by Agenois and Perigord. It was divided into Upper and Lower; and corresponds nearly with the department of Lot. Cahors is the capital town.

QUEZI-CUS, a genus of plants, belonging to the monocia class; and in the natural method ranking under the 50th order, Amentacea. See BOTANY Index.

The robus, or common English oak, grows from about 60 or 70 to 100 feet high, with a prodigious large trunk, and monstrous spreading head; oblong leaves, broadest towards the top; the edges acutely sinuate, having the angles obtuse. There is a variety, having the leaves finely striped with white. This species grows

4 G 2 ia
in great abundance all over England, in woods, forests, and hedge-rows; is naturally of an amazing large growth, there being accounts of some above 100 feet stature, with wonderful large trunks and spreading heads; and is supposed to continue its growth many centuries.

The suber, or cork-tree, grows 30 or 40 feet high, having a thick, rough, fungous, cleft bark, and oblong-oval undivided serrated leaves, downy underneath. This species furnishes that useful material cork; it being the bark of the tree, which becoming of a thick fungous nature, under which, at the same time, is formed a new bark, and the old being detached for use, the tree still lives, and the succeeding young bark becomes also of the same thick spongy nature in six or seven years, fit for barking, having likewise another fresh bark forming under it, becoming cork like the others in the like period of time; and in this manner these trees wonderfully furnish the cork for our use, and of which is made the corks for bottles, buxgs for barrels, and numerous other useful articles. The tree grows in great plenty in Spain and Portugal, and from these countries we receive the cork. The Spaniards burn it, to make that kind of light black we call Spanish black, used by painters. Cups made of cork are said to be good for helleth patients to drink out of. The Egyptians made coffins of cork; which being lined with a resinous composition, preserved dead bodies uncorrupted. The Spaniards line stone-walls with it, which not only renders them very warm, but corrects the moisture of the air.

Oak-trees, of all the above sorts, may be employed in gardening to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive gardens; the evergreen kinds in particular have great merit for all ornamental purposes in gardens. But all the larger growing kinds, both deciduous and evergreens, demand esteem principally as first-rate forest-trees for their timber. The English oak, however, claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood. Every possessor of considerable estates ought therefore to be particularly assiduous in raising woods of them, which is effected by sowing the acorns either in a nursery and the plants transplanted where they are to remain, or sowed at once in the places where they are always to stand. All the sorts will prosper in any middling soil and open situation, though in a loamy soil they are generally more prosperous: however, there are but few soils in which oaks will not grow; they will even thrive tolerably in gravelly, sandy, and clayey land, as may be observed in many parts of this country of the common oak.

The oak is of the utmost importance to Britain, and its cultivation deserves the utmost attention. Much, therefore, to the honour of the members of the London Society for encouraging Arts, Manufactures, and Commerce, they have excited particular attention to it; and many excellent observations, drawn from practice, will be found in their Transactions.

The propagation of the striped-leaved varieties of the common oak, and any particular variety of the other species, must be effected by grafting, as they will not continue the same from seed: the grafting may be performed upon any kind of oakling-stocks raised from the acorns, and train them for standards like others.

The oak is remarkable for its slowness of growth, bulk, and longevity. It has been remarked that a trunk has attained to the size only of 15 inches in diameter, and of some to 20, in the space of four-score years. As to bulk, we have an account of an oak belonging to Lord Powis, growing in Broomfield wood, at Ludlow in Shropshire, in the year 1754, the trunk of which measured 68 feet in girth, 23 in length, at which reckoning 90 feet for the larger branches, attained in the whole 1455 feet of timber, round measure, or 29 loads and five feet, at 50 feet to a load.

The Greendale oak, &c. we have already mentioned (see OAK). In the opinion of many, the Cotswold near Wetherby in Yorkshire is the fastest of the kind. Dr Hunter, in his edition of Evelyn, has given an engrav ing of it. Within three feet of the surface below it measures 16 yards, and close to the ground 25. In 1776, though in a rainy condition, it was 35 feet high, and its principal limb extended 16 yards from the bole. The foliage was very thin. If this measure were taken as the dimension of the central stem, the size of this tree would be enormous; but, like most very large trees, its stem is short, spreading wide at the base, its roots rising above the ground like butresses to the trunk, which is similar to a cylinder but to the foot of a cone. Mr Marsham says, "I found it in 1768, at four feet, 40 feet six inches; at five feet, 32 feet six inches; and at six feet, 32 feet one inch." Is the principal dimensions then, the size of the stem, it is exceeded by the Bentley oak; of which the same writer gives the following account: "In 1759 the oak at Holt-Forest, near Bentley, was at seven feet 34 inches high. There is a large excrescence at five and six feet; it would render the measure unfair. In 1778, this tree was increased half an inch in 19 years. It does not appear to be hollow, but by the triffing increase it makes it not sound." These dimensions, however, are exceeded by those of the Boddington oak. It grows in a piece of rich grass land, called the Old Oak Ground, belonging to Boddington-Manor Farm, near the turnpike-road between Cheltenham and Tew- bury, in the Vale of Gloucester. The stem is remarkably collected at the root, the sides of its trunk much more upright than those of large trees in general; and yet its circumference at the ground is about ten feet: measuring with a two-foot rule, it is more than 18 yards. At three feet high it is 43 feet, and smallest, i.e. from five to six feet high, it is 36 feet. At six feet it swells out larger, and forms an enormous head, which has been furnished with huge, and probably extensive, arms. But time and the fury of woe have robbed it of much of its grandeur; and the greatest extent of arm in 1793 was eight yards from the stem.

In the Gentleman's Magazine for May 1792, we have an account of an oak tree growing in Penshurst park in Kent, together with an engraving. It is the Bear or Bare oak, from being supposed to resemble that which Camden thought gave name to the county of Berkshire. The tradition at Penshurst is that the very tree planted on the day that celebrated Philip Sydney was born. "Some late writer says..."
Mr Rawlet have questioned this, and think that to have been a different tree, which was cut down several years ago, and was indeed much larger than this. I remember being once in the hollow of the present oak with the late Sir John Cullum; and his opinion then was, that its antiquity was greater than the period assigned. But, I assure you, the tradition of this place is constant for this tree; and, in confirmation of it, an old lady of 94 years of age, now living, has told me, that all the tenants used to furnish themselves with boughs from this tree, to stick in their hats, whenever they went to meet the earls of Leicester, as was always the custom to do at the end of the park when they came to recede at their seat there. This fine old oak stands upon a plain about 500 yards from their venerable mansion, near a large piece of water called Lawne-well. Ben Jonson and Galler have particularly noticed it; and from the distinguished owners of this place, it may be truly said to stand on classic ground. Within the hollow of it there is a seat, and it is capable of containing five or six persons with ease. The bark round the entrance was so much grown up, that it has lately been cut away to facilitate the access. The dimensions of the tree are these:

<table>

With respect to longevity, Linnaeus gives account of an oak 260 years old; but we have had traditions of some in England (how far to be depended upon we know not) that have attained to more than double that age. Mr Marshall, in a letter to Thomas Beevor, Esq. Bath Papers, vol. i. p. 79, makes some very ingenious calculations on the age of trees, and the increase of the Bentley oak, &c. that the Fortworth chestnut is 1100 years old.

Besides the grand purposes to which the timber is applied in navigation and architecture, and the bark in tanning of leather, there are other uses of less consequence, to which the different parts of this tree have been referred. The Highlanders use the bark to dye their yarn a brown colour, or, mixed with copperas, of a black colour. They call the oak the king of all the trees in the forest; and the herdsmen would think himself and his flock unfortunate if he had not a staff of it. The acorns are a good food to fatten swine and turkeys; and, after the severe winter of the year 1709, the poor people in France were miserably constrained to eat them themselves. They are, however, acorns produced from another species of oak, which are eaten to this day in Spain and Greece, with as much pleasure as chestnuts, without the dreadful compulsion of hunger.

**Quercus Marina**, the Sea Oak, in Botany, the name of a broad-leaved dichotomous sea-fucus. It is not agreed, among the late botanists, what was the sea-oak of Theophrastus; and the most ancient botanists, Clusius and Cæsalpinus, suppose it to have been a species of the shrubby coralline; but that seems by no means to have been the case, since Theophrastus says his sea-oak had a long, thick, and fleshy leaf; whence we may much more naturally conclude it to have been of the fucus class.

**Quercia**, a genus of plants, belonging to the triandria class; and in the natural method ranking under the 224 order, Caryophyllaceae. See Botany Index.

**Quesnay, Abraham du, marquis de Quesnay, admiral of the naval forces of France, and one of the greatest men of the 17th century, was born in Normandy in 1610. He contributed to the defeating of the naval power of Spain before Gattari; was dangerously wounded before Barcelona in 1642, and on other occasions: he went into the service of the Swedes, and became vice-admiral; gave the Danes an entire defeat, killed their admiral, and took his ship. He was recalled into France in 1647, and commanded the squadron sent to Naples. The sea-affairs of France being much fallen, he fitted out divers ships for the relief of the royal army that blockaded Bourdeaux; which was the principal cause of the surrender of the town. He was very fortunate in the last wars of Sicily, where he beat the Dutch thrice, and De Ruyter was killed. He also obliged the Algerines to sue in a very humble manner for peace from France. In short, Asia, Africa, and Europe, felt the effects of his valour. He was a Protestant; yet the king bestowed on him the land of Bouchem, and to immortalize his memory gave it the name of that great man. He died in 1683.

**Question**, in Logic, a proposition stated by way of interrogation.

**Question**, or **Torture**, See Rack.

**Questor**, or **Questor**, in Roman antiquity, an officer who had the management of the public treasure.

The questorship was the first office any person could bear in the commonwealth, and have a right to sit in the senate.

At first there were only two; but afterwards two others were created, to take care of the payment of the armies abroad, of selling the plunder, booty, &c. for which purpose they generally accompanied the consuls in their expeditions; on which account they were called peregrini, as the first and principal two were called urbani.

The number of questors was afterwards greatly increased. They had the keeping of the decrees of the senate: and hence came the two offices of questor principes, or augusti, sometimes called candidatus principis, whose office resembled in most respects that of our secretaries of state, and the questor palatinus, answering in a great measure to our lord-chancellor.

**Queue**, in Heraldry, signifies the tail of a beast; thus, if a lion be borne with a forked tail, he is blazoned double-queued.

**Queue d’Aronde**, or Swallow’s Tail, in Fortification, a detached or outwork, the sides of which open towards the champaign, or draw closer towards the gorge. Single or double tenailles are of this kind, and some cornworks, the sides of which are not parallel, but narrow at the gorge, and open at the head, resembling a swallow’s tail. When the sides are less than the gorge, the work is called centre queue d’aronde.

**Queue d’Aronde**, in carpentry, a method of jointing, also called dovetailing.

**Quevedo de Villegas, Francisco**, a celebrated Spanish poet, born at Madrid in 1570. He was descended
Quevedo, descended from a noble family, and was made a knight of St James; but was thrown into prison by order of Count Ovýrez, whose administration he satirized in his verses, and was not set at liberty till after that minister's disgrace. Quevedo wrote some heroic, lyric, and facetious poems. He also composed several treatises on religious subjects, and has translated some authors into Spanish. He died in 1644. The most known of his works are: 1. The Spanish Paradox. 2. The Adventurer Buscon. 3. Visions of Hell Reformed, &c. Quevedo was one of the greatest scholars and most eminent poets of his time. His youth was spent in the service of his country in Italy, where he distinguished himself with the utmost sagacity and prudence. His moral discourses prove his sound doctrine and religious sentiments, while his literary pieces display his infinite judgment and refined taste. His great knowledge of Hebrew is apparent from the report of the historian Mariana to the king, requesting that Quevedo might revise the new edition of the Bible of Aries Montana. His translations of Epicureus and Phocylides, with his imitations of Anacreon, and other Greek authors, show how well he was versed in that language: that he was a Latin scholar, his constant correspondence, from the age of twenty, with Lipsius, Chifflet, and Scippis, will sufficiently illustrate. As a poet, he excelled both in the serious and burlesque style, and was singularly happy in that particular turn we have since admired in Butler and Swift. His library, which consisted of about five thousand volumes, was reduced at his death to about two thousand, and is preserved in the convent of St Martin at Madrid.

QUICK, or QUICKEST HEDGE, among gardeners, denotes all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, under which name those young plants or sets are sold by the nursery-gardeners who raise them for sale.

The following method of propagating the common white thorn for hedges is recommended by Mr Taylor of Muston near Manchester, in a letter addressed to the Society for the Encouragement of Arts, &c. After premising that we have successfully repeated the experiment, we shall give the account of the process in his own words.

"Every one of you, I think, will allow that fences are material objects to be attended to in agriculture; you must also be convinced that there is no plant in this kingdom of which they can so properly be made as the CRATAEGUS OXYACANTHA LINN. or common white thorn. In consequence of my being convinced of this, I have been induced to make a few experiments to effect the better propagation of that valuable plant; the result of which, along with specimens of my success, I beg leave to submit to your inspection.

"In the year 1801, I had occasion to purchase a quantity of thorns, and finding them very dear, I was determined to try some experiments, in order if possible to raise them at a less expense. I tried to propagate them from cuttings of the branches, but with little or no success. I likewise tried if pieces of the root would grow; and I cut from the thorns which I had purchased about a dozen of such roots as pleased me, and planted them in a border along with those I had bought.

To my great astonishment, not one of them died; and in two years they became as good thorns as the average of those I had purchased. The thorns I purchased were three years old when I got them. In April 1802, I had occasion to move a fence, from which I procured as many roots of thorns as made me upwards of two thousand cuttings, of which I did not lose five in the hundred.

"In the spring of 1803, I likewise planted as many cuttings of thorn roots as I could get. In 1804, I did the same; and this year I shall plant many thousands.

"I have sent for your inspection specimens of the produce of 1802, 1803, and 1804, raised after my method, with the best I could get of those raised from haws in the common way, which generally lie one year in the ground before they vegetate. They are exactly one, two, and three years old, from the day they were planted.—I was so pleased with my success in raising so valuable an article to the farming interest of this kingdom, at so trifling an expense (for it is merely that of cutting the roots into lengths and planting them), that I was determined to make it known to the world, and could think of no better method than communicating it to your society; and should you so far approve of this method of raising thorns, as to think me entitled to any honorary reward, I shall receive it with gratitude, but shall feel myself amply repaid for any trouble I have been at, should you think it worthy a place in the next volume of your Transactions.

"The method of raising the thorns from roots of the plant, is as follows.

"I would advise every farmer to purchase a hundred or a thousand thorns, according to the size of his farm, and plant them in his orchard or garden, and when they have attained the thickness of my three-year-old specimens, which is the size I always prefer for planting in fences, let him take them and prune the roots in the manner I have pruned the specimen sent you, from which he will upon an average get ten or twelve cuttings from each plant, which is as good as thorns of the same thickness; so that you will easily perceive that in three years he will have a succession of plants fit for use, which he may if he pleases increase tenfold every time he takes them up.

"The spring (say in all April) is the best time to plant the cuttings, which must be done in rows half a yard asunder, and about four inches from each other in the row; they ought to be about four inches long, and planted with the top one-fourth of an inch out of the ground, and well fastened; otherwise they will not succeed so well.

"The reason why I prefer spring to autumn for planting the roots, is, that were they to be planted in autumn, they would not have got sufficient hold of the ground before the frost set in, which would raise them all from the ground: and, if not entirely destroy the plants, would oblige the farmer to plant them afresh.

"I have attached the produce of my three-year-old specimen to the plants it came from, cut in the way I always practise; on the thick end of the root I make two, and on the other end one cut, by which means the proper end to be planted uppermost, which is the thick one, may easily be known.

"Although I recommend the roots to be planted in April,
E April, yet the farmer may, where he pleases, take up the thorns he may want, and put the roots he has pruned off into sand or mould, where they will keep until he has leisure to cut them into proper lengths for planting; he will likewise keep them in the same way until planted.

"The great advantage of my plan is: first, that in case any one has raised from haws a thorn with remarkably large prickles, of vigorous growth, or possessing any other qualification requisite to make a good fence, he may propagate it far better and sooner, from roots, than by any other way. Secondly, in three years he may raise from roots a better plant than can in six years be raised from haws, and with double the quantity of roots; my three-year-old specimens would have been half as big again, had I not been obliged to move all my cuttings the second year after they were planted.

"It would not be a bad way, in order to get roots, to plant a hedge in any convenient place, and on each side trench the ground two yards wide, and two girts deep; from which, every two or three years, a large quantity of roots might be obtained, by trenching the ground over again, and cutting away what roots were found, which would all be young and of a proper thickness."" QUICKLIME, a general name for all calcareous substances when deprived of their fixed air; such as chalk, limestone, oyster-shells, &c. calcined. See LIME, CHEMISTRY, for an account of the properties and combinations of lime.

QUICKSILVER, or MERCURY, one of the metals, and so fusible that it cannot be reduced to a solid state but at a degree of cold, equal to 40 below C of Fahrenheit's thermometer. For the method of extracting quicksilver from its ore, &c. see Ores: Reduction of. For the various preparations, &c. see CHEMISTRY and MATERIA MEDICA Index; and for the natural history of the ores of quicksilver or mercury, see MINERALOGY Index.

Mines of quicksilver are very rare, inasmuch that, according to the calculations of Hoffman, there is 50 times more gold got every year out of the mines than mercury and its ores. But Dr. Lewis, in his notes upon Newman, says, that Cramer suspects that Hoffman only meant five times instead of 50; but neither the Latin nor the English edition of this author expresses any such thought; on the contrary, he adopts the same opinion; and only adds, that mercury is much more frequently met with than is commonly believed; but being so volatile in the fire, it often flies off in the roasting of ores, and escapes the attention of metallurgists.

According to Newman, the mines of Idria have produced at the rate of 231,778 pounds weight of mercury per annum; but those of Almaden in Spain produce much more. The chemists of Dijon inform us, that their annual produce is five or six thousand quintals, or between five and six hundred thousand pounds weight. In the year 1717 there were upwards of 2,500,000 pounds of quicksilver sent from them to Mexico, for the amalgamation of the gold and silver ores of that country.

At Guancavelica in Brasil the annual produce of the mines, according to Bemare, amounts to one million of pounds, which are carried overland to Lima, thence to Arica, and lastly to Potosi for the same purpose.

Besides these mines there are others in Brasil near Villa Rica, where such a quantity of cinnabar, and native running mercury, are found near the surface of the earth, that the black slaves often collect it in good quantities, and sell it for a trifling price to the apothecaries; but none of these mines have ever been worked or taken notice of by the owners. Gold naturally amalgamated with mercury is likewise met with in the neighbourhood of that place; and it is said that almost all the gold mines of that country are worked out by simply washing them out with running water, after reducing into powder the hard ores, which are sometimes imbedded in quartzose and rocky matrices.

In the duchy of Deux Ponts and in the Lower Austria the quicksilver flows from a schistose or stony matrix, and is probably, says Mr. Kirwan, mixed with some other metal, as its globules are not perfectly spherical. The mines of Friuli are all in similar beds or strata. The metal is likewise found visibly diffused through masses of clay or very heavy stone, of a white, red, or blue colour; of which last kind are the mines of Spain, some of Idria, and of Sicily. Mascagni found fluid quicksilver, as well as native cinnabar and mineral ethiops, near the lake of Travale in the duchy of Siena; but the quantity was so small as not to be worth the expense of working. On the other hand, the following mines afford profits to the owners after clearing all expenses, viz. those at Kremnnitz in Hungary; at Horowitz in Bohemia; Zorge in Saxony; Wollstein, Stahlberg, and Moeschfeld in the Palatinate. Mercury is also brought from Japan in the East Indies; but the greatest part of what is sold in Europe as Japan cinnabar is said to be manufactured in Holland.

Lemery, Pomot, and others, lay down some external marks by which those places are distinguished where there are mines of quicksilver, viz. thick vapours like clouds arising in the months of April and May; the plants being much larger and greener than in other places: the trees seldom bearing flowers or fruit, and putting forth their leaves more slowly than in other places; but, according to Newmann, these marks are far from being certain. They are not met with in all places where there is quicksilver, and are observed in places where there is none. Abundance of these cloudy exhalations are met with in the Hartz forest in Germany, though no mercury has ever been found there; to which we may add, that though vast quantities of mercurial ores are found at Almaden in Spain, none of the above-mentioned indications are there to be met with.

Native mercury was formerly sought from the mines of Idria with great avidity by the alchemists for the purpose of making gold; and others have showed such ridiculous an attachment to the Hungarian cinnabar, supposing it to be impregnated with gold; nay, we are informed by Newmann, that not only the cinnabar, antimony, and copper of Hungary, but even the vine trees of that country, were thought to be impregnated with the precious metal. Not many years ago a French chemist advertised that he had obtained a considerable quantity of gold from the ashes of vine twigs and stumps, as well as of the garden soil where they grew: but the falsehood of those assertions was demonstrated by the count de Lautragna to the satisfaction of the Royal Academy of Sciences.

The reduction of mercury into a solid state, so that...
Qui

Qui molinos, a Spanish priest, is the reputed author of Quietism; though the Illuminati in Spain had certainly taught something like it before. The sentiments of Molinos were contained in a book which he published at Rome in the year 1681, under the title of the Spiritual Guide; for which he was cast into prison in 1685, and where he publicly denounced the errors of which he was accused. This solemn recantation, however, was followed by a sentence of perpetual imprisonment, and he died in prison in the year 1696. Molinos had numerous disciples in Italy, Spain, France, and the Netherlands. One of the principal patrons and propagators of Quietism in France was Marie Bouvier de la Motte Guigny, a woman of fashion, remarkable for goodness of heart and regularity of manners; but of an unsettled temper, and subject to be drawn away by the seduction of a warm and unbridled fancy. She derived all ideas of religion from the feelings of her own heart, and described its nature to others as she felt it herself. Accordingly her religious sentiments made a great noise in the year 1687; and they were declared unsound, after accurate investigation, by several men of eminent piety and learning, and professedly confuted, in the year 1697, by the celebrated Bossuet.

Hence arose a controversy of greater moment between the prelate last mentioned and Fenelon archbishop of Cambrai, who seemed disposed to favour the system of Guigny, and who in 1697 published a book containing several of her tenets. Fenelon's book, by means of Bossuet, was condemned in the year 1699, by Innocent XII. and the sentence of condemnation was read by Fenelon himself at Cambrai, who exorted the people to respect and obey the papal decree. Notwithstanding this seeming acquiescence, the archbishop persisted to the end of his days in the sentiments, which, in obedience to the order of the pope, he retracted and condemned in a public manner.

A sect similar to this had appeared at Mount Athos in Thessaly, near the end of the 14th century, called Hesychasts, meaning the same with Quietists. They were a branch of the mystics, or those more perfect monks, who, by long and intense contemplation, endeavoured to arrive at a tranquillity of mind free from every degree of tumult and perturbation. In conformity to an ancient opinion of their principal doctors (who thought there was a celestial light concealed in the deepest retirements of the mind), they used to sit every day, during a certain space of time, in a solitary corner, with their eyes eagerly and immovably fixed upon the middle regions of the belly, or navel; and boasted, that while they remained in this posture, they found, in effect, a divine light beaming forth from their soul, which diffused through their hearts inexpressible sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the same celestial radiance that surrounded Christ during his transfiguration on the Mount. Barlaam, a monk of Calabria, from whom the Barlaamites derived their denomination, styled the monks who adhered to this institution Musalians and Euchites; and he gave them also the new name of Unbibilicant. Gregory Palamas, archbishop of Thessalonica, defended their cause against Barlaam, who was condemned in a council held at Constantinople in the year 1341.—See Fenelon's Max. des Saints.

4
The Mahometans seem to be no strangers to quietism. They expound a passage in the 17th chapter of the Koran, viz. "O thou soul which art at rest, return unto the Lord, &c." of a soul which, having, by pursuing the concatenation of natural causes, raised itself to the knowledge of that being which produced them and exists of necessity, rests fully contented, and acquiesces in the knowledge, &c. of him, and in the contemplation of his perfection.

Quillet, Claude, an eminent Latin poet of the 17th century, was born at Chonin, in Touraine, and practised physic there with reputation; but having declared against the pretended possession of the num of LOudun, in a manuscript treatise, the original of which was deposited in the library of the Sorbonne, he was obliged to retire into Italy, where he became secretary to the marshal d'Estrees, the French ambassador at Rome. In 1655, Quillet having published in Holland a Latin poem, entitled Callipedia, under the name of Galvadium Latus, he there inserted some verses against the cardinal Mazarin and his family; but that cardinal making him some gentle reproaches, he retired what related to the cardinal in another edition, and dedicated it to him, Mazarin having, before it was printed, given him an abbey. He died in 1661, aged 59, after having given Menage all his writings, and 500 crowns to pay the expense of printing them; but the abbé took the money and papers, and published none of them. His Callipedia, or the art of getting beautiful children, has been translated into English verse.

Quills, the large feathers taken out of the end of the wing of a goose, crow, &c. They are denominated from the order in which they are fixed in the wing; the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow-quills are chiefly used for drawing. In order to harden a quill, it is first softened, thrust the barrel into hot ashes, stirring it till it is soft, and then taking it out, press it almost flat upon your knee with the back of a penknife, and afterwards reduce it to a roundness with your fingers. If you have a number to harden, set water and alum over the fire, and while it is boiling, put in a handful of quills, the barrels only, for a minute, and then lay them by.

Quin, James, a celebrated performer on the English stage, was born at London in 1633. He was intended for the bar; but preferring Shakespeare to the statutes at large, he on the death of his father, when it was necessary for him to do something for himself, appeared on the stage at Drury-lane. In 1720, he first displayed his comic powers in the character of Falstaff, and soon after appeared to as great advantage in Sir John Brute; but it was upon Booth's quitting the stage that Quin appeared to full advantage, in the part of Cato. He continued a favourite performer until the year 1748, when, on some disgust between him and Mr Rich the manager, he retired to Bath, and only came up annually to act for the benefit of his friend Ryan; until the loss of two front teeth spoiled his utterance for the stage. While Mr Quin continued upon the stage, he constantly kept company with the greatest geniuses of the age. He was well known to Pope and Swift; and the earl of Chesterfield frequently invited

Vol. XVII. Part II.
over the sacrifices. They were also the interpreters of the Sybil's books; which, however, they never consulted but by an express order of the senate.

QUINQUAGENARIUS, in Roman antiquity, an officer who had the command of 50 men.

QUINQUAGESIMA SUNDAY, Shrove Sunday, so called as being about the 50th day before Easter.

QUINQUAVTIA, or QUINQUATRUS, was a festival kept at Rome in honour of Minerva, which began on the 18th of March, or, as others will have it, on the 19th, and lasted five days. On the first day they offered sacrifices and oblations without the effusion of blood; the second, third, and fourth, were spent in shows of gladiators; and on the fifth day they went in procession through the city. Scholars had a vacation during the solemnity, and presented their masters at this time with a gift or fee, called Minerval. Boys and girls used now to pray to the godde-s Minerva for wisdom and learning, of which she had the patronage. Plays were acted, and disputations held, at this feast, on subjects of polite literature. The quinquavtia were so called, because they lasted five days. There seems to be a strong resemblance between this festival and the panathenaea of the Greeks.

QUINQUENNALIS, in Roman antiquity, a magistrate in the colonies and municipal cities of that empire, who had much the same office as the edile at Rome.

QUINQUEREMIS, in the naval architecture of the ancients, is a name given to a galley which had five rows of oars. They divided their vessels in general into monocora and polyorca. The former had only one tire of rowers; the latter had several tires of them, from two or three up to 20, 30, or even 40; for such a vessel we have an account of in the time of Philopater, which required no less than 4000 men to row it.

Meibom has taken off from the imaginary improbability of there ever having been such a vessel, by reducing the enormous height supposed necessary for such a number of rows of oars and men to work them, by finding a better way of placing the men than others had thought of. The quinqueremes of the ancients had a number of rowers which was various; of which were rowers, and the rest soldiers. The Roman fleet at Messina consisted of 330 of these ships; and the Carthaginian, at Lilybæum, of 350 of the same size. Each vessel was 150 feet long. Thus 130,000 men were contained in the one, and 150,000 in the other, with the apparatus and provisions necessary for such expeditions as they were intended for. This gives so grand an idea of the ancient naval armaments, that some have questioned the truth of the history; but we find it related by Polybius, an historian too authentic to be questioned, and who expresses his wonder at it while he relates it.

QUINQUEVIRI, in Roman antiquity, an order of five priests, peculiarly appointed for the sacrifices to the dead, or celebrating the rites of Erebus.

QUINQUINA. See CINCHA, BOTANY AND MATERIA MEDICA INDEX.

QUINSY, or QUINZET. See MEDICINE, No 177—181.

QUINZEN, a town of France, in the department of Côtes de Nord, with a handsome castle. It is seated in a valley near the river Guy, and near a large forest of the same name, eight miles south of St Brieux, and 200 west of Paris. It had formerly the title of a duchy. W. Long. 2° 40'. N. Lat. 48° 26'.

QUINTESSANCE, in Chemistry, a preparation consisting of the essential oil of some vegetable substance, mixed and incorporated with spirit of wine.

QUINTESSANCE, in Alchemy, is a mysterious term, signifying the fifth or last and highest essence of power in a natural body.—Or when divested of its alchemical signification, and employed to express something that is intelligible, the word denotes merely the highest state of purification in which any body can be exhibited.

QUINTAL, the weight of 100 lbs. in most countries, but in England it is the cwt. or 112 lbs. Quintal was formerly used for a weight of lead, iron, or other common metal, usually equal to 100 lbs. at six scores to the hundred.

QUINTILE, in Astronomy, an aspect of the planets when they are 72 degrees distant from one another, or a fifth part of a zodiac.

QUINTILLIANUS, MARCUS FABRIUS, a celebrated Latin orator, and the most judicious critic of his time, was a native of Calagurris, or Calaborra, in Spain; and was the disciple of Domitianus Asper, who died in the year 59. He taught rhetoric at Rome for 20 years with great applause: and not only laid down rules for speaking, but exhibited his eloquence at the bar. Some authors imagine, but with little foundation, that he arrived at the consulship; but it is more certain that he was preceptor to the grandsons of the emperor Domitian's sister. There is still extant his excellent work, intitled, Institutiones Orators, which is a treatise of rhetoric in 12 books; where his precepts, judgment, and taste, are justly admired. These institutions were found entire by Poggius, in an old tower of the abbey of St Gal, and not in a grocer's shop in Germany as some authors have asserted. There is also attributed to Quintilian a dialogue De causis corruptae eloquentiae; but it is more commonly ascribed to Tactitus. The best editions of Quinlilian's works are those of Mr Obrecht, published at Strasburg in 2 vols 4to, in 1608, and of M. Cappemonier, in folio. There is an English translation by Mr Guthrie.

Quintilian had a son of the same name, on whom he bestows great praises. This son ought not to be confounded with Quintilian the father, or rather the grandfather, of him who is the subject of this article, and who wrote 145 declamations. Úgolin of Parma published the first 136 in the 17th century; the nine others were published in 1563 by Peter Ayrault, and afterwards by Peter Pithou in 1580. There have also been 19 other declamations printed under the name of Quintilian the Orator; but, in the opinion of Vossius, they were written neither by that orator nor his grandfather.

QUINTILIANS, a sect of ancient heretics, thus called from their prophetess Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Mary the sister of Moses, as having been a prophetess, &c. They added, that Philip the deacon had four daughters, who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, persifing prophetesses.
QUINTINUS MATYS, also called the Ferrer of Antwerp, famous for being transformed, by the force of love, from a blacksmith to a painter. He had followed the trade of a blacksmith and farrier for near twenty years; when falling in love with a painter's daughter who was very handsome, and disliked nothing but his trade, he quit it, and betook himself to painting, in which he made very great progress. He was a diligent and careful imitator of ordinary life, and succeeded better in representing the defects than the beauties of nature. Some historical performances of this master deserve commendation, particularly a Descent from the Cross, in the cathedral at Antwerp: but his best known picture is that of the two Misers in the gallery at Windsor. He died in 1529.

QUINTINIE, JOHN DE LA, a celebrated French gardener, born at Poictiers in 1626. He was brought up to the law; and acquitted himself so well at the bar as to acquire the esteem of the chief magistrate. M. Tamboneau, president of the chamber of accounts, engaged him to undertake the preceptorship of his only son, which Quintinie executed entirely to his satisfaction; applying his leisure hours to the study of writers on agriculture, ancient and modern, to which he had a strong inclination. He gained new lights by attending his pupil at Italy; for all the gardens about Rome being open to him, he failed not to add practice to his theory. On his return to Paris, M. Tamboneau gave up the management of his garden entirely to him; and Quintinie applied so closely to it, that he became famous all over France. Louis XIV. erected a new office purposely for him, that of director of the royal fruit and kitchen gardens; and these gardens, while he lived, were the admiration of the curious. He lived to a good old age; we have not learned the time of his death; his directions for the management of Fruit and Kitchen Gardens have been much esteemed.

QUINTUS CALABER, a Greek poet, who wrote a large Supplement to Homer's Iliad, in 14 books, in which a relation is given of the Trojan war from the death of Hector to the destruction of Troy. It is conjectured, from his style and manner, that he lived in the fifth century. Nothing certain can be collected either concerning his person or country. His poem was first made known by Cardinal Bessarion, who discovered it in St Nicholas's church, near Otranto in Calabria; from whence the author was named Quintus Calaber. It was first published at Venice by Aldus, but it is not said in what year.

QUINTUS CURTIUS. See Curtius.

QUINZY, QUINSEY, or Angina Pectoris. See Medicine, No. 402.

QUIRE OF PAPER, the quantity of 24 sheets.

QUIRINALIA, in antiquity, a feast celebrated among the Romans in honour of Romulus.

QUIRITES, in Roman antiquity. In consequence of the agreement entered into by Romulus and Tatius king of the Sabines, Rome was to retain its name, taken from Romulus, and the people were to be called Quirites, from Cures, the principal town of the Sabines, a name used in all public addresses to the Roman people. Dion. Hal. says, that each particular citizen was to be called Romanus, and the collective body of them Quirites; yet it appears by this ancient form of words used at funerals, Ollus Quirius letho datus est, that each private citizen was also called Quirius.

The origin of the word Quirites, which was at first peculiar to the Sabines, and became, in Romulus's time, the general name of the inhabitants of Rome, has been much sought for; and the most probable account antiquity gives us of it, is this: The word Quiris, according to Plutarch and some others, signified in the Sabine language, both "a dart," and "a warlike deity armed with a dart." It is uncertain whether the god gave name to the dart, or the dart to the god. But be that as it will, this Quiris, or Quirinus, was either Mars or some other god of war; and the worship of Quiris continued in Rome all Romulus's reign; but after his death he was honoured with the name Quirinus, and took the place of the god Quiris.

QUIRK, in a general sense, denotes a subtilty or artful distinction.

Quirk, in building, a piece of ground taken out of any regular ground-plot, or floor: thus, if the ground-plot were oblong or square, a piece taken out of a corner to make a court or yard, &c. is called a quirk.

QUI'SQUALIS, a genus of plants belonging to the decandria class, and in the natural method ranking under the 31st order, Veprecules. See Botany Index.

QUITO, a town of South America, in Peru (see Peru), seated between two chains of high mountains called Cordillera de los Andes, on much higher ground than the rest of habitable Peru. It is 300 yards higher than the level of the sea according to the exact observations. The town is 1600 yards long and 1200 broad, and is the seat of a bishop. It contains about 70,000 inhabitants, one-third of whom are originally Spaniards. Among the inhabitants are some persons of high rank and distinction, descended either from the original conquerors, or persons who at different times came from Spain invested with some lucrative post. The number of these, however, is but small. The commonalty, besides Spaniards, consist of Mestizos, Indians, and Negroes; but the last are not proportionally numerous. Merchandises and commodities of all sorts are extremely dear, partly on account of the difficulty of bringing them.

There are several religious communities at Quito, and two colleges or universities governed by Jesuits and Dominicans.

The principal courts held at Quito are that of the royal audience, which consists of the president, who is governor of the province with regard to law affairs; four auditors, who are at the same time civil and criminal judges; a royal fiscal, who, besides the causes brought before the audience, takes cognizance of everything relating to the revenue; and an officer styled the protector of the Indians, who solicits for them, and when they are injured pleads in their defence. The next is the treasury, the chief officers of which are an accountant, a treasurer, and a royal fiscal. The tribunal of the Croisade, which has a commissary, who is generally some dignitary of the church, and a treasurer. There is also a treasury for the effects of persons deceased: an institution established all over the Indies, for receiving the goods of those whose lawful heirs are in Spain, in order to secure them from those accidents to which they might be liable in private hands. There is like-
wise a commissary of the inquisition, with an alguazil-majors and familiars, appointed by the inquisition of Lima. The corporation consists of a corregidor, two ordinary alcaldes, chosen annually, and regidores. The latter superintend the election of the alcaldes, which is attended with no small disturbance, the people being divided into two parties, the Creoles and Europeans.

QUITTER-BONE. See FARRIERY, No. 347.

QUIT-RENT (quietus redditus, i.e. "quiet rent") is a certain small rent payable by the tenants of manors, in token of subjection, and by which the tenant goes quiet and free. In ancient records it is called white rent, because paid in silver money, to distinguish it from rent-corn, &c.

QUOAD hoc, is a term used in the pleadings and arguments of lawyers; being as much as to say, As to this thing the law is so and so.

QUOIN, or COIN, on board a ship, a wedge fastened on the deck close to the breech of the carriage of a gun, to keep it firm up to the ship's side. Cantic quoins are short three-legged quoins put between caisks to keep them steady.

QUOINS, in Architecture, denote the corners of brick or stone walls. The word is particularly used for the stones in the corners of brick buildings. When these stand out beyond the brick-work, their edges being chamfered off, they are called rustic quoins.

QUOTIDIAN, anything which happens every day. Hence, when the paroxysms of an ague recur Quotidian every day, it is called a quotidian ague. See Medicine, No. 164—164.

QUOTIDIANA DECEPTIVA. See Medicine, No. 150.

QUORUM, a word frequently mentioned in our statutes, and in commissions both of justices of the peace and others. It is thus called from the words of the commission, quorum A. B. unum esse volumus. For an example, where a commission is directed to seven persons, or to any three of them, whereof A. B. and C. D. are to be two; in this case, they are said to be of the quorum, because the rest cannot proceed without them: so a justice of the peace and quorum is one without whom the rest of the justices in some cases cannot proceed.

QUOTIENT, in Arithmetic, the number resulting from the division of a greater number by a smaller, and which shows how often the smaller is contained in the greater, or how often the divisor is contained in the dividend. The word is formed from the Latin quoties; q. d. How often is such a number contained in such another.

In division, as the divisor is to be dividend, so is unity to the quotient. Thus the quotient of 12 divided by 3 is 4; which is thus disposed, 3) 12 (4 quotient. See ARITHMETIC.

R.

R, or r, a liquid consonant, being the 17th letter of our alphabet. Its sound is formed by a guttural extrusion of the breath vibrated through the mouth, with a sort of quivering motion of the tongue drawn from the teeth, and canulated with the tip a little elevated towards the palate. In Greek words it is frequently aspirated with an h after it, as in rhapsody, rhetoric, &c. otherwise it is always followed by a vowel at the beginning of words and syllables.

Used as a numeral, R usually stood for 80; and with a dash over it thus R, for 80,000; but the Greek R, or \( \gamma \), with a small mark over it, signified 100; with the same mark under it, it denoted 1000 \( \times \) 10; thus \( \gamma \) signifies 100,000. In the Hebrew numeration \( \gamma \) denoted 200; and with two horizontal points over it 1000 \( \times \) 200; thus \( \gamma \) = 200,000.

In the prescriptions of physicians, R or \( \gamma \) stands for recipe, i.e. "take."

RAAB, a town of Lower Hungary, capital of Ja-vern, with a castle and a bishop's see. It is a strong frontier bulwark against the Turks, and has two bridges, one over a double ditch, and another that leads towards Alba Regalis. The surrounding country is plain, and there is nothing that seems to command it but a small hill at some distance, which is undermined and may be blown up. It was taken by Amurath III., with the loss of 20,000 men; but was surprised soon after by Count Palzi, who killed all the Turks that were found therein. It is seated at the confluence of the rivers Rab and Rabnitz, not far from the Danube, 32 miles west of Gran, and 55 south-east of Vienna. E. Long. 17. 25. N. Lat. 47. 48.

RABAC, a small port on the Arabian coast of the Red sea, in N. Lat. 22° 35' 40", by Mr Bruce's account. The entry to the harbour is from the E. N. E. and is about a quarter of a mile broad. The port extends about two miles in length to the eastward. The mountains are about three leagues to the north, and the town about four miles north by east from the entrance to the harbour. The water is good, and all ships may be supplied here from the wells which are in the neighbourhood of the town. The country is bare and uncultivated; but from the appearance of it, and the freshness of the water, Mr Bruce supposes that it sometimes rains among the mountains here, which is the more probable as it is considerably within the tropic.

RABAT, a large and handsome sea-port town of Africa,
Africa, in the kingdom of Fez and province of Tremesan. It has fine mosques and handsome palaces, and is seated at the mouth of the river Burrigrig, almost in the mid-way between Fez and Tangier. W. Long. 5. 28. N. Lat. 34. 40.

Rabat, together with Sallee, which is opposite to it, was formerly famous for fitting out piratical vessels; but the late emperor Sidi Mahomet subdued them both, and annexed them to the empire; since which time the harbour of Rabat has been so filled with the sand washed in by the sea as to render it unfit to carry on such piracies in future.

The town of Rabat, whose walls inclose a large space of ground, is defended on the sea-side by three forts tolerably well finished, which were erected some little time ago by an English renegado, and furnished with guns from Gibraltar. The houses in general are good, and many of the inhabitants are wealthy. The Jews, who are very numerous in this place, are generally in better circumstances than those of Larache or Tangier, and their women are extremely beautiful.

The castle, which is very extensive, contains a strong building, formerly used by the late emperor as his principal treasury, and a noble terrace, which commands an extensive prospect of the town of Sallee, the ocean, and all the neighbouring country. There are also the ruins of another castle, which is said to have been built by Jacob Almanzar, one of their former emperors, and of which at present very little remains but its walls, containing within them some very strong magazines for powder and naval stores. On the outside of these walls is a very high and square tower, handsomely built of cut stone, and called the tower of Hasen. From the workmanship of this tower, contrasted with the other buildings, a very accurate idea may be formed how greatly the Moors have degenerated from their former splendour and taste for architecture.

RABBETING, in Carpentry, the planing or cutting of channels or grooves in boards, &c.

In ship-carpentry, it signifies the letting in of the planks of the ship into the keel; which, in the rake and run of a ship, is hollowed away, that the planks may join the closer.

RABBI, or RABBINS, a title which the Pharisees and doctors of the law among the Jews assumed, and literally signifies masters or excellents.

There were several gradations before they arrived at the dignity of a rabbi; which was not conferred till they had acquired the profoundest knowledge of the law and the traditions. It does not, however, appear that there was any fixed age or previous examination necessary; but when a man had distinguished himself by his skill in the written and oral law, and passed through the subordinate degrees, he was saluted rabbin by the public voice.

Among the modern Jews, for near 700 years past, the learned men retain no other title than that of rabbi, or rabbins; they have great respect paid them, have the first places or seats in their synagogues, determine all matters of controversy, and frequently pronounce upon civil affairs; they have even power to excommunicate the disobedient.

RABBINISTS, among the modern Jews, an appellation given to the doctrine of the rabbins concerning traditions, in opposition to the Caraites; who reject all traditions. See CARAITE.

RABELAIS, FRANCIS, a French writer famous for his facetiousness, was born at Chinon in Touraine about the year 1483. He was first a Franciscan friar; but quitting his religious habit, studied physic at Montpellier, where he took his doctor's degree. It is said, that the chancellor du Pratt having abolished the privileges of the faculty of physic at Montpellier by a decree of the parliament, Rabelais had the address to make him revoke what he had done; and that those who were made doctors of that university wore Rabelais's robe, which is there held in great veneration. Some time after, he came to Rome, in quality of physician in ordinary to Cardinal John du Bellay, archbishop of Paris. Rabelais is said to have used the freedom to jeer Pope Paul III. to his face. He had quitted his religious connections for the sake of leading a life more agreeable to his taste; but renewed them on a second journey to Rome, when he obtained, 1536, a brief to qualify him for holding ecclesiastical benefices; and, by the interest of his friend Cardinal John du Bellay, he was received as a secular canon in the abbey of St. Maur near Paris. His profound knowledge in physic rendered him doubly useful; he being as ready, and at least as well qualified, to prescribe for the body as for the soul: but as he was a man of wit and humour, many ridiculous things are laid to his charge, of which he was quite innocent. He published several things; but his chief performance is a strange incoherent romance, called the History of Gargantua and Pantagruel, being a satire upon priests, popes, fools, and knaves of all kinds. This work contains a wild, irregular profusion of wit, learning, obscenity, low concits, andarrant nonsense; hence the shrewdness of his satire, in some places where he is to be understood, gains him credit for those where no meaning is discoverable. Some allusions may undoubtedly have been so temporary and local as to be now quite lost: but it is too much to conclude thus in favour of every unintelligible rhapsody; for we are not without English writers of great talents, whose sportive geniuses have betrayed them into puerilities, no less incoherent at the times of writing than those of Rabelais appear above two centuries after. He died about 1533.

RABBIT, in Zoology. See LEPUS, MAMMALIA Index.

The buck rabbits, like our boar cats, will kill the young ones if they can get at them; and the does in the warrens prevent this, by covering their stocks, or nests, with gravel or earth, which they close so artificially up with the hinder part of their bodies, that it is hard to find them out. They never suckle their young ones at any other time than early in the morning and late at night; and always, for eight or ten days, close up the hole at the mouth of the nest, in this careful manner, when they go out. After this they begin to leave a small opening, which they increase by degrees; till at length, when they are about three weeks old, the mouth of the hole is left wholly open that they may go out; for they are at that time grown big enough to take care of themselves, and to feed on grass.

People who keep rabbits tame for profit, breed them in hutches; but these must be kept very neat and clean, else they will be always subject to diseases. Care must be taken also to keep the bucks and does apart till the latter
Rabbits are subject to two principal infirmities. First, the rot, which is caused by giving them too large a quantity of greens, or from giving them green gathered with the dew or rain hanging in drops upon them. Excess of moisture always causes this disease. The greens therefore are always to be given dry; and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of their juices. On this account the very best food that can be given them, is the shortest and sweetest hay that can be got, of which one load will serve 200 couples a year; and out of this stock of 200, 200 may be eaten in the family, 200 sold in the markets, and a sufficient number kept in case of accidents.

The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner, in their boxes. This distemper is supposed to be owing to the rankness of their feeding; and the general cure is keeping the hay low, and giving them the prickly herb called caje thistle to eat.

The general computation of males and females is, that one buck-rabbit will serve for nine does: some allow 10 to one buck; but those who go beyond this always suffer for it in their breed.

Wild rabbits are either to be taken by small cur dogs, or by spaniels bred up to the sport; and the places of hunting those who struggle from their burrows, is under close hedges or bushes, or among corn fields and fresh pastures. The owners use to course them with small greyhounds; and though they are seldom killed this way, yet they are driven back to their burrows, and prevented from being a prey to others. The common method is by nets called purse-nets, and ferrets. The ferret is sent into the hole to fetch them out; and the purse-net being spread over the hole, takes them as they come out. The ferrets mouths must be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay-net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will escape.

Some who have no ferrets smoke the rabbits out of their holes with burning brimstone and ornament. This certainly brings them out into the nets; but then it is a very troublesome and offensive method, and is very detrimental to the place, as no rabbit will for a long time afterwards come near the burrows which have been fumed with such ingredients.

The following observations on the breeding and management of rabbits and some other animals appear to us to be of such importance, that we shall give them a place in the words of the author.

"In my travels through America," says the author, "I have often been surprised that no attempt has been made to introduce, for the purpose of propagation, that useful little animal, the warren rabbit, of such vast importance to the hat manufactory of England. It is chiefly owing to the fur of this animal that the English hats are so much esteemed abroad. It is a fact well known amongst the hat makers, that a hat composed of one half of coney wool, one-sixth old coat beaver, one-sixth pel t beaver, and one-sixth Vigoria wool, will wear far preferable to one made all of beaver, as it will keep its shape better, feel more firm, and wear bright and black much longer.

"The value of the coney wool, the produce of the United Kingdom only, is not less, I will venture to say, than 250,000l. per annum; but the quantity is much diminished, owing to the banishment and persecution they meet with on every side, and so many small warsens taken in for grain land; in consequence of which it is time that some protection should be afforded, if possible, to that important branch of British manufacture (in which coney wool is used) from suffering any inconvenience in the want of so essential an article, and the accomplishment of this grand object I conceive perfectly easy.

"General Observations.—When I speak of the warren rabbit, I have to observe, that there are in England, as well as in most parts of Europe, three other kinds, viz. the tame rabbit, of various colours, the fur of which is of little value, except the white; the shock rabbit, which has a long shaggy fur of little value; the bush rabbit, like those of America, which commonly sits as a hare, and the fur of which is of a rotten inferior quality.

"To return to the warren rabbit. There are two sorts in respect to colour, that is, the common gray, and the silver gray, but little or no difference in respect to the strength and felting qualities of the fur. The nature of this animal is to burrow deep in sandy ground, and there live in families, nor will they suffer one from a neighbouring family to come amongst them without a severe contest, in which the intruders are generally glad to retire with the loss of part of their coat, unless when pursued by an enemy, when they find protection.

"It is scarcely worth while for me to mention a thing so generally known, viz. that rabbits, particularly those of the warren, are the most prolific of all other four-footed animals in the world; nor do I apprehend any difficulty would attend the exporting this little quadruped with safety to any distance, provided it
was kept dry, and regularly supplied with clean sweet
food, and a due regard to the cleanliness of the boxes or
places of confinement.

"Twelve or fifteen pair of these valuable animals
taken to Upper Canada, and there enclosed within a
small space of ground suitable to their nature, but fur-
nished with a few artificial burrows at the first by way
of a nursery, spread over those now useless plains, islands,
and peninsulas, so well calculated to their nature, would,
I will make bold to say, the eighth year after their in-
truction, furnish the British market with a valuable
raw material, amounting to a large sum, increasing
every year with astonishing rapidity, so as to become,
in a few years, one amongst the first of national ob-
jects.

"It may be supposed by some, that the above project
is magnified beyond possibility, or even probability;
but the serious attention I have paid to the subject,
these many years past, as to all points for and against,
leaves no room to accuse myself of being too sanguine;
for, if properly managed a few years at the first, I
cannot find a single thing likely to interrupt their pro-
gress.

"Some idea of the astonishing increase of the rabbit
may be had from the following facts:

"An old doe rabbit will bring forth young nine times
in one year, and from four to ten each time; but to al-
low for casualties, state the number at five each litter.

In nine months - - - - - - - - - 45
The females of the first litter will bring forth five
times, the proportion of which is 25 females
produce - - - - - - - - - - - - - 62
Those of the second litter four times produce 50
Ditto of ditto third ditto three ditto ditto 37
Ditto of ditto second ditto two ditto ditto 25

Total in one year from one pair 219

"The third female race of the old dam, and the se-
cond of the first litter, seldom breed the first year, but
are early breeders in the spring following, when we
might expect an increase of the whole in proportion to
the first pair, if properly attended to and protected.

"It is generally allowed that hares are not more
than one-fourth as prolific as rabbits, notwithstanding,
able to an experiment tried by Lord Ribblesdale,
who enclosed a pair of hares for one year, the offspring
was (as I have been credited informed) 68: these ani-
mals, could they be exported to Upper Canada with sa-
fety, and there protected within enclosures for a few years,
would soon after spread over a large extent of country:
the fur is nearly as valuable as that of the rabbit.

"In that part of Upper Canada within the 45 degrees
of north latitude, and the southern and western bound-
daries, the climate is nearly the same as that of Eng-
land, a little hotter a few days in summer, and a little
colder a few days in winter, agreeable to Fahrenheit's
thermometer, which I have paid great attention to for
some years, comparing the same with the observations of
the English.

"The increase of most animals appears much greater
in proportion in America than in England, mankind
not excepted: that of sheep is very apparent to those
that pay attention to their breeding stock, which gives
me hopes, that in a few years we shall be able to pay
for our woollen cloths in wool. Finding the effect of
soil and climate so salutary to sheep, &c. it may be rea-
sonably supposed, that rabbits will answer the most san-
guine expectations, as I understand the wool of the sheep
retains all its nature the same as in England, particu-
larly its strength, and felting qualities among the bat-
ters, which assures me that rabbit wool from those bred
in Upper Canada will do the same; and there are some
millions of acres within the latitude and boundaries
which I have before described, suited to the nature of
the warren rabbit; nor do I apprehend that the wolves,
foxes, &c. of Upper Canada will be half so destructive
as the poachers in England.

"The guanaco, or camel sheep of South America, no
doubt will be a national object at some future period.
This is a tame, domestic animal, very hardy, and used
with much cruelty by the natives in travelling over the
mountains with their burdens; it shears a fleece of wool
of from 2 lb. to 3 lb. which is of dusky red on the back;
the sides inclined to white, and under the belly quite
white; its texture is very fine, yet strong; its felting
qualities very powerful, and is worth, when ready for
use, from five to fifteen shillings per pound. This ani-
mal would no doubt thrive, and do well in England,
Upper Canada, and in particular I should suppose in
New Holland.

"The beaver might be propagated to great advantage
in Scotland, Ireland, and northern parts of England.
It is an animal, when tamed, very familiar, and will
eat bread and milk, willow-sticks, elm bark, &c. and
no doubt might be imported with safety; but as these
two last-mentioned animals are not likely to be attended
to immediately, I shall say no more respecting them for
the present."

**Trans. of RABIRIUS. C. A Roman knight, who lent an im-
measurably sum of money to Ptolemy Auletes king of Egypt. courage-
The monarch afterwards not only refused to repay him, but even com-
mitted him, and endangered his life. Rabi-
rinus escaped from Egypt with difficulty; but at his re-
turn to Rome he was accused by the senate of having
lent money to an African prince for unlawful purposes.
He was ably defended by Cicero, and acquitted with
difficulty. — There was a Latin poet of the same
age of Augustus. He wrote a poem on the
victory which the emperor had gained over Antony at
Actium. Seneca has compared him to Virgil for e-
legance and majesty; but Quintilian is not so favourable
to his poetry. — And there was an architect in the reign
of Domitian called Rabirius. He built a celebrated
palace for the emperor, of which the ruins are still seen
at Rome.

**RACCOON. See Ursus, Mammalia Index.**

``RACE, in general, signifies running with others in
order to obtain a prize, either on foot, or by riding on
horse-back, in chariots, &c."

"The race was one of the exercises among the ancient
Grecian games, which was performed in a course con-
taining 125 pace; and those who contended in these
foot-races were frequently clothed in armour. Cha-
riot and horse races also made a part of the ancient
games.

"Races were known in England in very early times.
Fitz Stephen, who wrote in the days of Henry II.
mencions the great delight that the citizens of London
took
RACINE, John, a celebrated French poet, member of the French academy, treasurer of France in the generality of Molière, and a secretary to his majesty, was born at Paris in the month of August, 1639. He had a fine genius for the belles lettres, and became one of the first poets of the age. He produced his Thésée when but very young, and afterward other pieces, which met with great success, though they appeared when Cornelle was in his highest reputation. In his career, however, he did not fail to meet with all that opposition which envy and cabal are ever ready to set up against a superior genius. It was partly owing to chagrin from this circumstance that he took a resolution to quit the theatre for ever; although his genius was still in full vigour, being not more than 38 years of age. But he had also imbided in his infancy a deep sense of religion; and this, though it had been smothered for a while by his connections with the theatre, and particularly with the famous actress Champmelle, whom he greatly loved, and by whom he had a son, now at length broke out, and bore down all before it. In the first place, he resolved not only to write no more plays, but to do a rigorous penance for those he had written; and he actually formed a design of becoming a Carthusian friar. His religious director, however, a good deal wiser than he, advised him to think more moderately, and to take measures more suitably to his character. He put him upon marrying, and settling in the world: with which proposal this humble and tractable penitent complied; and immediately took to wife the daughter of a treasurer of France for Amiens, by whom he had seven children.

He had been admitted a member of the French academy in 1673, in the room of La Mothe le Vayer deceased; but spoiled the speech he made upon that occasion by pronouncing it with too much timidity. In 1677, he was nominated with Boileau, with whom he was ever in strict friendship, to write the history of Louis XIV.; and the public expected great things from two writers of their distinction, but were disappointed. Boileau and Racine, after having for some time laboured at this work, perceived that it was entirely opposite to their genius.

He spent the latter years of his life in composing a history of the house of Port-Royal, the place of his education, which, however, though finely drawn up, as many have asserted, has not been published. Too great sensibility, say his friends, but more properly his impotence of spirit, shortened the days of this poet.

Though he had conversed much with the court, he had not learned the wisdom, which is usually learned there, of disguising his real sentiments. Having drawn up a well-reasoned and well-written memorial upon the miseries of the people, and the means of relieving them, he one day lent it to Madame de Maintenon to read; when the king coming in, and demanding what and whose it was, commended the zeal of Racine, but disapproved of his meddling with things that did not concern him, and said with an angry tone, "Because he knows how to make good verses, does he think he knows everything? And would he be a minister of state, because he is a great poet?" These words hurt Racine greatly; he conceived dreadful ideas of the king's displeasure; and his chagrin and fears brought on a fever, of which he died the 22d of April 1699.

The king, who was sensible of his great merit, and always loved him, sent often to him in his illness; and finding after his death that he had more glory than riches, settled a hand-some pension upon his family. — There is nothing in the French language and letters more wit and elegance than his pieces in prose. Besides his plays, several of his letters have been published; he also wrote spiritual songs, epigrams, &c. Racine's works were printed at Amsterdam in 1722, in 2 vols 12mo, and the next year a pompous edition was printed in 2vols quarto.

RACING, the riding heats for a plate, or other premium. See Plate. The amusement of horse-racing, which is now so common, was not unknown among the great nations of antiquity, nor wholly unpractised by our ancestors in Britain, as we have already mentioned in the article RACE. In 1599, private matches between gentlemen, who were their own jockeys and riders, were very common; and in the reign of James I. public races were established at various places, when the discipline, and mode of preparing the horses for running, &c. were much the same as they are now. The most celebrated races of that time were called bell-courses, the prize of the conqueror being a bell: hence, perhaps, the phrase bearing the bell, when any thing of note is derived. In the latter end of Charles I.'s reign, races were performed in Hyde-Park. Newmarket was also a place for the same purpose, though it was first used for hunting. Racing was revived soon after the Restoration, and much encouraged by Charles II. who appointed races for his own amusement at Dachet Mead, when he resided at Windsor. Newmarket, however, now became the principal place. The king attended in person, established a house for his own accommodation, and kept and entered horses in his own name. Instead of bells, he gave a silver bowl or cup value 100 guineas; on which the prize the exploits and pedigree of the successful horse were generally engraved. Instead of the cup or bowl, the royal gift is now a hundred guineas. William III. not only added to the plates, but even founded an academy for riding; and Queen Anne continued the bounty of her ancestors, adding several plates herself. George I. towards the end of his reign, discontinued the plates, and gave in their room a hundred guineas. An act was passed in the 13th year of the reign of George II. for suppressing races by poneys and other small and weak horses,
the duke of Exeter's daughter, and still remains in the Tower of London, where it was occasionally used as an engine of state, not of law, more than once in the reign of Queen Elizabeth. But when, upon the assassination of Villiers duke of Buckingham, by Felton, it was proposed in the privy council to put the assassin to the rack in order to discover his accomplices; the judges, being consulted, declared unanimously, to that own honour and the honour of the English law, that no such proceeding was allowable by the laws of England. It seems astonishing that this usage of administering the torture should be said to arise from a tenderness to the lives of men; and yet this is the reason given for its introduction in the civil law, and its subsequent adoption by the French and other foreign nations, viz. because the laws cannot endure that any man should die upon the evidence of a false or even a single witness, and therefore contrived this method that innocence should manifest itself by a stout denial, or guilt by a plain confession; thus rating a man's virtue by the hardiness of his constitution, and his guilt by the sensibility of his nerves. The marquis Beccaria, in an exquisite piece of raillery, has proposed this problem, with a gravity and precision that are truly mathematical:

"The force of the muscles and the sensibility of the nerves of an innocent person being given; it is required to find the degree of pain necessary to make him confess himself guilty of a given crime." See Act of Faith, Inquisition, and Torture.

Rack, a spirituous liquor made by the Tartars of Tongula. This kind of rack is made of mare's milk, which is left to be sour, and afterwards distilled twice or thrice between two earthen pots closely stopped; whence the liquor runs through a small wooden pipe; this liquor is more intoxicating than brandy distilled from wine.

Rack, or Arack. See Arack. To Rack Wines, &c. To draw them off from their lees, after having stood long enough to cbb and settle. Hence rack-vintage is frequently used for the second voyage our wine-merchants used to make into France for racked wines.

Rackoon, a species of usus. See Ursus, Mammalia Insect.

Raconi, a populous town of Italy, in Piedmont, seated in a pleasant plain, on the road from Savillan to Turin, on the rivers Grana and Maesa. It belongs to the prince of Carignan, who has a handsome castle here. It is six miles from Savillan, and six from Carignan. E. Long. 7. 46. N. Lat. 44. 39.

Radclyffe, Dr John, an English physician of great eminence in his time, born at Wakefield in Yorkshire in 1650. He was educated at Oxford, and enrolled himself upon the physical line; but it was remarkable that he recommended himself more by his ready wit and vivacity, than by any extraordinary acquisitions in learning. He began to practise at Oxford in 1675; but never paid any regard to established rules, which he censured whenever he thought fit, with great freedom and acrimony; and as this drew all the old practitioners upon him, he lived in a continual state of hostility with them. Nevertheless, his reputation increased with his experience; so that, before he had been two years in business, his practice was very extensive among persons of high rank. In 1684 he removed to
Radcliffe, London, and settled in Bow-street, Covent Garden, where in less than a year he got into great employment. In 1657 the princess Anne of Denmark made him her physician; yet when her husband and she joined the prince of Orange, Radcliffe, either not choosing to declare himself, or unwilling to favour the measures then in agitation, excused himself from attending them, on the plea of the multitude of his patients. Nevertheless, he was often sent for to King William and other great personages, though he did not incline to be a courtier. He incurred some censure for his treatment of Queen Mary, who died of the smallpox; and soon after lost his place about the princess Anne, by his attachment to his bottle. He also totally lost the favour of King William by his uncourteous freedom; for, in 1669, when the king showed him his swollen ankles, while the rest of his body was emaciated, and asked him what he thought of them? "Why truly I would not have your majesty's two legs for your three kingdoms," replied Radcliffe. He continued increasing in business and insolence as long as he lived, continually at war with his brethren the physicians; who considered him in no other light than that of an active ingenious empiric, whom constant practice had at length brought to some degree of skill in his profession. He died in 1714; and if he never attempted to write anything himself, has perpetuated his name by founding a fine library at Oxford, to preserve the writings of other men.

Radialis, the name of two muscles in the arm. See Anatomy, Table of the Muscles.

Radiant, in Optics, is any point of a visible object from whence rays proceed.

Radiated flowers, in Botany, are such as have several siphonostele sets round a disk, in form of a radiant star; those which have no such rays are called discous flowers.

Radiation, the act of a body emitting or diffusing rays of light all round as from a centre.

Radical, in general, something that serves as a basis or foundation. Hence physicians talk much of a radical moisture. In grammar, we give the appellation radical to primitives, in contradistinction to compounds and derivatives. Algebraists also speak of the radical sign of quantities, which is the character expressing their roots.

Radicle, that part of the seeds of all plants which upon vegetation becomes their root, and is discoverable by the microscope. See Plant.

Radish. See Raphanus, Botany Index; and for the mode of culture, see Gardening Index.

Radius, in Geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference.

In Trigonometry, the radius is termed the whole side, or sine of 90°. See Sine.

Radius, in Anatomy, the exterior bone of the arm, descending along with the ulna from the elbow to the wrist.

Radnor, the county town of Radnorshire, in South Wales, distant from London about 150 miles. It is situated near the springhead of the river Somergil, in a fruitful valley at the bottom of a hill, where there are sheep grazing in abundance. It is a very ancient borough-town, whose jurisdiction extends near 12 miles round: the government of it is vested in a bailiff and 25 burgesses; and the population in 1801 was nearly 2000. Though it is the county town, the assizes are held at Presteigne; it has one privilege, however, that is very extraordinary, besides that of sending one member to parliament; and that is, it keeps a court of pleas for all actions, without being limited to any particular sum. It was formerly fenced with a wall and strong castle; but both were in a great measure demolished by Owen Glendower, when he assumed the title of Prince of Wales, upon the deposition of King Richard II. W. Long. 2. 45. N. Lat. 52. 10.

Radnorshire, a county of South Wales, is bounded on the north by Montgomeryshire; on the east by Shropshire and Herefordshire; on the south and south-west by Brecknockshire; and on the west by Cardiganshire; extending 30 miles in length and 25 in breadth. This county is divided into six hundreds, in which are contained three market-towns, 52 parishes, and in 1811 there were 4165 houses, and 20,900 inhabitants. It is seated in the diocese of Hereford, and sends two members to parliament, one for the county and one for the town of Radnor. The soil in general is but indifferent; yet some places produce corn, particularly the eastern and southern parts; but in the northern and western, which are mountainous, the land is chiefly stocked with horned cattle, sheep, and goats. See Radnorshire, Supplement.

Radix. See Root.

Raft, a sort of float, formed by an assemblage of various planks or pieces of timber, fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road than if they were separate. The timber and plank with which merchant-ships are laden, in the different parts of the Baltic sea, are attached together in this manner, in order to float them off to the shipping.

Rafters, in building, are pieces of timber which, standing by pairs on the rafter or raking piece, meet in an angle at the top, and form the roof of a building. See Architecture.

Rowley Ragg, a variety of whinstone or greenstone of a dusky or dark grey colour, with many small shining crystals, having a granular texture, and acquiring an ochry crust by exposure to the air.

Ragman's roll, Revisus Ragmanus's roll, so called from one Ragimund a legate in Scotland, who calling before him all the beneficed clergymen in that kingdom, caused them on oath to give in the true value of their benefices; according to which they were afterwards taxed by the court of Rome; and this roll, among other records, being taken from the Scots by Edward I. was delivered them in the beginning of the reign of Edward III.

Ragout, or Ragoo, a sauce, or seasoning, intended torouse the appetite when lost or languishing. This term is also used for any high-seasoned dish prepared of flesh, fish, greens, or the like: by stewing them with bacon, salt, pepper, cloves, and the like ingredients.

We have ragouts of celery, of endive, asparagus, cock's combs, giblets, crab fish, &c.

The ancients had a ragout called garum, made of the putrid guts of a certain fish kept till it dissolved into a mere saurf; which was thought such a dainty, that, according to Pliny, its price equalled that of the richest perfumes.

Ragstone,
RUGSTONE, a coarse kind of sandstone which is used as a whetstone for coarse cutting tools. It is found in the hills about Newcastle, and many other parts of England, where there are large rocks of it.

RAGULED, or RAGGED, in Heraldry, jagged or knotted. This term is applied to a cross formed of the trunks of two trees without their branches, of which they show only the stumps. Raguled differs from indented, in that the latter is regular, the former not.

RAGUSA, an ancient town of Sicily, in the Val di Noto, near the river Mavolo, 12 miles north of Modica. E. Long. 14° 59. N. Lat. 37° 00.

RAGUSA, a city of Dalmatia, and capital of Ragusa. It is about two miles in circumference, is pretty well built, and strong by situation, having an inaccessible mountain on the land-side, and on the side of the sea a strong fort. It is an archbishop's see, and was formerly a republic, with a doge like that of Venice, who continued a month only in his office. It carries on a considerable trade with the Turks. E. Long. 18° 10. N. Lat. 42° 50.

RAGUSE, a territory of Europe in Dalmatia, lying along the coast of the gulf of Venice, about 55 miles in length, and 20 in breadth. It was formerly a republic under the protection of the Turks and Venetians, but fell under the dominion of the French, and was since transferred to the Austrians, in whose possession it remains.

RAJA, or RAJA, the title of the Indian black princes, the remains of those who ruled there before the Moguls. Some of the rajas are said to preserve their independence, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul. The Indians call them rai; the Persians, raiun, in the plural; and our travellers rajas, or rajas.

RAJA, the Ray-Fish, in Ichthyology, a genus of fishes belonging to the cartilaginous order.

RAIANIA, a genus of plants belonging to the dicotia class; and in the natural method ranking under the 11th order, Sarmentacea. See Botany Index.

RAIEETEA, one of the South sea islands, named also Uliette.

RAIL. See Rails, Ornithology Index.

RAILLERY, according to Dr Johnson, means slight satire, or satirical remonstrance; and a beautiful writer of the last century compares it to a light which dazzles, and which does not burn. It is sometimes innocent and pleasant, and it should always be, so but it is most frequently offensive. Railillery is of various kinds; there is a serious, severe, and good-humoured railillery; and there is a kind which perplexes, a kind which offends, and a kind which pleases.

To rail well, it is absolutely necessary that kindness run through all you say; and you must ever preserve the character of a friend to support your pretensions to be free with a man. Allusions to past follies, hints to revive what a man has a mind to forget for ever, should never be introduced as the subjects of railery. This is not to thrust with the skill of fencers, but to cut with the barbarity of butchers. But it is below the character of men of humanity and good-breeding to be capable of mirth, while there is any in the company in pain and disorder.

RAIN, the descent of water from the atmosphere in the form of drops of a considerable size. By this circumstance it is distinguished from dew and fog; in the former of which the drops are so small that they are quite invisible; and in the latter, though their size be larger, they seem to have very little more specific gravity than the atmosphere itself, and may therefore be reckoned hollow spherules rather than drops. Some of the more general facts relative to the phenomena of rain have been already given under Meteorology. We shall here add some account of the speculations of philosophers on the same subject, in attempting to account for those phenomena.

It is universally agreed, that rain is produced by the water previously absorbed by the heat of the sun, or otherwise, from the terraqueous globe, into the atmosphere; but very great difficulties occur when we begin to explain why the water, once so closely united with the atmosphere, begins to separate from it. We cannot ascribe this separation to cold, since rain often takes place in very warm weather; and though we should suppose the condensation owing to the superior cold of the higher regions, yet there is a remarkable fact which will not allow us to have recourse to this supposition. It is certain that the drops of rain increase in size considerably as they descend. On the top of a hill, for instance, they will be small and inconsiderable, forming only a drizzling shower; but at the bottom of the same hill the drops will be excessively large, descending in an impetuous rain; which shows that the atmosphere is disposed to condense the vapours, and actually does so, as well where it is warm as where it is cold.

For some time the suppositions concerning the cause of rain were exceedingly insufficient and unsatisfactory. It was imagined, that when various congeries of clouds were driven together by the agitation of the winds, they mixed, and run into one body, by which means they were condensed into water. The coldness of the upper parts of the air also was thought to be a great means of collecting and condensing the clouds into water; which, being heavier than the air, must necessarily fall down through it in the form of rain. The reason why it falls in drops, and not in large quantities, was said to be the resistance of the air; whereby being broken, and divided into smaller and smaller parts, it at last arrives to us in small drops. But this hypothesis is entirely contrary to almost all the phenomena: for the weather, when coldest, that is, in the time of severe frost, is generally the most serene; the most violent rains also happen where there is little or no cold to condense the clouds; and the drops of rain, instead of being divided into smaller and smaller ones, as they approach the earth, are plainly increased in size as they descend.

Dr Derham accounted for the precipitation of the drops of rain from the vesicle being full of air, and meeting with an air colder than they contained, the air they contained was of consequence contracted into a smaller space; and consequently the watery shell rendered thicker, and thus specifically heavier, than the common atmosphere. But it has been shown, that the vesicle, if such they are, of vapour, are not filled with air, but with fire, or heat; and consequently, till they part with this latent heat, the vapour cannot be condensed. Now, cold is not always sufficient to effect this, since in the most severe frosts the air is very often serene, and parts with little or none of its vapour...
Rain, for a very considerable time. Neither can we admit the winds to have any considerable agency in this matter, since we find that blowing upon vapour is so far from condensing it, that it unites it more closely with the air, and wind is found to be a great promoter of evaporation.

According to Rohault, the great cause of rain is the heat of the air; which, after continuing for some time near the earth, is raised on high by a wind, and there thawing the snowy will or drops of half-frozen vesicle, reduces them to drops; which, coalescing, descend. Here, however, we ought to be informed by what means these vesicles are suspended in their half-frozen state; since the thawing of them can make but little difference in their specific gravity, and it is certain that they ascended through the air not in a frozen but in an aqueous state.

Dr. Clarke and others ascribe this descent of the rain rather to an alteration of the atmosphere than of the vesicles; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which, they say, depends chiefly or wholly upon terrestrial exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall. Now, the little vesicles being once upon the descent, will continue therein, notwithstanding the increase of resistance they every moment meet with. For, as they all tend to the centre of the earth, the farther they fall, the more coalitions they will make; and the more coalitions, the more matter will there be under the same surface; the surface increasing only as the squares, but the solidity as the cubes; and the more matter under the same surface, the less resistance will there be to the same matter. Thus, if the cold, wind, &c. act early enough to precipitate the ascending vesicles before they are arrived at any considerable height, the coalitions being but few, the drops will be proportionably small; and thus is formed a dew. If the vapours be more copious, and rise a little higher, we have a mist or fog. A little higher still, and they produce a small rain; if they neither meet with cold nor wind, they form a heavy thick dark sky. This hypothesis is equally unsatisfactory with the others; for, granting that the descent and condensation of the vapours are owing to a diminution of the atmosphere’s elasticity, by what is this diminution occasioned? To say that it is owing to terrestrial exhalations, is only solving one difficulty by another; since we are totally unacquainted both with the nature and operation of these exhalations. Besides, let us suppose the cause to be what it will, if it acts equally and at once upon all the vapour in the air, then all that vapour must be precipitated at once; and thus, instead of gentle showers continuing for a considerable length of time, we should have the most violent water-spouts, continuing only for a few minutes, or perhaps seconds, which, instead of refreshing the earth, would drown and lay waste every thing before them.

Since philosophers have admitted the electric fluid to such a large share in the operations of nature, almost all the natural phenomena have been accounted for by the action of that fluid; and rain, among others, has been reckoned an effect of electricity. But this word, unless it be explained, makes us no wiser than we were before; the phenomena of artificial electricity having been explained on principles which could scarce apply in any degree to the electricity of nature: and therefore all the solution we can obtain of the natural appearances of which we speak, comes to this, that rain is occasioned by a moderate electrification, hail and snow by one more violent, and thunder by the most violent of all; but in what manner this electrification is occasioned, has not yet been explained. The principles of electricity necessary to be attended to in the solution of the phenomena under consideration are the following:

1. The electric fluid and solar light are the same substances in two different modifications.

2. Electricity is the motion of the fluid when running, or attempting to run, in a continued stream from one place to another: heat is when the fluid has no tendency but to vibrate outwards and inwards to and from a centre; or at least when its streams converge to a point or focus.

3. The fluid acting as electricity, like water, or any other fluid, always tends to the place where there is least resistance.

On these three principles may the phenomena of atmospheric electricity, and the descent of rain by its means, he explained as follows:

1. The light or heat of the sun, acting in that peculiar manner which we call heat, unites itself with the moisture of the earth, and forms it into vapour, which thus becomes specifically lighter than air, and of consequence ascends in the atmosphere to a certain height.

2. Besides the quantity of light which is thus united to the water, and forms it into vapour, a very considerable quantity enters the earth, where it assumes the nature of electric fluid.

3. As the earth is always full of that fluid, every quantity which enters must displace an equal quantity which is already there.

4. This quantity which is displaced must escape either at a distance from the place where the other enters, or very near it.

5. At whatever place a quantity of electric matter escapes, it must electrify the air above that place where it has escaped; and as a considerable quantity of light must always be reflected from the earth into the atmosphere, where it does not combine with the aqueous vapour, we have thence another source of electricity to the air: as this quantity must undoubtedly assume the action of electric fluid, especially after the action of the sun has ceased. Hence the reason why in serene weather the atmospheric electricity is always strongest, and rather more so in the night than in the day.

6. From these considerations, we see an evident reason why there must commonly be a difference between the electricity of the earth and that of the atmosphere, excepting when an earthquake is about to ensue. The consequence of this must be, that as the action of the solar light continues to bring down the electric matter, and the earth continues to discharge an equal quantity of it into the atmosphere, some part of the atmosphere must at last become overloaded with it, and attempt to throw it back into the earth. This attempt will be vain, until a vent is found for the electricity at some other place; and as soon as this happens, the electrified atmosphere begins to throw off its superfluous electricity, and the earth to receive it. As the atmosphere itself
Rain. is a bad conductor, and the more so the drier it is, the electric matter attacks the small aqueous particles which are detained in it by means of the latent heat. These being unable to bear the impetus of the fluid, throw out their latent heat, which easily escapes, and thus makes a kind of vacuum in the electrified part of the atmosphere. The consequences of this are, that the aqueous particles being driven together in large quantity, at last become visible, and the sky is covered with clouds; at the same time a wind blows against these clouds, and, if there is no resistance in the atmosphere, will drive them away.

7. But if the atmosphere round the cloud is excessively electrified, and the earth is in no condition to receive the superfluous fluid excepting in that place which is directly under the cloud, then the whole electricity of the atmosphere for a vast way round will tend to that part only, and the cloud will be electrified to an extreme degree. A wind will now blow against the cloud from all quarters, more and more of the vapour will be extricated from the air by the electric matter, and the cloud will become darker and thicker, at the same time that it is in a manner stationary, as being acted upon by opposite winds; though its size is enlarged with great rapidity by the continual supplies of vapour brought by the winds.

8. The vapours which were formerly suspended invisibly by means of the latent heat are now suspended visibly by the electric fluid, which will not let them fall to the earth, until it is in a condition to receive the electric matter descending with the rain. It is easy to see, however, that thus every thing is prepared for a violent storm of thunder and lightning as well as rain. The surface of the earth becomes electrified from the atmosphere: but when this has continued for some time, a zone of earth considerably below the surface acquires an electricity opposite to that of the clouds and atmosphere; of consequence the electricity in the cloud being violently pressed on all sides, will at last burst out towards that zone where the resistance is least, as explained under the article Lightning. The vapours now having lost that which supported them, will fall down in rain, if there is not a sufficient quantity of electric matter to keep them in the same state in which they were before: but if this happens to be the case, the cloud will instantly be charged again, while little or no rain will fall; and hence very violent thunder sometimes takes place without any rain at all, or such as is quite inconsiderable in quantity.

9. When the electricity is less violent, the rain will descend in vast quantity, especially after every flash of lightning; and great quantities of electric matter will thus be conveyed to the earth, it sometimes happens that the drops have been observed to shine as if they were on fire, which has given occasion to the reports of fiery rain having fallen on certain occasions. If the quantity of electric matter is smaller, so that the rain can convey it all gradually to the ground, there will be rain without any thunder; and the greater the quantity of electricity the more violent will be the rain.

From this account of the causes of rain, we may see the reason why in warm climates the rains are excessive, and for the most part accompanied with thunder; for there the electricity of the atmosphere is immensely greater than it is with us. We may also see why in certain places, according to the situation of mountains, seas, &c. the rains will be greater than in others, and likewise why some parts of the world are exempted from rain altogether; but as a particular discussion of these would necessarily include an explanation of the causes and phenomena of Thunder, we shall for this reason refer the whole to be treated of under that article.

Whether this theory be just, however, it would be too assuming in us to say. It may admit of dispute; for we must grant that in the very best systems, though an occurrence so frequent, the theory of rain is but very imperfectly understood. Dr Hutton, whose speculations are always ingenious, though generally extraordinary, and much out of the common way, has given a new theory of rain in the first volume of the Transactions of the Royal Society of Edinburgh. It is well known that atmospheric air is capable of dissolving, with a certain degree of heat, a given quantity of water. The Doctor ascertains the ratio of the dissolving power of air, in relation to water, in different degrees of heat; and shows, that by mixing a portion of transparent humid warm air with a portion of cold air, the mixture becomes opaque, and part of the water will be precipitated; or, in other words, the vapour will be condensed into rain. The ratio which he states, however, does not appear to us to be supported by experience. Whether the electricity of the air changes in consequence of its depositing the water dissolved in it, or the change is a cause of this deposition, must remain uncertain; but, in either view, there must be an agent different from heat and cold, since the changes in these respects do not in other operations change the state of electricity. Dr Hutton supposes that heat and solution do not increase by equal increments; but that, in reality, if heat be supposed to increase by equal increments along a straight line, solution will be expressed by ordinates to a curve whose convex side is turned towards that line. That the power of solution is not increased in the same ratio with heat, is, however, hypothetical, except when we rise pretty high in the scale, when its proportional increase is a little doubtful; and it is not, in this paper, supported by experiment. The condensation of the breath in air is not an observation in point, except in air already saturated with vapour. It can amount, in any view, to no more than this, that to render it visible, the heat must be diminished in a greater proportion than can be compensated by the power of solution in the body of air, in which the portion expired is at first immersed. To explain rain from this cause, we must always suppose a constant diminution of heat to take place at the moment of the condensation of the vapour; but we actually find that the change from fluid state of vapour to the fluid state is attended with heat; so that rain may at once oppose its own cause, and continued rains would be impossible, without calling in the aid of other causes. From his own system, Dr Hutton endeavours to explain the regular and irregular seasons of rain, either respecting the generality of its appearance, or the regularity of its return. And to obviate the apparent exceptions of the theory, from the generality of rain, he explains the proportional quantities of rain, and adds a comparative estimate of climates, in relation to rain, with the meteorological observations made in our own climate.
As to the general quantity of rain that falls, and its proportion in several places at the same time, and in the same place at several times, we have many observations, journals, &c. in the Memoirs of the French Academy, the Philosophical Transactions, &c. Upon measuring, then, the rain falling yearly, its depth, at a medium, and its proportion in several places, is found as is in the following table:

<table>
<thead>
<tr>
<th>Location</th>
<th>Depth (Inches)</th>

As to the use of rain, we may observe, that it moreover...
Rain. stems and softens the earth, and thus fits it for affording nourishment to plants; by falling on high mountains, it carries down with it many particles of loose earth, which serve to fertilize the surrounding valleys, and purifies the air from noxious exhalations, which tend in their return to the earth to meliorate the soil; it moderates the heat of the air; and is one means of supplying fountains and rivers. However, vehement rains in many countries are found to be attended with barrenness and poorness of the lands, and miscarriage of the crops in the succeeding year: and the reason is plain; for these excessive storms wash away the fine mould into the rivers, which carry it into the sea, and it is a long time before the land recovers itself again. The remedy to the famine, which some countries are subject to from this sort of mischief, is the planting large orchards and groves of such trees as bear esculent fruit; for it is an old observation, that in years when grain succeeds worst, these trees produce most fruit of all. It may partly be owing to the thorough moistening of the earth, as deep as their roots go by these rains, and partly to their trunks stopping part of the light mould carried down by the rains, and by this means furnishing themselves with a coat of new earth.

Preternatural Rain. We have numerous accounts, in the historians of our own as well as other countries, of preternatural rains; such as the raining of stones, of dust, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what those who are authors of veracity and credit relate to us of this kind, so far as to suppose that the falling of stones and dust never happened; the whole mistake is, the supposing them to have fallen from the clouds: but as to the blood and frogs, it is very certain that they never fell at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine strictly whatever is reported of this kind, and is not to suffer himself to be deceived.

There are two natural methods by which quantities of stones and dust may fall in certain places, without their having been generated in the clouds or fallen as rain. The one is by means of hurricanes: the wind which we frequently see tearing off the tiles of houses, and carrying them to considerable distances, being equally able to take up a quantity of stones, and drop them again at some other place. But the other, which is much the most powerful, and probably the most usual way, is for the eruptions of volcanoes and burning mountains to toss up, as they frequently do, a vast quantity of stones, ashes, and cinders, to an immense height in the air: and these, being hurried away by the hurricanes and insupportable winds which usually accompany those eruptions, and being in themselves much lighter than common stones, as being half calcined, may easily be thus carried to vast distances; and there falling in places where the inhabitants know nothing of the occasion, they cannot but be supposed by the vulgar to fall on them from the clouds. It is well known, that, in the great eruptions of Etna and Vesuvius, showers of ashes, dust, and small cinders, have been seen to obscure the air, and overspread the surface of the sea for a great way, and cover the decks of ships; and this at such a distance, as it should appear scarce conceivable that they should have been carried to: and probably, if the accounts of all the showers of these substances mentioned by authors be collected, they will all be found to have fallen within such distances of volcanoes; and if compared as to the time of their falling, will be found to correspond in that also with the eruptions of those mountains. We have known instances of the ashes from Vesuvius having been carried thirty, nay, forty leagues, and peculiar accidents may have carried them yet farther. It is not to be supposed that these showers of stones and dust fall for a continuance in the manner of showers of rain, or that the fragments or pieces are as frequent as drops of water; it is sufficient that a number of stones, or a quantity of dust, fall at once on a place, where the inhabitants can have no knowledge of the part from whence they came, and the vulgar will not doubt their dropping from the clouds. Nay, in the canton of Berne in Switzerland, the inhabitants accounted it a miracle that it rained earth and sulphur upon them at a time that a small volcano terrifi ed them; and even while the wind was so boisterous, and hurricanes so frequent, that they saw almost every moment the dust, sand, and little stones torn up from the surface of the earth in whirlwinds, and carried to a considerable height in the air, they never considered that both the sulphur thrown up by the volcano, and the dust, &c. carried from their feet must fall soon after somewhere.

It is very certain that in some of the terrible storms of large hail, where the hailstones have been of many inches round, on breaking them there have been found what people have called stones in their middle; but these observers needed only to have waited the dissolving of one of these hailstones, to have seen the stone in its centre disintegrate itself, it being only formed of the particles of loose earthy matter, which the water exhaled, by the sun's heat, had taken up in extremely small molecules with it; and this only having served to give an opaque hue to the inner part of the congelation, to which the freezing of the water alone gave the apparent hardness of stone.

The raining of blood has been ever accounted a more terrible sight and more fatal omen than the other preternatural rains already mentioned. It is very certain that nature forms blood nowhere but in the vessels of animals; and therefore showers of it from the clouds are by no means to be credited. Those who suppose that what has been taken for blood has been actually seen falling through the air, have had recourse to flying insects for its origin, and suppose it the eggs or dung of certain butterflies discharged from them as they were high up in the air. But it seems a very wild conjecture, as we know of no butterfly whose excrements or eggs are of such a colour, or whose abode is so high, or whose flocks so numerous, as to be the occasion of this.

It is most probable that these bloody waters were never seen falling; but that people seeing the standing waters blood-coloured, were assured, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance of this took place at the Hague in the year 1670. Swarms of midges, who relates it, tells us, that one morning the whole town was in an uproar on finding their lakes and ditches full of blood, as they thought; and having been certainly full of water the night before, they agreed it must have rained blood in the night: but a certain physi-
R A I [ 624 ]

Rain. physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour; but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour and prodigious number gave a red tinge to the whole body of the water they lived in, on a less accurate inspection. The certainty that this was the case, did not however persuade the Hollanders to part with the miracle: they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy as the raining of blood would have been; and are assured to this day, that this portent foretold the scene of war and destruction which Louis XIV. afterwards brought into that country, which had before enjoyed 40 years of uninterrupted peace.

The animals which thus colour the water of lakes and ponds are the pulices arborescentes of Swammerdam, or the water-fleas with branched horns. These creatures are of a reddish-yellow or flame colour: they live about the sides of ditches, under weeds, and among the mud; and are therefore less visible, except at a certain time, which is in the end or beginning of June: it is at this time that these little animals leave their recesses to float loose about the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in one part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarmed the ignorant.

The raining of frogs is a thing not less wonderful in the accounts of authors who love the marvellous, than those of blood or stones; and this is supposed to happen so often, that there are multitudes who pretend to have been eye-witnesses of it. These rains of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than in the cold ones. In Italy they are very frequent; and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an instant in a shower of rain; they hopping everywhere between the people’s legs as they walk, though there was not the least appearance of them before. Nay, they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being rained down from the clouds; but, when strictly examined, it comes to nothing: for these frogs that are seen to fall, are always found dead, lamed, or bruised by the fall, and never hop about as the rest; and they are never seen to fall, except close under the walls of houses, from the roofs and gutters of which they have accidentally slipped down. Some people, who love to add to strange things yet stronger, affirm that they have had the young frogs fall into their hats in the midst of an open field; but this is idle, and wholly false.

Others, who cannot agree to their falling from the clouds, have tried to solve the difficulty of their sudden appearance, by supposing them hatched out of the egg, or spawn, by these rains. Nay, some have supposed them made immediately out of the dust: but there are unanswerable arguments against all these suppositions. Equivocal generation, or the spontaneous production of animals out of dust, is now wholly exploded. The fall from the clouds must destroy and kill these tender and soft-bodied animals: and they cannot be at this time hatched immediately out of eggs; because the young frog does not make its appearance from the egg in form, but has its hinder legs enveloped in a skin, and is what we call a tadpole; and the young frogs are at least 100 times larger at the time of their appearance, than the egg from which they should be hatched.

It is beyond a doubt, that the frogs which make their appearance at this time, were hatched and in being long before: but that the dry seasons had injured them, and kept them sluggishly in holes or covert; and that all the rain does, is the enlivening them, giving them new spirits, and calling them forth to seek new habitations, and enjoy the element they were destined in great part to live in. Theophrastus, the greatest of all the naturalists of antiquity, has affirmed the same thing. We find that the error of supposing these creatures to fall from the clouds was as early as that author’s time; and also that the truth, in regard to their appearance, was as early known; though, in the ages since, authors have taken care to conceal the truth, and to hand down to us the error. We find this venerable sage, in a fragment of his on the generation of animals which appear on a sudden, bantering the opinion, and asserting that they were hatched and living long before. The world owes, however, to the accurate Signior Redi, the great proof of this truth, which Theophrastus only has affirmed: for this gentleman, dissecting some of these new-appearing frogs, found in their stomachs herbs and other half-digested food; and, openly showing this to his credulous countrymen, asked them whether they thought that nature, which engendered, according to their opinion, these animals in the clouds, had also been so provident as to engender grass there for their food and nourishment?

To the raining of frogs we ought to add the raining of grasshoppers and locusts, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for the supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the egges of these and other like animals, cannot but know that some seasons will prove particularly favourable to the hatching them; and the prodigious number of eggs that many insects lay could not but every year bring us such abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the species by a very numerous stock of seeds, of which perhaps not one in 500 need take root in order to continue an equal number of plants. As it is thus also in regard to insects, it cannot but happen, that if a favourable season encourage the hatching of all those eggs, a very small number of which alone was necessary to continue the species, we must, in such seasons, have a proportionate abundance of them. There appeared about 50 years ago, in London, such a prodigious swarm of the little beetle called the lady-cow, that the very posts in the streets were everywhere covered with them. But thanks to the progress of philosophy among us, we had nobody to assert that it rained cow-ladies, but contented ourselves with saying that it had been a favourable season for their eggs. The prodigious number of a sort of grub which did vast mischief about the same period
period among the corn and grass by eating off their roots, might also have been supposed to proceed from its having raised grubs by people fond of making everything a prodigy; but our knowledge in natural history assured us, that these were only the hexapode worms of the common hedge-beetle called the cockchafer.

The raining of fishes has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c. were found in a manner covered with fishes of various sizes. Nobody here made any doubt of these having fallen from the clouds; nor did the absurdity of fish, of five or six inches long, being generated in the air, at all startle the people, or shake their belief in the miracle, till they found, upon inquiry, that a very well stocked fish-pond, which stood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fish left at the bottom of it, all the smaller fry having been tossed into their streets.

Upon the whole, all the supposed marvellous rains have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

In Sicily, after a great dearth of wheat in that country, there happened a violent storm of wind and rain, and the earth was afterwards covered, in many places, with small round seeds. The vulgar cried out that Providence had sent them food, and that it had rained millet; but these were, in reality, only the seeds of a species of veronica, or speedwell, very common in that country; and whose seeds were just ripe at that time, the wind had dislodged them from their capsules, and scattered them about. In our own country, we have histories of rains of this marvellous kind, but all fabulous. It was once said to rain wheat in Wiltshire; and the people were all alarmed at it as a miracle, till Mr. Cole showed them, that what they took for wheat was only the seeds or kernels of the berries of ivy, which being then fully ripe, the wind had dislodged from the sides of houses, and trunks of trees, on which the ivy that produced them crept.

And we even once had a raining of fishes near the coast of Kent in a terrible hurricane, with thunder and lightning. The people who saw small sprats strewn all about afterwards, would have it that they had fallen from the clouds; but those who considered how far the high winds have been known to carry the sea-water, did not wonder that they should be able to carry small fish with it so small a part of the way.

In the Philosophical Transactions for 1782, we have the following account of a preternatural kind of rain by Count de Gienon: "The morning of the 24th instant there appeared here a most singular phenomenon. Every place exposed to the air was found wet with a coloured cretaceous grey water, which, after evaporating and filtrating away, left every place covered with it to the height of two or three lines; and all the iron-work that was touched by it became rust.

"The public, inclined to the marvellous, fancied various causes of this rain, and began to fear for the animals and vegetables.

"In places where rain-water was used, they abstained from it: some suspecting vitriolic principles to be mixed with it, and others predicting some epidemical disorder.

"Those who had observed the explosions of Etna 20 days and more before, were inclined to believe it originated from one of them.

"The shower extended from N. 3/4 N. E. to S. 3/4 S. W. over the fields, about 70 miles in a right line from the vertex of Etna.

"There is nothing new in volcanoes having thrown up sand, and also stones, by the violent expansive force generated within them, which sand has been carried by the wind to distant regions.

"But the colour and subtilty of the matter occasioned doubts concerning its origin; which increased from the remarkable circumstance of the water in which it came incorporated; for which reasons some other principle or origin was suspected.

"It became, therefore, necessary by all means to ascertain the nature of this matter, in order to be convinced of its origin, and of the effects it might produce. This could not be done without the help of a chemical analysis. To do this then with certainty, I endeavoured to collect this rain from places where it was most probable no heterogeneous matter would be mixed with it. I therefore chose the plant called brassica capita, which having large and turned up leaves, they contained enough of this coloured water: many of these I emptied into a vessel, and left the contents to settle till the water became clear.

"This being separated into another vessel, I tried it with vegetable alkaline liquors and mineral acids; but could observe no decomposition by either. I then evaporated the water in order to reunite the substances that might be in solution; and touching it again with the aforesaid liquors, it showed a slight effervescence with the acids. When tried with the syrup of violets, this became a pale green; so that I was persuaded it contained a calcareous salt. With the decoction of galls no precipitation was produced.

"The matter being afterwards dried in the shade, it appeared a very subtle fine earth, of a cretaceous colour, but inert, from having been diluted by the rain.

"I next thought of calcining it with a slow fire, and it assumed the colour of a brick. A portion of this being put into a crucible, I applied to it a strong heat: by which it lost almost all its acquired colour. Again, I exposed a portion of this for a longer time to a very violent heat (from which a vitrification might be expected); it remained, however, quite soft, and was easily bruised, but returned to its original dusky colour.

"From the most accurate observations of the smoke from the three calcinations, I could not discover either colour or smell that indicated any arsenical or sulphureous mixture.

"Having therefore calcined this matter in three portions, with three different degrees of fire, I presented a good magnet to each: it did not act either on the first or second; a slight attraction was visible in many places on the third: this persuaded me, that this earth contains a martial principle in a metallic form, and not in a vitriolic substance.

"The nature of these substances then being discovered, their volcanic origin appears; for iron, the more it
RAI [626] RAI

is exposed to violent calcination, the more it is divided
by the loss of its phlogistic principle; which cannot
naturally happen but in the great chimney of a volcano.
Calcareous salt, being a marine salt combined with a
calcareous substance by means of violent heat, cannot be
otherwise composed than in a volcano.

As to their dreadful effects on animals and vegetables,
every one knows the advantageous use, in medi-
cine, both of the one and the other, and this in the same
form as they are thus prepared in the great laboratory
of nature.

"Vegetables, even in flower, do not appear in the
least macerated, which has formerly happened from
only showers of sand.

"How this volcanic production came to be mixed
with water may be conceived in various ways.

"Etna, about its middle regions, is generally sur-
rounded with clouds that do not always rise above its
summit, which is 2920 paces above the level of the sea.
This matter being thrown out, and descending upon the
clouds below it, may happen to mix and fall in rain
with them in the usual way. It may also be conjectured,
that the thick smoke which the volcanic matter
contained might, by its rarefaction, be carried by the
wind over that tract of country; and then cooling so as
to condense and become specifically heavier than the air,
might descend in that coloured rain.

I must, however, leave to philosophers (to whom
the knowledge of natural agents belongs) the examina-
tion and explanation of such phenomena, confining
myself to observation and chemical experiments. [Fig. 3]

See Meteorology. Supplement.

Rain, a well built and fortified town of Bavaria, one
of the keys of this electorate, on the Lech, 20 miles
west of Ingolstadt. N. Lat. 48° 51'. E. Long. 11° 12'.

Rain-Bird. See Cuculus, Ornithology Index.

Rainbow. See Optics.

In the Philosophical Transactions for 1793, we have
the following account of two rainbows seen by the Rev.
Mr Sturges.

"On the evening of the 9th of July 1792, between
seven and eight o'clock, at Alverstoke, near Gosport,
on the sea-coast of Hampshire, there came up, in the
south-east, a cloud with a thunder-shower; while the
sun shone bright, low in the horizon, to the north-
west.

In this shower two primary rainbows appeared,
AB and AC, not concentric, but touching each other
at A, in the south part of the horizon; with a second-
ary bow to each, DE and DF (the last very faint, but
discernible), which touched likewise at D. Both the
primary rainbows were very vivid for a considerable time,
and at different times nearly equally so; but the bow AB
was most permanent, was a larger segment of a circle,
and at last, after the other had vanished, became almost a
semicircle; the sun being near setting. It was a perfect
calm, and the sea was as smooth as glass.

"If I might venture to offer a solution of this ap-
pearance, it would be as follows. I consider the bow
AB as the true one, produced by the sun itself; and
the other, AC, as produced by the reflection of the sun
from the sea, which, in its perfectly smooth state, acted
as a speculum. The direction of the sea, between
the Isle of Wight and the land, was to the north-west in a
line with the sun, as it was then situated. The image
reflected from the water, having its rays issuing from a Rainbow
point lower than the real sun, and in a line coming from
beneath the horizon, would consequently form a bow
higher than the true one AB. And the showers, by
which that narrow part of the sea is bounded, would be
therefore the sun's actual setting intercept its rays from
the surface of the water, and cause the bow AC, which I
suppose to be produced by the reflection, to disappear
before the other."

The marine or sea bow is a phenomenon which may
be frequently observed in a much agitated sea, and is
occasioned by the wind sweeping part of the waves,
and carrying them aloft; which when they fall down are
refracted by the sun's rays, which paint the colours
of the bow just as in a common shower. These bows are
often seen when a vessel is sailing with considerable force,
and dashing the waves around her, which are raised
partly by the action of the ship and partly by the force
of the wind, and, falling down, form a rainbow; and
they are also often occasioned by the dashing of the
waves against the rocks on shore.

In the Philosophical Transactions, it is observed by
F. Bouzez, that the colours of the marine rainbow are
less lively, less distinct, and of shorter continuance, than
those of the common bow; and there are scarcely above
two colours distinguishable, a dark yellow on the side
next the sun, and a pale green on the opposite side.
But they are more numerous, there being sometimes 20
or 30 seen together.

To this class of bows may be referred a kind of white
or colourless rainbows, which Menzelius and others af-
firmed to have seen at noon-day. M. Marlotte, in his
fourth Essai de Physique, says, these bows are formed
in mists, as the others are in showers; and adds, that he
has seen several both after sunrising and in the night.
The want of colours he attributes to the smallness of the
vapours which compose the mist; but perhaps it is ra-
ther from the exceeding tenuity of the little vesicles of
the vapour, which being only little watery pellicles
bathed with air, the rays of light undergo but little re-
fraction in passing out of air into them; too little to se-
parate the differently coloured rays, &c. Hence the rays
are reflected from them, compounded as they came, that
is, white. Robaux mentions a coloured rainbow on the
grass; formed by the refractions of the sun's rays in
the morning dew. Rainbows have been also produced
by the reflection of the sun from a river; and in the
Philosophical Transactions, vol. I. p. 294. we have an
account of a rainbow, which must have been formed by
the exhalations from the city of London, when the sun
had been set 20 minutes, and consequently the centre
of the bow was above the horizon. The colours were the
same as in the common rainbow, but fainter.

It has often been made a subject of inquiry among the
curious how there came to be no rainbow before the
flood, which is thought by some to have been the case,
from its being made a sign of the covenant which the
Deity was pleased to make with man after that event.
Mr Whitehurst, in his Inquiry into the Original State
and Formation of the Earth, p. 173, &c. endeavours to
establish it as a matter of great probability at least, that
the antediluvian atmosphere was so uniformly temperate
as never to be subject to storms, tempests, or rain, and
of course it could never exhibit a rainbow. For our own
part, we cannot see how the earth at that period could
Rainbow. do without rain any more than at present; and it appears to us from Scripture equally probable that the rainbow was seen before the flood as after it. It was then, however, made a token of a certain covenant; and it would unquestionably do equally well for that purpose if it had existed before as if it had not.

Lunar Rainbow. The moon sometimes also exhibits the phenomenon of an iris or rainbow by the refraction of her rays in drops of rain in the night time. This phenomenon is very rare. In the Philosophical Transactions for 1783, however, we have an account of one seen in one year, and all in the same place, communicated in two letters by Marmaduke Tuastall, Esq. The first was seen 27th February 1782, at Great Bridge, Yorkshire, between seven and eight at night, and appeared in tolerably distinct colours, similar to a solar one, but more faint: the orange colour seemed to predominate. It happened at full moon; at which time alone they are said to have been always seen. Though Aristotle is said to have observed two, and some others have been seen by Snellius, &c. I can only find two described with any accuracy; viz. one by Plot, in his History of Oxfordshire, seen by him in 1675, though without colours; the other seen by a Derbyshire gentleman at Glapwell, near Chesterfield, described by Thoresby, and inserted in No. 331 of the Philosophical Transactions: this was about Christmas, 1710, and said to have had all the colours of the iris solaris. The night was windy; and though there was then a drizzling rain and dark cloud, in which the rainbow was reflected, it proved afterwards a light frost.

Two others were afterwards seen by Mr. Tunstall: one on July the 30th, about 11 o'clock, which lasted about a quarter of an hour, without colours. The other, which appeared on Friday October 18, was "perhaps the most extraordinary one of the kind ever seen. It was first visible about nine o'clock, and continued, though with very different degrees of brilliancy, till past two. At first, though a strongly marked bow, it was without colours; but afterwards they were very conspicuous and vivid in the same form as in the solar, though fainter; the red, green, and purple, were most distinguishable. About twelve it was the most splendid in appearance; its arc was considerably a smaller segment of a circle than a solar; its south-east limb first began to fail, and a considerable time before its final extinction: the wind was very high, nearly due west, most part of the time, accompanied with a drizzling rain. It is a singular circumstance, that three of these phenomena should have been seen in so short a time in one place, as they have been esteemed ever since the time of Aristotle, who is said to have been the first observer of them, and saw only two in 50 years, and since Plot and Thoresby, almost the only two English authors who have spoke of them, to be exceeding rare. They seem evidently to be occasioned by a refraction in a cloudy or turbid atmosphere, and in general are indications of stormy and rainy weather: so bad a season as the late summer having, I believe, seldom occurred in England. Thoresby, indeed, says, the one he observed was succeeded by several days of fine serene weather. One particular, rather singular, in the second, viz. of July the 30th, was its being six days after the full of the moon; and the last, though of so long a duration, was three days before the full: that of the 27th of February was exactly at the full, which used to be judged the only time they could be seen, though in the Encyclopaedia there is an account that Weidler observed one in 1719, in the first quarter of the moon, with faint colours, and in very calm weather. No lunar iris, I ever heard or read of, lasted near so long as that on the 18th instant, either with or without colours."

In the Gentleman's Magazine for August 1788 we have an account of a lunar rainbow by a correspondent, who saw it. "On Sunday evening the 17th of August (says he), after two days, on both of which, particularly the former, there had been a great deal of rain, together with lightning and thunder, just as the clocks were striking nine, 23 hours after full moon, looking through my window, I was struck with the appearance of something in the sky, which seemed like a rainbow. Having never seen a rainbow by night, I thought it a very extraordinary phenomenon, and hastened to a place where there were no buildings to obstruct my view of the hemisphere: here I found that the phenomenon was no other than a lunar rainbow; the moon was truly 'walking in brightness,' brilliant as she could be; not a cloud was to be seen near her; and over against her, toward the north-west, or perhaps rather more to the north, was a rainbow, a vast arch, perfect in all its parts, not interrupted or broken as rainbows frequently are, but unmitigatedly visible from one horizon to the other. In order to give some idea of its extent, it is necessary to say that as I stood toward the western extremity of the parish of Stoke Newington, it seemed to take its rise from the west of Hampstead, and to end, perhaps, in the river Lea, the eastern boundary of Tottenham; its colour was white, cloudy, or grayish, but a part of its western leg seemed to exhibit tints of a faint sickly green. I continued viewing it for some time, till it began to rain; and at length the rain increasing and the sky growing more hazy, I returned home about a quarter or 20 minutes past nine, and in ten minutes came out again; but by that time all was over, the moon was darkened by clouds, and the rainbow of course vanished."

Marine Rainbow, or Sea-bow. See the article Rainbow.

Rainbow Stone. See Moon-Stone.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun and those dried in ovens, is very obvious: the former are sweet and pleasant, but the latter have a latent acidity with the sweetness that renders them much less agreeable.

The common way of drying grapes for raisins, is to tie two or three bunches of them together while yet on the vine, and dip them into a hot lixivium of wood-sages, with a little of the oil of olives in it. This disposes them to shrink and wrinkle; and after this they are left on the vine three or four days separated on sticks in a horizontal situation, and then dried in the sun at leisure, after being cut from the tree. The finest and best raisins are those called in some places Damascus and Jube raisins; which are distinguished from the others by their size and figure: they are flat and wrinkled.
The raisins of the sun, and jar-raisins, are all dried by the heat of the sun; and these are the sorts used in medicine. However, all the kinds have much the same virtues: they are all nutritive and balsamic; they are allowed to be attenuant, are said to be good in nephritic complaints, and are an ingredient in pectoral decoctions: in which cases, as also in all others where astringency is not required of them, they should have the stones carefully taken out.

RAISIN-WINE. See WINE.

RAKKATH, in Ancient Geography, a town of Upper Galilee, thought to be Tiberias, (Talmud) but this is denied by Reland, who says that Rakkath was a town of the tribe of Naphtali.

RAKE is a well known instrument with teeth, by which the ground is divided. See Agriculture, Instruments.

RAKE also means a loose, disorderly, vicious, and thoughtless fellow.

RAKE of a Ship, is all that part of her hull which hangs over both ends of her keel. That which is before is called the fore rake or rake forward, and that part which is at the setting on of the stern-post is called the rake-oft or afterward.

RALEIGH, SIR WALTER, fourth son of Walter Raleigh, Esq. of Fardle, in the parish of Cornwood in Devonshire, was born in 1552 at Hayes, in the parish of Budley, a farm belonging to his father. About the year 1568, he was sent to Oriel college in Oxford, where he continued but a short time; for in the following year he embarked for France, being one of the hundred volunteers, commanded by Henry Champignyon, who, with other English troops, were sent by Queen Elizabeth to assist the queen of Navarre in defending the Protestants. In this service he continued for five or six years; after which he returned to London, and probably resided in the Middle Temple. But his enterprising genius would not suffer him to remain long in a state of inactivity. In 1577 or 1578, he embarked for the Low Countries with the troops sent by the queen to assist the Dutch against the Spaniards, and probably shared the glory of the decisive victory over Don John of Austria in 1578. On his return to England, a new enterprise engaged his attention. His half-brother, Sir Humphrey Gilbert, having obtained a patent to plant and inhabit some parts of North America, Mr Raleigh embarked in this adventure; but meeting with a Spanish fleet, after a smart engagement they returned, without success in 1579.

The following year, the king of Spain, in conjunction with the pope, having projected a total conquest of the English dominions, sent troops to Ireland to assist the Desmond in the Munster rebellion. Raleigh obtained a captain's commission under Lord Grey of Wilton, then deputy of Ireland, and embarked for that kingdom; where, by his conduct and resolution, he was principally instrumental in putting an end to the rebellious attempt. He returned to England; and attracted the notice of Queen Elizabeth, owing, as we are told in Naunton's Fragmenta Regalia, to the following accidental piece of gallantry. The queen, as she was one day taking a walk, being stopped by a splashy place in the road, our gallant young soldier took off his new Raleigh plush mantle, and spread it on the ground. Her majesty trod gently over the fair foot-cloth, surprised and pleased with the adventure. He was a handsome man, and remarkable for his gentility of address.

The queen admitted him to her court, and employed him first as an attendant on the French ambassador Simier on his return home, and afterwards to escort the duke of Anjou to Antwerp. During this excursion he became personally known to the prince of Orange; from whom, at his return, he brought special acknowledgments to the queen, who now frequently conversed with him. But the inactive life of a courtier did not suit the enterprising spirit of Mr Raleigh. In the year 1583, he embarked with his brother, Sir Humphrey Gilbert, on a second expedition to Newfoundland, in a ship called the Raleigh, which he built at his own expense; but was obliged to return on account of an infectious distemper on board. He was, however, little affected by this disappointment, that he now laid before the queen and council a proposal for exploring the continent of North America; and in 1584 obtained a patent empowering him to possess such countries as he should discover in that part of the globe. Accordingly Mr Raleigh fitted out two ships at his own expense, which sailed in the month of April, and returned to England about the middle of September, reporting that they had discovered and taken possession of a fine country called Windangoca, to which the queen gave the name of Virginia. About this time he was elected knight of the shire for the county of Devon, and soon after received the honour of knighthood; and enabled him to carry on his designs abroad, the queen granted him a patent for licensing the venders of wine throughout the kingdom. In 1585 he sent a fleet of seven ships to Virginia, commanded by his relation Sir Richard Greenville, who left a colony at Roanah of 107 persons, under the government of Mr Lane; and by the establishment of this colony he first imported tobacco into England. See NICOTIANA. In the same year Sir Walter Raleigh obtained a grant of 12,000 acres of the forfeited lands in the county of Cork in Ireland. About the same time he was made seneschal of the duchy of Cornwall, and warden of the stanneries; and grew into such favour with the queen, that even Leicester was jealous of his influence.

In 1587, he sent another colony of 150 men to Virginia, with a governor, Mr John White, and 16 assistants. About this time we find our knight distinguished by the titles of Captain of the queen's guards, and Lieutenant-general of Cornwall. From this period to the year 1593, he was continually engaged in projecting new expeditions, sending succours to the colonies abroad, defending the kingdom from the insults of the Spaniards, and transacting parliamentary business, with equal ability and resolution. Whilst so employed, he was publicly charged, in a libel written by the amiable Jesuit Parsons, with being an Atheist; a groundless and ridiculous imputation. In 1594, he obtained from the queen a grant of the manor of Sheerborne in Dorsetshire, where he built a magnificent house; but Sir Walter fell under the queen's displeasure on account of an intrigue with the daughter of Sir Nicholas Throgmorton, one of the maids of honour; however, he married the lady, and lived with her in great conjugal harmony.
He wrote A History of England, commencing with the Stuarts, which is much esteemed; as were his political essays and pamphlets, some of which were looked upon as master-pieces. His last publication, The Case of Authors by Profession, is an excellent and entertaining performance. He died in 1762.

RAM. See Ovis, Mamalia Index.

Battering Ram, in antiquity, a military engine used to batter down the walls of besieged places. See Battering Ram.

Ram's Head, in a ship, is a great block belonging to the fore and main hulls. It has three shivers in it, in which the hulls are put; and in a hole at the end are received the ties.

RAMADAN, a solemn season of fasting among the Mahometans. See Mahometanism.

RAMAH, in Ancient Geography, a town of Benjamin, near Gibea, (Judges) called Ramah of Saul (1 Sam. xxii.), six miles from Jerusalem to the north; memorable for the story of the Levite and his concubine: Taken and fortified by Baasha king of Israel, in order to annoy the kingdom of Judah. This Ramah is mentioned Isa. x. Jer. xxxi. and Math. ii. and is to be distinguished from Ramah of Samuel, 1 Sam. xix. called also Ramatha, 1 Sam. i. 19. and Ramathaim Zophim, ibid. i. 1. which lay a great way to the west, towards Joppa, near Lydda, 1 Maccab. ii. the birth-place of Samuel; adjoining to the mountains of Ephraim, and the place of his residence, 1 Sam. xv. &c. (Joseph.). Called Ramila in the lower age, (Gul. Tyrius). There is here a convent of the fathers of the Holy Land, inhabited only by Portuguese, Spaniards, and Italians.

RAMATH-Mizpe, (Joshua xiii.); Ramoth-Masph, (Septuagint, Vul.; ste); Ramoth in Gilead, or Remmoth Galaad, (Seyency); a town in that tract of Gilead called Maspha, or Mizpe, one of the cities of refuge.

RAMAZZINI, Bernardin, an Italian physician, born at Carpi near Modena in 1633. He was professor of medicine in the university of Modena for 18 years; and in 1700 accepted an invitation from Padua, where he was made rector of the college; and died in 1714. His works were collected and published in London, 1716; of which, his treatise De Morbis Artificum, “Of the peculiar maladies of artisans,” will always be esteemed useful and curious.

RAMEKINS, a fortress of the United Netherlands, on the south coast of the island of Walcheren in the province of Zeeland. One of the cautionary towns given to Queen Elizabeth for the repayment of the charges she had been at for the defence of this republic in its infancy. Four miles east of Flushing; in N. Lat. 51° 34'. E. Long. 4° 24'.

RAMESES, in Ancient Geography, a town built by the Israelites during their bondage in Egypt, and from which the Exodus took place, and which must have been towards and not far from the Arabian gulf, seeing in the third station the Israelites arrived on its shore.

RAMESSES, king of the Lower Egypt when Jacob went thither with his family, in the 1706th year before the Christian era. Ancient authors mention several other kings of Egypt of the same name; and it is thought that one of those prince erected in the temple of the sun at Thebes, the magnificent obelisk which the emperor Constantine caused to be removed to Alexandria.
RAMMES [630] RAMILLIES

Ramesses

Ramillies

dria in the year 334; and that prince dying, his son Constantius had the obelisk transported from Alexandria to Rome in 352, where it was erected in the grand Circus. Its height was 132 feet. When the Goths sacked the city of Rome in 459, they overthrew this obelisk, which continued buried in the sand till the time of Sixtus V. in 1590, when it was found broken in three pieces; which being joined together, it was set up in the square of St. John de Lateran. On the four sides of this wonderful obelisk are a number of figures and hieroglyphical characters, which, according to the explanation of Ammianus Marcellinus, contain the praises of Ramesses.

RAMIFICATION, the production of boughs or branches, or of figures resembling branches.

RAMILLIES, a small village of Brabant, in the Netherlands, 12 miles north of Namur, and 22 south-east of Brussels. Lat. 50° 51′. Long. 4° 48′. Famous for the battle fought by the allies commanded by the duke of Marlborough and M. d'Avruerquique, against that of the two crowns, commanded by the duke of Bavaria and Marshal Villeroi, the 22d of May 1706. See BRITAIN, N° 337.

The troops destined to compose the army of the allies being joined at the camp of Borculo the 20th of May, halted the 21st. On the 22d the army marched from Borculo in four columns, and posted itself the same day, with the right towards the mill of Quorrem, extending with the left towards Blehem; from this camp was discovered the army of the two crowns, which was encamped with the left at Over-Espin, and the right towards the wood of Chapiaraux, Heyliessee in their front, and Tulemont in the rear. It was resolved the same day to march the next morning towards the plain of Meerdorp or Mierda, to view the posture of the enemies, and determine what would be the proper means of attacking them according to the movement they should make. To this end, an advanced guard of 600 horse and all the quarter-masters of the army were sent forward on the 23d at break of day.

The same morning about four, the army marched in eight columns toward the aforesaid plain. The advanced guard and the quarter masters arrived about eight at the height of Meerdorp or Mierda; from whence the army of the enemy was seen in motion: a little after it was perceived that the enemy was marching through the plain of Mount St Andrew in four columns, of which information was given to the duke of Marlborough and M. d'Avruerquique, who immediately repaired to the said height; and by the time these generals were arrived there, the head of the enemy's army already appeared at the tomb of Ottomont upon the causeway, near the Mebaige; whereupon the duke of Marlborough and M. d'Avruerquique made the army advance with all expedition.

The enemy, as fast as they advanced, ranged in order of battle, with their right towards the tomb of Ottomont upon the Mebaige, extending with their left to Avruerquique, having Tranquiers in front of the right, into which they had thrown several battalions of infantry and 14 squadrons of dragoons, who had dismounted their horses to support them. They had placed many of their infantry and a considerable part of their artillery in the village of Ramillies, which fronted the right of their main body, as well as into the village of Offuz, which fronted the left of their infantry, and into the village of Autre-Eglise, quite on their left. The front Ramillies, between the village of Ramillies and Autre-Eglise was covered by a small stream of water, which rendered the meadows in some places marshes, and also by several roads covered with hedges; which difficulties prevented our cavalry of the right wing from coming to action. As fast as the army of the allies arrived it was ranged in order of battle; with the left towards Bonnef, and the right towards Folez, and everything was disposed in order to attack. To this end, four battalions were detached to attack the village of Francaleries, and 12 battalions to attack the village of Ramillies, which were to be supported by the whole infantry.

Our artillery began to cannonade the enemy at one; at about two, the attack began with the post of Francaleries, where our infantry had the good fortune to drive the enemy from the hedges, where they were advantageously posted, and at the same time all the cavalry of our left wing advanced to attack that of our enemy's right; soon after all was in action. Whilst the cavalry were engaged, the village of Ramillies was likewise attacked, and forced after a vigorous resistance.

The battle lasted about two hours, and was pretty obstinate; but so soon as our cavalry had gained ground enough to attack the enemy in flank, they began to give way; at the same time all their infantry were put in disorder, so that the whole retreated, in great confusion. The cavalry of our left wing formed a little upon the high ground, between Offuz and Mount St Andrew, to favour their retreat; but after the infantry and cavalry of our right wing had filed off between the bottom of the village of Ramillies and Offuz, the whole army marched in several columns to attack the enemy anew; but they gave way before we could come up with them, and retired in great confusion, some towards the defile of the abbey De la Ramée and towards Dongelberge, others towards Judogne, and others again towards Hougarde. They were pursued all night so closely that they were obliged to abandon all their artillery and baggage, part of which was found at Judogne and at Hougarde, with their chests of ammunition.

The enemy lost above 30,000 men, 60 cannon, eight mortars, standards, colours, baggage, &c.; we about 3000. The rest of the campaign was spent in the sieges of Ostend, Menin, and Ath. In fourteen days the duke defeated and dispersed the best appointed army the French ever had, and recovered all Spanish Brabant, the marquisate of the holy Roman empire. The army of the enemy consisted of 76 battalions and 142 squadrons, including the king's household troops (La Maison du Roi); and the army of the allies was 74 battalions and 123 squadrons. Considering the importance of the victory, the loss of the allies was very small, not above 1100 being killed, and 2600 wounded.

RAMISSERAM, a small island about 20 miles from that of Mannar, and the nearest channel of communication between Ceylon and the continent of India. When Mr Cordiner and his companions landed here in 1804, they entered the nearest choutry, or place erected for the accommodation of strangers, half a mile beyond which is the grand pagoda, or temple of Shivan, having nothing remarkable in its external appearance, when seen from a distance; but on a nearer inspection it is almost impossible to describe the ornaments and laboured workmanship.
RAM

Ramsay, Allan, a Scottish poet, was born at Leadhills in Lanarkshire, in October 1686. His father was employed in the management of Lord Hopetoun's mines at that place; but died while the poet was yet in his infancy, in consequence of which and the marriage of his mother soon after his father's death, it seems probable that during the earlier part of his life he continued in rather a destitute situation. He remained at Leadhills till he reached his fifteenth year, and as we have been assured by the relations of some very old persons who were the contemporaries of Ramsay, and who died not many years ago, he was employed in washing, preparing the lead ore for smelting, and other operations about the works in which the children of miners and young persons are usually occupied. The period of his residence on his native spot is fixed by himself in the following descriptive verses, which are part of a petition addressed to a Club in Edinburgh to be admitted a member.

Of Crawford Moor, born in Leadhills,
Where mineral springs Glengoner fill,
Which joins sweet-flowing Clyde.—
Native of Clydesdale's upper ward,
Bred fifteen summers there.

The extent of Ramsay's education, it may well be presumed, did not exceed what he could derive from the parish schoolmaster; and even the acquisition of what little could thus be obtained, from the circumstances that attended his early life, must have been often and greatly interrupted.

In 1701, when he was in his 15th year he was bound apprentice to a wigmaker in Edinburgh, and it appears from the record of his children's birth in the parish register that he continued in the same humble profession till the year 1716: for in that register his designation is wigmaker. One of the earliest of Ramsay's productions now known, an address to the most happy members of the Eazy Club, appeared in 1712, when he was 26 years of age, and three years after he was humorously appointed their poet laureat. Many of his poems about this time were published in the form of separate pamphlets. When he had followed the occupation of a wigmaker for a considerable time, he at last abandoned it for that of a bookseller, as being more congenial to the literary turn of his mind. His detached pamphlets were afterwards published by him in the year 1721, in one volume 4to, which was encouraged by a very liberal subscription. It was advertised as follows in the Edinburgh Evening Courant. "The Poems of Allan Ramsay, in a large quarto volume; fairly printed, with notes, and a complete glossary (as promised to the subscribers), being now finished; all who have generously contributed to carrying on of the design, may call for their copies as soon as they please, from the author, at the Mercury, opposite to Niddry's wynd, Edinburgh." The first volume of his well known collection, "The Tea-table Miscellany," was published in 1724, after which a second volume soon made its appearance; a third in 1727, and a fourth after another interval of time. He soon after published what is called the Evergreen, being a collection of Scots poems written by the ingenious prior to the year 1600. In 1725 appeared his Gentle Shepherd, part of which, called Patie and Roger, was printed in 1721, and Jenny and Meggy in 1723, the great success.

RAM

RAM

RAM
of which induced him to form them afterwards into a regular drama.

In the year 1728, he published a second volume of his poems, which was afterwards reprinted in 1800. These performances so rapidly enlarged the circle of his fame and reputation, that in 1731, an edition of his poetical works was published by the booksellers of London, and two years after they appeared at Dublin. He held an extensive correspondence with contemporary poets, among whom we find the facetious Hamilton of Gilbertfield, and the celebrated author of the Choice sent him two epistles. From his shop opposite to Niddry street, he removed to one at the east end of the Luckenbooths. In this shop he continued to sell and lend out books till he was far advanced in years; and we are informed that he was the first person who established a circulating library in Scotland. His collection of Fables appeared in 1730, after which period he may be said to have almost discontinued the occupation of an author.

Such, however, was his enterprising spirit, that he built, at his own expense, the first theatre for dramatic performances ever known in Edinburgh, which took place in what is called Carubber's close, in the year 1736; but he did not long enjoy his character of manager, for the magistrates of Edinburgh required him to shut it up, as an act of parliament prohibited all such amusements without a special licence and his majesty's letters patent. It is generally understood that he relinquished the trade of a bookseller about the year 1755, being then 69 years of age, and lived the remainder of his days in a small house erected by himself on the north side of the Castle-hill. A scabrous complaint, attended with excruciating pain, deprived him of his teeth, and after corroding one of his jaw bones, put a period to his existence on the 7th of June 1758, in the 71st year of his age.

Ramsay possessed a considerable share of poetical genius: Of this his Gentle Shepherd, which will continue to be admired as long as the language in which it is written shall be understood, and especially by the natives of North Britain, to whom only the peculiarities of dialect by which it is distinguishable can be familiar, affords the best proof. Some of his songs may contain far-fetched allusions and childish conceits; but many of them are equal, if not superior for their pastoral simplicity, to productions of a similar nature in any other language. Some of the imitations of the ancients by this poet are extremely happy, in particular Horace's Ode, \textit{Vides ut alta stet nux}, &c.; and some of his tales have all the excellencies of that species of composition. But of a great proportion of his other productions, it may be pronounced with truth that they are mere prosaic compositions, filled with the most common-place observations, and destitute even of the ornament of smooth versification and correct rhymes.

\textbf{Ramsay, Andrew Michael,} generally known by the name of the Chevalier Ramsay, was a polite Scots writer, born of a good family at Ayr in 1686. His good parts and learning recommended him to be tutor to the son of the earl of Wemyss; after which, receiving a disgust at the religion in which he had been educated, he, in the same ill humour reviewed other Christian churches; and, finding none to his liking, rested for a while in Deissau. While he was in this uncertain state of mind, he went to Leyden; where, falling into the company of one Poiret a mystic divine, he received the infection of mysticism: which prompted him to consult M. Fenelon, the celebrated archbishop of Cambrai, who had imbibed principles of the same nature; and who gained him over to the Catholic religion in 1709. The subsequent course of his life received its direction from his friend's counsel and connections with this priest; and being appointed governor to the duchess de Chatea Thierry, and the prince de Turenne, he was made a knight of the order of St. Lazarus. He was sent for to Rome by the chevalier de St. George, to undertake the education of his children; but he found so many intrigues and dissensions on his arrival there in 1724, that he obtained the chevalier's leave to return to Paris. He died in 1743, in the office of intendant of the duchess de Bouillon, prince de Turenne. The most capital work of his writing is the \textit{Travels of Cyrus}, which has been several times printed in English.

\textbf{Ramsay, The Rev. James,} so justly celebrated for his philanthropy, was born on the 25th of July 1753, at Fraersburgh, a small town in the county of Aberdeen, North Britain. His descent was honourable, being, through his father, from the Ramsays of Mcrose in Banffshire, and through his mother, from the Ogilvies of Purie in Angus. His parents were of characters the most respectable, but in circumstances by no means affluent. From his earliest years he discovered a serious disposition, and a strong thirst for knowledge; and after passing through the course of a Scotch grammar school education, he was inclined to pursue the studies requisite to fit him for the profession of a clergyman; an inclination with which the wishes of his mother, a woman of eminent piety, powerfully concurred. Several circumstances, however, conspired to divert him for a time from his favourite pursuit.

He was educated in the episcopal persuasion; and having been unhappy enough to lose his father while yet very young, he found, upon his advancing towards the state of manhood, that the joint fortunes of himself and his mother could not bear the expense of a regular education in either of the universities of Oxford or Cambridge, which he doubtless thought absolutely necessary to one who aspired to respectability in the church of England. Yielding, therefore, to necessity, he resolved to study surgery and pharmacy; and was with this view bound apprentice to Dr. Findlay, a physician \textit{(A)} in Fraserburgh. But though obliged to relinquish for a time his favourite studies, he did not think ignorance excusable in a surgeon more than in a clergyman, or conceive that he could ever become eminent in the profession in which circumstances had placed him, merely by skill in setting a bone or compound ing a medicine. He determined therefore, with the full approbation of his master, who

\textit{(A) In the remote towns of Scotland the same man generally acts in the triple capacity of physician, surgeon, and apothecary.}
who very soon discovered his talents for literature, to make himself acquainted with at least the outlines of the liberal arts and sciences; and with this view he repaired in 1750 to the King’s College and university of Aberdeen, where he obtained one of the bursaries or exhibitions which are there annually bestowed upon such candidates for them as display the most accurate knowledge of the Latin language. The small sum of five pounds, however (which none of these bursaries exceed), was still inadequate to the expense of residence in college; but our young student was soon to obtain a more valuable exhibition, and to obtain it likewise by his own merit.

During the long vacation he returned to his master Dr Findlay, and was by him intrusted with a very desperate case in surgery, of which his management may be said to have laid the foundation of his future fortunes. A female servant of one of the judges of the Court of Session, who, when the court was not sitting, resided in the neighbourhood of Fraserburgh, had been so dreadfully gored by a bull, that hardly any hopes were entertained of her recovery; but Mr Ramsay, who was there, treated the wound with such skilful attention, that, contrary to general expectation, his patient recovered. This attracted the judge’s notice, who having informed himself of the young man’s circumstances and character, recommended him so effectually to Sir Alexander Ramsay of Balmain, that he presented him with a bursary of 15 pounds a-year, which commenced at the next session or term, in the same college.

He now prosecuted his studies with comfort: and though he was detained in college a year longer than is usual, being obliged, upon his acceptance of a second bursary, to begin his course anew, he always considered this as a fortunate circumstance, because it gave him the celebrated Dr Reid three years for his preceptor. To that great and amiable philosoper he so recommended himself by his talents, his industry, and his virtues, that he was honoured with his friendship to the day of his death; for it was only to his masters that his conduct recommended him; Sir Alexander, to whose house he visited during some of the vacations, was so well pleased with his conversation, that he promised him another bursary, in his gift, of 25l a-year, to commence immediately on the expiration of that which he enjoyed. This promise he performed in the beginning of the year 1755; and at the solicitation of Dr Findlay, even paid the money per advance to enable the exhibitor to travel for the purpose of improving himself in his profession.

Thus provided, Mr Ramsay went to London, and studied surgery and pharmacy under the auspices of Dr Macaulay; in whose family he lived for two years, carressed and esteemed both by him and by his lady. Afterwards, having passed the usual examination at Surgeons-hall, he served in his medical capacity for several years in the royal navy; but how long he was continued in the station of a mate, or when and by whom he was first appointed surgeon, we have not been able to learn. He can say, however, upon the best authority, that by his humane and diligent discharge of his duty in either station, he endeared himself to the seamen, and acquired the esteem of his officers.

Of his humanity there is indeed one memorable instance, which must not be omitted. Whilst he acted as surgeon of the Arundel, then commanded by Captain (now Vice-admiral Sir Charles) Middleton, a slave-ship on her passage from Africa to the West Indies fell in with the fleet to which the Arundel belonged. An epidemic distemper, too common in such vessels, had swept away not only a great number of the unfortunate negroes, but also many of the ship’s crew, and among others the surgeon. In this distressed situation the commander of the Guineas ship applied to the English commodore for medical assistance; but not a surgeon or surgeon’s mate in the whole fleet, except Mr Ramsay, would expose himself to the contagion of so dangerous a distemper. Prompted, however, by his own innate benevolence, and fully authorised by his no less benevolent commander, the surgeon of the Arundel, regardless of personal danger, and trusting in that God to whom mercy is more acceptable than sacrifice, went on board the infected ship, visited all the patients, and remained long enough to leave behind him written directions for their future treatment. If a cup of cold water given in charity be entitled to a reward, how much more such an action as this? But the rewards of Christianity are not immediate. Mr Ramsay indeed escaped the contagion; but on his return to his own ship, just as he had got on the deck, he fell and broke his thigh-bone; by which he was confined to his apartment for ten months, and rendered in a small degree lame through the remainder of his life.

The fearlessness which he displayed on this occasion gained him the friendship and esteem of Sir Charles Middleton, no future action of his life had the smallest tendency to impair; but the fracture of his thigh-bone and his subsequent lameness determined him to quit the navy, and once more turn his thoughts towards the church. Accordingly, while the Arundel lay at St Christopher’s, he opened his views to some of the principal inhabitants of that island, by whom he was so strongly recommended to the bishop of London, that on his coming home with Sir Charles Middleton, who warmly joined in the recommendation, he was admitted into orders; after which he pre-ship immediately returned to St Christopher’s, where he was presented by the governor to two rectories, valued at 700l a-year.

As soon as he took possession of his livings, in 1763, he married Miss Rebecca Akers, the daughter of a planter of the best family-connections in the island, and began to regulate his household on the pious plan inculcated in his Essay on the Treatment and Conversion of the African Slaves in the British Sugar Colonies. He sumonned all his own slaves daily to the prayers of the family, when he took an opportunity of pointing out to them their duty in the plainest terms, reproving those that had done amiss, and commending such as had shown any thing like virtue; but he confessed that his occasions for reproof were more frequent than for commendation. As became his office and character, he inculcated upon others what he practised himself, and knew to be equally the duty of all. “On his first settlement as a minister in the West Indies, he made some public attempts to instruct slaves. He began to draw up some easy plain discourses for their instruction. He invited them to attend, on Sunday, at particular hours. He appointed hours at home to instruct such sensible slaves
R A M

[ 634 ]

R A M

as would of themselves attend. He repeatedly exhorted their masters to encourage such in their attendance. He recommended the French custom, of beginning and ending work by prayer. But inconceivable is the listlessness with which he was heard, and bitter was the censure heaped on him in return. It was quickly suggested, and generally believed, that he wanted to interrupt the work of slaves, to give them time, forsooth, to say their prayers, to make them mindful of their Christian duties, to render them incapable of being good slaves. In one word, he stood, in opinion, a rebel convicted against the interest and majesty of plantership. And as the Jews say, that in every punishment, with which they have been proved, since the bondage of Egypt, there has been an ounce of the golden call of Horeb; so might he say, that in every instance of prejudice (and they were not a few) with which, till within a year or two of his departure from the country, he was exercised, there was an ounce of his fruitless attempts to improve the minds of slaves. In the bidding prayer, he had inserted a petition for the conversion of those persons. But it was deemed so disagreeable a momento, that several white people, on account of it, left off attending divine service. He was obliged to omit the prayer entirely, to try and bring them back. In short, neither were the slaves at that time desirous of being taught, nor were their masters inclined to encourage them. That he was hurt by this neglect cannot be questioned, for he was benefited, warm and irritable; but he still retained many friends amongst the most worthy members of the community; and as he was conscious of having done nothing more than his duty, he consoled himself with reflecting, that those are "blessed whom men revile, and persecute, and speak all manner of evil against falsely, for the sake of the gospel."

Although his serious studies were now theological, he considered himself as answerable to God, his country, and his own family, for a proper use of every branch of knowledge which he possessed. He therefore took the charge of several plantations around him in the capacity of a medical practitioner; and attended them with unremitting diligence, and with great success. Thus he lived till the year 1777, when relinquishing the practice of physic entirely, he paid a visit to the place of his nativity, which he had not seen since 1755. His mother, whose latter days he had made comfortable by a handsome annuity, had been dead for some years; but he rewarded all who had been attentive to her, or in early life serviceable to himself; and he continued the pension to a sister who had a numerous family, for which her husband was unable to provide.

After remaining three weeks in Scotland, and near a year in England, during which time he was admitted into the confidence of Lord George Germaine, secretary of state for the American department, Mr Ramsay was appointed chaplain to Admiral Barrington, then going out to take a command in the West Indies. Under this gallant officer, and afterwards under Lord Rodney, he was present at several engagements, where he displayed a fortitude and zeal for the honour of his country which would not have disgraced the oldest admiral. To the navy, indeed, he seems to have been strongly attached; and he wrote, at an early period of his life, an Essay on the Duty and Qualifications of a Sea-officer, with such a knowledge of the service as would have done honour to the pen of the most experienced commander. Of the first edition of this essay the profits were by its benevolent author appropriated to the Magdalen and British lying-in hospitals, as those of the second and third (which last was published about the period of which we now write) were to the maritime school, or, in the event of its failure, to the maritime society.

Although caring for both the admirals under whom he served, and having such influence with the latter as to be able to render essential services to the Jews and other persons whom he thought harshly treated at the capture of St Eustatius, Mr Ramsay once more quitted the sea-service, and retired to his pastoral charge in the island of St Christopher's. There, however, though the former animosities against him had entirely subsided, and though his friendship was now solicited by every person of consequence in the island, he remained but a little while. Sick of the life of a planter and of the prospect of slavery around him, he resigned his livings, bade adieu to the island, and returned to England with his wife and family in the end of the year 1781. Immediately on his arrival, he was, through the interest of his steady friend Sir Charles Middleton, presented to the livings of Teston and Nettlestead in the county of Kent.

Here he was soon determined, by the advice of those whom he most respected, to publish an Essay, which had been written many years before, on the Treatment and Conversion of African Slaves in the British Sugar Colonies. The controversy in which this publication involved him, and the acrimony with which it was carried on, are so fresh in the memory of all our readers, that no man who thinks of the narrow limits within which our biographical articles must be confined, will blame us for not entering into a detail of the particulars. Torreys of obloquy were poured upon the benevolent author by writers who were unfair enough to conceal their names; and it must be confessed, that his replies abounded with sarcasms, which the most rational friends to the cause which he supported would not have been sorry to see blotted from his pages. The provocation, however, which he received was great; and Mr Ramsay, though an amiable, virtuous, and pious man, had a warmth of temper, which, though not deserving of praise, will be censured by none who reflect on the frailties of our common nature. That the particular calumnies propagated against him on this occasion were wholly groundless, it is impossible to doubt, if we admit him to have been possessed of common understanding. When some years ago a story was circulated, of Swift's having, when prebendary of Kilroot, been convicted before a magistrate of an attempt to commit a rape on the body of one of his parishioners, it was thought a sufficient confusion of the calumny to put the retailer of it in mind, that the dean of St Patrick's, though detected by the most powerful faction in the kingdom, lampooned without dread, and with great severity, the dean of Ferns for the very crime, of which, had this anecdote been true, he must have been conscious that all Ireland knew himself to be guilty! Such conduct cannot be reconciled to common sense. Had Swift been a ravisher, though he might have been penitent, and reasoned in general terms against giving way to such licentious passions, he would never have satisfied
Ramsey, a particular person for the crime of which he himself stood convicted. In like manner, had Mr Ramsey been a tyrant to his own slaves, though he might have argued against slavery in the abstract, on the broad basis of virtue and religion, he never could have arrayed for similar cruelty a number of individuals in the very island which witnessed his own enormities. But the melancholy part of the narrative is behind. The agitation given to his mind by these calamities, and the fatigues he underwent in his endeavours to rescue from misery the most helpless portion of the human race, contributed to shorten a life in no common degree useful. He had been for some time afflicted with a pain in his stomach, for which he was prevailed upon, though with great reluctance, to try the effects of air and exercise, by attempting a journey of 100 miles. But in London, being seized with a violent vomiting of blood, he was unable either to proceed or to be removed home; and in the house of Sir Charles Middleton he ended his days, on the 20th of July 1789, amidst the groans of his family, and the tears of many friends.—Thus did a man, of whom it is not too much to say, that "the blest song of many that were ready to perish came upon him;" for whatever be the fate of the slave-trade (see Slavery), it is certain that his writings have contributed much to meliorate the treatment of slaves. He left behind him a widow and three daughters: and his works, besides those to which we have alluded, consist of a volume of Sea-sermons, preached on board his majesty's ship the Prince of Wales, which show him to have been a master of true pulpit eloquence; and a Treatise on Signals, which was certainly written, and we think printed, though we know not whether it was ever published.

Ramsden's Machine for Dividing Mathematical Instruments, is an invention by which these divisions can be performed with exceeding great accuracy, such as would formerly have been deemed incredible. On discovering the method of constructing this machine, its inventor, Mr Ramsden of Piccadilly, received 61.5l. from the commissioners of longitude; engaging himself to instruct certain persons not exceeding ten, in the method of making and using this machine from the 28th October 1775 to 28th October 1777: also binding himself to divide all octants and sextants by the same engine, at the rate of three shillings for each octant, and six shillings for each brass sextant, with Nunius's divisions to half minutes, for as long time as the commissioners should think proper to let the engine remain in his possession. Of this sum of 61.5l. paid to Mr Ramsden, 300l. was given him as a reward for the improvement made by him in discovering the engine, and the remaining 31.5l. for his giving up the property of it to the commissioners. The following description of the engine, is that given upon oath by Mr Ramsden himself.

This engine consists of a large wheel of bell-metal, supported on a mahogany stand, having three legs which are strongly connected together by braces, so as to make it perfectly steady. On each leg of the stand is placed a conical friction pulley, whereon the dividing wheel rests: to prevent the wheel from sliding off the friction-pulleys, the bell-metal centre under it turns in a socket on the top of the stand.

The circumference of the wheel is ratched or cut (by a method which will be described hereafter) into 2160 teeth, in which an endless screw acts. Six revolutions of the screw will move the wheel a space equal to one degree.

Now a circle of brass being fixed on the screw arbor, having its circumference divided into 60 parts, each division will consequently answer to a motion of the wheel of 10 seconds, six of them will be equal to a minute, &c.

"Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbors that stand above the plane are turned of various sizes, to suit the centres of different pieces of work to be divided."

"When any instrument is to be divided, the centre of it is very exactly fitted on one of these arbors; and the instrument is fixed down to the plane of the dividing wheel, by means of screws, which fit into holes made in the radii of the wheel for that purpose."

"The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one end by finger-screws with the frame which carries the endless screw; while the other end embraces that part of the steel arbor, which stands above the instrument to be divided, by an angular notch in a piece of hardened steel; by this means both ends of the frame are kept perfectly steady and free from any shake."

"The frame carrying the dividing-point, or tracer, is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, as the radius of the instrument to be divided may require, and may be there fastened by tightening two clamps; and the dividing-point or tracer being connected with the clamps by the double-jointed frame, admits a free and easy motion towards or from the centre for cutting the divisions, without any lateral shake.

"From what has been said, it appears, that an instrument thus fitted on the dividing wheel may be moved to any angle by the screw and divided circle on its arbor, and that this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point or tracer, which can only move in a direct line tending to the centre, and is altogether freed from those inconveniencies that attend cutting by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion of contraction of the metal during the time of dividing."

"The screw-frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre: by this means any excentricity of the wheel and arbor would not produce any error in the dividing; and, by a particular contrivance (which will be described hereafter), the screw when pressed against the teeth of the wheel always moves parallel to itself; so that a line joining the centre of the arbor and the tracer continued, will always make equal angles with the screw."

"Figure 1. represents a perspective view of the engine."

"Figure 2. is a plan, of which figure 3. represents a section on the line PA."

"The large wheel A is 45 inches in diameter, and has
Ramden's has ten radii, each being supported by edge-bars, as represented in fig. 3. These bars and radii are connected by the circular ring B, 24 inches in diameter and three deep; and for greater strength, the whole is cast in one piece in bell-metal.

As the whole weight of the wheel A rests on its ring B, the edge-bars are deepest where they join it; and from thence their depth diminishes, both towards the centre and the circumference, as represented in fig. 3.

The surface of the wheel A was worked very even and flat, and its circumference turned true. The ring C, of fine brass, was fitted very exactly on the circumference of the wheel; and was fastened thereon with screws, which, after being screwed as tight as possible, were well rivetted. The face of a large chuck being turned very true and flat in the lathe, the flattened surface A of the wheel was fastened against it with hold-fasts; and the two surfaces and circumferences of the ring C, a hole through the centre and the plane part round it, and the lower edge of the ring B, were turned at the same time.

D is a piece of hard bell-metal, having the hole, which receives the steel arbor d, made very straight and true. This bell-metal was turned very true on an arbor; and the face, which rests on the wheel at B, was turned very flat, so that the steel arbor d might stand perpendicular to the plane of the wheel: this bell-metal was fastened to the wheel by six steel screws l.

A brass socket Z is fastened on the centre of the mahogany stand, and receives the lower part of the bell-metal piece D, being made to touch the bell-metal in a narrow part near the mouth, to prevent any obliquity of the wheel from bending the arbor: good fitting is by no means necessary here; since any shake in this socket will produce no bad effect, as will appear hereafter when we describe the cutting frame.

The wheel was then put on its stand, the lower edge of the ring B resting in the circumference of three conical friction-pulleys W, to facilitate its motion round its centre. The axis of one of these pulleys is in a line joining the centre of the wheel and the middle of the endless screw, and the other two placed so as to be at equal distances from each other.

Fi is a block of wood strongly fastened to one of the legs of the stand; the piece g is screwed to the upper side of the block, and has half holes, in which the transverse axis h turns: the half holes are kept together by the screws i.

The lower extremity of the conical pillar P terminates in a cylindrical steel-pin k, which passes through and turns in the transverse axis h, and is confined by a check and screw.

To the upper end of the conical pillar is fastened the frame G, in which the endless screw turns: the pivots of the screw are formed in the manner of two fru-tums of cones joined by a cylinder, as represented at X. These pivots are confined between half poles, which press only on the conical parts, and do not touch the cylindrical parts: the half holes are kept together by screws a, which may be tightened at any time, to prevent the screw from shaking in the frame.

On the screw-arbor is a small wheel of brass K, having its outside edge divided into 60 parts, and numbered at every 6th division with r, 2, &c. to 10. The number of revolutions of this wheel is shown by the index h on the frame G.

H represents a part of the stand, having a parallel slit in the direction towards the centre of the wheel, large enough to receive the upper part of the conical brass pillar P, which carries the screw and its frame: and as the resistance, when the wheel is moved by the endless screw, is against that side of the slit H which is towards the left hand, that side of the slit is faced with brass, and the pillar is pressed against it by a steel spring on the opposite side: by this means the pillar is strongly supported laterally, and yet the screw may be easily pressed from or against the circumference of the wheel, and the pillar will turn freely on its axis to take any direction given it by the frame L.

At each corner of the piece I are screws n of tempered steel, having polished conical points: two of them turn in conical holes in the screw frame near o, the points of the other two screws turn in holes in the piece Q; the screws being kept, which being tightened, prevent the conical pointed screws from unturning when the frame is moved.

L is a brass frame, which serves to connect the end of the less screw, its frame, &c. with the centre of the wheel: each arm of this frame is terminated by a steel screw, that may be passed through any of the holes q in the piece Q, as the thickness of work to be divided on the wheel may require, and are fastened by the finger-nuts r.

At the other end of this frame is a flat piece of tempered steel b, wherein is an angular notch: when the endless screw is pressed against the teeth on the circumference of the wheel, which may be done by turning the finger-screw S, to press against the spring t, this notch embraces and presses against the steel arbor d.

This end of the frame may be raised or depressed by moving the prismatic slide u, which may be fixed at any height by the four steel screws v.

The bottom of the frame has a notch k, whose plane is parallel to the endless screw; and by the point of the arbor d resting in this notch, this end of the frame is prevented from tilting. The screw S is prevented from unturning, by tightening the finger-nut u.

The teeth on the circumference of the wheel were cut by the following method:

Having considered what number of teeth on the circumference would be most convenient, which in this engine is 2160, or 360 multiplied by 6, I made two screws of the same dimensions, of tempered steel, in the manner hereafter described, the interval between the threads being such as I knew by calculation would come within the limits of what might be turned off the circumference of the wheel: one of the screws, which was intended for ratching or cutting the teeth, was notched across the threads, so that the screw, when pressed against the edge of the wheel and turned round, cut in the manner of a saw. Then having a segment of a circle a little greater than 60 degrees, of about the same radius with the wheel, and the circumference made true, from a very fine centre, I described an arch near the edge, and set off the chord of 60 degrees on this arch. This segment was put in the place of the wheel, the edge of it was ratched, and the number of revolutions...
Ramadan's revolutions and parts of the screw contained between
the interval of the 60 degrees were counted. The
radius was corrected in the proportion of 360 revolutions,
which ought to have been in 60 degrees, to the
number actually found; and the radius, so corrected,
was taken in a pair of beam-compasses: while the
wheel was on the lathe, one end of the compasses was
put in the centre, and with the other a circle was de-
scribed on the ring; then half the depth of the threads
of the screw being taken in dividers, was set from this
circle outwards, and another circle was described cut-
ting this point; a hollow was then turned on the edge of the wheel of the same curvature as that of the screw
at the bottom of the threads: the bottom of this holl-
low was turned to the same radius or distance from the
centre of the wheel, as the outward of the two circles
before mentioned.

Fig. 3.

"The wheel was now taken off the lathe; and the
bell-metal piece D was screwed on as before directed,
which after this ought not to be removed.

Fig. 1, 2, 3, on the ring C, about four-tenths of an inch within where
the bottom of the teeth would come. This circle was
divided with the greatest exactness I was capable of, first
into five parts, and each of these into three. These
parts were then bisected four times: (that is to say)
supporting the ring above the circumference of the wheel to con-
tain 2160 teeth, this being divided into five parts, each
would contain 482 teeth; which being divided into three
parts, each of them would contain 153; and this space
bisected four times would give 75, 36, 18, and 9: there-
fore each of the last divisions would contain nine teeth.
But, as I was apprehensive some error might arise from
quincunx-section and trisection; in order to examine the
accuracy of the divisions, I described another circle on
the ring C, one tenth of an inch within the former, and
divided it by continual bissections, as 2160, 1080, 540
270, 135, 67½, and 33½; and as the fixed wire (to be
described presently) crossed both the circles, I could
examine their agreement at every 135 revolutions; (af-
fter ratcheting, could examine it at every 33½): but, not
finding any sensible difference between the two sets of
divisions, I, for ratcheting, made choice of the former;
and, as the coincidence of the fixed wire with an inter-
section could be more exactly determined than with a
dot or division, I therefore made use of intersection in
both circles before described.

Fig. 7.

The arms of the frame L were connected by a thin
piece of brass of three-fourths of an inch broad, having a
hole in the middle of four-tenths of an inch in diameter;
across this hole a silver wire was fixed exactly in a line
to the centre of the wheel; the coincidence of this wire
with the intersections was examined by a lens seven-
tenths of an inch focus, fixed in a tube which was at-
tached to one of the arms L (A). Now a handle or
winch being fixed on the end of the screw, the division
marked on the end of the screw, the division marked 10
on the circle K was set to its index, and, by means of a
clamp and adjusting screw for that purpose, the inter-
section marked 1 on the circle C was set exactly to
 coincide with the fixed wire; the screw was then care-
fully pressed against the circumference of the wheel, by
turning the finger-screw S; then, removing the clamp,
I turned the screw by its handle nine revolutions, till
the intersection marked 240 came nearly to the wire;
then, unturning the finger-screw S, I released the screw
from the wheel, and turned the wheel back till the in-
tersection marked 2 exactly coincided with the wire,
and, by means of the clamp before mentioned, the di-
vision 10 on the circle being set to its index, the screw
was pressed against the edge of the wheel by the finger-
screw S; the clamps were removed, and the screw turn-
ed nine revolutions till the intersection marked 1
nearly coincided with the fixed wire; the screw was
released from the wheel by unturning the finger-screw
S, as before, the wheel was turned back till the inter-
section 3 coincided with the fixed wire; the division
10 on the circle being set to its index, the screw
was pressed against the wheel as before, and the screw
was turned nine revolutions, till the intersection 2
nearly coincided with the fixed wire, and the screw
was released; and I proceeded in this manner till the
teeth were marked round the whole circumference of the
wheel. This was repeated three times round, to
make the impression of the screw deeper. I then ratch-
ed the wheel round continually in the same direction
from the point ever disengaging the screw; and, in ratch-
ing the wheel about 300 times round, the teeth were
finished.

"Now it is evident, if the circumference of the wheel
was even one tooth or ten minutes greater than the
screw would require, this error would in the first
instance be reduced to 1/190 part of a revolution, or two
seconds and a half; and these errors or inequalities of
the teeth were equally distributed round the wheel at
the distance of nine teeth from each other. Now,
as the screw in ratching had continually held of several
teeth at the same time, and, these constantly changing,
the above-mentioned inequalities soon corrected them-
selves, and the teeth were reduced to a perfect equality.
The piece of brass which carries the wire was now ta-
ken away, and the cutting screw was also removed,
and a plain one (hereafter described) put in its place:
on one end of the screw is a small brass circle, having
its edge divided into 60 equal parts, and numbered at
every sixth division, as before mentioned. On the other
end of the screw is a ratchet-wheel C, having 60 teeth,
covered by the hollowed circle d, which carries two
Fig. 4.
clicks that catch upon the opposite sides of the ratchet
when the screw is to be moved forwards. The cylin-
der S turns on a strong steel arbor F, which passes
through and is firmly screwed to the piece Y: this
piece, for greater firmness, is attached to the screw-
frame G by the braces v; a spiral groove or thread
is cut on the outside of the cylinder S, which serves
both for holding the string, and also giving motion to
the lever J on its centre by means of a steel tooth n,
that works between the threads of the spiral. To the
lever is attached a strong steel pin m, on which a
brass socket r turns: this socket passes through a slit
in

(a) The intersections are marked for the sake of illustration, though properly invisible, because they lie under
the brass plate.
in the piece $p$, and may be tightened in any part of the slit by the finger-nut $f$. This piece serves to regulate the number of revolutions of the screw for each tread of the thread $R$.

Fig. 1. $T$ is a brass box containing a spiral string; a strong gut is fastened and turned three or four times round the circumference of this box, the gut then passes several times round the cylinder $S$, and from thence down to the thread $R$. Now, when the thread is pressed down, the string pulls the cylinder $S$ round its axis, and the clicks catching hold of the teeth on the ratchet carry the screw round with it, till, by the tooth $n$ working in the spiral groove, the lever $J$ is brought near the wheel $d$, and the cylinder stopped by the screw-head $x$ striking on the top of the lever $J$; at the same time the spring is wound up by the other end of the gut passing round the box $T$. Now, when the foot is taken off the thread, the spring unbinding itself pulls back the cylinder, the clicks leaving the ratchet and screw at rest till the piece $t$ strikes on the end of the piece $p$: the number of revolutions of the screw at each thread is limited by the number of revolutions the cylinder is allowed to turn back before the stop strikes on the piece $p$.

Fig. 1 & 4. When the endless screw was moved round its axis with a considerable velocity, it would continue that motion a little after the cylinder $S$ was stopped: to prevent this, the angular lever $a$ was made; that when the lever $J$ comes near to stop the screw $x$, it, by a small chamfer, presses down the piece $a$ of the angular lever; this brings the other end $a$ of the same lever forwards, and stops the endless screw by the steel pin $\mu$ striking upon the top of it; the foot of the lever is raised again by a small spring pressing on the brace $e$.

Fig. 1, 4, 6. "D, two clamps, connected by the piece $\omega$, slide one on each arm of the frame $L$, and may be fixed at pleasure by the four finger-screws $s$, which press against steel springs to avoid spoiling the arms: the piece $q$ is made to turn without shake between two conical pointed screws $f$, which are prevented from untwisting by tightening the finger-nuts $N$.

The piece $M$ is made to turn on the piece $q$ by the conical pointed screws $f$ resting in the hollow centers $a$.

As there is frequent occasion to cut divisions on inclined planes, for that purpose the piece $y$, in which the tracer is fixed, has a conical axis at each end, which turns in half-holes: when the tracer is set to any inclination, it may be fixed there by tightening the steel screws $b$.

Description of the Engine by which the endless screw of the Dividing Engine was cut.

Fig. 9. represents this engine of its full dimensions seen from one side.

Fig. 8. the upper side of the same as seen from above.

A represents a triangular bar of steel, to which the triangular holes in the pieces $B$ and $C$ are accurately fitted, and may be fixed on any part of the bar by the screws $D$.

$E$ is a piece of steel whereon the screw is intended to be cut; which, after being hardened and tempered, has its pivots turned in the form of two frustums of cones, as represented in the drawing of the dividing engine (fig. 5). These pivots were exactly fitted to the half holes $F$ and $T$, which were kept together by the screw $Z$.

$H$ represents a screw of untempered steel, having a pivot $I$, which turns in the hole $K$. At the other end of the screw is a hollow centre, which receives the hardened conical point of the steel pin $M$. When this point is sufficiently pressed against the screw, to prevent its shaking, the steel pin may be fixed by tightening the screws $Y$.

$N$ is a cylindrical, moveable on the screw $H$, which, to prevent any shake, may be tightened by the screws $O$. This nut is connected with the saddle-piece $P$ by means of the intermediate universal joint $W$, through which the arbor of the screw $H$ passes. A front view of this piece, with the section across the screw arbor, is represented at $X$. This joint is connected with the nut by means of two steel slips $S$, which turn on pins between the cheeks $T$ on the nut $N$. The other ends of these slips $S$ turn in like manner on pins $a$. One axis of this joint turns in a hole in the cock $b$, which is fixed to the saddle-piece; and the other turns in a hole $d$, made for that purpose in the same piece on which the cock $b$ is fixed. By this means, when the screw is turned round, the saddle-piece will slide uniformly along the triangular bar $A$.

$K$ is a small triangular bar of well-tempered steel, which slides in a groove on the saddle-piece $P$. The point of this bar or cutter is formed to the shape of the thread intended to be cut on the endless screw. When the cutter is set to take proper hold of the intended screw, it may be fixed by tightening the screw $E$, which presses the two pieces of brass $G$ upon it.

Having measured the circumference of the dividing-wheel, I found it would require a screw about one thread in a hundred coarser than the guide-screw $H$. The wheels on the guide-screw arbor $H$, and that on the steel $E$, on which the screw was to be cut, were proportioned to each other to produce that effect, by giving the wheel $L$ 198 teeth, and the wheel $Q$ 200. These wheels communicated with each other by means of the intermediate wheel $R$, which also served to give the threads on the two screws the same direction.

The saddle-piece $P$ is confined on the bar $A$ by means of the pieces $g$, and may be made to slide with a proper degree of tightness by the screws $n$. See Dividing Instruments, Supplement.

For Ramsden's equatorial or portable observatory, see Optics, No. 89; and Astronomy, No. 364. See also a long account of an equatorial instrument made by Mr. Ramsden by the direction of Sir George Shuckburgh in the Philosophical Transactions for 1793, art. x. p. 67. In this instrument the circle of declinations is four feet in diameter, and may be observed nearly to a second. The glass is placed between six pillars, which form the axis of the machine, and turn round by two pivots placed on two blocks of stone. See also Barometer.

RAMSEY, a town of Huntingdonshire, 68 miles north of London, and 12 north-east of Huntingdon. It is situated as it were in an island, being everywhere encompassed with fens, except on the west, where it is separated from the terra firma by a causeway for two miles. The neighbouring towns of Ramley and Whiteley, which are formed by the river Nene, abound with fish, especially eel and large pikes. It was once famous for
Ramsden's Machine.

Plate CXXVI.

For dividing Mathematical Instruments.

Fig. 1.
a very rich abbey, part of the gatehouse of which is still standing, and a neglected statue of Alwine; the epitaph on whose tomb, which is reckoned one of the oldest pieces of English sculpture extant, styles him "kinsman of the famous King Edward, alderman of all England, and miraculous founder of this abbey." It was dedicated to St. Dunstan, and its abbots were mitred and sat in parliament; and so many kings of England were benefactors to it, that its yearly rents, says Camden, were 7000l. The town was then called Ramsey the Rich; but by the dissolution of the abbey it soon became poor; and even lost its market for many years, till about 200 years ago it recovered it. It is held on Saturday, and is reckoned one of the most plentiful in England. In the year 1721 a great number of Roman coins was found here, supposed to have been hid by the monks on some incursion of the Danes. There is a charity school in the town for poor girls. In 1811 the number of inhabitants was 2390. W. Long. 5. 19. N. Lat. 52. 26.

RAMSEY, an island of South Wales, on the coast of Pembrokeshire, about two miles in length, and a half a mile in breadth. Near it are several small ones, known by the name of the bishop and his clerks. It is four miles west of St David's, and 17 north-east of Milfordhaven. It belongs to the bishopric of St David's, and was in the last age, says Camden, famous for the death of one Justinian, a most holy man, who retiring hither from Brittany, in that age rich in saints, and devoting himself entirely to God, lived a long time in solitude, and being at last murdered by his servant was enrolled among the martyrs. W. Long. 5. 20. N. Lat. 51. 55.

RAMSEY, in the Isle of Man, to the north, a most noted and spacious haven, in which the greatest fleet may ride at anchor with safety enough from all winds but the north-east, and in that case they need not be embayed. This town standing upon a beach of loose sand, or shingle, is in danger, if not timely prevented, of being washed away by the sea.

RAMSGATE, a sea-port town of Kent, in the isle of Thanet, five miles from Margate, where a very fine pier has been lately built for the security of ships that come into the harbour, being seated near the Downs between the north and south Foreland, 10 miles north-east of Canterbury. The town is situated in the cove of a chalky cliff. It was formerly but an obscure fishing village, but since the year 1688 has been improved and enlarged by a successful trade to Russia and the east country. But what renders it most worthy of notice, is the new harbour, which is one of the most capacious in England, if not in Europe. It was begun in the year 1750, but delayed by various interruptions. It consists of two piers; that to the east is built wholly of Purbeck stone, and extends itself into the ocean near 800 feet before it forms an angle; its breadth on the top is 26 feet, including a strong parapet wall, which runs along the outside of it. The other to the west is constructed of wood as far as the low water mark, but the rest is of stone. The angles, of which there are five in each pier, consist of 125 feet each, with octagons at the end of 66 feet diameter, leaving an entrance of 200 feet into the harbour, the depth of which admits of a gradual increase of 18 to 36 feet. In 1791 the population was 2221. E. Long. 1. 30. N. Lat. 51. 22.

RAMTRUT, a deity worshipped by the Ranazines of Hindostan, where he has a celebrated temple at Onor.

He is represented as more resembling a monkey than a man.

RAMUS, in general, denotes a branch of any thing, as of a tree, an artery, &c. In the anatomy of plants it means the first or lateral branches, which go off from the petiolum, or middle rib of a leaf. The subdivisions of these are called surculi; and the final divisions into the most minute of all, are by some called capitillenta; but both kinds are generally denominated surculi.

Ramus, Peter, was one of the most famous professors of the 16th century. He was born in Picardy in 1515. A thirst for learning promptly led him to go to Paris when very young, and he was admitted a servant in the college of Navarre. Spending the day in waiting on his masters, and the greatest part of the night in study, he made such surprising progress, that, when he took his master of arts degree, he offered to maintain a quite opposite doctrine to that of Aristotle. This raised him many enemies; and the two first books he published, Institutiones Dialecticae, and Aristotelicae Animadversiones, occasioned great disturbances in the University of Paris: and the opposition against him was not a little heightened by his deserting the Roman religion, and professing that of the Reformed. Being thus forced to retire from Paris, he visited the universities of Germany, and received great honours wherever he came. He returned to France in 1571, and lost his life miserably in the horrid massacre of St Bartholomew's day. He was a great orator, a man of universal learning, and endowed with very fine moral qualities. He published many books, which Teissier enumerates. Ramus's merit in his opposition to Aristotle, and his firmness in undermining his authority, is unquestionably great. But it has been doubted, and with much reason, whether he was equally successful in his attempts after a new logical institute. We have the following general outline of his plan in Dr. Enfield's History of Philosophy. "Considering dialectics as the art of deducing conclusions from premises, he endeavours to improve this art, by uniting it with that of rhetoric. Of the several branches of rhetoric, he considers invention and disposition as belonging equally to logic. Making Cicero his chief guide, he divides his treatise on dialectics into two parts, the first of which treats of the invention of arguments, the second of judgments. Arguments he derives not only from what the Aristotelians call middle terms, but from any kind of proposition, which, connected with another, may serve to prove any assertion. Of these he enumerates various kinds. Judgments he divides into axioms, or self-evident propositions, diamoxa, or deductions by means of a series of arguments. Both these he divides into various classes; and illustrates the whole by examples from the ancient orators and poets. "In the logic of Ramus, many things are borrowed from Aristotle, and only appear under new names; and many others are derived from other Grecian sources, particularly from the dialogues of Plato, and the logic of the Stoics. The author has the merit of turning the art of reasoning from the futile speculations of the schools to forensic and common use; but his plan is defective in confining the whole dialectic art to the single object of disputation, and in omitting many things, which respect the general culture of the understanding and the investigation of truth. Notwithstanding the defects of his system, we cannot, however, subscribe to the severe cen-
sure which has been passed upon Ramus by Lord Bacon and others; for much is, we think, due to him for having with so much firmness and perseverance asserted the natural freedom of the human understanding. The logic of Ramus obtained great authority in the schools of Germany, Great Britain, Holland, and France; and long and violent contests arose between his followers and those of the Stagyrite, till his fame vanished before that of Descartes. 17

RAN, in the old English writers, means open or public robbery, so manifest as not to be denied. Ran dicetur aperta rapina quae negari non potest. Lamb. 125. Leg. Canut. cap. 58. Hence it is now commonly said of one who takes the goods of another injuriously and violently, that he has taken or snatched all he could rap and ran.

RANA, or Ranula. See Ranula.

Rana, the frog; a genus of reptiles belonging to the order of amphibia. See ERPETOLOGY Index.

RANAI, one of the Sandwich islands discovered by Captain Cook, is about nine miles distant from Mowez and Morotot, and is situated to the south-west of the passing between these islands. The country towards the south is elevated and craggy; but the other parts of the island had a better appearance, and seemed to be well inhabited. It abounds in roots, such as sweet potatoes, taro, and yams; but produces very few plantains and bread-fruit trees. The south point of Ranai is in the latitude of 20° 46' north, and in the longitude of 203° 8' east.

RANCID, denotes a fatty substance, that is become rank or musty, or that has contracted an ill smell by being kept close.

RANDIA, a genus of plants belonging to the pentandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY Index.

RANDOLPH, THOMAS, an eminent English poet in the 17th century, was born in Northamptonshire 1605. He was educated at Westminster and Cambridge, and very early distinguished for his excellent genius; for at about nine or ten years of age he wrote the History of the Incarnation of our Saviour in verse. His subsequent writings established his character, and gained him the esteem and friendship of some of the greatest men of that age, particularly of Ben Johnson, who adopted him one of his sons in the muses. He died in 1634, and was honourably interred. He wrote, 1. The Muses Looking-glass, a comedy. 2. Amyntas, or the Impossible Dowry, a pastoral, acted before the king and queen. 3. Aristippus, or the Jovial Philosopher. 4. Ranalla The Conceited Pedlar. 5. The Jealous Lovers, a comedy; and several poems.

RANDOM shot, in Gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly or point blank.

The utmost random of any piece is about ten times as far as the bullet will go point-blank. The bullet will go farthest when the piece is mounted to about 45° above the level range. See GUNNERY and PROJECTILES.

RANGE, in Gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. If the piece lie in a line parallel to the horizon, it is called the right or level range: if it be mounted to 45°, it is said to have the utmost range: all others between 00 and 45° are called the intermediate ranges.

RANGER, a sworn officer of a forest, appointed by the king's letters patent; whose business is to walk through his charge, to drive back the deer out of the park, and for present all trespasses within his jurisdiction at the next forest court.

RANK, the order or place assigned a person suitable to his quality or merit.

RANK, is a straight line made by the soldiers of a battalion or squadron, drawn up side by side: this order was established for the marches, and for regulating the different bodies of troops and officers which compose an army.

RANK and Precedence, in the army and navy, are as follow:

Engineers RANK. Chief, as colonel; director, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner engineer, as ensign.

Navy RANK. Admiral, or commander in chief of his majesty's fleet, has the rank of a field-marshal; admirals, with their flags on the main-top-mast-head, rank with generals of horse and foot; vice-admirals, with lieutenant-generals; rear-admirals, as major-generals; commodores, with broad pendants, as brigadier-generals; captains of post-ships, after three years from the date of their first commission, as colonels; other captains, as commanding post-ships, as lieutenant-colonels; captains, not taking post, as majors; lieutenants, as captains.

Doubling of the Ranks, is the placing two ranks in one, frequently used in the manoeuvres of a regiment.

Ranks and Files, are the horizontal and vertical lines of soldiers when drawn up for service.

Ransom, a sum of money paid for the redemption of a slave, or the liberty of a prisoner of war. In our law books, ransom is also used for a sum paid for the pardon of some great offence, and to obtain the offender's liberty.

Ranula, a tumor under a child's tongue, which, like a ligature, hinders it from speaking or sucking.

Ranunculus, Crowfoot; a genus of plants of the polyandria order, belonging to the polyandria class; and in the natural order ranking under the 26th order, Multiandria. See Botany Index.

Rapacious Animals, are such as live upon prey.

Rape, in Law, the carnal knowledge of a woman forcibly and against her will. This, by the Jewish law, was punished with death, in case the damsel was betrothed to another man: and, in case she was not betrothed, then a heavy fine of fifty shekels was to be paid to the damsel's father, and she was to be the wife of the ravisher all the days of his life; without that power of divorce, which was in general permitted by the Mosaic law.

The civil law punishes the crime of ravishment with death and confiscation of goods: under which it includes both the offence of forcible abduction, or taking away a woman from her friends; and also the present offence of forcibly dishonouring her: either of which, without the other, is in that law sufficient to constitute a capital crime. Also the stealing away a woman from her parents or guardians, and debauching her, is equally penal by the emperor's edict, whether she consent or is forced. And this, in order to take away from women every opportunity of offending in this way; whom the Roman law suppose never to go astray without the seduction and arts of the other sex; and therefore, by restraining and making so highly penal the solicitations of the men, they meant to secure effectually the honour of the women. But our English law does not enter

Vol. XVII. Part II.

tain quite such sublime ideas of the honour of either sex, as to lay the blame of a mutual fault upon one of the transgressors only; and therefore makes it a necessary ingredient in the crime of rape, that it must be against the woman's will.

Rape was punished by the Saxon laws, particularly those of King Athelstan, with death; which was also agreeable to the old Gothic or Scandinavian constitution. But this was afterwards thought too hard: and in its stead another severe, but not capital, punishment was inflicted by William the Conqueror, viz. castration and loss of eyes; which continued till after Bracton wrote, in the reign of Henry III. But in order to prevent malicious accusations, it was then the law, (and, it seems, still continues to be so in appeals of rape), that the woman should, immediately after, go to the next town, and there make discovery to some credible person of the injury she has suffered; and afterwards should acquaint the high constable of the hundred, the coroners, and the sheriff with the outrage. This seems to correspond in some degree with the laws of Scotland and Aragon, which require that complaint must be made within 24 hours: though afterwards by statute Westm. 1. c. 13, the time of limitation in England was extended to 40 days. At present there is no time of limitation fixed: for, as it is usually now punish-
ment, and a fine at the king's will. But this lenity
being productive of the most terrible consequences, it
was, in ten years afterwards, 13 Edw. I. found neces-
sary to make the offence of forcible rape by statute
Westm. 2. c. 34. And by statute 18 Eliz. c. 7. it is
made felony without benefit of clergy: as is also the
abominable wickedness of carnally knowing or abusing
any woman-child under the age of ten years, in which
case the consent or non-consent is immaterial, as by rea-
son of her tender years she is incapable of judgment and
discretion. Sir Matthew Hale is indeed of opinion, that
such profligate actions committed on an infant under the
age of twelve years, the age of female discretion by the
common law, either with or without consent, amount to
rape and felony; as well since as before the statute of
Queen Eliz. but that law has in general been held
only to extend to infants under ten; though it should
seem that damsels between ten and twelve are still un-
der the protection of the statute Westm. 1. the law with
respect to their seduction not having been altered by ei-
ther of the subsequent statutes.

A male infant, under the age of fourteen years, is
presumed by law incapable to commit a rape, and there-
fore it seems cannot be found guilty of it. For though
in other felonies "multitudo supplet satetem," yet, as
this particular species of felony, the law supposes an im-
becility of body as well as mind.

The civil law seems to suppose a prostitute or common
harlot incapable of any injuries of this kind: not allow-
ing any punishment for violating the chastity of her,
who hath indeed no chastity at all, or at least hath no
regard to it. But the law of England does not judge
so hardly of offenders, as to cut off all opportunity of
retreat even from common strumpets, and to treat
them as never capable of amendment. It therefore
holds it to be felony to force even a concubine or
harlot; because the woman may have forsaken that
unlawful course of life: for, as Bracton well ob-
erves, "licit meretrix fuerit anteae, certe tunc tempo-
ris non fuit, cum reclamando nequitas: ejus consentire
noluit."

As to the material facts requisite to be given in evi-
dence and proved upon an indictment of rape, they are
of such a nature, that though necessary to be known
and settled, for the conviction of the guilty and preser-
vation of the innocent, and therefore are to be found in
such criminal treatises as discourse of these matters in
detail, yet they are highly improper to be publicly dis-
sussed, except only in a court of justice. We shall
therefore merely add upon this head a few remarks from
Sir Matthew Hale, with regard to the competency and
credibility of witnesses; which may, salvo pudore, be
considered.

And, first, the party ravished may give evidence up-
on oath, and is in law a competent witness: but the cre-
dibility of her testimony, and how far she is to be be-
lieved, must be left to the jury upon the circumstances
of fact that concur in that testimony. For instance: if
the witness be of good fame; if she be discovered to be
the offended; and made search for the offender; if she
be found and caught; if her story be confirmed by these
and the like concurrence of the circumstances, which give greater probability
to her evidence. But, on the other side, if she be of
evil fame, and stand unsupported by others; if she con-
cealed the injury for any considerable time after she had
opportunity to complain; if the place, where the fact
was alleged to be committed, was where it was possible
she might have been heard, and she made no outcry
these and the like circumstances carry a strong, but not
conclusive, presumption that her testimony is false or
feigned.

Moreover, if the rape be charged to be committed
on an infant under 12 years of age, she may still be
a competent witness, if she hath sense and understanding
enough to know the nature and obligations of an oath,
and, even if she hath not, it is thought by Sir Mat-
thew Hale, that she ought to be heard without oath,
to give the court information; though that alone will
not be sufficient to convict the offender. And be it of
this opinion, first. Because the nature of the offence
being secret, there may be no other possible proof of
the actual fact; though afterwards there may be con-
current circumstances to corroborate it, proved by
other witnesses: and, secondly. Because the law al-
 lows what the child told her mother, or other rela-
tions, to be given in evidence, since the nature of the
case admits frequently of no better proof; and there
is much more reason for the court to hear the narra-
tion of the child herself, than to receive it at second-
hand from those who swear they heard her say so.
And indeed it seems now to be settled, that in these
cases infants of any age are to be heard; and, if they
have any idea of an oath, to be also sworn: it being
found by experience, that infants of very tender years
often give the clearest and truest testimony. But in
any of these cases, whether the child be sworn or not,
it is to be wished, in order to render her evidence cre-
dible, that there should be some concurrent testimony
of time, place, and circumstances, in order to make
out the fact; and that the conviction should not be
grounded singly on the unsupported accusation of an
infant under years of discretion. There may be there-
fore, in many cases of this nature, witnesses who are
competent, that is, who may be admitted to be heard;
and yet, after being heard, may prove not to be cre-
dible, or such as the jury is bound to believe. For one
excellence of the trial by jury is, that the jury are triers
of the credit of the witnesses, as well as of the truth
of the fact.

"It is true (says this learned judge), that rape is a
most detestable crime, and therefore ought severely and
impartially to be punished with death; but it must be
remembered, that it is an accusation easy to be made,
hard to be proved, but harder to be defended by the
party accused, though innocent." He then relates two
very extraordinary cases of malicious prosecution for this
crime, that had happened within his own observation;
and concludes thus: "I mention these instances, that
we may be the more cautious upon trials of offences
of this nature, wherein the court and jury may with so
much ease be imposed upon, without great care and vi-
gilance; the heinousness of the offence many times tran-
spiring the judge and jury with so much indignation,
that they are over-hastily carried to the conviction of
the persons accused thereof, by the confidered testimony
of sometimes false and malicious witnesses."

RAPHAEL D'URBINO, the greatest, most sublime,
and most excellent painter that has appeared, since the
revival of the fine arts, was the son of an indifferent
painter named Sessaio, and was born at Urbino on Good
Friday.
RAPIN de Thouars, Paul de, a celebrated historian, was the son of James de Rapin lord of Thoyras, and was born at Castres in 1661. He was educated at first under a tutor in his father's house; and afterwards sent to Pouyrauxens, and thence to Samur. In 1679 he returned to his father, with a design to apply himself to the study of the law, and was admitted an advocate; but some time after, reflecting that his being a Protestant would prevent his advancement at the bar, he resolved to quit the profession of the law, and apply himself to that of the sword; but his father would not consent to it. The revocation of the edict of Nantes in 1685, and the death of his father, which happened two months after, made him resolve to come to England; but as he had no hopes of any settlement here, his stay was but short. He therefore soon after went to Holland, and listed himself in the company of French volunteers at Utrecht, commanded by M. Rapin his cousin-german. He attended the prince of Orange into England in 1688; and the following year the lord Kingston made him an ensign in his regiment, with which he went into Ireland, where he gained the esteem of his officers at the siege of Carrickfergus, and had soon a lieutenant's commission. He was present at the battle of the Boyne, and was shot through the shoulder at the siege of Limerick. He was soon after captain of the company in which he had been ensign; but, in 1693, resigned his company to one of his brothers, in order to be tutor to the earl of Portland's son. In 1699, he married Marianne Testard; but this marriage neither abated his care of his pupil, nor prevented his accompanying him in his travels. Having finished this employment, he returned to his family, which he had settled at the Hague; and here he continued some years. But as he found his family increase, he resolved to retire to some cheap country; and accordingly removed, in 1707, to Wesel, where he wrote his History of England, and some other pieces. Though he was of a strong constitution, yet 17 years application (for so long was he in composing the history just mentioned) entirely ruined his health. He died in 1725. He wrote in French, 1. A Dissertation on the Whigs and Tories. His History of England, printed at the Hague in 1726 and 1727, in 9 vols 4to, and reprinted at Trewoux in 1728, in 10 vols 4to. This last edition is more complete than that of the Hague. It has been translated into English, and improved with Notes, by the reverend Mr Tindal, in 2 vols folio. This performance, though the work of a foreigner, is deservedly esteemed as the fullest and most impartial collection of English political transactions extant. The readers of wit and vivacity, however, may be apt to complain of him for being sometimes rather tedious and dull.

RAPINE, in Law, taking away another's goods, &c. by viol-nce.

RAPPIERSWIL, a town of Switzerland, on the
ambassador; all of which were believed in England and other parts of Europe in the beginning of this century. (See Petrified City.) Mr. Bruce informs us, that it is situated about five days' journey south from Bengazi; but has no water excepting one fountain, which has a disagreeable taste and seems to be impregnated with alum. Hence it has obtained the name of Ras-Sem, or the fountain of poison. The only remains of antiquity in this place consist of the ruins of a tower or fortification, which, in the opinion of Mr. Bruce, is as late as the time of the Vandals; but he says he cannot imagine what use they made of the water; and they had no other within two days' journey of the place.—Here our traveller saw many of the animals called jerboa, a kind of mice; which, he says, seem to partake as much of the nature of a bird as of a quadruped.

RASAY, one of the Hebrides islands, is about 13 miles long and two broad. It contains 700 inhabitants, has plenty of limestone and freestone; feeds great numbers of black cattle; but has neither deer, hares, nor rabbits. The only appearance of a harbour in Rasay is at Clachan bay, where Mr. Macleod the proprietor of the island resides. Rasay presents a bold shore, which rises to the height of mountains; and here the natives have, with incredible labour, formed many little cornfields and potato grounds. These heights decrease at the south end, where there are some farms and a good-looking country. Mr. Macleod is sole proprietor of this island and of Rona and Fladda at the north end of it, which are only proper for grazing.

The house of Rasay is pleasantly situated near the south-west end of the island, which is the most level part of it. It has an extensive and excellent garden, and is surrounded with forest trees of considerable magnitude; another proof that trees will grow upon the edge of the sea, though it must be allowed that the channel here is narrow. Immediately behind the house of Rasay are the ruins of an ancient chapel, now used as the family burying-place.

RASCIANS, a poor oppressed people who dwelt on both sides of the Danube, and who, about the year 1794, being weary of the Turkish thrall, first took 13 of their vessels upon that river; and then drawing together a body of 15,000 men between Bude and Belgrade, twice defeated the pash of Temeswar with a body of 14,000 Turks. They afterwards took Baczkerek, four miles from Belgrade, and the castle of Ottad; then laying siege to that of Beche, on the Teyessa, the old pash of Temeswar marched to relieve it with 11,000 men; but the Rascians encountering them, slew near 10,000, and took 18 pieces of cannon. The consequence of this victory was the reduction of Wessetz and Lottz. Then, sending to the archduke for aid and gunners, they offered to put themselves and their country under the emperor's protection.

RASOR-BILL, a species of alca. See Alca, Ornithology Index.

Rasor-Fish, a genus of shell-fish. See Solen, Conchology Index.

RASTALI, John, a printer and miscellaneous writer, was born in London, probably about the end of the 15th century, and educated at Oxford. Returning from the university, he settled in the metropolis, and commenced printer, "then esteemed (says Wood) a profession fit for any scholar or ingenious man." He married...
RAT

Lastall, the sister of Sir Thomas More, with whom, we are told, he was very intimate, and whose writings he strenuously defended. From the title-page of one of his books, he appears to have lived in Cheapside, at the sign of the Mermaid. He died in the year 1536; and left two sons, William and John: the first of whom became a judge in Queen Mary's reign, and the latter a justice of peace. This John Lastall, the subject of the present article, was a zealous Papist; but Bale says that he changed his religion before his death. He wrote, 1. Natura naturata. Plu. calls it a copious (poësia) and ingenious comedy, describing Europe, Asia, and Africa, with cuts. What sort of a comedy this was, is not easy to conceive. Probably it is a cosmographical description, written in dialogue, and therefore styled a comedy. 2. The pastyme of the people; the cronicles of diverse realms, and most especially of the realm of England, being translated into Latin, compiled and emprinted in Cheapside, at the sign of the crown, next Pollys gate, cum privilegio, fol. 3. Ecclesia Johannis Lastall, 1542, was one of the prohibited books in the reign of Henry VIII. 4. Legum Anglicanarum vocabula explicata. French and Latin. Lond. 1567, 8vo. And some other works.

RASTADT, a town of Germany, in the circle of Suabia and duchy of Baden, with a handsome castle. It is remarkable for a treaty concluded here between the French and imperialists in 1714; and near this place the French defeated the imperial troops in July 1796; in 1798 a congress was held here for the conclusion of a peace between France and Germany; but it broke up in 1799, when, not far from Rastadt, the French liberated the prisoners, and were murdered by a party of Austrian hussars. See FRANCE, No. 501. Rastadt is seated on the river Mer, near the Rhine. E. Long. 8. 14. N. Lat. 48. 54.

RASTENBURG, a fine city in Prussia, on the Guber, surrounded with a wall, and since 1629 also with a rampart. It is 46 miles south-east of Köningsberg. E. Long. 21. 30. N. Lat. 54. 20.

RAT. See Mus, Mammalia Index; and for an account of the methods of destroying rats, see VERMIN, Destruction of.

RAT-Island, a small detached part of the island of Lundy, off the north coast of Devon. Though noted in Dorn's map of the country, it is not worth mention here, but as giving opportunity to subjoin a farther notice of Lundy, which island was purchased a few years since by Mr. Cleveland, M. P., for about 1200 guineas, who has a small villa on it: not more than 400 acres are cultivated: it is let altogether for 70l. a year. The soil is good, though no trees will grow on the island. It has fine springs of water; the houses are seven; the inhabitants, men, women, and children, do not exceed 24. The bird called murre, whose eggs are very large and fine, the Lundy parrot, and rabbits, are the chief produce; these abound, and are taken for the feathers, eggs, and skins, principally. They have now (1794) 700 bullocks and 400 sheep, but the latter do not thrive. They pay no taxes: fishing skills often call with necessary; the situation is very pleasant, and the rocks around, which are large, and partly granite, are wild and romantic. It had probably more inhabitants once, as human bones have been ploughed up. It has no place of worship, and no public-house; but strangers are always welcome. Eight cannon lie on the battle-

ments on the top of a very steep precipice, under which is a curious cavern. Lord Gower, Mr. Benson, and Sir J. B. Warren, K. B., have been former proprietors. See LUNDY.

RAT-Tails, or Arrests. See Farriery Index.

RATAFIA, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly of cherries and apricots.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmeg, cloves; and to 20 pounds of cherries 10 quarts of brandy. The vessel is left open 10 or 12 days, and then stopped close for two months before it be tapped. Ratafia of apricots is prepared two ways, viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy, with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for six or ten days; then straining the liquor, and putting it up for use: or else, by infusing the apricots, cut in pieces, in brandy, for a day or two, passing it through a straining bag, and then putting in the usual ingredients.

RATCH, or Rash, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, and make the clock strike. See CLOCK.

RATCHETS, in a watch, are the small teeth at the bottom of the fusy or barrel, which stops it in winding up.

RATE, a standard or proportion, by which either the quantity or value of a thing is adjusted.

RATES, in the navy, the orders or classes into which the ships of war are divided, according to their force and magnitude.

The regulation which limits the rates of men of war to the smallest number possible, seems to have been dictated by considerations of political economy, or of that of the simplicity of the service in the royal dock-yards. The British fleet is accordingly distributed into six rates, exclusive of the inferior vessels that usually attend on naval armaments; as sloops of war, armed ships, bomb-ketches, fire-ships and cutters, or schooners, commanded by lieutenants.

Ships of the first rate mount 100 cannon, having 42-pounders on the lower deck, 24-pounders on the middle deck, 12-pounders on the upper deck, and 6-pounders on the quarter-deck and fore-castle. They are manned with 850 men, including their officers, scamen, marines, and servants.

In general, the ships of every rate, besides the captain, have the master, the boatswain, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the chaplain, have their mates or assistants, in which are comprehended the sail-maker, the master at arms, the armourer, the captain's clerk, the gunsmith, &c.

The number of other officers is always in proportion to the rate of the ship. Thus a first-rate has six lieutenants, six master's mates, twenty-four midshipmen, and five surgeon's mates, who are considered as gentlemen: besides the following petty officers; quarter-masters and their mates, fourteen; boatswain's mates and yeomen, eight; gunner's mates and assistants, six; quarter-gunnery, twenty-five; carpenter's mates, two, besides fourteen...
fourteen assistants; with one steward and steward's mate to the purser.

If the dimensions of all ships of the same rate were equal, it would be the simplest and most perspicuous method to collect them into one point of view in a table: but as there is no invariable rule for the general dimensions, we must content ourselves with but a few remarks on ships of each rate, so as to give a general idea of the difference between them.

The Victory, one of the last built of our first rates, is 222 feet 6 inches in length, from the head to the stem of her keel. 151 feet 4 inches; that of her gun-deck, or lower deck, 186 feet; her extreme breadth is 51 feet 10 inches; her depth in the hold, 21 feet 6 inches; her burden, 2162 tons; and her poop reaches 6 feet before the miz-mast.

Ships of the second rate carry 90 guns upon three decks; of which those on the lower battery are 32-pounders; those on the middle, 18-pounders; on the upper-deck, 12-pounders; and those on the quarter-deck, 6-pounders, which usually amount to four or six. Their complement of men is 750, in which there are six lieutenants, four master's mates, 24 midshipmen, and four surgeon's mates, 14 quarter masters and their mates, eight boatswain's mates and yeomen, six gunner's mates and yeomen, with 22 quarter-gunners, two carpenter's mates, with 10 assistants, and one steward and steward's mate.

Ships of the third rate carry from 64 to 80 cannon, which are 32, 18, and 9 pounders. The 80-gun ships, however, begin to grow out of repute, and to give way to those fitted with 74, 70, &c., which have only two whole batteries; whereas the former have three, with 28 guns planted on each, the cannon of their upper deck being the same as those on the quarter-deck and fore-castle of the latter, which are 9-pounders. The complement in a 74 is 650, and in a 64, 500 men; having, in peace, four lieutenants, but in war, five; and when an admiral is aboard six. They have three master's mates, 16 midshipmen, three surgeon's mates, 10 quarter-masters, and their mates, six boatswain's mates and yeomen, four gunner's mates and yeomen, with 18 quarter-gunners, one carpenter's mate, with eight assistants, and one steward and steward's mate under the purser.

Ships of the fourth rate mount from 60 to 70 guns, upon two decks, and the quarter-deck. The lower tier is composed of 24-pounders, the upper tier of 12-pounders, and the cannon on the quarter-deck and fore-castle are 6-pounders. The complement of a 50 gun ship is 330 men, in which there are three lieutenants, two master's mates, 10 midshipmen, two surgeon's mates, eight quarter-masters and their mates, four boatswain's mates and yeomen, one gunner's mate and yeoman, with 12 quarter-gunners, one carpenter's mate and six assistants, and a steward and steward's mate.

All vessels of war, under the fourth rate, are usually comprehended under the generic name of frigates, and never appear in the line of battle. They are divided into the 5th and 6th rates; the former mounting from 40 to 32 guns, and the latter from 28 to 20. The largest of the fifth rate have two decks of cannon, the lower battery being of 18-pounders, and that of the upper-deck of 9-pounders; but those of 36 and 32 guns have one complete deck of guns, mounting 12-pounders, besides the quarter-deck and fore-castle, which carry 6-pounders. The complement of a ship of 44 guns is 280 men; and that of a frigate of 36 guns, 240 men. The first has three, and the second two lieutenants; and both have two master's mates, six midshipmen, two surgeon's mates, six quarter-masters and their mates, two boatswain's mates, and one yeoman, one gunner's mate and one yeoman, with 10 or 11 quartermasters, and one purser's steward.

Frigates of the 6th rate carry 9 pounds, those of 28 guns having 3-pounders on their quarter-deck, with 200 men for their complement; and those of 24, 160 men: the former has two lieutenants, the latter, one; and both have two master's mates, four midshipmen, one surgeon's mate, four quarter-masters and their mates, one boatswain's mate and one yeoman, one gunner's mate and one yeoman, with six or seven quarter-gunners, and one purser's steward.

The sloops of war carry from 18 to 8 cannon, the largest of which have six-pounders; and the smallest, viz. those of 8 or 10 guns, four-pounders. Their officers are generally the same as in the 6th rates, with little variation; and their complements of men are from 120 to 60, in proportion to their force or magnitude. N. B. Bomb-vessels are on the same establishment as sloops; but fire-ships and hospital ships are on that of fifth-rates.

Nothing more evidently manifests the great improvement of the marine art, and the degree of perfection to which it has arrived in Britain, than the facility of managing our first rates; which were formerly esteemed incapable of government, unless in the most favourable weather of the summer.

Ships of the second rate, and those of the third, which have three decks, carry their sails remarkably well, and labour very little at sea. They are excellent in a general action, or in cannonading a fortress. Those of the third rate, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action, and in general to suit the different exigencies of the naval service.

The fourth-rates may be employed on the same occasions as the third-rates, and may be also destined amongst the foreign colonies, or on expeditions of great distance; since these vessels are usually excellent for keeping and sustaining the sea.

Vessels of the fifth rate are too weak to suffer the shock of a line of battle; but they may be destined to lead the convoys of merchant ships, to protect the commerce in the colonies, to cruise in different stations, to accompany squadrons, or be sent express with necessary intelligence and orders. The same may be observed of the sixth rates.

The frigates, which mount from 28 to 38 guns upon one deck, with the quarter-deck, are extremely proper for cruising against privateers, or for short expeditions, being light, long, and usually excellent sailors.
are mostly used in linings. The frize is a sort of coarse
rateen, and the druggest is a rateen half linen half woolen.

RATIFICATION, an act of approving and con-
fiming something done by another in our name.

RATIO, in Arithmetic and Geometry, is that rela-
tion of homogeneous things which determines the quan-
tity of one from the quantity of another, without the in-
tervention of a third.

The numbers, lines, or quantities, A and B, being
proposed, their relation to another may be consid-
ered under one of these two heads: 1. How much A ex-
cceeds B, or B exceeds A? And this is found by taking
A from B, or B from A, and is called arithmetical rea-
son or ratio. 2. Or how many times, or parts of a
time, A contains B, or B contains A? and this is called
geometric reason or ratio; (or, as Euclid defines it,
it is the mutual habituc, or respect, of two magnitudes
of the same kind, according to quantity; that is, as to
how often the one contains, or is contained in, the
other); and is found by dividing A by B, or B by
A. And here note, that that quantity which is referred
to another quantity is called the antecedent of the ratio:
and that to which the other is referred is called the con-
sequent of the ratio; as in the ratio of A to B, A is
the antecedent, and B the consequent. Therefore any
quantity, as antecedent, divided by any quantity as a
consequent, gives the ratio of that antecedent to the
consequent.

Thus the ratio of A to B is \( \frac{A}{B} \), but the ratio of B
to A is \( \frac{B}{A} \); and, in numbers, the ratio of 12 to 4 is
\( \frac{12}{4} = 3 \), or triple; but the ratio of 4 to 12 is \( \frac{4}{12} = \frac{1}{3} \)
or subtriple.

And here note, that the quantities thus compared
must be of the same kind; that is, such as by multipli-
cation may not exceed one the other, or as these
quantities are said to have a ratio between them, which,
being multiplied, may be made to exceed one another.
Thus a line, how short soever, may be multiplied, that is,
produced so long as to exceed any given right line; and
consequently these may be compared together, and the
ratio expressed: but as a line can never, by any multipli-
cation whatever, be made to have breadth, that is,
to be made equal to a superficies, how small soever;
these can therefore never be compared together, and
consequently have no ratio or respect to one another,
according to quantity; that is, as to how often the
one contains, or is contained in, the other. See QUAN-
tITY.

RATIOCINATION, the act of reasoning. See REASONING.

RATION, or Ratis, in the army, a portion of
ammunition, bread, drink, and forage, distributed to
each soldier in the army, for his daily subsistence, &c.
The horse have rations of hay and oats when they cannot
get out to forage. The ration of bread are regu-
lated by weight. The ordinary ration of a foot soldier
is a pound and a half of bread per day. The officers
have several rations according to their quality and the
number of attendants they are obliged to keep.—When
the ration is augmented on occasions of rejoicing, it is
called a double ration. The ships crews have also their
rations or allowances of biscuit, pulse, and water, pro-
portioned according to their stock.

RATIONALE, a solution or account of the princi-
pies of some opinion, action, hypothesis, phenomenon or
the like.

RATIBOR, a town of Prussian Silesia, and ca-
capital of a duchy of the same name, with a castle. It
has been twice taken by the Swedes, and is seated on
the river Oder, in a country fertile in corn and fruits,
15 miles north-east of Troppau and 142 east of Prague.
E. Long. 18. 10. N. Lat. 50. 14.

RATISBON, an ancient, large, handsome, and
strong city of Germany, in Bavaria, with a bishop's
see, whose bishop was a prince of the empire. It is
called by the Germans Regensburg, from the river Re-
gens, which runs under a lime stone bridge, and throws
itself into the Danube below the cities and the rivers
Lubera and N. and mix with it above the city. The
French call it Ratisbon, in imitation of the Latin; it was
formerly subject to the kings of Bavaria, who made it the
place of their residence; but it was declared free by
the emperor Frederick I. and continued a free and im-
perial city till 1806, when it was united to the kingdom
of Bavaria. It was the first city of the bench of Swabia,
and contained within its walls five different free states
of the empire; namely, the bishop, the abbot of St
Emmerman, the abbesses of the Low and High Munster,
and the city. The inhabitants of Ratisbon had the pri-
ivilege not to be cited before other tribunals, unless for
actions above 400 florins. The senats was composed
of 17 members, and there was a council of 16, charged
with the government of the state. The Catholics have
the exercise of their religion in the cathedral church
and others, and the Lutherans in three churches which
they have built. The magistrates and officers of the
city are all Protestants; and it is to be remarked, that
although there are about 22 Catholic churches, yet there
are very few Catholic citizens; the magistracy not al-
lowing the freedom of the town to be given to Catholics
living there. As this city is large, elegant, and full of
magnificent houses, it was chosen many years for the
place of holding the diet, upon account of the conve-
nieney, to many neighbouring princes and states, of
sending their provisions by land and water, without
great expense. The town-house, in the midst of which
the diet met, is extremely magnificent. In the year
1740, however, when there was a war in Germany, the
diet met at Frankfort on the Main, till after the death
of the emperor Charles VII; and since the new con-
stitution of Germany was established, the meetings of the
diet have again been transferred to Frankfort. Provi-
sions are very plentiful at Ratisbon in time of peace.
The inhabitants have a good deal of trade, the river on
which it stands being navigable, and communicating
with a great part of Germany. It is 35 miles southeast
of Nuremberg, 66 north of Munich, and 195 west of
Vienna, and contains about 23,000 inhabitants. E.
Long. 12. 5. N. Lat. 48.

RATLINES, or, as the sailors call them, rattins,
those lines which make the ladder steps to go up the
shrouds and pattocks, hence called the ratisins of the
shrouds.

RATOLFZEL,
RATOFEZEL, a strong town of Germany, in Swabia, near the west end of the lake Constance. It is seated on that part of it called Bodensee, and belongs to the house of Austria, who took it from the duke of Wirtemburg, after the battle of Nordlingen. It is 12 miles west of the city of Constance. It is defended by the impregnable castle of Hohen Dwel, on an inaccessible hill in the middle of a plain, the rock of which is flint, so that a few men may hold it out against an army.

RATTLESNAKE. See CrotaLus, OPHIOLOGY Index.

RATTLESNAKE Root. See PolyGala, BOTANY Index.

RATZEBURG, or Ratzemberg, an ancient town of Germany, in the circle of Lower Saxony, and in the duchy of Lawenburg, with a bishop's see and a castle. The town depends on the duchy of Lawenburg, and the cathedral church on that of Ratzeburc. It is seated on an elevation, and is almost surrounded with a lake 25 miles in length and three in breadth. The duke of Lawenburg seized and fortified it in 1689, and the king of Denmark took it in 1693; but it was dismantled, and restored in 1700 to the duke, who re-fortified it. This town has been frequently pillaged, particularly in 1553, by Francis duke of Saxo Lawenburg, because the canons refused to elect his son Magnus their bishop. It is nine miles south of Lubec. This place is noted for its excellent beer. E. Long. 10° 38'. N. Lat. 53° 47'.

RAVA, a town of Poland, and capital of a pala
tinate of the same name, with a fortified castle, where they keep state prisoners. The houses are built of wood, and there is a Jesuit's college. It is seated in a morass covered with water, which proceeds from the river Rava, with which it is surrounded. It is 45 miles south of Błoko, and 50 south-west of Warsaw. The palatinate is bounded on the north by that of Błoko, on the east by that of Mazovia, on the south by that of Sanidomer, and on the west by that of Lenceza.

RAVELIN, in Fortification, was anciently a flat bastion placed in the middle of a curtain; but now a detached work composed only of two faces, which make a salient angle without any flanks, and raised before the countergaarde of the place. See Fortification.

RAVEN. See CORYUS, ORNITHOLOGY Index.

Sea Raven, or corvo marinio of Kongo in Africa, in Ichthyology, is about six feet long; but the most singular circumstance appertaining to this creature is the stone found in its head, to which the natives ascribe some medicinal virtues, and the delicate taste of its hard roe, which is still much admired, when dried in the sun, and becomes as hard as a stone.

RAVENGLAS, a town of Cumberland in England, situated between the rivers Irk and Esk, which, with the sea, encompass three parts of it. It is a well built place, and has a good road for shipping, which brings it some trade. E. Long. 0° 5'. N. Lat. 54° 20'.

RAVENNA, in Ancient Geography, a noble city of Gallia Cispadana; a colony of Thessalians, on the Adriatic, in washes or a boggy situation, which proved a natural security to it. The houses were all of wood, the communication by bridges and boats, and the town kept sweet and clean by the tides carrying away the mud and soil. (Strabo). Anciently it had a port at the mouth of the Bedesia; Augustus added a new port, capacious to hold a fleet, for the security of the Adriatic, between which and the city lay the Via Cassia. In the lower age it was the seat of the Ostrogoths for 72 years; but being recovered by Narses, Justinian's general, it became the residence of the exarchs, magistrates sent by the emperor from Constantinople, for 175 years, when it was taken by the Longobards. It is still called Ravenna, and is the capital of the province of Romagna in the states of the Church. It contains about 14,000 souls. The seat of the western or Roman empire was by Honorius translated to Ravenna about the year 424, and hence the country in which it stood was called Romania. It had a very flourishing trade till the sea withdrew two miles from it, which has been a great detriment. The fortifications are of little importance, and the citadel is gone to ruin. It is now most remarkable for the excellent wine produced in its neighbourhood. The mausoleum of Theodora is still to be seen, remarkable for being covered by a single stone 28 feet in diameter and 15 thick. It was at Ravenna that the duke of Nemours fell, after having gained a most decisive victory over the confederate army, in 1511.

RAVENSBURG, a county of Germany, in Westphalia, bounded on the north by the bishoprics of Osnaburg and Minden, on the east by Lemgow, on the south by the bishopric of Paderborn, and on the west by that of Münster. It belongs to the king of Prussia, and has its name from the castle of Ravensburg. The population amounts to about 81,812.

RAVENSBURG, a town of Germany, formerly free and imperial, but now subject to Wirtemberg. It is well built, and the public structures are handsome. The inhabitants are partly Protestants and partly Papists. It is seated on the river Chensu, in E. Long. 9° 46'. N. Lat. 47° 44'.

RAVET, an insect shaped like a may-bug, or cockchafer, (see Scarabeus), with which the island of Guadaloupe is much pestered. It has a stinking smell, preys upon paper, books, and furniture, and whatever they do gnaw is discoloured by their ordure. These nasty insects, which are very numerous, and appear chiefly by night, would be intolerable, were it not for a large spider, some of them as long as man's fist, which intangles them in its web, and otherwise surprises them. On which account the inhabitants of the island are very careful of these spiders.

RAVILLIAC, Francis, the infamous assassin of Henry IV. of France, was a native of Angouleme, and at the time of his execution was about one or two years of age and thirty years of age. See France, No. 150, and Henry IV. of France. Ravillac was the son of parents who lived upon alms. His father was that sort of inferior retainer to the law, to which the vulgar give the name of Petitjean, and his son had been bred up in the same way. Ravillac had set up a claim to an estate, but the cause went against him; this disappointment affected his mind deeply: he afterwards taught a school, and, as himself said, received charitable gifts, though but of a very small value, from the parents of those whom he taught; and yet his distress was so great, that he had much ado to live. When he was seized for the king's murder, he was very loosely guarded; all were permitted to speak with him who pleased; and it was thought
a fact by the seditious sermons and books of the Jesuits, whom Henry, rather out of fear than love, had recalled and caressed, and to whom he had bequeathed his heart.

Neither the dying words of Ravillac, nor so much of his process as was published, were credited by his contemporaries. Regult the historian says, that there were two different opinions concerning this assassination; one, that it was conducted by some grandees, who sacrificed that monarch to their old resentments; the other, that it was done by the emissaries of the Spaniards. Letters from Brussels, Antwerp, Mechlin, and other places, were received before the 15th of May, with a report of the king's death. Though nothing occurs in the examinations of Ravillac that were first published, in reference to his journeys to Naples and other places; yet as these are set down as certain truths by good authors, so there are probable grounds to believe that they were not fictitious. It appears from Sir Ralph Winwood's Memorials, that Ravillac had been no longer alive at Brussels. Amongst other circumstances that created a very great doubt, whether the assassin spoke truth, were the things found in his pocket at the time he was seized; amongst which was a chaplet, a figure of a heart made in cotton, in the centre of which he said there was a bit of the true cross, but when cut there was none, which he affirmed was given him by a canon at Angoulesme, a piece of paper with the arms of France painted upon it, another full of characters, and a third containing verses for the meditation of a criminal going to execution. The provost of Pluviers, or Petiviers, in Beaune, about six miles from Paris, had said openly on the day that Henry IV. was murdered, "This day the king is either slain or dangerously wounded." After the king's death was known, he was seized and sent prisoner to Paris; but, before he was examined, he was found hanged in the strings of his drawers. His body was, notwithstanding, hung up by the heels on the common gibbet on the 15th of June. What increased the suspicions grounded on this man's end, was his having two sons Jesuits, and his being a dependant on the family of Monseigneur d'Entragues.

RAUN, a town of some strength upon the river Marne, remarkable for a bloody skirmish between the Prussians and Austrians, in August 1744. The king of Prussia, intending to get possession of Berain, sent thither six battalions, with eight cannon, and 800 horse; but General Festititz being there with a great party of his corps, and M. Luchesi with 1000 horse, they not only repulsed the Prussians, but attacked them in their turn, and, after a warm dispute, obliged them to retire with considerable loss.

RAURICUM, in Ancient Geography, a town of the Raurici, situated over against Abona, a mountain from which the Danube takes its rise. A Roman colony led by L. Manlius Plancus the scholar and friend of Cicero: called Colonia Raurica (Pliny), Raurica (Inscription), Augusta Rauricorum. The town was destroyed in Julian's time. It is now commonly called Augst, a village greatly decayed from what it formerly was. It is situated on the Rhine, distant about two hours to the east of Basel. The country is now the canton of Basel.

RAY, JOHN, a celebrated naturalist, was the son of Mr. Roger Ray a blacksmith, and was born at Black Notly.
Notly in Essex in 1628. He received the first rudiments of learning at the grammar-school at Braintree; and in 1644 was admitted into Catharine-Hall in Cambridge, from whence he afterwards removed to Trinity college in that university. He took the degree of master of arts, and became at length a senior fellow of the college; but his intense application to his studies having injured his health, he was obliged at his leisure hours to exercise himself by riding or walking in the fields, which led him to the study of plants. He noted from John Parkinson, and the Phytologia Britannica, the places where curious plants grew; and in 1638 rode from Cambridge to the city of Chester, from whence he went into North Wales, visiting many places, and among others the famous hill of Snowdon; returning by Shrewsbury and Gloucester. In 1650 he published his Catalogus Plantarum circa Cantabrigiam nascentium, and the same year was ordained deacon and priest. In 1661 he accompanied Francis Willoughby, Esq. and others, in a search of plants and other natural curiosities in the north of England and Scotland; and the next year made a western tour from Chester, and through Wales, to Cornwall, Devonshire, Dorsetshire, Hampshire, Wiltshire, and other counties. He afterwards travelled with Mr Willoughby and other gentlemen through Holland, Germany, Italy, France, &c. took several tours in England, and was admitted fellow of the Royal Society. In 1672 his intimate and beloved friend Mr Willoughby died in the 37th year of his age, at Middleton Hall, his seat at Yorkshire; "to the infinite and unpeakeable loss and grief (says Mr Ray) of myself, his friends, and all good men." There having been the closest and sincerest friendship between Mr Willoughby and Mr Ray, who were men of similar natures and tastes, from the time of their being fellow collegians, Mr Willoughby not only confided in Mr Ray, in his lifetime, but also at his death: for he made him one of the executors of his will, and charged him with the education of his sons Francis and Thomas, leaving him also for life 60l. per annum. The eldest of these young gentlemen, not being four years of age, Mr Ray, as a faithful trustee, betook himself to the instruction of them; and for their use composed his Nomenclator Classicus, which was published this very year, 1672. Francis the eldest dying before he was of age, the younger became Lord Middleton. Not many months after the death of Mr Willoughby, Mr Ray lost another of his best friends, Bishop Wilkins; whom he visited in London the 18th of November 1672, and found near expiring by a total suppression of urine for eight days. As it is natural for the mind, when it is hurt in one part, to seek relief from another; so Mr Ray, having lost some of his best friends, and being in a manner left destitute, conceived thoughts of marriage; and accordingly, in June 1673, did actually marry a gentlewoman of about 20 years of age, the daughter of Mr Oakley of Launton in Oxfordshire. Towards the end of this year, came forth his "Observations Topographical, Moral, &c." made in foreign countries; to which was added his Catalogus Stirpium in exteriis regionibus observatum: and about the same time, his Collection of unusual or local English words, which he had gathered up in his travels through the counties of England. After having published many books on subjects foreign to his profession, he at length resolved to publish in the character of a divine, as well as in that of a natural philosopher, in which view he published his excellent demonstration of the being and attributes of God, entitled The Freedom of God manifested in the Works of the Creation, 8vo, 1697. The rudiments of this work were read in some college lectures; and another collection of the same kind he enlarged and published under the title of Three Physico-theological discourses, concerning the Chaos, Deluge, and Dissolution of the World, 8vo, 1692. He died in 1705. He was modest, affable, and communicative; and was distinguished by his probity, charity, sobriety, and piety. He wrote a great number of works; the principal of which, besides those already mentioned, are, 1. Catalogus Plantarum Anglica. 2. Dictionarium Trilingue secundum locos communia. 3. Historia Plantarum, Species haecensibus edita, sinque inapuer multus noviter inventas et descriptas complectens, three vols. 4. Methodus Plantarum nov. et Tabulis, 8vo, and several other works on plants. 5. Synopsis Medicinæ Animalium Quadrupedum et Serpentis generis, 8vo. 6. Synopsis Medicinæ Arum et Piscium. 7. Historia Insectorum, opus posthumum. 8. Methodus Insectorum. 9. Philosophical Letters, &c.

RAYNAL, WILLIAM THOMAS, or the Abbé Raynal, was born about the year 1712, and received his education among the celebrated order of the Jesuits, and became one of their number. Their value and excellence chiefly consisted in assigning to each member his proper employment. Among them it was that Raynal acquired a taste for literature and science, and by them he was afterwards expelled, but for what reason is certainly known, although the abbé Barruel ascribes it to impolicy. Soon after this event he associated with Voltaire, d'Alembert, and Diderot, by whom it is said, he was employed to furnish the articles in theology for the Encyclopédie; but he employed the abbé Yvon to furnish them for him, whom Barruel allows to have been an inoffensive and upright man.

His first work, which is justly regarded as an eminent performance, is entitled "Political and Philosophical History of the European Settlements in the East and West Indies." The style of this work is admirable; it contains many just reflections both of a political and philosophical nature, and has been translated into every European language. We believe this performance was followed by a small tract in the year 1756, entitled "The Revolution of America," in which he pleading the cause of the colonists with much zeal, causes the conduct of the British government, and discovers an acquittance with the principles of the different factions, which has induced a belief that he had been furnished with materials by those who knew the merits of the dispute much better than any foreigner could reasonably be supposed to do.

The French government instituted a prosecution against him on account of his history of the East and West Indies; but with so little severity was it conducted, that sufficient time was allowed him to retire to the dominions of his Prussian majesty, by whom he was protected, notwithstanding he had treated the character of that sovereign with very little ceremony. Even the most despotic princes showed him much kindness, although he always animadverted on their conduct without reserve; and he lived in the good graces of the...
press of Russia. At one period the British house of commons showed him a very singular mark of respect. The speaker having been informed that Raynal was a spectator in the gallery, public business was instantly suspended, and the stranger was conducted to a more honorable situation. But when a friend of Dr. Johnson’s asked him respecting the same personage, “Will you give me leave, doctor, to introduce you to the abbé Raynal?” he turned on his heel, and said, “No, sir.”

A love of liberty was the principal trait in Raynal’s character, of which he gave no proper or accurate definition in his earlier writings; but when he beheld the abuse of liberty in the progress of the French Revolution, he nobly attempted to retrieve his errors. In the month of May 1791, he addressed to the Constituent Assembly, a letter the most eloquent, argumentative, and impressive, that perhaps was ever composed upon any subject whatever. He observes among other things; “I have long dared to speak to kings of their duty; suffer me now to speak to the people of their errors, and to their representatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. It is true that I am to look back with horror at myself for being one of those who, by feeling a noble indignation against arbitrary power, may perhaps have furnished arms to licentiousness. Do then, religion, the laws, the royal authority, and public order, demand back from philosophy and reason the ties which united them to the grand society of the French nation, as if, by exposing abuses, and teaching the rights of the people and the duties of princes, our criminal efforts had broken these ties? But, no!—never have the bold conceptions of philosophy been represented by us as the strict rule for acts of legislation.”

He afterwards completely proves, that it was not the business of the assembly to abolish every ancient institution; that the genius of the French people is such, that they never can be happy or prosperous but under a well regulated monarchical government; and that, if they wished not the nation to fall under the worst kind of despotism, they must increase the power of the king.

Besides the works already mentioned, he was the author of “A History of the Parliament of England,” &c. “History of the Stadtholderate;” “The History of the Divorce of Catharine of Arragon by Henry VIII.” and “A History of the Revocation of the Edict of Nantz,” in four volumes; but he committed many of his papers to the flames during the sanguinary reign of Robespierre. He was deprived of all his property during the revolution, and died in poverty in the month of March 1796, in the 8th year of his age.

RAY, in Optics, a beam of light emitted from a radiant or luminous body. See Light and Optics.

Inflected Rays, those rays of light which, on their near approach to the edges of bodies, in passing by them, are bent out of their course, being turned either from the body or towards it. This property of the rays of light is generally termed diffraction by foreigners, and Dr. Hooke sometimes called it deflection.

Reflected Rays, those rays of light which, after falling upon the body, do not go beyond the surface of it, but are thrown back again.

Refraed Rays, those rays of light which, after falling upon any medium, enter its surface, being bent either towards or from a perpendicular to the point on which they fell.

Penet of Rays, a number of rays issuing from a point of an object, and diverging in the form of a cone.

RAZOR, a well-known instrument, used by surgeons, barbers, &c. for shaving off the hair from various parts of the body. As shaving to many people is a most painful operation, cutlers in different countries have long applied their skill to remove that inconvenience. Some have invented soaps of a peculiar kind to make the operation more easy, and some have invented straps. With respect to razors, some artists have succeeded rather by accident than from any fixed principle; and therefore we have found great inequality in the goodness of razors made by the same artist.

A correspondent assures us, that he has for 40 years past been at much pains to find out razors made by the best makers both in England and Scotland, and was fortunate enough, at last, to discover a kind made by a Scotchman of the name of Logan, which he called magnetic razors, because they were directed to be touched with an artificial magnet before using. These, our friend assures us, are most excellent razors, and he has used them for upwards of 20 years. He says likewise that they continue in good order, without requiring to be ground; but that the great drawback on their being generally used, is the price, which is higher than most people are able or disposed to give for that instrument. Our correspondent, who resides in the vicinity of London, also informs us, that lately the famous surgeon’s instrument-maker, Mr. Savigny in Pall Mall, after numberless experiments, in the course of above 20 years, has at length brought razors to a degree of perfection never yet equalled; and with such certainty, that the purchaser is in no danger of a disappointment, though the price is very moderate. By these, we are told, the operation of shaving is performed with greater ease, more perfectly, and more expeditiously than with any other.

RE, in Grammar, an inseparable particle added to the beginning of words to double or otherwise modify their meaning; as in re-action, re-move, re-export, &c.

RE-ACTION, in Physiology, the resistance made by all bodies to the action or impulse of others that endeavour to change its state whether of motion or rest, &c.

READING, the art of delivering written language with propriety, force, and elegance.

“Who must not judge so unfavourably of eloquence or good reading (says the illustrious Fenelon), as to reckon it only a frivolous art, that a declaimer uses to impose upon the weak imagination of the multitude, and to serve his own ends. It is a very serious art, designed to instruct people; to suppress their passions and reform their manners; to support the laws, direct public councils, and to make men good and happy.”

Reason and experience demonstrate, that delivery in reading ought to be less animated than in interested speaking. In every exercise of the faculties of speech, and those expressions of countenance and gesture with which it is generally attended, we may be considered to be interested ways in one of the two following situations: First, de-speaking, giving our bosom sentiments on circumstances which relate to ourselves or others; or, secondly, repeating something that was spoken on a certain occasion for the
Reading.

amusement or information of an auditor. Now, if we observe the deliveries natural to these two situations, we shall find, that the first may be accompanied with every degree of expression which can manifest itself in us, from the lowest of sympathy to the most violent and energetic of the superior passions; while the latter, from the speaker's chief business being to repeat what he heard with accuracy, discovers only a faint imitation of those signs of the emotions which we suppose agitated him from whom the words were first borrowed. — The use and necessity of this difference of manner is evident; and if we are attentive to these natural signs of expression, we shall find them conforming with the greatest nicety to the slightest and most minute movements of the breast.

This repetition of another's words might be supposed to pass through the mouth of a second or third person; and in these cases, since they were not ear and eye witnesses of him who first spoke them, their manner of delivery would want the advantage necessarily arising from an immediate idea of the original one; hence, on this account, this would be a still less lively representation than that of the first repeater. But as, from a daily observation of every variety of speech and its associated signs of emotion, mankind soon become pretty well acquainted with them, and this in different degrees, according to their discernment, sensibility, &c. experience shows us that these latter repeaters (as we call them) might conceive and use a manner of delivery which, though less characteristic perhaps, would on the whole be no way inferior to the first, as to the common natural expression proper for their situation. It appears, therefore, that repeaters of every degree may be esteemed upon a level as to animation, and that our twofold distinction above contains accurately enough the whole variety of ordinary delivery; — we say ordinary, because there is another very peculiar kind of delivery sometimes used in the person of a repeater, of which it will in this place be necessary to take some notice. What we mean here is mimicry; an accomplishment which, when perfectly and properly displayed, never fails of yielding a high degree of pleasure. But since this pleasure chiefly results from the principle of imitation respecting manner, and not from the purport of the matter communicated; since, comparatively speaking, it is only attainable by few persons, and practised only on particular occasions; — on these accounts it must be refused a place among the modes of useful delivery taught us by general nature, and esteemed a qualification purely anomalous.

These distinctions with regard to a speaker's situation of mind premised, let us see to which of them an author and his reader may most properly be referred, and how they are circumstances with regard to one another.

The matter of all books is, either what the author says in his own person, or an acknowledged recital of the words of others: hence an author may be esteemed both an original speaker and a repeater, according as what he writes is of the first or second kind. Now a reader must be supposed either actually to personate the author, or one whose office is barely to communicate what he has said to an auditor. But in the first of these suppositions he would, in the delivery of what is the author's own, evidently commence mimic; which being, as above observed, a character not acknowledged by general nature in this department, ought to be rejected generally improper. The other supposition therefore must be accounted right; and then, as to the chief matter of the book, the reader is found to be exactly in the situation of a repeater, save that he takes what delivers from the page before him instead of his memory. It follows then, in proof of our initial proposition, that, if we are directed by nature and propriety, the manner of our delivery in reading ought to be infused with warmth and energy to what we should use, were it language before us, the spontaneous effusions of our hearts in the circumstances of those out of whose mouth it is supposed to proceed.

Evident as the purport of this reasoning is, it has so much as been glanced at by the writers on the subject we are now entered upon, or any of its kindest ones; which has occasioned a manifest want of accuracy in several of their rules and observations. Among the rest, this precept has been long reverberated from author to author as a perfect standard for propriety in reading. "Deliver yourselves in the same manner as you would, were the matter your own original sentiment uttered directly from the heart." As all kinds of very must, have many things in common, the rule in many articles be undoubtedly right; but, from what has been said above, it must be as certainly faulty with respect to several others; as it is certain nature confounded by signs two things so very different, as a copy and an original, an emanation derived immediately from the sun, and its weaker appearance in the last reflection. The precepts we have to offer for improving the above-mentioned rule, shall be delivered under the head of accent, emphasis, modulation, expression, pause, &c.

I. Accent. — In attending to the affections of the voice when we speak, it is easy to observe, that, independent of any other consideration, one part of it differs from another, in stress, energy, or force of utterance. In words we find one syllable differing from another with respect to this mode; and in sentences one or more words as frequently vary from the rest in a similar manner. This stress with regard to syllables is called accent, and contributes greatly to the variel harmony of language. Respecting words, it is termed emphasis; and its chief office is to assist the sense, force, or perspicuity of the sentence — of which we shall under the next head.

"Accent (as described in the Lectures on Elocution) is made by us two ways; either by dwelling longer upon one syllable than the rest, or by giving it a sounder percussion of the voice in utterance. Of the first of these we have instances in the words Glory, father, birth, and of the last in battle, habit, border. So that accent with us is not referred to time, but to sound, quality, not quality; to the more equal or precise motion of the voice, not to the variation of the voice inflexions."

In theatrical declamation, in order to give it more power and solemnity, it is usual to dwell longer than common upon the unaccented syllables; and the author who quoted has endeavoured to prove (p. 51. 52.) the practice faulty, and to show (p. 55.) that "though it (true solemnity) may demand a slower utterance than usual, yet it requires that same proportion in part
of quantity be observed in the syllables, as there is in musical notes when the same tune is played in quicker or slower time." But that this deviation from ordinary speech is not a fault, as our author asserts; nay, that on the contrary it is a real beauty when kept under proper regulation, the following observations it is hoped will sufficiently prove.

(I.) It is a truth of the most obvious nature, that those things which on their application to their proper senses have a power of raising in us certain ideas and emotions, are ever differently modified in their constituent parts when different effects are produced in the mind: and also (II.) that, within proper bounds, we are to suppose these constituent parts to be proportionally increased or diminished as to quantity, this effect would still be the same as to quality.—For instance: The different ideas of strength, swiftness, &c. which are raised in us by the same species of animals, is owing to the different form of their corresponding parts; the different effects of music on the passions, to the different airs and movements of the melody; and the different expressions of human speech to a difference in tone, speed, &c. of the voice. And these peculiar effects would still remain the same, were we to suppose the animals above alluded to, to be greater or lesser, within their proper bounds: the movement of the music quicker or slower, provided it did not palpably interfere with that of some other species; and the pitch of the voice higher or lower, if not carried out of the limits in which it is observed on similar occasions naturally to move. Further (III.) since, respecting the emotions more especially, there are no rules to determine a priori what effect any particular attribute or modification of an object will have upon a percipient, our knowledge of this kind most evidently be gained from experience. Lastly, (IV.) In every art imitating nature we are pleased to see the characteristic members of the pattern heightened a little farther than perhaps it ever was carried in any real example, provided it be not bordering upon some ludicrous and disagreeable provinces of excess.

Now for the application of these premisses.—To keep pace and be consistent with the dignity of the tragic muse, the delivery of her language should necessarily be dignified; and this it is plain from observation (I.) cannot be accomplished otherwise than by something different in the manner of it from that of ordinary speech; since dignity is essentially different from familiarity. But how must we discover this different manner? By attending to nature: and in this case she tells us, that besides using a slower delivery, and greater distinctness of the words (which every thing merely grave requires, and gravity is a concomitant of dignity, though not its essence,) we must dwell a little longer upon the unsounded syllables than we do in common. As to what our author observes in the above quotation, of dignity's only requiring a slower utterance than ordinary, while the proportion of the syllables as to quantity continues the same; it is apprehended the remark (II.) respecting quickness and slowness of movement will show it to be not altogether true. For since the delivery is not altered in form, its expression must be still of the same kind, and perhaps what may be rightly suggested by the term gravely familiar.

But something farther may be yet said in defence of this artificial delivery, as our author calls it. It is not the movement of any thing, of whatever species, when dignified or solemn, in general of an equable and deliberate nature (as in the minuet, the military step, &c.)? And in theatrical declamation, is not the propensity to introduce this equableness so strong, that it is almost impossible to avoid it wholly, were we ever so determined to do it? If these two queries be answered in the affirmative (as we are persuaded they will), while the first supports our argument for the propriety of the manner of delivery in question, the second discovers a kind of necessity for it. And that this manner may be carried a little further in quantity on the stage than is usual in real life, the principle (IV.) of heightening nature will justify, provided fashion (which has ever something to do in these articles) give it a sanction; for the precise quantity of several heightenings may be varied by this great legislator almost at will.

II. Emphasis.—As emphasis is not a thing annexed to particular words, as accent is to syllables, but owes its rise chiefly to the meaning of a passage, and must therefore vary its seat according as that meaning varies, it will be necessary to explain a little farther the general idea given of it above.

Of man's first disobedience, and the fruit
Of that forbidden tree, whose mortal taste
Brought death into the world, and all our woe, &c.
Sing heav'nly muse, &c.

Supposing, in reference to the above well-known lines, that originally other beings, besides men, had disobeyed the commands of the Almighty, and that the circumstance were well known to us, there would fall an emphasis upon the word man's in the first line, and hence it would be read thus:

Of man's first disobedience, and the fruit, &c.

But if it were a notorious truth, that mankind had transgressed in a peculiar manner more than once, the emphasis would fall on first, and the line be read,

Of man's first disobedience, &c.

Again, admitting death (as was really the case) to have been an unheard of and dreadful punishment brought upon man in consequence of his transgression; on that supposition the third line would be read,

Brought death into the world, &c.

But if we were to suppose mankind knew there was such an evil as death in other regions, though the place they inhabited had been free from it till their transgression; the line would run thus,

Brought death into the world, &c.

Now from a proper delivery of the above lines, with regard to any one of the suppositions we have chosen, it is evident that the emphasis they illustrate is effected by a manifest delay in the pronunciation, and a tone something fuller and lower than is used in ordinary; and that an office is solely to determine the meaning of a sentence with reference to something said before, presupposed by the author as general knowledge, or in order to remove an ambiguity where a passage is capable of having more senses given it than one.

But,
Reading.

But, supposing in the above example, that none of the senses there pointed out were precisely the true one, and that the meaning of the lines were no other than what is obviously suggested by their simple construction; in that case it may be asked, if in reading them there should be no word dignified with the emphatical accompaniments above described? The answer is, Not one with an emphasis of the same kind as that which we have just been illustrating; yet, it is nevertheless true, that on hearing these lines we read, we shall find some words distinguished from the rest by a manner of delivery bordering a little upon it (a). And these words will in general be such as seem the most important in the sentence, or on other accounts to merit this distinction. But as at best it only enforces, graces, or enlivens, and not fixes the meaning of any passage, and even caprice and fashion (b) have often a hand in determining its place and magnitude, it cannot properly be reckoned an essential of delivery. However, it is of too much moment to be neglected by those who would wish to be good readers; and, for the sake of distinction, we may not unaptly denominate both the kinds of energies in question, by the terms emphasis of sense, and emphasis of force (c).

Now from the above account of these two species of emphasis it will appear, "that in reading, as in speaking, the first of them must be determined entirely by the sense of the passage, and always made alike: But as to the other, taste alone seems to have a right of fixing its situation and quantity." Farther: Since the more essential of these to energies is solely the work of nature (as appears by its being constantly found in the common reading conversation of people of all kinds of capacities and degrees of knowledge), and the most ignorant person never fails of using it rightly in the effusions of his own heart, it happens very luckily, and ought always to be remembered, that provided we understand what we read, and give way to the dictates of our own feeling, the emphasis of sense can scarce ever avoid falling spontaneously upon its proper place.

Here it will be necessary to say something by way of reply to a question which will naturally occur to the mind of every one. As the rule for the emphasis of sense requires we should understand what we read before it can be properly used, it is incumbent upon us never to attempt to read what we have not previously studied for that purpose? In answer to this, it must be observed, that though such a step will not be without its advantages; yet, as from the fairness of printed types, the well-known pauses of punctuation, and a long acquaintance with the phraseology and construction of our language, &c. experience tells us it is possible to comprehend the sense at the first reading, a previous perusal of what is to be read does not seem necessary to all, though, if they would wish to appear to advantage, it may be expedient to many; and it is this circumstance which makes us venture upon extemporary reading, and give it a place among our amusements.—Similar remarks might be made with regard to modulation, expression, &c. did not what is here observed naturally anticipate them.

III. Modulation (d). Every person must have observed

(a) The following lines will illustrate both these kinds of stresses: For, to convey their right meaning, the word any is evidently to be pronounced louder and fuller than those with the accent over them.

Get wealth and place, if possible with grace;

If not, by any means get wealth and place.—Pope.

This couplet is accented in the manner we find it in the Essay on Elocution by Mason. And if, according to the judgment of this author, the words thus distinguished are to have an emphatical stress, it must be of the inferior kind above mentioned, and which a little farther on we call emphasis of force; while the word any in a different type alone possesses the other sort of energy, and which is there contradistinguished by the term emphasis of sense.

(b) Among a number of people who have had proper opportunities of learning to read in the best manner it is now taught, it would be difficult to find two, who, in a given instance, would use the emphasis of force alike, either as to place or quantity. Nay some scarcely use any at all: and others will not scruple to carry it much beyond anything we have a precedent for in common discourse; and even now and then throw it upon words so very trifling in themselves, that it is evident they do it with no other view, than for the sake of the variety it gives to the modulation.—This practice, like the introduction of discords into music, may without doubt be indulged now and then; but were it too frequent, the capital intent of these energies would manifestly either be destroyed or rendered dubious.

(c) The first of these terms answers to the simple emphasis described in the Lectures on Elocution, and the second nearly to what is there called complex. The difference lies in this. Under complex emphasis the author seems (for he is far from being clear in this article) to include the tones simply considered of all the emotions of the mind; as well the tender and languid, as the forcible and exulting. Our term is intended to be confined to such modes of expression alone as are marked with an apparent stress or increase of the voice.

(d) The author of the Introduction to the Art of Reading, not allowing that there is any variation of tone, as to high and low, in the delivery of a complete period or sentence, places modulation solely in the diversification of the key-note and the variety of syllables, as to long or short, swift or slow, strong or weak, and loud or soft. As we are of a different opinion, our idea of modulation is confined purely to harmonious inflexions of voice. These qualities of words, it is true, add greatly both to the force and beauty of delivery; yet, since some of them are fixed and not arbitrary (as long and short), and the others (of swift and slow, strong and weak, loud and soft) may be considered as modes of expression which do not affect the modulation as to tone, it will agree best with our plan to
linged, that, in speaking, the voice is subject to an alteration of sound, which in some measure resembles the movement of a tune. These sounds, however, are evidently nothing like so much varied as those that are strictly musical; and we have attempted to show in the preceding chapter, that, besides this, they have an essential difference in themselves. Nevertheless, from the general similitude of these two articles, they possess several terms in common; and the particular we have now to examine is in both of them called modulation. This affection of the voice, being totally arbitrary, is differently characterized in different parts of the world; and, through the power of custom, every place is inclined to think their own the only one natural and agreeable, and the rest affected with some barbarous twang or ungainly variation (e). It may be observed, however, that though there is a general uniform cast or fashion of modulation peculiar to every country, yet it by no means follows that there is or can be anything fixed in its application to particular passages; and therefore we find different people will in any given instance, use modulations something different, and nevertheless be each of them equally agreeable.

But, quitting these general remarks, we shall (as our purpose requires it) consider the properties of modulation a little more minutely.

First, then, we may observe, that, in speaking, there is a particular sound (or key-note, as it is often called) in which the modulation for the most part runs, and to which its occasional inflexions, either above or below, may in some respects be conceived to have a reference, like that which common music has to its key-note. Yet there is this difference between the two kinds of modulation, that whereas the first always concludes in the key-note, the other frequently concludes a little below it (Φ). This key-note, in speaking, is generally the sound given at the outset of every complete sentence or period; and it may be observed on some occasions to vary its pitch through the limits of a musical interval of a considerable magnitude. The tones, that fall a little lower than the key at the close of a sentence or period, are called cadences. These cadences, if we are accurate in our distinctions, will, with respect to their offices, be found of two kinds; though they meet so frequently together, that it may be best to conceive them only as answering a double purpose. One of these offices is to assist the sense, and the other to decorate the modulation. An account of the first may be seen in the section on Pauses; and the latter will be found to show itself pretty frequently in every thing grave and plaintive, or in poetic description and other highly ornamented language, where the mind is by its influence brought to feel a placid kind of dignity and satisfaction. These two cadences, therefore, may be conveniently distinguished by applying to them respectively the epithets significant and ornamental.

We have already observed, that reading should in some things differ from speaking; and the particular under consideration seems to be one which ought to vary a little in these arts. For,

Modulation in reading serves a twofold purpose. At the same time that it gives pleasure to the ear on the principles of harmony, it contributes through that medium to preserve the attention. And since written language (when not purely dramatical) is in general more elegant in its construction, and musical in its periods, than the oral one; and since many interesting particulars are wanting in reading, which are present in speaking, that contribute greatly to fix the regard of the hearer; it seems reasonable, in order to do justice to the language, and in part to supply the incitements of attention just alluded to, that in the former of these two articles a modulation should be used something more harmonious and artificial than in the latter. Agreeably to this reasoning, it is believed, we shall find every reader, on a narrow examination, adopt more or less a modulation thus ornamented: though, after all, it must be acknowledged there are better grounds to believe, that the

---

*estem these properties as respectively belonging to the established laws of pronunciation and the imitative branch of expression mentioned in the end of the ensuing head.*

(e) From what accounts we have remaining of the modulation of the ancients, it appears to have been highly ornamented, and apparently something not unlike our modern recitative; particularly that of their theatrical declamation was music in its strictest sense, and accompanied with instruments. In the course of time and the progress of refinement, this modulation became gradually more and more simple, till it has now lost the genius of music, and is entirely regulated by taste. At home here, every one has heard the ring-song cant, as it is called, of

Ti ti dum dum, ti ti dum ti dum de,
Ti dum ti dum, ti dum ti dum de;

which, though disgustful now to all but to mere rustics on account of its being out of fashion, was very probably the favourite modulation in which heroic verses were recited by our ancestors. So fluctuating are the taste and practices of mankind! But whether the power of language over the passions has received any advantage from the change just mentioned, will appear at least very doubtful, when we recollect the stories of its former triumphs, and the inherent charms of musical sounds.

(Φ) As musical sounds have always an harmonical reference to a key or fundamental note, and to which the mind is still secretly attending, no piece of music would appear perfect, that did not close in it, and so naturally put an end to expectation. But as the tones used in speech are not musical, and therefore cannot refer harmonically to any other sound, there can be no necessity that this terminating sound (and which we immediately below term the cadence) should either be used at all, or follow any particular law as to form, &c. farther than what is imposed by taste and custom.
the practice has been hitherto directed intuitively by nature, than that it was discovered by the inductions of reason. We shall conclude this head with a rule for modulation in reading. "In every thing dramatic, colloquial, or of simple narrative, let your modulation be the same as in speaking; but when the subject is flowery, solemn, or dignified, add something to its harmony, diversify the key-note, and increase the frequency of cadences in proportion to the merit of the composition."

It will readily be seen, that the precepts here drawn from a comparison between speaking and reading, would be very inadequate, were they left destitute of the assistance of taste, and the opportunity of frequently hearing and imitating masterly readers. And indeed, to these two great auxiliaries we might very properly have referred the whole matter at once, as capable of giving sufficient directions, had we not remembered that our plan required us to found several of our rules as much on the principles of a philosophical analysis, as on those more familiar ones which will be found of greater efficacy in real practice.

IV. Expression. 1. There is no composition in music, however perfect as to key and melody, but, in order to do justice to the subject and ideas of the author, will require, in the performing, something more than an exact adherence to tune and time. This something is of a nature, too, which perhaps can never be ade-
quately pointed out by any thing graphic, and results entirely from the taste and feeling of the performer. It is that which chiefly gives music its power over the passions, and characterises its notes with what we mean by the words sweet, harsh, dull, lively, plaintive, joyous, &c. for it is evident every sound, considered ab-
stractedly, without any regard to the movement, or high and low, may be thus modified. In practical music, this commanding particular is called Expression; and as we find certain tones analogous to it frequently coa-
lescing with the modulation of the voice, which indicate our passions and affections (thence more particularly pointing out the meaning of what we say) the term is usually applied in the same sense to speaking and reading.

These tones are not altogether peculiar to man.---Every animal, that is not dumb, has a power of making several of them. And from their being able, unassisted by words, to manifest and raise their kindred emotions, they constitute a kind of language of themselves. In this language of the heart man is eminently conversant; for we not only understand it in one another, but also in many of the inferior creatures subjected by providence to our service.

The expression here illustrated is one of the most es-
sential articles in good reading, since it not only gives a finishing to the sense, but, on the principles of sympathy and antipathy, has also a peculiar efficacy in interesting the heart. It is likewise an article of most difficult at-
tainment; as it appears from what follows, that a mas-

terly reader ought not only to be able to incorporate it with the modulation properly as to quality, but in any degree as to quantity.

Every thing written being a proper imitation of speech, expressive reading must occasionally partake of all its tones. But from what was said above, of the difference between reading and speaking, it follows, reason-

able, that these signs of the emotions should be less strongly characterised in the former article than in the latter. Again, as several of these tones of expression are in themselves agreeable to the mind, and raise in us agree-
able emotions (as those of pity, remorse, or whatever indicates happiness and goodness of heart), and others disagreeable (as those of a boisterous, rude, violent, and depraved nature, &c.) it farther appears, since reading is an art improving and not imitating nature, that, in whatever degree we abate the expressions of the tones above alluded to in the first case, it would be eligible to make a greater abatement in the latter. But as to the quantities and proportional magnitudes of these abate-
ments, they, like many other particulars of the same nature, must be left solely to the taste and judgment of the reader.

To add one more remark, which may be of service on more accounts than in suggesting another reason for the doctrine above. Let it be remembered, that though in order to acquit himself agreeably in this article of expression, it will be necessary every reader should feel his subject as well as understand it; yet, that he may preserve a proper ease and masterliness of delivery, it is also necessary he should guard against discovering too much emotion and perturbation.

From this reasoning we deduce the following rule, for the tones which indicate the passions and emotions.

"In reading, let all your tones of expression be bor-
rowed from those of common speech, but something more faintly characterised. Let those tones which signi-

y any disagreeable passion of the mind, be still more faint than those which indicate their contrary; and pre-

serve yourself so far from being affected with the subject, as to be able to proceed through it with that peculiar kind of ease and masterliness, which has its charms in this as well as every other art."

We shall conclude this section with the following ob-
observation, which relates to speaking as well as reading. When words fall in our way, whose "sounds seem an echo to the sense," as squirr, buzz, hum, rattle, his, jar, &c. we ought not to pronounce them in such a man-
ner as to heighten the imitation, except in light and ludi-
crous subjects. For instance, they should not in any other case be sounded squirrr, buzz, um, mm, m,
rrrattle, &c. On the contrary, when the imitation lies in the movement, or flow and structure of a whole passage (which frequently happens in poetry), the deliv-
ery may always be allowed to give a heightening to it with the greatest propriety; as in the following in-
stances, out of a number more which every experienced rea-
der will quickly recollect.

In these deep solitudes and awful cells,
Where heav'nly pensive Contemplation dwells,
And ever-musing Melancholy reigns—

POPE's Eloisa to Abelard.

With easy course
The vessels glide unless their speed be stopp'd
By dead calms, that oft lie on these smooth seas.

DYER'S Fleete

Softly sweet in Lydian measure,
Soon he soothe'd his soul to pleasure.

DRYDEN's Ode on St Cecilia's Day.

Stil
Reading.

Still gathering force it snores, and, urg'd a main,
Whirls, leaps, and thunder'd down impetuous to the plain.

Pope's Iliad, b. 13.

For who to dumb forgetfulness a prey,
This pleasing anxious being ere resign'd,
Left the warm precincts of the cheerful day,
Nor cast one longing lingering look behind?

Gray's Elegy.

Expression. 2. Besides the particular tones and modifications of voice above described, which always accompany and express our inward agitations, nature has in these cases endowed us with another language, which, instead of the ear, addresses itself to the eye, thereby giving the communications of the heart a double advantage over those of the understanding, and as a double chance to preserve so inestimable a blessing. This language is what arises from the different, almost involuntary, movements and configurations of the face and body in our emotions and passions, and which, like that of tones, every one is formed to understand by a kind of intuition.

When men are in any violent agitation of mind, this co-operating expression (as it is called) of face and gesture is very strongly marked, and totally free from the mixture of any thing which has a regard to gracefulness, or what appearance they may make in the eyes of others. But in ordinary conversation, and where the emotions are not so warm, fashionable people are perpetually insinuating, into their countenance and action, whatever they imagine will add to the ease and elegance of their deportment, or impress on the spectator an idea of their amiableness and breeding. Now, though the above-mentioned natural organical signs of the emotions should accompany every thing spoken, yet from what was observed in the introductory part of this article (like the tones we have just treated upon), they should in reading be much less strongly expressed, and those suffer the greatest diminution that are in themselves the most uneasy. And as it was in the last section recommended to the reader to preserve himself as far as from being affected in all passionate subjects as to be able to keep a temperate command over the various affections of the voice, &c. so under the sanction of this subordinate feeling may accompany his delivery more frequently with any easy action or change of face, which will contribute to set off his manner, and make it agreeable on the principles of art.

As these calm decorations of action (as we may call them) are not altogether natural, but have their rise from a kind of institution, they must be modelled by the practices of the polite. And though mankind differ from one another scarce more in any particular than in that of talents for adopting the graceful actions of the body, and hence nothing determinate can be said of their nature and frequency; yet even those, most happily calculated to acquit themselves well in their use, might profit by considering that it is better greatly to abridge the display, than to over-do it ever so little. For the peculiar modesty of deportment with which the inhabitants of this kingdom are endowed, makes us in common endeavour to suppress many signs of an agitated mind; and in such cases the bodily ones in particular are very sparingly used. We have also a natural and rooted dislike to any kind of affectation; and to no species, that we can recollect, a greater, than to that which is seen in a person who pretends to mimicry and courtly gesture, without possessing the advantages and talents they require; and of which not many people, comparatively speaking, have any remarkable share.

The inference of this is too obvious to need drawing out, and we would particularly recommend it to the consideration of those readers who think the common occurrences of a newspaper, &c. cannot be properly delivered without a good deal of elbow room.

Although it is impossible to come to particulars in any directions of this kind, yet there is one article of our present subject on which a serviceable remark may be made. In ordinary discourse, when we are particularly pressing and earnest in what we say, the eye is naturally thrown upon those to whom we address ourselves: And in reading, a turn of this organ now and then upon the hearers, when any thing very remarkable or interesting falls in the way, has a good effect in gaining it a proper attention, &c. But this should not be too frequently used; for if so, besides its having a tendency to confound the natural import of different passages, it may not be altogether agreeable to some to have their own reflexions broken in upon by a signal, which might be interpreted to hint at their wanting regulation.

One observation more, and then we shall attempt to recapitulate the substance of this section in the form of a precept. Though it is, when strictly examined, inconsistent, both in speaking and reading, to imitate with action what we are describing, yet as in any thing comic such a practice may suggest ideas that will accord with those of the subject, it may there be now and then indulged in either of these articles.

In a manner similar to that directed with regard to tones, moderate your bodily expressions of the signs of the emotions. And in order to supply, as it were, this deficiency, introduce into your carriage such an easy gracefulness, as may be consistent with your requirements in these particulars, and the necessary dread which should ever be present of falling into any kind of affectation or grimace.

V. Pauses. Speech consisting of a succession of distinct words, must naturally be liable (both from a kind of accident, and a difficulty there may be in beginning certain sounds or portions of phrases immediately on the ending of certain others) to several small intermissions of voice; of which, as they can have no meaning, nothing farther need here be said. There are, however, some pauses, which the sense necessarily demands; and to these the substance of this section is directed.

The pauses are in part to distinguish the members of sentences from one another, the terminations of complete periods, and to afford an opportunity for taking breath. Besides this, they have a very graceful effect in the modulation, on the same account they are so essential in music.—In both articles, like blank spaces in pictures, they set off and render more conspicuous whatsoever the disjoin or terminate.

Were language made up of nothing but short colloquial sentences, these pauses, though they might do no harm, and would generally be graceful, would however be superseded as to use by the completeness and nor-
Reading. 

Reading, softness, as we may say, of the meaning. But in more diffuse language, composed of several detached sentences, and which require some degree of attention in order to take in the sense, the intermissions of voice under consideration are of the greatest service, by signifying to the mind the progress and completion of the whole passage. Now, though in extensive and differently formed periods there may be members whose completeness of sense might be conceived of various degrees, and hence might seem to require a set of pauses equally numerous; yet, since the sense does not altogether depend upon these intermissions, and their ratios to one another, if capable of being properly defined, could not be accurately observed, grammarians have ventured to conceive the whole class of pauses as reducible to the four or five kinds now in use, and whose marks and ratios are well known (C); presuming that under the eye of taste, and with the assistance of a particular to be next mentioned, they would not fail in all cases to suggest intermissions of voice suitable to the sense. But in many of these extensive and complex periods, rounded with a kind of redundancy of matter, where the full sense is long suspended, and the final words are not very important, there would be some hazard of a misapprehension of the termination, had we not more evident and infallible notice of it than that which is given by the pause. This notice is the cadence, referred to in the section on Modulation; which, as is there observed, besides the ornamental variety it affords, appears from these remarks to be a very necessary and serviceable article in perspicuous delivery.

As this cadence naturally accompanies the end of every entire sense, circumstanced as above mentioned, it may sometimes fall before the semicolon, but more generally before the colon, as well as the period: For these marks are often found to terminate a complete sense: and in these cases, the relation what follows has to what went before, is signified to the mind by the relative shortness of the stop, and the form of introducing the additional matter. Nor can any bad consequence arise from thus founding distinctions on ratios of time, which it may be said are too nice to be often rightly hit upon; for if the confusion should happen between that of the colon and period, there is perhaps so trifling a difference between the nature of the passages they succeed, as to make a small inaccuracy of no consequence. And as to the rests of the semicolon and period, it will not be easy to mistake about them, as their ratio is that of two to one. Add to this the power which the matter and introduction of the subsequent passages have to rectify any slight error here made, and we shall be fully satisfied, that the pauses are as usually explained, with the cadence above described, and a proper knowledge of the language, will convey sufficient information to the understanding of the constructive nature of the passages after which they are found.

It may be observed, that in natural speech, according to the warmth and agitation of the speaker, the rests are often short and injudiciously proportioned, and hence that every thing thus delivered cannot be so graceful as it might have been from a proper attention to their magnitude and effects.

Pauses then, though chiefly subjected to the sense, are, as was remarked at the outset, serviceable in beautifying the modulation, &c. And since books are often inaccurately printed as to points, and people’s tastes differ some little about their place and value, it appears, that “although in reading great attention should be paid to the stops, yet a greater should be given to the sense, and their correspondent times occasionally lengthened beyond what is usual in common speech;” which observation contains all that we shall pretend to lay down by way of rule for the management of pauses in the delivery of written language.

As there are two or three species of writing, which have something singular in them, and, with regard to the manner in which they should be read, a few particular remarks seem necessarily required, we shall conclude this article with laying them before the reader:

1. Of Plays, and such like conversation-pieces. Writings of this kind may be considered as intended for two different purposes: one to unfold subject matter for the exercise of theatrical powers; and the other to convey amusement, merely as fable replete with pleasing incidents and characteristic manners. Hence there appears to be great latitude for the display of a consistent delivery of these performances: for while, on one hand, a good reader of very inferior talents for mimickry may be heard with a tolerable degree of pleasure; on the other, if any person is qualified to give a higher degree of life and force to the dialogue and characters by delivering them as an actor, he must be fully at liberty to start from the confinement of a chair to a posture and area more suited to his abilities; and, if he be not deceived in himself, his hearers will be considerable gainers by the change.—The next article is,

2. Sermons or other orations, which in like manner may be conceived intended for a double purpose. First, as matter for the display of oratorical powers; and, secondly, as persuasive discourses, &c. which may be

(c) Supposing the comma (,) one time, the semicolon (;) will be two; the colon (:) three, and the period (.) as also the marks of interrogation (?) and admiration (!) four of these times. The blank line (— or ——), and the breaks between paragraphs, intimate still greater times; and by the same analogy may be reckoned a double and quadruple period respectively. Now and then these blank lines are placed immediately after the ordinary points, and then they are conceived only as separating for the eye the different natures of the matter;—as a question from an answer,—precept from example,—premises from inferences, &c. in which case their import is evident. But of late some authors have not scrupled to confound these distinctions; and to make a blank serve for all the pauses universally, or the mark of an indefinite rest, the quantity of which is left to the determination of the reader’s taste. A practice, it is imagined, too destructive of the intended precision of these typical notices to be much longer adopted.
be read like any other book. Therefore it appears (for reasons similar to those above) that according as clergymen are possessed of the talents of elocution, they may consistently either rehearse their sermons, in the manner of an extemporary harangue, or deliver them in the more humble capacity of one who is content to entertain and instruct his hearers with reading to them his own or some other person’s written discourse.

That either of these manners of delivery (or a mixture of them), in either of the cases above mentioned, is agreeable, we find on a careful examination. For this will show us how frequently they run into one another; and that we are so far from thinking such transitions wrong, that, without a particular attention that way, we scarce ever perceive them at all.

3. POETRY is the next and last object of our present remarks. This is a very peculiar kind of writing, and as much different from the language of ordinary discourse as the movements of the dance are from common walking. To ornament and improve whatever is subservient to the pleasures and amusements of life, is the delight of human nature. We are also pleased with a kind of excess in any thing which has a power to amuse the fancy, inspire us with enthusiasm, or awaken the soul to a consciousness of its own importance and dignity. Hence one pleasure, at least, takes its rise, that we feel in contemplating the performances of every art; and hence the language of poetry, consisting of a measured rhythmus, harmonious cadences, and an elevated picturesque diction, has been studied by the ingenious, and found to have a powerful influence over the human breast in every age and region. There is such an affinity between this language and music, that they were in the earlier ages never separated; and though modern refinement has in a great measure destroyed this union, yet it is with some degree of difficulty in rehearsing these divine compositions we can forget the singing of the muse.

From these considerations (and some kindred ones mentioned in sect. ii.) in repeating verses they are generally accompanied with a modulation rather more ornamented and musical than is used in any other kind of writing. And accordingly, as there seems to be the greatest propriety in the practice, the rule for this particular in the section just referred to, will allow any latitude in it that can gain the sanction of taste and pleasure.

Rhymes in the lighter and more soothing provinces of poetry are found to have a good effect; and hence (for reasons like those just suggested) it is certainly absurd to endeavour to smother them by a feeble pronunciation, and running one line precipitately into another, as is often affected to be done by many of our modern readers and speakers. By this method they not only destroy one source of pleasure intended by the composer (which though not great is nevertheless genuine), but even often supply its place with what is really disagreeable, by making the rhymes, as they are interruptedly perceived, appear accidental blemishes of a different style, arising from an unmeaning recurrence of similar sounds. With regard then to reading verses terminated with rhyme, the common rule, which directs to pronounce the final words full, and to distinguish them by a slight pause even where there is none required by the sense, seems the most rational, and conse-

quentely most worthy of being followed. See DECLAMATION, NARRATION, and ORATORY.

READING, a town of Berkshire in England, pleasantly situated on the river Kennet, near its confluence with the Thames. It had once a fine rich monastery, of which there are large ruins remaining. It had also a castle built by King Henry I. afterwards ruined. It is a corporation, enjoys several privileges, and sends two members to parliament. The two navigable rivers render it a fit place for trade. It had 10,738 inhabitants in 1811. W. Long. 1. c. N. Lat. 51. 25.

READINGS, or Various READINGS, in criticism, are the different manners of reading the texts of authors in ancient manuscripts, where a diversity has arisen from the corruption of time, or the ignorance of copyists. A great part of the business of critics lies in settling the readings by confronting the various readings of the several manuscripts, and considering the agreement of the words and sense. Readings are also used for a sort of commentary or gloss on a law, text, passage, or the like, to shew the sense an author takes it in, and the application he conceives to be made of it.

RE-AGGRAVATION, in the Roman ecclesiastical law, the last monitory, published after three admonitions, and before the last excommunication. Before they proceed to fulminate the last excommunication, they publish an aggravation, and a re-aggravation. Fevret observes, that in France the minister is not allowed to come to re-aggravation, without the permission of the bishop or official, as well as that of the lay judge. See EXCOMMUNICATION.

REAL, CÉASAR VICHARD DE ST, a polite French writer, son of a counsellor to the senate of Chambery in Savoy. He came young to France, distinguished himself at Paris by several ingenious productions, and resided there a long time without title or dignity, intent upon literary pursuits. He died at Chambery in 1692, advanced in years, though not in circumstances. He was a man of great parts and penetration, a lover of the sciences, and particularly fond of history. A complete edition of his works was printed at Paris, in 3 vols 4to. 1715, and another in 6 vols 12mo.

REAL PRESENCE. See TRANSUBSTANTIATION.

REALGAR, a preparation of arsenic. See ARSENIC.

REALNEY, CHEMISTRY Index.

REALISTS, a sect of school philosophers formed in opposition to the Nominalists. Under the Realists are included the Scotists, Thomists, and all excepting the followers of Ocham. Their distinguishing tenet is, that universals are realities, and have an actual existence out of an idea or imagination; or, as they express it in the schools, a parte rei; whereas the nominalists contend, that they exist only in the mind, and are only ideas, or manners of conceiving things.—Dr Odo, or Oudard, a native of Orleans, afterwards abbot of St Martin de Tournay, was the chief of the sect of the realists. He wrote three books of dialectics, where, on the principles of Boëthius and the ancients, he maintained that the object of that art is things, not words; whence the sect took its rise and name.

REALITY, in the schools, a diminutive of res, "thing," first used by the Scotists, to denote a thing which may exist of itself; or which has a full and absolute
REALE, a country which gives its head or governor the denomination of a king.

RE-ANIMATION means the reviving or restoring to life those who are apparently dead. Sudden death is dreaded by every human being, and it is one of those evils against which the Church of England prays in her Litany. Accidents, however, cannot always be prevented; but, after they have happened, it is often possible to prevent their effects. This, by the establishment of what with great propriety has been called the Humane Society, has been abundantly proved: for, in the course of 12 years immediately after their institution, they were the means of saving the lives of 850 persons, who otherwise would in all human probability have been lost to the community. Since that period, they have saved many more; and various persons, even in the most distant parts of the kingdom, by following their directions, have done the same. To preserve one human being from premature death, we must consider as of the utmost consequence both as citizens and Christians; how much more the preservation of thousands. It appears from the writings of Doctors Mead, Winlow, Bruhier, Fothergill, Haller, Lecat, Tessot, Van Engelen, Guummer, and others, that they had prepared the way for institutions similar to the Humane Society: for in their works they have elucidated the principles on which they go, and furnished directions for the practice they favour. See DEATH, Premature INTERMENT, and DROWNING.

REAR, a term frequently used in composition, to denote something behind, or backwards, in respect of another; in opposition to VAN.

REAR of an Army, signifies, in general, the hindermost part of an army, battalion, regiment, or squadron; also the ground behind either.

REAR-Guard, is that body of an army which marches after the main-body; for the march of an army is always composed of an advanced-guard, a main body, and a rear-guard; the first and last commanded by a general. The old grand guards of the camp always form the rear-guard of the army, and are to see that every thing come safe to the new camp.

REAR Half files, are the three hindmost ranks of the battalion, when it is drawn up six deep.

REAR-Line of an army encamped, is always 1200 feet at least from the centre line; both of which run parallel to the front line, as also to the reserve.

REAR-Rank, is the last rank of a battalion, when drawn up, and generally 16 or 18 feet from the centre line when drawn up in open order.

REASON, a faculty or power of the mind, whereby it distinguishes good from evil, truth from falsehood. See METAPHYSICS.

REASONING, Ratiocination, the exercise of that faculty of the mind called reason; or it is an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known. See LOGIC, Part III.

REAUAMUR, RENE ANTOINE FERCAULT, SIEUR DE, a person distinguished for his laborious researches into natural knowledge, was born at Rochelle in 1683, of a family belonging to the law. After having finished his early studies in the place of his birth, he began a course of philosophy at Poitiers, and of civil law at Reims Bourges; but soon relinquished the latter, to apply himself, according to his taste, to mathematics, physics, and natural history. Being come to Paris, he was received into the Academy of Sciences in 1708. From that hour he was wholly employed in natural history, to which his inclination particularly led him, and his inquiries were not confined to any one part of it. His memoirs, his observations, his discoveries on the formation of shells, spiders, muscles, the marine flea, the berry which affords the purple colour, and on the cause of the numinosity of the torpedo, excited the curiosity of the public, and early procured our author the character of an able, curious, and entertaining naturalist. Filled with zeal for the welfare and advantage of society, and the progress and perfection of arts, he endeavoured in all his researches to promote the public good. We were indebted to him for the discovery of the turquois mines in Languedoc. He also found out a substance, which is used to give false stones a colour, which is obtained from a certain fish called in the French Able or Abete; * See ft. 203. Blay of our writers. His experiments on the art of turning iron into steel obtained him a pension of 12,000 livres; and this reward was to be continued to the Academy to support the expense which might accrue in this art.

He continued his inquiries on the art of making tin and porcelain, and endeavoured to render our terracottameters more useful than those of former times; he composed a curious history of rivers where gold dust is found in France; and gave so simple and easy a detail of the art of gathering this dust, that persons have been employed for that purpose.

He also made curious and important observations on the nature of flints, on the banks of fossil shells, from whence is obtained in Touraine an excellent manure for land; as likewise on birds and their preservation, on their method of building nests; on insects; and a great number of other subjects, not less curious than useful.

He imagined at first, that a certain varnish would keep eggs fresh; but the waste of time and money, &c. showed him the inconvenience of such a process. He afterwards adopted the method practised for time immemorial in Greece and the islands of the Archipelago, which is to steep or immerse eggs in oil, or melted fat; by this means, not being exposed to the air or to frost, they are well preserved, and contract no bad smell. Another experiment still more important made by our author, was to introduce into France the art of hatching fowls and birds, as practised in Egypt, without covering the eggs. Active, sedulous, and attentive, he was early in his study, often at six in the morning. Exact in his experiments and observations, he let no circumstance escape him. His writings must be of great use to future philosophers. In society, he was distinguished through life for his modest and agreeable behaviour. His probity, benevolence, goodness of heart, and other amiable qualities, as well natural as acquireed, endeared him to his countrymen. He died in the 76th year of his age, on the 18th of October 1757, and left this world filled with sentiments of piety. His death was the consequence of a fall, which happened at the castle of Barnardiere on the Maine, where he went to pass his vacation. He bequeathed to the Academy of Sciences...
REBELLION, Rebellio, among the Romans, was a term where those who had been formerly overcome in battle, and yielded to their subjection, made a second resistance; but with us it is generally used for the taking up arms traitorously against the king, whether by natural subjects, or others when once subdued; and the word rebel is sometimes applied to him who wilfully breaks a law; also to a villain disobeying his lord.

There is a difference between enemies and rebels. Enemies are those who are out of the king’s allegiance: therefore subjects of the king, either in open war, or rebellion, are not the king’s enemies, but traitors. And David prince of Wales, who levied war against Edw. I., because he was within the allegiance of the king, had sentence pronounced against him as a traitor and rebel. Private persons may arm themselves to suppress rebels, enemies, &c.

REBELLIous assembly, is a gathering together of twelve persons or more, intending or going about to practice or put in use unlawfully, of their own authority, any thing to change the law or statutes of the realm; or to destroy the inclosures of any ground, or banks of any fish-pond, pool, or conduit, to the intent the same shall lie waste and void; or to destroy the deer in any park, or any barren of conies, doves, or fish in ponds; or any house, barns, mills, or bays; or to burn stacks of corn; or abate rents, or prices of victuals, &c.

REBUS, an enigmatical representation of some name, &c., by using figures or pictures instead of words, or parts of words. Camden mentions an instance of this absurd kind of wit in a gallant who expressed his love to a woman named Rose Hill, by painting in the border of his gown a rose, a hill, an eye, a loaf, and a well, which, in the style of the rebus, reads, "Rose Hill I love well." This kind of wit was long practised by the great, who took the pains to find devices for their names. It was, however, happily ridiculed by Ben Jonson, in the humorous description of Abel Drugger’s device in the Alchemist; by the Spectator, in the device of Jack of Newberry; at which time the rebus, being raised to sign-posts, was grown out of fashion at court.

REBUS is also used by the chemical writers sometimes to signify some m.i.k., and sometimes for what they call the ultimate matter of which all bodies are composed.

REBUS, in Heraldry, a coat of arms which bears an allusion to the name of the person; as three castles, for Castleton; three cups, for Butler; three conies, for Conisby; a kind of bearings which are of great antiquity.

REUBER, (from the Fr. boner, i.e. repellere, to put back or bar), is the answer of defendant to plaintiff’s surrejoinder; and plaintiff’s answer to the rebutter is called a surrebutter; but it is very rare the parties go so far in pleading.

REBUTTER is also where a man by deed or fine grants to warranty any land or hereditament to another; and the person making the warranty, or his heir, sues him to whom the warranty is made, or his heir or assignee, for the same thing; if he who is so sued pleads the deed or fine with warranty, and pray judgment, if the plaintiff shall be received to demand the thing which he ought to warrant to the party against the warranty in the deed, &c. this is called a rebutter. And if I grant to a tenant,
Recpetition, or Recapitulation, is a summary, or a concise and transient enumeration of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view. See Oratory, No. 37 and 127.

Recension, or Recensio, was an account taken by the censors, every lustrum, or half of the Roman people. It was a general survey; at which the equites, as well as the rest of the people, were to appear. New names were now put upon the censor’s list; and old ones cancelled. The recensio, in short, was a more solemn and accurate sort of probatio, and answered the purpose of a review, by showing who were fit for military service.

Receipt, in Botany, one of the seven parts of fruitification, defined by Linneus to be the base which connects or supports the other parts.

Receptaculum Chylis, or Pecquet’s Reservoir, the reservoir or receptacle for the chyle, situated in the left side of the upper vertebra of the loins, under the sora and the vessels of the left kidney.

Rechabites, a kind of religious order among the ancient Jews, instituted by Jonadab the son of Rechab, comprehending only his own family and posterity. Their founder prescribed them three things: first, not to drink any wine; secondly, not to build any houses, but to dwell in tents; and thirdly, not to sow any corn, or plant vines.

The Rechabites observed these rules with great strictness, as appears from Jer. xxxvi. 6, &c. Wherein St Jerome, in his 18th epistle to Paulinus, calls them monachi, monks. Jonadab, their founder, lived under Jeshobiah, king of Judah, contemporary with Jehu king of Israel; his father Rechab, from whom his posterity were demoted, descended from Raguel or Jethro, father-in-law to Moses, who was a Kenite, or of the race of Ken: whence Kenite and Rechabite are used as synonymous in Scripture.

Recheat, in hunting, a lesson which the huntsman plays on the horn, when the hounds have lost their game, to call them back from pursuing a counter scent.

Recipe, in Medicine, a prescription, or remedy, so called because always beginning with the word recipe, i.e., take; which is generally denoted by the abbreviature Rx. See Prescription, Extemporaneus.

Reciprocal, in general, something that is mutual, or which is returned equally on both sides, or that affects both parties alike.

Reciprocal Terms, among logicians, are those which have the same significiation; and consequently are convertible, or may be used for each other.

Reciprocal, in Mathematics, is applied to quantities which multiplied together produce unity. Thus x and y are reciprocal quantities. Likewise 1 is said to be the reciprocal of x, which is again the reciprocal of 1.

Reciprocal Figures, in Geometry, those which have the antecedents and consequents of the same ratio both figures.

Reciprocal Proportion, is when in four numbers the fourth is less than the second by so much as the first is greater than the third, and vice versa. See Proportion and Arithmetic, chap. vi. Great use is made of this reciprocal proportion by Sir Isaac Newton and others, in demonstrating the laws of motion.

Recital, in Law, means the rehearsing or making mention in a deed or writing of something which has been done before.

Recitativo, or Recitative, in Music, a kind of singing, that differs but little from ordinary recitation; such as that in which several parts of the liturgy are rehearsed in cathedrals; or that which actors commonly deliver themselves on the stage of opera, when they are to express some action or passion; to relate some event; or to reveal some design.

Reckenhausen, a strong town of Cologne, now of the Rhenish Prussia provinces. The abbess of its nunnery had formerly the power of punishing offenders with death, and she alone was obliged to the vow of chastity.

Reckoning, or a Ship’s Reckoning, in Navigation, is that account whereby at any time it may be known where the ship is, and on what course or course she is to steer, in order to gain her port; and that account taken from the log-board is called the dead reckoning. See Navigation.

Reclaiming, or Reclaiming, in our ancient customs, a lord’s pursuing, prosecuting, and recalling his vassal, who had gone to live in another place without his permission.

Reclaiming is also used for the demanding of a person, or thing, to be delivered up to the prince or state to which it properly belongs; when, by any irregular means, it is come into another’s possession.

Reclaiming, in Fowling, is taming a hawk, &c. and making her gentle and familiar.

A partridge is said to reclaim, when she calls the young ones together, upon their scattering too far from her.

Reclination of a Plane, in Dialling. See Dialling.

Recluse, among the Papists, a person shut up in a small cell of a hermitage, or monastery, and cut off not only from all conversation with the world, but also with the house. This is a kind of voluntary imprisonment, from a motive either of devotion or penance.

The word is also applied to incontinent wives, whose husbands procure to be thus kept in perpetual imprisonment in some religious house.
Recluses were anciently very numerous. They took an oath never to stir out of their retreat; and having entered it, the bishop set his seal upon the door; and the reclus was to have every thing necessary for the support of life conveyed to him through a window. If he was a priest, he was allowed a small oratory, with a window, which looked into the church, through which he might make his offerings at the mass, hear the singing, and answer those who spoke to him; but this window had curtains before it, so that he could not be seen. He was allowed a little garden, adjoining to his cell, in which he might plant a few herbs, and breathe a little fresh air. If he had disciples, their cells were contiguous to his, with only a window of communication, through which they conveyed necessaries to him, and received his instructions. If a reclus fell sick, his door might be opened for persons to come in and assist him, but he himself was not to stir out.

RECOGNITION, in Law, an acknowledgement; a word particularly used in our law books for the first chapter of the statute 1 Jac. I. by which the parliament acknowledged, that, after the death of Queen Elizabeth, the crown had rightfully descended to King James.

RECOGNIZANCE, in Law, is an obligation of record, which a man enters into before some court of record or magistrate duly authorised, with condition to do some particular act; as to appear at the assizes, to keep the peace, to pay a debt, or the like. It is in most respects like another bond: the difference being chiefly this, that the bond is the creation of a fresh debt or obligation de novo, the recognizance is an acknowledgement of a former debt upon record; the form whereof is, "that A. B. doth acknowledge to owe to our lord the king, to the plaintiff, to C. D. or to the like, the sum of ten pounds," with condition to be void on performance of the thing stipulated: in which case the king, the plaintiff, C. D. &c. is called the cognizer, i.e. cui cognoscitur; as he that enters into the recognizance is called the cognizer, is qui cognoscit. This being certified to, or taken by the officer of some court, is witnessed only by the record of that court, and not by the party's seal: so that it is not in strict propriety a deed, though the effects of it are greater than a common obligation; being allowed a priority in point of payment, and binding the lands of the cognizor from the time of enrolment on record.

RECOIL, or REBOUND, the starting backward of a fire-arm after an explosion. Mersennus tells us, that a cannon 12 feet in length, weighing 640 lbs. gives a ball of 24 lb. an uniform velocity of 640 feet per second. Putting, therefore, \( W = 6400 \), \( w = 14 \), \( V = 640 \), and \( v = \) the velocity with which the cannon recoils; we shall have (because the moments of the cannon and ball are equal) \( W = 640 \), and so \( v = \frac{W}{V} \) = 24.3; that is, it would recoil at the rate of 24.3 feet per second, if free to move.

RECOLLECTION, a mode of thinking, by which ideas sought after by the mind are found and brought to view.

RECONNOITRE, in military affairs, implies to view and examine the state of things, in order to make RECONNOITRE a report thereof.

Parties ordered to reconnoitre are to observe the country and the enemy; to remark the routes, conveniences, and inconveniences of the first; the position, march, or forces of the second. In either case, they should have an expert geographer, capable of taking plans readily; he should be the best mounted of the whole, in case the enemy happen to scatter the escort, that he may save his work and ideas. See WAR.

RECORD, an authentic testimony in writing, contained in rolls of parchment, and preserved in a court of record. See COURT.

TRIAL by RECORD, a species of trial which is used only in one particular instance: and that is where a matter of record is pleaded in any action, as a fine, a judgement, or the like; and the opposite party pleads, nulli record, that there is no such matter of record existing. Upon this, issue is tendered and joined in the following form, "and this he prays may be inquired of by the record, and the other doth the like;" and here-upon the party pleading the record has a day given him to bring it in, and proclamation is made in court for him to bring forth the record by him pleading alleged, or else he shall be condemned; and, on his failure, his antagonist shall have judgment to recover. The trial, therefore, of this issue is merely by the record: for, as Sir Edward Coke observes, a record or enrollment is a monument of so high a nature, and importhe in itself such absolute verity, that if it be pleaded that there is no such record, it shall not receive any trial by witness, jury, or otherwise, but only by itself. Thus titles of nobility, as whether earl or not earl, baron or not baron, shall be tried by the king's writ or patent only, which is matter of record. Also in case of an alien, whether alien friend or enemy, shall be tried by the league or treaty between his sovereign and ours; for every league or treaty is of record. And also, whether a man be held in ancient demesne or not, shall be tried by the record of domesday in the king's exchequer.

RECORDE, ROBERT, physician, and mathematician, was descended of a respectable family in Wales, and lived in the time of Henry VIII. Edward VI. and Mary. The time of his birth is not exactly known, but it must have been about the beginning of the 16th century; for he was entered of the university of Oxford about 1525, and was elected fellow of All-Souls college in 1527. As he made physic his profession, he went to Cambridge, where he was honored with the degree of doctor in that faculty in 1545, and very much esteemed by all who were acquainted with him, for his extensive knowledge of many of the arts and sciences. He afterwards returned to Oxford, where he publicly taught arithmetic and mathematics, as he had done prior to his going to Cambridge, and that with great applause. It appears that he afterwards went to London, and was, it is said, physician to Edward VI. and to Mary, to whom some of his books are dedicated; yet he was buried in the king's-bench prison, Southwark, where he was confined for debt in the year 1558, at a very immature age.

He published several works on mathematical subjects, chiefly in the form of dialogue between master and scholar, of which the following is a list:

The Pathway to Knowledge, containing the first principle
REC [ 664 ]

The Ground of Arts, teaching the perfect works and practice of Arithmeticke, both in whole numbers and fractions, after a more easie and exacte forme then in former time hath been set forth, 8vo, 1552.

The Castle of Knowledge, containing the Explication of the Sphere both Celestiall and Materiall, and divers other things incident thereto. With sundry pleasant proverbs and certaine newe demonstrations not written before in any vulgare worikes. Lond. fol. 1556.

The Whetstone of Witte, which is the second part of Arithmetike, containing the extraction of roots; the Cossike practice, with the rules of equation; and the worikes of surde numbers. Lond. 4to, 1557.

Wood says that he was the author of several pieces on physic, anatomy, politics, and divinity, but it is uncertain whether these were ever published. Sherburne says that he also published Cosmographic Ianogenae; that he wrote a book De arte facienda horologiwm, and another De usu gibborum, et de statu temporum, none of which we have had an opportunity of seeing.

RECORDE, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

The recorder of London is chosen by the lord mayor and aldermen; and as he is held to be the mouth of the city, delivers the judgment of the courts therein, and records and certifies the city-customs. See LONDON, No 78.

RECOVERY, or Common Recovery, in English law, a species of assurance by matter of record; concerning the original of which it must be remarked, that common recoveries were invented by the ecclesiastics to elude the statutes of mortmain (see TAIL); and afterwards encouraged by the finesse of the courts of law in 12 Edward IV, in order to put an end to all fettered inheritances, and bar not only estates-tail, but also all remainders and reversions expectant thereon. We have here, therefore, only to consider, first, the nature of a common recovery; and, secondly, its force and effect.

1. A common recovery is a suit or action, either actual or fictitious: and in it the lands are recovered against the tenant of the freehold; which recovery, being a supposed adjudication of the right, binds all persons, and vests a free and absolute fee-simple in the recoverer. To explain this as clearly and concisely as possible, let us, in the first place, suppose David Edwards to be tenant of the freehold, and desirous to suffer a common recovery, in order to bar all entails, remainders, and reversions, and to convey the same in fee-simple, to Francis Golding. To effect this, Golding is to bring an action against him for the lands; and he accordingly sues out a writ called a praecipe quod reddat, because these were its initial or most operative words when the law proceedings were in Latin. In this writ the demandant Golding alleges, that the defendant Edwards (here called the tenant) has no legal title to the land; but that he came into possessi-
Recovery.

Edition in lands from the common vouchee (which there is a possibility in contemplation of law, though a very improbable one, of his doing), these lands would supply the place of those so recovered from him by collusion, and would descend to the issue in tail. The reason will also hold with equal force as to most remainder-men and reversions, to whom the possibility will remain and revert, as a full recompense for the reality which they were otherwise entitled to: but it will not always hold; and therefore, as Pigott says, the judges have been even astutis, in inventing other reasons to maintain the authority of recoveries. And, in particular, it hath been said, that though the estate-tail is gone from the recoveree; yet it is not destroyed, but only transferred, and still subsists; and will ever continue to subsist (by construction of law) in the recoverer, his heirs and assigns: and as the estate-tail so continues to subsist for ever, the remainders or reversions expectant on the determination of such estate-tail can never take place.

To such awkward shifts, such subtle refinements, and such strange reasonings, were our ancestors obliged to have recourse, in order to get the better of that stubbon statutes de donis. The design for which these contrivances were set on foot, was certainly laudable; the unriveting the fitters of estates-tail, which were attended with a legion of mischiefs to the commonwealth: but, while we applaud the end, we cannot but admire the means. Our modern courts of justice have indeed adopted a more manly way of treating the subject; by considering common recoveries in no other light than as the formal mode of conveyance by which tenant in tail is enabled to alienate his land. But, since the ill consequences of fettered inheritances are now generally seen and allowed, and of course the utility and expediency of setting them at liberty are apparent, it hath often been wished that the process of this conveyance was shortened, and rendered less subject to niceties, by either totally repealing the statutes de donis; which perhaps, by reviving the old doctrine of conditional fees, might give birth to many litigations: or by vesting in every tenant in tail, of full age, the same absolute fee-simple estate, which now he may obtain whenever he pleases, by the collateral fiction of a common recovery; though this might possibly bear hard upon those in remainder or reversion, by abridging the chances they would otherwise frequently have, as no recovery can be suffered in the intervals between term and term, which sometimes continue for near five months together: or, lastly, by empowering the tenant in tail to bar the estate-tail by a solemn deed, to be made in term-time, and enrolled in some court of record; which is liable to neither of the other objections, and is warranted not only by the usage of our American colonies, but by the precedent of the statute 21 Jac. I. c. 19. which, in the case of a bankrupt tenant in tail, empowers his commissioners to sell the estate at any time, by deed indented and enrolled. And if, in so national a concern, the emoluments of the officers concerned in passing recoveries are thought to be worthy attention, those might be provided for in the fees to be paid upon each enrollment.

2. The force and effect of common recoveries may appear from what has been said, to be an absolute bar not only of all estates-tail, but of remainders and reversion expectant on the determination of such estates.

So that a tenant in tail may, by this method of assurance, convey the lands held in tail to the recoverer his heirs and assigns, absolutely free and discharged of all conditions and limitations in tail, and of all remainders and reversions. But, by statute 34 and 35 H. VII. c. 20. no recovery had against tenant in tail of the king's gift, whereof the remainder or reversion is in the king, shall bar such estate-tail, or the remainder or reversion of the crown. And by the statute 11 H. VII. c. 20. no woman, after her husband's death, shall suffer a recovery of lands settled on her by her husband, or settled on her husband and her by any of his ancestors. And by statute 14 Eliz. c. 8. no tenant for life, of any sort, can suffer a recovery so as to bind them in remainder or reversion. For which reason, if there be tenant for life, with remainder in tail, and other remainders over, and the tenant for life is desirous to suffer a valid recovery, either he, or the tenant to the præcipite by him made, must vouch the remainder-man in tail, otherwise the recovery is void: but if he does vouch such remainder-man, and he appears and vouches the common vouchee, it is then good; for if a man be vouched and appears, and suffers the recovery to be had, it is as effectual to bar the estate-tail as if he himself were the recoveree.

In all recoveries, it is necessary that the recoveree, or tenant to the præcipite, as he is usually called, be actually seized of the freehold, else the recovery is void. For all actions to recover the seizin of lands must be brought against the actual tenant of the freehold, else the suit will lose its effect; since the freehold cannot be recovered of him who has it not. And, though these recoveries are in themselves fabulous and fictitious, yet it is necessary that there be actœres fabulae, properly qualified. But the nicety thought by some modern practitioners to be requisite in conveying the legal freehold, in order to make a good tenant to the præcipite, is removed by the provisions of the statute 14 Geo. II. c. 20. which enacts, with a retrospect and conformity to the ancient rule of law, that, though the legal freehold be vested in lessees, yet those who are entitled to the next freehold estate in remainder, or reversion, may make a good tenant to the præcipite; and that, though the deed or fine which creates such tenant be subsequent to the judgment of recovery, yet if it be in the same term, the recovery shall be valid in law: and that though the recovery itself do not appear to be entered, or be not regularly entered on record, yet the deed to make a tenant to the præcipite, and declare the uses of the recovery, shall after a possession of 20 years be sufficient evidence on behalf of a purchaser for valuable consideration, that such recovery was duly suffered.

Recovery of persons drowned, or apparently dead. See RE-ANIMATION, and the articles there referred to.

Recreant, Cowardly, Faint-hearted; formerly a word very reproachful. See Battel.

Recrement, in Chemistry, some superfluous matter separated from some other that is useful; in which sense it is the same with scories, scapes, and excrements.

Recrimination, in Law, an accusation brought by the accused against the accuser upon the same fact.

Recruits, in military affairs, new-raised soldiers designed to supply the place of those who have lost
RECTANGLE, in Geometry, the same with a right-angled parallelogram. See GEOMETRY.

RECTIFICATION, in Chemistry, is nothing but the repetition of a distillation or sublimation several times, in order to render the substance purer, finer, and freer from aqueous and earthy parts.

RECTIFICATION, in Geometry, is the method of finding a right line equal to a curve. The rectification of curves is a branch belonging to the higher geometry, in which the use of the inverse method of fluxions is of singular utility.

RECTIFICATION of Spirits. See DISTILLATION.

RECTIFIER, in Navigation, an instrument consisting of two parts, which are two circles, either laid one upon, or let into the other, and so fastened together in their centres, that they represent two compasses, one fixed, the other moveable: each of them divided into the 32 points of the compass, and 360°, and numbered both ways, from the north and the south, ending at the east and west, in 90°.

The fixed compass represents the horizon, in which the north and all the other points of the compass are fixed and immovable.

The moveable compass represents the mariner's compass; in which the north and all other points are liable to variation.

In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass. But if the instrument be made of wood, there is an index instead of the thread.

Its use is to find the variation of the compass, to rectify the course at sea; having the amplitude or azimuth given.

RECTIFYING the GLOBE. See GEOGRAPHY INDEX.

RECTILINEAR, in Geometry, right-lined; thus figures whose perimeter consists of right lines, are said to be rectilinear.

RECTITUDE, in Philosophy, refers either to the act of judging or of willing; and therefore whatever comes under the denomination of rectitude, is either what is true or what is good, these being the only objects about which the mind exercises its two faculties of judging and willing.

Moral rectitude, or uprightness, is the choosing and pursuing those things which the mind, upon due inquiry and attention, clearly perceives to be good; and avoiding those that are evil. See MORAL PHILOSOPHY.

RECTOR, a term applied to several persons whose offices are very different: 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tithes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris, and also in those of Scotland. It is also applied to the head master of large schools in Scotland, as in the high school of Edinburgh. 3. Rector is also used in several convents for the superior officer who governs the house: and the Jesuits give this name to the superiors of such of their houses as are either seminaries or colleges.

RECTORY, a parish-church, parsonage, or spiritual living, with all its rights, tithes, and glebes.

RECTORY is sometimes used for the rector's mansion or parsonage-house.

RECTUM, in Anatomy, the third and last of the large intestines or guts. See ANATOMY, No. 93.

RECTUS, in Anatomy, a name common to several pairs of muscles, so called on account of the straightness of their fibres.

RECUERATORI, among the Romans, were commissioners appointed to take cognizance of private matters in dispute, between the subjects of the state and foreigners, and to take care that the former had justice done them. It came at last to be used for commissioners, to whom the praetor referred the determination of any affair between one subject and another.

RECURRENTS, in Anatomy, a name given to several large branches of nerves sent out by the par vagum from the upper part of the thorax to the larynx.

RECURVIFORMA, a genus of birds belonging to the order of grallae of Linnaeus, and that of palmeides of Pennant and Latham. See ORNITHOLOGY INDEX.

RECUERANTS, such persons as acknowledge the pope to be the supreme head of the church, and refuse to acknowledge the king's supremacy; who are hence called Papish recuents. The penal laws against Papists are now abolished in Britain and in Ireland; and in all probability they will quickly be allowed the amplest privileges.

RED, one of the colours called simple or primary: being one of the shades into which the light naturally divides itself when refracted through a prism. See CHROMATICS.

RED, in Dyeing, see that article.—Some reckon six kinds or casts of red, viz. scarlet-red, crimson-red, madder-red, half-grain red, lively orange-red, and scarlet of cochineal: but it is easy to see that there can be but one proper species of red; namely, the reflection of the light exactly in such a manner as it is refracted by the prism; all other shades being adulterations of that pure colour, with yellow, brown, &c.

RED, in Heraldry. See Gules.

REDBird. See MUSCICAPA, ORNITHOLOGY INDEX.

REDBreast. See MOTACILLA, ORNITHOLOGY INDEX.

RED-Book of the exchequer, an ancient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellany treatises relating to the times before the conquest.

RED-Lead. See CHEMISTRY INDEX.

RED-Precipitate of Mercury. See CHEMISTRY INDEX.

RED Russia, or Little Russia, a province of Poland, bounded on the west by Upper Poland, on the north by Lithuania, on the east by Little Tartary, and on the south by Moldavia, Transylvania, and a part of Hungary. It comprehends Russia properly so called, Volhynia, and Podolia. It is about 650 miles in length, and from 150 to 250 in breadth. It consists chiefly of large fields, but little cultivated on account of the frequent inroads of the Tartars, and because there is no water carriage. It had the name of Red Russia, from the colour of the hair of its inhabitants. The western part is now subject to Austria, the east to Russia.

RED-Sea, or Arabic Gulf, so much celebrated in sacred
Red Sea, ere it history, separates Arabia from Upper Ethiopia and part of Egypt. This sea is 350 leagues in length and 40 in breadth. As no river falls into it of sufficient force to counteract the influence of the tide, it is more affected by the motions of the great ocean than any of the inland seas nearly in the same latitude. It is not much exposed to tempests: the winds usually blow from north to south, and being periodical, like the monsoons of India, invariable determine the season of sailing into or out of this sea. It is divided into two gulfs: that to the east was called the Eulatinic gulf, from the city Aela in the north end of it; and that to the west the Hieropolitic, from the city of Hieropolis; the former of which belongs to Arabia, and the latter to Egypt.

Mr Bruce has made many observations on this sea, which are worthy of notice. With regard to the name, he says it was certainly derived from Edom or Esau, the son of Jacob; though in another place he says, he wonders that writers have not rather supposed it to have got the epithet of Red, from the colour of the sand on its coasts, than for other reasons they have alleged. With regard to any redness in the water itself, or in the bottom, which some have asserted, our traveller assures us that there is no such thing. It is more difficult to assign a reason for the Hebrew name of it, which signifies the Sea of Wrecks; as he never saw a weed throughout the whole extent of it. "Indeed, (says he) upon the slightest consideration, it will occur to anyone, that a narrow gulf, under the immediate influence of the monsoons, blowing from contrary points six months each year, would have too much agitation to produce such vegetables, seldom found but in stagnant waters, and seldom, if ever, found in salt ones. My opinion then is, that it is from the large trees or plants of white coral, spread everywhere over the bottom of the Red sea, perfectly in imitation of plants on land, that the sea has obtained this name." I saw one of these, which, from a root nearly central, threw out ramifications of an almost circular form, measuring 26 feet every way.

Our author has also made many useful observations on the navigation of this sea. "All the western shore (he says) is bold, and has more depth of water than the east; but on this side there is neither anchoring ground nor shoals. It is rocky, with a considerable depth of water everywhere; and there are a number of sunken rocks, which, though not visible, are sufficiently near the surface to destroy a large ship." The cause of this, in Mr Bruce's opinion, is, that the mountains on the side of Abyssinia and Egypt are all of hard stone, porphyry, many different kinds of marble, granite, alabaster, and barytes. These being all composed of solid materials, therefore, can part with very little dust or sand, which might otherwise be blown from them into the sea. On the opposite coast, viz. that of Hejaz and Tahamah, on the Arabian side, the whole consists of moving sands; a large quantity of which is blown from the south-east by the dry winter monsoons; which being lodged among the rocks on that side, and confined there by the north-east or summer monsoon, which is in a contrary direction, hides them from coming over to the Egyptian side. Hence the western coast is full of sunk rocks for want of sand to cover them, with which they would otherwise become islands. They are naked and bare all round, with sharp points like spears, while on the east side, every rock becomes Red Sea. an island, and every two or three islands become an harbour. On the ends of the principal of these harbours the people have piled up great heaps of stones to serve as signals: "and it is in these (says Mr Bruce) that the large vessels from Cairo to Jidja, equal in size to our large 74 gun ships (but from the cisterns of mason work built within for holding water, I suppose double their weight), after navigating their portion of the channel in the day-time, come safely and quietly to at four o'clock in the afternoon; and in these little harbours pass the night, to sail into the channel again next morning."

The western channel of the Red sea was chosen, in the days of the Ptolemies, for the track of the Indian and African commerce. The monarch erected a great number of cities all along the western coast; and notwithstanding the dangers of the navigation, we do not hear that it was ever abandoned on account of them.

From the observations made by our author on the navigation of the Red sea, he undertakes to point out a safe passage for large ships to the gulf of Suez, so that they may be able to judge of the propriety of their own course themselves, without trusting implicitly to the pilots they meet with, who are often very ignorant of their profession. This sea, according to Mr Bruce, may be divided into four parts, of which the channel occupies two, till near the latitude of 26°, or that of Cosseir. On the west it is deep water, with many rocks; and on the east it is full of islands, as has been already mentioned. Between these islands there are channels and harbours of deep water, where ships may be protected in any wind; but a pilot is necessary in sailing among these from Mocha to Suez, and the voyage besides can be continued only during part of the day. Ships bound to Suez without the consent of the sheriffs of Mecca, that is, without any intention of selling their cargo at Jidja, or paying custom there, ought to take in their fresh water at Mocha, or if there be any reason against this, a few hours will carry them to Azab or Saba on the Abyssinian coast, where they may be plentifully supplied, but it must be remembered, "that the people here are Galla, the most treacherous and villainous wretches on earth." Here not only water may be procured, but plenty of sheep, goats, with some myrrh, and incense in the proper season. Great caution, however, must be used in dealing with the people, as even those of Mocha, who are absolutely necessary to them in their commercial dealings, cannot trust them without surety or hostages. Not many years ago, the surgeon and mate of the Elgin East Indian, with several other sailors, were murdered by these savages as they went ashore to purchase myrrh, though they had a letter of safe conduct from the sheikh.

To such as do not want to be known, our author recommends a low black island on the coast of Arabia, named Camaran, in latitude 15° 30'. It is distinguished by a white house or fortress on the west end of it; where water is to be had in still greater plenty than at Azab; but no provisions, or such only as are very bad, can be procured. If it is necessary not to be seen at all on the coast, the island of Fossit is recommended by our author as having excellent water, with a saint or monk, whose office is to keep the wells clean. This is one of the chain of islands which stretches almost across
Red Sea. across the gulf from Lobeiah to Masnah, and from actual observation by Mr. Bruce, is found to be situated in N. Lat. 15° 59' 43". E. Long. 42° 47'. From this to Yambo, there is a safe watering-place; and there is an absolute necessity for having a pilot before you come to Ras Mahomet; because over the Ælantic gulf, the mountains of Aucha, and the cape itself, there is often a thick haze, which lasts for many days together, and a number of ships are lost by mistaking the eastern bay or Ælantic gulf for the entrance of the gulf of Suez; the former has a ridge of rocks nearly across it. After reaching Sheduau, a large island, about three leagues farther in a north-by-west direction, there is a bare rock distinguished by no particular name; but so situated that ships ought not to come within three leagues of it. This rock is to be left to the westward at the distance just mentioned; after passing which you meet with shoals forming a pretty broad channel, with soundings from 15 to 30 fathoms; and again, on standing directly for Tor, there are two other oval sands with sunk rocks in the channel, between which you are to steer. Tor may be known at a distance by two hills that stand near the water-side; which, in clear weather, may be seen six leagues off. Just to the north-east of these is the town and harbour, where there are some palm trees about the houses, the more remarkable, as being the first that are seen on the coast. The soundings in the way to Tor harbour are clean and regular; and, by giving the beacon a small birth on the larboard hand, you may haul in a little to the northward, and anchor in five or six fathoms." In spring tides, it is high water at Tor nearly about 12 o'clock: in the middle of the gulf there is no perceptible tide, but at the sides it runs at the rate of more than two knots in the hour. Tor itself is but a small village, with a convent of monks belonging to those of Mount Sinai. It was taken by Don John de Castro, and fortified, soon after its discovery by the Portuguese; but has never since been a place of any consideration; serving now only for a watering-place to the ships trading to or from Suez.—From this place there is a distinct view of Mounts Horeb and Sinai, which appear above and behind the others, with their tops frequently covered with snow in the winter.

Mr. Bruce next proceeds to consider some questions which may be reckoned matters of curiosity rather than anything else. One of these is concerning the level of the water of this sea itself, which has been supposed several feet above that of the Mediterranean. "To this (says our author) I answer, that the fact has been supposed to be so by antiquity, and alleged as a reason why Ptolemy's canal was made from the bottom of the Hecropolitic gulf rather than brought due north across the isthmus of Suez; in which last case it was feared it would submerge a great part of Asia Minor. But who has ever attempted to verify this by experiment? or who is capable of settling the difference of levels, amounting, as supposed, to some feet and inches, between two points 120 miles distant from each other, over a desert that has no settled surface, but is changing its height every day? Besides, since all seas are in fact but one, what is it that hinders the Indian ocean to flow to its level? What is it that keeps the Indian ocean up? Till this last branch of the question is resolved, I shall take it for granted that no such difference of level exists, whatever Ptolemy's engineers might have pretended to him; because, to suppose it fact, is to suppose the violation of one very material law of nature."

The next thing considered by our author is the passage of the Israelites through the Red Sea. At the place where he supposes the passage to have been, the sea is not quite four leagues broad, so that it might easily have been crossed in one night without any miracle. There is about 14 fathom water in the channel, and nine at the sides, with good anchorage everywhere; the farthest side is a low sandy coast, and a very easy landing place. "The draught of the bottom of the gulf (says he) given by Dr. Pococke, is very erroneous in every part of it. It was proposed to Mr. Niebuhr, when in Egypt, to inquire upon the spot, whether there were not some ridges of rocks where the water was shallow, so that an army at particular times might pass over? Secondly, whether the Etesian winds, which blow strongly all summer from the north-west, could not blow so violently against the sea, as to keep it back on a heap, so that the Israelites might have passed without a miracle? And a copy of these queries was left for me to join in their inquiries likewise. But I must confess, however learned the gentlemen were who proposed these doubts, I did not think they merited any attention to solve them. If the Etesian winds, blowing from the north-west in summer, could keep up the sea as a wall on the right or to the south, of fifty feet high, still the difficulty would remain of building the wall on the left hand or to the north. Besides, water standing in that position for a day, must have lost the nature of a fluid. Whence came that cohesion of particles that hindered that wall to escape at the sides? This is as great a miracle as that of Moses. If the Etesian winds had done this once, they must have repeated it many a time before and since, from the same causes. Yet Diodorus Siculus says, the Troglodytes, the indigenous inhabitants of that very spot, had a tradition from father to son, from their very earliest and remotest ages, that once this division of the sea did happen there; and that, after leaving the bottom some time dry, the sea again came back and covered it with great fury. The words of this author are of the most remarkable kind. We cannot think this heathen is writing in favour of revelation. He knew not Moses, nor says a word about Pharaoh and his host; but records the miracle of the division of the sea in words nearly as strong as those of Moses, from the mouths of unbiased designing pagans."

Red-Shank. See Scolopax.
Red-Start. See Motacilla.
Ornithology Index.
Red-Wing. See Turdus.
REDANS, in Field Fortification. See the article Redens.

REDDENDUM, in Law, is used substantively for the clause in a lease wherein the rent is reserved to the lessor. The proper place for it is next after the limitation of estate.

REDDITIO, was the third part of the sacrifice of the heathens, and consisted of the solemn act of putting in again the entrails of the victims, after they had been religiously inspected. See Sacrifice.

REDDLE, a soft, heavy, red, ferruginous earth, of great
RED

Reddell
Reduction

Redemption, in Law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon reimbursing the purchase-money with legal costs.

Redemption, in Theology, denotes the recovery of mankind from sin and death, by the obedience and sacrifice of Christ, who on this account is called the Redeemer of the world. See Theology.

Redens, Redans, or Redant, in Fortification, a kind of indented work in form of the teeth of a saw, with salient and re-entering angles; to the end that one part may flank or defend another. It is likewise called saw-work and indented work. The lines or faces in this flank one another.

Redens are used in fortifying walls, where it is not necessary to be at the expense of building bastions; as when they stand on the side of a river running through a garrison town, a marsh, the sea, &c. But the fault of such fortification is, that the besiegers from one battery may ruin both the sides of the tenaille or front of a place, and make an assault without fear of being enflamed, since the defences are mined. The parapet of the corridor is likewise often redented or carried on by the way of redens. The redens was used before bastions were invented, and some people think them preferable.

Redi, Francis, an Italian physician and polite scholar, was born at Arezzo in Tuscany in 1626. His ingenuity and learning recommended him to the office of first physician to Ferdinand II. duke of Tuscany; and he contributed not a little toward the compiling of the Dictionary of La Crusca. He wrote upon vipers, upon the generation of insects, and composed a good deal of poetry. All his writings are in Italian; and his language is so fine and pure, that the authors of the Dictionary of La Crusca have often cited it as a standard of perfection. He died in 1697.

Redintegration, is the finding the integral or fluent again from the fluxion. See Fluxions.

Redoubt, in Fortification, a small square fort, without any defence but in front; used in trenches, lines of circumvallation, contravallation, and approach; as also for the lodgings of corps de-garde, and to defend passages.

Reduction, in the schools, a manner of bringing a term or propositions, which was before opposite to some other, to be equivalent to it.

Reduction, in Arithmetic, that rule whereby numbers of different denominations are brought into one denomination. See Arithmetic.

Reduction of Equations, in Algebra, is the clearing them from all superfluous quantities, bringing them to their lowest terms, and separating the known from the unknown, till at length only the unknown quantity is found on one side, and known ones on the other. The reduction of an equation is the last part of the resolution of the problem. See Algebra.

Reduction of a figure, design, or draught, is the making a copy thereof, either larger or smaller than the original; still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction. See the article Compass.

There are various methods of reducing figures, &c. the most easy is by means of the pentagram, or parallelogram; but this hath its defects. See the article Pentagram.

The best and most usual methods of reduction are as follow: 1. To reduce a figure, as ABCDE (fig. 1.), into a less compass. About the middle of the figure, as x, pitch on a point, and from this point draw lines to its several angles A, B, C, &c. then drawing the line ab parallel to AB, bc parallel to BC, &c. you will have the figure a b c d e similar to ABCDE.

If the figure a b c d e had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as x, x, x, &c. and to draw lines, viz. DC, CB, &c. parallel to the sides d c, c b, &c.

2. To reduce a figure by the angle of proportion, suppose the figure ABCDE (fig. 2.) required to be diminished in the proportion of the line AB to a b (fig. 3.) draw the indeterminate line GH (fig. 4.), and from G to H set off the line AB. On G describe the arch and HI. Set off the line a b as a chord on HI, and draw GI. Then with the angle IGH you have all the measures of the figure to be drawn. Thus to lay down the point c, take the interval BC, and upon the point G describe the arch KL. Also on the point G describe MN; and upon A, with the distance MN, describe an arch cutting the preceding one in c, which will determine the side bc. And after the same manner are the other sides and angles to be described. The same process will also serve to enlarge the figure.

3. To reduce a figure by a scale. Measure all the sides of the figure, as ABCDE (fig. 2.) by a scale, and lay down the same measures respectively from a smaller scale in the proportion required.

4. To reduce a map, design, or figure, by squares. Divide the original into little squares, and divide a fresh paper of the dimensions required into the same number of squares, which are to be larger or less than the former, as the map is to be enlarged or diminished. This done in every square of the second figure, draw what you find in its correspondent one in the first.

Reduction, in Metallurgy, is the bringing back metallic substances which have been changed into scoriæ or ashes, or otherwise divested of their metallic form, into their natural and original state of metals again. See Ores, Reduction of.

Reduction, in Surgery, denotes an operation whereby a dislocated, luxated, or fractured bone, is restored to its former state or place.

Redundancy, a fault in discourse, consisting in the use of a superfluity of words. Words perfectly synonymous are redundant, and ought to be retrenched.

Redundant, in Music. What the French call une accord superflue, which we have translated a redundant chord in the article Music (from D'Alambert), has by others been rendered a chord extremely sharp, as in the translation of Rameau's Principles of Composition. Their nature will be best understood by a few examples, and an account of the number of tones, semitones, or lesser intervals, contained in each.

The second redundant is composed of a major tone,
Redundant and a minor semitone; as from fa to sol sharp. Its proportion is as 64 to 75.

Revealing.

The third redundant consists of two tones and a semitone, as fa la, sharp. Its proportion is as 96 to 125.

The fourth redundant is the same with the tritone.

From these examples compared with the same intervals in their natural state, the reader may form a general idea of what is meant by redundant.

REFF, REIS, or RES, a little Portuguese coin. See Money Table.

REED, in Botany See ARUNDO and BAMBOO.

There are two sorts of reeds, says Hasselquist, growing near the Nile. One of them has scarce any branches; but is furnished with numerous leaves, which are narrow, smooth, channelled on the upper surface; and the plant is about 11 feet high. The Egyptians make ropes of the leaves. They lay them in water like hemp, and then make them into good strong cables. These, with the bark of the date tree, form almost the only cable used in the Nile. The other sort is of great consequence. It is a small reed, about two or three feet high, full branched, with short, sharp, lanceet-shaped leaves. The roots, which are thick as the stem, creep and mat themselves together to a considerable distance. This plant, the same as the one named in the text, is the very soil of Egypt owing: for the matted roots have stopped the earth which floated in the waters, and thus formed, out of the sea, a country that is habitable.

Fire-Reeds. See Fire-Skip.

Reed, a term in the west of England for the straw used by thatchers, which is wheat straw finely combed, consisting of stiff, unbranched, and unbroken stalks of great length, carefully separated from the straw used for fodder by the thrasher, and bound in sheaves or nitches, each of which weighs 28lbs, and are sold from 21s. to 31s. per hundred nitches, according to the season.

This is a great improvement in the art of thatching, as it gives a finish to the work which cannot be attained by straw, rough and tumbled together, without any separation of the long and short: it is also a readier mode of working.

Reef, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so much wind; which contracting or taking up the sail they call a reef, or reefing the sail: so also when a top-mast is sprung, as they call it, that is when it is cracked, or almost broken in the cap, they cut off the lower piece that was near broken off, and setting the other part, now much shorter, in the step again, they call it a recved top-mast.

Reel, in the manufactories, a machine serving for the office of reeling. There are various kinds of reels; some very simple, others very complex.

Reeling, in the manufactories, the winding of silk, cotton, or the like, into a skain, or upon a button, to prevent its entangling. It is also used for the charging or discharging of bobbins, or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c. Reeling is performed in different ways, and on different engines.

Reeving, in the sea-language, the putting a rope through a block: hence to pull a rope out of a block, is called unreewing.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange due upon a bill of exchange that comes to be protested, and to be refunded the bearer by the drawer or indorser.

REFLECTION, among ecclesiastics, a spare meal or repast, just sufficient for the support of life: hence the hall in convents, and other communities, where the monks, nuns, &c. take their refectio or meals in common, is called the refectory.

REFERENCE, in writing, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something omitted in the text is added, and which is to be inserted either in reading or copying.

REFINING, in general, the art of purifying a thing; including not only the essaying or refining of metals, but likewise the depuration or clarification of liquors. See Clarification; and Pharmacy, under Materia Medica, and Ores, Reduction of.

Gold and silver may be refined by several methods, which are all founded on the essential properties of these metals, and acquire different names according to their kinds. Thus, for instance, gold having the property of no other metal, except silver, of resisting the action of sulphur, of antimony, of nitrous acid, or marine acid, may be purified by these agents from all other metallic substances, and consequently may be refined. These operations are distinguished by proper names, as purification of gold by antimony, parting, concentrated parting, dry parting. The term refining is chiefly applied to the purification of gold and silver by lead in the cupel. See Ores, Reduction of.

REFLECTION, the return or progressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction.

Circular Instrument of Reflection, an instrument for measuring angles to a very great degree of accuracy. It was invented by the celebrated astronomer Mr. Tobias Mayer of Gottingen, principally with a view to do away the errors of the divisions of the limb; and has since been much improved by the Chevalier de Borda, and M. J. H. de Magellan. This instrument is particularly applicable to the measuring of the distances of the heavenly bodies, and was used by the French in their part of the operation for determining the difference of meridians of Paris and Greenwich. For the description, rectification, and use of this instrument, see Navigation.

Reflection of the Rays of Light, in Optics, is their return, after approaching so near the surface of bodies as to be thereby repelled or driven backwards.

For the causes of reflection, see Optics Index, at Rays of Light, and Reflection of Light, &c. For the application of the doctrine of reflection to mirrors, see Optics. See also Mirror, Burning Glass, and Glass-grinding; and for the coating of glasses, see the article Foliating of Looking-glasses, &c. See also Telescope.

Reflection of Heat, see Chemistry, No. 170.

Reflection of Cold. For an account of this curious phenomenon, see also Chemistry, No. 272.

It has been generally supposed that this fact was first noticed by Professor Pictet of Geneva; but we have been informed from good authority (for we have not
REFLECTION is also used figuratively, for an operation of the mind, whereby it turns its view backwards as it were upon itself, and makes itself and its own operations the object of its disquisition; and by contemplating the manner, order, and laws, which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein. See METAPHYSICS.

REFLECTORS for Light-Houses, have of late years been very successfully adopted instead of coal fires. They are composed of a number of square plane glass mirrors, similar to those which, it is said, were employed by Archimedes in setting fire to the Roman fleet at the siege of Syracuse. The mirrors are an inch square, and are disposed close to each other in the concave of a parabolic segment, formed of stucco, or any other substance which retains them in their place. Stucco, however, is found to answer sufficiently well, and is employed in the reflectors of all the light-houses which have been erected round the coast of Scotland.

The parabolic moulds are from three to five or six feet in diameter, and in the centre of each there is a long shallow lamp of tin plate, filled with whale oil. There are six cotton wicks in each lamp nearly contiguous to each other, and so disposed as to stand in no need of trimming for the space of six hours. The light is reflected from each mirror spread over the concave surface, and is as it were multiplied by the number of mirrors. Tin plate covers the back of the stucco moulding, from which a tube immediately over the lamp proceeds to the roof of the light-room, and answers the purpose of a funnel, through which the smoke passes without3 sullying the face of the mirror. The light-room is a lantern of from eight to twelve sides, entirely made of glass, fixed in frames of cast iron, and roofed with copper. The reflectors with their lamps are placed on circular benches passing round the inside of this lantern, at about 18 inches from the glass frames, so that the concave surfaces of two or three of the reflectors front each point of the compass, and throw a blaze of light in all directions.

There is a hole in the roof, directly over the centre of the room, through which all the funnels pass, and by which fresh air is also conveyed to the lamps. This light-room is fixed in such a manner on the top of a round tower, that no weather can move it; and the number of the reflectors, and the height of the tower, are greater or less according as the light is intended to be seen at a greater or less distance.

It has been proposed to make the concave surface of the parabolae one specular of metal, instead of covering it over with a number of plain glass mirrors, or to diminish the size of each mirror, if they are preferred to the metallic speculum. It must be obvious to every man who knows any thing of optics, that either of these alterations would be improper. The brightest metal does not reflect so much light as plain clear glass, and if the size of the mirrors were diminished, the number of joinings would be increased, in each of which some light is lost.

A man wholly guided by theory, would be ready to condemn light-houses of this description; because a violent storm will shake the firmest building, which, in his opinion, would throw the whole rays of light into the air, and thus mislead the bewildered mariner. Experience, however, shows, that such apprehensions are groundless, and that light-houses with lamps and reflectors, are in all respects preferable to those with fires burning in the open air. They are less expensive; they give a more brilliant light, and are seen at a greater distance, and cannot be obscured by smoke, or driven down on the lee side by the most violent wind. If to this we add, that the lamps do not stand in need of trimming so often as fires require fuel, and that the light-man is never exposed to the weariness must allow that light-houses with reflectors are not so liable to be neglected in stormy weather as those with open fires, which alone must give the former a preference over the latter.

It has been asserted, and particularly stated, in the supplement to the third edition of this work, that Mr Smith of Edinburgh, the principal, and we believe now the sole contractor for managing and keeping in repair the light-houses round the coast of Scotland, is the first who conceived the idea of illuminating light-houses by means of lamps and reflectors. We do not understand that Mr Smith himself ever claimed the merit of this invention; but it appears that reflectors, such as are described above, were invented by Mr Ezekiel Walker of Lynn Regis, who says, in a letter dated October 1801, and addressed to the editor of the Monthly Magazine, that such reflectors were made and fixed up under his direction, in a light-house on the coast of Norfolk, in the year 1779; and adds further, that in the year 1785, at the request of the trustees of the Board of Trade, the parliament for erecting four light-houses, on the northern coast of Great Britain, he instructed Mr Smith in this method of constructing light-houses. Mr Walker's statement of the fact is confirmed by a letter from Mr Grieve, then lord provost of Edinburgh, who informs Mr Walker that the trustees had agreed to pay the premium required for communicating the invention, and that Mr Smith was engaged to go to Lynn Regis to receive instructions from Mr Walker in the method of constructing the new reflectors.

REFLEX, in Painting, means those places in a picture which are supposed to be illuminated by light reflected from some other body in the same piece. See Painting, Part I. sect. 2. and 5.

REFLUX, the backward course of water, has the same meaning as the ebbing of the sea, and is opposed to flood, flux, or the flowing of the sea. See TIDES.

REFORM means a change from worse to better, a reestablishment or revival of former neglected discipline, or a correction of abuses therein. The term is much used in a monastic sense for the reducing an order or congregation of religious to the ancient severity of the rule from which it had gradually swerved, or even for improving on the ancient rule or institution itself, and voluntarily making it more severe. In this sense the order of St Bernard is said to be only a reform of that of St Benedict. In this country it is applied both to politics and religion, and may innocently be applied to...
to any endeavours to change an establishment from worse to better. But it appears at present to have been chiefly made a pretence for designs which could not fairly or safely be avowed.

A reform in religion and in parliament (see Parliament), has, we know, been most loudly called for by men whose religious notions are immensely different from what has been generally reckoned christianity, and whose designs, as has been legally proved, went to the overthrow of all civil order. For insidious purposes like these, the word reform is a good cloak, especially if any thing can be fixed upon, either in the religion or government of the state, which, with the help of exaggeration and distortion, can be represented to the weak and unthinking as extremely defective and erroneous.

The general error of these men seems to be, that having picked up a set of speculative notions which flatter their own pride and the pride of those who listen to them, they will allow nothing to the arguments of their opponents or the experience of mankind. They think so often and so much upon their ideal reforms, that while they imagine their notions are liberal and extensive, they become contracted beyond imagination; while their judgments, of course, are warped with the most inveterate prejudices (see Prejudice). They see, or think they see, the propriety of their schemes; but they seldom, perhaps never, reflect, that that may be true in speculation or in theory which cannot possibly be reduced to practice. They will not take the world as it is, and allow it to profit by the wisdom and experience of ages; but they will reform it according to those ideas of right which they have learned from their own speculations and airy theories; seldom considering what may be done, they are determined to do what they think ought to be done. Liberty of conscience, and liberty of action, have been claimed by them as the inalienable rights of man, and so we ourselves are disposed to think them; nor have we heard that in this country they have been denied to any man, or set of men, so far as has been thought consistent with the safety of the state, and that of the other individuals who compose it. At the same time, the very same men hesitate not to blame, with acrimony the most violent, and to the utmost of their power to restrain, the actions and opinions of those who, with equal conviction, often on better grounds, and generally with more modesty, differ from them.

Amidst that excessive ardoir, too, with which they propagate their opinions, they forget the extreme danger of withdrawing the attention of that part of the community, who must earn their bread by the sweat of their brow, from their proper occupations, to the tempestuous sea of political debate, for which their education and mode of life cannot possibly have qualified them. It requires but very little penetration, however, to be able to see, that it can be of no real service either to the individuals themselves, or to the community at large, in whatever light we look upon it. Indeed, to make those the judges of the law, and the reformers of the legislature, who have all their lives been employed in manual labour, is the extreme of folly; and yet it is what some men of considerable abilities, and from whom we had reason to expect better things, have more than once attempted. The effect of such a mode of seduction, (and it deserves no better name), when it shall become general, instead of serving the purposes of a real reform, must be to annihilate all civil order. Dissatisfaction is the most powerful check to honest industry; and dissatisfaction and idleness must be the effect of the wanderings of such men in the labyrinths of politics; which, for uncultivated minds especially, paves the way for every species of vice, and gradually ripens them for any wickedness, however atrocious. For the truth of these remarks, we appeal to the history of mankind from the creation to the present time: and we would seriously request the sober friends of reform, and many such, we doubt not, there are, to reflect, that in the present day we have more to fear from licentiousness than from despotism; from reform carried to an extreme than from the pretended attempts either of kings or ministers to annihilate our real liberty.

It may also be worth while to consider, that times of public danger are not generally the best adapted to attempt changes of government; because what might satisfy one party would probably be thought too little by another, and divisions at such a period are most dangerous. When, therefore, attempts are made for reform which appear to be inconsistent with the safety of the state, restrictions must be used, which may by speculative men be thought severe and unnecessary, but of which they themselves are the causes. These restrictions too will be patiently submitted to by the wiser part of the community, when in more peacable times they would neither have been thought of nor allowed.

Speculative reasoners may speak as much as they will of enlightening the minds of men, and of reforming government by the dictates of a refined and impassionate philosophy; but when they come to apply their notions to practice, they will either find their representations little better than empty sounds, and therefore inefficient; or, as is more generally found to be the case, these schemes which in theory appeared to be perfect, will in practice, when combined with the malignant and ambitious passions of men, lead to ruin and disorder. The first institution of government, except among the Jews, was unquestionably the effect of passion and interest combined; and this passion and this interest, restrained within due bounds, is productive of much happiness. That government, we believe, too, will be best supported, and most productive of happiness, in which the mutual passions and interests of the individuals who compose it are so equally poised as to support one another, and to promote each the ends and success of the other: and this by the ablest reasoners and the best men has been thought to be the case with the British constitution. If the modern favourers of reform should think this an unstable support, if they will consider the world as it ever has been, and as it is, they will find it the only one we have, except religion; and they will then be inclined to make the best of it. If after all, however, they should be disposed to doubt the position, we have only further to request them, with the sincerity of men and of Christians, to consult their own breasts, and seriously to consider the probable motives of those who act with them. They will then perhaps see, and they surely ought to acknowledge, that
few men have acted more according to the impulse of passion, interest, and ambition, than those who have for some time past sounded the tocsin of reform.

REFORMATION, in general, an act of reforming or correcting an error or abuse in religion, discipline, or the like. By way of eminence the word is used for that great alteration and reformation in the corrupted system of Christianity, begun by Luther in the year 1517.

Under the article HISTORY (sect. ii.), the various corruptions in religion, the oppressions and usurpations of the clergy, and the extreme insolence of the popes, have been so fully treated of, that any further detail here is unnecessary. It is sufficient to observe, that before the period of the Reformation, the pope had in the most audacious manner declared himself the sovereign of the whole world. All the parts of it which were inhabited by those who were not Christians, he accounted to be inhabited by no body; and if Christians took it into their heads to possess any of those countries, he gave them full liberty to make war upon the inhabitants without any provocation, and to treat them with no more humanity than they would have treated wild beasts. The countries, if conquered, were to be parcelled out according to the pope's pleasure; and dreadful was the situation of that prince who refused to obey the will of the holy pontiff, of which many instances will occur to the reader in the various historical articles of this work. In consequence of this extraordinary authority which the pope had assumed, he at last granted to the king of Portugal all the countries to the eastward of Cape Non in Africa, and to the king of Spain all the countries to the westward of it. In this, according to the opinions of some, was completed in his person the character of Antichrist sitting in the temple of God, and showing himself as God. He had long before, say they, assumed the supremacy belonging to the Deity himself in spiritual matters; and now he assumed the same supremacy in worldly matters also, giving the extreme regions of the earth to whom he pleased. The Reformation, therefore, they consider as the immediate effect of divine power taking vengeance on this and all other deviations from the system of truth; while others consider it merely as an effect of natural causes, and which might have been foreseen and prevented, without abridging the papal power in any considerable degree.

Be this as it will, however, the above-mentioned partition was the last piece of insolence which the pope ever had, or in all probability ever will have, in his power to exercise, in the way of parceling out the globe to his adherents. Everything was quiet, every heretic exterminated, and the whole Christian world supinely acquiesced in the enormous absurdities which were inculcated upon them; when, in 1517, the empire of superstition began to decline, and has continued to do so ever since. The person who made the first attack on the extravagant superstitions then prevailing was Martin Luther; the occasion of which is fully related under the article LUTHER. By some it is pretended, that the only motive which Luther had in beginning the Reformation was his enmity to the Dominican friars, who had excluded his order (the Augustins) from all share in the painful traffic of indulgencies. But this does not seem at all probable, if we consider that such a motive would not naturally have led him to deny the virtue of indulgences, as such conduct could not but exclude him for ever from any chance of a share in the traffic, which otherwise perhaps he might have obtained.

Besides, the extreme contrariety of this traffic to the by Luther common principles of reason and honesty was so great, that we cannot wonder at finding one man in the world who had sense enough to discern it, and virtue enough to oppose such an infamous practice. In all probability, however, the insignificance of the first reformer was the reason why he was not persecuted and exterminated at his first beginning, as others had been before him. Another reason probably might be, that he did not at once attack the whole errors of Popery, but brought about his reformation gradually, probably as it occurred to himself, and as we have related in the account of his life.

The Reformation began in the city of Wurttemberg in Switzer-land by Zuingius. The Franciscan friars, who had the care of pronouncing indulgences in Switzerland, were opposed by Zuingius, a man not inferior in understanding and knowledge to Luther himself. He proceeded with the greatest vigour, even at the very beginning, to overturn the whole fabric of Popery; but his opinions were declared erroneous by the universities of Cologne and Louvain. Notwithstanding this, the magistrates of Zurich approved of his proceedings; and that whole canton, together with those of Bern, Basil, and Chafhausen, embraced his opinions.

In Germany, Luther continued to make great advances, without being in the least intimidated by the ecclesiastical censures which were thundered against him from all quarters, he being continually protected by the German princes either from religious or political motives, so that his adversaries could not accomplish his destruction as they had done that of others. The princes, who were upon bad terms with the court of Rome, took advantage of the success of the new doctrines; and in their own dominions easily overturned a church which had lost all the respect and veneration of the inferior ranks. The court of Rome had disobliged some of the smaller princes in the north of Germany, whom the pope probably thought too insignificant to be worthy of the managing, and the universally established the Reformation in their own dominions. Melancthon, Carlostadius, and other men of eminence, also greatly forwarded the work of Luther; and in all probability the Popish hierarchy would have soon come to an end, in the northern parts of Europe at least, had not the emperor Charles V. given a severe check to the progress of reformation in Germany. In Germany opposed by Char. V. order to follow out the schemes dictated by his ambition, he thought it necessary to ingratiate himself with the pope; and the most effectual method of doing this was by destroying Luther. The pope's legates insisted that Luther ought to be condemned by the diet of Worms without either trial or hearing; as being a most notorious,avored, and incorrigible heretic. However, this appeared unjust to the members of the diet, and he was summoned to appear; which he accordingly did without hesitation. There is not the least doubt that his appearance there had been his last in this world, had not the astonishing respect that was paid him, and...
the crowds who came daily to see him, deterred his judges from delivering the church from the author of such a pestilential heresy; which they were strongly solicited by the pope's party to do. He was therefore permitted to depart with a safe conduct for a certain time; after which he was in the state of a proscribed criminal, to whom it was unlawful to perform any of the offices of humanity.

During the confinement of Luther in a castle near Wartburg, the Reformation advanced rapidly; almost every city in Saxony embracing the Lutheran opinions. At this time an alteration in the established forms of worship was first ventured upon at Wittemberg, by abolishing the celebration of private masses, and by giving the cup as well as the bread to the laity in the Lord’s supper. In a short time, however, the new opinions were condemned by the university of Paris, and a refutation of them was attempted by Henry VIII. of England. But Luther was not to be thus intimidated. He published his animadversions on both with as much acrimony as if he had been refuting the meanest adversary; and a controversy managed by such illustrious antagonists drew a general attention, and the Reformers daily gained new converts both in France and England.

But while the efforts of Luther were thus every where crowned with success, the divisions began to prevail which have since so much agitated the reformed churches. The first dispute was between Luther and Zuinglius concerning the manner in which the body and blood of Christ were present in the eucharist. Luther and his followers, though they had rejected the notion of transubstantiation, were nevertheless of opinion that the body and blood of Christ were really present in the Lord’s supper, in a way which they could not pretend to explain. Carlstadt, who was Luther’s colleague, first suggested another view of the subject, which was afterwards confirmed and illustrated by Zuinglius, namely, that the body and blood of Christ were not really present in the eucharist; and that the bread and wine were no more than external symbols to excite the remembrance of Christ’s sufferings in the minds of those who received it. Both parties maintained their tenets with the utmost obstinacy; and, by their divisions, first gave their adversaries an argument against them, which to this day the Catholics urge with great force; namely, that the Protestants are so divided, that it is impossible to know who is right or wrong; and that there cannot be a stronger proof than these divisions, that the whole doctrine is false.

To these intestine divisions were added the horrors of a civil war, occasioned by oppression on the one hand, and enthusiasm on the other. In 1525, a great number of seditious fanatics arose on a sudden in different parts of Germany, took arms, united their forces, and made war against the empire, laying waste the country with fire and sword, and committing everywhere the greatest cruelties. The greatest part of this furious mob was composed of peasants and vassals, who groaned under heavy burdens, and declared that they were no longer able to bear the despotic government of their chiefs; and hence this sedition had the name of the rustic war, or the war of the peasants. At first this rabble declared, that they had no other motives than the redress of their grievances; but no sooner had the enthusiastic Munzer, or Munster, the anaconstitutional Munster, put himself at their head, than the face of things was entirely changed, and the civil commotions in Saxony and Thuringia exceedingly increased, of which an account is given under the article ANABAPTISTS.

In the mean time Frederic, surnamed the Wise, elector of Saxony, and Luther’s great patron, departed this life, and was succeeded by his brother John. Frederic, though he had protected and encouraged Luther, yet was at no pains to introduce the reformed religion into his dominions. But with his successor it was otherwise. For he, convinced that Luther’s doctrine must soon be totally destroyed and suppressed unless it received a speedy and effectual support, ordered Luther and Melanthon to draw up a body of laws relating to the form of ecclesiastical government, the method of public worship, &c. which was to be proclaimed by heralds throughout his dominions. This example was followed by all the princes and states of Germany who renounced the papal supremacy; and a like form of worship, discipline, and government, was thus introduced into all the churches which disowned from that of Rome. This open resuscitation of the Roman jurisdiction soon changed the face of affairs; and the patrons of Poperg soon intimated, in a manner not at all ambiguous, that they intended to make war on the Lutheran party; which would certainly have been put in execution, had not the troubles that took place in Europe discouraged their measures.

On the other hand, the Lutherans, apprised of these hostile intentions, began also to deliberate on a proper plan of defence against this superstitious violence with which they were in danger of being assailed. The diet of the empire assembled at Spire, in the year 1526; where the emperor’s ambassadors were desired to use their utmost endeavours to suppress all disputes about religion, and to insist upon the rigorous execution of the sentence which had been pronounced against Luther and his followers at Worms. The greatest part of the German princes opposed this motion with the utmost resolution, declaring that they could neither execute that sentence, nor come to any determination with regard to the doctrines by which it had been occasioned, before the whole matter was submitted to the decision of a council lawfully assembled; alleging farther, that the decision of controversies of this nature belonged properly to it, and to it alone. This opinion, after long and very warm debates, was adopted by a great majority, and at length consented to by the whole assembly: for it was unanimously agreed to present a solemn address to the emperor, intreating him to assemble, without delay, a free and general council; while in the mean time it was also agreed, that the princes of the empire should, in their respective dominions, be at liberty to manage ecclesiastical affairs in the manner they should think most proper; yet so as to be able to give to God and the emperor a proper account of their administration when it should be required of them.

These resolutions proved extremely favourable to the cause of reformation; neither had the emperor any leisure for some time to give disturbance to the reformed. The war, which at this time ensued between him and the pope, gave the greatest advantage to the friends of the reformed, and considerably augmented their number. Several princes, whom the fear of persecution and punishment
punishment had hitherto prevented from lending their assistance, publicly renounced the Romish superstition, and introduced among their subjects the same forms of religious worship, and the same system of doctrine, that had been received in Saxony. Others, though placed in such circumstances as discouraged them from acting in an open manner against the interests of the Roman pontiff, were, however, far from discovering the smallest opposition to those who withdrew the people from his despotic yoke; nor did they molest the private assemblies of those who had separated themselves from the church of Rome. And in general, all the Germans who, before these resolutions of the diet of Spire, had rejected the papal discipline and doctrine, were now, in consequence of the liberty they enjoyed, wholly employed in bringing their schemes and plans to a certain degree of consistence, and in adding vigour and firmness to the cause in which they were engaged. But this tranquillity and liberty was of no long duration. In 1529, a new diet was assembled at the same place by the emperor, after he had quieted the troubles in various parts of his dominions, and concluded a peace with the pope. The power which had been granted to princes of managing ecclesiastical affairs till the meeting of a general council, was now revoked by a majority of votes; and every change declared unlawful that should be introduced into the doctrine, discipline, or worship of the established religion, before the determination of the approaching council was known. This decree was considered as iniquitous and intolerable by the electors of Saxony, the landgrave of Hesse, and other members of the diet, who were persuaded of the necessity of a reformation. The promise of speedily assembling a general council, they looked upon to be an artifice of the church of Rome; well knowing, that a free and lawful council would be the last thing to which the pope would consent. When, therefore, they found that all their arguments and remonstrances made no impression upon Ferdinand the emperor’s brother, who presided in the diet, Charles himself being then at Barcelona, they entered a solemn protest against this decree on the 15th of April, and appealed to the emperor and a future council. Hence arose the denomination of Protestants, which from this period has been given to those who separated from the communion of the church of Rome. The princes of the empire who entered this protest, were John elector of Saxony; George elector of Brandenburg; Ernest and Francis dukes of Lüneburg; the landgrave of Hesse; and the prince of Anhalt. These were seconded by 13 imperial towns, viz. Strasburg, Ulm, Nuremberg, Constance, Rottengen, Windseim, Memmingen, Nortlingen, Lindaw, Kempton, Heilbron, Wissenburg, and St Gall.

The dissentient princes, who were the protectors and heads of the reformed churches, had no sooner entered their protest, than they sent proper persons to the emperor, who was then upon his passage from Spain to Italy, to acquaint him with their proceedings in this matter. The ministers employed in this commission executed it with the greatest tardiness, and presence of mind; but the emperor, exasperated at the audacity of those who presumed to differ from him, caused the ambassadors to be arrested. The news of this violent step made the Protestant princes conclude, that their personal safety, and the success of their cause, depended entirely upon their own courage and union. They determined, therefore, to enter into a solemn confederacy: for which purpose they held several meetings at Rot, Nuremberg, Smalcald, and other places; but so different were their opinions and views, that they could determine upon nothing.

One great obstacle to the intended confederacy was the dispute which had arisen between Luther and Zuinglius concerning the real presence of Christ in the Lord’s Supper. To terminate this dispute, if possible, Philip, landgrave of Hesse, invited, in the year 1529, to a conference at Marburg, Luther and Zuinglius, together with several other of the more eminent doctors who adhered to the respective parties of these contending chiefs: but this measure was not attended with the salutary effects which were expected from it. The divines disputed for four days in presence of the landgrave. Luther attacked Oecolampadius, and Zuinglius was attacked by Melancthon. Zuinglius was accused of heresy, not only on account of his explanation of the nature and design of the Lord’s Supper, but also in consequence of the false notions he was supposed to have adopted concerning the divinity of Christ, the efficacy of the divine word, original sin, and some other parts of the Christian doctrine. This illustrous reformer, however, cleared himself from the greatest part of these charges with the most triumphant evidence, and in such a manner as appeared satisfactory even to Luther himself: but their dissension concerning the manner of Christ’s presence in the eucharist still remained; nor could either of the contending parties be persuaded to abandon, or even to modify, their opinions on that matter. The only advantage, therefore, which resulted from the meeting was, that the jarring doctors formed a kind of truce, by agreeing to a mutual toleration of their sentiments, and leaving to the disposal of Providence the cure of their divisions.

In the mean time news were received that the emperor designed to come into Germany, with a view to terminate all religious differences at the approaching diet of Augsburg. Having foreseen some of the consequences of those disputes, and, besides, taken the advice of men of wisdom, sagacity, and experience, he became at certain times more cool in his proceedings, and more impartial in his opinions both of the contending parties and the merits of the cause. He, therefore, in an interview with the pope at Bologna, insisted, in the most serious and urgent manner, on the necessity of a general council. His remonstrances and expostulations, however, could not move the pontiff; who maintained with zeal the papal prerogatives, reproached the emperor with an ill-judged clemency, and alleged that it was the duty of that prince to support the church, and to execute speedy vengeance upon that obstinate heretical faction who dared to call in question the authority of Rome and its pontiff. To this discourse the emperor paid no regard; looking upon it as a most iniquitous thing; and a measure directly opposite to the laws of the empire, to confirm and unheard a set of men who had always approved themselves good citizens, and deserved well of their country in several respects. His Origin of theo thereof indeed it was not easy for the emperor to form a clear idea of the matters in debate, since there was no
regular system as yet composed, by which it might be known with certainty what were the true causes of Luther's opposition to the pope. The elector of Saxony, therefore, ordered Luther, and other eminent divines, to commit to writing the chief articles of their religious system, and the principal points in which they differed from the church of Rome. Luther, in compliance with this order, delivered to the elector at Torgau 17 articles which had been agreed upon in a conference at Sulzbach in 1529; from whence these received the name of the articles of Torgau. But though these were deemed by Luther a sufficient declaration of the sentiments of the reformers, yet it was judged proper to enlarge them, in order to give perspicuity to their arguments, and strength to their cause. In this work Melancthon was employed; in which he showed a proper deference to the counsel of Luther, and expressed his sentiments and doctrine with the greatest elegance and perspicuity; and thus came forth to view the famous Confession of Augsburg.

On the 15th of June 1530, Charles arrived at Augsburg, and the diet was opened five days after. The Protestants received a formal permission to present an account of their tenets to the diet on the 25th of the same month; in consequence of which, at the time appointed, Christian Bayer, chancellor of Saxony, read, in the German language, before the emperor and the princes assembled, the confession of Augsburg above mentioned. It contained 28 chapters, of which 21 were employed in representing the religious opinions of the Protestants, and the other seven in pointing out the errors and superstitions of the church of Rome. The princes heard it with the deepest attention and recollection of mind: it confirmed some in the principles they had embraced; surprised others; and many, who before this time had little or no idea of the religious sentiments of Luther, were now not only convinced of their innocence, but delighted with their purity and simplicity. The copies of this Confession, which after being read were delivered to the emperor, were signed by John elector of Saxony, George marquis of Brandenburg, Ernest duke of Lauenburg, Philipp Landgrave of Hesse, Wolfgang prince of Anhalt, and by the imperial cities of Nuremberg and Reutlingen.

The creatures of the church of Rome who were present at this diet employed John Faber, afterwards bishop of Vienna, together with Eckius, and another doctor named Cocklaüs, to draw up a refutation of the Protestant confession: which refutation having been publicly read, the emperor required the Protestant members to acquiesce in it, and put an end to the religious disputes by an unlimited submission to the opinions and doctrines contained in this answer. But this demand was far from being complied with. The Protestants declared on the contrary, that they were by no means satisfied with the reply of their adversaries; and earnestly desired a copy of it, that they might more fully demonstrate its extreme insufficiency and weakness. But this reasonable request was refused by the emperor; who interposed his supreme authority to prevent any farther proceedings in this matter, and solemnly prohibited the publication of any new writings or declarations that might contribute to lengthen out these religious debates. This, however, did not reduce the Protestants to silence. The divines of that communion, who had been present at the diet, endeavored to recollect the arguments and objections employed by Faber, and had again recourse to the pen of Melancthon, who refuted them in an ample and satisfactory manner, in a piece which was presented to the emperor on the 22d of September, but which Charles refused to receive. This answer was afterwards enlarged by Melancthon, when he had obtained a copy of Faber's reply; and was published in the year 1531, with the other pieces that related to the doctrine and discipline of the Lutheran church, under the title of A Defence of the Confession of Augsburg.

Matters now began to draw towards a crisis. There were only three ways of bringing to a conclusion these religious differences. 1. To grant the Protestants a toleration and privilege of serving God as they thought proper: 2. To compel them to return to the church of Rome by the violent methods of persecution; or, 3. That a reconciliation should be made, upon fair, candid, and equitable terms, by engaging each of the parties to temper their zeal with moderation, to abstain reciprocally the rigour of their pretensions, and remit something of their respective claims. The third expedient was most generally approved of, being peculiarly agreeable to all who had at heart the welfare of the empire; nor did the pope seem to look upon it either with aversion or contempt. Various conferences therefore were held between persons eminent for piety and learning on both sides; and nothing was omitted that might have the least tendency to calm the animosities and heal the divisions which reigned between the contending parties. But the differences were too great to admit of a reconciliation; and therefore the votaries of Rome had recourse to the powerful arguments of imperial edicts, and the force of the secular arm. On the 10th of November, a severe decree was issued out by the express order of the emperor (during the absence of the Hessian and Saxo princes, who were the chief supporters of the Protestant cause), in which every thing was manifestly adapted to deject the friends of religious liberty, excepting only a faint and dubious promise of engaging the pope to assemble a general council about six months after the separation of the diet. In this decree the dignity and excellence of the Popish religion were extolled beyond measure, a new degree of severity and force was added to that which had been published at Worms against Luther and his adherents, the changes which had been introduced into the doctrine and discipline of the Protestant churches were severely censured, and a solemn order was addressed to the princes, cities, and states, who had thrown off the Papal yoke, to return to their allegiance to Rome, so pain of incurring the indignation and vengeance of the emperor as the patron and protector of the church. Of this formidable decree the elector of Saxony and confederated princes were no sooner informed than they assembled in order to deliberate on the measures proper to be taken in such a crisis. In the years 1530 and 1531, as they met, first at Snaicail, and afterwards at Franconia, where they formed a solemn alliance and conference, with the intention of defending vigorously their religion and liberties against the dangers and encroachments with which they were threatened by the edict of Augsburg, without attempting, however, any thing offensive against the votaries of Rome; and into this confederacy they in
of peace was concluded at Nuremburg in 1532, between the emperor and the Protestant princes, on the following conditions; viz. That the latter should furnish a subsidy for carrying on the war against the Turks, and acknowledge peace of peace of Ferdinand lawful king of the Romans; and that Nuremburg, the emperor on his part should abrogate and annul the edicts of Worms and Augsburg, and allow the Lutherans the free and undisturbed exercise of their religious doctrine and discipline, until a rule of faith was fixed either in the free general council that was to be assembled in the space of six months, or in a diet of the empire.

Soon after the conclusion of the peace at Nuremburg, died John elector of Saxony, who was succeeded by his son John Frederic, a prince of invincible fortitude and magnanimity, but whose reign was little better than one continued train of disappointments and calamities. The religious truce, however, gave new vigour to the reformation. Those who had hitherto been only secret enemies to the Roman pontiff, now publicly threw off his yoke; and various cities and provinces of Germany enlisted themselves under the religious standards of Luther. On the other hand, as the emperor had now no other hope of terminating the religious disputes but by the meeting of a general council, he repeated his requests to the pope for that purpose. The pontiff (Clement VII.) whom the history of past councils filled with the greatest uneasiness, endeavoured to retard what he could not with decency refuse. At last, in 1533, he made a proposal by his legate to assemble a council at Mantua, Placentia, or Bologna; but the Protestants refused their consent to the nomination of an Italian council, and insisted that a controversy which had its rise in the heart of Germany, should be determined within the limits of the empire. The pope, by his usual artifices, eluded the performance of his own promise; and, in 1534, was cut off by death, in the midst of his stratagems. His successor Paul III. seemed to show less reluctance to the assembling a general council, and in the year 1537 expressed his inclination to convene one at Mantua; and, the year following actually sent circular letters for that purpose through all the states and kingdoms under his jurisdiction. This council was summoned by a bull issued out on the 24 of June 1536, to meet at Mantua the following year: but several obstacles prevented its meeting; one of the most material of which was, that Frederic duke of Mantua had no inclination to receive at once so many guests, some of them very turbulent, into the place of his residence. On the other hand, the Protestants were firmly persuaded that, as the council was assembled in Italy, and by the authority of the pope alone, the latter must have had an undue influence in that assembly; of consequence, that all things must have been carried by the votaries of Rome. For this reason they assembled at Protestant Smalcald in the year 1537, where they solemnly protested against the partial and corrupt council, and, at the same time, had a new summary of their doctrine drawn up by Luther, in order to present it to the assembled bishops if it should be required of them. This summary, which had the title of The Articles of Smalcald is commonly joined with the creeds and confessions of the Lutheran church.

After the meeting of the general council in Mantua fruitless was thus prevented, many schemes of accommodation were proposed both by the emperor and the Protestants; but,
but, by the artifices of the church of Rome, all of them came to nothing. In 1541, the emperor appointed a conference at Worms on the subject of religion, between persons of piety and learning chosen from the contending parties. This conference, however, was, for certain reasons, more of a farce than a matter of fact which was to be held at Ratisbon that same year, and in which the principal subject of deliberation was a memorial presented by a person unknown, containing a project of peace. But the conference produced no other effect than a mutual agreement of the contending parties to refer their matters to a general council, or, if the meeting of such a council should be prevented, to the next German diet.

This resolution was rendered ineffectual by a variety of incidents, which widened the breach, and put off to a farther day the deliberations which were designed to heal it. The pope ordered his legate to declare to the diet of Spire, assembled in 1542, that he would, according to the promise he had already made, assemble a general council, and that Trent should be the place of its meeting, if the diet had no objection to that city. Ferdinand, and the princes who adhered to the cause of the pope, gave their consent to this proposal; but it was vehemently objected to by the Protestants, both because the council was summoned by the authority of the pope only, and also because the place was within the jurisdiction of the pope; whereas they desired a free council, which should not be biased by the dictates, nor awed by the proximity of the pontiff. But this procrastination produced no effect. Paul III. persisted in his purpose, and issued out his circular letters for the convocation of the council, with the approbation of the emperor. In justice to this pontiff, however, it must be observed, that he showed himself not to be averse to every reformation. He appointed four cardinals, and three other persons eminent for their learning, to draw up a plan for the reformation of the church in general, and of the church of Rome in particular. The reformation proposed in this plan was indeed extremely superficial and partial, yet it contained some particulars which could scarcely have been expected from those who composed it. They complained of the pride and ignorance of the bishops, and proposed that none should receive orders but learned and pious men; and that therefore care should be taken to have proper masters for the instruction of youth. They condemned translations from one benefice to another, grants of reservation, non-residence, and pluralities. They proposed that some convents should be abolished; that the liberty of the press should be restrained and limited; that the colloquies of Erasmus should be suppressed; that no ecclesiastic should enjoy a benefice out of his own country; that no cardinal should have a bishopric; that the quorums of St. Anthony and several other saints should be abolished; and, which was the best of all their proposals, that the effects and personal estates of ecclesiastics should be given to the poor. They concluded with complaining of the prodigious number of indigent and ragged priests who frequented St. Peter’s church; and declared, that it was a great scandal to see the whores lodged so magnificently at Rome, and riding through the streets on fine mules, while the cardinals and other ecclesiastics accompanied them in the most courteous manner.—This plan of reformation was turned into ridicule by Luther and Sturmian; and indeed it left unredressed the most intolerable grievances of which the Protestants complained.

All this time the emperor had been labouring to persuade the Protestants to consent to the meeting of the council at Trent; but when he found them fixed in their opposition to this measure, he began to listen to the demands of the emperor. The emperor and the pope, and resolved to terminate the disputes by force of arms. The elector of Saxony and landgrave of Hesse, who were the chief supporters of the Protestant cause, upon this took proper measures to prevent their being surprised and overwhelmed by a superior force; but, before the horrors of war commenced, the great reformer Luther died in peace at Ayselben, the place of his nativity, in 1546.

The emperor and the pope had mutually resolved on the destruction of all who should dare to oppose the council of Trent. The meeting of it was to serve as a signal for taking up arms; and accordingly its deliberations were scarcely begun in 1546, when the Protestants perceived undisguised signs of the approaching storm, and a formidable union between the emperor and pope, which threatened to crush and overwhelm them at once. This year indeed there had been a new conference at Ratisbon upon the old subject of accommodating differences in religion; but from the manner in which the debates were carried on, it plainly appeared that these differences could only be decided in the field of battle. The council of Trent, in the mean time, promulgated their decrees; while the reformed princes, in the diet of Ratisbon, protested against their authority, and were on that account proscribed by the emperor, who raised an army to reduce them to obedience. See Father Paul’s History of the Council of Trent, and our articles Father Paul, and Trent.

The elector of Saxony and the landgrave of Hesse led their forces into Bavaria against the emperor, and cannonaded his camp at Ingolstadt. It was supposed that this would bring on an engagement, which would probably have been advantageous to the cause of the reformed; but this was prevented, chiefly by the perjury of Maurice duke of Saxony, who invaded the dominions of his uncle. Divisions were also fomented among the confederate princes, by the dissimulation of the emperor; and France failed in paying the subsidy which had been promised by its monarch: all which so discouraged the heads of the Protestant party, that their army soon dispersed, and the elector of Saxony was obliged to direct his march homewards. But he was pursued by the emperor, who made several forced marches, with a view to destroy his enemy before he should have time to recover his vigour. The two armies met near Mulberg, on the Elbe, on the 24th of April 1547; and, after a bloody action, the elector was entirely defeated, and himself taken prisoner.—Maurice, who had so basely betrayed him, was now declared elector of Saxony; and by his intrigues Philip landgrave of Hesse, the other chief of the Protestants, was persuaded to throw himself on the mercy of the emperor, and to implore his pardon.

To this be consented, relying on the promise of Charles for obtaining forgiveness, and being restored to liberty; but, notwithstanding these expectations, he was unjustly detained prisoner, by a scandalous violation of the most solemn convention. It is said that the emperor retracted his promise, and deluded this unhappy prince by the ambiguity
The ambiguity of two German words. History indeed can scarcely afford a parallel to the perfidious, mean-spirited, and despotick behaviour of the emperor in the present case. After having received in public the humble submission of the prince on his knees, and after having set him at liberty by a solemn treaty, he had him arrested anew without any reason, Nay, without any pretence, and kept him close prisoner for several years. When Maurice remonstrated against this new confinement, the emperor answered, that he had never promised that the landgrave should not be imprisoned anew, but only that he should be exempted from perpetual imprisonment; and, to support this assertion, he produced the treaty, into which his ministers had perfidiously foisted einiger gefangen, which signifies a "perpetual prison," instead of einiger gefangen, which signifies "any prison." This, however, is contested by some historians.

The affairs of the Protestants now seemed to be desperate. In the diet of Augsburg, which was soon after called, the emperor required the Protestants to leave the decision of these religious disputes to the wisdom of the council which was to meet at Trent. The greatest part of the members consented to this proposal, being convinced by the powerful argument of an imperial army, which was at hand to dispel the darkness from the eyes of such as might otherwise have been blind to the force of Charles's reasoning. However, this general submission did not produce the effect which was expected from it. A plague which broke out, or was said to do so, in the city, caused the greatest part of the bishops to retire to Bologna; by which means the council was in effect dissolved, nor could all the intrigues and remonstrances of the emperor prevail upon the pope to reassemble it without delay. During this interval, therefore, the emperor judged it necessary to fall upon some method of accommodating the religious differences, and maintaining peace until the council so long expected should be finally obtained. With this view he ordered Julius Pelagius, bishop of Naumburg, Michael Sidonius, a creature of the pope, and John Agricola, a native of Asseleben, to draw up a formulary which might serve as a rule of faith and worship, till the council should be assembled: but as this only was a temporary expedient, and had not the force of a permanent or perpetual institution, it thence obtained the name of the Interim.

This project of Charles was formed partly with a design to vent his resentment against the pope, and partly to answer other political purposes. It contained all the essential doctrines of the church of Rome, though considerably softened by the artful terms which were employed, and which were quite different from those employed before and after this period by the council of Trent. There was even an affected ambiguity in many of the expressions, which made them susceptible of different senses, and applicable to the sentiments of both communions. The consequence of all this was, that the imperial creed was republied by both parties. However, it was promulgated with great solemnity by the emperor at Augsburg. The elector of Mentz, without even asking the opinion of the princes present, gave a sanction to this formula, as if he had been commissioned to represent the whole diet. Many kept silence through fear, and that silence was interpreted as a tacit consent. Some had the courage to oppose it, and these were reduced by force of arms; and the most deplorable scenes of bloodshed and violence were acted throughout the whole empire.

Maurice, elector of Saxony, who had hitherto kept neutral, now assembled the whole of his nobility and clergy, in order to deliberate on this critical affair. At the head of the latter was Melancthon, whose word was respected as a law among the Protestants. But this reconciler had not the courage of Luther; and was therefore by on all occasions ready to make concessions, and to propose schemes of accommodation. In the present case, therefore, he gave it as his opinion, that the whole of the book called Interim could not by any means be adopted by the Protestants; but at the same time he declared, that he saw no reason why this book might not be approved, adopted and received, as an authoritative rule in things that did not relate to the essential parts of religion, and which he accounted indifferent. But this scheme, instead of cementing the differences, made them worse than ever; and produced a division among the Protestants themselves, which might have overthrown the Reformation entirely, if the emperor and pope had seized the opportunity.

In the year 1549, the pope (Paul III.) died; and a new was succeeded by Julius III., who, at the repeated solicitations of the emperor, consented to the re-assembling of a council at Trent. A diet was again held at Augsburg under the cannon of an imperial army, and Charles laid the matter before the princes of the empire. Most of those present gave their consent to it, and among the rest Maurice elector of Saxony; who consented on the following conditions: 1. That the points of doctrine which had already been decided there, should be re-examined. 2. That this examination should be made in presence of the Protestant divines. 3. That the Saxons should have a liberty of voting as well as of deliberating in the council. 4. That the pope should not pretend to preside in that assembly, either in person or by his legates. This declaration of Maurice was read in the diet, and his deputies insisted upon its being entered into the registers, which the archbishop of Mentz obstinately refused. This diet was concluded in the year 1551; and, at its breaking up, the emperor desired the assembled princes and states to prepare all things for the approaching council, and promised to use his utmost endeavours to procure moderation and harmony, impartiality and charity, in the transactions of that assembly.

On the breaking up of the diet, the Protestants took such steps as they thought most proper for their own safety. The Saxons employed Melancthon, and the Wurttembergers Bregius, to draw up Confessions of Faith to be laid before the new council. The Saxon divines, however, proceeded no farther than Nuremberg, having received secret orders from Maurice to stop there; For the elector, perceiving that Charles had formed designs against the liberties of his German princes, resolved to take the most effectual measures for crushing his ambition at once. He therefore entered with the utmost secrecy and expedition into an alliance with the king of France and several of the German princes, for the security of the rights and liberties of the empire; after which, assembling a powerful army, he marched against the emperor, who lay with his troops at Innsbruck, and, expecting no such peace by the elector was so much dispirited, that he was willing to make of Saxony peace.
peace almost on any terms. The consequence of this
was, that he concluded a treaty at Passau, by which the
Protestants is considered as the basis of their religious
liberty. By the first three articles of this treaty it was
agreed, that Maurice and the confederates should lay
down their arms, and lend their troops to Ferdinand to
assist him against the Turks; and that the landgrave of
Hesse should be set at liberty. By the fourth it was
agreed, that the rule of faith called the Interim should
be considered as null and void: that the contending par-
ties should enjoy the free and undisturbed exercise of
their religion, until a diet should be assembled to deter-
mine amicably the present disputes (which diet was to
meet in the space of six months); and that this reli-
gious liberty should continue always, in case it should
be found impossible to come to a uniformity in doc-
trinity and worship. It was also determined, that all
those who had suffered banishment, or any other cala-
mity, on account of their having been concerned in the
league or war of Smalcalad, should be reinstated in their
privileges, possessions, and employments; that the impe-
rial chamber at Spire should be open to the Protestants
as well as to the Catholics; and that there should al-
ways be a certain number of Lutherans in that high
court. To the peace Albert, marquis of Brandenburg,
refused to subscribe; and continued the war against
the Roman Catholics, committing such ravages in the em-
prise, that a confederacy was at last formed against him.
At the head of this confederacy was Maurice elector of
Saxony, who died of a wound received in a battle
fought on the occasion in 1553.

The assembling of the diet promised by Charles was
prevented by various incidents; however, it met at
Augsburg in 1555, where it was opened by Ferdinand
in name of the emperor, and terminated those deplorable
calamities which had so long desolated the empire. Af-

ter various debates, the following acts were passed, on
the 25th of September: That the Protestants who fol-
lowed the Confession of Augsburg should be for the fu-
ture considered as entirely free from the jurisdiction of
the Roman pontiff, and from the authority and superin-
tendence of the bishops; that they were left at perfect
liberty to enact laws for themselves relating to their re-
ligious sentiments, discipline, and worship; that all the
inhabitants of the German empire should be allowed to
determine themselves to that church whose doctrine and worship
they thought the most pure and consonant to the spirit
of true Christianity; and that all those who should in-
jure or persecute any person under religious pretences,
and on account of their opinions, should be declared and
proceeded against as public enemies of the empire, in-
vaders of its liberty, and disturbers of its peace.

This was the Reformation established in many parts
of the German empire, where it continues to this day;
nor have the efforts of the Popish powers at any time
been able to suppress it, or even to prevent it from gain-
ing ground. It was not, however, in Germany alone
that a reformation of religion took place. Almost all
the kingdoms of Europe began to open their eyes to the
truth about the same time. The reformed religion was
propagated in Sweden, soon after Luther's rupture with
the church of Rome, by one of his disciples named Olau
Petr. The zealous efforts of this missionary were so-
coupled by Gustavus Vasa, whom the Swedes had raised
to the throne in place of Christian II, whose horrid barbarity lost him the crown. This prince,
however, was as prudent as he was zealous; and, as the
minds of the Swedes were in a fluctuating state, he wise-
ly avoided all kind of vehemence and precipitation in
spreading the new doctrine. Accordingly, the first ob-
ject of his attention was the instruction of his people in
the sacred doctrines of the Holy Scriptures: for which
purpose he invited into his dominions several learned
Germans, and spread abroad through the kingdom the
Swedish translation of the Bible that had been made
by Olaus Petri. Some time after this, in 1526, he ap-
pointed a conference at Upsal, between this reformer
and Peter Gallius, a zealous defender of the ancient super-
pition, in which each of the champions was to bring
forth his arguments, that it might be seen on which
side the truth lay. In this dispute Olaus obtained a sig-
nal victory; which contributed much to confirm Gusta-
vus in his persuasion of the truth of Luther's doctrine,
and to promote its progress in Sweden. The follow-

ing year another event gave the finishing stroke to its propa-
gation and success. This was the assembly of the states
at Vesteras, where Gustavus recommended the doc-
trine of the reformers with such zeal, that, after warm
debates fomented by the clergy in general, it was un-
animously resolved that the reformation introduced by
Luther should have place in Sweden. This resolution
was principally owing to the firmness and magnanimity
of Gustavus, who declared publicly, that he would lay
down the sceptre and retire from the kingdom, rather
than rule a people enslaved by the orders and authority
of the pope, and more contrived by the tyranny of
their bishops than by the laws of their monarch. From
this time the papal empire in Sweden was entirely over-
thrown, and Gustavus declared head of the church.

In Denmark, the reformation was introduced as early as
the year 1521, in consequence of the ardent desire
discovered by Christian II. of having his subjects in-
structed in the doctrines of Luther. This monarch,
notwithstanding his cruelty, for which his name has
been rendered odious, was nevertheless desirous of deliv-
ering his dominions from the tyranny of the church of
Rome. For this purpose, in the year 1520, he sent for
Martin Reinard, one of the disciples of Carlstadt, out
of Saxony, and appointed him professor of divinity at
Hafnia; and after his death, which happened in 1521,
he invited Carlstadt himself to fill that important place.
Carlstadt accepted of this office indeed, but in a short
time returned to Germany; upon which Christian used
his utmost endeavours to engage Luther to visit his do-
nominia, but in vain. However, the progress of Chris-
tian, in reforming the religion of his subjects, or rather
of advancing his own power above that of the church,
was checked, in the year 1523, by a conspiracy, by
which he was deposed and banished; his uncle Fred-
ic, duke of Holstein and Sleswic, being appointed his
successor.

Frederic conducted the reformation with much great-
er prudence than his predecessor. He permitted the
Protestant doctors to preach publicly the sentiments
of Luther, but did not venture to change the estab-
ished government and discipline of the church. How-
ever, he contributed greatly to the progress of the refor-
mation, by his successful attempts in favour of religious
liberty in an assembly of the states held at Odensee in
1527.
contempt. Their fate was very severe, being persecuted with unparalleled fury; and though many princes of the blood, and of the first nobility, had embraced their sentiments, yet in no part of the world did the reformers suffer so much. At last all commotions were quelled by the fortitude and magnanimity of Henry IV., who in the year 1558 granted all his subjects full liberty of conscience by the famous Edict of Nantes, and seemed to have thoroughly established the reformation throughout his dominions. During the minority of Louis XIV., however, this edict was revoked by Cardinal Mazarine, since which time the Protestants have often been cruelly persecuted; nor was the profession of the reformed religion in France at any time so safe as in most other countries of Europe.

In the other parts of Europe the opposition to the church of Rome was but faint and ambiguous before the diet of Augsburg. Before that period, however, it appears from undoubted testimony, that the doctrine of Luther had made a considerable, though probably secret, progress through Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands; and in all these countries many friends, of whom several repaired to Wittenberg, in order to enlarge their knowledge by means of Luther's conversation. Some of these countries threw off the Roman yoke entirely, and in others a considerable number of the people embraced the principles of the reformed religion. It is certain indeed, and some Roman Catholics themselves acknowledge it without hesitation, that the Papal doctrines and authority had been much injured by the various persecutions which had taken place, and that the force of the secular arm had been employed to support the tottering edifice. In the Netherlands particularly, the most grievous persecutions took place, so that the emperor Charles V. upwards of 100,000 were destroyed, while still greater cruelties were exercised upon the people by his son Philip II. The revolt of the United Provinces, however, and motives of real policy, at last put a stop to these furious proceedings; and, though in many provinces of the Netherlands, the establishment of the Popish religion was still continued, the Protestants have been long free from the danger of persecution on account of their principles.

The reformation made considerable progress in Spain in Italy and Italy soon after the rupture between Luther and the Roman pontiff. In all the provinces of Italy, but more especially in the territories of Venice, Tuscany, and Naples, the superstition of Rome lost ground, and great numbers of people of all ranks expressed an aversion to the Papal yoke. This occasioned violent and dangerous commotions in the kingdom of Naples in the year 1546; which, however, were at last quelled by the united forces of Charles V. and his viceroy Don Pedro di Toledo. In several places the pope put a stop to the progress of the reformation, by letting loose the inquisitors, who spread dreadful marks of their barbarity through the greatest part of Italy. These formidable ministers of superstition put so many to death, and perpetrated such horrid acts of cruelty and oppression, that most of the reformed consulted their safety by a voluntary exile, while others returned to the religion of Rome, at least in external appearance. But the inquisition, which frightened into the profession of Popery several Protestants in other parts of Italy, could never make its way into the kingdom of Naples; nor could either
Though Henry had not the least idea of rejecting any, even of the most absurd Romish superstitions, yet as the oppressions of the clergy suited very ill with the violence of his own temper, he was pleased with every opportunity of lessening their power. In the parliament of 1531, he showed his design of humbling the clergy in the most effectual manner. An obsolete statute was revived, from which it was pretended that it was criminal to submit to the legantine power which had been exercised by Cardinal Wolsey. By this stroke the whole body of clergy was declared guilty at once. They were too well acquainted with Henry's disposition, however, to reply, that their ruin would have been the certain consequence of their not submitting to Wolsey's commission, which had been given by royal authority. Instead of making any defence of this kind, they chose to throw themselves on the mercy of their sovereign; which, however, it cost them 118,840l. to procure. A confession was likewise extorted from them, that the king was protector and supreme head of the church of England; though some of them had the dexterity to get a clause inserted, which invalidated the whole submission, viz. in so far as is permitted by the law of Christ.

The king, having thus begun to reduce the power of the clergy, kept no bounds with them afterwards. He did not indeed attempt any reformation in religious matters; nay, he persecuted most violently such as did attempt this in the least. Indeed, the most essential article of his creed seems to have been his own supremacy: for whoever denied this, was sure to suffer the most severe penalties, whether Protestant or Papist. But an account of the absurd and cruel conduct of this prince, and of his final quarrel with the pope on account of his refusing a dispensation to marry Anne Boleyn, is given under the article ENGLAND, No. 235—292.

He died in 1547, and was succeeded by his only son Edward VI. The amiable prince, whose early youth was crowned with so many disasters, and whose life that would have done honour to advanced years, gave new spirit and vigour to the Protestant cause, and was its brightest ornament, as well as its most essential support. He encouraged learned and pious men of foreign countries to settle in England, and addressed a particular invitation to Martin Bucer and Paul Fagius, whose moderation added a lustre to their other virtues, that, by the ministry and labours of these eminent men, in concert with those of the friends of the Reformation in England, he might purge his dominions from the sordid fictions of popery, and establish the pure doctrines of Christianity in their place. For this purpose, he issued out the wisest orders for the restoration of true religion; but his reign was too short to accomplish fully such a glorious purpose. In the year 1553, he was taken from his loving and afflicted subjects, whose sorrow was inexpressible, and suited to their loss. His sister Mary (the daughter of Catharine of Aragon, from whom Henry had been separated by the famous divorce), a furious bigot to the church of Rome, and a princess whose natural character, like the spirit of her religion, was despotic and cruel, succeeded him on the British throne, and imposed anew the arbitrary laws and the tyrannical yoke of Rome upon the people of England. Nor were the methods she employed in the cause of
being a churchman, waited on the doctor, who in dis-
course with the mayor took out of a cloke-bag a
leather box, saying unto him, Here is a commission
that shall lash the Heretics of Ireland, calling the Pro-
stants by that title. The good woman of the house
being well affected to the Protestant religion, and also
having a brother named John Edmonds of the same
persuasion, then a citizen in Dublin, was much troubled
at the doctor's words, but watching her convenient time
while the mayor took his leave, and the doctor com-
plimented him down the stairs, she opens the box, takes
the commission out, and places in lieu thereof a sheet of
paper with a pack of cards wrapt up therein, the knife
of clubs being faced uppermost. The doctor was led
up to his chamber, suspecting nothing of what had been
done, put up the box as formerly. The next day go-
ing to the water-side, wind and weather serving him,
he sails towards Ireland, and landed on the 7th of Oc-
tober 1558 at Dublin. Then coming to the castle, the
lord Fitz-Walters being lord-deputy, sent for him to
come before him and the privy-council; who, coming
in, after he had made a speech relating upon what ac-
count he came over, he presents the box unto the lord-
deputy; who causing it to be opened, that the secretary
might read the commission, there was nothing save a
pack of cards with the knife of clubs uppermost;
which not only startled the lord-deputy and council,
but the doctor, who assured them he had a commission,
but knew not how it was gone. Then the lord-deputy
made answer: Let us have another commission, and we
will shuffle the cards in the meanwhile. The doctor
being troubled in his mind, went away, and returned in
To England, and coming to the court obtained another
commission; but when the news came to him that the queen was dead: and thus
God preserved the Protestants of Ireland." Queen
Elizabeth was so delighted with this story, which was
related to her by Lord Fitz-Walter on his return to
England, that she sent for Elizabeth Edmonds, whose
husband's name was Mustershad, and gave her a pen-
sion of 40l. during her life.

In Scotland, the seeds of reformation were very early
of the Re-
formation, by several noblemen who had resided in Germany
during the religious disputes there. But for many years
it was suppressed by the power of the pope, seconded by
inhuman laws and barbarous executions. The most
eminent
opponent of the Papal jurisdiction was John Knox,
a disciple of Calvin, a man of great zeal and invincible
fortitude. On all occasions he raised the drooping spir-
ts of the reformers, and encouraged them to go on
with their work notwithstanding the opposition and
treachery of the queen-regent; till at last, in 1561, by
the assistance of an English army sent by Elizabeth,
Popery was in a manner totally extirpated throughout
the kingdom. From this period the form of doctrine,
worship, and discipline established by Calvin at Geneva,
has had the ascendancy in Scotland. But for an account
of the difficulties which the Scottish reformers had
to struggle with, and the manner in which these were
overcome, &c. see SCOTLAND.

For further information on the subject of the refor-
mation in general we refer our readers to the works
of Burnet and Brandt, to Beausobre's Histoire de la
Reformation dans l'Empire, et les Etats de la Confession
de Augsburg, depuis 1517—1530, in 4 vols 8vo, Berlin
4 R 2 1753,
REFLECTION, in general, is the deviation of a moving body from its direct course, occasioned by the different density of the medium in which it moves; or it is a change of direction occasioned by a body's falling obliquely out of one medium into another. The word is chiefly made use of with regard to the rays of light. See OPTICS Index, at Refraction.

REFRACTION of Altitude, the arc or portion of a vertical circle, by which the altitude of a star is increased by the refraction of light.

REFRACTION of Ascension and Declension, an arc of the equator, by which the ascension and declension of a star, whether right or oblique, is increased or diminished by the refraction.

REFRACTION of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by refraction.

REFRACTION of Latitude, an arc of a circle of latitude, by which the latitude of a star is increased or diminished by the refraction.

REFRACTION of Longitude, an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

REFRACTION, Terrestrial, is that which makes terrestrial objects appear to be raised higher than they are in reality, in observing their altitudes. The quantity of this refraction is estimated at one-tenth by Dr. Maskelyne; at one-fourteenth by Le Gentil; and by De Lambre at one-eleventh. But there can be no fixed quantity of this refraction, since it depends upon the state of the atmosphere, which is extremely variable. Some singular effects of this refraction have been noticed, and in particular the following, which were observed by Mr. Latham at Hastings, during a very hot day, on which it was high water about two o'clock P.M. The day was also perfectly calm.

"On Wednesday, July 26. about five o'clock in the afternoon, while I was sitting in my dining-room at this place, which is situated upon the Parade, close to the sea-shore, nearly fronting the south, my attention was engaged by a number of people running down to the seaside. Upon inquiring the reason, I was informed that the coast of France was plainly to be distinguished by the naked eye. I immediately went down to the shore, and was surprised to find that, even without the assistance of a telescope, I could very plainly see the cliffs on the opposite coast; which, at the nearest part, are between 40 and 50 miles distant, and are not to be discerned, from that low situation, by the aid of the best glasses. They appeared to be only a few miles off, and seemed to extend for some leagues along the coast. I pursued my walk along the shore eastward, close to the water's edge, conversing with the sailors and fishermen upon the subject. They at first could not be persuaded of the reality of the appearance; but they soon became so thoroughly convinced, by the cliffs gradually appearing more elevated, and approaching nearer, as it were, that they pointed out and named to me the different places that had been accustomed to visit; such as the Bay, the Old Head or Man, the Windmill, &c., at Boulogne; St. Vaury, and other places on the coast of Picardy; which they afterwards confirmed to me as they viewed them through their telescopes. Their observations were, that the places appeared as near as six miles if they were sailing at a small distance, into the horizon."

REFRANGIBILITY of LIGHT, the disposition of rays to be refracted. The term is chiefly applied to the disposition of rays to produce different colours, according to their different degrees of refrangibility. See CHROMATICS and OPTICS passim.

REFRIGERATIVE, in Medicine, a remedy which refreshes the inward parts by cooling them; a hypodermic,pleura, &c.

REFRIGERATORY, in Chemistry, a vessel filled with cold water, through which the worm passes until it is freed; the use of which is to condense the vapour as they pass through the worm.

CITIES of REFUGES, were places provided in Asia, for such as against their will should happen to find refuge. Of these cities there were three on each side of the Jordan: on this side were Kedesh of Naphtali, Hebron, and Shechem; beyond Jordan were Bezer, Golan, and Ramoth-Gilead. When any of the Hebrews, or strangers that dwelt in their country, happened to spill the blood of a man, they might retire whither to be safe from the reach of the violent attempts of the relations of the deceased, and to prepare for their defence and justification before the judges. The manner of the trials: first before the judges of the city of refuge to which he had fled; and secondly before the judges of his own city. If he was acquitted, he was not immediately set at liberty; but, to inspire a degree of horror against even involuntary homicide, he was conducted to the place of refuge, and obliged to continue there for a sort of banishment till the death of the high-priest. If, before this time, he ventured out, the revenger of blood might freely kill him; but after the high-priest's death he was at liberty to go where he pleased without molestation. It was necessary that the person who fled to any of the cities of refuge should understand some trade or calling, that he might not be burthensome to the inhabitants. The cities of refuge were required to be well supplied with water and necessary provisions. They were also to be of such access, to have good roads leading to them, with commodious bridges where there was occasion. The width of the roads was to be 32 cubits or 48 feet at least. It was further required, that at all cross-ways direction-roads should be erected, with an inscription pointing out the road to the cities of refuge. The 1st of Adar, which answers to our February, was appointed for the city magistrates to see that the roads were in good condition. No person in any of these cities was allowed to make weapons, lest the relations of the deceased should be furnished with the means of gratifying the revenge. Deut. xix. 3, 4, 5; Josh. xx. 7. The other cities of refuge were conditionally promised to be never granted. See ASYLUM.

REFUGEES, a term at first applied to the Free Protestants, who, by the revocation of the Edit of Nantes were constrained to fly from persecution, and take refuge in foreign countries. Since that time, however, it has been extended to all such as leave their country in time of distress; and hence, since the revival of the British
Regale, a magnificent entertainment or treat, given to ambassadors and other persons of distinction, to entertain or do them honour.

It is usual in Italy, at the arrival of a traveller of eminence, to send him a regale, that is, a present of sweet-meats, fruits, &c. by way of refreshment.

Regalia, in Law, the rights and prerogatives of a king. See Prerogative.

Regalia is also used for the apparatus of a coronation; as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the cross, four several swords, &c. —The regalia of Scotland were deposited in the castle of Edinburgh in the year 1707, in what is called the jewel office. The room was a few years ago opened by some commissioners appointed by the king, when the large chest in which it is supposed they were placed was examined; but nothing was found in it. It is very generally thought that the regalia were carried to the Tower of London in the reign of Queen Anne; and a crown is there shown which is called the Scotch crown. This, however, does not appear to be the real crown of Scotland. It seems, therefore, most probable that the Scottish regalia must have been taken away by stealth, and either destroyed or melted down.

Lord of Regality, in Scots Law. See Law, No. 170.

Court of Regard. See Forest Courts.

Regardant, in Heraldry, signifies looking behind; and it is used for a lion or other beast, with his face turned towards his tail.

Regarder, an ancient officer of the king's forest, sworn to make the regard of the forest every year; that is, to take a view of its limits, to inquire into all offences and defaults committed by the foresters within the forest, and to observe whether all the officers execute their respective duties. See Forest Laws.

Regata, or Regatta, a species of amusement peculiar to the republic of Venice. This spectacle has the power of exciting the greatest emotions of the heart, admiration, enthusiasm, a sense of glory, and the whole train of our best feelings. The grand regata is only exhibited on particular occasions, as the visits of foreign princes and kings at Venice.

It is difficult to give a just idea of the ardour that the notice of a regata spreads among all classes of the inhabitants of Venice. Proud of the exclusive privilege of giving such a spectacle, through the wonderful local circumstances of that city, they are highly delighted with making preparations a long time before, in order to contribute all they can towards the perfection and enjoyment of the spectacle. A thousand interests are formed and augmented every day; parties in favour of the different competitors who are known; the protection of young noblemen given to the gondoliers in their service; the desire of honours and rewards in the aspirants; and, in the midst of all this, that ingenious national industry, which awakens the Venetians from their habitual indolence, to derive advantage and business from the agitation of the moment; all these circumstances united give to the numerous inhabitants of this lovely city a degree of spirit and animation which render it during that time a delightful abode in the eyes of the philosopher and the stranger. Crowds of people flock from the adjacent parts, and travellers joyfully repair to this scene of gaiety and pleasure.

Although it is allowable for any man to go and inscribe his name in the list of combatants until the fixed number is complete, it will not be amiss to remark one thing, which has relation to more ancient times. The state of a gondolier is of much consideration among the people; which is very natural, having been the primitive condition of the inhabitants of this country. But, besides this general consideration, there are among them some families truly distinguished and respected by their equals, whose antiquity is acknowledged, and who, on account of a succession of virtuous men, able in their profession, and honoured for the prizes they have carried off in these contests, form the body of noble gondoliers; often more worthy of that title than the higher order of nobility, who only derive their honours from the merit of their ancestors, or from their own riches. The consideration for those families is carried so far, that, in the disputes frequently arising among the gondoliers in their ordinary passage of the canals, we sometimes see a quarrel instantly made up by the simple interposition of a third person, who has chosen to be of this revered body. They are rigid with respect to misalliances in their families, and they endeavour reciprocally to give and take their wives among those of their own rank. But we must remark here, with pleasure, that these distinctions infer no inequality of condition, nor admit any oppression of inferiors, being founded solely on laudable and virtuous opinions. Distinctions derived from fortune only, are those which always outrage nature, and often virtue.

In general, the competitors at the great regatas are chosen from among these families of reputation. As soon as they are fixed upon for this exploit, they spend the intermediate time in preparing themselves for it, by a daily, assiduous, and fatiguing exercise. If they are in service, their masters during that time not only give them their liberty, but also augment their wages. This custom would seem to indicate, that they look upon them as persons consecrated to the honour of the nation, and under a sort of obligation to contribute to its glory.

At last the grand day arrives. Their relations assemble together; they encourage the heroes, by calling to their minds the records of their families; the women present the oar, beseeching them, in an epic tone, to remember that they are the sons of famous men, whose steps they will be expected to follow: this they do with as much solemnity as the Spartan women presented the shield to their sons, bidding them to return with or upon it. Religion, as practiced among the lower class of people, has its share in the preparation for this enterprise. They cause masses to be said; they make vows to some particular church; and they arm their boats for the contest with the images of those saints who are most in vogue. Sorcerers are not forgotten upon this occasion. For gondoliers who have lost the race often declare, that witchcraft had been practised against them, or certainly they must have won the day. Such a supposition prevents a poor fellow from thinking ill of himself, an opinion that might be unfavourable to him another time.

The
The course is about four miles. The boats start from a certain place, run through the great wading canal, which divides the town into two parts, turn round a picket, and, coming back the same way, go and seize the prize, which is fixed at the acutest angle of the great canal, on the convex side, so that the point of sight may be the more extended, and the prize seized in the sight of the spectators on both sides.

According to the number of competitors, different races are performed in different sorts of boats; some with one oar and others with two. The prizes proposed are four, indicated by four flags of different colours, with the different value of the prizes marked upon them.—These flags, public and glorious monuments, are the prizes to which the competitors particularly aspire. But the government always add to each a gentle sum of money; besides that the conquerors, immediately after the victory, are surrounded by the beau monde, who congratulate and make them presents; after which they go, bearing their honourable trophy in their hand down the whole length of the canal, and receive the applause of innumerable spectators.

This grand canal, ever striking by the singularity and beauty of the buildings which border it, is, upon these occasions, covered with an infinity of spectators, in all sorts of barges, boats, and gondolas. The element on which they move is scarcely seen; but the noise of oars, the agitation of arms and bodies in perpetual motion, indicate the spectacle to be upon the water. At certain distances, on each side of the shore, are erected little amphitheatres and scaffolds; where are placed bands of music, and the harmonious sound of which predominates now and then over the buzzing noise of the people. Some days before a regatta, one may see on the great canal many boats for pleasure and entertainment. The young noble, the citizen, the rich artizan, mounts a long boat of six or eight oars; his gondoliers decorated with rich and singular dresses, and the vessel itself adorned with various stuffs. Among the nobles there are always a number who are at a considerable expense in these decorations; and at the regatta itself exhibit on the water personages of mythologic story, with the heroes of antiquity in their train, or amuse themselves with representing the costumes of different nations: in short, people contribute with a mad sort of magnificence, from all quarters, to this masquerade, the favourite diversion of the Venetians. But these great machines, not being the less in motion on account of their ornaments, are not merely destined to grace the show: they are employed at the regatta, at every moment, to range the people, to protect the course, and to keep the avenue open and clear to the goal.

The nobility, kneeling upon cushions at the prow of their vessels, are attentive to these matters, and announce their orders to the most restive, by darting at them little gilded or silvered balls, by means of certain bows, with which they are furnished on this occasion. And this is the only appearance of coercion in the Venetian police on these days of the greatest tumult: nor is there to be seen, in any part of the city, a body of guards or patrol, nor even a gun or a halbert. The mildness of the nation, its gaiety, its education in the habit of believing that the government is ever awake, that it knows and sees every thing; its respectful attachment to the body of patricians; the sole aspect of certain officers of the police in their robes, dispersed in different places, at once operate and explain that tranquillity, that security, which we see in the midst of the greatest confusion, and that surprising docility in so lively and fiery a people. Regatas have been attempted on the river Thames, but they were but humble imitations of the Venetian amusement.

REGEL, or RIGEL, a fixed star of the first magnitude, in Orion’s left foot.

REGENERATION, in Theology, the act of being born again by spiritual birth, or the change of heart and life experienced by a person who forsakes a course of vice, and sincerely embraces a life of virtue and piety.

REGENSBURG, or RATZEBURG. See RATZEBURG.

REGENT, one who governs a kingdom during the minority or absence of the king.

In France, the queen-mother had the regency of the kingdom during the minority of the king, under the title of queen-regent.

In England, the methods of appointing this guardian or regent have been so various, and the duration of his power so uncertain, that from hence alone it may be collected that his office is unknown to the common law; and therefore (as Sir Edward Coke says, 4 Inst. 58.) the surest way is to have him made by authority of the great council in parliament. The earl of Pembroke by his own authority assumed in very troublesome times the regency of Henry III. who was then only nine years old; but was declared of full age by the pope at 17, confirmed the great charter at 18, and took upon him the administration of the government at 20. A guardian and councils of regency were named for Edward III. by the parliament, which deposed his father; the young king being then 15, and not assuming the government till three years after. When Richard II. succeeded at the age of 11, the duke of Lancaster took upon him the management of the kingdom till the parliament met, which appointed a nominal council to assist him. Henry V. on his deathbed named a regent and a guardian for his infant son Henry VI. then nine months old: but the parliament altered his disposition, and appointed a protector and council, with a special limited authority. Both these princes remained in a state of pupillage till the age of 23. Edward V. at the age of 13, was recommended by his father to the care of the duke of Gloucester; who was declared protector by the privy council. The statutes 25 Hen. VIII. c. 12. and 28 Henry VIII. c. 7. provided, that the successor, if a male and under 18, or if a female and under 16, should be till such age in the governance of his or her natural mother (if approved by the king), and such other counsellors as his majesty should by will or otherwise appoint: and be accordingly appointed his 16 executors to have the government of his son Edward VI. and the kingdom, which executors elected the earl of Hartford protector. The statutes 24 Geo. II. c. 24. in case the crown should descend to any of the children of Frederic late prince of Wales under the age of 18, appointed the princess dowager; and that of 5 Geo. III. c. 27. in case of a like descent to any of his present majesty’s children, empowers the king to name either the queen or princess dowager, or any descendant of King George II. residing in this kingdom; to be guardian and regent till the successor attains such age, assisted by
REGICIDE, KING-KILLER, a word chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution of Charles I.

REGIMEN was a feast celebrated at Rome on the 24th of February, in commemoration of the expulsion of Tarquinus Superbus, and the abolition of regal power. It was also performed on the 26th of May, when the king of the sacrifices, or Res Sacrorum, offered bean flour and bacon, in the place where the assemblies were held. The sacrifice being over, the people hastened away with all speed, to denote the precipitate flight of King Tarquin.

REGIMEN, the regulation of diet, and, in a more general sense, of all the non-naturals, with a view to preserve or restore health. See ABSTINENCE, ALIMENT, FOOD, DIET, DRINK, and MEDICINE.

The vicissitude of exercise and rest forms also a necessary part of regimen. See EXERCISE.

It is beneficial to be at rest now and then, but more so frequently to use exercise; because inaction renders the body weak and listless, and labour strengthens it. But a medium is to be observed in all things, and too much fatigue is to be avoided: for frequent and violent exercise overpowers the natural strength, and wastes the body; but moderate exercise ought always to be used before meals. Now, of all kinds of exercise, riding on horseback is the most convenient, and: or if the person be too weak to bear it, riding in a coach, or at least in a litter: next follow fencing, playing at ball, running, walking. But it is one of the inconveniences of old age, that there is seldom sufficient strength for using bodily exercise, though it be extremely requisite for health: wherefore frictions with the flesh-brush are necessary at this time of life; which should be performed by the person himself, if possible; if not, by his servants.

Sleep is the sweet soother of cares, and restorer of strength; as it repairs and replaces the wastes that are made by the labours and exercises of the day. But excessive sleep has its inconveniences; for it blunts the senses, and renders them less fit for the duties of life. The proper time for sleep is the night, when darkness and silence invite and bring it on: day-sleep is less refreshing; which rule, if it be proper for the multitude to observe, much more is the observance of it necessary for persons addicted to literary studies, whose minds and bodies are more susceptible of injuries.

REGIMENT, in Grammar, that part of syntax, or construction, which regulates the dependency of words, and the alterations which one occasions in another.

REGIMENT for Seamen. See SEAMEN.

REGIMENT, is a body of men, either horse, foot, or artillery, commanded by a colonel, lieutenant-colonel, and major. Each regiment of foot is divided into companies; but the number of companies differs: though in Britain our regiments are generally 10 companies, one of which is always grenadiers, exclusive of the two independent companies. Regiments of horse are commonly six troops, but there are some of nine. Dragoon regiments are generally in war time 8 troops, and in time of peace but 6. Each regiment has a chaplain, quarter master, adjutant, and surgeon. Some German regiments consist of 2000 foot; and the regiment of Picardy in France consisted of 6000, being 120 companies, of 50 men in each company.
REGIS PETER SYLVARUS, a French philosopher, was born in Laon in 1510. He studied law and medicine at the universities of Paris and Montpellier, and later taught at the University of Paris. He was a prominent figure in the development of the philosophy of Descartes and the history of science.

The works of this author are best known for their contributions to the philosophy of science, particularly in the areas of mathematics, logic, and metaphysics. He was a key figure in the development of the philosophy of René Descartes, and his influence can be seen in the works of many later philosophers.

In his book "The Use of Reason and of Fiction" (1599, 1600), he argued for the importance of fictional narratives in scientific inquiry. His ideas on the nature of the mind and the soul, as well as his views on the nature of language and the role of imagination in thought, have had a lasting impact on the philosophy of mind.

His work on logic and metaphysics, particularly his concept of the "analytic" and "synthetic" propositions, has been influential in the development of modern logical and philosophical thought. His ideas on the nature of experience and the role of imagination in thought have also had a significant impact on the development of the philosophy of mind.

In summary, Regis Peter Sylvarus was a key figure in the development of the philosophy of science and mathematics, and his ideas have had a lasting impact on the philosophy of mind and logic.
2. Parish-registers are books in which are registered the baptisms, marriages, and burials, of each parish. Registers were kept both at Athens and Rome, in which were inserted the names of such children as were to be brought up, as soon as they were born. Marcus Aurelius required all free persons to give in accounts of their children, within 30 days after the birth, to the treasurer of the empire, in order to their being deposited in the temple of Saturn, where the public acts were kept. Officers were also appointed as public registers in the provinces, that recourse might be had to their lists of names, for settling disputes, or proving any person's freedom.

Registers, in Commerce, are vessels which obtain a permission, either from the king of Spain, or the council of the Indies, to traffic in the ports of the Spanish West Indies; which are thus called, from their being registered before they set sail from Cadiz for Buenos Ayres.

Registers, in Chemistry, are holes, or chinks with stopples, contrived in the sides of furnaces, to regulate the fire; that is, to make the heat more intense or remiss, by opening them to let in the air, or keeping them close to exclude it. There are also registers in the steam-engine. See Steam-Engine.

REGISTRAR, an officer in the English universities, who has the keeping of all the public records.

REGIUM, Regium Leptidi, Regium Lepidum in Ancient Geography, a town of Caesalpine Gaul, on the Via Æmilia, so called from Æmilius Lepidus, who was consul with C. Flaminius; but whence it was sur

named Regium is altogether uncertain. Tacitus relates, that at the battle of Bedriacum, a bird of an unusual size was seen perching in a famous grove near Regium Lepidum. Now called Reggio, a city of Modena. E. Long. 11°. 0. N. Lat. 44° 45'. See REGGIO.

REGNARD, John Francis, one of the best French comic writers after Molière, was born at Paris in 1647. He had scarcely finished his studies, when an ardent passion for travelling carried him over the greatest part of Europe. When he settled in his own country, he was a treasurer of France, and lieutenant of the waters and forests: he wrote a great many comedies; and, though naturally of a gay genius, died of chagrin in the 52d year of his age. His works, consisting of comedies and travels, were printed at Rouen, in 5 vols. 12mo. 1732.

REGNIER, Mathurin, the first French poet who succeeded in satire, was born at Chartres in 1573. He was brought up to the church, a place in which his de

baucheries rendered him very unsuitable; and these by his own confession were so excessive, that at 30 he had all the infirmities of age. Yet he obtained a canonry in the church of Chartres, with other benefices; and died in 1613. There is a neat Elzevir edition of his works, 12mo. 1632. Leyden; but the most elegant is that with notes by M. Brosselet, 4to. 1729. London.

Regnier des Marres, Seraphin, a French poet, born at Flémalle in 1643. He distinguished himself early by his poetical talents, and in 1684 was made perpetual secretary to the French academy on the death of Mez

say: it was he who drew up all those papers in the name of the academy against Furetière; the king gave him the priory of Grammont, and he had also an abbey.

He died in 1713, and his works are, French, Italian, Spanish, and Latin poems, 2 vols.; a French gram

mar; and an Italian translation of Anacreon's odes, with some other translations.

REGNUM, in Ancient Geography, a town of the Regni, a people in Britain, next the Cantii, now Surry, Sussex, and the coast of Hampshire, (Camden) a town situated, by the Itinerary numbers, on the confines of the Belgae, in a place now called Ringwood, in Hampshire, on the rivulet Avon, running down from Salisbury, and about ten miles or more distant from the sea.

Regrator, signifies him who buys and sells any wares or victuals in the same market or fair; and regrators are particularly described to be those who buy, or get into their hands, in fairs or markets, any grain, fish, butter, cheese, sheep, lambs, calves, swine, pigs, geese, capons, hens, chickens, pigeons, conies, or other dead victuals whatsoever, brought to a fair or market to be sold there, and do sell the same again in the same fair, market, or place, or in some other within four miles thereof.

Regrating is a kind of huckstrey, by which victuals are made dearer; for every seller will gain something, which must of consequence enhance the price. And, in ancient times, both the engrosser and regrator were comprehended under the word forestaller. Regrators are punishable by loss and forfeiture of goods, and imprisonment, according to the first, second, or third offence, &c.

REGENSBERG, a handsome though small town of Switzerland, in the canton of Zurich, and capital of a bailiwick of the same name, with a strong castle, seated on a hill, which is part of Mount Jura. There is a well sunk through a rock, 36 fathoms deep.

Regular, denotes any thing that is agreeable to the rules of art: thus we say, a regular building, verb, &c.

A regular figure in geometry, is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides is commonly termed an equilateral triangle or square, as all others with more sides are called regular polygons.

Regular Body, called also Platonic Body, is a body or solid comprehended by like, equal, and regular plane figures, and whose solid angles are all equal.

The plane figures by which the solid is contained are the faces of the solid; and the sides of the plane figures are the edges or linear sides of the solid.

There are only five regular solids, viz.

The tetrahedron, or regular triangular pyramid, having four triangular faces;

The hexahedron, or cube, having six square faces;

The octahedron, having eight triangular faces.

The dodecahedron, having twelve pentagonal faces;

The icosahedron, having twenty triangular faces.

Besides these five, there can be no other regular bodies in nature.

Regular, in a monastery, a person who has taken the vows, because he is bound to observe the rules of the order he has embraced.

Regulation, a rule or order prescribed by a superior, for the proper management of some affair.

Regulator of a Watch, the small spring belonging
longing to the balance; serving to adjust its motions, and make it go faster or slower. See Watch.

REGULBUM, or REGULVUM, (Notitia Imperii); mentioned nowhere else more early: a town of the Cantii, in Britain. Now Reculver, a village on the coast, near the island Thanet, towards the Thames, to the north of Canterbury, (Camden).

REGULUS, M. Attilius, a consul during the first Punic war. He reduced Brundisium, and in his second consulship he took 64 and sunk 30 galleys of the Carthaginian fleet, on the coasts of Sicily. Afterwards he landed in Africa; and so rapid was his success, that in a short time he made himself master of about 200 places of consequence on the coast. The Carthaginians sued for peace, but the conqueror refused to grant it; and soon after he was defeated in a battle by Xanthippus, and 30,000 of his men were left on the field of battle, and 1,500 taken prisoners. Regulus was in the number of the captives, and he was carried in triumph to Carthage. He was sent by the enemy to Rome, to propose an accommodation and an exchange of prisoners; and if his mission was unsuccessful, he was bound by the most stringent oaths to return to Carthage without delay. When he came to Rome, Regulus dissuaded his countrymen from accepting the terms which the enemy proposed; and when his opinion had such influence on the senate, Regulus retired to Carthage agreeable to his engagements. The Carthaginians were told that their offers of peace had been rejected at Rome by the means of Regulus; and therefore they prepared to punish him with the greatest severity. His eye-brows were cut, and he was exposed for some days to the excessive heat of the meridian sun, and afterwards confined in a barrel, whose sides were everywhere filled with large iron spikes, till he died in the greatest agonies. His sufferings were heard of at Rome; and the senate permitted his widow to inflict whatever punishment she pleased on some of the most illustrious captives of Carthage which were in their hands. She confined them also in presses filled with sharp iron points; and was so exquisite in her cruelty, that the senate interfered, and stopped the barbarity of her punishment. Regulus died about 251 years before Christ.—Memmius, a Roman, made governor of Greece by Caligula. While Regulus was in his province, the emperor wished to bring the celebrated statue of Jupiter Olympus by Phidias to Rome, but this was supernaturally prevented; and according to ancient authors, the ship which was to convey it was destroyed by lightning, and the workmen who attempted to remove the statue were terrified away by sudden noises. A man who condemned Scipio.—Roscius, a man who held the consulship but for one day, in the reign of Vittellius.

REGULUS, in Astronomy, a star of the first magnitude, in the constellation Leo; called also, from its situation, Cor Leonis, or the Lion's Heart; by the Arabs, Alhabar; and by the Chaldeans, Kalheleced, or Kurbaleced; from an opinion of its influencing the affairs of the heavens.

REGULUS, in Chemistry, the metallic matter that falls to the bottom of the crucible, in the melting of ores or impure metallic substances. It is the finest or purest part of the metal; and, according to the alchemists, is denominated regulus, or little king, as being the first-born of the royal metallic blood. According to them, it is really a son, but not a perfect man; i. e. not yet a perfect metal, for want of time and proper nourishment. To procure the regulus of metals, &c. flux powders are commonly used; as nitre, tartar, &c. which purges the sulphureous part adhering to the metal, by attracting and absorbing it to themselves.

REHEARSAL, in Music and the Drama, an essay or experiment of some composition, generally made in private, previous to its representation or performance in public, in order to render the actors and performers more perfect in their parts.

REICHENBERG, in Bohemia, 95 miles west of Prague, 205 north-west of Vienna, N. Lat. 50 2. E. Long. 12. 25. is only remarkable as the place where the Prussian army defeated the Austrians on the 21st of April 1757. The Austrian army, commanded by Count Königseck, was posted near Reichenberg, and was attacked by the Prussians under the command of the prince of Brunswick Bevern. The Prussians were 20,000 and the Austrians 18,000: the action began at half past six in the morning, when the Prussian lines were formed, and attacked the Austrian cavalry, which was ranged in three lines of 30 squadrons, and whose two wings were sustained by the infantry, which was posted among the fallen trees and intrenchments. The Austrians had a village on their right, and a wood on their left, where they were intrenched. The Prussian dragoons and grenadiers cleared the intrenchment and wood, and entirely routed the Austrian cavalry; at the same time, the redoubts that covered Reichenberg were taken by General Leestwitz; and the Austrians were entirely defeated. The Prussians had seven officers and 100 men killed; 14 officers and 150 men wounded. The Austrians had 1000 men killed and wounded; 20 of their officers and 400 men taken prisoners. The action ended at eleven.

REID, Thomas, D. D. an eminent philosopher and distinguished literary character, was the son of Lewis Reid, minister of the parish of Strachan in the county of Kincardine, North Britain. His mother was the daughter of Mr Gregory of Kinnaidie in Banffshire, was one of twenty-nine children, and was sister to David, James, and Charles Gregories, who were at the same period professors of astronomy or mathematics, in the universities of Oxford, Edinburgh, and St Andrews.

Dr Reid was born at the parsonage house of Strachan, in April 1710, and received the elementary parts of his education at the parish-school of Kincardine-o’-Neil. The parochial schools of Scotland are said to have been much superior at that period to what they are at present, and young men went from them well furnished with philosophical learning to the different universities. The early progress of young Reid must have been very extraordinary, since he was qualified to profit by the lectures of the professors at the age of twelve. He soon gave very striking proofs that he inherited the genius of his mother’s family, and was conspicuous among the students of mathematics, in a college where that science has always been cultivated with zeal and success. He continued longer at the university than the usual term of years, as he had been appointed to the office of librarian, which was a situation very agreeable to him, as it gave him such an ample opportunity of gratifying his passion for study. About this time he became intimately attached to John Stewart, afterwards professor of mathematics in Marischal college, which connection greatly strengthened his predilection for mathematical studies.
He resigned the office of librarian in the year 1736, and accompanied Mr. Stewart to England, when they paid a visit to London, Oxford, and Cambridge, and were introduced to several persons of the first literary distinction. On account of his relation to Dr. David Gregory, he had ready access to the celebrated Martin Folkes, whose house might be said to contain many of the most interesting objects to be met with in the metropolis. He saw Dr. Bentley at Cambridge, with whose erudition he was much delighted, as well as amused with his vanity; and he also conversed frequently with Sanderson, the blind mathematician. Dr. Reid refers in his specifications to this gentleman's blindness, as a singular phenomenon in the history of the human mind.

Dr. Reid maintained an uninterrupted friendship with the learned and amiable Mr. Stewart till the year 1766, at which time Mr. Stewart was carried off by a malignant fever. The circumstances attending the death of this excellent man deeply wounded the sensibility of Dr. Reid; for his wife and daughter were carried off by the same disorder, and buried with him in one grave.

The King's college of Aberdeen presented Dr. Reid to the living of New-Machar in the year 1737; but such was the zeal of the people against the laws of patronage at that time, that he not only met with violent opposition, but was also exposed to personal danger. But his attention to the duties of his office was so exemplary, his temper so mild and forbearing, and his spirit of humanity so active, that in a short time he subdued their prejudices; and when at last called in the course of providence to a different situation, the very people who had been guilty of gross and indecent outrages against him followed him, on his departure, with their benedictions and tears.

In 1740, he married Elizabeth, daughter of his uncle, Dr. George Reid, physician in London, after which his popularity at New-Machar was greatly increased. Her manners were so accommodating, and so numerous were her kind offices to the sick and the indigent, that the departure of the family from the neighbourhood was looked upon as a general misfortune. The manner in which several old men were accustomed to speak upon the subject is worthy of being kept in remembrance. "We fought, said they, against Dr. Reid when he came, and we would have fought for him when he went away."

The greater part of his residence at New-Machar was devoted to the most intense study, particularly directing his attention to the laws of external perception, and of the other principles which constitute the basis of human knowledge. He unbended his mind by the amusements of gardening and botany, of which he was extremely fond, even in old age.

The professors of King's College, in the year 1752, made choice of Dr. Reid to be professor of philosophy, originating wholly from the high opinion they were led to entertain of his talents and erudition. We are not acquainted with the particular plan which he adopted and pursued in the course of his lectures; but his department at that period comprehended mathematics and physics, logics and ethics, a practice then followed in the other universities of Scotland, instead of appointing a professor for each distinct branch.

Dr. Reid had not been long in Aberdeen, till in conjunction with Dr. John Gregory, he projected a literary society which continued for a number of years, and met once a week. The writings of Reid, Gregory, Campbell, Beattie and Gerard, evince the numerous advantages which the members derived from this institution, as they were in the habit of subjecting such works as they intended for publication, to the test of friendly criticism.

It is perhaps not too much to assert, that of all the publications which appeared about this time, the Inquiry into the Human Mind by Dr. Reid, discovered by far the greatest originality and profound thinking. It appears that he had conceived the plan, and deeply meditated upon it, long before its publication; yet without the applause of his literary associates, it is more than probable that his native modesty might have prevented him from giving it to the world.

The publication of Mr. Hume's Treatise of Human Nature, in 1739, led him to question the principles commonly received with regard to the human understanding. He admitted, when a youth, but without any attentive examination, the opinion that upon which Mr. Hume's scepticism was raised; but when he carefully adverted to the consequences which these principles appeared to involve, he instantly began to suspect their truth. To subvert the sceptical theory of Mr. Hume was the grand object of Dr. Reid's Inquiry, which he submitted to the examination of Mr. Hume himself. That philosopher, even after he had seen some parts of the work, discovers not a little of the Jewish spirit of unbelief that any good thing should come out of Nazareth; and considering his antagonist as a clergyman, and belonging to an order of men from whom prejudice would not allow him to expect any soundness of reasoning in matters of science, he betrays more than want of good humour, as Dr. Reid's biographer expresses himself, when he says in no very courteous language in a letter to Dr. Blair, "I wish that the parsons would confine themselves to their old occupation of worrying one another, and leave philosophers to argue with temper, moderation, and good manners." But though Mr. Hume, as appears from the words just quoted, was very angry that a clergyman should become a philosopher, on a second perusal of the Inquiry, he seems to have held very different sentiments, when he wrote to the author himself in the following terms.

"By Dr. Blair's means, I have been favoured with the perusal of your performance, which I have read with great pleasure and attention. It is certainly very rare, that a piece so deeply philosophical is written (written) with so much spirit, and affords so much entertainment to the reader; though I must still regret the disadvantages under which I read it, as I never had the whole performance at once before me, and could not be able fully to compare one part with another. To this reason, chiefly, I ascribe some obscurities, which, in spite of your short analysis or abstract, still seem to hang over your system. For I must do you the justice to own, that when I entered into your ideas, no man appears to express himself with greater perspicuity than you do; a talent which, above all others, is requisite in that species of literature which you have cultivated. As I was desirous to be of some use to you, I kept a watchful eye all along over your style; but it is really so correct, and so good English, that I found not anything worth the remarking. There is only one passage in this chapter, where you make use of the phrase hinder to do instead of hinder from doing, which is the English one; but I could not find
find the passage when I sought for it. You may judge how exceptionable the whole appeared to me, when I could remark so small a blemish."

The impression made on the minds of speculative men by the publication of Dr Reid's Inquiry was as great as could reasonably be expected from the nature of his undertaking. It was not level to the comprehension of the multitude, nor even addressed to them; and as it examined opinions with the utmost freedom which had obtained the sanction of the highest authorities, it had little prospect of conciliating the favour of the learned. Some, however, there were, who perceived the extent of his views, and beheld in his pages the true spirit and language of inductive investigation, which made proselytes of many, and was, by them, warmly recommended to the attention of others. The Inquiry of Dr Reid was so much esteemed by the learned body of teachers then in the university of Glasgow, that they gave him an invitation to the vacant professorship of moral philosophy, in the year 1763. It was no doubt with a considerable degree of reluctance that he resolved to leave Aberdeen; yet so numerous were the allusions which Glasgow presented to a man of his extensive erudition and deep research, that he gave it the preference. That seminary of learning could then boast of a Moor, a Simon, a Black, a Leechman, the two Wilsons, father and son, and an acute, discriminating Millar, with all of whom he was more or less intimate, and whose fascinating conversation made him in some measure forget that he was long acquainted with men of genius in the university of Aberdeen.

Dr Reid's merit as a public teacher arose principally from that fund of original philosophy which is characteristic of his writings; and from his invincible patience and perseverance in recommending such principles as he conceived to be of the last importance to human happiness. His style, too, was simple and perspicuous; his character grave and possessed of authority; and his students felt such an interest in the doctrines which he inculcated, that he never failed to be heard with the most profound attention.

In the year 1773 his remarks on Aristotle's logic appeared in Lord Kames's Sketches of the History of Man, of which he himself has favoured us with the following account. "In attempting to give some account of the Analytics, and of the Topics of Aristotle, ingenuity obliges me to confess, that though I have often purposed to read the whole with care, and to understand what is intelligible, yet my courage and patience always failed before I had done. Why should I throw away so much time and painful attention upon a thing of so little use? If I had lived in those ages when the knowledge of Aristotle's Organon entitled a man to the highest rank in philosophy, ambition might have induced me to employ upon it some years of painful study; and less, I conceive, would not be sufficient. Such reflections as these always got the better of my resolution when the first ardour began to cool. All I can say is, that I have read some part of the different books with care, some slightly, and some perhaps not at all. I have glanced over the whole often; and when any thing attracted my attention have dipped into it till my appetite was satisfied."

But in spite of his modest declarations, it is matter of doubt with some, whether any of his publications does him more honour than his perspicuous view of this complicated system. It is unquestionably superior to any other analysis of these writings we have yet seen, an opinion amply confirmed by the sentiments of different literary characters who were intimately acquainted with the works of Aristotle.

Dr Reid declined reading lectures in the university for some years before his death; and he devoted this period to the task of preparing for the press his great work, which was published in two volumes 4to, the first in 1785, entitled, "Essays on the Intellectual Powers of Man;" and the second in 1788, entitled, "Essays on the Active Powers of Man." His Essay on Quantity, occasioned by reading a Treatise, in which Simple and Compound Ratios are applied to Virtue and Merit, was composed previous to the year 1748, and was published in the Philosophical Transactions of London for that year. This paper affords some light with regard to the progress of his speculations about this time. The Inquiry into the Human Mind, of which we have already taken notice, appeared in 1764; and at this time he was complimented with the degree of Doctor in Divinity. In the year 1796 (the last of his mortal existence), he was prevailed upon to spend with his friends at Edinburgh a few weeks during the summer. From that visit he returned to Glasgow in his usual health and spirits, and for some time continued to devote a portion of his time to the exercise both of body and mind. About the end of September the same year, he was seized with a violent disorder, with which he maintained a severe struggle; and this, together with repeated strokes of the palsy, put a final period to his long and useful life on the 7th of October, and in the 87th year of his age.

As to his bodily constitution, few men have been more indebted to nature than Dr Reid. In this respect he was athletic and vigorous, and his muscular strength was uncommonly great; advantages which were powerfully seconded by his temperance, exercise, and the unclouded serenity of his temper. Deep and collected thought was very conspicuous in his countenance, and all his looks were expressive of kindness and good will.

With respect to his character, his rectitude was inflexible and intrepid; his attachment to truth was pure; and he had an entire command over all his passions, which he acquired by the unwearied exertions of a long life. When, therefore, he found it necessary to dispute the conclusions of others in any of his writings, he never employed any expressions to irritate those whom he was anxious to convince, and the asperity of his opponents could not provoke him to repress his spirit of liberality and good-humour; for he considered the interpenetration with which controversy is usually carried on, as an enemy to the progress of useful knowledge, and as having done more harm to the practice than service to the theory of morality. He uniformly maintained the dignity of philosophy in private life, and he united in his character the most amiable modesty and gentleness, with the noblest spirit of independence. He never solicited any favours from the great, and all his academical or other preferments were conferred upon him by those who were real judges of his merit, and thought he deserved them. To a sound, cautious, and discriminating judgment, a singular patience and perseverance of thought,
thought, and fixed attention to the operations of his own mind, he
added the curiosity of a naturalist and the
eyes of an observer, and of course his information was
accurate and extensive. His sensibility was of an active and lively nature, and wherever he could command the
means of relieving the distressed, he always employed
them with the utmost secrecy possible.

His works are now in the hands of the public, and we
believe we may venture to assert, that they will always be
much esteemed, while sound sense continues to be
precluded to unintelligible jargon, sophistry, or impiety.
He has divested metaphysics of mystery, and rendered
intelligible the most profound speculations, by the regu-
lar and constant use of words in one determined sense.

In the state in which he found the philosophical world,
it was Dr Reid’s opinion, that his talents could not be
so usefully employed, as in combating the schemes of those
who aimed at the complete subversion of religion,-
both natural and revealed. He apprehended the op-
ations of his own mind with a clearness which gave to his
language a perspicuity and precision that the language
of Locke never possessed; and in this respect he is
decidedly superior to all his predecessors.

REINDEER, or Tuaradus. See CERVIS, ENTO-
MOLGY. Index.

REINS, in Anatomy, the same with KIDNEYS. See
ANATOMY Index.

REINS of a Bridle, are two long slips of leather, fas-
tened on each side of a curb or snaffle, which the rider
holds in his hand, to keep the horse in subjection.

There is also what is called false reins; which is a
lath of leather, passed sometimes through the arch of
the banquet, to bend the horse’s neck.

REJOINER, in Law, is the defendant’s answer to
the plaintiff’s replication or reply. Thus, in the
court of chancery, the defendant puts in an answer to
the plaintiff’s bill, which is sometimes also called an
exception; the plaintiff’s answer to that is called a repica-

cion, and the defendant’s answer to that a rejoinder.

REISKE, JOHN JAMES, a profound scholar and emi-
nent critic, was born in 1706 at a small town in the
duchy of Anhalt in Germany. His connections, it
would appear, were in a humble situation of life; and
in consequence of the narrow circumstances in which he
was placed, he had many difficulties to struggle with
during the early part of his education. These, however,
by unabating perseverance he surmounted, and in 1733
went to Leipzig, where he remained for five years in the
ardent pursuit of his studies. Here he acquired an ex-
tensive knowledge of the Arabic, and was engaged in
the translation of a book from that language, which
was afterwards published. With the view of prosecuting
with greater advantage the study of Arabic, which had
become with him a favourite object of pursuit, he tra-
vell’d on foot to Leyden, where new difficulties attend-
ed him. While he remained in Leyden he was employed
in arranging the Arabic manuscripts belonging to the
university, and for this labour he received a very small
remuneration. During his residence here, part of his
time was occupied in the translation of various essays
from the German and French languages into Latin. The
these essays afterwards appeared in the Miscellanea
Crítica. About the same time also, our learned author
translated into Latin the whole of the Chariton from
the Greek and the Geography of Abulafia from the
Arabic.

Having spent eight years at Leyden, Reiske was
driven from this place by jealousy and calumny, which it
is said were excited against him chiefly by the younger
Barman, in consequence of his critical strictures on the
edition of Petronius published by that author; but be-
fore his departure from this learned seminary, he had
obtained the degree of doctor of physic, which was confer-
pd in a manner highly to his honour. He after-
wards visited different parts of Germany, and at last set-
tled a second time at Leipzig, where he remained for
twelve years. But although he had received the ap-
pointment of professor of Arabic, the emoluments of
his office were so scanty, that he had yet to struggle with
all the difficulties attendant on poverty, and merely to
procure a subsistence was obliged to engage in the hub-
ler employments of literary labour, and submit to the
severe and ill-requited drudgery of editing works for
booksellers, or contributing detached papers to periodi-
cal publications. About this time the Acta Eruditorum
were greatly indebted to the labours of our author.
But in the midst of all the difficulties and hardships now
alluded to, he prepared and published a work of pro-
found learning and great merit. This work, which ex-
tended to five volumes, appeared under the title of Ani-
malversones in Actores Graecos, and added much to
our author’s reputation.

In the year 1758, in consequence of the death of
Hultschusius, he obtained a situation, which was not only
honourable but lucrative. This was the place of rec-
tor of the academy of Leipzig, in which he continued
during the remainder of his life. He was now raised
above want, and being free from the difficulties and
embarrassments which had hitherto constantly attended
him, he was thus enabled in the midst of learned ease
to prosecute his favourite studies.

In the year 1764 Reiske married E. C. Muller, a wo-
man of great learning, and of whom it is said that her
knowledge, especially in Greek literature, was little
inferior to that of her husband. In all his literary labours
she was an useful associate; but the assistance which she
had contributed to his great work, the edition of the Greek
Orators, was particularly valuable. Thus passed the
latter period of the life of this learned man. He died in
1774, possessing a very distinguished reputation as a
scholar and a critic. The number of the works which
he superintended and published is very great. The most
approved are the following: “Remarks upon Greek
Authors.” An “Edition of the Greek Orators,” in
12 vols. 8vo, which was completed by his widow.
“Dionysius Halicarnassensis,” in 7 vols. “Plutarch’s

RELAND, ADRIAN, an eminent Orientalist, born
at Ryp, in North Holland, in 1676. During three
years study under Surenhusius, he made an uncommon
progress in the Hebrew, Syriac, Chaldee, and Arabic
languages, and these languages were always his fa-
vourite study. In 1703, he was, by the recommenda-
tion of King William, appointed professor of Oriental
languages and ecclesiastical antiquities in the university
of Utrecht, and died of the small-pox in 1718. He
was distinguished by his modesty, humanity, and learn-
ing; and carried on a correspondence with the most
eminent
eminent scholars of his time. His principal works are,
1. An excellent description of Palestine. 2. Five dissertations on the Medals of the ancient Hebrews, and several other dissertations on different subjects. 3. An Introduction to the Hebrew Grammar. 4. The Antiquities of the ancient Hebrews. 5. On the Mahometan Religion. These works are all written in Latin.

RELATION, the mutual respect of two things, or what each is with regard to the other. See METAPHYSICS, No. 93, &c., and 128, &c.

Relation, in Geometry. See Ratio.

Relation, is also used for analogy. See ANALOGY and METAPHYSICS.

RELATIVE, something relating to or respecting another.

Relative, in Music. See Mode.

RELATIVE Terms, in Logic, are words which imply relation; such are master and servant, husband and wife, &c.

In grammar, relative words are those which answer to some other word foregoing, called the antecedent; such are the relative pronouns qui, quae, quod, &c. and in English, who, whom, which, &c. The word answering to these relatives is often understood, as, "I know whom you mean;" or "I know the person whom you mean."

RELAXATION, in Medicine, the act of loosening or slackening; or the looseness or slackness of the fibres, nerves, muscles, &c.

RELAY, a supply of horses placed on the road, and appointed to be ready for a traveller to change, in order to make the greater expedition.

RELEASE, in Law, is a discharge or conveyance of a man's right in lands or tenements, to another that hath some former estate in possession. The words generally used therein are "remised, released, and for ever quitclaimed." And these releases may enure, either, 1. By way of enlarging an estate, or enlarging the estate: as, if there be tenant for life or years, remainder to another in fee, and he in remainder releases all his right to the particular tenant and his heirs, this gives him the estate in fee. But in this case the releseer must be in possession of some estate, for the release to work upon; for if there be lessee for years, and, before he enters and is in possession, the lessor releases to him all his right in the-reversion, such release is void for want of possession in the releseer. 2. By way of passing an estate or mitter the estate: as when one of two coparceners releaseth all his right to the other, this passeth the fee-simple of the whole. And, in both these cases, there must be a privity of estate between the releseer and releseee; that is, one of their estates must be so related to the other, as to make but one and the same estate in law. 3. By way of passing a right or mitter le droit: as if a man be disseised, and releaseth to his disseisor all his right; thereby the disseisor acquires a new right, which changes the quality of his estate, and renders that lawful which before was tortious. 4. By way of extinguishment: as if my tenant for life makes a lease to A for life, remainder to B and his heirs, and I release to A; this extinguishes my right to the reversion, and shall enure to the advantage of B's remainder as well as of A's particular estate. 5. By way of entry and seoffment: as if there be two joint disseissors, and the disseisor releases to one of them, he shall be sole seiz'd, and shall keep out his former companion; which is the same in effect as if the disseisee had entered, and thereby put an end to the disseissors in fee. And hereupon we may observe, that when a man has in himself the possession of lands, he must use the common law convey the freehold by feoffment and livery; which makes a notorious interest in the country: but if a man has only a right or a future interest, he may convey that right or interest by a mere release to him that is in possession of the land: for the occupancy of the relesee is a matter of sufficient notoriety already.

RELEVANCY, in Scots Law. See Law, No. clxxvi. 48.

RELICTION, in the Roman church, the remains of the bodies or clothes of saints or martyrs, and the instruments by which they were put to death, devotedly preserved, in honour to their memory; kissed, revered, and carried in procession.

The respect which was justly due to the martyrs and teachers of the Christian faith, in a few ages increased almost to adoration; and at length adoration was really paid both to departed saints and to relics of holy men or holy things. The abuses of the church of Rome, with respect to relics, are very flagrant and notorious. For such was the rage for them at one time, that, as F. Mibillon a Benedictine justly complains, the altars were loaded with suspected relics; numerous spurious ones being everywhere offered to the piety and devotion of the faithful. He adds, too, that bones are often consecrated, which, so far from belonging to saints, probably do not belong to Christians. From the catacombs many relics have been taken, and yet it is not known who were the persons interred therein. In the 17th century, relics were tried by fire, and those which did not consume were reckoned genuine, and the rest not. Relics were, and still are, preserved on the altars whereon mass is celebrated; a square hole being made in the middle of the altar, big enough to receive the hand, and herein is the relic deposited, being first wrapped in red silk, and inclosed in a leaden box.

The Romanists plead antiquity in behalf of relics: For the Manichees, out of hatred to the flesh, which they considered as an evil principle, refused to honour the relics of saints; which is reckoned a kind of proof that the Catholics did it in the first ages.

We know, indeed, that the touching of linen cloths on relics, from an opinion of some extraordinary virtues derived therefrom, was as ancient as the first ages, there being a hole made in the coffins of the 40 martyrs at Constantinople expressly for this purpose. The honouring the relics of saints, on which the church of Rome afterwards founded her superstitious and lucrative use of them, as objects of devotion, as a kind of charms or amulets, and as instruments of pretended miracles, appears to have originated in a very ancient custom, that prevailed among Christians, of assembling at the cemeteries or burying-places of the martyrs, for the purpose of commemorating them, and of performing divine worship. When the profession of Christianity obtained the protection of the civil government, under Constantine the Great, stately churches were erected over their sepulchres, and their names and memories were treated with every possible token of affection and respect. This reverence, however, gradually exceeded all reasonable bounds;
Reics in [ 695 ]

Relics; and those prayers and religious services were thought to have a peculiar sanctity and virtue, which were performed over their tombs. Hence the practice, which afterwards obtained, of depositing relics of saints and martyrs under the altars in all churches. This practice was then thought of such importance, that St. Ambrose would not consecrate a church because it had no relics; and the council of Constantinople in Trullo ordained, that those altars should be demolished under which there were found no relics. The rage of procuring relics for this and other purposes of a similar nature, became so excessive, that in 386 the emperor Theodosius the Great was obliged to pass a law, forbidding the people to dig up the bodies of the martyrs, and to traffic in their relics.

Such was the origin of that respect for sacred relics, which afterwards was perverted into a formal worship of them, and became the occasion of innumerable processions, pilgrimages, and miracles, from which the church of Rome hath derived incredible advantage. In the end of the ninth century, it was not sufficient to reverence departed saints, and to confide in their intercessions and succours, to clothe them with an imaginary power of healing diseases, working miracles, and delivering from all sorts of calamities and dangers; their bones, their clothes, the apparel and furniture they had possessed during their lives, the very ground which they had touched, or in which their putrified carcasses were laid, were treated with a stupid veneration, and supposed to retain the marvellous virtue of healing all disorders both of body and mind, and of defending such as possessed them against all the assaults and devices of the devil. The consequence of all this was, that every one was eager to provide himself with these salutary remedies; consequently, great numbers undertook fatiguing and perilous voyages, and subjected themselves to all sorts of hardships; while others made use of this delusion to accumulate their riches, and to impose upon the miserable multitude by the most impious and shocking inventions. As the demand for relics was prodigious and universal, the clergy employed the utmost dexterity to satisfy all demands, and were far from being nice in the methods they used for that end. The bodies of the saints were sought by fasting and prayer, instituted by the priest in order to obtain a divine answer and an infallible direction, and this pretended direction never failed to accomplish their desires; the holy carcass was always found, and that always in consequence, as they impiously gave out, of the suggestion and inspiration of God himself. Each discovery of this kind was attended with excessive demonstrations of joy, and animated the zeal of those devout seekers to enrich the church still more and more with this new kind of treasure. Many travelled with this view into the eastern provinces, and frequented the places which Christ and his disciples had honoured with their presence, that, with the bones and other sacred remains of the first heralds of the gospel, they might comfort dejected minds, calm trembling consciences, save sinking states, and defend their inhabitants from all sorts of calamities. Nor did these pious travellers return home empty; the craft, dexterity, and knavery of the Greeks, found a rich prey in the stupid credulity of the Latin relic-hunters, and made a profitable commerce of this new devotion. The latter paid considerable sums for legs and arms, skulls and jaw-bones (several of which were Pagan, and some not human), and other things that were supposed to have belonged to the primitive worthies of the Christian church; and thus the Latin churches came to the possession of those celebrated relics of St. Mark, St. James, St. Bartholomew, Cyprian, Pantaleon, and others, which they show at this day with so much ostentation. But there were many who, unable to procure for themselves these spiritual treasures by voyages and prayers, had recourse to violence and theft; for all sorts of means, and all sorts of attempts in a cause of this nature, were considered, when successful, as pious and acceptable to the Supreme Being. Besides the arguments from antiquity to which the Papists refer, its vindication of their worship of relics, of which the reader may form some judgment from this article, Bellarmin turned to Scripture in support of it, and cites the following passages, viz. Exod. xiii. 9.; Deut. xxxiv. 6.; 2 Kings xiii. 21.; 2 Kings xxiii. 16, 17, 18.; Isaiah xi. 16.; Matthew xi. 20, 21, 22.; Acts v. 12—15.; Acts xix. 11, 12. See PoPE.

The Roman Catholics in Great Britain do not acknowledge any worship to be due to relics, but merely a high veneration and respect, by which means they think they honour God, who they say, wrought very extraordinary miracles by them. But, however proper this veneration and respect may be, its abuse has been so great and so general, as fully to warrant the rejection of them altogether.

Relics are forbidden to be used or brought into England by several statutes; and justices of peace are empowered to search houses for popish books and relics, which, when found, are to be defaced and burnt, &c. 3 Jac. I. cap. 26.

REICT, in Law, the same with Widow.

RELIEF (Relevamen; but, in Domesday, Relevatio, Relevatium), signifies a certain sum of money, which the tenant, holding by knight’s service, grand serjeancy, or other tenure (for which homage or legal service is due), and being at full age at the death of his ancestor, paid unto his lord at his entrance. See PrIMER.

Though receipts had their original while feuds were only life estates, yet they continued after feuds became hereditary; and were therefore looked upon, very justly, as one of the greatest grievances of tenures: especially when, at the first, they were merely arbitrary and at the will of the lord; so that, if he pleased to demand an exorbitant relief, it was in effect to diseninherit the heir. The English ill brooked this consequence of their newly adopted policy; and therefore William the Conqueror by his laws uncertain the relief, by directing (in imitation of the Danish heriots), that a certain quantity of arms, and habiliments of war, should be paid by the earls, barons, and Bavassures respectively; &c, if the latter had no arms, they should pay 100 shillings. William Rufus brooked through this composition, and again demanded arbitrary uncertain reliefs, as due by the feudal laws; thereby in effect obliging every heir to new-purchase or redem his land: but his brother Henry I., by the charter before mentioned, restored his father’s law; and ordained, that the relief to be paid should be according to the law so established, and not an arbitrary redemption.—But afterwards, when, by an ordinance in 27 Hen. II. called the aussie of arms, it was provided, that every man’s armour should descend to his heir, for defence of the realm, and it thereby became, impracticable.
Relief

Religion.

Relief is the act of paying these acknowledgments in arms according to the laws of the Conqueror, the composition was universally accepted of 100 shillings for every knight's fee, as we find it ever after established. But it must be remembered, that this relief was only then payable, if the heir at the death of his ancestor had attained his full age of 21 years.

To RELIEVE the GUARD, is to put fresh men upon guard, which is generally every 24 hours.

To RELIEVE the TRENCHES, is to relieve the guard of the trenches, by appointing those for that duty who have been there before.

To RELIEVE the SENTINELS, is to put fresh men upon that duty from the guard, which is generally done every two hours, by a corporal who attends the relief, to see that the proper orders are delivered to the soldier who relieves.

RELIEVO, or RELIEF, in Sculpture, &c. is the projection or standing out of a figure which arises prominent from the ground or plane on which it is formed; whether that figure be cut with the chisel, moulded, or cast.

There are three kinds or degrees of relief, viz. alto, basso, and demi-relievo. The alto-relievo, called also haut-relief, or high-relievo, when the figure is formed after nature, and projects as much as the life. Basso-relievo, bass-relief, or low-relievo, is when the work is raised a little from the ground, as in medals, and the frontispieces of buildings; but particularly in the histories, festoons, foliages, and other ornaments of friezes. Demo-relievo is when one half of the figure rises from the plane. When, in a basso-relievo, there are parts that stand clear out, detached from the rest, the work is called a demi-basso.

In architecture, the relief or projection of the ornaments ought always to be proportioned to the magnitude of the building it adorns, and to the distance at which it is to be viewed.

RELIEVO, or RELIEF, in Painting, is the degree of boldness with which the figures seem, at a due distance, to stand out from the ground of the painting.

The relief depends much upon the depth of the shadow, and the strength of the light; or in the height of the different colours, bordering on one another; and particularly on the difference of the colour from that of the ground; thus, when the light is so disposed as to make the nearest parts of the figure advance, and is well diffused on the masses, yet insensibly diminishing, and terminating in a large spacious shadow, brought off insensibly, the relief is said to be bold, and the clare obscure well understood.

RELIGION (RELIGIO), is a Latin word derived, according to Cicero, from relegere, to re-consider; but according to Servius and most modern grammarians, from religare, to bind fast. The reason assigned by the Roman orator for deducing religio from relego, is in these words, "qui autem omnia, quae ad cultum deorum pertinere, diligentiter retraharet, et tamanum relegaret, sunt dicti religiosi ex relegendo." The reason given by Servius for his derivation of the word is, "quod mentem religio religet." If the Ciceronian etymology be the true one, the word religion will denote the diligent study of whatever pertains to the worship of the gods; but according to the other derivation, which we are inclined to prefer, it denotes that obliga-

which we feel on our minds from the relation in which we stand to some superior power. In either case, the import of the word religion is different from that of theology, as the former signifies a number of practical duties, and the latter a system of speculative truths. Theology is therefore the foundation of religion, or the science from which it springs; for no man can study what pertains to the worship of superior powers till he believe that such powers exist, or feel any obligation on his mind from a relation of which he knows nothing.

This idea of religion, as distinguished from theology, comprehends the duties not only of those more refined and complicated systems of theism or polytheism which have prevailed among civilized and enlightened nations, such as the polytheism of the Greeks and Romans, and the theism of the Jews, the Mahometans, and the Christians; it comprehends every sentiment of obligation which human beings have ever conceived themselves under to superior powers, as well as all the forms of worship which have ever been practised through the world, however fantastic, immoral, or absurd.

When we turn our eyes to this feature of the human constitution, we find it peculiarly interesting. Mankind is distinguished from the brutal tribes, and elevated to a higher rank, by the rational and moral faculties with which they are endowed; but they are still more widely distinguished from the inferior creation, and more highly exalted above them, by being made capable of religious notions and religious sentiments. The slightest knowledge of history is sufficient to inform us, that religion has ever had a powerful influence in moulding the sentiments and manners of men. It has sometimes dignified, and sometimes degraded, the human character. In one region or age it has been favourable to civilization and refinement; in another, it has occasionally cramped the genius, deprived the morals, and deformed the manners of men. The varieties of religion are innumerable; and the members of every distinct sect must view all who differ from them as more or less mistaken with respect to the most important concerns of man. Religion seems to be congenial to the heart of man; for wherever human society subsists, there we are certain of finding religious opinions and sentiments.

It must, therefore, be an important subject of speculation to the man and the philosopher to consider the origin of religion; to inquire, How far religion in general has a tendency to promote or to injure the order and happiness of society? and, above all, to examine, What particular religion is best calculated to produce a happy influence on human life?

We shall endeavour to give a satisfactory answer to each of these questions; reserving to the article Theology the consideration of the dogmas of that particular religion which, from our present inquiries, shall appear to be true, and to have the happiest influence on human life and manners.
efforts of their own reason visible effects to invisible
causes, must have discovered the existence of superior powers, and communicated the discovery to their associates and followers; or, lastly, the universal belief in such powers, must have been derived by tradition from a primordial revelation, communicated to the progenitors of the human race.

One or other of these hypotheses must be true, because a fourth cannot be framed. But we have elsewhere (Polytheism, No. 2.) examined the reasoning which has been employed to establish the first, and shall see that it proceeds upon false notions of human nature.

We should likewise pronounce it contrary to fact, could we believe, on the authority of some of its patrons, who are not ashamed to contradict one another, that the Kamtschatkans and other tribes, in the lowest state of reasoning and morals, have no ideas whatever of Deity. We proceed, therefore, to consider the second hypothesis, which is much more plausible, and will bear a stricter scrutiny.

That the existence and many of the attributes of the Deity are capable of rigid demonstration, is a truth which cannot be controverted either by the philosopher or the Christian; for “the invisible things of Him from the creation of the world are clearly seen, being understood by the things that are made, even His eternal power and Godhead” (see Metaphysics, Part III. chap. vi. and THEOLOGY, No. 8, 9.). But surely it would be rash to infer, either that every truth for which, when it is known, the ingenuity of man can frame a demonstration, is therefore discoverable by human sagacity, or that all the truths which have been discovered by a Newton or a Locke might therefore have been discovered by untutored barbarians. In mathematical science there are few demonstrations of easier comprehension than that given by Euclid, of the theorem of which Pythagoras is the reputed author; yet no man ever dreamed that a boy capable of being made to understand that theorem, must therefore have sagacity equal to the sage of Samos, or that such a boy, having never heard of the relation between the hypothesis and other two sides of a right-angled triangle, would be likely to discover that the square of the former is precisely equal to the sum of the squares of the latter. Just so it seems to be with the fundamental truths of theology. There can hardly be conceived a demonstration less intricate, or more conclusive, than that which the man of science employs to prove the existence of at least one God, possessed of boundless power and perfect wisdom. And could we suppose that the human race had remained without any knowledge of God in the world, till certain lucky individuals had by some means or other made themselves masters of the rules of logic, and the philosophy of causes, there can be no doubt but that these individuals might have discovered the existence of superior powers, and communicated their discovery to their associates and followers. But this supposition cannot be admitted, as it is contradicted by the evidence of all history. No nation or tribe has ever been found, in which there is not reason to believe that some notions were entertained of superior and invisible powers, upon which depends the happiness or misery of mankind: and from the most authentic records of antiquity, it is apparent that very pure principles of theism prevailed in some nations long before the rules of logic, and the philosophy of causes, were thought of by any people under heaven.

The supposition before us is inadmissible upon other accounts. Some modern philosophers have fancied that the original progenitors of mankind were left entirely to themselves from the moment of their creation; that they wandered about for ages without the use of speech and in the lowest state of savagism; but that they gradually civilized themselves, and at last stumbled upon the contrivance of making articulate sounds significant of ideas, which was followed by the invention of arts and sciences, with all the blessings of religion and legislation in their train. But this is a wild reverie, inconsistent with the phenomena of human nature.

It is a well known fact, that a man blind from birth, and suddenly made to see, would not by means of his newly acquired sense discern either the magnitude or figure of distance of objects, but would conceive every thing which communicated to him visible sensations inseparably united to his eye or his mind (see METAPHYSICS, No. 49—53.). How long his sense of sight would remain in such an imperfect state, we cannot positively say; but from attending to the visible sensations of infants, we are confident that weeks, if not months, elapse before they can distinguish one thing from another.

We have indeed been told, that Cheselden’s famous patient, though he was at first in the state which we have described, learned to distinguish objects by sight in the course of a few hours, or at the most of a few days: but admitting this to a certain extent to be true, it may easily be accounted for. The disease called a cata- clete does not always occasion total blindness; but let us suppose the eyes of this man to have been so completely dimmed as to communicate no sensation whatever upon being exposed to the rays of light; still we must remember that he had long possessed the power of loco-motion and all his other senses in perfection. He was therefore well acquainted with the real, i.e. the tangible magnitude, figure, and distance of many objects; and having been often told that the things which he touched would, upon his acquisition of sight, communicate new sensations to his mind, differing from each other according to the distance, figure, and magnitude of the objects by which they were occasioned, he would soon learn to infer the one from the other, and to distinguish near objects by means of his sight.

The progenitors of the human race, however, if left to themselves from the moment of their creation, had not the same advantages. When they first opened their eyes, they had neither moved, nor handled, nor heard, nor smelled, nor tasted, nor had a single idea or notion treasured up in their memories; but were in all these respects in the state of new-born infants. Now, we should be glad to be informed by those sages who have conducted mankind through many generations in which they were mutum et turpe pacem that that happy period when they invented language, how the first men were taught to distinguish objects by their sense of sight, and how they contrived to live till this most necessary faculty was acquired? It does not appear that men are like brutes, provided with a number of instincts which guide them blindfold and without experience to whatever is necessary for their own preservation (see Instinct): On the contrary, all voyagers tell us that
Religion. In strange and uninhabited countries, they dare not venture to taste unknown fruits unless they perceive that these fruits are eaten by the fowls of the air. But without the aid of instinct, or of some other guide equally to be depended upon, it is not in our power to conceive how men dropped from the hands of their Creator, and left from that instant wholly to themselves, could move a single step without the most imminent danger, or even stretch out their hands to lay hold of the food which we may suppose to have been placed within their reach. They could not, for many days, distinguish a precipice from a plain, a rock from a pit, or a river from the meadows through which it rolled. And in such circumstances, how could they possibly exist, till their sense of sight had acquired such perfection as to be a sufficient guide to all their necessary motions? Can any consistent theist suppose that the God whose goodness is so conspicuously displayed in all his works, would leave his noblest creature on earth, a creature for whose comfort alone many other creatures seem to have been formed, in a situation so forlorn as this, where his immediate destruction appears to be inevitable? No! This supposition cannot be formed, because mankind still exist.

8 but from an original revelation.

This opinion appears to be the writings of Moses.

Will it then be said, that when God formed the first men, he not only gave them organs of sensation, and souls capable of arriving by discipline at the exercise of reason, but that he also impressed upon their minds adequate ideas and notions of every object in which they were interested; brought all their organs, external and internal, at once to their utmost possible state of perfection; taught them instantaneously the laws of reasoning; and, in one word, stored their minds with every branch of useful knowledge? This is indeed our own opinion; and it is perfectly agreeable to what we are taught by the Hebrew lawgiver. When God had formed Adam and Eve, Moses does not say that he left them to acquire by slow degrees the use of their senses and reasoning powers, and to distinguish as they could fruits that were salutary from those that were poisonous: No: he placed them in a garden where every tree but one bore fruit for food; he warned them particularly against the fruit of that tree; he brought before them the various animals which roamed through the garden; he arranged these animals into their proper genera and species; and by teaching Adam to give them names, he communicated to the first pair the elements of language. This condescension appears in every respect worthy of perfect benevolence; and indeed without it the helpless man and woman could not have lived one whole week. But it cannot be supposed, that amidst so much useful instruction the gracious Creator would neglect to communicate to his rational creatures the knowledge of himself; to inform them of their own origin, and the relation in which they stood to him; and to state in the plainest terms the duties incumbent on them in return for so much goodness.

10 The mode of communication not certainly known.

In what manner all this knowledge was communicated, cannot be certainly known. It may have been in either of the following ways conceivable by us, or in others of which we can form no conception. God may have miraculously stored the minds of the first pair with adequate ideas and notions of sensible and intellectual objects; and then by an internal operation of his own Spirit have enabled them to exert at once their rational faculties so as to discover his existence and attributes, together with the relation in which as creatures they stood to him their Almighty Creator. Or, after rendering them capable of distinguishing objects by means of their senses, of comparing their ideas, and understanding a language, he may have exhibited himself under some sensible emblem, and conducted them by degrees from one branch of knowledge to another, as a schoolmaster conducts his pupils, till they were sufficiently acquainted with every thing relating to their own happiness, and duty, as rational, moral, and religious creatures. In determining the question before us, it is of no importance whether infinite wisdom adopted either of these methods, or some other different from them, both which we cannot conceive. The ordinary process in which men acquire knowledge is, by the laws of their nature, extremely tedious. They cannot reason before their minds be stored with ideas and notions; and they cannot acquire these but through the medium of their senses long exercised on external objects.

The progenitors of the human race, left to inform themselves by this process, must have inevitably perished before they had acquired one distinct notion; and it is the same thing with respect to the origin of religion. Whether God preserved them from destruction by an internal or external revelation. If he stored their minds at once with the rudiments of all useful knowledge, and rendered them capable of exercising their rational faculties, so as, by tracing effects to their causes, to discover his being and attributes, he revealed himself to them as certainly as he did afterwards to Moses, when to him he was condescended to speak face to face.

If this reasoning be admitted as fair and conclusive, and we apprehend that the principles on which it proceeds cannot be considered as ill-founded, we have, on this point, advanced so far as to prove that mankind must have been originally enlightened by a revelation. But it is scarce possible necessary to observe, that this revelation must have been handed down through succeeding generations. It could not fail to reach the era of the deluge. It is not absurd to suppose, that he who spake from heaven to Adam, spake also to Noah. And both the revelation which had been handed down to the postdeluvian patriarch by tradition, and that which was communicated immediately to himself, would be by him made known to his descendants. Thus it appears almost impossible that some part of the religious sentiments of mankind should not have been derived from revelation; and that not of the religious sentiments of one particular family or tribe, but of almost all the nations of the earth.

This conclusion, which we have deduced by fair reasoning from the benevolence of God and the nature of mankind is confirmed by the authority of the Jewish and Christian Scriptures, which are entitled to more implicit credit than all the other records of ancient history.

When we review the internal and external evidence of the authenticity of these sacred books, we cannot for a moment hesitate to receive them as the genuine word of God. If we examine their internal character, they everywhere appear to be indeed the voice of Heaven. The creation of the world—the manner in which this globe was first peopled—the deluge which swept away its inhabitants—the succeeding views of the state of mankind
Religion. mankind in the next ages after the deluge—the calling of Abraham—the legislation of Moses—the whole series of events which befell the Jewish nation—the prophecies—the appearance of Jesus Christ, and the promulgation of his gospel, as explained to us in the Scriptures—form one series, which is, in the highest degree, illustrative of the power, wisdom, and goodness of the Supreme Being.

While it must be allowed that the human mind is ever prone to debase the sublime principles of true religion by enthusiasm and superstition, reason and candor will not for a moment hesitate to acknowledge, that the whole system of revelation represents the Supreme Being in the most sublime and amiable light: that, in it, religion appears essentially connected with morality: that the legislative code of Moses was such as no legislator ever formed and established among a people equally rude and uncultivated: that the manners and morals of the Jews, vicious and savage as they may be in some instances appear, yet merit a much higher character than those either of their neighbours, or of almost any other nation, whose circumstances and character were in other respects similar to theirs: that there is an infinite difference between the Scripture prophecies and the oracles and predictions which prevailed among heathen nations: and that the miracles recorded in those writings which we esteem sacred were attended with circumstances which entitle them to be ranked in a very different class from those which enthusiasm and imposture have fabricated among other nations. See Miracle and Prophecy.

But the evidence of the divine origin of the primitive religion rests particularly on the authority of the first five books of the Old Testament, it may be thought incumbent on us to support our reasoning on this subject, by proving, that the author of those books was indeed inspired by God. This we shall endeavour to do by one decisive argument; for the nature of the article, and the limits prescribed us, admit not of our entering into a minute detail of all that has been written on the divine legislation of Moses.

If the miracles recorded in the book of Exodus, and the other writings of the Hebrew lawgiver, were really performed; if the first-born of the Egyptians were all cut off in one night, as is there related; and if the children of Israel passed through the Red sea, the waters being divided, and forming a wall on their right hand and on their left—it must necessarily be granted, that Moses was sent by God; because nothing less than a divine power was sufficient to perform such wonderful works. But he who supposes that those works were never performed, must affirm that the books recording them were forged, either at the era in which the miracles are said to have been wrought, or at some subsequent era: There is no other alternative.

That they could not be forged at the era in which they affirm the miracles to have been wrought, a very few reflections will make incontrovertibly evident. These books inform the people for whose use they were written, that their author, after having inflicted various plagues upon Pharaoh and his subjects, brought them, to the number of 600,000, out of Egypt with a high hand; that they were led by a pillar of cloud through the day, and by a pillar of fire through the night, to the brink of the Red sea, where they were almost overtaken by the Egyptians, who had pursued them with chariots and horses; that, to make a way for their escape, Moses stretched out his rod over the sea, which was immediately divided, and permitted them to pass through on dry ground, between two walls of water; and that the Egyptians, pursuing and going in after them to the midst of the sea, were all drowned by the return of the waters to their usual state, as soon as the Hebrews arrived at the further shore. Is it possible now that Moses or any other man could have persuaded 600,000 persons, however barbarous and illiterate we suppose them, that they had witnessed all these wonderful works, if no such works had been performed? Could any art or eloquence persuade all the inhabitants of Edinburgh and Leith, that they had yesterday walked on dry ground through the Firth to Kinghorn, the waters being divided and forming a wall on their right hand and on their left? If this question must be answered in the negative, it is absolutely impossible that the books of Moses, supposing them to have been forged, could have been received by the people who were alive when those wonders are said to have been wrought.

Let us now inquire, whether, if they be forgeries, in any era they could have been received as authentic at any subsequent period; and we shall soon find this supposition as impossible as the former. The books claiming Moses for their author speak of themselves as delivered by him, and from his days kept in the ark of the covenant; and Deut. xxviii. 44, to the forgery. They speak of themselves likewise, not only as a history of miracles wrought by their author, but as the statutes or municipal law of the nation, of which a copy was to be always in the possession of the priests, and another in that of the supreme magistrate. Deut. Now, in whatever age we suppose these books to have been forged, they could not possibly be received as authentic; because no copy of them could then be found either with the king, with the priests, or in the ark, though, as they contain the statute law of the land, it is not conceivable that, if they had existed, they could have been kept secret. Could any man, at this day, forge a book of statutes for England or Scotland, and make it pass upon these nations for the only book of statutes which they had ever known? Was there ever since the world began a book of slam statutes, and these, too, multifarious and burdensome, imposed upon any people as the only statutes by which they and their fathers had gone before for ages? Such a forgery is evidently impossible.

But the books of Moses have internal proofs of authenticity, which no other books of ancient statutes ever had. They not only contain the laws, but also give an historical account of their enactment, and the reasons upon which they were founded. Thus they tell us, that the rite of circumcision was instituted as a mark of the covenant between God and the founder of the Jewish nation, and that the practice of it was enforced by the declaration of the Almighty, that every uncircumcised man-child should be cut off from his people. They inform us that the annual solemnity of the passover was instituted in commemoration of their deliverance, when God slew, in one night, all the first-born of the Egyptians; that the first-born of Israel, both of men and beasts, were on the same occasion dedicated for ever to God, who took the Levites instead of the first-born of...
R E L [ 700 ] R E L

the men; that this tribe was consecrated as priests, by whose hands alone the sacrifices of the people were to be offered; that it was death for any person of a different tribe to approach the altar, or even to touch the ark of the covenant; and that Aaron’s budding rod was kept in the ark in memory of the wonderful destruction of Korah, Dathan, and Abiram, for their rebellion against the priesthood.

Is it possible now, if all these things had not been practised among the Hebrews from the era of Moses, with a retrospect to the signal mercies which they are said to commemorate, that any man or body of men could have persuaded a whole nation, by means of forged books, that they had always religiously observed such institutions? Could it have been possible, at any period posterior to the Exodus, to persuade the Israelites that they and their fathers had all been circumcised on the eighth day from their birth, if they had been conscious themselves that they had never been circumcised at all? or that the passover was kept in memory of their deliverance from Egyptian bondage, if no such festival was known among them?

But let us suppose that circumcision has been practised, and all their other rites and ceremonies observed from time immemorial, without their knowing any reason of such institutions: still it must be confessed, that the forger of these books, if they were forged, constructed his narrative in such a manner as that no man of common sense could receive it as authentic. He says it was death to touch the ark! As such an assertion was never heard of before, and as the ritual he was endeavouring to make them esteem sacred was oppressively multifarious; surely some daring spirit would have ventured to put his versatility to the test by moving the ark and even offering sacrifices; and such a test would at once have exposed the imposture. The budding rod, too, and the pot of manna, which, though long preserved, were never before heard of, must have produced inquiries that could not fail to end in detection. These books speak likewise of weekly sabbaths, daily sacrifices, a yearly expiation, and monthly festivals, all to be kept in remembrance of great things, particularly specified as done for the nation at an early period of its existence. If this was not the case, could the forger of the books have persuaded the people that it really was? The enlightened reasoners of this nation would be offended were we to compare them with the ancient Israelites; but surely they will not say that we are partial to that people, if we bring them to a level with the most savage tribes of the Russian empire, who profess Christianity! Now, were a book to be forged containing an account of many strange things done a thousand years ago in Siberia by an Apollinarius, or any other philosopher or hero, numbers of the barbarians inhabiting that country would, we doubt not, give implicit credit to the legend: But were the author, in confirmation of his narrative, to affirm, that all the Siberians had from that day to this kept sacred the first day of the week in memory of his hero; that they had all been baptized or circumcised in his name; that in their public judicatories they had sworn by his name, and upon that very book which they had never seen before; and that the very same book was their law and their gospel, by which for a thousand years back the actions of the whole people had been regulated—surely the grossest savage among them would reject with contempt and indignation a forgery so palpable.

If this reasoning be conclusive, the books of Moses must indubitably be authentic, and he himself must have been inspired by the spirit of God. But this point being established, the question respecting the origin of the primeval religion is completely answered. The writer of the book of Genesis informs us, that Adam and Noah received many revelations from the Author of their being, and that their religion was founded on the principles of the purest theism. How it degenerated among the greater part of their descendants into the grossest idolatry, has been shown at large in another place. See Polytheism.

II. Having thus answered the first question proposed for discussion in the present article, we now proceed to consider the second, and to inquire whether and how far religious sentiments have a tendency to injure or to promote the welfare of society? This is a subject of the utmost importance; and if we prove successful in our inquiries, we shall be enabled to determine whether the governors of mankind ought carefully to support religious establishments, or whether the philosopher who calls himself a citizen of the world, and professes to feel the most eager desire to promote the interests of his species, acts consistently when he labours to exterminate religion from among men.

A celebrated French financier, a man of abilities, and virtue, who has published a book on the importance of religious opinions, labours to show that religious establishments are indispensably necessary for the maintenance of civil order, and demonstrates how weak the influence of political institutions is on the morals of mankind; but he refuses to review the history of past ages in order to discover how far religious opinions have actually been injurious or beneficial to the welfare of society; choosing rather to content himself with the result of a series of metaphysical disquisitions.

We admire the spirit which induced a man who had spent a considerable part of his life amid the hurry of public business, to become the strenuous advocate of religion; but we cannot help thinking that, notwithstanding the eloquence, the acuteness, and the knowledge of mankind which he has displayed, his refusing to admit the evidence of facts, concerning the influence of religion on society, may possibly be regarded by its enemies as a tacit acknowledgment that the evidence of facts would be unfavourable to the cause which he wishes to defend. The fallacy of general reasonings, and the inutility of metaphysics for the purposes of life, are so universally acknowledged, that they have long been the theme of declamation. Though the abuses of religion, as well as the abuses of reason, the perversion of any of the principles of the human mind, and the misuse of the gifts of Providence, may have often produced effects hurtful to the virtue and happiness of mankind; yet, after tracing religion to a divine origin, we cannot, for a moment, allow ourselves to think that the primary tendency of religion must be hostile to the interest of society, or that it is necessary to view it abstractly in order that we may not behold it in an odious light. Often has the sceptic attacked religion with artful malice; but perhaps none of his attacks has been so skilfully directed as that which has first ridiculed the absurdity of the most absurd superstitions, and
and afterwards laboured to prove that the most absurd system of polytheism is more favourable to the interests of society than the purest and most sublime theism. Instances in which the abuse of religion had tended to deprave the human heart, and had led to the most shocking crimes, have been assiduously collected, and displayed in all the aggravating colours in which eloquence could array them; till at length even the friends of true religion have been alarmed; and it has become a fashionable opinion, that nothing but self-interest or bigotry can prompt men to represent religion as the friend of civil order. But let us try if, by a candid consideration of what effects have resulted to society from religious principles, in general, without comparing these with regard to truth or falsehood, we can advance any thing to vindicate the character of religion.

Notions of Deity in general, of various orders of divinities, of their moral character, of their influence on human life, of a future state, and of the immortality of the human soul, constitute the leading articles of religion. Let us view these together with the rites to which they have given rise, and we may perhaps be enabled to form some well-grounded notions on this important point.

1. Having proved that the first religious principles entertained by men were derived from revelation, it is impossible to suppose that they could produce effects injurious to society. If religion of any kind has ever lessened the virtue or disturbed the peace of men, it must have been that religion which springs from a belief in a multitude of superior powers actuated by passions, and of whom some were conceived as benevolent and others as malicious beings. That such sentiments should have produced vices unknown in societies where pure theism is professed, will be readily admitted. Even the few atheists who live in Christian or Mahometan countries are restrained by the laws, by a desire to promote the honour of the sect, and by many other considerations, from indulging in practices which the example of the false gods of antiquity sanctioned in their votaries. But in determining the present question, we must not compare the virtues of the pagan world with those of individual atheists in modern Europe, but with those of nations professing atheism; and such nations are nowhere to be found. We can however easily conceive, that in a society unsawed by any notions of God or a future state, no such laws would be enacted as those which restrain the sensual appetites; of which the criminal indulgence was one of the greatest stigmas on the pagan worship of antiquity. In such societies, therefore, those vices would be practised constantly to which paganism gave only an occasional sanction; and many others, in spite of the utmost vigilance of human laws, would be perpetrated in secret, which the most profligate pagans viewed with horror. Conscience, though acting with all her energy, would not be able to command any regard to the laws of morality: No virtue would be known; social order would be nowhere observed; the midnight assassin would everywhere be found; and in the general scramble mankind would be exterminated from the face of the earth.

The worst species of paganism, even that which prevails among savages who worship evil spirits, affords greater security than this. It is indeed shocking to think that demons should be worshipped, while deities, who are regarded as being all benevolence, are treated with contempt: And it has been asked, if the influence of such religious sentiments on the moral practice of the idolaters must not naturally be, to cause them to treat their friends and benefactors with ingratitude, and to humble themselves with mean submission before a powerful enemy?

They do not appear to have produced such effects on the morality of the savages by whom they were entertained. The benevolent deities were neglected, only because their benevolence was unnecessary. A voluntary favour merits a grateful return: a design to prey provokes resentment. But when you become, by accident, the instrument of any man's good fortune, the world will scarce consider him as owing you any obligation: the stone which bruises your foot excites only a momentary emotion of resentment. Those gods who could not avoid doing good to men might not receive a profession of thanks for their services; and yet a favour conferred by a human benefactor commands the warmest gratitude. But those rude tribes appear to have had so much wisdom as to confer a less absolute malice on their malevolent deities, than the benevolence which they attributed to their more amiable order of superior beings: though the latter could not possibly do them any thing but good, and that constantly; yet the former were not under an equally indispensable necessity of persevering in depressing them under calamities. On their malevolent deities they conferred a freedom of agency which they denied to the benevolent. No wonder, then, that they were more assiduous in paying their court to the one than to the other. They might with as much propriety have thought of being grateful to the boar or stag whose flesh supported them, as to deities who were always benevolent, because they could not possibly be otherwise. Though negligent of such deities, this can scarce be thought to have had any tendency to render them ungrateful to benefactors like themselves. And yet, it must not be dissembled, that the American Indians, among whom such religious sentiments have been found to prevail, are said to be very little sensible to the emotions of gratitude. An Indian receives a present without thinking of making any grateful acknowledgments to the bestower. He pleases his fancy or gratifies his appetite with what you have given, without seeming to consider himself as under the smallest obligation to you for the gift.

It may be doubted, however, whether this spirit of ingratitude originates from, or is only collateral with, that indifference which refuses adoration and worship to the benevolent divinities. If the former be actually the case, we must acknowledge that those religious notions which we now consider, though preferable to general atheism, are in this respect unfriendly to virtue. But if the Indians may be thought to owe the ingratitude for which they are distinguished to the opinion which they entertain of the existence of a benevolent order of deities, whose benevolence is necessary and involuntary, their ideas of the nature of their malevolent demons do not appear to have produced equal effects on their moral sentiments. However submissive to those dreaded beings, they are far from showing the same tame and cowardly submission to their human enemies: towards them,
Religion. them they seem rather to adopt the sentiments of their demons. Inveterate rancour and brutal fury, inhuman cruelty and inconceivable cunning, are displayed in the hostilities of tribes at war; and we know not, after all, if even these sentiments do not owe somewhat of their force to the influence of religion.

Yet let us remember that these same Indians have not always represented to us unamiable a light; or, at least, other qualities have been ascribed to them which seem to be inconsistent with those barbarous dispositions. They have been described as peculiarly susceptible of conjugal and parental love; and he who is so cannot be destitute of virtue.

2. But leaving the religion of savages, of which very little is known with certainty, let us proceed to examine what is the natural influence of that mixed system of theology which represents to the imagination of men a number of superior and inferior divinities, actuated by the same passions and feelings with themselves, and often using circumstances of power and knowledge for no other purpose but to enable them to violate the laws of moral order with impunity. This is the celebrated polytheism of the Greeks and Romans, and most other nations of antiquity (see Polytheism). Could its influence be favourable to virtue?

At first view every one will readily declare, that such a system must have been friendly to profligacy; if you commit the government of the universe, and the inspection of human society, to a set of beings who are often disposed to regard vice with a less disadvantageous eye than virtue, and who, though there be an established order by which virtue is discriminated from vice, and right from wrong, yet scruple not to violate that order in their own conduct; you cannot expect them to require in you a degree of rectitude of which they themselves appear incapable. A Mercury will not discourage the thievish arts of the trader; a Bacchus and a Venus cannot shun upon debauchery; Mars will behold with savage delight all the cruelties of war. The Thracians, indeed, one of the most barbarous nations of antiquity, whose ferocity was little if at all inferior to that of the Indians who have been distinguished as cannibals, was the favourite nation of Mars; among whom stood his palace, to which he repaired when about to mount his chariot, and arm himself for battle. Even Jupiter, who had been guilty of so many acts of tyrannical caprice, had been engaged in such a multitude of amorous intrigues, and seemed to owe his elevated station as monarch of the sky, not to superior goodness or wisdom, but merely to a superior degree of brutal force, could not be feared as the avenger of crimes, or revered as the impartial rewarder of virtues.

That this system had a pernicious effect on morals, and that, as compared with pure atheism, it was injurious to society, cannot be denied; but yet, when contrasted with atheism, it was not without its favourable effects. It was so connected with the order of society, that, without its support, that order could scarce have been maintained. The young ruse might perhaps justify himself by the example of Jupiter, or Apollo, or other amorous divinity; the frail virgin or matron might complain of Cupid, or boast of imitating Venus; and the thief might practise his craft under the patronage of Mercury. But if we take the whole system together, if we consider with what views those deities were publicly worshipped, what temples were raised, what rites instituted, what sacrifices offered, and what temples consecrated; we shall perhaps find it necessary to acknowledge that the general effect of that mixed and incoherent system of polytheism which prevailed among the Greeks and Romans was favourable to society. To state a particular instance; the ancilia of Mars and the fire of Vesta were thought to secure the perpetuity of the Roman empire. As long as the sacred ancile, which had been dropped from heaven for that benivolent purpose, was safely preserved in those holy archives in which it had been deposited; and as long as the sacred fire of Vesta was kept burning, without being once extinguished, or at least suffered to remain for an instant in that state; so long was Rome to subsist and flourish. And, however, simple and absurd the idea which connected the prosperity of a nation with the preservation of a piece of wood in a certain place, or with the constant blazing of a flame upon an altar; yet no fact can be more certain, than that the patriotism and enthusiastic veneration which the Romans, which we so much extol and admire, were, in many instances, owing in no inconsiderable degree to the veneration which they entertained for the ancile and the vestal fire.

A numerous series of facts occur in the Roman literature, which show the happy effects of their religious opinions and ceremonies on their sentiments concerning social order and the public welfare. How powerful was the influence of the sacramentum administered to the soldiers when they enlisted in the service of their country? The promises made, the idea of the powers invoked, and the rites performed on that occasion, produced so deep and so awful an impression on their minds, that no danger, nor distress, nor discontent, could prompt them to violate their engagements. The responses of the oracles, too, though the dictates of deceit and imposture, were often of singular service to those to whom they were uttered; when they inspired the warrior, as he marched out to battle, with the confidence of success, they communicated to him new vigour, and more heroic valour, by which he was actually enabled to gain, or at least to deserve, the success which they promised. Again, when in times of public distress, the anguish and the priest directed some games to be celebrated, certain sacrifices to be offered, or some other solemnities to be performed, in order to appease the wrath of the offended deities; it is plain that the means were not at all suited to accomplish the end proposed by them; yet still they were highly beneficial. When the attention of the whole people was turned entirely to those solemnities by which the wrath of heaven was to be averted, they were roused from that despondency under which the sense of the public distress or danger might have otherwise caused them to sink: the public union was at the same time more closely cemented, and the hearts of the people knit together; and when persuaded, that by propitiating the gods they had removed the cause of their distress, they acquired such calmness and strength of mind as enabled them to take more direct and proper measures for the safety of the state.

Could we view the ancient Greeks and Romans setting in public or in private life under the influence of that system of superstition which prevailed among them; could...
could we perceive how much it contributed to the maintenance of civil order; could we behold Numa and Lycurgus establishing their laws, which would otherwise have met with a very different reception, under the sanction of divinities; could we observe all the beneficial effects which arise to communities from the celebration of religious ceremonies, we should no longer hesitate to acknowledge, that those principles in the human heart by which we are susceptible of religious sentiments, are so eminently calculated to promote the happiness of mankind, that even when perverted and abused, their influence is still favourable.

The ideas which prevailed among the nations of the heathen world concerning a future state of retribution were, it must be confessed, not very correct. Some of the poets, we believe, have represented them in an unfair light: both Homer and Virgil have conducted their heroes through the realms of Pluto, and have taken occasion to unfold to us the secrets of those dreary abodes. The scenes are wild and fanciful; the rewards of the just and virtuous are of no very refined or dignified nature: and of the punishments inflicted on the guilty, it is often hard to say for what ends they could be inflicted; whether to correct and improve, or for the gratification of revenge or whim: they are often so whimsical and unsuitable, that they cannot with any degree of propriety be ascribed to any cause but blind chance or wanton caprice. A great dog with three tongues, a pewish old boatman with a leaky ferry boat, demanding his freight in a surly tone, and an uxorious monarch, are objects too familiar and ludicrous not to degrade the dignity of those awful scenes which are represented as the mansions of the dead, and to prevent them from making a deep enough impression on the imagination. The actions and qualities too, for which departed spirits were admitted into Elysium, or doomed to the regions of suffering, were not always of such a nature as under a well-regulated government on earth would have been thought to merit reward, or to be worthy of punishment. It was not always virtue or wisdom which conducted to the Elysian fields, or gained admission into the society of the immortal gods.

Ganymede was for a very different reason promoted to be the cup-bearer of Jove; and Hercules and Bacchus could not surely plead that any merits of that kind entitled them to seats in the council, and at the banquets of the immortals. That doctrine, likewise, which represented mortals as hurried by fate to the commission of crimes, which they could no more abstain from committing than the sword can avoid to obey the impulse of a powerful and violent arm, plunging it into the breast of an unresisting antagonist, could not but produce effects unfavourable to virtue; and it afforded a ready excuse for the most extravagant crimes.

Yet, after all, he who attentively considers the ideas of the Greeks and Romans concerning the moral government of the world and a future state of rewards and punishments, will probably acknowledge, that their general influence must have been favourable to virtue and moral order. Allow them to have been incorrect and dashed with absurdity; still they represent punishments prepared for such qualities and actions as were injurious to the welfare of society; whilst, for those qualities which rendered men eminently useful in the world, they hold forth a reward. Though incorrect, their ideas concerning a future state were exceedingly distinct; they were not vague or general, but such as might be readily conceived by the imagination, in all their circumstances, as really existing. When a man is told that for such a deed he will be put to death, he may shudder and be alarmed, and think of the deed as what he must by no means commit; but place before his mind the spectacle of the executioner, and the apparatus for his execution, call him to behold some other criminal mounting the scaffold, addressing his last words in a wild scream of despair to the surrounding spectators, and then launching into eternity—his horror of the crime, and his dread of the punishment, will now be much more powerfully excited. In the same manner, to encourage the soldier marching out to battle, or the mariner setting sail under the prospect of a storm, promise not, merely in general terms, a liberal reward; be sure to specify the nature of the reward which you mean to bestow; describe it so as that it may take hold on the imagination, and may rise in opposition to the images of death and danger with which his courage is to be assailed.

If these phenomena of the human mind are fairly stated, it is true that general ideas produce no very powerful effects on the sentiments and dispositions of the human heart, it must then be granted, that though the scenes of future reward and punishment, which the heathens considered as prepared for the righteous and the wicked, were of a somewhat motley complexion; yet still, as they were distinct and even minute draughts, they must have been favourable to virtue, and contributed in no inconsiderable degree to the support of civil order.

Another thing of which we may take notice under this head, is the vast multiplicity of deities with which the Greek and Roman mythology peopled all the regions of nature. Flocks and fields, and woods and groves, had all their guardian deities. These were somewhat capricious at times, it is true, and expected to have attention paid them. But yet the faithful shepherd, and the industrious farmer, knew generally how to acquire their friendship; and in the idea of deities enjoying the same simple pleasures, partaking in the same labours, protecting their possessions, and bringing forward the fruits of the year, there could not but be something of a very pleasing nature, highly favourable to industry, which would animate the labours, and cheer the festivals, of the good people who entertained such a notion: nay, would diffuse a new charm over all the scenes of the country, even in the gayest months of the year.

From all of these particular observations, we think ourselves warranted to conclude, that notwithstanding the mixed characters of the deities who were adored by the celebrated nations of antiquity; though they are in many instances represented as conspicious for vices and frolics; however vain, absurd, and morally criminal, some of the rites by which they were worshipped may have been, and however, incorrect the notions of the heathens concerning the moral government of the universe and a future state of retribution; yet still, after making a just allowance for all these imperfections, the general influence of their religious system was rather favourable than unfavourable to virtue and to the order and happiness of society.
But if such be the natural tendency of those principles by which the human heart is made susceptible of religious sentiments, that even the enthusiasm and absurd superstition are productive of beneficial effects more than sufficient to counterbalance whatever is malignant in their influence on society—surely a pure rational religion, the doctrines of which are founded in undeniable truth, and all the observances which it enjoins calculated to promote by their direct and immediate effects some useful purposes, must be in a very high degree conducive to the dignity and the happiness of human nature. Indeed one collateral proof of the truth of any religion, which must have very considerable weight with all who are not of opinion that the system of the universe has been produced and hitherto maintained in order and existence by blind chance, will be its having a stronger and more direct tendency than others to promote the interests of moral virtue and the happiness of mankind in the present life. Even the testimony of thousands, even miracles, prophecies, and the sanction of remote antiquity, will scarce have sufficient weight to persuade us, that a religion is of divine origin, if its general tendency appear to be rather unfavourable than advantageous to moral virtue.

III. We shall therefore, in the next place, endeavour to determine, from a comparative view of the effects produced on the character and circumstances of society by the most eminent of these various systems of different religions which have been in different ages or in different countries established in the world, how far any one of them has in this respect the advantage over the rest; and, if the utility of a system of religion were to be received as a test of its truth, what particular system might, with the best reason, be received as true, while the rest were rejected.

1st. The principle upon which we here set out is, that all, or almost all, systems of religion with which we are acquainted, whether true or false, contribute more or less to the welfare of society. But as one field is more fruitful, and one garden less overgrown with weeds than another; so, in the same manner, one system of religious opinions and ceremonies may be more happily calculated than others to promote the true interests of mankind. In opposition to those philosophers who are so vehement in their declamations against the inequality of ranks, we have ever been of opinion, that refinement and civilization contribute to the happiness of human life. The character of the solitary savage is, we are told, more dignified and respectable than that of the philosopher and the hero, in proportion as he is more independent. He is indeed more independent; but his independence is that of a stone, which receives no nourishment from the earth or air, and communicates none to animals or vegetables around it.

In point of happiness, and in point of respectability, we cannot hesitate a moment, let philosophers say what they will, to prefer a virtuous, enlightened, and polished Briton, to any of the rudest savages, the least acquainted with the restraints and the sympathies of social life, that wander through the wild forests of the western world. But if we prefer civilization to barbarism, we must admit, than in this view Christianity has the advantage over every other religious system which has in any age or country prevailed.
Religion.

It is not, indeed, in any considerable degree that the absurd superstitions of those rude tribes, who can scarce be said to be formed into any regular society, can contribute to their happiness. Among them the faculty of reason is but in a very low state; and the moral principle usually follows the improvement or the depression of the reasoning faculty. Their appetites and merely animal passions are almost their only principles of action: their first religious notions, if we suppose them not to be derived from revelation or tradition, are produced by the operation of gratitude, or grief, or hope, or fear, upon their imaginations. And to these, however wild and fanciful, it is not improbable that they may owe some of their earliest moral notions. The idea of superior powers naturally leads to the thought that those powers have some influence on human life. From this they will most probably proceed to fancy one set of actions agreeable, another offensive, to those beings to whom they believe themselves subject And this, perhaps, is the first distinction that savages can be supposed to form between actions, as right or wrong, to be performed or to be avoided. But if this be the case, we must acknowledge, that the religious notions of the savage, however absurd, contribute to elevate his character, and to improve his happiness, when they call forth the moral principle implanted in his breast.

But if the social state be preferable to a state of wild and solitary independence, even the rude superstitions of unenlightened tribes of savages are in another respect beneficial to those among whom they prevail. They usually form, as has been already observed under this article, the basis of civil order. Religious opinions may lead the great body of the community to reverence some particular set of institutions, some individual, or some family, which are represented to them as peculiarly connected with the gods whom they adore. Under this sanction some form of government is established; they are taught to perform social duties, and rendered capable of social enjoyments. Not only Numa and Lycurgus, but almost every legislator who has sought to civilize a rude people, and reduce them under the restraints of legal government, have endeavored to impress their people with an idea that they acted with the approbation, and under the immediate direction of superior powers. We cannot but allow that the rude superstitions of early ages are productive of these advantages to society; but we have already acknowledged, and it cannot be denied, that they are also attended with many unhappy effects. When we view the absurdities intermixed with the systems of religion which prevailed among most of the nations of antiquity, we cannot help lamenting that so noble a principle of human nature as our religious sentiments should be liable to such gross perversion; and when we view the effects which they produce on the morals of mankind, and the forms of society, though we allow them to have been upon the whole rather beneficial than hurtful, yet we cannot but observe, that their unhappy effects are by far more numerous than if they had been better directed. What unhappy effects, for instance, have been produced by false notions concerning the condition of human souls in a future state. Various nations have imagined that the scenes and objects of the world of spirits are only a shadowy representation of the things of the present world. Not only the souls of men, according to them, inhabit those regions; all the inferior animals and vegetables, and even inanimate bodies that are killed or destroyed here, are supposed to pass into that visionary world; and, existing there in unsubstantial forms, to execute the same functions, or serve the same purposes, as on earth. Such are the ideas of futurity that were entertained by the inhabitants of Guinea. And by these ideas they were induced, when a king or great man died among them, to provide for his comfortable accommodation in the world of spirits, by burying with him meat and drink for his subsistence, slaves to attend and serve him, and wives with whom he might still enjoy the pleasures of love. His faithful subjects vied with each other in offering, one a servant, another a wife, a third a son or daughter, to be sent to the other world in company with the monarch, that they might there be employed in his service. In New Spain, in the island of Java, in the kingdom of Benin, and among the inhabitants of Hindostan, similar practices on the same occasion, owing no doubt to similar notions of futurity, have been prevalent. But such practices as these cannot be viewed with greater contempt on account of the opinions which have given rise to them, than horror on account of their unhappy effects on the condition of those among whom they prevail. A lively impression of the enjoyments to be obtained in a future state, together with some very false or incorrect notions concerning the qualities or actions which were to entitle the departing soul to admission into the scene of those enjoyments, is said to have produced equally unhappy effects among the Japanese. They not only bribe their priests to solicit for them; but looking upon the enjoyments of the present life with disgust or contempt, they used to dash themselves from precipices, or cut their throats, in order to get to paradise as soon as possible.

Various other superstitions subsisting among rude nations might here be enumerated, as instances of the perversion of the religious principles of the human heart, which render them injurious to virtue and happiness. The austerities which have been practised, chiefly among rude nations, as means of propitiating superior powers, are especially worthy of notice.—When the favourite idol of the Banians is carried in solemn procession, some devotees prostrate themselves on the ground, that the chariot in which the idol is carried may run over them; others, with equal enthusiasm, dash themselves on spikes fastened on purpose to the car. Innumerable are the ways of torture which have been invented and practised on themselves by men ignorantly striving to recommend themselves to the favour of heaven. These lamentable instances in which religious sentiments have been so ill directed by the influence of imagination, and unenlightened erring reason, as to produce unhappening effects on the human character, and oppose the happiness of social life.—

Though we have argued, that even the most absurd systems of religion that have prevailed in the world, have been upon the whole rather beneficial than injurious to the dignity and happiness of human nature; yet if it shall not appear, as we proceed farther in our comparison.
Religion. The view of the effects of religion on society, that others have been attended with happier effects than these superstitions which belong to the rude ages of society, we may scarce venture to brand the infidel with the appellation of fool, for refusing to give his assent to religious doctrines, or to act under their influence.

2d, The polytheism of the Greeks and Romans, and other heathen nations in a similar state of civilization, we have already considered as being, upon the whole, rather favourable than unfavourable to virtue; but we must not partially conceal its defects. The vicious characters of the deities which they worshipped, the incorrect notions which they entertained concerning the moral government of the universe and a future retribution, the absurdity of their rites and ceremonies, and the criminal practices which were intermixed with them, must have altogether had a tendency to produce both the reasoning and the moral principles of the human mind. The debaucheries of the monarch of the gods, and the fidelity with which his example in that respect was followed by the whole crowd of the inferior deities, did, we know, dispose the devout heathen, when he felt the same passions which had asserted their power over the gods, to gratify them without scruple. It is a truth, however, and we will not attempt to deny or conceal it, that the genius of the polytheism of the Greeks and Romans was friendly to the arts; to such of them especially as are raised to excellence by the vigorous exertion of a fine imagination; music, poetry, sculpture, architecture, and painting, all of these arts appear to have been considerably indebted for that perfection, to which they attained, especially among the Greeks, to the splendid and fanciful system of mythology which was received among those ingenious people. But we cannot give an equally favourable account of its influence on the sciences. There was little in that system which could contribute to call forth reason. We may grant indeed, that if reason can be so stained with absurdity as to be roused to a more vigorous exertion of her powers, and a more determined assertion of her rights in consequence of surveying it; in that case, this system of mythology might be favourable to the exercise and improvement of reason; not otherwise.

The connection of paganism with morality was too imperfect for it to produce any very important effects on the morals of its votaries. Sacrifices and prayers, and temples and festivals, not purity of heart and integrity of life, were the means prescribed for propitiating the favour of the deities adored by the Pagans. There were other means, too, besides true heroism and patriotism, of gaining admission into the Elysian fields, or obtaining a seat in the council of the gods. Xenophon, in one of the most beautiful parts of his Memoirs of Socrates, represents Hercules wooed by Virtue and Pleasure in two fair female forms, and deliberating with much anxiety which of the two he should prefer. But this is the fiction of a philosopher desirous to improve the fables of antiquity in such a way as to render them truly useful. Hercules does not appear, from the tales which are told us of his adventures, to have been at any such pains in choosing his way of life. He was received into the palace of Jove, without having occasion to plead that he had-through life been the faithful follower of that goddess to whom the philosopher makes him give the preference; his being the son of Jove, and his wild adventures, were sufficient without any other merits to gain him that honour. The same may be said concerning many of the other demi-gods and heroes who were advanced to heaven, or conveyed to the blissful fields of Elysium. And whatever might be the good effects of the religion of Greece and Rome in general upon the civil and political establishments, and in some few instances on the manners of the people, yet still it must be acknowledged to have been but ill calculated to impress the heart with such principles as might in all circumstances direct to a firm, uniform tenor of virtuous conduct.

But after what has been said on the character of this religion elsewhere (see Polytheism), and in the second part of this article, we cannot without repetition enlarge farther on it here. Of the Jewish religion, however, we have as yet said little, having an axe reserved to this place whatever we mean to introduce under the article, concerning its influence on society.

3d, When we take a general view of the circumstances in which the Jewish religion was established, the effects which it produced on the character and fortune of the nation, the rites and ceremonies which it enjoined, and the singular political institutions to which it gave a sanction, it may perhaps appear hard to determine, whether it were upon the whole more or less beneficial to society than the polytheism of the Egyptians, Greeks, and Romans. But if such be the judgement which preconceived prejudices, or a hasty and careless view, have induced some to form of this celebrated system; there are others who, with equal keenness, and sounder reasoning, maintain, that it was happily calculated, not only to accomplish the great design of preparing the way for the promulgation of the Gospel, but likewise to render the Jews a more refined and virtuous people, and a better regulated community, than any neighbouring nation. In the first place, the attributes of the Deity were very clearly exhibited to the Jews in the establishment of their religion. The miracles by which he delivered them from servitude, and conducted them out of Egypt, were striking demonstrations of his power; that condescension with which he forgave their repeated acts of perverseness and rebellion, was a most convincing proof of his benevolence; and the impartiality with which he observered the violation of his laws were rewarded and punished, even in the present life, might well convince them of his justice. A part of the laws which he dictated to Moses are of eternal and universal obligation; others of them were local and particular, suited to the character of the Jews, and their circumstances in the land of Canaan. The Jewish code, taken altogether, is not to be considered as a complete system of religion, or laws calculated for all countries and all ages of society. When we consider the expediency of this system, we must take care not to overlook the design for which the Jews are said to have been separated from other nations, the circumstances in which they had lived in Egypt, the customs and manners which they had contracted by their intercourse with the natives of that country, the manner in which they were to acquire to themselves settlements by extinguishing the nations of Canaan, the rank which they were to hold among the nations of Syria and the adjacent countries, together with the difficulty of
Religion

of restraining a people so little civilized and enlight
ced from the idolatrious worship which prevailed among
their neighbours: All these circumstances were cer
tainly to be taken into account; and had the legislator
of the Jews not attended to them, his institutions must
have remained in force only for a short period; nor
could they have produced any lasting effects on the
character of the nation. With a due attention to these
circumstances, let us descend to an examination of par
culars.

Although in every religion or superstition that has
prevailed through the world, we find one part of its
institutions to consist in the enjoining of certain festivals
to be celebrated by relaxation from labour, and the per
formance of certain ceremonies in honour of the gods;
yet in none, or almost none besides the Jewish, do we
find every seventh day ordained to be regularly kept
holy. One great end which the legislator of the Jews
had in view in the institution of the Sabbath was, to im
press them with a belief that God was the maker of
the universe. In the early ages of the world a great part
of mankind imagined the stars, the sun, the moon, and
the other planets, to be eternal, and consequently ob
jects highly worthy of adoration. To convince the Is
raelites of the absurdity of this belief, and prevent them
from adopting that idolatry, Moses taught them, that
those conspicuous objects which the Gentile nations re
spected as eternal, and endowed with divine power and
intelligence, were created by the hand of God; who,
according to the things of nothing, and giving them form,
order, and harmony, in the space of six days, rested on the seventh from all his works. Various passages in the Old Testament concur to show,
that this was one great end of the institution of the
Sabbath. The observance of the Sabbath, and detesta
tion of idolatrous worship, are frequently inculcated to
gether; and, again, the break of the Sabbath, and the
worship of idols, are usually reproved at the same
time. Another good reason for the institution of a
Sabbath might be, to remind the Jews of their deliv
erance from bondage, to inspire them with humanity to
strangers and domestics, and to mitigate the rigours of
servitude.

The purposes for which the other festivals of the
Jewish religion were instituted appear also of sufficient
importance. The great miracle, which, after a series of
other miracles, all directed to the same end, finally
effected the deliverance of the Jews out of Egypt, and
their actual departure from that land of servitude, might
well be commemorated in the feast of the passover. To
call to the minds of posterity the history of their an
cestors, to impress them with an awful and grateful sense
of the goodness and greatness of God, and to make them
think of the purposes for which his almighty power had been so signally exerted, were surely good
reasons for the institution of such a festival. The feast
of Pentecost celebrated the first declaration of the law
by Moses, in the space of fifty days after the feast of
the passover. It served also as a day of solemn thank
sgiving for the blessings of a plentiful harvest. On the
feast of tabernacles, they remembered the wanderings
of their ancestors through the wilderness, and expressed
their gratitude to heaven for the more comfortable cir
cumstances in which they found themselves placed.
The feast of new moons served to fix their calendar, and
determine the times at which the other festivals were
to be celebrated; on it trumpets were sounded, to give
public notice of the event which was the cause of the
festival; no servile works were performed, divine ser
vice was carefully attended, and the first fruits of the
month were offered to the Lord. The Jewish legisla
tor limited his festivals to a very small number, while
the heathens devoted a considerable part of the year to
the celebration of theirs. But we perceive the occas
ions upon which the Jewish festivals were celebrated
to have been of suitable importance; whereas those of
the heathens were often celebrated on trifling or ridic
ulous occasions. Piety and innocent recreation shared
the Jewish festival; the festivals of the heathens were
chiefly devoted to debauchery and idleness.

The Hebrews had other solemn seasons of devotion
besides the weekly Sabbath and these annual festivals.
Every seventh year they rested from labour: they were
then neither to plough, to sow, nor to prune; and what
ever the earth produced spontaneously that year belonged
rather to strangers, orphans, and the poor, than to the
proprietors of the ground. On this year insolvent
debtors were discharged from all debts contracted by
purchasing the necessaries of life; and the great end of
this release from debts contracted during the preceding
six years, appears to have been to prevent the Hebrew
from flying to the Gentiles and forsaking his religion
when embarrassed in his circumstances. None but nat
ive Israelites and proselytes of righteousness were ad
mitted to this privilege; it was refused to strangers,
and even to proselytes of the gate. The jubilee was
a festival to be celebrated every fiftieth year. It pro
duced the same effect with the sabbatical year as to rest
from labour and the discharge of debts; with this addi
tion, that in the year of the jubilee slaves obtained
their freedom, and the land reverted to the old pro
prieters. On the year of the jubilee, as on the sabbat
ical year, the lands were to rest uncultivated, and
lawsuits were now to terminate. The chief design of this
institution appears to have been, to preserve the order
of ranks and property originally established in the He
brew state. None but Israelites or circumcised con
verts could enjoy the benefit of this institution; nor
could even those hope to regain their estates on the
year of the jubilee, if they sold them for any other pur
pose but to supply their necessities. The law relative
to usury was evidently founded on the same plan of
polity with respect to property. To almost any other
nation such a law, it must be confessed, would have been
unsuitable and unjust: but as the Jews were not de
signed for a trading nation, they could have little occa
sion to borrow, unless to relieve distress; and as an in
dulgence to people in such circumstances, the Jew was
forbidden to exact usury from his brother to whom he
had lent money.

The Jewish legislator, we may well think, would be of clean
disposed to adopt every proper method to prevent his and um
nation from falling away into the idolatry of heathen
clean beasts, and nations. Probably one reason of the distinctions be
the place
between clean beasts which they were permitted to eat, o. worshp
and unclean beasts, the eating of which they were taught
to consider as pollution, was to prevent them from con
vivial intercourse with profane nations, by which they
might be seduced to idolatry. We do not readily sit
down at table with people who are fond of dishes which

4 U 2
Religion. We regard with abhorrence. And if the Jews were taught to loathe the flesh of some of those animals which were among the greatest delicacies of the Gentiles, they would naturally of consequence avoid sitting down at meat with them, either at their ordinary meals or at those entertainments which they prepared in honour of their deities; and this we may with good reason consider as one happy mean to preserve them from idolatry. Besides, the Jews were permitted, or rather enjoined, to eat animals which the Gentiles reverenced as sacred, and from which they religiously withheld all violence. Goats, sheep, and oxen, were worshipped in Egypt (see Polytheism and Pan); and several learned writers are of opinion, that Moses directed his people to sacrifice and eat certain of the favourite animals of the Egyptians, in order to remove from their minds any opinions which they might have otherwise entertained of the sanctity of those pretended deities. Many of the observances which Moses enjoined with regard to food, appear to have been intended to inspire the Israelites with contempt for the superstitions of the people among whom they had so long sojourned. They were to kill the animal which the Egyptians worshipped; to roast the flesh which that people ate raw; to eat the head, which they never ate; and to dress the entrails, which they set apart for divination. These distinctions concurred with the peculiarities of their dress, language, government, customs, places and times of worship, and even the natural situation of their country, by which they were in a manner confined and fortified on all sides, to separate them in such a manner from neighbouring nations, that they might escape the infection of their idolatry. And if we reflect both on the design for which Providence separated the Israelites from other nations, and on the probability that, in the state of society in which mankind were during the earlier period of the Jewish history, the Jews, by mixing with other nations would rather have been themselves converted to idolatry than have converted idolatrous nations to the worship of the true God; we cannot but be satisfied, that even this, however it may at first appear, was a benefit, not a disadvantage; and in the author of their legislation wisdom, not caprice.

But not only in the distinctions of meats, and between clean and unclean animals, does the legislator of the Jews appear to have laboured to fix a barrier between them and other nations, which might preserve them from the contagion of idolatry—we shall not err, perhaps, if we ascribe many particulars of their worship to this design in the instigator. The heathens had gods who presided over woods, rivers, mountains, and valleys, and to each of these they offered sacrifices and performed other rites of worship in a suitable place. Sometimes the grove, sometimes the mountain top, at other times the bank of the river or the brink of the spring, was the scene of their devotions. But as the unity of the divine nature was the truth the most earnestly inculcated on the children of Israel; so in order to impress that truth on their minds with the more powerful efficacy, they were taught to offer their sacrifices and other offerings only in one place, the place chosen by the Lord; and death was threatened to those who dared to disobey the command. To confirm this idea, one of the prophets intimates, that when idolatry should be abolished, the worship of God should not be confined to Jerusalem, but it would then be lawful to worship him anywhere.

The whole institutions and observances of the Jewish religion appear to have been designed and happily calculated to impress the minds of the people with veneration and respect for the Deity. All the festivals which either commemorated some gracious dispensation of his providence towards their ancestors, or served as days of thanksgiving for the constant returns of his goodness to those who celebrated them, and all the other rites designed to fortify them against idolatry, served at the same time to impress their hearts with awful reverence for the God of Jacob. Various other particulars in the institutions of the Jewish economy appear to have been directed solely to that end. Into the most sacred place, the Holy of Holies, none but the high priest was admitted, and he only once a year. No fire was used in sacrifice but what was taken from the altar. Severe punishments were on various occasions inflicted on such as presumed to meddle in the service of the sanctuary in a manner contrary to what the law had directed. All the laws respecting the character, the circumstances, and the services, of the priests and the Levites, appear plainly to have a similar tendency.

In compliance with the notions of Deity which naturally prevailed among a gross and rude people, though no visible object of worship was granted to the Jews, yet they were allowed in their wanderings through the wilderness to have a tabernacle or portable temple, in which the soverign of the universe sometimes deigned to display some rays of his glory. Incapable as they were of conceiving aright concerning the spiritual nature and the omnipresence of the Deity, they might possibly have thought Jehovah careless and indifferent about them, had they been at no time favoured with a visible demonstration of his presence.

The sacrifices in use among the Gentiles in their sacred worship of idols were permitted by the Jewish legislators; but he directed them to be offered with views very different from those with which the Gentiles sacrificed to their idols. Some of the sacrifices of the Jewish ritual were designed to avert the indignation of the Deity; some to expiate offences and purify the heart; and all of them to abolish or remove idolatry. Litigations or abolutions entered likewise into the Jewish ritual; but these were recommended and enjoined by Moses for purposes widely different from those which induced the heathens to place so high a value upon them. The heathens practised them with magical and superstitions ceremonies; but in the Jewish ritual they were intended simply for the cleansing away of impurities and pollutions.

The theoretical form of government to which the Jews were subject, the rewards which they were sure of receiving, and the punishments which were equally liable to suffer in the present life, had a powerful effect to remove superstition and preserve them from idolatry, as well as to support all the social virtues among them. They were promised a numerous offspring, a land flowing with milk and honey, long life, and victory over their enemies, on the condition of their paying a faithful obedience to the will of their heavenly Sovereign; plague, famine, disease, defeats, and death, were threatened as the punishments to be inflicted on those who violated...
violated his laws; and these sanctions, it must be allowed, were happily accommodated to the genius of a rude and carnal-minded people, attentive only to present objects, and not likely to be influenced by remote and spiritual considerations.

There were other rites and prohibitions in the Mosaic law, which appear to have had but little connection with religion, morals, or policy. These may be more liable to be objected against, as adding an unnecessary weight to a burden which, though heavy, might yet have been otherwise borne in consideration of the advantages connected with it. Even these, however, may perhaps admit of being viewed in a light in which they shall appear to have been, in no way unfavourable to the happiness of those to whom they were enjoined. They appear to have had none of them an immoral tendency: all of them had, in all probability, a tendency to remove or prevent idolatry, or to support, in some way or other, the religious and the civil establishment to which they belonged.

From these views of the spirit and tendency of the Jewish religion, we may fairly conclude it to have been happily calculated to promote the welfare of society. In comparing it with other religions, it is necessary to reflect on the peculiar purposes for which it was given; that its two principal objects were to preserve the Jews a separate people, and to guard them against the contagion of the surrounding idolatry. When these things are taken into consideration, every candid mind acquainted with the history of ancient nations will readily acknowledge that the whole system, though calculated indeed in a peculiar manner for them, was as happily adapted for the purposes for which it had been wisely and graciously intended, as it is possible to imagine any such system to be. It would be unhappy, indeed, if on a comparison of pure theism with polytheism, the latter, with all its absurdities, should be found more beneficial to mankind than the former. The theism of the Jews was not formed to be disseminated through the earth; that would have been inconsistent with the purposes for which it is said to have been designed. But while the Jews were separated by their religion from all other nations, and perhaps, in some degree, fixed and rendered stationary in their progress towards refinement, they were placed in circumstances, in respect to laws, and government, and religion, and moral light, which might with good reason render them the envy of every other nation in the ancient world.

IV. The Christian religion next demands our attention. It is to be considered as an improvement of the Jewish, or a new superstructure raised on the same basis. If the effects of the Jewish religion were beneficial to those among whom it was established, they were confined almost to them alone. But is the spirit of Christianity equally pure and benign? Is its influence equally beneficial and more diffusive than that of Judaism? Does it really merit to have triumphed over both the theism of the Jews and the polytheism of the heathens?

If we consider the doctrines and precepts of the Christian religion, nothing can be more happily calculated to raise the dignity of human nature, and promote the happiness of mankind. The happiness of the individual is best promoted by the exercise of love and gratitude towards God, and resignation to his providence; of humanity, integrity, and good will towards men; and by the due government of our appetites and passions. Social happiness again proceeds from the members of society entertaining a disinterested regard for the public welfare; being actively industrious each in his proper sphere of exertion; and being strictly just and faithful, and generously benevolent in their mutual intercourse. The tenor of the gospel inculcates these virtues; it seems everywhere, through the whole of the Christian code, to have been the great design of its Author to inspire mankind with mild, benevolent, and peaceable dispositions, and to form them to courteous manners. Christianity again represents the Deity and his attributes in the fairest light; even so as to render our ideas of his nature, and the manner in which he exerts his power, consistent with the most correct principles of morality that can be collected from all the other religions that have prevailed in the earth, and from the writings of the most admired philosophers. The ritual observances which Christianity enjoins are few in number, easy to perform, decent, expressive, and edifying. It inculcates no duties but what are founded on the principles of human nature, and on the relation in which men stand to God, their Creator, Redeemer, and Sanctifier; and it prescribes accurate rules for the regulation of the conduct. The assistance of the spirit of God is promised in this sacred volume to those who assiduously labour to discharge the duties which it enjoins; and it exhibits a striking example of spotless purity, which we may safely venture to imitate. The gospel teaches that worldly afflictions are incident to both good and bad men; a doctrine highly conducive to virtue, which consoles us in distress, prevents despair, and encourages us to persist firmly in our integrity under every difficulty and trial.

Christianity represents all men as children of the same God, and heirs of the same salvation, and levels all distinctions of rich and poor, an accidental and insignificant in the sight of him who rewards or punishes with impartiality according to the merits of his creatures. This doctrine is highly favourable to virtue, as it tends to humble the proud, and to communicate dignity of sentiment to the lowly; to render princes and inferior magistrates moderate and just, gentle and condescending, to their inferiors. It further requires husbands to be affectionate and indulgent to their wives, wives to be faithful and respectful to their husbands, and both to be true and constant to each other. Such is the purity of the gospel, that it forbids us even to harbour impure thoughts; it requires us to abandon our vices, however dear to us; and to the cautious wisdom of the serpent it directs us to join the innocent simplicity of the dove. The Christian dispensation, to prevent a perseverance in immorality, offers pardon for the past, provided the offender forsakes his vicious practices, with a firm resolution to act differently in the future. Sanctions of the gospel have a natural tendency to exalt the mind above the paltry pursuits of this world, and to render the Christian incorruptible by wealth, honours, or pleasures. The true Christian not only abstains from injustice towards others, but even forgives those injuries which he himself suffers, knowing that he cannot otherwise hope for forgiveness from God. Such are the precepts, such the spirit, and such the general tendency of the gospel. Even those who refused to give credit to its doctrines and history have yet acknowledged the excellence
Religion. The excellence of its precepts. They have acknowledged, that "no religion ever yet appeared in the world, of which the natural tendency was so much directed to promote the peace and happiness of mankind as the Christian; and that the gospel of Christ is one continued lesson of the strictest morality, of justice, benevolence, and universal charity." These are the words of Bolingbroke, one of its keenest and most insidious opponents. Without examining the effects of this religion on society, we might almost venture to pronounce with confidence, that a religion, the precepts of which are so happily formed to promote all that is just and excellent, cannot but be in the highest degree beneficial to mankind. By reviewing the effects which it has actually produced, the favourable opinion which we naturally conceive of it, after considering its precepts, cannot but be confirmed.

47 The virtues it recommends. One circumstance we must take notice of as rather unfavourable to this review. It is really impossible to do justice to Christianity through a discussion of its merits. The virtues which it has a natural tendency to produce and cherish in the human heart, are not of a noisy ostentatious kind; they often escape the observation of the world. Temperance, gentleness, patience, benevolence, justice, and general purity of manners, are not the qualities which most readily attract the admiration and obtain the applause of men. The man of Ross, whom Mr Pope has so justly celebrated, was a private character; his name is now likely to live, and his virtues to be known to the latest posterity: and yet, however disinterested his virtues, however beneficial his influence to all around him, had his character not attracted the notice of that eminent poet, his name would perhaps ere this time have been lost in oblivion. Individuals in private life seldom engage the attention of the historian; his object is to record the actions of princes, warriors, and statesmen. Had not the professors of Christianity in the earlier ages of its existence been exposed to persecutions, and unjust accusations from which they were called on to vindicate themselves, we should be strangers to the names and virtues of saints and martyrs, and to the learning and endowments of the first apologists for Christianity. We can therefore only trace the general influence of the institutions of Christianity on society. We cannot hope to make an accurate enumeration of particulars. In many of the countries in which it has been established, it has produced a very favourable change on the circumstances of domestic life. Polygamy, a practice repugnant to the will of our Creator (see Polygamy), who has declared his intentions in this instance in the plainest manner, by causing nearly equal numbers of males and females to be brought into the world, was never completely abolished but by Christianity.

48 Its effects on the manners of nations. The practice of divorce, too, though in some cases proper and even necessary, had been so much abused at the time of our Saviour's appearance in the world, that he found reason to declare it unlawful, unless in the case of adultery. The propriety and reasonableness of this prohibition will sufficiently appear, if we consider, that when divorces are easily obtained, both parties will often have nothing else in view at the period of marriage than the dissolution of their nuptial engagements after a short cohabitation; the interests of the husband and the wife will almost always be separate; and the children of such a marriage are scarce likely to enjoy the cordial affection and tender watchful care of either parent. The husband in such a case will naturally be to his wife, not a friend and protector, but a tyrant; and, of course, not love, gratitude, or a sense of duty, will be the principles of the wife's obedience.

In another instance, likewise, Christianity has produced an happy change on the circumstances of domestic life; it must be acknowledged to have contributed greatly to the abolition of slavery, or at least to the mitigation of the rigour of servitude. The customs and laws of the Romans in relation to slaves were cruel and severe. Masters were often so inhuman as to remove aged, sick, or infirm slaves, into an island in the Tiber, where they suffered them to perish without pity or assistance. The greater part of the subjects of many of those republics which enjoyed the most liberty, groaned under tyrannical oppression; they were condemned to drag out a miserable existence in hard labour, under inhuman usage, and to be transferred like beasts from one master to another. The hardships of slavery were eased, not by any particular precept of the Gospel, but by the gentle and humane spirit which breathed through the general tenor of the whole system of doctrines and precepts of which the Gospel consists. It must indeed be allowed, that a trade in slaves is at present carried on by people who presume to call themselves Christians, and protected by the legislature of Christian states: but the spirit of the Christian code condemns the practice, and the true Christian will not engage in it.

Partly by the direct and conspicuous, partly by the secret and unseen, influence of Christianity since its promulgation in the world, the hearts of men have been gradually softened; even barbarians have been forsook to mildness and humanity; the influence of self-love has been checked and restrained; and even war, amid all the pernicious improvements by which men have sought to render it more terrible, has assumed much more of the spirit of mildness and peace than ever entered into it during the reign of heathenism.

If we review the history of mankind with a view to their political circumstances, we shall find, that by some means or other, it has happened, since the time when the Gospel was first preached, that both systems of legislation and forms of government have been raised to much greater perfection, at least in those parts of the world into which the religion of Jesus has made its way, and obtained an establishment.

The popular government of the Romans, notwithstanding the multiplicity of their laws, and the imperfections of their political constitution, was, no doubt, happily enough adapted to promote the increase of the power and the extension of the empire of Rome. In Greece there were various republics, the wisdom and impartiality of whose laws have been highly celebrated. But we apprehend that there is a sufficient number of well authenticated facts to warrant us to affirm, that since Christianity has been propagated, and has had sufficient time to produce its full effect on arts, manners, and literature, even under governments the form of which might appear less favourable than the celebrated models of antiquity to the liberty and happiness of the people in general, these actually have been much better provided for than under the laws of Athens or Sparta, or even of Rome in the days of the consul. It is just
By the laws of Zoroaster the Persians committed incest. Religion.

just and happy observation of Montesquieu, who has attributed so much to the influence of climate and local circumstances, that "the mildness so frequently recommended in the Gospel is incompatible with the despotism of a despotic age with which an arbitrary tyrant punishes his subjects, and exercises himself in cruelty. It is the Christian religion (says he) which, in spite of the extent of empire, and the influence of climate, has hindered despotism from being established in Ethiopia, and has carried into Africa the manners of Europe. The heir to the empire of Ethiopia enjoys a principality, and gives to other subjects an example of love and obedience. Nor far from hence may be seen the Mahometan shutting up the children of the king of Sennar, at whose death the council sends to murder them in favour of the prince who ascends the throne. Let us set before our eyes (continues that eloquent writer), in the third chapter of the 24th book of his Spirit of Laws, on one hand the continual massacres of the kings and generals of the Greeks and Romans, and on the other the destruction of people and cities by the famous conquerors Timur Beg and Jenghiz Khan, who ravaged Asia; and we shall perceive, that we owe to Christianity in government a certain political law, and in war a certain law of nations, which allows to the conqueror the great advantages of liberty, laws, wealth, and always religion, when the conqueror is not blind to his own interest."

These are the reflections of no common judge in this matter, but one who had long studied the history of nations, and observed the phenomena of the various forms of society, with such success as few others have attained.

But on no occasion has the mild influence of Christianity been more eminently displayed, or more happily exerted, than in softening and humanizing the barbarians who overturned the Roman empire. The idolatrous religion which prevailed among those tribes before their conversion to Christianity, instead of disposing them to cultivate humanity and mildness of manners, contributed strongly to render them fierce and blood-thirsty, and eager to distinguish themselves by deeds of savage valor. But no sooner had they settled in the dominions of Rome, and embraced the principles of Christianity, than they became a mild and generous people.

We are informed by Mosheim, who was at pains to collect his materials from the most authentic sources, that in the 10th century Christian princes exerted themselves in the conversion of nations whose fierceness they had experienced, in order to soften and render them more gentle. The mutual humanity with which nations at war treat each other in modern times, is certainly owing, in a great measure, to the influence of the mild precepts of the Gospel. It is a fact worthy of notice, too, that during the barbarous ages, the spiritual courts of justice were more rational and impartial in their decisions than civil tribunals.

How many criminal practices which prevailed among heathen nations have been abolished by their conversion to Christianity! Christians of all nations have been observed to retain the virtues and reject the vicious practices of their respective countries. In Parthia, where polygamy prevailed, they are not polygamists; in Persia, the Christian father does not marry his own daughter.

By the laws of Zoroaster the Persians committed incest. Religion.

Religion. many happy effects on the circumstances and the characters of Pagans and infidels, who have had opportunities of beholding the virtues of Christians, and learning the excellence of the morality of the gospel. Those virtues—which distinguished the character of the apostate Julian were surely owing in no considerable degree to his acquaintance with Christianity; and it is an undeniable fact, that after the propagation of Christianity through the Roman empire, even while the purity of that holy religion was gradually beclouded, the manners of those Pagans who remained unconverted became more pure, and their religious doctrine and worship less immoral and absurd. We might here adduce a tedious series of facts to the same purpose. Whenever Christians have had any intercourse with Pagan idolaters, and have not concealed the laws of the gospel, nor shown by their conduct that they disregarded them, even those who have not been converted to Christianity have, however, been improved in their dispositions and manners by its influence. The emperor, whose virtues we have mentioned as arising, in a certain degree, from his acquaintance with Christianity, in a letter to an Heathen pontiff, desires him to turn his eyes to the means by which the superstition of Christians was propagated; by kindness to strangers, by sanctity of life, and by the attention which they paid to the burial of the dead. He recommends an imitation of their virtues, exalts him to cause the priests of Galatia to be attentive to the worship of their gods, and authorises him to strip them of the sacerdotal function, unless they obliged their wives, children, and servants, to pay attention to the same duties. He likewise enjoins works of beneficence, desires the priest to relieve the distressed, and to build houses for the accommodation of strangers of whatever religion: and says it is a disgrace for Pagans to disregard those of their own religion, while Christians do kind offices to strangers and enemies. This is indeed an eminent instance of the happy influence of Christianity even on the sentiments and manners of those who regarded the Christian name with abhorrence.

Upon the whole, then, may we not, from the particulars here exhibited concerning the influence of this religion on the manners and happiness of men in society, conclude that Christianity is infinitely superior to the superstitions of Paganism? as being in its tendency uniformly favourable to the virtue and the happiness of mankind, and even to the system of religion and laws delivered by Moses to the children of Israel. Because, while the religion of the Jews was calculated only for one particular nation, and it may almost be said for one particular stage in the progress of society, Christianity is an universal religion, formed to exert its happy influence in all ages and among all nations; and has a tendency to dispel the shades of barbarism and ignorance, to promote the cultivation of the powers of the human understanding, and to encourage every virtuous refinement of manners.

V. Another religion, which has made and still makes a conspicuous figure in the world, remains yet to be examined. The religion of Mahomet is that which we here allude to. Whether we consider through what an extensive part of the globe that religion prevails, the political importance of the nations among whom it is professed, or the striking peculiarity of character by which it is distinguished from all other religious systems—"it is for all these reasons well worthy of particular notice. Like the Jewish religion, it is not barely a system of religious doctrines and general moral precepts; it forms both the civil legislature and the religious system of those nations among whom it is professed; and, like it too, it would appear to be calculated rather for one particular period in the progress of mankind from rudeness to refinement, than for all ages and all states of society.

The history of its origin is pretty well known, and we have had occasion to enlarge upon it under a former article (see Mahomet and Mahometanism). We are not here to trace the imposture of the prophet, or to consider the arts by which he so successfully accomplished his designs; but merely to consider the morality of his religion, and its influence on civil order and the happiness of society.

If we view the state of the nations among whom it is established, we cannot hesitate a moment to declare it friendly to ignorance, to despotism, and to impiety of manners. The Turks, the Persians, and the Malays are all Mahometans; and in reviewing their history and considering their present state, we might find a sufficient number of facts to justify the above assertion; and we must not neglect to observe, that, as those nations are not known to have ever been since their conversion to Mahometanism under a much happier government, or in a much more civilized state than at present, it cannot be, with any degree of fairness, argued, with respect to Mahometanism as with respect to Christianity, that it is only when its influence is so opposed by other causes as to prevent it from producing its full effects, that it does not conduct those societies among which it is established to a high state of civilization and refinement.

One, and that by no means an inconsiderable, part of those, the Koran, was occasionally invented to solve some difficulties with which the prophet found himself at the time perplexed, or to help him to the gratification of his ruling passions, lust and ambition. When he and his followers were at any time unsuccessful in those wars by which he sought to propagate his religion, to prevent them from falling away into unbelief, or sinking into despondency, he took care to inform them that God suffered such misfortunes to befall believers, as a punishment for their sins, and to try their faith. The doctrine of predestination, which he assiduously inculcated, had a happy effect to persuade his followers to rush boldly into the midst of death and danger, at his command. He prevailed with Zeyd to put away his wife, married her himself, and pretended that his crime had the approbation of heaven; and, in the Koran, he introduces the Deity approving of this marriage. Being repulsed from the siege of Mecca, he made a league with the inhabitants; but on the very next year, finding it convenient to surprise the city, by violating this treaty, he justified his perfidy by teaching his followers to disregard promises or leagues made with infidels. In some instances again, we find absurd prohibitions enjoined for similar reasons: his officers, having on some occasion drunk to excess, excited much riot and confusion in the camp, he prohibited the use of wine and other intoxicating liquors among his followers in future. Now, though it must be acknowledged that many evils arise from the use of these liquors, yet we cannot but think that,
that, when used in moderation, they are in many cases beneficial to men; and certainly as much allowed by God as opium, which the Mahometans have substituted in their place.

Mahomet is allowed to have copied from the Christian and the Jewish religions, as well as from the idolatrous superstitions which prevailed through Arabia, and thus to have formed a motley mixture of reason and absurdity, of pure theism and wild superstition. He considered also the circumstances of his country, and the prejudices of his countrymen. When he attended to the former, he was generally judicious enough to suit his doctrines and decisions to them with sufficient skill; the latter he also managed with the greatest art: but he entered into accommodation with them in instances when a true prophet or a wise and upright legislator would surely have opposed them with decisive vigour. Where the prophet indulges his own fancy, or borrows from the superstitions of his countrymen, nothing can be more ridiculous than that rhapsody of lies, contradictions, and extravagant fables, which he delivers to his followers. Amazing are the absurdities which he relates concerning the patriarchs, concerning Solomon, and concerning the animals that were assembled in Noah's ark.

But in the whole tissue of absurdities of which his system consists, there is nothing more absurd, or more happily calculated to promote impurity of manners, than his descriptions of heaven and hell; the ideas of future rewards and punishments which he sought to impress on the minds of his followers. Paradise was to abound with rivers, trees, fruits, and shady groves; wine which would not intoxicate was to be there plentifully served up to believers; the inhabitants of that happy region were all to enjoy perpetual youth; and their powers of enjoyment were to be enlarged and invigorated, in order that so many fine things might not be thrown away upon them. "Instead of inspiring the blessed inhabitants of paradise with a liberal taste for harmony and science, conversation and friendship (says Mr Gibbon), Mahomet idly celebrates the pearls and diamonds, the robes of silk, palaces of marble, dishes of gold, rich wines, artificial dainties, numerous attendants, and the whole train of sensual luxury. Seventy two hours, or black-eyed girls of resplendent beauty, blooming youth, virgin purity, and exquisite sensibility, will be created for the use of the meanest believer; a moment of pleasure will be prolonged for 1000 years, and his faculties will be increased 100 fold, to render him worthy of his felicity." It must be acknowledged that he allows believers other more refined enjoyments than these; thus they are to see the face of God morning and evening; a pleasure which is far to exceed all the other pleasures of paradise. The following is his description of the punishments of hell: The wicked are there to drink nothing but boiling stinking water; breathe nothing but hot winds; dwell for ever in continual burning fire and smoke; eat nothing but brimstones, and thorns, and the fruit of a tree that rivet out of the bottom of hell, whose branches resemble the heads of devils, and whose fruits shall be in their bellies like burning pitch.

All that we can conclude from a general view of the religion of Mahomet, from considering the character of the prophet, or from reviewing the history of the nations whom it has been established, is, that it is one tissue of absurdities, with a few truths, however, and valuable precepts incongruously intermixed; that a great part of it is unfavourable to virtuous manners, to wise and equal laws, and to the progress of knowledge and refinement. It often inculcates in a direct manner sentiments that are highly immoral; it substitutes trifling superstitious observances in the room of genuine piety and moral virtue; and it gives such views of futurity as render purity of heart no necessary qualification for seeing God.

Surely, therefore, even the deist, who rejects all but natural religion, would not hesitate to prefer Christianity, and even Judaism, to the religion of Mahomet. Judaism, calculated for a peculiar people, was undoubtedly much more sublime and much more happily framed to render that people virtuous and happy in the circumstances in which they were placed; and Christianity we find to be an universal religion, suited to all circumstances and to all the stages of society, and acting, wherever it is received, with more or less force to the support of civil order, virtuous manners, improvement of arts, and the advancement of science. However, as Mahometanism forms in some measure a regular system, as it has borrowed many of the precepts and doctrines of Judaism and Christianity, not indeed without corrupting and degrading them; and as it has contributed considerably to the support of civil government, although in a very imperfect form, in those countries in which it has obtained an establishment; for all these reasons we cannot but give it the preference to the superstitions of Paganism.

The whole result of our inquiries under this article, Conclusion, therefore, is, 1. That as man, by the constitution of his mind, is naturally fitted for acquiring certain notions concerning the existence of invisible superior beings, and their influence on human life; so the religious ideas which we find to have in all ages of the world, and in all the different stages of the progress of society, prevailed among mankind, appear to have originated partly from the natural exertions of the human imagination, understanding, and passions, in various circumstances, and partly from supernatural revelation. 2. That though religious opinions, together with the moral precepts, and the rites of worship connected with them, may appear to have been in numerous instances injurious to the virtue and happiness of society; yet, as they have often contributed to lead the mind to form moral distinctions, when it would otherwise in all probability have been an entire stranger to such distinctions; and as they have always contributed in an essential manner to the establishment and the support of civil government;—it must therefore be acknowledged that they have always, even in their humblest state, been more beneficial than hurtful to mankind. 3. That when the different systems of religion that have prevailed in the world are comparatively viewed with respect to their influence on the welfare of society, we find reason to prefer the polytheism of the Greeks and Romans to the rude, wilder, religious ideas and ceremonies that have prevailed among savages; Mahometanism, perhaps in some respects, to the polytheism of the Greeks and Romans; Judaism, however, to Mahometanism; and Christianity to all of them.

RELIGIOUS, in a general sense something that relates to religion.—We say, a religious life, religious society,
RELIGIOUS, is also used substantially for a person engaged by solemn vows to the monastic life; or a person shut up in a monastery to lead a life of devotion and austerity, under some rule or institution. The male religious we popularly call monks and friars; the female, nuns and carmeliesses.

REMBRANDT VAN RHIN, a Flemish painter and engraver of great eminence, was born in 1606, in a mill upon the banks of the Rhine, from whence he derived his name of Van Rhin. This master was born with a creative genius, which never attained perfection. It was said of him, that he would have invented painting, if he had not found it already discovered. Without study, without the assistance of any master, but by his own instinct, he formed rules, and a certain practical method for colouring; and the mixture produced the designed effect. Nature is not set off to the greatest advantage in his pictures; but there is such a striking truth and simplicity in them, that his heads, particularly his portraits, seem animated, and rising from the canvas. He was fond of strong contrasts of light and shade. The light entered in his working-room only by a hole, in the manner of a camera obscura, by which he judged with greater certainty of his productions. This artist considered painting like a theatre, where the characters do not strike unless they are exaggerated. He did not pursue the method of the Flemish painters, of finishing his pieces. He sometimes gave his light so thick touches, that it seemed more like modelling than painting. A head of his has been shown, the nose of which was as thick of paint, as that which he copied from nature. He was told one day, that by his peculiar method of employing colours, his pieces appeared rough and uneven—he replied, he was a painter, and not a dyer. He took a pleasure in dressing his figures in an extraordinary manner: with this view he had collected a great number of eastern caps, ancient armour, and drapery since out of fashion. When he was advised to consult antiquity to attain a better taste in drawing, as his was usually heavy and uneven, he took his counsellor to the closet where these old vestments were deposited, saying, by way of derision, those were his antiques.

Rembrandt, like most men of genius, had many caprices. Being one day at work, painting a whole family in a single picture, word being brought him that his monkey was dead, he was so affected at the loss of this animal, that, without paying any attention to the persons who were sitting for their pictures, he painted the monkey upon the same canvas. This whim could not fail of displeasing those for whom the piece was designed; but he would not efface it, choosing rather to lose the sale of his picture.

This freak will appear still more extraordinary in Rembrandt, when it is considered that he was extremely avaricious; which vice daily grew upon him. He practised various stratagems to sell his prints at a high price. The public were very desirous of purchasing them, and not without reason. In his prints the same taste prevails as in his pictures; they are rough and irregular, but picturesque. In order to heighten the value of his prints, and increase their price, he made his son sell them as if he had purloined them from his father; others he Remarked exposed at public sales, and went thither himself in disguise to bid for them; sometimes he gave out that he was going to leave Holland, and settle in another country. These stratagems were successful, and he got his own price for his prints. At other times he would print his plates half finished, and expose them to sale; he afterwards finished them, and they became fresh plates. When they wanted retouching, he made some alterations in them, which promoted the sale of his prints a third time, though they differed but little from the first impressions.

His pupils, who were not ignorant of his avarice, one day painted some pieces of money upon cards; and Rembrandt no sooner saw them, than he was going to take them up. He was not angry at the pleasantry; but it had no effect in checking his avarice. He died in 1664.

REMEMBRANCE, is the idea of something formerly known recur again to the mind without the operation of a like object on the external sensory. See MEMORY and REMINISCENCE.

REMEMBRANCERS, anciently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first fruits. The king's remembrancer enters in his office all recognizances taken before the barons for any of the king's debts, for appearances or observing of orders; he also takes all bonds for the king's debts, &c. and makes out processes thereon. He likewise issues processes against the collectors of the customs, excise, and others, for their accounts; and informations upon penal statutes are entered and used in his office, where all proceedings in matters upon English bills in the exchequer-chamber remain. His duty farther is to make out the bills of compositions upon penal laws, to take the statement of debts; and into his office are delivered all kinds of indentures and other evidences which concern the assuring any lands to the crown. He every year in crustino animarum, reads in open court the statute for election of sheriffs; and likewise openly reads in court the oaths of all the officers, when they are admitted.

The lord treasurer's remembrancer is charged to make out process against all sheriffs, escheators, receivers, and bailiffs for their accounts. He also makes out writs of fieri facias, and extent for debts due to the king, either in the pipe or with the auditors: and process for all such revenue as is due to the king on account of his tenures. He takes the account of sheriffs; and also keeps a record, by which it appears whether the sheriffs or other accountants pay their proffers due at Easter and Michaelmas; and at the same time he makes a record, whereby the sheriffs or other accountants keep their prefixed days: there are likewise brought into his office all the accounts of customers, comptrollers, and accountants, in order to make entry thereof on record; also all estrates and amercements are certified here, &c.

The remembrancer of the first-fruits takes all compositions and bonds for the payments of first-fruits and tenths; and makes out process against such as do not pay the same.

REMINISCENCE, that power of the human mind, whereby it recollects itself, or calls again into its remembrance,
words of the prophet Amos, all commentators are agreed: "Ye have borne the tabernacle of your Moloch, and Chinn your images, the star of your god, which ye made to yourselves." But if this coincidence between the Christian preacher and the Jewish prophet be admitted, it follows, that Chinn and Remphan are two names of one and the same deity. This is indeed farther evident from the LXX translators having substituted in their version the word פָּעְשֵׁר, instead of Chinn, which we read in the Hebrew and English Bible. But the question which still remains to be answered is, what god was worshipped by the name of Remphan, Raphan, or Chinn for about the other divinity here mentioned there is no dispute. See Moloch.

That Chinn or Remphan was an Egyptian divinity, cannot be questioned; for at the era of the Exodus the Hebrews must have been strangers to the idolatrous worship of all other nations; nor are they ever accused of any other than Egyptian idolatries during their 40 years wanderings in the wilderness, till towards the end of that period that they became infected by the Moabites with the worship of Baal-peor. That Moloch, Molek, Melch, or Milcom, in its original acceptation, denotes a king or chief, is known to every oriental scholar; and therefore when it is used as the name of a god, it undoubtedly signifies the sun, and is the same divinity with the Egyptian Osiris. Reasoning in this way, many critics, and we believe Selden is in the number, have concluded that Chinn, and of course Remphan, is the planet Saturn; because Chinn is written Cyn, Canun, Cheven, Chevvin; all of which are modern oriental names of that planet.

But against this hypothesis insurmountable objections present themselves to our minds. It is universally allowed (see Polytheism), that the first objects of idolatrous worship were the sun and moon, considered as the king and queen of heaven. The fixed stars, indeed, and the planets, were afterwards gradually admitted into the Pagan rubric; but we may be sure that those would be first associated with the two prime luminaries which most resembled them in brightness, and were supposed to be most benignant to man. But the planet Saturn appears to the naked eye with so feeble a lustre, that, in the insanity of astronomy, it could not make such an impression on the mind as to excite that admiration which we must conceive to have always preceded planetary worship. It is to be observed, too, that by the Pagan writers of antiquity Saturn is constantly represented as a star of baleful influence. He is termed the leaden planet; the planet of malevolent aspect; the dismal, the human star. That the Egyptians, at so early a period as that under consideration, should have adored as one of their greatest gods a planet obscure in its appearance, distant in its situation, and baleful in its influence, is wholly incredible.

There is, however, another star which they might naturally adore, and which we know they actually did adore, as one of their most beneficent gods, at a very early period. This is the ζευς or ζης of the Greeks, the canis or stella caniculae of the Romans, and the dog-star of modern Europe. By the Egyptians it was called Sothis or Soth, which signifies safety, beneficence, fecundity; and it received this name, because making its appearance in the heavens at the very time when the Nile overflowed the country, it was supposed
to regulate the inundation. On this account Plutarch (Is. et Osiris) tells us, they believed the soul of their illustrious benefactress Isis to have transmigrated into the star Sothis, which they therefore worshipped as the divinity which rendered their country fruitful. It made its appearance, too, on the first day of the month Tisith (a), which was the beginning of the Egyptian year, and as such celebrated with feasting and festivity; and being by much the brightest star in the heavens, Horapollo (cap. 3) informs us it was considered as sovereign over the rest. A combination of so many important circumstances might have induced a people less superstitious than the Egyptians to pay divine homage to that glorious luminary, which was confounded with Isis, who had been long regarded with the highest veneration; and as Isis was the wife and sister of Osiris, and always associated with him, the star of Isis or Remphan was naturally associated with Moebkh, the same with Osiris.

But it will be asked, how the star which by the Egyptians was called Soth or Sothis came to be worshipped by the Hebrews under the appellation of Chiaun or Remphan? This is a very pertinent question, and we shall attempt to answer it. Every one knows that the pronounciation of oriental words is very uncertain; and that as the vowels were often omitted in writing, it is of very little importance to the meaning how they be supplied, provided we retain the radical consonants. The word Chiaun may with equal propriety be written Khiu, Kian, or even Kyon, the Hebrew yod being convertible into the Greek υ or the Roman y; but the words Canne, Chan, Can, or Khan, which are often diversified into Khen, Kyn, Cohen, Cahan, signifying Head, Chief, Prince, King, &c. are diffused through a great part of Asia and Europe. In the Chinese language Quin, which signifies a King, is so similar to the word Chiaun or Khiu under consideration, that no etymologist will hesitate to pronounce them of the same original and the same import. The word Kan or Khan is universally known to be an honorary title in Tartary; and Kanu or Kan, which is manifestly cognate of the word Chian or Kuan, is, in the Pek Chu or old Persian language, the epithet applied to the dynasty of princes which succeeded Cyrus the Great. Among the Scythians or ancient Tartars, Ghian signifies the Sun and likewise the day; and Kung, Kinning, Kun, runs through all the dialects of the Gothic tongue, everywhere denoting a chief or sovereign. In the Syrian dialect, Kon signifies a prince; and hence the Almighty is styled (Gen. xiv. 19.) Konah, which is translated possession, but might have, with perhaps more propriety, been rendered Sovereign of heaven and earth. In Hebrew, the word Kahan or Kahn, which is the very same with Khan or Kan, signifies either a priest or a prince; and in Egypt Kon was the name of the first Hercules or the sun. Hence the same word in composition denotes greatness, as Can-obus the great serpent; Can-athoth, the great Thoth or Mercury; Can-osiris, the great Osiris.

From this deduction we would conclude, that the word, which is found in so many tongues, and always denotes Chief, Prince, Sovereign, is the very word Chiaun which the Egyptians and Hebrews applied to Sothis, as being, in their conceptions, the chief or sovereign of all the stars. This will appear still more probable, when we have ascertained the import of the word Remphan, or, as the LXX have it, Raiphan.

Phan, the latter part of this word, is unquestionably the same with Pan, the most ancient of the Egyptian gods (see PAN). It is likewise a cognate of the Hebrew Phanah, conspectus, spectavit, vidit; and the radical word seems to be Phan, which signifies sometimes the countenance, and sometimes light. Hence Phenethon, which is compounded of pha "light," eth or eph, "fire," and on, "strength," came to be one of the names of the sun. Rai, which we commonly write Rajah, has long signified, among the Indians, a subordinate prince; and we know, that between India and Egypt there was a very early intercourse. Raiphan, therefore, may be either the royal light or the bright prince, subordinate to Osiris; and in either sense, it was a very proper epithet of Sothis in the Egyptian calendar. The word Rem or Rom, again (for it is sometimes written Remphan, and sometimes Rompha), is no other than the Hebrew Rem, "high, exalted." Hence Remphan is the high or exalted light, which Sothis certainly was.

For this etymological disquisition we are indebted to Dr Doig, the learned author of Letters on the Savage State, who has written a dissertation on Chiaun and Remphan, of such value that we hope it will not be much longer withheld from the public. The ascertaining the identity of those names, and the god to which they belonged, is the least of its merit; for it will be found to throw much light upon many passages in the Old Testament. What confirms his interpretation is, that the idol consecrated by the Egyptians to Sothis or the dog-star, was a female figure with a star on her head; and hence the prophet upbraids his countrymen with having borne the Star of their deity.

ACTION of REMOVING, in Scots Law. See LAW, No. cxxviii, 18.

REMBRIA, festivals established at Rome by Romulus to appease the manes of his brother Remus. They were afterwards called Lemuria, and celebrated yearly.

REMUS, the brother of Romulus, was exposed together with his brother, by the cruelty of his grandfather. In the contest which happened between the two brothers about building a city, Romulus obtained the preference, and Remus, for ridiculing the rising walls, was put to death by his brother's orders, or by Romulus himself (see ROMULUS). The Romans were afflicted with a plague after this murder; upon which the oracle was consulted, and the manes of Remus appeased by the institution of the Lemuria.

RENU, something belonging to the reins or Kidneys.

RENCOUNTER, in the military art, the encounter of two little bodies or parties of forces. In which sense renecounter is used is opposed to a pitched battle.

RENCOUNTER, in single combats, is used by way of contradistinction

(a) This was the case at a very remote period; but it is otherwise at present, owing to the Precession of the Equinoxes. See that article.
RENDEZVOUS, or RENDEVOUS, a place appointed to meet in at a certain day and hour.

RENDSBURG, the frontier town in Holstein, is regularly built, and better fortified than any in the Danish dominions. It is situated on a canal which runs from the Baltic. This is a work of considerable commercial consequence, and deserves to be particularly noticed. It has its source three miles north of Kiel, forming the boundary of Holstein and Sileswick, and by means of it ships of 140 tons can come up from the Baltic. This canal was begun in 1777, and it is intended to make it stretch across the whole peninsula, the utility of which will be clearly perceived by all those who are acquainted with the value of inland navigation. Rendsburg is a place of considerable trade, and contains about 2800 inhabitants, including the garrison which is usually stationed there.

RENEALMIA, a genus of plants belonging to the monandria class. See Botany Index.

RENEGADE, or RENEGADO, a person who has apostatized or renounced the Christian faith to embrace some other religion, particularly Mahometanism.

RENFREWSHIRE, a royal borough, and the county town of Renfrewshire, situated not far from the south bank of the Clyde, about five miles west from Glasgow, and three north from Paisley. It has only one narrow street half a mile long, and its trade is inconsiderable, though favourably situated for commerce. The river Clyde having shifted its bed, a canal was formed in it, by which vessels of 200 tons burden can come up to the town during spring tides. The manufacture of thread has been long carried on here, and that of soap and candles to a great extent. Many looms are constantly employed in the fabrication of silk and muslin. In the year 1164 it became memorable for a battle between Somerled thane of Argyll and Gilchrist earl of Angus, in which the former was defeated. King Robert II. made it a royal borough; and charters were afterwards granted to it by James VI. and Queen Anne. Its political constitution consists of a provost, two bailies, and 16 councillors, who have the management of about 360l. of annual revenue, arising from lands, salmon fishing, &c. In the year 1791 the population amounted to 1628. The soil consists of clay, sand, and rich loam, the latter of which is the most predominant. The whole of the land is enclosed and well cultivated. It is a place of very great antiquity, as we find mention is made of it in the chartularies of the abbeys of Dunfermline and Paisley.

RENFREWSHIRE, a small but populous county of Scotland, bounded on the south-west by the hills which run along the northern part of Ayrshire; towards the west and north by the river Clyde, and on the east by Lanarkshire. It is rather level along the north-east and north part of it; and it has few hills which rise to any considerable height. But the summits of Balagich and Dunware, in the parish of Eaglesham, are about 1000 feet above the level of the sea.

The waters of Renfrewshire are not extensive, but human industry has rendered them of considerable importance; and they are rather employed to turn some vast water wheel or other pieces of machinery, than to give variety to the beauties of a park, or to please the eye with the romantic scenery which nature sometimes delights to display. The chief rivers are the White and Black Cart, and the Grief, which ultimately form a junction and discharge themselves into the Clyde below Inchinnan bridge.

The number of lakes in this county is increased for the purpose of collecting water to give motion to the machinery of cotton mills, or to answer the demands of extensive bleachfields.

The general appearance of this county is favourable to agriculture, the population being very extensive, and the inclosures numerous, while manure in abundance is obtained from the neighbouring towns. Commerce and manufactures have been so often successfully pursued, producing great and sudden riches, that in a greater or less degree they occupy the attention of almost every individual. Although a considerable part of it might be constantly kept with advantage under arable crops, yet so extensive is the demand for the products of the dairy, that a very large proportion of the soil is perpetually kept in grass. With respect to crops, potatoes generally constitute a part of every rotation. This is the usual arrangement: Oats from grass; potatoes or barley dunged; oats, with five pounds of red clover and three furlongs of rye-grass; hay for two years; pasture.

The proprietors of land in this county have shewn a laudable zeal for the making of excellent roads, which are constantly kept in the best repair; and steavans are fixed at every toll-bar to prevent carts from being overloaded; 15 cwt. being allowed in the vicinity of Paisley as the load for a cart with one horse.

The mineral productions are not very extensive, but they are very abundant in the vicinity of Paisley. No coal has been met with near Greenock or Port-Glasgow; but what is called osmund stone is found in the parishes of Eaglesham and Kilbarchan, so very soft at first that it may be cut with a chisel, but it becomes much harder by exposure to the air. It is of various colours; breaks in every direction; readily absorbs water; and if recently heated in the fire, the absorption is accompanied with a hissing noise. There are two mineral springs in the same vicinity of Eaglesham; the one possessing a purgative quality, and the other is regarded as a remedy for what is called the moor-ill in black cattle.

The most remarkable field of minerals is in the vicinity of Paisley; the most singular being the coal at Quarreltown, upwards of 50 feet thick, consisting of five strata in contact with each other (A). The Hurlet coal, belonging to Lord Glasgow, about three miles south-east of Paisley, is five feet three inches thick, and supposed to have been wrought for more than two centuries. Inflammable air and fixed air are met with in this mine, but from the precautions adopted accidents are not so frequent as might otherwise be apprehended. The coal mines of Hurlet have for a long time afforded the materials for a copperas manufactory on a small scale; and

(A) For a detailed account of this singular mass of coal, the reader is referred to the Appendix to Williams's Mineral Kingdom, by Dr Millar, 2 vols. 8vo, 1809.
Renfrewshire, one of the most extensive manufactories of alum in Britain has been established and successfully carried on by a spirited and enterprising company, for several years past, at the same place. Coal is also found in the upper part of the county, as in the parish of Cathcart, and also not far from Renfrew. Limestone is abundant in many parts of the county, as in the parish of Cathcart; and at Lord Glasgow's coal works at Hurlet, it forms a very considerable stratum covering the coal. But one of the most remarkable masses of limestone is found at the entrance to a romantic glen called Gleniffer, three miles to the south of Paisley. The limestone is in a mass of about 10 feet thick, dips to the centre, and is wrought by driving mines under a thick mass of whinstone which covers it. Ironstone is also abundant along with the coal strata in some parts of the county.

The ruins of an old castle, called the Peel, to which the lairds of Semple retreated in times of imminent danger, are still to be seen in an island of Castle Semple loch; and the ruins of the castle of Newark, lower down the country, are even at this day deserving of attention. They are lofty, and have still an air of magnitude, and some parts of it were inhabited about half a century ago. It is situated on the eastern part of the bay containing the town and harbour of Port Glasgow and Newark. This castle is very ancient, is the property of Lord Belhaven, but when it was erected cannot be fully ascertained. Mearns Castle, another ruin, stands in the south-east part of the county, near the village and church of the same name. Crookstone Castle is situated about three miles to the south-east of Paisley. The strong position and commanding prospect of this magnificent ruin must have rendered it a favourite residence of the powerful family of Lennox, to whom it originally belonged. Near the castle there is a yew-tree, venerable from its antiquity, but still more so, according to the legendary lore of the country, as having afforded its shade to the unfortunate Queen Mary and her equally unfortunate husband Darnley. If this be true, the said tree is not less than three centuries old.

There are four cups in the parish of Kilmacolm which were used by the celebrated reformer John Knox at the dispensation of the Lord's supper. They are formed of the purest silver, and seem to have been originally intended for candlesticks, although necessity converted them into communion cups. This sacred use of them, joined to their antiquity, makes them much esteemed by the people at large.

Renfrew is the only royal borough in this county, a privilege which was conferred upon it by Robert Bruce. It elects a member of parliament along with Glasgow, Dunbarton, and Rutherglen.

The other towns are Paisley, Greenock, Port Glasgow; and some of smaller note, as Kilbarchan, Lochwinnoch, Neilston, Gourock, and Auld Kirk. Among these deserves also to be mentioned Johnston, which within a period of little more than 20 years has become a large town, owing to the progress and prosperity of the cotton manufacture.

The manufacture of silk gauze was introduced into Paisley about the year 1760, in imitation of that of Spittalfields in London; experiencing at first many difficulties to which new inventions are very frequently exposed. Patterns and designs of fancy works were originally composed at Paris; but the manufacturers at

Paisley established draughtsmen of their own, and the Renfrew patterns thus executed were sent to London and Paris in order to be approved of. By means of industry and genius properly encouraged, the most curious fabrics came to be devised; and the vast variety of elegant and highly ornamented gauze manufactured here is allowed to be superior to every thing of the kind which had formerly made its appearance. Even London itself was obliged to relinquish this manufacture; merchants from the metropolis came to carry it on at Paisley; and warehouses were opened in London, in Dublin, and Paris, for vending their commodities. We formerly said that Paisley must contain upwards of 25,000 inhabitants (Paisley); but we have since seen a more recent computation, by which they are stated at upwards of 31,000.

The whole population of Renfrewshire amounted to 78,000 in 1801, of which Paisley alone contained much more than a third, and in 1811 it was 92,596. In the year 1755 the population of this county was 26,645, so that in the course of sixty years it has more than tripled. The following table exhibits a view of the population of each parish according to the reports communicated to the Statistical History of Scotland.

See Renfrewshire, Supplement.

Renfrew, a town of France, and capital of the department of Ille et Vilaine. Before the revolution it had a bishop's see, two abbeyes, a parliament, and a mint. The houses are six or seven stories high, and the suburbs of larger extent than the town itself. The cathedral church is large, and the parliament-house a handsome structure. The great square belonging to it is surrounded with handsome houses. There is a tower, formerly a pagan temple, which now contains the town-clock. It is seated on the river Vilaine, which divides it into two parts, and was anciently fortified, but the walls are now in ruins, and the ditch nearly filled up. The population in 1817 was 29,000. The siege of the city by Edward III. king of England is very celebrated in history. The English and Breton army consisted of 40,000 men; and nevertheless, after having remained before it six months, were
were obliged to retire without success. E. Long. c. 23.

RENNET. See Runnet.

RENT, in Law, a sum of money, or other consideration, issuing yearly out of lands or tenements.

RENTERING, in the manufactories, the same with fine-drawing. It consists in sewing two pieces of cloth edge to edge, without doubling them, so that the seam scarcely appears; and hence it is denominated fine drawing. It is a French word meaning the same thing, and is derived from the Latin retorse, of which here, because the seam is drawn in or covered. We are told, that in the East Indies, if a piece of fine muslin be torn and afterwards mended by the fine drawers, it will be impossible to discover where the rent was.

In this country the dexterity of the fine-drawers is not so great as that of those in the east; but it is still such as to enable them to defraud the revenue, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole as a piece, and by that means avoid the duties, penalties, &c. The trick was discovered in France by M. Savary.

RENTERING, in tapestry, is the working new warp into a piece of damaged tapestry, whether eaten by the rats or otherwise destroyed, and on this warp to restore the ancient pattern or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers is included that of renterers. Fine-drawing is particularly used for a rent or hole, which happens in dressing or preparing a piece of cloth artfully sewed up the sned with silk. All fine-drawings are reckoned defects or blemishes, and should be allowed for in the price of the piece.

REVVERSE, INVERTED, in Heraldry, is when any thing is set with the head downwards, or contrary to its natural way of standing. Thus, a chevron reverse is a chevron with the point downwards. They use also the same term when a beast is laid on its back.

RENUNCATION, the act of renouncing, abdicating, or relinquishing, any right, real or pretended.

REPARETTE, a smart, ready reply, especially in matters of wit, humour, or raillery. See RAillery.

REPEALING, in Law, the revoking or annulling of a statute or the like.

No act of parliament shall be repealed the same session in which it was made. A deed or will may be repealed in part, and stand good for the rest. It is held that a pardon of felony may be repealed on disproving the suggestion thereof.

REPELLENTS, in Medicine, remedies which are supposed to drive back a morbid humour into the mass of blood, from whence it was unduly secreted.

REPELLENTIA, in general, means sorrow for any thing past. In theology it means such a sorrow for sin as produces newness of life, or such a conviction of the evil and danger of a sinful course as is sufficient to produce shame and sorrow in the review of it, and effectual resolutions of amendment. In this sense the evangelical writers use metanoia and metanoeo. See Penitence and THEOLOGY.

REPERCUSSION, in Music, a frequent repetition of the same sound.

REPERTORY, a place wherein things are orderly disposed, so as to be easily found when wanted. The indices of books are repertoires, showing where the Repertory matters sought for are treated of. Common-place books are also kinds of repertoires.

REPETEND, in Arithmetic, signifies that part of an infinite decimal fraction, which is continually repeated ad infinitum. Thus in the numbers 2. 13 \( \frac{13}{3} \) \&c., the figures 13 are the repetend and marked thus \( \frac{13}{3} \). These repetends chiefly arise in the reduction of vulgar fractions to decimals. Thus, \( \frac{5}{3} \approx 0.333 \) \&c. = \( \frac{1}{3} \).

REPETITION, the reiterating of an action.

REPETITION, in Music, denotes a reiterating or playing over again the same part of a composition, whether it be a whole strain, part of a strain, or double strain, &c.

When the song ends with a repetition of the first strain, or part of it, the repetition is denoted by \( da capo \), or D. C. i.e., "from the beginning."

REPETITION, in Rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words. See Oratory, No 67—80.

The nature and design of this figure is to make deep impressions on those we address. It expresses anger and indignation, full assurance of what we affirm, and a vehement concern for what we have espoused.

REPHIDIM, in Ancient Geography, a station of the Israelites near Mount Horeb, where they murmured for want of water; when Moses was ordered to smite the rock Horeb, upon which it yielded water. Here Joshua discomfited the Amalekites. This rock, out of which Moses brought water, is a stone of a prodigious height and thickness, rising out of the ground; on two sides of which are several holes, by which the water ran. (Thenen). REPLEGIARE, in Law, signifies to redeem a thing taken or detained by another, by putting in legal sureties.

DE HOMINE REPLEGIANDO. See HOMINE.

REPLEVIN, in Law, a remedy granted on a distress, by which the first possessor has his goods restored to him again, on his giving security to the sheriff that he will pursue his action against the party distraining, and return the goods or cattle if the taking them shall be adjudged lawful.

In a replevin the person distrained becomes plaintiff; and the person distraining is called the defendant or avouant, and his justification an avouery.

At the common law replevins are by writ, either out of the king's bench or common pleas; but by statute, they are by plaint in the sheriff's court, and court baron, for a person's more speedily obtaining the goods distrained.

If a plaint in replevin be removed into the court of king's bench, &c. and the plaintiff makes default and becomes non-suited, or judgment is given against him, the defendant in replevin shall have the writ of retorno habendo of the goods taken in distress. See the next article.

REPLEVY, in Law, is a tenant's bringing a writ of replevin, or replegari facias, where his goods are taken by distress for rent; which must be done within five days after the distress, otherwise at the five days' end they are to be appraised and sold.

This word is also used for bailing a person, as in the case of a homine replegiando.

REPORT,
REPORT, the relation made upon oath, by officers
or persons appointed to visit, examine, or estimate the
state, expenses, &c. of any thing.

REPORT, in Law, is a public relation of cases judi-
cially argued, debated, resolved, or adjudged in any of the
king's courts of justice, with the causes and reasons of
the same, as delivered by the judges. Also when the
court of chancery, or any other court, refers the stat-
ing of a case, or the comparing of an account, to a master
of chancery, or other referee, his certificate thereon is
called a report.

REPOSE, in Poetry, &c. the same with rest and
pause. See Rest, &c.

REPOSE, in Painting, certain masses or large assem-
blages of light and shade, which being well conducted,
prevent the confusion of objects and figures, by enga-
ging and fixing the eye so as it cannot attend to the
other parts of the painting for some time; and thus lead-
ing it to consider the several groups gradually, proceed-
ing as it were from stage to stage.

REPRESENTATION, in the drama, the exhibition
of a theatrical piece, together with the scenes, ma-
achinery, &c.

REPRESENTATIVE, one who personates or supplies
the place of another, and is invested with his right
and authority. Thus the house of commons are the rep-
resentatives of the people in parliament. See Commons
and Parliament.

REPRIEVE, in Criminal Law, (from reprendre, "to
take back") is the withdrawing of a sentence for an in-
terval of time; whereby the execution is suspended. See
Judgment.

This may be, first, ex arbitrio judicis, either before or
after judgment: as, where the judge is not satisfied with
the verdict, or the evidence is suspicious, or the indict-
ment is insufficient, or he is doubtful whether the of-
ence be within clergy: or sometimes if it be a small
felony, or any favourable circumstances appear in the
criminal's character, in order to give room to apply to
the crown for either an absolute or conditional pardon.
These arbitrary reprieves may be granted or taken off
by the justices of gaol-delivery, although their session
be finished, and their commission expired: but this ra-
ther by common usage than of strict right.

Reprieves may also be ex necessitate legis: as where
a woman is finally convicted, and pleads her pregnan-
cy. Though this is no cause to stay judgment, yet it
is to respite the execution till she be delivered.

This is a mercy dictated by the law of nature, in favorem pro-
Fils; and therefore no part of the bloody proceedings in
the reign of Queen Mary hath been more justly detes-
ted, than the cruelty that was exercised in the island of
Guernsey, of burning a woman big with child; and,
when through the violence of the flame the infant
sprang forth at the stake, and was preserved by the by-
standers, after some deliberations of the priests who as-
sisted at the sacrifice, they cast it into the fire as a young
heretic. A barbarity which they never learned from
the laws of ancient Rome; which direct, with the same
humanity as our own, quod pregnantis mulieres damnati
paenae differatur, quod paret : which doctrine has also
prevailed in England, as early as the first memorials of
our laws will reach. In case this plea be made in stay
of execution, the judge must direct a jury of twelve ma-
trous or discreet women to inquire into the fact: and

if they bring in their verdict quick with child (for bar-
relly with child, unless it be alive in the womb, is not suf-
ficient), execution shall be stayed generally till the next
session; and so from session to session, till either she is
delivered, or proves by the course of nature not to have
been with child at all. But if she once hath had the
benefit of this reprieve, and been delivered, and after-
wards becomes pregnant again, she shall not be intitled
to the benefit of a farther respite for that cause. For
she may now be executed before the child is quick in the
womb; and shall not, by her own incontinence, evade
the sentence of justice.

Another cause of regular reprieve is, if the offender
become non compos between the judgment and the award
of execution: for regularly, though a man be compos
when he commits a capital crime, yet if he becomes
non compos after, he shall not be indicted; if after in-
dictment, he shall not be convicted; if after convic-
tion, he shall not receive judgment; if after judgment,
he shall not be ordered for execution: for fortissim solo fu-
rore puniitur; and the law knows not but he might have
offered some reason, if in his senses, to have stayed these
respective proceedings. It is therefore an irrevocable
rule, when any time intervenes between the attinder
and the award of execution, to demand of the prisoner
what he hath to allege why execution should not be
awarded against him; and, if he appears to be insane,
the judge in his discretion may and ought to reprieve
him. Or, the party may plead in bar of execution;
which plea may be either pregnancy, the king's pard-
on, an act of grace, or diversity of person, viz. that
he is not the same that was attainted, and the like.
In this case a jury shall be impanelled to try this collateral
issue, namely, the identity of his person; and not
whether guilty or innocent, for that has been decided
before. And in these collateral issues the trial shall be
quiescent; and no time allowed the prisoner to make his
defence or produce his witnesses, unless he will make
oath that he is not the person attainted: neither shall
any peremptory challenges of the jury be allowed the
prisoner, though formerly such challenges were held to
be allowable whenever a man's life was in question. If
neither pregnancy, insanity, non-identity, nor other plea,
will avail to avoid the judgment, and stay the execution
consequent thereupon, the last and surest resort is in the
king's most gracious pardon; the granting of which is the
most amiable prerogative of the crown. See the ar-
ticle Pardon.

REPRISALS, a right which princes claim of tak-
ing from their enemies any thing equivalent to what
they unjustly detain from them or their subjects. For
as the delay of making war may sometimes be detri-
mental to individuals who have suffered by deprivations
from foreign potentates, our laws have in some respects
armed the subject with power to impel the pra-
rogative; by directing the ministers of the crown to issue
letters of marque and reprisal upon due demand: the
prerogative of granting which is nearly related to, and
plainly derived from, that other of making war; this
being indeed only an incomplete state of hostilities, and
generally ending in a formal denunciation of war. These
letters are grantable by the law of nations, whenever
the subjects of one state are oppressed and injured by those
of another; and justice is denied by that state to which
the oppressor belongs. In this case letters of marque
and
feel no remorse or misgiving of conscience, it is considered as a sign of reprobation; which by the casuists has been distinguished into positive and negative. The first is that whereby God is supposed to create men with a positive and absolute resolution to damn them eternally. This opinion is countenanced by St Augustine and other Christian fathers, and is a peculiar tenet of Calvin and most of his followers. The church of England, in *The thirty-nine Articles*, teaches something like it; and the church of Scotland, in the *Confession of Faith*, maintains it in the strongest terms. But the notion is generally exploded, and is believed by no rational divine in either church, being totally injurious to the justice of the Deity.

Negative or conditional reprobation is that whereby God, though he has a sincere desire to save men, and furnishes them with the necessary means, so that all if they will may be saved, yet sees that there are many who will not be saved by the means, however powerful, that are afforded them; though by other means which the Deity sees, but will not afford them, they might be saved. Reprobation respects angels as well as men, and respects the latter either fallen or unfallen. See *Predestination*.

**REPRODUCTION** is usually understood to mean the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be raised from slips and cuttings; and some late observations have shown, that there are some animals which have the same property. The polype* was the first instance we had of this; but we had scarce time to wonder at the discovery Mr Trembley had made, when Mr Bonnet discovered the same property in a species of water-worm. Amongst the plants which may be raised from cuttings, there are some which seems to possess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again.

It deserves inquiry, whether or not the great Author of nature, when he ordained that certain insects, as these polypes and worms, should resemble those plants in that particular, allowed them this power of being reproduced in the same degree? or, which is the same thing, whether this reproduction will or will not take place in whatever part the worm is cut? In order to try this, Mr Bonnet entered on a course of many experiments on the water-worms which have this property. These are, at their common growth, from two to three inches long, and of a brownish colour, with a cast of reddish. From one of these worms he cut off the head and tail, taking from each extremity only a small piece of a twelfth of an inch in length; but neither of these pieces was able to reproduce what was wanting. They both perished in about 24 hours; the tail first, and afterwards the head. As to the body of the worm from which these pieces were separated, it lived as well as before, and seemed indeed to suffer nothing by the loss, the head-part being immediately used as if the head was thereon, boring the creature’s way into the mud. There are, besides these two other points in which the reproduction will not take place; the one of these is about the fifth or sixth ring from the head, and the other at the same distance from the tail; and in all probability the condition of the great artery in these parts is the cause of this.

What is said of the want of the reproductive power of these parts relates only to the head and tail ends; for in the body, it feels very little if any convenience from...
the loss of what is taken off, and very speedily reproduces those parts. Where then does the principle of life reside in such worms, which, after having their heads cut off, will have not only the same motions, but even the inclinations, that they had before? and yet this difficulty is very small, compared to several others which at the same time offer themselves to our reason. Is this wonderful reproduction of parts only a natural consequence of the laws of motion? or is there lodged in the body of the creature a chain of minute buds or shoots, a sort of little embryos, already formed and placed in such parts among the reproduction nerves? Are these worms only mere machines? or are they, like more perfect animals, a sort of compound, the springs of whose motions are actuated or regulated by a sort of soul? And if they have themselves such a principle, how is it that this principle is multiplied, and is found in every separate piece? Is it to be granted that there are in these worms, not a single soul (if it is to be so called) in each, but that each contains as many souls as there are pieces capable of reproducing perfect animals? Are we to believe with M. Spighi, that these sorts of worms are all heart and brain from one end to the other! This may be; but yet if we knew that it was so, we should know in reality but very little the more for knowing it: and it seems, after all, that in cases of this kind we are only to admire the works of the great Creator, and sit down in silence.

The nice sense of feeling in spiders has been much talked of by naturalists; but it appears that these worms have yet somewhat more surprising in them in regard to this particular. If a piece of stick, or any other substance, be brought near them, they do not stay for its touching them, but begin to leap and frisk about as soon as it comes towards them. There want, however, some further experiments to ascertain whether this be really owing to feeling or to sight; for though we can discover no distinct organs of sight in these creatures, yet they seem affected by the light of the sun or a candle, and always frisk about in the same manner at the approach of either; nay, even the moon-light has some effect upon them.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a tree, every piece of which will in the same manner produce other trees. The case is the same with these worms: they are cut in pieces, and these several pieces become perfect animals; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. It had been supposed by some that these worms were oviparous: but Mr Bonnet, on cutting one of them to pieces, having observed a slender substance, resembling a small filament, to move at the end of one of these pieces, separated it; and on examining it with a glass, found it to be a perfect worm, of the same form with its parent, which lived and grew larger in a vessel of water into which he put it. These small bodies are easily divided, and very readily complete themselves again, in a day usually, by the production of a head to the part that wants one; and, in general, the smaller and slenderer the worms are, the sooner they complete themselves after this operation. When the bodies of the large worms are examined by the microscope, it is very easy to see the appearance of the young worms alive, and moving about within them:

but it requires greater precision and exactness to be certain of this; since the ramifications of the great artery have very much the appearance of young worms, and they are kept in a sort of continual motion by the sy- stoles and diastoles of the several portions of the artery, which serve as many hearts. It is very certain, that what we force in regard to these animals by our operations, is done also naturally every day in the brooks and ditches where they live. A curious observer will find in these places many of them without heads or tails, and some without either; as also other fragments of various kinds, all of which are then in the act of completing themselves: but whether accidents have reduced them to this state, or they thus purposely throw off parts of their body for the reproduction of more animals, it is not easy to determine. They are plainly liable to many accidents, by which they lose the several parts of their body, and must perish very early if they had not a power of reproducing what was lost: they often are broken into two pieces, by the resistance of some hard pieces of mud which they enter; and they are subject to a disease, a kind of gangrene, rotting off the several parts of their bodies, and must inevitably perish by it, had they not this surprising property.

This worm was a second instance, after the polypus, of the surprising power in an animal of recovering its most essential parts when lost. But nature does not seem to have limited her beneficence in this respect to these two creatures. Mr Bonnet tried the same experiments on another species of water-worm, differing from the former in being much thicker. This kind of worm, when divided in the summer season, very often shows the same property: for if it be cut into two or three pieces, the pieces will lie like dead for a long time, but afterwards will move about again; and will be found in the state of rest to have recovered a head, or a tail, or both. After recovering their parts, they move very little; and, according to this gentleman's experiments, seldom live more than a month.

It should seem, that the more difficult success of this kind of worm, after cutting, and the long time it takes to recover the lost parts, if it do recover them at all, is owing to its thickness; since we always find in that species of worms which succeeds best of all, that those which are thickest always recover their parts much sooner than the others.

The water-insects also are not the only creatures which have this power of recovering their lost parts. The earth affords us some already discovered to grow in this manner from their cuttings, and these not less deserving our admiration than those of the water: the common earth-worms are of this kind. Some of these worms have been divided into two, others into three or four pieces; and some of these pieces, after having passed two or three months without any appearance of life or motion, have then begun to produce a head or tail, or both. The reproduction of the annus, after such a state of rest, is no long work; a few days do it; but it is otherwise with the head, that does not seem to perform its functions in the divided pieces till about seven months after the separation. It is to be observed, that in all these operations both on earth and water-worms, the hinder part suffers greatly more than the fore part in the cutting; for it always twists itself about a long time, as if actuated by strong convulsions; whereas the head
The reproduction of several parts of lobsters, crabs, &c. makes also one of the great curiosities in natural history. That, in lieu of an organic part of an animal broken off, another shall rise perfectly like it, may seem inconsistent with the modern system of generation, where the animal is supposed to be wholly formed in the egg. Yet has the matter of fact been well attested by the fishermen, and even by several virtuous who have taken the point into examination, particularly M. de Renaur and M. Pernault, whose skill and accuracy in things of this nature will hardly be questioned. The legs of lobsters, &c. consist each of five articulations: now, when any of the legs happen to break by any accident, as in walking, &c. which frequently happens, the fracture is always found to be in a part near the fourth articulation; and what they thus lose is precisely reproduced some time afterwards; that is, a part of a leg shoots out, consisting of four articulations, the first whereof has two claws as before; so that the loss is entirely repaired.

If a lobster's leg be broken off by design at the fourth or fifth articulation, what is thus broken off always comes again; but it is not so if the fracture be made in the first, second, or third articulation. In those cases, the reproduction is very rare if things continue as they are. But what is exceedingly surprising is, that they do not: for, upon visiting the lobster wherein these barren and unhappy articulations, at the end of two or three days, all the other articulations are found broken off to the fourth; and it is suspected they have performed the operation on themselves, to make the reproduction of a leg certain.

The part reproduced is not only perfectly like that which it replaces, but also, in a certain space of time, grows equal to it. Hence it is that we frequently see lobsters, which have their two big legs unequal, and that in all proportions. This shows the smaller leg to be a new one.

A part thus reproduced being broken, there is a second reproduction. The summer, which is the only season of the year when the lobsters eat, is the most favourable time for the reproduction. It is then performed in four or five weeks; whereas it takes up eight or nine months in any other season. The small legs are sometimes reproduced, but more rarely, as well as more slowly, than the great ones: the horns do the same.

The experiment is most easily tried on the common crab.

REPTILES, in Natural History, a kind of animals denominated from their creeping or advancing on the belly. Or reptiles are those animals, which, instead of feet, rest on one part of the body, while they advance forward with the rest. Such are earthworms, snakes, caterpillars, &c. Indeed, most of the reptiles have feet; only those very small, and the legs short in proportion to the bulk of the body.

Naturalists observe a world of artful contrivance for the motion of reptiles. Thus, in particular, in the earthworm, Dr. Willis tells us, the whole body is only a chain of annular muscles; or, as Dr. Derham says, it is only one continued spiral muscle, the orbicular fibres whereof being contracted, render each ring narrower and longer than before; by which means it is enabled, like the worm of an angrier, to bore its passage into the earth. Its reptile motion might also be explained by a wire wound on a cylinder, which, when slipped off, and one end extended and held fast, will bring the other near to it. So the earthworm having shot out or extended his body (which is with a wreathing), it takes hold by these small feet it hath, and so contracts the hinder part of its body. Dr. Tyson adds, that when the forepart of the body is stretched out and applied to a plane at a distance, the hind part relaxing and shortening is easily drawn towards it as a centre.

Its feet are disposed in a quadruple row the whole length of the worm, with which, as with so many books it fastens down sometimes this and sometimes that part of the body to the plane, and at the same time stretches out or drags after it another.

The creeping of serpents is effected after a somewhat different manner; there being a difference in their structure, in that these last have a compound ring of bones articulated together.

The body here is not drawn together, but as it were complicated; part of it being applied on the rough ground, and the rest ejaculated and shot from it, which being set on the ground in its turn, brings the other after it. The spine of the back variously wreathed has the same effect in leaping, as the joints in the feet of other animals; they make their leaps by means of muscles, and extend the piece or folds. See EREPTOLOGY and OZILOGY.

REPTILIA, the name of one of the orders of the class Amphibia, including tortoises, frogs, lizards. See EREPETOLOGY.

REPUBLIC, or COMMONWEALTH, a popular state or government; or a nation where the people have the government in their own hands. See GOVERNMENT, ARISTOCRACY, DEMOCRACY, and MONARCHY.

REPUBLIC of Letters, a phrase used collectively of the whole body of the studious and learned people.

REPUDIATION, in the Civil Law, the act of divorcing. See DIVORCE.

REPULSION, in Physics, that property of bodies whereby they recede from each other, and, on certain occasions, mutually avoid coming into contact.

Repulsion, as well as attraction, has of late been considered as one of the primary qualities of all matter, and has been much used in explaining the phenomena of nature: thus the particles of air, fire, steam, electric fluid, &c. are all said to have a repulsive power with respect to one another. That this is the case with the air, and vapour of all kinds, is certain; because when they are compressed into a small space, they expand with great force: but as to fire, light, and electricity, our experiments fail: nay, the supposition of a repulsive power among the particles of the electric fluid is inconsistent with the phenomena, as has been demonstrated under the article Electricity. Even in those fluids, air and steam, wherein a repulsive power most manifestly exists, it is demonstrable that the repulsion cannot be a primary quality, since it can be increased to a great degree by heat, and diminished by cold: but it is impossible that a primary quality of matter can be increased or diminished by any external circumstances whatever; for whatever property depends on external circumstances, is not a primary but a secondary one.
 Requests.

The pulison of electrified bodies is explained under the article Electricity: that of others is less subject to investigation; and the most that can be said concerning it is, that it is not a consequence of a modification of fire, and in others of electricity. Reptuation means credit, honour, or the character of good; and since we are destined to live in society, it is necessary and useful more or less to every human being. There is no man, except one who is overgrown with pride and self-conceit, or whose actions are bad, but pays attention to his reputation, and wishes to possess the good opinion of his neighbours or the world. The love of reputation and of fame are the most powerful springs of action; but though they proceed from the same principle, the means of attaining them, and the effects of them, are not altogether the same.

Many means indeed serve equally to support the reputation, and to increase the fame, differing only in degrees; others, however, belong peculiarly either to the one or to the other. An honest reputation is within the reach of the bulk of mankind; it is obtained by the social virtues and the constant practice of the common duties of life. This kind of reputation indeed is neither extensive nor brilliant, but it is often the most useful in point of happiness. Wit, talents, and genius, are the necessary requisites for fame; but those advantages are perhaps less real in their consequence than those arising from a good reputation. What is of real use costs little; things rare and splendid require the greatest labour to procure, and yield perhaps a more ideal happiness.

Fame can be possessed, comparatively speaking, but by few individuals; as it requires either very superior abilities, supported by great efforts, or very fortunate circumstances. It is constituted by the applause of mankind, or at least by that of a single nation; whilst reputation is of much less extent, and arises from different circumstances. That reputation which is founded on deceit and artifice is never solid; and the most honourable will always be found to be the most useful. Every one may safely, and indeed ought to, aspire to the consideration and praise due to his condition and merit; but he who aspires to more, or who seeks it by dishonest means, will at length meet with contempt.

REQUESTS. In law, a supplication or petition preferred to a prince, or to a court of justice; begging relief in some conscientious cases where the common law grants no immediate redress.

Court of Requests (curia requisitionum) was a court of equity, of the same nature with the court of chancery, but inferior to it; principally instituted for the relief of such petitioners as in conscientious cases addressed themselves by supplication to his majesty. Of this court the lord privy-seal was chief judge, assisted by the masters of requests; and it had beginning about the 5 Hen. VII., according to Sir Julius Caesar's tractate upon this subject; though Mr. Gwyn, in his preface to his Readings, saith it began from a commission first granted by King Henry VIII. This court, having assumed great power to itself, so that it became burdensome, Mich. anno 40 and 41 Eliz. in the court of common pleas it was adjudged upon solemn argument, that the court of requests was no court of judicature, &c. and by stat. 16 and 17 Car I. cap. 10. it was taken away.

There are still courts of requests, or courts of consommation, constituted in London and other trading and populous districts for the recovery of small debts.

The first of these was established in London so early as the reign of Henry V. III. by an act of their common council; which, however, was certainly insufficient for that purpose, and illegal, till confirmed by statute 3 Jac. I. c. 15, which has since been explained and amended by statute 14 Geo. II. c. 10. The constitution is this: two aldermen and four commoners sit twice a week to hear all causes of debt not exceeding the value of forty shillings; which they examine in a summary way, by the oath of the parties or other witnesses, and make such order therein as is consonant to equity and good conscience. The time and expense of obtaining this summary redress are very considerable, which make it a great benefit to trade; and thereupon divers trading towns and other districts have obtained acts of parliament for establishing in them courts of conscience upon nearly the same plan as that in the city of London.

By 25 Geo. III. c. 45. (which is confined to prosecutions in courts of conscience in London, Middlesex, and the borough of Southwark,) and by 26 Geo. Ill. c. 38. (which extends the provisions of the former act to all other courts instituted for the recovery of small debts,) it is enacted, that after the first day of September 1786, no person whatsoever, being a debtor or defendant, and who has been or shall be committed to any gaol or prison, by order of any court or commissioners authorized by any act or acts of parliament for constituting or regulating any court or courts for the recovery of small debts, where the debt does not exceed twenty shillings, shall be kept or continued in custody, on any pretence whatsoever, more than twenty days from the commencement of the last mentioned act; or from the time of his, her, or their commitment to prison; and where the original debt does not amount to or exceed the sum of forty shillings, more than forty days from the commencement of the said act, or from the time of his, her, or their commitment as aforesaid; and all gaolers are thereby required to discharge such persons accordingly. And by sect. 2. if it shall be proved to the satisfaction of the court, that any such debtor has money or goods which he has willfully and fraudulently concealed: in that case the court shall have power to enlarge the aforesaid times of imprisonment for debts under twenty shillings, to any time not exceeding thirty days, and for debts under forty shillings, to any time not exceeding sixty days; which said ground of farther detention shall be specified in the said commitment. And that (by sect. 3.) at the expiration of the said respective times of imprisonment, every such person shall immediately be discharged, without paying any sum of money, or other reward or gratuity whatsoever, to the gaoler of such gaol on any pretence whatsoever; and every gaoler demanding or receiving any fee for the discharge of any such person, or keeping any such person prisoner after the said respective times limited by the said act, shall forfeit five pounds, to be recovered in a summary way before two justices of the peace, one moiety thereof to be paid to the overseers of the poor of the parish where the offence shall be committed, and the other to the informer.

REQUIEM, in the Romish history, a mass sung for the rest of the soul of a person deceased.

RESCISSION,
RESCISSION, in the Civil Law, an action intended for the annulling or setting aside any contract, deed, &c.

RESCRIPT, an answer delivered by an emperor, or a pope, when consulted by particular persons on some difficult question or point of law, to serve as a decision thereof.

RESEDA, a genus of plants belonging to the dodecandria class, and in the natural method ranking under the 9th order, Miscellanea. See Botany Index. The Luteola or Dyer's-weed, Yellow-weed, Weld, or Wild-wood, is one of the most valuable of the species, on account of its extensive use in dyeing. See Dyeing. The odorata or mignonette is well known for the sweetness of its fragrance, and as an ornament of the flower-garden.

RESEMBLANCE and DISSIMILITUDE, the relations of likeness and difference among objects. See COMPARISON.

The connection that man hath with the beings around him, requires some acquaintance with their nature, their powers, and their qualities, for regulating his conduct. For acquiring a branch of knowledge so essential to our well-being, motives alone of reason and interest are not sufficient: nature hath providentially superadded curiosity, a vigorous propensity, which never is at rest. This propensity alone attaches us to every new object; and incites us to compare objects, in order to discover their differences and resemblances.

Resemblance among objects of the same kind, and dissimilitude among objects of different kinds, are too obvious and familiar to gratify our curiosity in any degree: its gratification lies in discovering differences among things where resemblance prevails, and resemblances where difference prevails. Thus a difference in individuals of the same kind of plants or animals, is deemed a discovery, while the many particulars in which they agree are neglected; and in different kinds, any resemblance is greedily remarked, without attending to the many particulars in which they differ.

A comparison of the former neither tends to gratify our curiosity, nor to set the objects compared in a stronger light: two apartments in a palace, similar in shape, size, and furniture, make separately as good a figure as when compared; and the same observation is applicable to two similar compartments in a garden: on the other hand, oppose a regular building to a fall of water, or a good picture to a towering hill, or even a little dog to a large horse, and the contrast will produce no effect. But a resemblance between objects of the same kind, have remarkably an enlivening effect. The poets, such of them as have a just taste, draw all their similies from things that in the main differ widely from the principal subject; and they never attempt a contrast, but where the things have a common genus, and a resemblance in the capital circumstances: place together a large and a small sized animal of the same species, the one will appear greater, the other less, than when viewed separately: when we oppose beauty to deformity, each makes a greater figure by the comparison. We compare the dress of different nations with curiosity, but without surprise; because they have no such resemblance in the capital parts as to please us by contrasting the smaller parts. But a new cut of a sleeve, or of a pocket, enchanteth by its novelty; and, in opposition to the former fashion, raises some degree of surprise.

That resemblance and dissimilitude have an enlivening effect upon objects of sight, is made sufficiently evident; and that they have the same effect upon objects of the other senses, is also certain. Nor is that law confined to the external senses; for characters contrasted make a greater figure by the opposition: Iago, in the tragedy of Othello, says,

He hath a daily beauty in his life
That makes me ugly.

The character of a sot, and of a rough warrior, are nowhere more successfully contrasted than in Shakespeare:

Hotspur. My liege, I did deny no prisoners:
But I remember, when the fight was done,
When I was dry with rage, and extreme toil,
Breathless and faint, leaning upon my sword,
Came there a certain lord, neat, trimly dress'd,
Fresh as a bridegroom, and his chin, new-reap'd,
Show'd like a stubble-land at harvest-home.
He was perfumed like a milliner;
And 'twixt his finger and his thumb he held
A pouncet-box, which ever and anon
He gave his nose:—and still he smil'd and talk'd;
And as the soldiers bare dead bodies by,
He call'd them unto'|a, unmann'd,
To bring a slovenly unhusand'sd corpse
Betwixt the wind and his nobility.
With many holiday and lady terms
He question'd me: among the rest, demand'd
My pris'ners in your Majesty's behalf.
I then, all smarting with my wounds; being gall'd
To be so pester'd with a popinjay,
Out of my grief, and my impatience,
Answer'd, neglectingly, I know not what:
He shou'd, or should not; for lie made me mad,
To see him shine so brisk, and smell so sweet,
And talk so like a waiting gentlewoman,
Of guns, and drums, and wounds, (God save the mark!)
And telling me, the sovereign thing on earth
Was parricide for an inward bruise;
And that it was great pity, so it was,
This villainous saltpetre should be digg'd
Out of the bowels of the harmless earth,
Which many a good tall fellow bad destroy'd
So cowardly: and but for these vile guns,
He would himself have been a soldier.

First part, Henry IV. act i. sc. 4.

Passions and emotions are also inflamed by comparison. A man of high rank humbles the bystanders even to annihilate them in their own opinion: Caesar, beholding the statue of Alexander, was greatly mortified, that now, at the age of 32, when Alexander died, he had not performed one memorable action.

Our opinions also are much influenced by comparison. A man whose opulence exceeds the ordinary standard is reputed richer than he is in reality; and wisdom or weakness, if at all remarkable in an individual, is generally carried beyond the truth.

The opinion a man forms of his present distress
Could I forget
What I have been, I might the better bear
What I'm destin'd to. I'm not the first
That have been wretched; but to think how much
I have been happier.

Southern's Innocent Adultery, act ii.

The distress of a long journey makes even an indifferent inn agreeable: and, in travelling, when the road is good, and the horseman well covered, a bad day may be agreeable, by making him sensible how snug he is.

The same effect is equally remarkable, when a man opposes his condition to that of others. A ship tossed about in a storm, makes the spectator reflect upon his own ease and security, and puts these in the strongest light.

A man in grief cannot bear mirth; it gives him a more lively notion of his unhappiness, and of course makes him more unhappy. Satan, contemplating the beauties of the terrestrial paradise, has the following exclamation:

With what delight could I have walk'd thee round,
If I could joy in ough, sweet interchange
Of hill and valley, rivers, woods, and plains,
Now land, now sea, and shores with forest crown'd,
Rocks, dens, and caves! but I in none of these
Find place or refuge; and the more I see
Pleasures about me, so much more I feel
Torment within me, as from the hateful siege
Of contraries: all good to me becomes
Bane, and in heav'n much worse would be my state.

Paradise Lost, book ix. l. 114.

The appearance of danger gives sometimes pleasure, sometimes pain. A timorous person upon the battlements of a high tower, is seized with fear, which even the consciousness of security cannot dissipate. But upon one of a firm head, this situation has a contrary effect: the appearance of danger heightens, by opposition, the consciousness of security, and consequently the satisfaction that arises from security: here the feeling resembles that above mentioned, occasioned by a ship labouring in a storm.

The effect of magnifying or lessening objects by means of comparison is to be attributed to the influence of passion over our opinions. This will evidently appear by reflecting in what manner a spectator is affected, when a very large animal is for the first time placed beside a very small one of the same species. The first thing that strikes the mind is the difference between the two animals, which is so great as to occasion surprise; and this, like other emotions, magnifying its object, makes us conceive the difference to be the greatest that can be: we see, or seem to see, the one animal extremely little, and the other extremely large. The emotion of surprise arising from any unusual resemblance, serves equally to explain, why at first view we are apt to think such resemblance more entire than it is in reality. And it must be observed, that the circumstances of more or less, which are the proper subjects of comparison, raise a perception so indistinct and vague as to facilitate the effect described; we have no
The final cause of the propensity is an additional proof of its existence. Human works are of no significance till they be completed; and reason is not always a sufficient counterbalance to indulgence: some principle over and above is necessary to excite our industry, and to prevent our stepping short in the middle of the course.

We need not lose time to describe the co-operation of the foregoing propensity with surprise, in producing the effect that follows any unusual resemblance or dissimilitude. Surprise first operates, and carries our opinion of the resemblance or dissimilitude beyond truth. The propensity we have been describing carries us still farther; for it forces upon the mind a conviction, that the semblance or dissimilitude is complete. We need no better illustration, than the resemblance that is fancied in some pebbles to a tree or an insect; which resemblance, however faint in reality, is conceived to be wonderfully perfect. The tendency to complete a resemblance acting jointly with surprise, carries the mind sometimes so far, as even to presume upon future events. In the Greek tragedy entitled Phineidae, those unhappy women seeing the place where it was intended they should be slain, cried out with anguish, "They now Arist. Port. saw their cruel destiny had condemned them to die in that place, being the same where they had been exposed in their infancy."

The propensity to advance every thing to its perfection, not only co-operates with surprise to deceive the mind, but of itself is able to produce that effect. Of this we see many instances where there is no place for surprise; and the first we shall give is of resemblance. Unumquoque eadem modo dissolvetur quo colligatur est, is a maxim in the Roman law that has no foundation in truth; for tying and loosing, building and demolishing, are acts opposite to each other, and are performed by opposite means: but when these acts are connected by their relation to the same subject, their connection leads us to imagine a sort of resemblance between them, which by the foregoing propensity is conceived to be as complete as possible. The next instance shall be of contrast. Addison observes, Spectator, No. 265. "That the palest features look the most agreeable in white; that a face which is overflushed appears to advantage in the deepest scarlet; and that a dark complexion is not a little alleviated by a black hood."

The foregoing propensity serves to account for these appearances: to make this evident, one of the cases shall suffice. A complexion, however dark, never approaches to black; when these colours appear together, their opposition strikes us; and the propensity we have to complete the opposition, makes the darkness of complexion vanish out of sight.

The operation of this propensity, even were there no ground for surprise, is not confined to opinion or conviction: so powerful it is, as to make us sometimes proceed to action, in order to complete a resemblance or dissimilitude. If this appear obscure, it will be made clear by the following instance. Upon what principle is the lex talionis founded, other than to make the punishment resemble the mis-chief? Reason discovers that there ought to be a conformity or resemblance between...
tween a crime and its punishment; and the foregoing propensity impels us to make the resemblance as complete as possible. Titus Livius*, under the influence of that propensity, accounts for a certain punishment, by a resemblance between it and the crime too subtle for common apprehension. Speaking of Mettus Fufettius, the Alban general, who, for treachery to the Romans his allies, was sentenced to be torn to pieces by horses, he puts the following speech in the mouth of Tullius Hostilius, who decried the punishment. "Metu Fuffetti, inquit, si ipse discere posses fidem ac fideva servare, vives tibi ea disciplina unde adhibita est. Nunc, quoniam tuum insanabile ingenium est, at tu tuo supplicio doce humanum genus ea sancta credere, quae tibi violata sunt. Ut rigor paulo ante animam inter Eidenatem Romanamque rem anquiratum gessisti, ita jam corpus passim distraheendum dabis." By the same influence, the sentence is often executed upon the very spot where the crime was committed. In the Electra of Sophocles, Egistheus is dragged from the theatre into an inner room of the supposed palace, to suffer death where he murdered Agamemnon. Shakespeare, whose knowledge of nature is not less profound than extensive, has not overlooked this propensity:

"Othello. Get me some poison, Iago, this night. I'll not expostulate with her, lest her body and her beauty unprovid mine mind again. This night, Iago."

"Iago. Do it not with poison; strangle her in her bed, even in the bed she hath contaminated."

"Othello. Good, good: the justice of it pleases: very good." Othello, act iv. sc. 5.

Persons in their last moments are generally seized with an anxiety to be buried with their relations. In the Amynta of Tasso; the lover, hearing that his mistress was torn to pieces by a wolf, expresses a desire to die the same death.

Upon the subject in general we have two remarks to add. The first concerns resemblance, which, when too entire, hath no effect, however different in kind the things compared may be. The remark is applicable to works of art only; for natural objects of different kinds have scarce ever an entire resemblance. To give an example in a work of art: Marble is a sort of matter very different from what composes an animal; and marble cut into a human figure, produces great pleasure by the resemblance: but if a marble statue be coloured like a picture, the resemblance is so entire as at a distance to make the statue appear a real person: we discover the mistake when we approach; and no other emotion is raised, but surprise occasioned by the deception: the figure still appears a real person, rather than an imitation; and we must use reflection to correct the mistake. This cannot happen in a picture; for the resemblance can never be so entire as to disguise the imitation.

The other remark belongs to contrast. Emotions make the greatest figure when contrasted in succession; but then the succession ought neither to be rapid, nor immoderately slow: if too slow, the effect of contrast becomes faint by the distance of the emotions; and if rapid, no single emotion has room to expand itself to its full size, but is stifled, as it were, in the birth by a succeeding emotion. The funeral oration of the bishop of Meaux upon the duchess of Orleans, is a perfect bodge-podge of cheerful and melancholy representations, following each other in the quickest succession: yet, opposite emotions are best felt in succession; but each emotion separately should be raised to its due pitch, before another be introduced.

What is above laid down, will enable us to determine a very important question concerning emotions raised by the fine arts, viz. Whether ought similar emotions to succeed each other, or dissimilar? The emotions raised by the fine arts are for the most part too nearly related to make a figure by resemblance; and for that reason their succession ought to be regulated as much as possible by contrast. This holds confessedly in epic and dramatic compositions; and the best writers, led perhaps by taste more than by reason, have generally aimed at that beauty. It holds equally in music: in the same cantata all the variety of emotions that are within the power of music, may not only be indulged, but, to make the greatest figure, ought to be contrasted. In gardening, there is an additional reason for the rule: the emotions raised by that art, are at best so faint, that every artifice should be employed to give them their utmost vigour: a field may be laid out in grand, sweet, gay, neat, wild, melancholy scenes; and when these are viewed in succession, grandeur ought to be contrasted with neatness, regularity with wildness, and gaiety with melancholy, so as that each emotion may succeed its opposite: nay, it is an improvement to intermix in the succession rude uncultivated spots as well as unbounded views, which in themselves are disagreeable, but in succession heighten the feeling of the agreeable object; and we have nature for our guide, which in her most beautiful landscapes often intermixes rugged rocks, dirty marshes, and barren stony heaps. The greatest masters of music have the same view in their compositions: the second part of an Italian song seldom conveys any sentiment: and, by its harshness, seems purposely contrived to give a greater relish for the interesting part of the composition.

A small garden, comprehended under a single view, affords little opportunity for that embellishment. Dissimilar emotions require different tones of mind; and therefore in conjunction can never be pleasant: gaiety and sweetness may be combined, or wildness and gloominess; but a composition of gaiety and gloominess is distasteful. The rude uncultivated compartment of furze and broom in Richmond garden, hath a good effect in the succession of objects; but a spot of that nature would be insufferable in the midst of a polished parterre or flower-plot. A garden, therefore, if not of great extent, admits not dissimilar emotions; and in ornamenting a small garden, the safest course is to confine it to a single expression. For the same reason, a landscape ought also to be confined to a single expression; and accordingly it is a rule in painting, that if the subject be gay, every figure ought to contribute to that emotion.

It follows from the foregoing train of reasoning, that a garden near a great city ought to have an air of solitude. The solitariness, again, of a waste country ought to be contrasted in forming a garden; no temples, no obscure walks; but jets d'eau, cascades, objects active, gay, and splendid. Nay, such a garden should in some measure, avoid imitating nature, by taking on an extraordinary
MENTAL RESERVATIONS, the great refuge of religious hypocrites, who use them to accommodate their consciences with their interests: the Jesuits are zealous advocates for mental reservations; yet are they real lies, as including an intention to deceive.

RESERVE, in Law, the same with reservation. See Reser- nation.

Body of Reserve, or Corps de Reserve, in military affairs, the third or last line of an army, drawn up for battle; so called because they are reserved to sustain the rest as occasion requires, and not to engage but in case of necessity.

RESERVOIR, a place where water is collected and reserved, in order to be conveyed to distant places through pipes, or supply a fountain or jet d'eau.

RESET, in Law, the receiving or harbouring an outlawed person. See Outlawry.

Res的东西, in the Canon and Common Law, the abode of a person or incumbent upon his benefice; and his assiduity in attending on the same.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers, inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

RESIDUAL ANALYSIS, a calculus invented by Mr Landen, and proposed as a substitute for the method of fluxions. The design of it was to avoid introducing the idea of motion, and of quantities infinitely small, into mathematical investigation. The residual analysis accordingly proceeds, by taking the difference of the same function of a variable quantity in two different states of that quantity, and denoting the relation of this difference to the difference between the two states of the said variable quantity. This relation being first generally expressed, is next considered in the case when the difference of the two states of the variable quantity is equal; and by that means it is obvious, that the same thing is done as when the function of a variable quantity is assigned by the ordinary methods.

The evolutions of the functions, considered in this very general view, requires the aid of a new theorem, discovered by Mr Landen, and remarkable for its simplicity and great extent. It is, that

\[ \frac{x^n - u^n}{x - u} \]

if \( x \) and \( u \) are any two variable quantities

\[ \frac{1 + \frac{u}{x} + \frac{u^2}{x^2} + \cdots + \frac{u^m}{x^m}}{1 + \left(\frac{u}{x}\right)^n + \left(\frac{u}{x}\right)^n + \cdots + \left(\frac{u}{x}\right)^n} \]

where \( m \) and \( n \) are any integer numbers.

This theorem is the basis of the calculus, and from the expressions \( \frac{x^n - u^n}{x - u} \) and \( x^n - u^n \) having the form of what algebraists denominate residues, the inventor gave to his method the name of the residual analysis.

Mr Landen published the first account of this method in 1736, which he denominated A Discourse concerning the

VOL. XVII. PART II.
RESISTANCE OF FLUIDS.

RESISTANCE, or Resisting Force, in Philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect. See Mechanics, Hydrodynamics, and Pneumatics.

Of all the resistances of bodies to each, there is undoubtedly none of greater importance than the resistance or reaction of fluids. It is here that we must look for a theory of naval architecture, for the impulse of the air is our moving power, and this must be modified so as to produce every motion we want by the form and disposition of our sails; and it is the resistance of the water which must be overcome, that the ship may proceed in her course; and this must also be modified to our purpose, that the ship may not drive like a log to leeward, but on the contrary may ply to windward, that she may answer her helm briskly, and that she may be easy in all her motions on the surface of the troubled ocean. The impulse of wind and water makes them ready and indefatigable servants in a thousand shapes for driving our machines; and we should lose much of their service did we remain ignorant of the laws of their action: they would sometimes become terrible masters, if we did not fall upon methods of eluding or softening their attacks.

We cannot refuse the ancients a considerable knowledge of this subject. It was equally interesting to them as to us; and we cannot read the accounts of the naval exertions of Phoenicia, Carthage, and Rome, exertions which have not been surpassed by any thing of modern date, without believing that they possessed much practical and experimental knowledge of this subject. It was not, perhaps, possessed by them in a strict and systematic form, as it is now taught by our mathematicians; but the master-builders, in their dockyards, did undoubtedly exercise their genius in comparing the forms of their finest ships, and in marking those circumstances of form and dimension which were in fact accompanied with the desirable properties of a ship, and thus framing to themselves maxims of naval architecture in the same manner as we do now. For we believe that our naval architects are, not disposed to
Resistance of Fluids.

Grant that they have profited much by all the labours of the mathematicians. But the ancients had not made any great progress in the physicomathematical sciences, which consist chiefly in the application of calculus to the phenomena of nature. In this branch they could make none, because they had not the means of investigation. A knowledge of the motions and actions of fluids is accessible only to those who are familiarly acquainted with the fluxionary mathematics; and without this key there is no admittance. Even when possessed of this guide, our progress has been very slow, hesitating, and devious; and we have not yet been able to establish any set of doctrines which are susceptible of an easy and confident application to the arts of life. If we have advanced farther than the ancients, it is because we have come after them, and have profited by their labours, and even by their mistakes.

Sir Isaac Newton was the first (as far as we can recollect) who attempted to make the motions and actions of fluids the subject of mathematical discussion. He had invented the method of fluxions long before he engaged in his physical researches; and he proceeded in these spha exi facem preferente. Yet even with this guide he was often obliged to grope his way, and to try various bye-paths, in the hopes of obtaining a legitimate theory. Having exerted all his powers in establishing a theory of the lunar motions, he was obliged to rest contented with an approximation instead of a perfect solution of the problem which ascends the motions of three bodies mutually acting on each other. This convinced him that it was in vain to expect an accurate investigation of the motions and actions of fluids, where millions of unseen particles combine their influence. He therefore cast about to find some particular case of the problem which would admit of an accurate determination, and at the same time furnish circumstances of analogy or resemblance sufficiently numerous for giving limiting cases, which should include between them those other cases that did not admit of this accurate investigation. And thus, by knowing the limit to which the case proposed did approximate, and the circumstances which regulated the approximation, many useful propositions might be deduced for directing us in the application of these doctrines to the arts of life.

He therefore figured to himself a hypothetical collection of matter which possessed the characteristic property of fluidity, viz. the quaedam versus propagation of pressure, and the most perfect intermixture (perdon the uncouth term) of parts, and which formed a physical whole or aggregate, whose parts were connected by mechanical forces, determined both in degree and in direction, and such as rendered the determination of certain important circumstances of their motion susceptible of precise investigation. And he concluded, that the laws which he should discover in these motions must have a great analogy with the laws of the motions of real fluids: And from this hypothesis he deduced a series of propositions, which form the basis of almost all the theories of the impulse and resistance of fluids which have been offered to the public since his time.

It must be acknowledged, that the results of this theory agree but ill with experiment, and that, in the way in which it has been zealously prosecuted by subsequent mathematicians, it proceeds on principles or suppositions which are not only gratuitous, but even false. But it affords such a beautiful application of geometry and calculus, that mathematicians have been as it were fascinated by it, and have published systems so elegant and so extensively applicable, that one cannot help lamenting that the foundation is so flimsy. John Bernoulli's theory, in his dissertation on the communication of motion, and Bouguer's in his Traité du Naufrage, and in his Théorie du Mouvement et de la Mâture des Vaisseaux, must ever be considered as among the finest specimens of physicomathematical science which the world has seen. And, with all its imperfections, this theory still furnishes (as was expected by its illustrious author) many propositions of immense practical use, they being conformed to the limits to which the real phenomena of the imperceptible and resistance of fluids really approximate. So that when the law by which the phenomena deviate from the theory is once determined by a well chosen series of experiments, the hypothetical theory becomes almost as valuable as a true one. And we may add, that although Mr d'Alembert, by treading warily in the steps of Sir Isaac Newton in another route, has discovered a genuine and unexceptionable theory, the process of investigation is so intricate, requiring every finesse of the most abstruse analysis, and the final equations are so complicated, that even their most expert author has not been able to deduce more than one simple proposition (which too was discovered by Daniel Bernoulli by a more simple process) which can be applied to any use. The hypothetical theory of Newton, therefore, continues to be the groundwork of all our practical knowledge of the subject.

We shall therefore lay before our readers a very short view of the theory, and the manner of applying it. We shall then show its defects (all of which were pointed out by its great author), and give a historical account of the many attempts which have been made to amend it or to substitute another; in all which we think it our duty to show, that Sir Isaac Newton took the lead, and pointed out every path which others have taken, if we except Daniel Bernoulli and d'Alembert; and we shall give an account of the chief sets of experiments which have been made on this important subject, in the hopes of establishing an empirical theory, which may be employed with confidence in the arts of life.

We know by experience that force must be applied to a body in order that it may move through a fluid, resistance, such as air or water; and that a body projected with any velocity is gradually retarded in its motion, and generally brought to rest. The analogy of nature makes us imagine that there is a force acting in the opposite direction, or opposing the motion, and that this force resides in, or is exerted by, the fluid. And the phenomena resemble those which accompany the known resistance of active beings, such as animals. Therefore we give to this supposed force the metaphorical name of Resistance. We also know that a fluid in motion will hurry a solid body along with the stream, and that it requires force to maintain it in its place. A similar analogy makes us suppose that the fluid exerts force, in the same manner as when an active being impels the body before him; therefore we call this the Impulsion of a Fluid. And as our knowledge of nature...
Resistance of Fluids.

The resistance of fluids is such that the mutual actions of bodies are in every case equal and opposite, and that the observed change of motion is the only indication, characteristic, and measure of the changing force, the forces are the same (whether we call them impulsion or resistances) when the relative motions are the same, and therefore depend entirely on these relative motions. The force, therefore, which is necessary for keeping a body immoveable in a stream of water, flowing with a certain velocity, is the same with what is required for moving this body with this velocity through stagnant water. To any one who admits the motion of the earth round the sun, it is evident that we can neither observe nor reason from a case of a body moving through still water, nor of a stream of water pressing upon or impelling a quiescent body.

A body in motion appears to be resisted by a stagnant fluid, because it is a law of mechanical nature that force must be employed in order to put any body in motion. Now the body cannot move forward without putting the contiguous fluid in motion, and force must be employed for producing this motion. In like manner, a quiescent body is impelled by a stream of fluid, because the motion of the contiguous fluid is diminished by this solid obstacle; the resistance, therefore, or impulse, no way differs from the ordinary communications of motion among solid bodies.

Sir Isaac Newton, therefore, begins his theory of the resistance and impulse of fluids, by selecting a case where, although he cannot pretend to ascertain the motions themselves which are produced in the particles of a contiguous fluid, he can tell precisely their mutual ratios.

He supposes two systems of bodies such, that each body of the first is similar to a corresponding body of the second, and that each is to each in a constant ratio. He also supposes them to be similarly situated, that is, at the angles of similar figures, and that the homologous lines of these figures are in the same ratio with the diameters of the bodies. He further supposes, that they attract or repel each other in similar directions, and that the accelerating connecting forces are also proportional; that is, the forces in the one system are to the corresponding forces in the other system in a constant ratio, and that, in each system taken apart, the forces are as the squares of the velocities directly, and as the diameters of the corresponding bodies, or their distances, inversely.

This being the case, it legitimately follows, that if similar parts of the two systems are put into similar motions, in any given instant, they will continue to move similarly, each correspondent body describing similar curves, with proportional velocities: For the bodies being similarly situated, the forces which act on a body in one system, arising from the combination of any number of adjoining particles, will have the same direction with the force acting on the corresponding body in the other system, arising from the combined action of the similar and similarly directed forces of the adjoining correspondent bodies of the other system; and these compound forces will have the same ratio with the simple forces which constitute them, and will be as the squares of the velocities directly, and as the distances, or any homologous lines inversely; and therefore the chords of curvature, having the direction of the centripetal or centrifugal forces, and similarly inclined to the tangents of the curves described by the corresponding bodies, will have the same ratio with the distances of the particles. The curves described by the corresponding bodies will therefore be similar, the velocities will be proportional, and the bodies will be similarly situated at the end of the first moment, and exposed to the action of similar and similarly situated centripetal or centrifugal forces; and this will again produce similar motions during the next moment, and so on for ever. All this is evident to any person acquainted with the elementary doctrines of curvilinear motions, as delivered in the theory of physical astronomy.

From this fundamental proposition, it clearly follows, that if two similar bodies, having their homologous lines being proportional to those of the two systems, be similarly projected among the bodies of those two systems with any velocities, they will produce similar motions in the two systems, and will themselves continue to move similarly; and therefore will, in every subsequent moment, suffer similar diminutions or retardations. If the initial velocities of projection be the same, but the densities of the two systems, that is, the quantities of matter contained in an equal bulk or extent, be different, it is evident that the quantities of motion produced in the two systems in the same time will be proportional to the densities; and if the densities are the same, and uniform in each system, the quantities of motion produced will be as the squares of the velocities, because the motion communicated to each corresponding body will be proportional to the velocity communicated, that is, to the velocity of the impelling body; and the number of similarly situated particles which will be agitated will also be proportional to this velocity. Therefore, the whole quantities of motion produced in the same moment of time will be proportional to the squares of the velocities. And lastly, if the densities of the systems are uniform, or the same through the whole extent of the systems, the number of particles impelled by similar bodies will be as the surfaces of these bodies.

Now the diminutions of the motions of the projected bodies are (by Newton's third law of motion) equal to the motions produced in the systems; and these diminutions are the measures of what are called the resistances opposed to the motions of the projected bodies. Therefore, combining all these circumstances, the resistances are proportional to the similar surfaces of the moving bodies, to the densities of the systems through which the motions are performed, and to the squares of the velocities, jointly.

We cannot form to ourselves any distinct notion of fluid, otherwise than as a system of small bodies, or a collection of particles, similarly or symmetrically arranged, the centres of each being situated in the angles of regular solids. We must form this notion of it, whether it is proper to us, or not, that the particles are little globules in mutual contact, or, with the partisans of corpuscular attractions and repulsions, we suppose the particles kept at a distance from each other by means of these attractions and repulsions mutually balancing each other. In this last case, no other arrangement is consistent with a quiescent equilibrium; and in this case, it is evident, from the theory of curvilinear motions, that the agitation...
RESISTANCE OF FLUIDS.

4 law of Prop. I. The resistances, and (by the third law of motion), the impulsions of fluids on similar bodies, are proportional to the surfaces of the solid bodies, to the densities of the fluids, and to the squares of the velocities, jointly.

We must now observe, that when we suppose the particles of the fluid to be in mutual contact, we may either suppose them elastic or unelastic. The motion communicated to the collection of elastic particles must be double of what the same body, moving in the same manner, would communicate to the particles of an elastic fluid. The impulse and resistance of elastic fluids must therefore be double of those of unelastic fluids.—But we must caution our readers not to judge of the elasticity of fluids by their sensible compressibility. A diamond is incomparably more elastic than the finest foot ball, though not compressible in any sensible degree.—It remains to be decided, by well chosen experiments, whether water be not as elastic as air. If we suppose, with Boscoth, the particles of perfect fluids to be at a distance from each other, we shall find it difficult to conceive a fluid void of elasticity. We hope that the theory of their impulse and resistance will suggest experiments which will decide this question, by pointing out what ought to be the absolute impulse or resistance in either case. And thus the fundamental proposition of the impulse and resistance of fluids, taken in its proper meaning, is susceptible of a rigid demonstration, relative to the only distinct notion that we can form of the internal constitution of a fluid. We say, taken in its proper meaning; namely, that the impulse or resistance of fluids is a pressure, opposed and measured by another pressure, such as a pound weight, the force of a spring, the pressure of the atmosphere, and the like. And we apprehend that it would be very difficult to find any legitimate demonstration of this leading proposition different from this, which we have now borrowed from Sir Isaac Newton, Prop. 23. B. II. Princip. We acknowledge that it is prolix and even circuitous: but in all the attempts made by his commentators and their copyists to simplify it, we see great defects of logical argument, or assumption of principles, which are not only gratuitous, but inadmissible. We shall have occasion, as we proceed, to point out some of these defects; and doubt not but the illustrious author of this demonstration had exercised his uncommon patience and sagacity in similar attempts, and was dissatisfied with them all.

Before we proceed farther, it will be proper to make a general remark, which will save a great deal of discussion. Since it is a matter of universal experience, that every action of a body on others is accompanied by an equal and contrary re-action; and since all that we can demonstrate concerning the resistance of bodies during their motions through fluids proceeds on this supposition (the resistance of the body being assumed as equal and opposite to the sum of motions communicated to the particles of the fluid, estimated in the direction of the bodies motion), we are intituled to proceed in the contrary order, Resistance of Fluids.

and to consider the impulsions which each of the particles of fluid exerts on the body at rest, as equal and opposite to the motion which the body would communicate to that particle if the fluid were at rest, and the body were moving equally swift in the opposite direction. And therefore the whole impulsion of the fluid must be conceived as the measure of the whole motion which the body would thus communicate to the fluid. It must therefore be also considered as the measure of the resistance which the body, moving with the same velocity, would sustain from the fluid. When, therefore, we shall demonstrate any thing concerning the impulsion of a fluid, estimated in the direction of its motion, we must consider it as demonstrated concerning the resistance of a quiescent fluid to the motion of that body, having the same velocity in the opposite direction. The determination of these impulsions being much easier than the determination of the motions communicated by the body to the particles of the fluid, this method will be followed in most of the subsequent discussions.

The general proposition already delivered is by no means sufficient for explaining the various important phenomena observed in the mutual actions of solids and fluids. In particular, it gives us no assistance in ascertaining the modifications of this resistance or impulse, which depend on the shape of the body and the inclination of its impelled or resisted surface to the direction of the motion. Sir Isaac Newton found another hypothesis necessary; namely, that the fluid should be so extremely rare that the distance of the particles may be incomparably greater than their diameters. This additional condition is necessary for considering their actions as so many separate collisions or impulsions on a solid body. Each particle must be supposed to have abundant room to rebound, or otherwise escape, after having made its stroke, without sensibly affecting the situations and motions of the particles which have not yet made their stroke: and the motion must be so swift as not to give time for the sensible exertion of their mutual forces of attractions and repulsions.

Keeping these conditions in mind, we may proceed to determine the impulsions made by a fluid on surfaces of every kind: And the most convenient method to pursue in this determination, is to compare them all either with the impulse which the same surface would receive from the fluid impinging on it perpendicularly, or with the impulse which the same stream of fluid would make when coming perpendicularly on a surface of such extent as to occupy the whole stream.

It will greatly abbreviate language, if we make use of a few terms explained.

By a stream, we shall mean a quantity of fluid moving in one direction, that is, each particle moving in parallel lines; and the breadth of the stream is a line perpendicular to all these parallels.

A filament means a portion of this stream of very small breadth, and it consists of an indefinite number of particles following one another in the same direction, and successively impinging on, or gliding along, the surface of the solid body.

The base of any surface exposed to a stream of fluid, is that portion of a plane perpendicular to the stream, which is covered or protected from the action of the stream.
Resistance of Fluids.

Plate CCCCLX. fig. 1.

Stream by the surface exposed to its impulse. Thus the base of a sphere exposed to a stream of fluid is its great circle, whose plane is perpendicular to the stream. If BC (fig. 1.) be a plane surface exposed to the action of a stream of fluid, moving in the direction DC, then BR, or SE, perpendicular to DC, is its base.

Direct impulse shall express the energy or action of the particle or filament, or stream of fluid, when meeting the surface perpendicularly, or when the surface is perpendicular to the direction of the stream.

Absolute impulse means the actual pressure on the impelled surface, arising from the action of the fluid, whether striking the surface perpendicularly or obliquely; or it is the force impressed on the surface, or tendency to motion which it acquires, and which must be opposed by an equal force in the opposite direction, in order that the surface may be maintained in its place. It is of importance to keep in mind, that this pressure is always perpendicular to the surface. It is a proposition founded on universal and uncontradicted experience, that the mutual actions of bodies on each other are always exerted in a direction perpendicular to the touching surfaces. Thus, it is observed, that when a billiard ball A is struck by another B, moving in any direction whatever, the ball A always moves off in the direction perpendicular to the plane which touches the two balls in the point of mutual contact, or point of impulse. This inductive proposition is supported by every argument which can be drawn from what we know concerning the forces which connect the particles of matter together, and are the immediate causes of the communication of motion. It would employ much time and room to state them here; and we apprehend that it is unnecessary: for no reason can be assigned why the pressure should be in any particular oblique direction. If any one should say that the impulse will be in the direction of the stream, we have only to desire him to take notice of the effect of the rudder of a ship. This shows that the impulse is not in the direction of the stream, and is therefore in some direction transverse to the stream.

He will also find, that when a plane surface is impelled obliquely by a fluid, there is no direction in which it can be supported but the direction perpendicular to itself. It is quite safe, in the mean time, to take it as an experimental truth. We may, perhaps, in some other part of our work, give what will be received as a rigorous demonstration.

Relative or effective impulse means the pressure on the surface estimated in some particular direction. Thus BC (fig. 1.) may represent the sail of a ship, impelled by the wind blowing in the direction DC. GO may be the direction of the ship's keel, or the line of her course. The wind strikes the sail in the direction GH parallel to DC; the sail is urged or pressed in the direction GI, perpendicular to BC. But we are interested to know what tendency this will give the ship to move in the direction GO. This is the effective or relative impulse. Or BC may be the transverse section of the sail of a common wind-mill. This, by the construction of the machine, can move only in the direction GP, perpendicular to the direction of the wind; and it is only in this direction that the impulse produces the desired effect. Or BC may be half of the prow of a punt or lighter, riding at anchor by means of the cable DC, attached to the prow C. In this case, GQ, parallel to DC, is that part of the absolute impulse which is employed in straining the cable.

The angle of incidence is the angle FGC contained between the direction of the stream FG and the plane BC.

The angle of obliquity is the angle OGC contained between the plane and the direction GO, in which we wish to estimate the impulse.

Prop. II. The direct impulse of a fluid on a plane surface, is to its absolute oblique impulse on the same sur- face, as the square of the radius to the square of the sine of the angle of incidence.

Let a stream of fluid, moving in the direction DC, (fig. 1.), act on the plane BC. With the radius GH describe the quadrant ABF; draw CA perpendicular to CE, and draw MNBS parallel to CE. Let the particle F, moving in the direction FG, meet the plane in G, and in FG produced take GH to represent the magnitude of the direct impulse, or the impulse which the particle would exert on the plane AC, by meeting it in V. Draw GI and HK perpendicular to BC, and HI perpendicular to GI. Also draw BR perpendicular to DC.

The force GH is equivalent to the two forces GI and GK; and GK being in the direction of the plane has no share in the impulse. The absolute impulse, therefore, is represented by GI; the angle GHI is equal to FGC, the angle of incidence; and therefore GH is to GI as radius to the sine of the angle of incidence. Therefore the direct impulse of each particle or filament is to its absolute oblique impulse as radius to the sine of the angle of incidence. But further, the number of particles or filaments which strike the surface AC, is to the number of those which strike the surface BC as AC to NC; for all the filaments between LA and MB go past the oblique surface BC without striking it. But BC = NC = rad. = sin. NBC = rad. = sin. FGC = rad. = sin. incidence. Now the whole impulse is as the impulse of each filament, and as the number of filaments exerting equal impulses jointly; therefore the whole direct impulse on AC is to the whole absolute impulse on BC, as the square of radius to the square of the sine of the angle of incidence.

Let S express the extent of the surface, i the angle of incidence, o the angle of obliquity, v the velocity of the fluid, and d its density. Let F represent the direct impulse, f the absolute oblique impulse, and the relative or effective impulse: And let the tabular sizes and cosines be considered as decimal fractions of the radius unity.

This proposition gives us F = R* sin. i = 1. sin. i, and therefore f = F X sin. i. Also, because impulses are in the proportion of the extent of surface similarly impelled, we have, in general, f = F X sin. i.

The first who published this theorem was Pardies, in his Oeuvres de Mathematique, in 1763. We know that Newton had investigated the chief propositions of the Principia before 1679.

Prop. III. The direct impulse on any surface is to the effective oblique impulse on the same surface, as the cube of radius to the solid, which has for its base the square of the sine of incidence, and the sine of obliquity for its height.
RESISTANCE OF FLUIDS.

For, when $GH$ represents the direct impulse of a particle, $GI$ is the absolute oblique impulse, and $GO$ is the effective impulse in the direction $GO$. Now $GI$ is to $GO$ as radius to the sine of $GIO$, and $GIO$ is the complement of $IOG$, and is therefore equal to $CGO$, the angle of obliquity.

Therefore $f: \phi = R : \sin \theta$.
But $F: f = R : \sin \theta$.
Therefore $F: \phi = R : \sin \theta$.

Cor. 1. The effective impulse in the direction of the stream on any plane surface $BC$, is to the direct impulse on its base $BE$ or $SE$, as the square of the sine of the angle of incidence to the square of the radius.

If an isosceles wedge $ABC$ (fig. 3.) be exposed to a stream of fluid moving in the direction of its height $CD$, the impulse on the sides is to the direct impulse on the base as the square of half the base $AD$ to the square of the side $AC$, or as the square of the sine of half the angle of the wedge to the square of the radius. For it is evident, that in this case the two transverse impulses, such as $GP$ in fig. 1, balance each other, and the only impulse which can be observed is the sum of the two impulses, such as $GQ$ of fig. 1, which are to be compared with the impulses on the two halves $AD$, $DB$ of the base. Now $AC: AB = \text{rad.} : \sin \theta$, and $ACD$ is equal to the angle of incidence.

Therefore, if the angle $ABC$ is a right angle, and $ACD$ is half a right angle, the square of $AC$ is twice the square of $AD$, and the impulse on the sides of a rectangular wedge is half the impulse on its base.

Also, if a cube $ACDF$, (fig. 4.) be exposed to a stream moving in a direction perpendicular to one of its sides, and then to a stream moving in a direction perpendicular to one of its diagonal planes, the impulse in the first case will be to the impulse in the second as $\sqrt{2}$ to 1.

Call the perpendicular impulse on a side $F$, and the perpendicular impulse on its diagonal plane $f$, and the effective oblique impulse on its sides $\phi$; we have

$$F: f = AC: AB = 1: \sqrt{2},$$
$$f: \phi = AC: AD = 2: 1.$$

Therefore

$$F: \phi = 2: \sqrt{3}, = \frac{2}{\sqrt{3}},$$
or very nearly as 10 to 7.

The same reasoning will apply to a pyramid whose base is a regular polygon, and whose axis is perpendicular to the base. If such a pyramid is exposed to a stream of fluid moving in the direction of the axis, the direct impulse on the base is to the effective impulse on the pyramid, as the square of the radius to the square of the sine of the angle which the axis makes with the sides of the pyramid.

And in like manner, the direct impulse on the base of a right cone is to the effective impulse on the conical surface, as the square of the radius to the square of the sine of half the angle at the vertex of the cone. This is demonstrated, by supposing the cone to be a pyramid of an infinite number of sides.

We may in this manner compare the impulse on any polygonal surface with the impulse on its base, by comparing apart the impulses on each plane with those in their corresponding bases, and taking their sum.

And we may compare the impulse on a curved surface with that on its base, by resolving the curved surface into elementary planes, each of which is impelled by an elementary filament of the stream.

The following beautiful proposition, given by La Sueur and Jaquier, in their commentary on the second book of Newton's Principia, with a few examples of its application, will suffice for any further account of this theory.
RESISTANCE OF FLUIDS.

**Prop. V.** Let ADB (fig. 5.) be the section of a surface of simple curvature, such as is the surface of a cylinder. Let this be exposed to the action of a fluid moving in the direction AC. Let BC be the section of the plane (which we have called its base), perpendicular to the direction of the stream. In AC produced, take any length CG; and on CG describe the semicircle CHG, and complete the rectangle BCGO. Through any point D of the curve draw ED parallel to AC, and meeting BC and OG in Q and P. Let DF touch the curve in D, and draw the chord GH parallel to DF, and HKM perpendicular to CG, meeting ED in M. Suppose this to be done for every point of the curve ADB, and let LMN be the curve which passes through all the points of intersection of the parallels EDP and the corresponding perpendiculars HKM.

The effective impulse on the curve surface ADB in the direction of the stream, is to its direct impulse on the base BC as the area BCNL is to the rectangle BCGO.

Draw e d q m p parallel to EP and extremely near it. The arc D d of the curve may be conceived as the section of an elementary plane, having the position of the tangent DF. The angle EDF is the angle of incidence of the filament ED d c. This is equal to CGH, because ED, DF, are parallel to CG, GH; and (because CHG is a semicircle) CH is perpendicular to GH. Also CG : CH = CK : CQ and CG : CK = CG² : CH² = rad.² : sin.², CHG = rad.² : sin.² incid. Therefore if CG, or its equal DP, represent the direct impulse on the point Q of the base, CK, or its equal QM, will represent the effective impulse on the point D of the curve. And thus, Q q P will represent the direct impulse of the filament on the element Q m of the base, and Q q M will represent the effective impulse of the same filament on the element D d of the curve. And, as this is true of the whole curve ADB, the effective impulse on the whole curve will be represented by the area BCNL; and the direct impulse on the base will be represented by the rectangle BCGO; and therefore the impulse on the curve-surface is to the impulse on the base as the area BLMNC is to the rectangle BOCG.

It is plain, from the construction, that if the tangent to the curve at A is perpendicular to AC, the point N will coincide with G. Also, if the tangent to the curve at B is parallel to AC, the point L will coincide with B.

Whenever, therefore, the curve ADB is such that an equation can be had to exhibit the general relation between the abscissa AR and the ordinate DR, we shall deduce an equation which exhibits the relation between the abscissa CK and the ordinate KM of the curve LMN; and this will give us the ratio of BLNC to BOGC.

Thus, if the surface is that of a cylinder, so that the curve BDAₙ (fig. 6.), which receives the impulse of the fluid, is a semicircle, make CG equal to AC, and construct the figure as before. The curve BMG is a parabola, whose axis is CG, whose vertex is G, and whose parameter is equal to CG. For it is plain, that CC = DC, and GH = CQ = MK. And CG × GK = GH² = KM². That is, the curve is such that the square of the ordinate KM is equal to the rectangle in the abscissa GK and a constant line GC; and therefore a parabola whose vertex is G. Now, it is well known, that the parabolic area BMGC is one third of the parallelogram BCGO. Therefore the impulse on the quadrant ADB is two thirds of the impulse on the base BC. The same may be said of the quadrant A d and its base b. Therefore, The impulse on a cylinder or half cylinder is two thirds of the impulse on its transverse plane through the axis; or it is two thirds of the direct impulse on one side of a parallelepiped of the same breadth and height.

**Prop. VI.** If the body be a solid generated by the revolution of the figure BDAC (fig. 5.) round the axis AC; and if it be exposed to the action of a fluid moving in the direction of the axis AC; the effective impulse in the direction of the stream is to its direct impulse on its base, as the solid generated by the revolution of the figure BLMN is to the axis CN to the cylinder generated by the revolution of the rectangle BOGC.

This scarcely needs a demonstration. The figures ADBLMNA is a section of these solids by a plane passing through the axis; and what has been demonstrated of this section is true of every other, because they are all equal and similar. It is therefore true of all the solids, and (their base) the circle generated by the revolution of BC round the axis AC.

Hence we easily deduce, that The impulse on a sphere is one half of the direct impulse on its great circle, or on the base of a cylinder of equal diameter.

For in this case the curve BMN (fig. 6.) generates the solid expressing the impulse on the sphere, and this is a paraboloid, and the solid is a parabolic conoid. This conoid is to the cylinder generated by the revolution of the rectangle BOGC round the axis CG, as the sum of all the circles generated by the revolution of the rectangle TOGC round the axis TG, to the sum of as many squares described on the ordinates KT. Draw BOG cutting MK. The square on MK is to the square on BC or TO as the abscissa GK to the abscissa GC (by the nature of the parabola), or as SK to BK; because SK and BK are respectively equal to GK and GC. Therefore the sum of all the squares on ordinates, such as MK, is to the sum of as many squares on ordinates, such as TK, as the sum of all the lines SK to the sum of as many lines KT that is, as the triangle BGC to the rectangle BOGC that is, as one to two: and therefore the impulse on a sphere is one half of the direct impulse on its great circle.

From the same construction we may very easily deduce a very curious and seemingly useful truth, that all conical bodies having the circle whose diameter AB (fig. 3.) for its base, and BD for its height, one which sustains the smallest impulse or meets the smallest resistance is the frustum AGHB of the cone ACB so constructed, that EF being taken equal to EF, EA is equal to EC. This frustum, though not so conspicuous than the cone AFB of the same height, will be less resisted.

Also, if the solid generated by the revolution of BDAC (fig. 5.) have its anterior part covered with
Resistance of Fluids.

The conclusion is the same whatever be the surface that is resisted, whatever be the fluid that resists, and whatever be the velocity of the motion. In this inductive and familiar manner we learn, that the direct impulse or resistance of an unelastic fluid on any plane surface, is equal to the weight of a column of the fluid having the surface for its base, and twice the full necessary for acquiring the velocity of the motion for its height: and if the fluid is considered as elastic, the impulse or resistance is twice as great. See Newt. Princ. B. II. prop. 35. and 38.

It now remains to compare this theory with experiments. Many have been made, both by Sir Isaac Newton, and by subsequent writers. It is much to be lamented, that in a matter of such importance, both to the philosopher and to the artist, there is such a disagreement in the results with each other. We shall mention the experiments which seem to have been made with the greatest judgment and care. Those of Sir Isaac Newton were chiefly made by the oscillations of pendulums in water, and by the descent of balls both in water and in air. Many have been made by Mariotte (Traité de Mouvement des Eaux). Gravesande has published, in his System of Natural Philosophy, experiments made on the resistance or impulsions on solids in the midst of a pipe or canal. They are extremely well contrived, but are on so small a scale that they are of very little use. Daniel Bernoulli, and his pupil Professor Kraft, have published in the Comment. Acad. Petropol. experiments on the impulse of a stream or vein of water from an orifice or tube: These are of great value. The Abbe Bossut has published others of the same kind in his Hydrodynamique. Mr Robins has published, in his New Principles of Gunnery, many valuable experiments on the impulse and resistance of air. The Chev. de Borda, in the Mem. Acad. Paris, 1763 and 1767, has given experiments on the resistance of air and also of water, which are very interesting. The most complete collection of experiments on the resistance of water are those made at the public expense by the institution of the academy of sciences, consisting of the marquis de Condorcet, Mr d'Alembert, Abbe Bossut, and others. The Chev. de Buat, in his Hydraulique, has published some of the most curious and valuable experiments, where many important circumstances are taken notice of, which had never been attended to before, and which give a view of the subject totally different from what is usually taken of it. Don George d'Ullio, in his Examen Maritime, has also given some important experiments, similar to those adduced by Bouger in his Manoeuvre des Vaisseaux but leading to very different conclusions. All these should be consulted by such as would acquire a practical knowledge of this subject. We must content ourselves with giving their most general and steady results. Such as,

1. It is very consonant to experiment that the resistances are proportional to the squares of the velocities. When the velocities of water do not exceed a few feet per second, no sensible deviation is observed. In very small velocities the resistances are sensibly greater than in this proportion, and this excess is plainly owing to the viscosity or imperfect fluidity of water. Sir Isaac Newton has shown that the resistance arising from
Resistance of Fluids.

In the experiments made with bodies floating on the surface of water, there is an addition to the resistance arising from the inertia of the water. The water beeps up a little on the anterior surface of the floating body, and is depressed behind it. Hence arises a hydrostastitical pressure, acting in concert with the true resistance. A similar thing is observed in the resistance of air, which is condensed before the body and rarefied behind it, and thus an additional resistance is produced by the unbalanced elasticity of the air; and also because the air, which is actually displaced, is denser than common air. These circumstances cause the resistances to increase faster than the squares of the velocities; but, even independent of this, there is an additional resistance arising from the tendency to rarefaction behind a very swift body; because the pressure of the surrounding fluid can only make the fluid fill the space left with a determined velocity.

We have had occasion to speak of this circumstance more particularly under Gunnery and Pneumatics, when considering very rapid motions. Mr. Robins had remarked that the velocity at which the observed resistance of the air began to increase so prodigiously, was that of about 1100 or 1200 feet per second, and that this was the velocity with which air would rush into a void. He concluded, that when the velocity was greater than this, the ball was exposed to the additional resistance arising from the unbalanced stastitical pressure of the air, and that this constant quantity behaved to be added to the resistance arising from the air's inertia in all greater velocities. This is very reasonable; but he imagined that in smaller velocities there was no such unbalanced pressure. But this cannot be the case: for although in smaller velocities the air will still fill up the space behind the body, it will not fill it up with air of the same density. This would be to suppose the motion of the air into the deserted place to be instantaneous. There must therefore be a rarefaction behind the body, and a pressure backward; arising from unbalanced elasticity, independent of the condensation on the anterior part. The condensation and rarefaction are caused by the same thing, viz. the limited elasticity of the air. Were this infinitely great, the smallest condensation before the body would be instantly diffused over the whole air, and so would the rarefaction, so that no pressure of unbalanced elasticity would be observed; but the elasticity is such as to propagate the condensation with the velocity of sound only, i.e. the velocity of 1142 feet per second. Therefore this additional resistance does not commence precisely at this velocity, but is sensible in all smaller velocities, as is very justly observed by Euler. But we are not yet able to ascertain the law of its increase, although it is a problem which seems susceptible of a tolerably accurate solution.

Precisely similar to this is the resistance to the motion of floating bodies, arising from the accumulation or gorging up of the water on their anterior surface, and its depression behind them. Were the gravity of the water infinite, while its inertia remains the same, the wave raised up at the prow of a ship would be instantly diffused over the whole ocean, and it would therefore be infinitely small, as also the depression behind the poop. But this wave requires time for its diffusion; and while it is not diffused, it acts by hydrostastitical pressure. We are equally unable to ascertain the law of variation of this part of the resistance, the mechanism of waves being but very imperfectly understood. The height of the wave in the experiments of the French academy could not be measured with sufficient precision (being only observed en passant) for ascertaining its relation to the velocity. The Chev. Baut attempted it in his experiments, but without success. This must evidently make a part of the resistance in all velocities; and it still remains an undecided question, "What relation it bears to the velocities?" When the solid body is wholly buried in the fluid, this accumulation does not take place, or at least not in the same way: it may, however, be observed. Every person may recollect, that in a very swift running stream a large stone at the bottom will produce a small swell above it; unless it lies very deep, a nice eye may still observe it. The water, on arriving at the obstacle, glides past it in every direction, and is deflected on all hands; and therefore what passes over it is also deflected upwards, and causes the water over it to rise above its level. The nearer that the body is to the surface, the greater will be the perpendicular rise of the water, but it will be less diffused; and it is uncertain whether the whole elevation will be greater or less. By the whole elevation we mean the area of a perpendicular section of the elevation by a plane perpendicular to the direction of the stream. We are rather disposed to think that this area will be greatest when the body is near the surface. D'Uloa has attempted to consider this subject scientifically; and is of a very different opinion, which he confirms by the single experiment to be mentioned by and by. Mean time, it is evident, that if the water, which glides past the body cannot fall in behind it with sufficient velocity for filling up the space behind, there must be a void there; and thus a hydrostastitical pressure must be superadded to the resistance arising from the inertia of the water. All must have observed, that if the end of a stick held in the hand be drawn slowly through the water, the water will fill the place left by the stick, and there will be no curled wave: but if the motion be very rapid, a hollow trough or gutter is left behind, and is not filled up till at some distance from the stick, and the wave which forms its sides is very much broken and curled. The writer of this article has often looked into the water from the poop of a second rate man of war when she was sailing at 12 miles per hour, which is a velocity of 16 feet per second nearly; and he not only observed that the back of the rudder was naked for about two feet below the load water-line, but also that the trough or wake made by the ship was filled up with water which was broken and foaming to a considerable depth, and to a considerable distance from the vessel. There must therefore have been a void. He never saw the wave perfectly transparent (and therefore completely filled with water) when the velocity exceeded 9 or 10 feet per second. While this
Resistance of Fluids.

It is known, says he, that the water would flow out at this hole with the velocity \( v = \sqrt{2 \varphi h} \), and \( u^* = 2 \varphi h \) of Fluids.

and \( h = \frac{u}{2 \varphi} \). It is also known that the pressure \( p \) on the orifice \( o \) is \( \varphi o \cdot h = \frac{u^3}{2 \varphi} = \frac{h}{2} \).

Now, let this little surface \( o \) be supposed to move with the velocity \( v \). The fluid would meet it with the velocity \( u + v \), or \( u - v \), according as it moved in the opposite or in the same direction with the eflux. In the equation \( p = \frac{1}{2} o u^* \), substitute \( u = v \) for \( v \), and we have the pressure on \( o \) as \( p = \frac{1}{2} (u^* \cdot h) = \frac{3}{2} (\sqrt{2 \varphi h} - u^*) \).

This pressure is a weight, that is, a mass of matter \( m \) actuated by gravity \( \varphi \), or \( p = \varphi m \), and \( m = \varphi \left(\sqrt{\frac{h}{2 \varphi}}\right)^2 \).

This elementary surface being immersed in a stagnant fluid, and moved with the velocity \( v \), will sustain on one side a pressure \( \varphi o \left(\sqrt{h + \frac{v}{2 \varphi}}\right) \), and on the other side a pressure \( \varphi o \left(\sqrt{h - \frac{v}{2 \varphi}}\right) \); and the sensible resistance will be the difference of these two pressures, which is \( \varphi o 4 \sqrt{\frac{h}{2 \varphi}} \), or \( \varphi o 4 \sqrt{h} \), that is, \( \varphi o \sqrt{h} \), because \( \sqrt{2 \varphi} = 8 \); a quantity which is in the subduplicate ratio of the depth under the surface of the fluid, and the simple ratio of the velocity of the resisted surface jointly.

There is nothing in experimental philosophy more certain than that the resistances are very nearly in the duplicate ratio of the velocities; and we cannot conceive by what experiments the ingenious author has supported this conclusion.

But there is, besides, what appears to us to be an essential defect in this investigation. The equation exhibited no resistance in the case of a fluid without weight, which was the case. Now a theory of the resistance of fluids should exhibit the retardation arising from inertia alone, and should distinguish it from that arising from any other cause; and moreover, while it assigns an ultimate sensible resistance proportional (ceteris paribus) to the simple velocity, it assumes as a first principle that the pressure is \( u + v \).

It also gives a false measure of the statical pressures: for these (in the case of bodies immersed in our waters at least) are made up of the pressure of the incumbent water, which is measured by \( h \), and the pressure of the atmosphere, a constant quantity.

Whatever reason can be given for setting out with the principle that the pressure on the little surface \( o \), moving with the velocity \( u \), is equal to \( \frac{1}{2} o (u + v)^2 \), makes it indispensably necessary to take for the velocity \( u \), not that with which water would issue from a hole whose depth under the surface is \( h \), but the velocity

\[ \frac{f A}{2} \]

with

(A) There is something very unaccountable in these experiments. The resistances are much greater than any other author has observed.
Resistance of Fluids.

with which it will issue from a hole whose depth is $h + 33$ feet. Because the pressure of the atmosphere is equal to that of a column of water 33 feet high, for this is the acknowledged velocity with which it would rush in to the void left by the body. Therefore this velocity (which does not exist) has any share in the effort, we must have for the fluxion of pressure not $\frac{4\sqrt{\frac{h}{2}}} {2\Phi}$ but $\frac{4\sqrt{\frac{h+33}{2}}} {2\Phi}$. This would not only give pressure or resistances many times exceeding those that have been observed in our experiments, but would also totally change the proportions which this theory determines. It was at any rate improper to embarrass an investigation, already very intricate, with the pressure of gravity, and with two motions of efflux, which do not exist, and are necessary for making the pressures in the ratio of $u+c$ and $u-v$.

Mr. Prony has been at no pains to inform his readers of his reasons for adopting this theory of resistance, so contrary to all received opinions, and to the most distinct experiments. Those of the French academy, made under greater pressures, gave a much smaller resistance; and the very experiments adduced in support of this theory are extremely deficient, wanting fully one-third of what the theory requires. The resistances by experiment were 152 and 267, and the theory required 204 and 39. The equation, however, deduced from the theory is greatly deficient in the expression of the pressures caused by the accumulation and depression, stating the heights of them as $\frac{c}{2\Phi}$. They can never be so high, because the heaped-up water flows off at the sides, and it also comes in behind the sides; so that the pressure is much less than half the weight of a column whose height is $\frac{c}{2\Phi}$, both because the accumulation and depression are less at the sides than in the middle, and because, when the body is wholly immersed, the accumulation is greatly diminished. Indeed in this case, the final equation does not include their effects, though as real in this case as when part of the body is above water.

Upon the whole, we are somewhat surprised that an author of D'Uillon's eminence should have adopted a theory so unnecessary and so improperly embarrassed with foreign circumstances; and that Mr. Prony should have inserted it with the explanation by which he was to abide, in a work destined for practical use.

This point, on the effect of deep immersion, is still much contested; and it is a received opinion, by many not accustomed to mathematical researches, that the resistance is greater in greater depths. This is assumed as an important principle by Mr. Gordon author of a Theory of Naval Architecture; but on very vague and slight grounds; and the author seems unacquainted with the manner of reasoning on such subjects. It shall be considered afterwards.

With these corrections it may be asserted that theory and experiment agree very well in this respect, and that the resistance may be asserted to be in the duplicate ratio of the velocity.

We have been more minute on this subject, because it is the leading proposition in the theory of the action of fluids. Newton's demonstration of it takes no notice of the manner in which the various particles of the fluid are put in motion, or the motion which each in particular acquires. He only shows, that if there be nothing concerned in the communication but pure inertia, the sum total of the motions of the particles, estimated in the direction of the bodies motion, or that of the stream, will be in the duplicate ratio of the velocity. It was therefore of importance to show that this part of the theory was just. To do this, we had to consider the effect of every circumstance which could be combined with the inertia of the fluid. All these had been foreseen by that great man, and are most briefly, though perspicuously, mentioned in the last scholium to prop. 36. B. II.

2. It appears from a comparison of all the experiments, that the impulses and resistances are very nearly and nearly in the proportion of the surfaces. They appear, however, to increase somewhat faster than the surfaces. The chevalier Borda found that the resistance, with the same mean velocity, to a surface of

The deviation in these experiments from the theory increases with the surface, and is probably much greater in the extensive surfaces of the sails of ships and windmills, and the hulls of ships.

3. The resistances do by no means vary in the duplicate ratio of the sines of the angles of incidence.

As this is the most interesting circumstance, having a chief influence on the particular modifications of the resistance of fluids, and as on this depends the whole theory of the construction and working of ships, and the action of water on our most important machines, and seems most immediately connected with the mechanism of fluids, it merits a very particular consideration. We cannot do a greater service than by rendering more generally known the excellent experiments of the French academy.

Fifteen boxes or vessels were constructed, which were 2 feet wide, 2 feet deep, and 4 feet long. One end of them was a parallelepiped of these dimensions; the others had prows of a wedge-form, the angle ACB (fig. 8) varying by 120 degrees from 12° to 180°; so that the angle of incidence increased by 6° from one to another. These boxes were dragged across a very large basin of smooth water (in which they were immersed two feet) by means of a line passing over a wheel connected with a cylinder, from which the actuating weight was suspended. The motion became perfectly uniform after a very little way; and the time of passing over 96 French feet with this uniform motion was very carefully noted. The resistance was measured by the weight employed, after deducting a certain quantity (properly estimated) for friction, and for the accumulation of the water against the anterior surface. The results of the many experiments are given in the following table; where column 1st contains the angle of the prow, column 2nd contains the resistance as given by the preceding theory, column 3rd contains the resistance exhibited in the experiments, and column 4th, contains the deviation of the experiment from the theory.
The resistance to 1 square foot, French measure, moving with the velocity of 2,56 feet per second, was very nearly 7,525 pounds French.

Reducing these to English measures, we have the surface = 1,353 feet, the velocity of the motion equal to 2,726 feet per second, and the resistance equal to 8,234 pounds avoidoposs. The weight of a column of fresh water of this base, and having for its height the fall necessary for communicating this velocity, is 8,225 pounds avoidoposs. The resistances to other velocities were accurately proportional to the squares of the velocities.

There is great diversity in the value which different authors have deduced for the absolute resistance of water from their experiments. In the value now given nothing is taken into account but the inertia of the water. The accumulation against, the forepart of the box was carefully noted, and the statical pressure backwards, arising from this cause, was subtracted from the whole resistance to the drag. There had not been sufficient variety of experiments for discovering the share which tenacity and friction produced; so that the number of pounds set down here may be considered as somewhat superior to the mere effects of the inertia of the water.

We think, upon the whole, that it is the most accurate determination yet given of the resistance to a body in motion; but we shall afterwards see reason for believing, that the impulse of a running stream having the same velocity is somewhat greater; and this is the form in which most of the experiments have been made.

Also observe, that the resistance here given is that to a vessel two feet broad and deep and four feet long. The resistance to a plane of two feet broad and deep would probably have exceeded this in the proportion of 15,22 to 14,54, for reasons we shall see afterwards.

From the experiments of Chevalier Buat, it appears that a body of one foot square, French measure, and two feet long, having its centre 15 inches under water, moving three French feet per second, sustained a pressure of 1454 French pounds, or 15,63 English. This reduced in the proportion of 3 to 2,56 gives 11,43 pounds, considerably exceeding the 8,24.

Mr Bouger, in his Manoevre des Vaissaux, says, that he found the resistance of sea-water to a velocity of one foot to be 23 ounces poids de Marc.

The chevalier Borda found the resistance of sea-water to the face of a cubic foot, moving against the water one foot per second, to be 21 ounces nearly. But this experiment is complicated: the wave was not deduced; Resistance and it was not a plane, but a cube.

Don George d'Uzzo found the impulse of a stream of sea-water, running two feet per second, on a foot square, to be 15 pounds English measure. This greatly exceeds all the values given by others.

From these experiments we learn, in the first place, Consequer, that the direct resistance to a motion of a plane surface from through water, is very nearly equal to the weight of a column of water having that surface for its base, and for its height the fall producing the velocity of the motion. This is but one half of the resistance determined by the preceding theory. It agrees, however, very well with the best experiments made by other philosophers on bodies totally immersed or surrounded by the fluid; and sufficiently shows, that there must be some fallacy in the principles or reasoning by which this result of the theory is supposed to be deduced. We shall have occasion to return to this again.

But we see that the effects of the obliquity of incidence deviate enormously from the theory, and that this deviation increases rapidly as the acuteness of the prow increases. In the prow of 60° the deviation is nearly equal to the whole resistance pointed out by the theory, and in the prow of 12° it is nearly 40 times greater than the theoretical resistance.

The resistance of the prow of 90° should be one-half the resistance of the base. We have not such a prow; but the medium between the resistance of the prow of 96 and 84 is 5790, instead of 500.

These experiments are very conform to those of other authors on plane surfaces. Mr Robins found the resistance of the air to a pyramid of 45°, with its apex foremost, was to that of its base as 1000 to 1411, instead of one to two. Chevalier Borda found the resistance of a cube, moving in water in the direction of the side, was to the oblique resistance, when it was moved in the direction of the diagonal, in the proportion of 5 4/5 to 7; whereas it should have been that of $\sqrt{2}$ to 1, or of 10 to 7 nearly. He also found, that a wedge whose angle was 90°, moving in air, gave for the proportion of the resistances of the edge and base 7281 : 10000, instead of 5000 : 10000. Also, when the angle of the wedge was 60°, the resistances of the edge and base were 53 and 100, instead of 25 and 100.

In short, in all the cases of oblique plane surfaces, the resistances were greater than those which are assigned by the theory. The theoretical law agrees tolerably with observation in large angles of incidence, that is, in incidences not differing very far from the perpendicular; but in more acute prows the resistances are more nearly proportional to the sines of incidence than to their squares.

The academicians deduced from these experiments an expression of the general value of the resistance, which corresponds tolerably well with observation. Thus let $x$ be the complement of the half angle of the prow, and let $P$ be the direct pressure or resistance, with an incidence of 90°, and $p$ the effective oblique pressure:

$\tan x = \frac{P \times \cos \alpha}{p + 3,153 \left(\frac{2}{5}\right)^{3/25}}$. This gives for a prow of 12° an error in defect about 7°, and in larger angles it is much nearer the truth; and this is exact enough for any practice.

This is an abundantly simple formula; but if we introduce...
Resistance of Fluids.

Introduction to Calculations of the Resistances of Curvilinear Prows, it renders them so complicated as to be almost useless; and what is worse, when the calculation is completed for a curvilinear prow, the resistance which results is found to differ widely from experiment. This shows that the motion of the fluid is so modified by the action of the most prominent part of the prow, that its impulse on what succeeds is greatly affected, so that we are not allowed to consider the prow as composed of a number of parts, each of which is affected as if it were detached from all the rest.

As the very nature of naval architecture seems to require curvilinear forms, in order to give the necessary strength, it seemed of importance to examine more particularly the deviations of the resistances of such prows from the resistances assigned by the theory. The academicians therefore made vessels with prows of a cylindrical shape; one of these was a half cylinder, and the other was one-third of a cylinder, both having the same breadth, viz. two feet, the same depth, also two feet, and the same length, four feet. The resistance of the half cylinder was to the resistance of the perpendicular prow in the proportion of 13 to 25, instead of being as 13 to 19.5. The chevalier Borda found nearly the same ratio of the resistances of the half cylinder, and its diametrical plane when moved in air. He also compared the resistances of two prisms or wedges, of the same breadth and height. The first had its sides plane, inclined to the base in angles of 60°: the second had its sides portions of cylinders, of which the planes were the chords, that is, their sections were arches of circles of 60°. Their resistances were as 139 to 100, instead of being as 133 to 220, as required by the theory; and as the resistance of the first was greater in proportion to that of the base than the theory allows, the resistance of the last was less.

Mr. Robins found the resistance of a sphere moving in air to be to the resistance of its great circle as 1 to 2.278; whereas theory requires them to be as 1 to 2. He found, at the same time, that the absolute resistance was greater than the weight of a cylinder of air of the same diameter, and having the height necessary for acquiring the velocity. It was greater in the proportion of 49 to 40 nearly.

Borda found the resistance of the sphere moving in water to be to that of its great circle as 1000 to 2508, and it was one-ninth greater than the weight of the column of water whose height was that necessary for producing the velocity. He also found the resistance of air to the sphere was to its resistance to its great circle as 1 to 2.45.

It appears, on the whole, that the theory gives the resistance of oblique plane surfaces too small, and that of curved surfaces too great; and that it is quite unfit for ascertaining the modifications of resistance arising from the figure of the body. The most prominent part of the prow changes the action of the fluid on the succeeding parts, rendering it totally different from what it would be were that part detached from the rest, and exposed to the stream with the same obliquity. It is of no consequence, therefore, to deduce any formula from the valuable experiments of the French academy. The experiments themselves are of great importance, because they give us the impulses on plane surfaces with every obliquity. They therefore put it in our power to select the most proper obliquity in a thousand important cases. Resistance.

By appealing to them, we may learn what is the proper angle of the sail for producing the greatest impulse in the direction of the ship's course; or the best inclination of the sail of a windmill, or the best inclination of the float of a water-wheel, &c. &c. These deductions will be made in their proper places in the course of this work. We see also, that the deviation from the simple theory is not very considerable till the obliquity is great; and that, in the inclinations which other circumstances would induce us to give to the floats of water wheels, the sails of windmills, and the like, the results of the theory are sufficiently agreeable to experiment, for rendering this theory of very great use in the construction of machines. Its great defect is in the impulses on curved surfaces, which puts a stop to our improvement of the science of naval architecture, and the working of ships.

But it is not enough to detect the faults of the theory: we should try to amend it, or to substitute another. It is a pity that so much ingenuity should have been thrown away in the application of a theory so defective. Mathematicians were seduced, as has been already observed, by the opportunity which it gave for exercising their calculus, which was a new thing at the time of publishing this theory. Newton saw clearly the defects of it, and makes no use of any part of it in his subsequent discussions, and plainly has used it merely as an introduction, in order to give some general notions in a subject quite new, and to give a demonstration of one leading truth, viz. the proportionality of the impulses to the squares of the velocities. While we profess the highest respect for the talents and labours of the great mathematicians who have followed Newton in this most difficult research, we cannot help being sorry that some of the greatest of them continued to attach themselves to a theory which he neglected, merely because it afforded an opportunity of displaying their profound knowledge of the new calculus, of which they were willing to ascribe the discovery to Leibnitz. It has been in a great measure owing to this that we have been so late in discovering our ignorance of the subject. Newton had himself pointed out all the defects of this theory; and he set himself to work to discover another which should be more conformable to the nature of things, retaining only such deductions from the other as his great sagacity assured him would stand the test of experiment. Even in this he seems to have been mistaken by his followers. He retained the proportionality of the resistance to the square of the velocity. This they have endeavoured to demonstrate in a manner conformable to Newton's determination of the oblique impulses of fluids; and under the cover of the agreement of this proposition with experiment, they introduced into mechanics a mode of expression, and even of conception, which is inconsistent with all accurate notions of these subjects. Newton's proposition was, that the motions communicated to the fluid, and therefore the motions lost by the body, in equal times, were as the squares of the velocities; and he conceived them as proper measures of the resistances. It is a matter of experience, that the forces or pressures by which a body must be supported in opposition to the impulses of fluids, are in this very proportion. In determining the proportion of the direct and oblique resistances of plane surfaces,
RESISTANCE OF FLUIDS.

Resistance of Fluids. 743

Resistance surfaces, he considers the resistances to arise from mutual collisions of the surface and fluid, repeated at intervals of time too small to be perceived. But in making this comparison, he has no occasion whatever to consider this repetition; and when he assigns the proportion between the resistance of a cone and of its base, he, in fact, assigns the proportion between two simultaneous and instantaneous impulses. But the mathematicians who followed him have considered this repetition as equivalent to an augmentation of the initial or first impulse; and in this way have attempted to demonstrate that the resistances are as the squares of the velocities. When the velocity is double, each impulse is double, and the number in a given time is double; therefore, say they, the resistance, and the force which will withstand it, is quadruple; and observation confirms their deduction; yet nothing is more gratuitous and illogical. It is very true that the resistance, conceived as Newton conceives it, the loss of motion sustained by a body moving in the fluid, is quadruple; but the instantaneous impulse, and the force which can withstand it, is, by all the laws of mechanics, only double. What is the force which can withstand a double impulse? Nothing but a double impulse. Nothing but impulse can be opposed to impulse; and it is a gross misconception to think of stating any kind of comparison between impulse and pressure. It is this which has given rise to much jargon and false reasoning about the force of percussion. This is stated as infinitely greater than any pressure, and as equivalent to a pressure infinitely repeated. It forced the abettors of these doctrines at last to deny the existence of all pressure whatever, and to assert that all motion, and tendency to motion, was the result of impulse. The celebrated Euler, perhaps the first mathematician, and the lowest philosopher, of this century, says, "since motion and impulse are seen to exist, and since we see that by means of motion pressure may be produced, as when a body in motion strikes another, or as when a body moved in a curved channel presses upon it, merely in consequence of its curvilinear motion, and the exertion of a centrifugal force; and since Nature is most wisely economical in all her operations; it is absurd to suppose that pressure, or tendency to motion, has any other origin; and it is the business of a philosopher to discover by what motion any observed pressure is produced." Whenever any pressure is observed, such as the pressure of gravity, of magnetism, of electricity, condensed air, nay, of a spring, and of elasticity and cohesion themselves, however disparate, nay, opposite, the philosopher must immediately cast about, and contrive a set of motions (creating pro re natai the movers) which will produce a pressure like the one observed. Having pleased his fancy with this, he cries out bocu "this will produce the pressure;" efustra fit per plurà quant feist potæs per paciuncia, therefore in this way the pressure is produced." Thus the vortices of Descartes are brought back in triumph, and have produced vortices without number, which fill the universe with motion and pressure.

Such bold attempts to overturn long-received doctrines in mechanics, could not be received without much criticism and opposition; and many able dissertations appeared from time to time in defence of the common doctrines. In consequence of the many objections to the comparison of pure pressure with pure percussion or impulse, John Bernoulli and others were at last obliged to assert that there were no perfectly hard bodies in nature, nor could be, but that all bodies were elastic; and that in the communication of motion by percussion, the velocities of both bodies were gradually changed by their mutual elasticity acting during the finite but imperceptible time of the collision. This was, in fact, giving up the whole argument, and banishing percussion, while their aim was to get rid of pressure. For what is elasticity but a pressure? and how shall it be produced? To act in this instance, must it arise from a still smaller impulse? But this will require another elasticity, and so on without end.

These are all legitimate consequences of this attempt to state a comparison between percussion and pressure. Numberless experiments have been made to confirm the statement; and there is hardly an itinerant lecturer showman who does not exhibit among his apparatus Gravescande's machine (Vol. I. plate xxxv. fig. 4.). But nothing affords so specious an argument as the experimented proportionality of the impulse of fluids to the square of the velocity. Here is every appearance of the accumulation of an infinity of minute impulses, in the known ratio of the velocity, each to each, producing pressures which are in the ratio of the squares of the velocities.

The pressures are observed; but the impulses or percussions, whose accumulation produces these pressures, are only supposed. The rare fluid, introduced by Newton for the purpose already mentioned, either does not exist in nature, or does not act in the manner we have said, the particles making their impulse, and then escaping through among the rest without affecting their motion. We cannot indeed say what may be the proportion between the diameter and the distance of the particles. The first may be incomparably smaller than the second, even in mercury, the densest fluid which we are familiarly acquainted with; but although they do not touch each other, they act nearly as if they did, in consequence of their mutual attractions and repulsions. We have seen air a thousand times rarer in some experiments than in others, and therefore the distance of the particles at least ten times greater than their diameters; and yet, in this rare state, it propagates all pressures or impulses made on any part of it to a great distance, almost in an instant. It cannot be, therefore, that fluids act on bodies by impulse. It is very possible to conceive a fluid advancing with a flat surface against the flat surface of a solid. The very first and superficial particles may make an impulse; and if they were annihilated, the next might do the same: and if the velocity were double, these impulses would be double, and would be withstood by a double force, and not a quadruple, as is observed: and this very circumstance that a quadruple force is necessary, should have made us conclude that it was not to impulse that this force was opposed. The first particles having made their stroke, and not being annihilated, must escape laterally. In their escape to do a very small part of a fluid can make any impulse on a surface. But a very caping they effectually prevent every further impulse, because they come in the way of those filaments which would have struck the body. The whole process seems to be somewhat as follows:

When the flat surface of the fluid has come into contact with the plane surface $AD$ (fig. 7) perpendicular to the direction $DC$ of their motion, they must deflect...
to both sides equally, and in equal portions, because no reason can be assigned why more should go to either side. By this means the filament EF, which would have struck the surface in G, is deflected before it arrives at the surface, and describes a curved path EFHK, continuing its rectilinear motion to I, where it is intercepted by a filament immediately adjoining to EF, on the side of the middle filament DC. The different particles of DC may be supposed to impinge in succession at C, and to be deflected at right angles; and gliding along CB, to escape at B. Each filament in succession, outwards from DC, is deflected in its turn; and being hindered from even touching the surface CB, it glides off in a direction parallel to it; and thus EF is deflected in I, moves parallel to CB from I to H, and is again deflected at right angles, and describes HK parallel to DC. The same thing may be supposed to happen on the other side of DC.

And thus it would appear, that except two filaments immediately adjoining to the line DC, which bisects the surface at right angles, no part of the fluid makes any impulse on the surface AB. All the other filaments are merely pressed against it by the lateral filaments without them, which they turn aside, and prevent from striking the surface.

In like manner, when the fluid strikes the edge of a prism or wedge ACB (fig. 8), it cannot be said that any real impulse is made. Nothing binds us from supposing C a mathematical angle or indivisible point, not susceptible of any impulse, and serving merely to divide the stream. Each filament EF is effectually prevented from impinging at G in the line of its direction, and with the obliquity of incidence EGC, by the filaments between EF and DC, which glide along the surface CA; and it may be supposed to be deflected when it comes to the line CF which bisects the angle DCA, and again deflected and rendered parallel to DC at I. The same thing happens on the other side of DC; and we cannot in that case assert that there is any impulse.

We now see plainly how the ordinary theory must be totally unfit for furnishing principles of naval architecture, even although a formula could be deduced from such a series of experiments as those of the French Academy. Although we should know precisely the impulse, or, to speak now more cautiously, the action of fluid on a surface Gl. (fig. 9) of any obliquity, when it is alone, detached from all others, we cannot in the smallest degree tell what will be the action of part of a stream or fluid advancing towards it, with the same obliquity, when it is preceded by an adjoining surface CG, having a different inclination; for the fluid will not glide along CG in the same manner as if it made part of a more extensive surface having the same inclination. The previous deflections are extremely different in these two cases; and the previous deflections are the only changes which we can observe in the motions of the fluid, and the only causes of that pressure which we observe the body to sustain, and which we call the impulse on it. This theory must, therefore, be quite unfit for ascertaining the action on a curved surface, which may be considered as made up of an indefinite number of successive planes.

We now see with equal evidence how it happens that the action of fluids on solid bodies may and must be opposed by pressures, and may be compared with and measured by the pressure of gravity. We are not compared ring forces of different kinds, percussions with pres sures, but pressures with each other. Let us see whether this view of the subject will afford us any method of comparison or absolute measurement.

When a filament of fluid, that is, a row of corpuscles, are turned out of their course EF (fig. 7), and forced to take another course IH, force is required to produce this change of direction. The filament is prevented from proceeding by other filaments which lie between it and the body, and which deflect it in the same manner as if it were contained in a bended tube, and it will press on the concave filament next to it as it would press on the concave side of the tube. Suppose such a bended tube ABE (fig. 10.), and that a ball A is projected along it with any velocity, and moves in it without friction: it is demonstrated, in elementary mechanics, that the ball will move with undiminished velocity, and will press on every point, such as B, of the concave side of the tube, in a direction BF perpendicular to the plane CBD, which touches the tube in the point B. This pressure on the adjoining filament, on the concave side of its path, must be withstood by that filament which deflects it; and it must be propagated across that filament to the next, and thus augment the pressure upon that next filament already pressed by the deflection of the intermediate filament; and thus there is a pressure towards the middle filament, and towards the body, arising from the deflection of all the outer filaments; and their accumulated sum must be conceived as immediately exerted on the middle filaments and on the body, because a perfect fluid transmits every pressure undiminished.

The pressure BF is equivalent to the two BH, BG, one of which is perpendicular, and the other parallel, to the direction of the original motion. By the first of these (taken in any point of the curvilinear motion of any filament), the two halves of the stream are pressed together; and in the case of fig. 7. and 8. exactly balance each other. But the pressures, such as BG, must be ultimately withstood by the surface ABC; and it is by these accumulated pressures that the solid body is urged down the stream; and it is these accumulated pressures which we observe and measure in our experiments. We shall anticipate a little, and say that it is most easily demonstrated, that when a ball A (fig. 10.) moves with undiminished velocity in a tube so incurvated that its axis at E is at right angles to its axis at A, the accumulated action of the pressures, such as BG, taken for every point of the path, is precisely equal to the force which would produce or extinguish the original motion.

This being the case, it follows most obviously, that if the two motions of the filaments are such as we have described and represented by fig. 7. the whole pressure in the direction of the stream, that is, the whole pressure which can be observed on the surface, is equal to the weight of a column of fluid having the surface for its base, and twice the fall productive of the velocity for its height, precisely as Newton deduced it from other considerations; and it seems to make no odds whether the fluid be elastic or inelastic, if the deflections and velocities are the same. Now it is a fact, that no difference in this respect can be observed in the actions of air and water; and this had always appeared a great defect in Newton's theory: but it was only a defect of
Resistance of Fluids.

Resistance of Fluids. But it is also true, that the observed action is but one-half of what is just now deduced from this improved view of the subject. Whence arises this difference? The reason is this: We have given a very erroneous account of the motions of the filaments. A filament EF does not move as represented in fig. 7, with two rectangular inflections at I and H, and a path IH between them parallel to CB. The process of nature is more like what is represented in fig. 11. It is observed, that at the anterior part of the body AB, there remains a quantity of fluid ADB, almost, if not altogether stagnant, of a singular shape, having two curved concave sides A, D, B, D along which the middle filaments glide. This fluid is very slowly changed.—The late Sir Charles Knowles, an officer of the British navy, equally eminent for his scientific professional knowledge and for his military talents, made many beautiful experiments for ascertaining the paths of the filaments of water. At a distance up the stream, he allowed small jets of a coloured fluid, which did not mix with water, to make part of the stream; and the experiments were made in troughs with sides and bottom of plate-glass. A small taper was placed at a considerable height above, by which the shadow of the coloured filament was most distinctly projected on a white plane held below the trough, so that they were accurately drawn with a pencil. A few important particulars may be here mentioned.

The still water ADC, fig. 11, lasted for a long while before it was renewed; and it seemed to be gradually wasted by abrasion, by the adhesion of the surrounding water, which gradually licked away the outer parts from D to A and B; and it seemed to renew itself in the direction CD, opposite to the motion of the stream. There was, however, a considerable intricacy and eddy in this motion. (seemingly superficial) water was continually, but slowly, flowing outward from the line DC, while other water was seen within and below it, coming inwards and going backwards.

The coloured lateral filaments were most constant in their form, while the body was the same, although the velocity was in some cases quadrupled. Any change which this produced seemed confined to the superficial filament.

As the filaments were deflected, they were also constipated, that is, the curved parts of the filaments were nearer each other than the parallel straight filaments up the stream; and this constipation was more considerable as the prow was more obtuse and the deflexion greater.

The inner filaments were ultimately more deflected than those without them; that is, if a line be drawn touching the curve EFIH in the point H of contrary flexure, where the concavity begins to be on the side next the body, the angle HK, contained between the axis and the tangent line, is so much the greater as the filament is nearer the axis.

When the body exposed to the stream was a box of upright sides, flat bottom, and angular prow, like a wedge, having its edge also upright, the filaments were not all deflected laterally, as theory would make us expect; but the filaments near the bottom were also deflected downwards as well as laterally, and glided along at some distance under the bottom, forming lines of double curvature.

The breadth of the stream that was deducted was much greater than that of the body; and the sensible deflection began at a considerable distance up the stream, especially in the outer filaments.

Lastly, the form of the curves was greatly influenced by the proportion between the width of the trough and that of the body. The curvature was always less when the trough was very wide in proportion to the body.

Great varieties were also observed in the motion or velocity of the filaments. In general, the filaments increased in velocity outwards from the body to a certain small distance, which was nearly the same in all cases, and then diminished all the way outward. This was observed by inequalities in the colour of the filaments, by which one could be observed to outstrip another. The retardation of those next the body seemed to proceed from friction; and it was imagined that without this the velocity there would always have been greater.

These observations give us considerable information respecting the mechanism of these motions, and the action of fluids upon solids. The pressure in the duplicate ratio of the velocities comes here again into view. We found, that although the velocities were very different, the curves were precisely the same. Now the observed pressures arise from the transverse forces by which each particle of a filament is retained in its curvilinear path; and we know that the force by which a body is retained in any curve is directly as the square of the velocity, and inversely as the radius of curvature. The curvature, therefore, remaining the same as the transverse force, and consequently the pressure on the body, must be as the square of the velocity; and, on the other hand, we can see pretty clearly (indeed it is rigorously demonstrated by d'Alembert), that whatever be the velocities, the curves will be the same. For it is known in hydraulics, that it requires a fourfold or ninefold pressure to produce a double or triple velocity. And as all pressures are propagated through a perfect fluid without diminution, this fourfold pressure, while it produces a double velocity, produces also fourfold transverse pressures, which will retain the particles, moving twice as fast, in the same curvilinear paths. And thus we see that the impulses, as they are called, and resistances of fluids, have a certain relation to the weight of a column of fluid, whose height is the height necessary for producing the velocity. How it happens that a plane surface, immersed in an extended fluid, sustains just half the pressure which it would have sustained had the motions been such as are sketched in fig. 7th, is a matter of more curious and difficult investigation. But we see evidently that the pressure must be less than what is there assigned; for the stagnant water ahead of the body greatly diminishes the ultimate deflections of the filaments:

And it may be demonstrated, that when the part BE of the canal, fig. 10, is inclined to the part AB in an angle less than 90°, the pressures BG along the whole canal are as the versed sine of the ultimate angle of deflection, or the versed sine of the angle which the part BF makes with the part AB. Therefore, since the deflections resemble more the sketch given in fig. 11, the accumulated sum of all these forces BG of fig. 10, must be less than the similar sum corresponding to fig. 7, that is, less than the weight of the column of fluid, having twice the productive height for its height. How it is just one half, shall be our next inquiry.
RESISTANCE OF FLUIDS.

And here we must return to the labours of Sir Isaac Newton. After many beautiful observations on the nature and mechanism of continued fluids, he says, that the resistance which they occasion is but one half of that occasioned by the rare fluid which had been the subject of his former proposition; "which truth," (says he, with his usual caution and modesty), "I shall endeavour to show."

He then enters into another, as novel and as difficult an investigation, viz. the laws of hydrodynamics, and endeavors to ascertain the motion of fluids through orifices when urged by pressures of any kind. He endeavors to ascertain the velocity with which a fluid escapes through a horizontal orifice in the bottom of a vessel, by the action of its weight, and the pressure which this vein of fluid will exert on a little circle which occupies part of the orifice. To obtain this, he employs a kind of approximation and trial, of which it would be extremely difficult to give an extract; and then, by increasing the diameter of the vessel and of the hole to infinity, he accommodates his reasoning to the case of a plane surface exposed to an indefinitely extended stream of fluid; and, lastly, giving to the little circular surface the motion which he had before ascribed to the fluid, he says, that the resistance to a plane surface moving through an unelastic fluid, is equal to the weight of a column of the fluid whose height is one-half of that necessary for acquiring the velocity; and he says, that the resistance of a globe is, in this case, the same with that of a cylinder of the same diameter. The resistance, therefore, of the cylinder or circle is four times less, and that of the globe is twice less than their resistance on a rare elastic fluid.

But the determination, though founded on principles or assumptions, which are much nearer to the real state of things, is liable to great objections. It depends on his method for ascertaining the velocity of the issuing fluid; a method extremely ingenious, but defective. The cataract, which he supposes, cannot exist as he supposes, descending by the full action of gravity, and surrounded by a funnel of stagnant fluid. For, in such circumstances, there is nothing to balance the hydrostatical pressure of this surrounding fluid; because the whole pressure of the central cataract is employed in producing its own descent. In the next place, the pressure which he determines is beyond all doubt one half of what is observed on a plane surface in all our experiments. And, in the third place, it is repugnant to all our experience, that the resistance of a globe or of a pointed body is as great as that of its circular base. His reasons are by no means convincing. He supposes them placed in a tube or canal; and since they are supposed of the same diameter, and therefore leave equal spaces on their sides, he concludes, that because the water escapes by their sides with the same velocity, they will have the same resistance. But this is by no means a necessary consequence. Even if the water should be allowed to exert equal pressures on them, the pressures being perpendicular to their surfaces, and these surfaces being inclined to the axis, while in the case of the base of a cylinder, it is in the direction of the axis, there must be a difference in the accumulated or compound pressure in the direction of the axis. He indeed says, that in the case of the cylinder or the circle obstructing the canal, a quantity of water remains stagnant on its upper surface; viz. all the water whose motion would not contribute to the most ready passage of the fluid between the cylinder and the sides of the canal or tube; and that this water may be considered as frozen. If this be the case, it is indifferent what is the form of the body that is covered with this mass of frozen or stagnant water. It may be a hemisphere or a cone; the resistance will be the same. But Newton by no means, assigns, either with precision or with distinct evidence, the form and magnitude of this stagnant water, so as to give confidence in the results. He contents himself with saying, that it is that water whose motion is not necessary or cannot contribute to the most easy passage of the water.

There remains, therefore, many imperfections in this theory. But notwithstanding these defects, we cannot disregard the efforts and sagacity of this great philosopher, who, after having discovered so many sublime truths of mechanical nature, ventured to trace out a path for the solution of a problem which no person had yet attempted to bring within the range of mathematical investigation. And his solution, though inaccurate, shines throughout with that inventive genius and that fertility of resource, which no man ever possessed to so eminent a degree.

Those who have attacked the solution of Sir Isaac Newton have not been more successful. Most of them, instead of principles, have given a great deal of calculus; and the chief merit which any of them can claim, is that of having deduced some single proposition which happens to quadrat with some single case of experiment, while their general theories are either inapplicable, from difficulty and obscurity, or are discordant with more general observation.

We must, however, except from this number Daniel Bernoulli, who was not only a great geometer, but one of the first philosophers of the age. He possessed all the talents, and was free from the faults of that celebrated family; and while he was the mathematician of Europe who penetrated farthest in the investigation of this great problem, he was the only person who felt, or at least who acknowledged, its great difficulty.

In the 2d volume of the Comment, Petropol. 1727, he proposes a formula for the resistance of fluids, deduced from considerations quite different from those on which Newton founded his solution. But he delivers it with modest diffidence; because he found that it gave a resistance four times greater than experiment. In the same dissertation he determines the resistance of a sphere to be one half of that of its great circle. But in his subsequent treatise of Hydrodynamics, a work which must ever rank among the finest productions of the age, and is equally eminent for refined and elegant mathematics, and ingenious and original thoughts in dynamics, he calls this determination in question. It is indeed founded on the same hypothetical principles which have been unskillfully detached from the rest of Newton's physics, and made the groundwork of all the subsequent theories on this subject.

In 1741, Mr Daniel Bernoulli published another dissertation (in the 8th volume of the Com. Petropol.) on the action and resistance of fluids, limited to a very particular case; namely, to the impulse of a vein of fluid passing.
RE SISTANCE OF FLUIDS.

Fluid falling perpendicularly on an infinitely extended plane surface. This he demonstrates to be equal to the weight of a column of the fluid whose base is the area of the vein, and whose height is twice the fall producing the velocity. This demonstration is drawn from the true principles of mechanics and the acknowledged laws of hydraulics, and may be received as a strict physical demonstration. As it is the only proposition in the whole theory that has as yet received a demonstration accessible to readers not versant in all the refinements of modern analysis; and as the principles on which it proceeds will undoubtedly lead to a solution of every problem which can be proposed, once that our mathematical knowledge shall enable us to apply them—we think it our duty to give it in this place, although we must acknowledge, that this problem is so very limited, that it will hardly bear an application to any case that differs but a little from the express conditions of the problem. There do occur cases however in practice, where it may be applied to very great advantage.

Daniel Bernoulli gives two demonstrations; one of which may be called a popular one, and the other is more scientific and introductory to further investigation. We shall give both.

Bernoulli first determines the whole action, exerted in the efflux of the vein of fluid. Suppose the velocity of efflux v, which would be acquired by falling through the height h. It is well known that a body moving during the time of this fall with the velocity v would describe a space $\frac{1}{2}h$. The effect, therefore, of the hydraulic action is, that in the time t of the fall h, there issues a cylinder or prism of water whose base is the cross section a or area of the vein, and whose length is 2h. And this quantity of matter is now moving with the velocity v. The quantity of motion, therefore, which is thus produced is $2ahv$; and this quantity of motion is produced in the time t. And this is the accumulated effect of all the expelling forces, estimated in the direction of the efflux. Now, to compare this with the exertion of some pressing power with which we are familiarly acquainted, let us suppose this pillar $2ah$ to be frozen, and, being held in the hand, to be dropped. It is well known, that in the time t it will fall through the height h, and will acquire the velocity v, and now possesses the quantity of motion $2ahv$—and all this is the effect of its weight. The weight, therefore, of the pillar $2ah$ produces the same effect, and in the same time, and (as may easily be seen) in the same gradual manner, with the expelling forces of the fluid in the vessel, which expelling forces arise from the pressure of all the fluid in the vessel. Therefore the accumulated hydraulic pressure, by which a vein of a heavy fluid is forced out through an orifice in the bottom or side of a vessel, is equal (when estimated in the direction of the efflux) to the weight of a column of the fluid, having for its base the section of the vein, and twice the fall productive of the velocity of efflux for its height.

Now let $\triangle ABC$ (fig. 12.) be a quadrangular vessel with upright plane sides, in one of which is an orifice $EF$. From every point of the circumference of this orifice, suppose horizontal lines $E_1, F_1, &c.$ which will mark a similar surface on the opposite side of the vessel. Suppose the orifice $EF$ to be shut. There can be no doubt but that the surfaces $EF$ and $E_1F_1$ will be equally pressed in opposite directions. Now open the orifice $EF$; the water will rush out, and the pressure on $EF$ is now removed. There will therefore be a tendency in the vessel to move in the direction $Ee$. And this tendency must be precisely equal and opposite to the whole effort of the expelling forces. This is a conclusion as evident as any proposition in mechanics. It is, thus that a gun recoils and a rocket rises in the air; and on this is founded the operation of Mr. Papens or Dr. Barker's mill, described in all treatises of mechanics, and most learnedly treated by Euler in the Berlin Memoirs.

Now, let this stream of water be received on a circular plane MN, perpendicular to its axis, and let this circular plane be of such extent, that the vein escapes from its sides in an infinitely thin sheet, the water flowing off in a direction parallel to the plane. The vein by this means will expand into a trumpet-like shape, having curved sides, $EKG, FLH$, fig. 13. We abstract at present the action of gravity which would cause the vein to bend downwards, and occasion a greater velocity at $H$ than at $G$; and we suppose the velocity equal in every part of the circumference. It is plain, that if the action of gravity be neglected after the water has issued through the orifice $EF$, the velocity in every point of the circumference of the plane MN will be that of the efflux through $EF$.

Now, because $EKG$ is the natural shape assumed by the vein, it is plain, that if the whole vein were covered by a tube or mouth-piece, fitted to its shape, and perfectly polished, so that the water shall slide along it, without any friction (a thing which we may always suppose), the water will exert no pressure whatever on this trumpet mouth-piece. Lastly, let us suppose that the plane MN is attached to the mouth-piece by some bits of wire, so as to allow the water to escape all round by the narrow chink between the mouth-piece and the plane: We have now a vessel consisting of the upright part $\triangle ABC$, the trumpet $\triangle GKEFLH$, and the plane MN; and the water is escaping from every point of the circumference of the chink $\triangle GHN M$ with the velocity v. If any part of this chink were shut up, there would be a pressure on that part equivalent to the motion of efflux from the opposite part. Therefore, when all is open, these efforts of efflux balance each other all round. There is not therefore any tendency in this compound vessel to move to any side. But take away the plane MN, and there would immediately arise a pressure in the direction $Ee$ equal to the weight of the column $2ah$. This is therefore balanced by the pressure on the circular plane MN, which is therefore equal to this weight, and the proposition is demonstrated.

A number of experiments were made by Professor Kraft at St. Petersburg, by receiving the vein on a plane MN (fig. 12.) which was fastened to the arm of a balance $OPQ$, having a scale R hanging on the opposite arm. The resistance or pressure on the plane was measured by weights put into the scale R; and the velocity of the jet was measured by means of the distance $KH$, to which it spouted on a horizontal plane.

The results of these experiments were as conformable to the theory as could be wished. The resistance was always a little less than what the theory required, and expen-

Difference between this theory and the exact results on which it is founded, greatly exceeded its half; the result of the generally received theories. This defect should be expected; for cound of the or.
Resist. by theory 1701 1710 1631 1524 1428 1372
Resist. by experiment 1425 1475 1456 14 x 14.3 1421

In order to demonstrate this proposition in such a manner as to furnish the means of investigating the whole mechanism and action of moving fluids, it is necessary to prove an elementary theorem of curvilinear motion.

If a particle of matter describe a curve line ABCDE (fig. 14.) by the continual action of deflecting forces, which vary in any manner, both with respect to intensity and direction, and if the action of these forces, in every point of the curve, be resolved into two directions, perpendicular and parallel to the initial direction AK; then,

1. The accumulated effect of the deflecting forces, estimated in a direction AD perpendicular to AK, is to the final quantity of motion as the sine of the final change of direction is to radius.

Let us first suppose that the deflecting forces act by starts, at equal intervals of time, when the body is in the points A, B, C, E. And let AN be the deflecting force, which, acting at A, changes the original direction AK to AB. Produce AB till BH = AB, and complete the parallelogram BFC. Then BF is the force which, by acting at B, changes the motion BH (the continuation of AB) to BC. In like manner make CA (in the direction of the particle of matter) equal to BC, and complete the parallelogram CFA. CF is the deflecting force at C, &c.

Draw BO parallel to AN, and GBK perpendicular to AK. Also draw lines through C and E perpendicular to AK, and draw through B and C lines parallel to AK. Also draw also H, H, h, i parallel to AK.

It is plain that BK = BO or AN estimated in the direction perpendicular to AK, and that BG = BF estimated in the same way. And since BH = AB, H or IM is equal to BK. Also CI is equal to BG.

Therefore CM = equal to AP. By similar reasoning it appears that E = E + h + i = GKH. Therefore CE = equal to BG = AP. Therefore if CE be taken for the measure of the final velocity or quantity of motion, \( E \) will be the accumulated effect of the deflecting forces estimated in the direction AD perpendicular to AK. But \( E \) is to CE as the sine of \( CE \) is to radius; and the angle \( CE \) is the angle contained between the initial and final directions, because CM is parallel to AK. Now let the intervals of time diminish continually and the frequency of the impulses increase. The deflection becomes ultimately continuous, and the motion curvilinear, and the proposition is demonstrated.

We see that the initial velocity and its subsequent changes do not affect the conclusion, which depends entirely on the final quantity of motion.

2. The accumulated effect of the accelerating forces, when estimated in the direction AK of the original motion, or in the opposite direction, is equal to the difference between the initial quantity of motion and the product of the final quantity of motion by the cosine of the change of direction.

For \( C = C \), \( m = M \), \( f = F \), \( B = B \), \( M = M \), \( L = A K = F G \), \( A K = A O = O = P N \).

Therefore \( P N + F G + Q \) (the accumulated impulse in the direction \( O A = A O - C M = A O - C E \times \cos \) sine of \( E C M \).

Cor. 1. The same action, in the direction opposite to that of the original motion, is necessary for causing a body to move at right angles to its former direction as for stopping its motion. For in this case, the cosine of the change of direction is \( = 0 \), and \( A O - C E \times \cos = 0 \), \( = A O \), \( = A O \) the original motion.

Cor. 2. If the initial and final velocities are the same, the accumulated action of the accelerating forces, estimated in the direction of \( O A \), is equal to the product of the original quantity of motion by the versed sine of the change of direction.

The application of these theorems, particularly the second, to our present purpose is very obvious. All the filaments of the jet were originally moving in the direction of its axis, and they are finally moving along the resisting plane, or perpendicular to their former motion. Therefore their transverse forces in the direction of the axis are (in cumulo) equal to the force which would stop the motion. For the aggregate of the simultaneous forces of every particle in the whole filament is the same with that of the successive forces of one particle, as it arrives at different points of its curvilinear path. All the transverse forces, estimated in a direction perpendicular to the axis of the vein, precisely balance and sustain each other; and the only forces which can produce a sensible effect are those in a direction parallel to the axis. By these all the inner filaments are pressed towards the plane MN, and must be withstood by it. It is highly probable, nay certain, that there is a quantity of stagnant water in the middle of the vein which sustains the pressures of the moving filaments without it, and transmits it to the solid plate. But this does not alter the case. And, fortunately, it is of no consequence what changes happen in the velocities of the particles while each is describing its own curve. And it is from this circumstance, peculiar to this particular case of perpendicular impulse, that we are able to draw the conclusion. It is by no means difficult to demonstrate that the velocity of the external surface of this jet is constant, and indeed of every jet which is not acted on by external forces after it has quitted the orifice: but this discussion is quite unnecessary here. It is however extremely difficult to ascertain, even in this most simple case, what is the velocity of the internal filaments in the different points of their progress.
Such is the demonstration which Mr. Bernoulli has given of this proposition. Limited as it is, it is highly valuable, because derived from the true principles of hydraulics.

He hoped to render it more extensive and applicable to oblique impulses, when the axis AC of the vein (Fig. 15) is inclined to the plane in an angle of ACN. But here all the simplicity of the case is gone, and we are now obliged to ascertain the motion of each filament. It might not perhaps be impossible to determine what must happen in the plane of the figure, that is, in a plane passing through the axis of the vein, and perpendicular to the plane MN. But even in this case it would be extremely difficult to determine how much of the fluid will go in the direction EKG, and what will go in the path FLH, and to ascertain the form of each filament, and the velocity in its different points. But in the real state of the case, the water will dissipate from the centre C on every side; and we cannot tell in what proportions. Let us however consider a little what happens in the plane of the figure, and suppose that all the water goes either in the course EKG or in the course FLH. Let the quantities of water which take these two courses have the proportions of p and μ. Let \( \sqrt{2a} \) be the velocity at A, \( \sqrt{2b} \) the velocity at G, and \( \sqrt{2b} \) the velocity at H. ACG and ACH are the two changes of direction, of which let c and \(-c\) be the cosines. Then, adopting the former reasoning, we have the pressure of the watery plate GKEGM on the plane in the direction AC = \( \frac{p}{\mu} \times 2a - 2c \), and the pressure of the plane HLFACN = \( \frac{p}{\mu} \times 2a - 2c \), and their sum

\[ \frac{p}{\mu} \times 2a - 2c + \frac{p}{\mu} \times 2a - 2c \]

which being multiplied by the sine of ACM, or \( \sqrt{1 - c^2} \), gives the pressure perpendicular to the plane MN = \( \frac{p}{\mu} \times 2a - 2c \) plus \( \frac{p}{\mu} \times 2a \)

\[ \sqrt{1 - c^2} \]

But there remains a pressure in the direction perpendicular to the axis of the vein, which is not balanced, as in the former case, by the equality on opposite sides of the axis. The pressure arising from the water which escapes at G has an effect opposite to that produced by the water which escapes at H. When this is taken into account, we shall find that their joint efforts perpendicular to AC are \( \frac{p}{\mu} \times 2a \sqrt{1 - c^2} \), which being multiplied by the cosine of ACM, gives the action perpendicular to MN = \( \frac{p}{\mu} \times 2ac \sqrt{1 - c^2} \).

The sum or joint effort of all these pressures is

\[ \frac{p}{\mu} \times 2a - 2c \sqrt{1 - c^2} + \frac{p}{\mu} \times 2a \sqrt{1 - c^2} \]

Thus, from this case, which is much simpler than can happen in nature, seeing that there will always be a lateral efflux, the determination of the impulse is as uncertain and vague as it was sure and precise in the former case.

It is therefore without proper authority that the absolute impulse of a vein of fluid on a plane which receives it wholly, is asserted to be proportional to the sine of incidence. If indeed we suppose the velocity in G and H are equal to that at A, then \( b = b \), \(-a\), and the whole impulse is \( 2a \sqrt{1 - c^2} \), as is commonly supposed. But this cannot be. Both the velocity and quantity at H are less than those at G. Nay, frequently there is no efflux on the side H when the obliquity is very great. We may conclude in general, that the oblique impulse will always bear to the direct impulse a greater proportion than that of the sine of incidence to radius. If the whole water escapes at G, and none goes off laterally, the pressure will be \( 2a + 2a \sqrt{1 - c^2} \). The experiments of the Abbé Bosset show in the plainest manner that the pressure of a vein, striking obliquely on a plane which receives it wholly, diminishes faster than in the ratio of the square of the sine of incidence; whereas, when the oblique plane is wholly immersed in the stream, the impulse is much greater than in this proportion, and in great obliquities is nearly as the sine.

Nor will this proposition determine the impulse of a fluid on a plane wholly immersed in it, even when the impulse is perpendicular to the plane. The circumstances are now wanting on which we can establish a calculation, namely, the angle of final deflection. Could this be ascertained for each filament, and the velocity of the filament, the principles are completely adequate to an accurate solution of the problem. In the experiments which were mentioned to have been made under the inspection of Sir Charles Knowles, a cylinder of six inches diameter was exposed to the action of a stream moving precisely one foot per second; and when certain deductions were made for the water which was held adhering to the posterior base (as will be noticed afterwards), the impulse was found equal to 3\( \frac{1}{4} \) ounces avoirdupois. There were 36 coloured filaments distributed on the stream, in such situations as to give the most useful indications of their curvature. It was found necessary to have some which passed under the body and some above it; for the form of these filaments, at the same distance from the axis of the cylinder, was considerably different: and those filaments which were situated in planes neither horizontal nor vertical took a double curvature. In short, the curves were all traced with great care, and the deflecting forces were computed for each and reduced to the direction of the axis; and they were summed up in such a manner as to give the impulse of the whole stream. The deflections were marked as far as a head of the cylinder as they could be as-usually observed. By this method the impulse was computed to be 2\( \frac{1}{8} \) ounces, differing from observation \( \frac{1}{4} \) of an ounce, or about \( \frac{1}{8} \) of the whole; a difference which may most reasonably be attributed to the adhesion of the water, which must be most sensible in such small velocities. These experiments may therefore be considered as giving all the confirmation that can be desired of the justness of the principles. This indeed hardly admits of a doubt: but, alas! it gives but small assistance; for all this is empirical, in as far as it leaves us in every case the task of observing the form of the curves and
and the velocities in their different points. To derive service from this most judicious method of Daniel Bernoulli, we must discover some method of determining, à priori, what will be the motion of the fluid whose course is obstructed by a body of any form. And here we cannot omit taking notice of the casual observations of Sir Isaac Newton when attempting to determine the resistance of the plane surface or cylinder, or sphere exposed to a stream moving in a canal. He says, that the form of the resistant surface is of less consequence, because there is always a quantity of water stagnant upon it, and which may therefore be considered as frozen; and he therefore considers that water only whose motion is necessary for the most expeditious discharge of the water in the vessel. He endeavours to discriminate that water from the rest; and although it must be acknowledged that the principle which he assumes for this purpose is very gratifying, because it only shows, that if certain portions of the water, which he determines very ingeniously, were really frozen, the rest will issue, as he says, and will exert the pressure which he assigns; still we must admire his fertility of resource, and his sagacity in thus foreseeing what subsequent observation has completely confirmed. We are even disposed to think, that in this casual observation Sir Isaac Newton has pointed out the only method of arriving at a solution of the problem; and that, if we could discover what motions are not necessary for the most expeditious passage of the water, and could thus determine the form and magnitude of the stagnant water which adheres to the body, we should much more easily ascertain the real motions which occasion the observed resistance. We are here disposed to have recourse to the economy of nature, the improper use of which we have sometimes taken the liberty of reprehending. Mr. Maupertuis published as a great discovery his principle of smallest action, where he showed that in all the mutual actions of bodies the quantity of action was a minimum; and he applied this to the solution of many difficult problems with great success, imagining that he was really reasoning from a contingent law of nature, selected by its infinitely wise Author, viz. that on all occasions there is the smallest possible exertion of natural powers. Mr. D'Alembert has, however, shown (vid. Encyclopédie Françoise, Action) that this was but a whim, and that the minimum observed by Maupertuis is merely a minimum of calculation, peculiar to a formula which happens to express a combination of mathematical quantities which frequently occurs in our way of considering the phenomena of nature, but which is no natural measure of action.

But the chevalier D'Arcy has shown, that in the trains of natural operations which terminate in the production of motion in a particular direction, the intermediate communications of motion are such that the smallest possible quantity of motion is produced. We seem obliged to conclude, that this law was heeded in the present instance; and it seems a problem not above our reach to determine the motions which result from it. We would recommend the problem to the eminent mathematicians in some simple case, such as the proposition already demonstrated by Daniel Bernoulli, or the perpendicular impulse on a cylinder included in a tubular canal; and if they succeed in this, great things may be expected. We think that experience gives great encouragement. We see that the resistance to a plane surface is a very small matter greater than the weight of an equal volume of a column of the fluid having the full productive of the velocity for its height, and the small excess is most probably owing to adhesion, and the measure of the real resistance is probably precisely this weight. The velocity of a spouting fluid was found, in fact, to be that acquired by falling from the surface of the fluid; and it was by looking at this, as at a pole star, that Newton, Bernoulli, and others, have with great sagacity and ingenuity discovered much of the laws of hydraulics, by searching for principles which would give this result. We may hope for similar success.

In the mean time, we may receive this as a physical truth, that the perpendicular impulse or resistance of a plane surface, wholly immersed in the fluid, is equal to the weight of the column having the surface for its base, and the fall producing the velocity for its height.

This is the medium result of all experiments made in these precise circumstances. And it is confirmed by a set of experiments of a kind wholly different, and which seem to point it out more certainly as an immediate consequence of hydraulic principles.

If Mr. Pitot's tube be exposed to a stream of fluid issuing from a reservoir or vessel, as represented in fig. 16 with the open mouth P pointed directly against this stream, the fluid is observed to stand at K in the upright tube, precisely on a level with the fluid AB in the reservoir. Here is a most unexceptionable experiment, in which the impulse of the stream is actually opposed to the hydrostatical pressure of the fluid on the tube. Pressure is in this case opposed to pressure, because the issuing fluid is deflected by what stays in the mouth of the tube, in the same way in which it would be deflected by a firm surface. We shall have occasion by and by to mention some most valuable and instructive experiments made with this tube.

It was this which suggested to the great mathematician Euler another theory of the impulse and resistance of fluids, which must not be omitted, as it is applied in his elaborate performance On the Theory of the Construction and Working of Ships, in two volumes 4to, which was afterwards abridged and used as a text-book in some marine academies. He supposes a stream of fluid ABCD (fig. 17.), moving with any velocity, to strike the plane BD perpendicularly, and that part of it goes through a hole EF, forming a jet EGHF. Mr. Euler says, that the velocity of this jet will be the same with the velocity of the stream. Now compare this with an equal stream issuing from a hole in the side of a vessel with the same velocity. The one stream is urged out by the pressure occasioned by the impulse of the fluid; the other is urged out by the pressure of gravity. The effects are equal, and the modifying circumstances are the same. The causes are therefore equal, and the pressure occasioned by the impulse of a stream of fluid, moving with any velocity, is equal to the weight of a column of fluid whose height is productive of this velocity, &c. He then determines the oblique impulse by the resolution of motion, and deduces the common rules of resistance, &c.

But all this is without just grounds. This gentleman was always satisfied with the slightest analogies which would give him an opportunity of exhibiting his great
Resistance of Fluids.

...great dexterity in algebraic analysis, and was not afterwards startled by any discordancy with observation. Analysis magis fidendum is a frequent assertion with him.

Though he wrote a large volume, containing a theory of light and colours totally opposite to Newton's, he has published many dissertations on optical phenomena on the Newtonian principles, expressly because his own principles non ideo facile ansam praebat analysis inmedium.

Not a shadow of argument is given for the leading principle in this theory, viz. that the velocity of the jet is the same with the velocity of the stream. None can be given, but saying, that the pressure is equivalent to its production; and this is assuming the very thing he labours to prove. The matter of fact is, that the velocity of the jet is greater than that of the stream, and may be greater almost in any proportion. Which curious circumstance was discovered and ingeniously explained long ago by Daniel Bernoulli in his Hydrodynamica. It is evident that the velocity must be greater.

We are disposed to think that, in a fluid perfectly incompressible, the velocity will be double, or at least increased in the proportion of 1 to $\sqrt{2}$. If the fluid is in the smallest degree compressible, even in the very small degree that water is, the velocity at the first impulse may be much greater. D. Bernoulli found that a column of water moving 5 feet per second, in a tube some hundred feet long, produced a velocity of 135 feet per second in the first moment.

There being this radical defect in the theory of Mr. Euler, it is needless to take notice of its total insufficiency for explaining oblique impulses and the resistance of curvilinear plans.

We are extremely sorry that our readers are deriving so little advantage from all that we have said; and that having taken them by the hand, we are thus obliged to give up, with only a few scattered rays of light, to direct our steps. Let us see what assistance we can get from Mr. d'Alembert, who has attempted a solution of that problem in a method entirely new and extremely ingenious. He saw clearly, that all the followers of Newton had forsaken the path which he had marked out for them in the second part of his investigation, and that merely amused themselves with the mathematical discussion with which his introductory hypothesis gave them an opportunity of occupying themselves. He paid the deserved tribute of applause to Daniel Bernoulli for having introduced the notion of pure pressure as the chief agent in this business; and he saw that he was in the right road, and that it was from hydrostatical principles alone that we had any chance of explaining the phenomena of hydrostatics. Bernoulli had only considered the pressures which were excited in consequence of the curvilinear motions of the particles. Mr. d'Alembert even thought that these pressures were not the consequences, but the causes, of these curvilinear motions. No internal motion can happen in a fluid of Fluids; but in consequence of an unbalanced pressure; and every such motion will produce an inequality of pressure, which will determine the succeeding motions. He therefore endeavoured to reduce all to the discovery of those disturbing pressures, and thus to the laws of hydrostatics.

In whatever manner any number of bodies are supposed to act on each other, and by these actions come to change their present motions, if we conceive that the motion which each body would have in the following instant (it it became free), is resolved into two other motions; one of which is the motion which it really takes in the following instant; the other will be such, that if each body had no other motion but this second, the whole bodies would have remained in equilibrio.

We here observe, that the motion which each body would have in the following instant, if it continued as it is, is a continuation of the motion which it has in the first instant. It may therefore perhaps be better expressed thus:

If the motions of bodies, anyhow acting on each other, be considered in two consecutive instants, and if we conceive the motion which it has in the first instant as compounded of two others, one of which is the motion which it actually takes in the second instant, the other is such, that if each body had only those second motions, the whole system would have remained in equilibrio.

The proposition itself is evident. For if these motions be not such as that an equilibrium of the whole system would result from them, the other component motions would not be those which the bodies really have after the change; for they would necessarily be altered by these unbalanced motions. See D'Alembert Essai de Dynamique.

Assisted by this incontestable principle, M. d'Alembert demonstrates, in a manner equally easy and simple, those propositions which Newton had so curiously deduced from his hypothetical fluid, showing that they were not limited to this hypothesis, viz. that the motions produced by similar bodies, similarly projected in them, would be similar; that whatever were the pressures, the curves described by the particles would be the same; and that the resistances would be proportional to the squares of the velocities. He then comes to consider the fluid as having its motions constrained by the form of the canal or by solid obstacles interposed.

We shall here give a summary account of his fundamental proposition.

It is evident, if the body ADCE (fig. 18.) did not form an obstruction to the motion of the water, the account of particles would describe parallel lines TF, OK, PS, &c., mental pro...
RESISTANCE OF FLUIDS.

Curvature will be insensible, and the fluid included in the space ZYHQ will move uniformly as if the solid body were not there. The motions on the other side of the axis AC will be the same; and we need only attend to one-half, and we shall consider these as in a state of permanency.

No body changes either its direction or velocity otherwise than by insensible degrees: therefore the particle which is moving in the axis will not reach the vertex A of the body, where it behaved to deflect instantaneously at right angles. It will therefore begin to be deflected at some point F a-head of the body, and will describe a curve FM, touching the axis in F, and the body in M; and then, gliding along the body, will quit it at some point L, describing a tangent curve, which will join the axis again (touching it) in R; and thus there will be a quantity of stagnant water FAM before or a head of the body, and another LCPR behind or astern of it.

Let a be the velocity of a particle of the fluid in any instant, and a" its velocity in the next instant. The velocity a may be considered as composed of a' and a". If the particles tended to move with the velocities a" only, the whole fluid would be in equilibrium (general principles), and the pressure of the fluid would be the same as if all were stagnant, and each particle were urged by a force 
\[ \frac{a'}{t} \]
expressing an indefinitely small moment of time. (N.B. \( \frac{a''}{t} \) is the proper expression of the accelerating force, which, by acting during the moment t, would generate the velocity a'; and a" is supposed an indeterminate quantity, different perhaps for each particle). Now let a be supposed constant, or a \( \equiv \alpha \). In this case a" \( \equiv \alpha \). That is to say, no pressure whatever will be exerted on the solid body unless there happen changes in the velocities or directions of the particles.

Let a and a' be the motions of the particles in two consecutive instants. They would be in equilibrium if urged only by the force \( \frac{a'}{t} \). Therefore if a be the point where the particles which describe the curve FM begin to change their velocity, the pressure in D would be equal to the pressure which the fluid contained in the canal \( \gamma \) FMD would exert, if each particle were solicited by its force \( \frac{a'}{t} \). The question is therefore reduced to finding the curvature in the canal \( \gamma \) FMD, and the accelerating forces \( \frac{a'}{t} \) in its different parts.

It appears, in the first place, that no pressure is exerted by any of the particles along the curve FM: for suppose that the particle a (fig. 19) describes the indefinitely small straight line ab in the first instant, and bc in the second instant; produce ab till b'd = a'b; and joining dc, the motion ab or bd may be considered as composed of bc, which the particle really takes in the next instant, and a motion dc which should be destroyed. Draw bi parallel to dc, and ic perpendicular to bc. It is plain that the particle b, solicited by the forces be, ei (equivalent to dc) should be in equilibrium. This being established, bc must be \( \equiv 0 \), that is, there will be no accelerating or retarding force at b; for if there be, draw bm (fig. 20) perpendicular to bF, and the same parallel aq infinitely near it. The part bn of the fluid contained in the canal nq m would sustain some pressure from n towards n, or from n towards b. Therefore since the fluid in this stagnant canal should be in equilibrium, there must also be some action, at least in one of the parts bm, m q, n q, to counterbalance the action on the part bn. But the fluid is stagnant in the space FAM (in consequence of the law of continuity). Therefore there is no force which can act on bm, m q, n q; and the pressure in the canal in the direction bn or n b is nothing, or the force b e = 0, and the force it is perpendicular to the canal; and there is therefore no pressure in the canal FM, except what proceeds from the part \( \gamma \) F, or from the force e i; which last being perpendicular to the canal, there can be no force exerted on the point M, but what is propagated from the part \( \gamma \) F.

The velocity therefore in the canal FM is constant if finite, or indefinitely small if variable: for, in the first case, the force be would be absolutely nothing; and in the second case, it would be an infinitesimal of the second order, and may be considered as nothing in comparison with the velocity, which is of the first order. We shall see by and by that the last is the real state of the case. Therefore the fluid, before it begins to change its direction in F, begins to change its velocity in some point \( \gamma \) a-head of F, and by the time that it reaches F its velocity is as it were annihilated. Cor. 1. Therefore the pressure in any point D arises both from the retardations in the part \( \gamma \) F, and from the particles which are in the canal MD: as these last move along the surface of the body, the force \( \frac{a'}{t} \) destroyed in every particle, is compounded of two others, one in the direction of the surface, and the other perpendicular to it; call these \( \rho \) and \( \rho' \). The point D is pressed perpendicularly to the surface MD; 1st, by all the forces \( \rho \) in the curve MD; 2d, by the force \( \rho' \) acting on the single point D. This may be neglected in comparison of the indefinite number of the others: therefore taking in the arch MD, in an infinitely small portion N m = \( \nu \), the pressure on DN, perpendicular to the surface of the body, will be \( \int \rho \, ds \); and this 
\( \int \rho \, ds \)
must be so taken as to be \( \equiv 0 \) in the point M.

Cor. 2. Therefore, to find the pressure on D, we must find the force \( \rho \) on any point N. Let \( \mu \) be the velocity of the particle N, in the direction N m in any instant, and \( \mu + \mu \) its velocity in the following instant; we must have 
\( \int \rho \, ds \) = \( \int \rho \, ds \).

Therefore the whole question is reduced to finding the velocity \( \mu \) in every point N, in the direction N m.

And this is the aim of a series of propositions which follow, in which the author displays the most accurate and precise conception of the subject, and great address and elegance in his mathematical analysis. He at length brings out an equation which expresses the pressure on the body in the most general and unexceptionable manner. We cannot give an abstract, because the train of reasoning is already concise in the extreme; nor can we even exhibit the final equation; for it is conceived in
the most refined and abstruse form of indeterminate functions, in order to embrace every possible circumstance. But we can assure our readers, that it truly expresses the solution of the problem. But, alas! it is of no use. So imperfect is our mathematical knowledge, that even Mr. d'Alembert has not been able to exemplify the application of the equation to the simplest case which can be proposed, such as the direct impulse on a plane surface wholly immersed in the fluid. All that he is enabled to do, is to apply it (by some modifications and substitutions which take it out of its state of extreme generality) to the direct impulse of a vein of fluid on a plane which deflects it wholly, and thus to show its conformity to the solution given by Daniel Bernoulli, and to observation and experience. He shows, that this impulse (independent of the deficiency arising from the plane's not being of infinite extent) is somewhat less than the weight of a column whose base is the section of the vein, and whose height is twice the fall necessary for communicating the velocity. This great philosopher and geometer concludes by saying, that he does not believe that any method can be found for solving this problem that is certain and simple, and imagines, that if the deductions from it shall be found not to agree with experiment, we must give up all hopes of determining the resistance of fluids by theory and analytical calculus. He says analytical calculus; for all the physical principles on which the calculus proceeds are rigorously demonstrated, and will not admit of a doubt. There is only one hypothesis introduced in this investigation, and this is not a physical hypothesis, but a hypothesis of calculation. It is, that the quantities which determine the ratios of the second fluxions of the velocities, estimated in the directions parallel and perpendicular to the axis AC (fig. 18.) are functions of the abscissa AP, and ordinate PM of the curve. Any person, in the least acquainted with mathematical analysis, will see, that without this supposition no analysis or calculus whatever can be instituted. But let us see what is the physical meaning of this hypothesis. It is simply this, that the motion of the particle M depends on its situation only. It appears impossible to form any opinion, and if we form such an opinion, it is as clear as day light that the case is desperate, and that we must renounce all hopes.

We are sorry to bring our labours to this conclusion; but we are of opinion, that the only thing that remains is, for mathematicians to attach themselves with firmness and vigour to some simple cases; and, without aiming at generality, to apply M.'s d'Alembert's or Bernoulli's mode of procedure to the particular circumstances of the case. It is not improbable but that, in the solutions which may be obtained of these particular cases, circumstances may occur which are of a more general nature. These will be so many laws of hydraulics to be added to our present very scanty stock; and these may have points of resemblance, which will give birth to laws of still greater generality. And we repeat our expression of hopes of some success, by endeavouring to determine, in some simple cases, the minimum possible of motion. The attempts of the Jesuit commentators on the Principles do them honour, and have really given us great assistance in the particular case which came through their hands.

Vol. XVII. Part II.

And we should multiply experiments on the resistance of bodies. Those of the French academy are undoubtedly of inestimable value, and will always be appealed to. But there are circumstances in those experiments which render them more complicated than is proper for a general theory, and which therefore limit the conclusions which we wish to draw from them. The bodies were floating on the surface. This greatly modifies the deflections of the filaments of water, causing some to deflect laterally, which would otherwise have remained in one vertical plane; and this circumstance also necessarily produced what the academicians called the remon, or accumulation on the anterior part of the body, and depression behind it. This produced an additional resistance, which was measured with great difficulty and uncertainty. The effect of adhesion must also have been very considerable, and very different in the different cases; and it is of difficult calculation. It cannot perhaps be totally removed in any experiment, and it is necessary to consider it as making part of the resistance in the most important practical cases, viz. the motion of ships. Here we see that its effect is very great. Every seaman knows that the speed, and impetus of a very fast-sailed ship, is greatly increased by greasing her bottom. The difference is too remarkable to admit of a doubt; nor should we be surprised at this, when we attend to the diminution of the motion of water in long pipes. A smooth pipe four and a half inches diameter, and 500 yards long, yields but one-fifth of the quantity which it ought to do independent of friction. But adhesion does a great deal which cannot be compared with friction. We see that water flowing through a hole in a thin plate will be increased in quantity fully one-third, by adding a little tube whose length is about twice the diameter of the hole. The adhesion therefore will greatly modify the action of the filaments both on the solid body and on each other, will change both the forms of the curves and the velocities in different points; and this is a sort of objection to the only hypothesis introduced by d'Alembert. Yet it is only a sort of objection; for the effect of this adhesion, too, must undoubtedly depend on the situation of the body.

The form of these experiments of the academy is ill-adapted to the examination of the resistance of bodies wholly immersed in the fluid. The form of experiment adopted by Robins for the resistance of air, and afterwards by the chevalier Borda for water, is far from these inconveniences, and is susceptible of equal accuracy. The great advantage of both is the exact knowledge which they give us of the velocity of the motion; a circumstance essentially necessary, and but imperfectly known in the experiments of Mariotte and others, who examined quiescent bodies exposed to the action of a stream. It is extremely difficult to measure the velocity of a stream. It is very different in its different parts. It is swiftest of all in the middle superficial filament, and diminishes as we recede from this towards the sides or bottom, and the rate of diminution is not precisely known. Could this be ascertained with the necessary precision, we should recommend the following form of experiment as the most simple, easy, economical, and accurate.

Let a, b, c, d (fig. 21.) be four hooks placed in a horizontal plane at the corners of a rectangular parallelogram,
Resistance of Fluids.

66 Simple experiment for measuring the velocity of a stream.

Fig. 10.

Fig. 11.

leogram, the sides $a, b, c, d$ being parallel to the direction of the stream $ABCD$, and the sides $a, b, c, d$ being perpendicular to it. Let the body $G$ be fastened to an axis $ef$ of stiff-tempered steel-wire, so that the surface on which the fluid is to act may be inclined to the stream in the precise angle we desire. Let this axis have hooks at its extremities, which are hitched into the loops of four equal threads, suspended from the hooks $a, b, c, d$; and let $H$ be a fifth thread, suspended from the middle of the line joining the points of suspension $a, b$. Let $HIK$ be a graduated arch, whose centre is $H$, and whose plane is in the direction of the stream. It is evident that the impulse on the body $G$ will be measured (by a process well known to every mathematician) by the deviation of the thread $He$ from the vertical line $HI$; and this will be done without any intricacy of calculation, or any attention to the centres of gravity, of oscillation, or of percussion. These must be accurately ascertained with respect to that form in which the pendulum has always been employed for measuring the impulse or velocity of a stream. These advantages arise from the circumstance, that the axis $ef$ remains always parallel to the horizon. We may be allowed to observe, by the bye, that this would have been a great improvement of the beautiful experiments of Mr. Robins and Dr. Hutton on the velocities of cannon-shot, and would have saved much intricate calculation, and been attended with many important advantages.

The great difficulty is, as we have observed, to measure the velocity of the stream. Even this may be done in this way with some precision. Let two floating bodies be dragged along the surface, as in the experiments of the academy, at some distance from each other laterally, so that the water between them may not be sensibly disturbed. Let a horizontal bar be attached to them, transverse to the direction of their motion, at a proper height above the surface, and let a spherical pendulum be suspended from this, or let it be suspended from four points, as here described. Now let the deviation of this pendulum be noted in a variety of velocities. This will give us the law of relation between the velocity and the deviation of the pendulum. Now, in making experiments on the resistance of bodies, let the velocity of the stream, in the very filament in which the resistance is measured, be determined by the deviation of this pendulum.

It was greatly to be wished that some more palpable argument could be found for the existence of a quantity of stagnant fluid at the anterior and posterior parts of the body. The one already given, derived from the consideration that no motion changes either its velocity or direction by finite quantities in an instant, is unexceptionable. But it gives us little information. The smallest conceivable extent of the curve $FM$ in fig. 18, will answer this condition, provided only that it touches the axis in some point $F$, and the body in some point $M$, so as not to make a finite angle with either. But surely there are circumstances which rigorously determine the extent of this stagnant fluid. And it appears without doubt, that if there were no cohesion or friction, this space will have a determined ratio to the size of the body (the figures of the bodies being supposed similar). Suppose a plane surface $AB$, as in fig. 11, there can be no doubt but that the figure $a, b, b$ will in every case be similar. But if we suppose an infinite adhesion or tenacity which is constant, this may make a change both in its extent and its form: for its constancy of form depends on the disturbing forces being always as the squares of the velocity; and this ratio of the disturbing forces is preserved, while the inertia of the fluid is the only agent and patient in the process. But when we add to this the constant (that is, invariable) disturbing force of tenacity, a change of form and dimensions must happen. In like manner, the friction, or something analogous to friction, which produces an effect proportional to the velocity, must alter this necessary ratio of the whole disturbing forces. We may conclude, that the effect of both these circumstances will be to diminish the quantity of this stagnant fluid, by licking it away externally; and to this we must ascribe the fact, that the part $FAM$ is never perfectly stagnant, but is generally disturbed with a whirling motion.

We may also conclude, that this stagnant fluid will be more incurved between $F$ and $M$ than it would have been, independent of tenacity and friction; and that the arch $LR$ will, on the contrary, be less incurved. And, lastly, we may conclude, that there will be something opposite to pressure, or something which we may call abstraction, exerted on the posterior part of the body which moves in a tenacious fluid, or is exposed to the stream of such a fluid; for the stagnant fluid $LCR$ adheres to the surface $LC$, and the passing fluid tends to draw it away both by its tenacity and by its friction. This must augment the apparent impulse of the stream on such a body; and it must greatly augment the resistance, that is, the motion lost by the body in its progress through the tenacious fluid; for the body must drag along with it this stagnant fluid, and drag it in opposition to the tenacity and friction of the surrounding fluid. The effect of this is most remarkably seen in the resistances to the motion of pendulums; and the chevalier Buat, in his examination of Newton's experiments, clearly shows that this constitutes the greatest part of the resistance.

This most ingenious writer has paid great attention to this part of the process of nature, and has laid the foundation of a theory of resistance entirely different from all the preceding. We cannot abridge it; and it is too imperfect in its present condition to be offered as a body of doctrine: but we hope that the ingenious author will prosecute the subject.

We cannot conclude this dissertation (which we accept as our knowledge to be very unsatisfactory and imperfect) without better, than by giving an account of some experiments of the chevalier Buat, which seem of immense consequence, and tend to give us very new views of the subject. Mr. Buat observed the motion of water issuing from a glass cylinder through a narrow ring formed by a bottom of smaller diameter; that is, the cylinder was open at both ends, and there was placed at its lower end a circle of smaller diameter, by way of bottom, which left a ring all around. He threw some powdered sealing wax into the water, and observed with great attention the motion of its small particles. He saw those which happened to be in the very axis of the cylinder ascend along the axis with a motion pretty uniform.
RESISTANCE OF FLUIDS.

since uniform, till they came very near the bottom; from this they continued to descend very slowly, till they were almost in contact with the bottom; they then deviated from the centre, and approached the orifice in straight lines and with an accelerated motion, and at last darted into the orifice with great rapidity. He had observed a thing similar to this in a horizontal canal, in which he had set up a small board like a dam or barrier, over which the water flowed. He had thrown a gooseberry into the water, in order to measure the velocity at the bottom, the gooseberry being a small matter heavier than water. It approached the dam uniformly till about three inches from it. Here it almost stood still, but it continued to advance till almost in contact. It then rose from the bottom along the inside of the dam with an accelerated motion, and quickly escaped over the top.

Hence he concluded, that the water which covers the anterior part of the body exposed to the stream is not perfectly stagnant, and that the filaments recede from the axis in curves, which converge to the surface of the body as different hyperbolas converge to the same asymptote, and that they move with a velocity continually increasing till they escape round the sides of the body.

He had established (by a pretty reasonable theory, confirmed by experiment) a proposition concerning the pressure which water in motion exerts on the surface along which it glides, viz. that the pressure is equal to that which it would exert if at rest minus the weight of the column whose height would produce the velocity of the passing stream. Consequently the pressure which the stream exerts on the surface perpendicularly exposed to it will depend on the velocity with which it glides along it, and will diminish from the centre to the circumference. This, says he, may be the reason why the impulse on a plane wholly immersed is but one half of that on a plane which deflects the whole stream.

He contrived a very ingenious instrument for examining this theory. A square brass plate ABGF (fig. 22.) was pierced with a great number of holes, and fixed in the front of a shallow box represented edgewise in fig. 23. The back of this box was pierced with a hole c, in which was inserted the tube of glass CDE, bent square at D. This instrument was exposed to a stream of water, which beat on the brass plate. The water having filled the box through the holes, stood at an equal height in the glass tube when the surrounding water was stagnant; but when it was in motion, it always stood in the tube above the level of the smooth water without, and thus indicated the pressure occasioned by the action of the stream.

When the instrument was not wholly immersed, there was always a considerable accumulation against the front of the box, and a depression behind it. The water before it was by no means stagnant: indeed it should not be, as Mr. Buat observes; for it consists of the water which was escaping on all sides, and therefore upwards from the axis of the stream, which meets the plate perpendicularly in c considerably under the surface. It escapes upwards; and if the body were sufficiently immersed, it would escape in this direction almost as easily as laterally. But in the present circumstances, it heaps up, till the elevation occasions it to fall off sidewise as fast as it is renewed. When the instrument was immersed more than its semidiameter under the surface, the water still rose above the level, and there was a great depression immediately behind this elevation. It is consequence of this difficulty of escaping upwards, the water flows off laterally; and if the horizontal dimensions of the surface is great, this lateral efflux becomes more difficult, and requires a greater accumulation. From this it happens, that the resistance of broad surfaces equally immersed is greater than in the proportion of the breadth. A plane of two feet wide and one foot deep, when it is not completely immersed, will be more resisted than a plane two feet deep and one foot wide; for there will be an accumulation against both: and even if these were equal in height, the additional surface will be greatest in the widest body; and the elevation will be greater, because the lateral escape is more difficult.

The circumstances chiefly to be attended to are these. Circumstances chiefly to be attended to in this case are the height of the water in the tube DE was more than 1/2 of the height necessary for producing the velocity when only the central hole was open. When various holes were opened instrument at different distances from the centre, the height of the water in DH continually diminished as the hole was nearer the border. At a certain distance from the border the water at E was level with the surrounding water, so that no pressure was exerted on that hole. But the most unexpected and remarkable circumstance was, that in great velocities, the holes at the very border, and even to a small distance from it, not only sustained no pressure, but even gave out water; for the water in the tube was lower than the surrounding water. Mr. Buat calls this a non-pressio. In a case in which the velocity of the stream was three feet, and the pressure on the central hole caused the water in the vertical tube to stand 33 lines or 1/4 of an inch above the level of the surrounding smooth water, the action on a hole at the lower corner of the square caused it to stand 12 lines lower than the surrounding water. Now the velocity of the stream in this experiment was 36 inches per second. This requires 21 1/2 lines for its productive fall; whereas the pressure on the central hole was 33. This approaches to the pressure on a surface which deflects it wholly. The intermediate holes gave every variation of pressure, and the diminution was more rapid as the holes were nearer the edge; but the law of diminution could not be observed.

This is quite a new and most unexpected circumstance in the action of fluids on solid bodies, and is consistent with the principles, that the subject more intricate than ever; yet it is by no means inconsistent with the genuine principles of hydrostatics or hydrodynamics. In as far as M. Buat's or hydraulic-proposition concerning the pressure of moving fluids fails, it is true, it is very reasonable to say, that when the lateral velocity with which the fluid tends to escape exceeds the velocity of percussion, the height necessary for producing this velocity must exceed that which would produce the other, and a non-pressio must be observed. And if we consider the forms of the lateral filaments near the edge of the body, we see that the concavity of the curve is turned toward the body, and that the centrifugal forces tend to diminish their pressure on the body. If the middle alone were struck with a considerable velocity, the water might even
Resistance of Fluids.

Even rebound, as if frequently observed. This actual rebounding is here prevented by the surrounding water, which moves with the same velocity, but the pressure may be almost annihilated by the tendency to rebound of the inner filaments.

Part (and perhaps a considerable part) of this apparent non-precision is undoubtedly produced by the tenacity of the water, which sticks with it the water lying in the hole. But at any rate, this is an important fact, and gives great value to these experiments. It gives a key to many curious phenomena in the resistance of fluids; and the theory of M. Buet deserves a very serious consideration. It is all contained in the two following propositions.

1. "If, by any cause whatever, a column of fluid, whether moving part of an indurated fluid, or contained in solid canals, come to move with a given velocity, the pressure which it exerted before its motion, either on the adjoining fluid or on the side of the canal, is diminished by the height of a column having the height necessary for communicating the velocity of the motion. For 33 is 4 of 214."

He attempted to ascertain the medium pressure on the whole surface, by opening 625 holes dispersed all over it. With the same velocity of current, he found the height in the tube to be 29 lines, or 74 more than the height necessary for producing the velocity. But he justly concluded this to be too great a measure, because the holes were 4 of an inch from the edge; had there been holes at the very edge, they would have sustained a non-pressure, which would have diminished the height in the tube very considerably. He exposed to the same stream a conical funnel, which raised the water to 34 lines. But this could not be considered as a measure of the pressure on a plane solid surface; for the adjoining fluid was undoubtedly sucked out, as in these, and the filaments more reflected than they would have been by a plane surface. Perhaps something of this happened even in every small hole in the former experiments. And this suggests some doubt as to the accuracy of the measurement of the pressure and of the velocity of a current by Mr. Pitot's tube. It certainly sends some corrections absolutely necessary. It is a fact, that when exposed to a vein of fluid coming through a short passage, the water in the tube stands on a level with that in the reservoir. Now we know that the velocity of this stream does not exceed what would be produced by a fall equal to 214 of the head of water in the reservoir. Mr. Buet made many valuable observations and improvements on this most useful instrument, which will be taken notice of in the articles Rivers and Water-Works.

Mr. Buet, by a scrupulous attention to all the circumstances, concludes that the medium pressure on the whole surface is equal to 21.5 of the weight of a column, having the surface for its base, and the productive fall for its height. But we think that there is an uncertainty in this conclusion; because the height of the water in the vertical tube was undoubtedly augmented by an hydrostatical pressure arising from the accumulation of water above the body which was expected to stream.

Since the pressures are as the squares of the velocities, or as the heights \( h \) which produce the velocity, we may express this pressure by the symbol \( \frac{h^2}{2g} \), or \( \mu \), or \( \frac{h^2}{2g} \), or \( \frac{h^2}{2g} \), the value of \( h \) being \( 1.186 \). To exceed considerably the result of the experiments in the French academy, in these it does not appear sensibly exceeds unity. Note, that in these experiments the body was moved through still water; but in it is exposed to a stream. These are generally supposed to be equivalent, on the authority of the theory of motion, which makes every action depend on relative motions. We shall by and by see some cases of difference.

The writers on this subject seem to think that this is completed when they have considered the action of the fluid on the anterior part of the body, or the part which it is before the broadest section, and have paid little or no attention to the hinder part. Yet we are most interested in the subject, the naval war, and seem convinced that it is of no less importance to attend to the form of the hinder part of the ship. In the universal practice of all nations it has been the hinder part more acute than the fore part. It has undoubtedly been deduced from experience; it is in direct opposition to any notions which a ship would naturally form on this subject. Mr. Buet, therefore, thought it very necessary to examine the action of the water on the hinder part of the body by the same method. And, previous to this examination, it is necessary to acquire some scientific notions of the subject, not the following very curious and instructive experiments.

Two little conical pipes (fig. 24) were inserted into the upright side of a prismatical vessel. They were an inch long, and their diameters at the inner ends were five and four lines. A was 37 lines on the surface, and B was 73. A glass syphon was cut off the shape represented in the figure, and its inner diameter was 23 lines. It was placed with its axis in the axis, and even with the base of the conical pipes being about the vessel was filled with water, and it was made to stand on a level in the base of the syphon, the upper part being full of air. When this syphon was applied to the pipe A, and the water running freely, it rose 39 lines in the short; so much as much in the other. When it was applied to the pipe B, the water rose 41 lines in the one, and the syphon, and sunk as much in the other.

The reasons in this manner from the experiment. The rings comprehended between the end of the syphon on the sides of the conical tube being the narrowest of the orifice, the water issued with the velocity corresponding to the height of the water in the end above the orifice, diminished for the contraction; therefore the cylinder of water immediately below the mouth of the syphon issued with the same velocity. The tube would be emptied through a height equal to the head of water (charge). If, on the contrary, the cylinder of water, immediately before the mouth of the syphon, were stagnant, the water in it would not fall pressure on the mouth of the syphon, and the water in the syphon would be level with the water in the tube.
RESISTANCE OF FLUIDS.

Between these extremes we must find the real state of the case, and we must measure the force of non-pressure by the rise of the water in the syphon.

We see that in both experiments it bears an accurate proportion to the depth under the surface. For $73:32=41$ very nearly. He therefore estimates the non-pressure to be $75 \times \frac{3}{4}$ of the height of the water above the orifice.

We are disposed to think that the ingenious author has not reasoned accurately from the experiment. In the first place, the force indicated by the experiment, whatever be its origin, is certainly double of what he supposes; for it must be measured by the sum of the rise of the water in one leg, and its depression in the other, the weight of the air in the bend of the syphon being neglected. It is precisely analogous to the force acting on the water oscillating in a syphon, which is acknowledged to be the sum of the elevation and depression. The force indicated by the experiment therefore is $1\frac{3}{4}$ of the height of the water above the orifice.

The force exhibited in this experiment bears a still greater proportion to the productive height; for it is certain that the water did not issue with the velocity acquired by the fall from the surface, and probably did not exceed $\frac{1}{2}$ of it. The effect of contraction must have been considerable and uncertain. The velocity should have been measured both by the amplitude of the jet and by the quantity of water discharged. In the next place, we apprehend that much of the effect is produced by the tenacity of the water, which draws along with it the water which would have slowly issued from the syphon, had the other end not dipped into the water of the vessel. We know, that if the horizontal part of the syphon had been continued far enough, and if no retardation were occasioned by friction, the column of water in the upright leg would have accelerated like any heavy body, and when the last of it had arrived at the bottom of that leg, the whole in the horizontal part would be moving with the velocity acquired by falling from the surface. The water of the vessel which issues through the surrounding ring very quickly acquires a much greater velocity than what the water descending in the syphon would acquire in the same time, and it draws this last water along with it both by tenacity and friction: and it draws it out till its action is opposed by the want of equilibrium produced in the syphon, by the elevation in the one leg and the depression in the other. We imagine that little can be concluded from the experiment with respect to the real non-pressure. Nay, if the sides of the syphon be supposed infinitely thin, so that there would be no curvature of the filaments of the surrounding water at the mouth of the syphon, we do not very distinctly see any source of non-pressure: For we are not altogether satisfied with the proof which Mr. Bost affords for this measure of the pressure of a stream of fluid gliding along a surface, and obstructed by friction or any other cause. We imagine that passing water in the present experiment would be a little retarded by accelerating continually the water descending in the syphon, and renewed at the top, supposing the upper end open; because this water would not of itself acquire more than half this velocity. It however acts it out, till it not only resists with a force equal to the weight of the whole vertical column, but even exceeds it by $\frac{3}{4}$. This it is able to do, because the whole pressure by which the water issues from an orifice has been shown (by Daniel Bernoulli) to be equal to twice this weight. We therefore consider this beautiful experiment as chiefly valuable, by giving us a measure of the tenacity of the water; and we wish that it were repeated in a variety of depths, in order to discover what relation the force exerted bears to the depth. It would seem that the tenacity, being a certain determinate thing, the proportion of 100 to 112 would not be constant; and that the observed ratio would be made up of two parts, one of them constant, and the other proportional to the depth under the surface.

But still this experiment is intimately connected with the matter in hand; and this apparent non-pressure on the hinder part of a body exposed to a stream, from whatever cause it proceeds, does operate in the action of water on this hinder part, and must be taken into the account.

We must therefore follow the chevalier de Boute, in further his discussions on this subject. A prismatic body, having its prow and poop equal and parallel surfaces, and plunged horizontally into a fluid, will require a force to keep it firm in the direction of its axis precisely equal to the difference between the real pressures exerted on its prow and poop. If the fluid is at rest, this difference will be nothing, because the opposite dead pressures of the fluid will be equal: but in a stream, there is superadded to the dead pressure on the prow the active pressure arising from the deflections of the filaments of this fluid.

If the dead pressure on the poop remained in its full intensity by the perfect stagnation of the water behind it, the whole sensible pressure on the body would be the active pressure only on the prow, represented by $m \cdot h$. If, on the other hand, we could suppose that the water behind the body moved continually away from it (being renewed laterally) with the velocity of the stream, the dead pressure would be entirely removed from its poop, and the whole sensible pressure, or what must be opposed by some external force, would be $m \cdot h - \frac{1}{4}$ $A$. Neither of these can happen; and the real state of the case must be between these extremes.

The following experiments were tried: The pond-Experiment was exposed to the action of fluid, the brass plate being turned down the stream. The velocity was again 36 inches per second.

The central hole $A$ alone being opened, gave a non-pressure of...
Another of larger dimensions, but having fewer holes, indicated a non-pressure of 1.4.

But the most remarkable, and the most important phenomena were the following:

The first box was fixed to the side of another box, so that, when all was made smooth, it made a perfect cube, of which the perforated brass plate made the poop.

The apparatus being now exposed on the stream, with the perforated plate looking down the stream, the hole A indicated a non-pressure of 7.2.

B - - - - - - 8
C - - - - - - 6

Here was a great diminution of the non-pressures produced by the distance between the prow and the poop. This box was then fitted in the same manner, so as to make the poop of a box three feet long. In this situation the non-pressures were as follows:

Hole A - - - - - 1.5
B - - - - - 3.2

The non-pressures were still farther diminished by this increase of length. The box was then exposed with all the holes open, in three different situations:

1st, Single, giving a non-pressure - 13.1
2d, Making the poop of a cube - 5.3
3d, Making the poop of a box three feet long - 3.0

Another larger box:

1st, Single - - - - - 12.2
2d, Poop of a cube - - - - 5.2
3d, Poop of the long box - - - - 3.2

Great utility of them in ship-building.

Those are most valuable experiments. They plainly show how important it is to consider the action on the hinder part of the body. For the whole impulse or resistance, which must be withstood or overcome by the external force, is the sum of the active pressure on the fore-part, and of the non-pressure on the hinder-part; and they show that this does not depend solely on the form of the prow and poop, but also, and perhaps chiefly, on the length of the body. We see that the non-pressure on the hinder-part was prodigiously diminished (reduced to one-fourth) by making the length of the body triple of the breadth. And hence it appears, that merely lengthening a ship, without making any change in the form either of her prow or her poop, will greatly diminish the resistance to her motion through the water; and this increase of length may be made by continuing the form of the midship frame in several timbers along the keel, by which the capacity of the ship, and her power of carrying sail, will be greatly increased, and her other qualities improved, while her speed is augmented.

It is surely of importance to consider a little the physical cause of this change. The motions are extremely complicated, and we must be contented if we can but perceive a few leading circumstances.

The water is turned aside by the anterior part of the body, and the velocity of the filaments is increased, and they acquire a divergent motion, by which they also push aside the surrounding water. On each side of the body, therefore, they are moving in a divergent direction, and with an increased velocity. But as they are on all sides pressed by the fluid without them, their motions gradually approach parallelism, and their velocities to an equality with the stream. The progressive velocity, or that in the direction of the stream, is checked, at least at first. But since we observe the filaments constipated round the body, and that they are not deflected at right angles to their former direction, it is plain that the real velocity of a filament in its oblique path is augmented. We always observe, that a stone lying in the sand, and exposed to the wash of the sea, is laid bare at the bottom, and the sand is generally washed away to some distance all round. This is owing to the increased velocity of the water which comes into contact with the stone. It takes up more sand than it can keep floating, and it deposits it at a little distance all around, forming a little bank, which surrounds the stone at a small distance. When the filaments of water have passed the body, they are pressed by the ambient fluid into the place which it has quitted, and they glide round its stern, and fill up the space behind. The more divergent and the more rapidly they are, when about to fall in behind, the more of the circumambient pressure must be employed to turn them into the trough behind the body, and less of it will remain to press them to the body itself. The extreme of this must obtain when the stream is obstructed by a thin plane only. But when there is some distance between the prow and the poop, the divergence of the filaments which had been turned aside by the prow, is diminished by the time that they have come abreast of the stern, and should turn in behind it. They are therefore more readily made to converge behind the body, and a more considerable part of the surrounding pressure remains unexpendited, and therefore presses the water against the stern; and it is evident that this advantage must be so much the greater as the body is longer. But the advantage will soon be susceptible of no very considerable increase: for the lateral and divergent, and accelerated filaments, will soon become so nearly parallel and equally rapid with the rest of the stream, that a great increase of length will not make any considerable change in these particulars; and it must be accompanied with an increase of friction.

These are very obvious reflections. And if we attend minutely to the way in which the almost stagnant fluid behind the body is expended and renewed, we shall see all these effects confirmed and augmented. But as we cannot say anything on this subject that is precise, or that can be made the subject of computation, it is needless to enter into a more minute discussion. The diminution of the non-pressure towards the centre most probably arises from the smaller force which is necessary to be expended in the infliction of the lateral filaments, already inflected in some degree, and having their velocity diminished. But it is a subject highly deserving the attention of the mathematicians; and we presume to invite them to the study of the motions of these lateral filaments passing the body, and pressed into its wake by forces which are susceptible of no difficult investigation. It seems highly probable, that if a prismatic box, with a square stern, were fitted with an addition precisely shaped like the water which would (abstracting tenacity and friction) have been stagnant behind it, the quantity of non-pressure would be the smallest possible. The mathematician would surely discover circumstances which
Resistance of Fluids.

When the velocity is three feet per second, requiring the productive height 21.5 lines, the heights corresponding to the non-pressure on the hoop of a thin plane is 14.4 lines (taking in several circumstances of judicious correction, which we have not mentioned), that of a foot cube is 5.83, and that of a box of triple length is 3.31.

Let $q$ express the variable ratio of these to the height producing the velocity, so that $q = \frac{V}{L}$ may express the non-pressure in every case; we have,

For a thin plane cube,

\[ q = 0.68, \quad 0.271, \quad 0.153 \]

It is evident that the value of $q$ has a dependence on the proportion of the length, and the transverse section of the body. A series of experiments on prismatoid bodies showed Mr de Buat that the deviation of the filaments was similar in similar bodies, and that this obtained even in dissimilar prisms, when the lengths were as the square-roots of the transverse sections. Although therefore the experiments were not sufficiently numerous for deducing the precise law, it seemed not impossible to derive from them a very useful approximation.

By a dexterous comparison he found, that if $e$ expresses the length of the prism, and $s$ the area of the transverse section, and $L$ expresses the common logarithm of the quantity to which it is prefixed, we shall express the non-pressure pretty accurately by the formula

\[ L = \frac{1}{4s} \sqrt{e}. \]

Hence arises an important remark, that when the height corresponding to the non-pressure is greater than $\sqrt{e}$, and the body is little immersed in the fluid, there will be a void behind it. Thus a surface of a square inch, just immersed in a current of three feet per second, will have a void behind it. A foot square will be in a similar condition when the velocity is 12 feet.

We must be careful to distinguish this non-pressure from the other causes of resistance, which are always necessarily combined with it. It is superadditive to the active impression on the prow, to the statical pressure of the accumulation a-head of the body, the statical pressure arising from the depression behind it, the effects of friction, and the effects of tenacity. It is indeed next to impossible to estimate them separately, and many of them are actually combined in the measures now given. Nothing can determine the pure non-pressures till we can ascertain the motions of the filaments.

M. de Buat here takes occasion to controvert the universally adopted maxim, that the pressure occasioned by a stream of fluid on a fixed body is the same with that on a body moving with equal velocity in a quiescent fluid. He repeated all these experiments with the perforated box in still water. The general distinction was, that both the pressures and the non-pressure in this case were less, and that the odds were chiefly to be observed near the edges of the surface. The general factor of the pressure of a stream on the anterior surface of fluids was $m = 1.186$; but that on a moving body through a still fluid is only $m = 1$. He observed no non-pressure even at the very edge of the prow, but even a sensible pressure. The pressure, therefore, or resistance is more equably diffused over the surface of the prow than the impulse is. He also found that the resistances diminished in a less ratio than the squares of the velocities, especially in small velocities.

The non-pressures increased in a greater ratio than the squares of the velocities. The ratio of the velocities to a small velocity of 2½ inches per second increased geometrically, the value of $q$ increased arithmetically; and we may determine $q$ for any velocity $V$ by this proportion

\[ \frac{L}{2.2} : \frac{V}{2.2} = 0.5 : q, \text{ and } q = \frac{V}{2.8}. \]

That is, let the common logarithm of the velocity, divided by 2½, be considered as a common number; divide this common number by 2.8, the quotient is $q$, which must be multiplied by the productive height. The product is the pressure.

When Pitot’s tube was exposed to the stream, we had $m = 1$; but when it is carried through still water, $m = 1.22$. When it was turned from the stream, we had $q = 0.177$; but when carried through still water, $q$ is $0.138$. A remarkable experiment.

When the tube was moved laterally through the water and supper, so that the motion was in the direction of the plane of the mouth, the non-pressure was $m = 1$. This is one of his chief arguments for his theory of non-pressure. He does not give the detail of the experiment, and only remarks that the result is in his table.

As a body exposed to a stream deflects the fluid, heaps it up, and increases its velocity; so a body moved through a still fluid turns it aside, causes it to swell up before it, and gives it a real motion alongside of it in the opposite direction. And as the body exposed to a stream has a quantity of fluid almost stagnant both before and behind; so a body moved through a still fluid carries before it and drags after it a quantity of fluid, which accompanies it with nearly an equal velocity. This addition to the quantity of matter in a motion must make a diminution of its velocity; and this forms a very considerable part of the observed resistance.

We cannot, however, help remarking that it would require very distinct and strong proof indeed to overturn not turn the common opinion, which is founded on our most well founded and certain and simple conceptions of motion, and on a law of nature to which we have never observed an exception. M. de Buat’s experiments, though most judiciously contrived, and executed with scrupulous care, are by no means of this kind. They were, of absolute necessity, very complicated; and many circumstances, impossible to avoid or to appreciate, rendered the observation, or at least the comparison, of the velocities, very uncertain.

We can see but two circumstances which do not admit of an easy or immediate comparison in the two states of the problem. When a body is exposed to a stream in our experiments, in order to have an impulse made on it, there is a force tending to move the body backwards, independent of the real impulse or pressure, or still was occasioned by the deflection of the stream. We cannot ter have
Resistance of Fluids.

Resistance of fluids is the opposition that a fluid offers to the motion of a body through it. A stream is not a continuous fluid, but only one that has a current of greater force than the surrounding fluid.

Suppose a body floating on this stream. It will not sail down along with the stream, but it will sail down the stream, and will therefore go faster along the canal than the stream does: for it is floating on an inclined plane; and if we examine it by the laws of hydraulics, we shall find, that besides its own tendency to slide down this inclined plane, there is an odds of hydrostatical pressure, which pushes it down this plane. It will therefore go along the canal faster than the stream. For this acceleration depends on the difference of pressure at the two ends, and will be more remarkable as the body is larger, and especially as it is longer. This may be distinctly observed. All floating bodies go into the stream of the river, because there they find the smallest obstruction to the acquisition of this motion along the inclined plane; and when a number of bodies are thus floating down the stream, the largest and longest outstrip the rest. A log of wood floating down in this manner may be observed to make its way very fast among the chips and saw-dust which float alongside of it.

Now when, in the course of our experiments, a body is supported against the action of the stream, and the impulse is measured by the force employed to support it, it is plain that part of this force is employed to act against that tendency which the body has to outstrip the stream. This does not appear in our experiment, when we move a body with the velocity of this stream through still water having a horizontal surface.

The other distinguishing circumstance is, that the retardations of a stream arising from friction are found to be nearly as the velocities. When, therefore, a stream moving in a limited canal is checked by a body put in its way, the diminution of velocity occasioned by the friction of the stream having already produced its effect, the impulse is not affected by it; but when the body puts the still water in motion, the friction of the bottom produces some effect, by retarding the recess of the water. This, however, must be next to nothing.

The chief difference will arise from its being almost impossible to make an exact comparison of the velocities: for when a body is moved against the stream, the relative velocity is the same in all the filaments. But when we expose a body to a stream, the velocity of the different filaments is not the same; because it decreases from the middle of the stream to the sides.

Mr. Buat found the total sensible resistance of a plate 12 inches square, and measured, not by the height of water in the tube of the perforated box, but by weights acting on the arm of a balance, having its centre 15 inches under the surface of a stream moving three feet per second, to be 19.46 pounds; that of a cube of the same dimensions was 15.22; and that of a prism three feet long was 13.87; that of a prism six feet long was 14.27. The three first agree extremely well with the determination of m and q, by the experiments with the perforated box. The total resistance of the last was undoubtedly much increased by friction, and by the retrograde force of so long a prism floating in an inclined stream. This last by computation is 0.223 pounds; this added to h (m+q), which is 13.39, gives 13.61, leaving 0.46 for the effect of friction.

If the same resistances be computed on the supposition that the body moves in still water, in which case we have m=1, and q for a thin plate =0.433; and if q be computed for the lengths of the other two bodies by the formula \[ q = \frac{L}{\sqrt{s}} \]; we shall get for the resistances 14.94; 12.22; and 11.49.

Hence M. Buat concludes, that the resistances in this and of the two states are nearly in the ratio of 13 to 10. This, he thinks, will account for the difference observed in the experiments of different authors.

M. Buat next endeavours to ascertain the quantity of water which is made to adhere in some degree to a body which is carried along through still water, or which remains nearly stagnant in the midst of a stream. He takes the sum of the motions in the direction of the stream, viz. the sum of the actual motions of all those particles which have lost part of their motion, and he divides this sum by the general velocity of the stream. The quotient is equivalent to a certain quantity of water perfectly stagnant round the body. Without being able to determine this with precision, he observes, that it augments as the resistance diminishes; for in the case of a longer body, the filaments are observed to converge to a greater distance behind the body. The stagnant mass in front of the body is more constant; for the deflection and resistance at the prow are observed not to be affected at the length of the body. M. Buat, in a very nice analysis of these circumstances, comes to this conclusion, that the whole quantity of fluid, which in this manner accompanies the solid body, remains the same, whatever is the velocity. He might have deduced it at once, from the consideration that the curves described by the filaments are the same in all velocities.

He then relates a number of experiments made to ascertain the absolute quantity thus made to accompany the body. These were made by causing pendulums to oscillate in fluids. Newton had determined the resistances to such oscillation by the diminution of the arches of vibration. M. Buat determines the quantity of dragged fluid by the increase of their duration; for the stagnation or dragging is in fact adding a quantity of matter to be moved, without any addition to the moving force. It was ingeniously observed by Newton, that the time of oscillation was not sensibly affected by the resistance of the fluid: a compensation, almost complete, being made by the diminution of the arches of vibration; and experiment confirmed this. If, therefore, a great augmentation of the time of vibration be observed, it must be ascribed to the additional quantity of matter which is thus dragged into motion, and it may be employed for its measurement. Thus, let \( a \) be the length of a pendulum swinging seconds in vacuo, and \( l \) the length of a second's pendulum swinging in a fluid. Let \( p \) be the weight of the body in the fluid, and \( P \) the weight of the body displaced by it; \( P+P \) will express its weight in vacuo, and \( \frac{P+P}{P} \) will be the ratio of these weights. We shall therefore have \( \frac{P+P}{P} = \frac{a}{7} \).

Let \( n \) express the sum of the fluid displaced, and the fluid dragged along, \( n \) being a greater number than unity,
RESISTANCE OF FLUIDS.  

PLATE CCCCLXI.
Resistance of Fluids.

Since unity, to be determined by experiment. The mass in a state of motion is no longer \( P + p \), but \( P + \frac{a}{n} p \), while its weight in the fluid is still \( p \). Therefore we must have

\[
I = \frac{a}{n(1 + \frac{a}{P})}, \quad \text{and} \quad n = \frac{a}{P(1 - \frac{a}{P})} + 1.
\]

A prodigious number of experiments made by M. Baut on spheres vibrating in water gave values of \( n \), which were very constant, namely, from 1.5 to 1.7; and by considering the circumstances which accompanied the variations of \( n \) (which he found to arise chiefly from the curvature of the path described by the ball), he states the mean value of the number \( n \) at 1.583.

So that a sphere in motion drags along with it about \( \frac{a}{P} \) of its own bulk of fluid with a velocity equal to its own.

He made similar experiments with prisms, pyramids, and other bodies, and found a complete confirmation of his assertion, that prisms of equal lengths and sections, though dissimilar, dragged equal quantities of fluid; that similar prisms and prisms not similar, but whose lengths were as the square root of their sections, dragged quantities proportional to their bulk.

He found a general value of \( n \) for prismatic bodies, which alone may be considered as a valuable truth; namely, that

\[
n = 0.707 \frac{a}{P} + 1.13.
\]

From all these circumstances, we see an intimate connection between the pressures, non-pressures, and the fluid dragged along with the body. Indeed this is immediately deducible from the first principles; for what Mr Baut calls the dragged fluid is in fact a certain portion of the whole change of motion produced in the direction of the bodies motion.

It was found, that with respect to thin planes, spheres, and pyramidal bodies of equal bases, the resistances were inversely as the quantities of fluid dragged along.

The intelligent reader will readily observe, that these views of the Chevalier Baut are not so much discoveries of new principles as they are classifications of consequences, which may all be deduced from the general principles employed by D'Alembert and other mathematicians. But they greatly assist us in forming notions of different parts of the procedure of nature in the mutual action of fluids and solids on each other. This must be very acceptable in a subject which it is by no means probable that we shall be able to investigate with mathematical precision. We have given an account of these last observations, that we may omit nothing of consequence that has been written on the subject; and we take this opportunity of recommending the Hydrostatical of Mr Baut as a most ingenious work, containing more original, ingenious, and practically useful thoughts, than all the performances we have met with. Its doctrine of the principle of uniform motion of fluids in pipes and open canals, will be of immense service to all engineers, and enable them to determine with sufficient precision the most important questions in their profession; questions which at present they are hardly able to guess at. See Rivers and Water-Works.

The only circumstance which we have not noticed in detail, is the change of resistance produced by the void, or void tendency to a void, which obtains behind the body; and we omitted a particular discussion, merely because we could say nothing sufficiently precise on the subject. Persons not accustomed to the discussions in the physical and mathematical sciences, are apt to entertain doubts or false notions connected with this circumstance, which we shall attempt to remove; and with this we shall conclude this dissertation.

If a fluid were perfectly incompressible, and were contained in a vessel incapable of extension, it is impossible that any void could be formed behind the body; and in this case it is not very easy to see how motion could be performed in it. A sphere moved in such a medium could not advance the smallest distance, unless some particles of the fluid, in filling up the space left by it, moved with a velocity next to infinite. Some degree of compressibility, however small, seems necessary. If this be insensible, it may be rigidly demonstrated, that an external force of compression will make no sensible change in the internal motions, or in the resistances. This indeed is not obvious, but is an immediate consequence of the quaquaversal pressure of fluids. As much as the pressure is augmented by the external compressions on one side of a body, so much is it augmented on the other side; and the same must be said of every particle. Nothing more is necessary for securing the same motions by the same partial and internal forces; and this is fully verified by experiment. Water remains equally fluid under any compressions. In some of Sir Isaac Newton's experiments balls of four inches diameter were made so light as to preponderate in water only three grains. These balls descended in the same manner as they would have descended in a fluid where the resistance was equal in every part; yet, when they were near the bottom of a vessel nine feet deep, the compression round them was at least 2400 times the moving force; whereas, when near the top of the vessel, it was not above 50 or 60 times.

But in a fluid sensibly compressible, or which is not confined, a void may be left behind the body. Its motion may be so swift that the surrounding pressure may not suffice for filling up the deserted space; and, in this case, a statistical pressure will be added to the resistance. This may be the case in a vessel or pond of water having an open surface exposed to the finite or limited pressure of the atmosphere. The question now is, whether the resistance will be increased by an increase of external pressure? Supposing a sphere moving near the surface of water, and another moving equally fast at four times the depth. If the motion be so swift that a void is formed in both cases, there is no doubt but that the sphere which moves at the greatest depth is most resisted by the pressure of the water. If there is no void in either case, then, because the quadruple depth would cause the water to flow in with only a double velocity, it would seem that the resistance would be greater; and indeed the water flowing in laterally with a double velocity produces a quadruple non-pressure.—But, on the other hand, the pressure at a small depth may be insufficient for preventing a void, while that below effectually prevents it; and this was observed in some experiments of Chevalier de Borda. The effect, therefore, of greater immersion, or of greater compression, in an elastic fluid, does not follow a precise ratio of the pressure, but depends partly on absolute quantities. It cannot, therefore, be stated by any very simple formula what increase or diminution of resistance will result.
RESISTANCE OF FLUIDS.

It is evident, that a smaller elevation will suffice when the body is more immersed, because the check or impulse given by the body below is propagated, not vertically only, but in every direction; and therefore the elevation is not confined to that part of the surface which is immediately above the moving body, but extends so much further laterally as the centre of agitation is deeper: Thus, the elevation necessary for the passage of the body is so much smaller; and it is the height only of this accumulation or wave which determines the backward pressure on the body. D'Ullon's equation may happen to quadrate with two experiments at different depths, without being nearly just; for any two points may be in a curve, without exhibiting its equation. Three points will do it with some approach to precision; but four, at least, are necessary for giving any notion of its nature. D'Ullon has only given two experiments, which we mentioned in another place.

We may here observe, that it is this circumstance which immediately produces the great resistance to the motion of a body through a fluid in a narrow canal.—The fluid cannot pass the body, unless the area of the section be sufficiently extensive. A narrow canal prevents the extension sideways. The water must therefore heap up, till the section and velocity of diffusion are sufficiently enlarged, and thus a great backward pressure is produced. (See the second series of Experiments by the French Academicians; see also Franklin's Essays). It is important, and will be considered in another place.

Thus have we attempted to give our readers some account of one of the most interesting problems in the whole of mechanical philosophy. We are sorry that so little advantage can be derived from the united efforts of the first mathematicians of Europe, and that there is so little hope of greatly improving our scientific knowledge of the subject. What we have delivered will, however, enable our readers to peruse the writings of those who have applied the theories to practical purposes. Such, for instance, are the treatises of John Bernoulli, of Bouguer, and of Euler, on the construction and working of ships, and the occasional discussions of different authors on water-mills. In this last application the ordinary theory is not without its value, for the impulses are nearly perpendicular; in which case they do not materially deviate from the duplicate proportion of the sign of incidence. But even here this theory, applied as it commonly is, misleads us exceedingly. The impulse on one float may be accurately enough stated by it; but the authors have not been attentive to the motion of the water after it has made its impulse; and the impulse on the next float is stated the same as if the parallel filaments of water, which were not stopped by the preceding float, did impinge on the opposite part of the second, in the same manner, and with the same obliquity and energy, as if it were detached from the rest. But this does not in the least resemble the real process of nature.
RESISTANCE OF FLUIDS.

Resistance is supposed to be all that is impelled by the parallel filaments of the stream; whereas the water bends round the lower edge of the float B by the surrounding pressure, and rises on the float c all the way to f. In like manner, the float D, instead of receiving an impulse on the very small portion DG, is impelled all the way from D to g, not much below the surface of the stream. The surfaces impelled at once, therefore, greatly exceed what this slovenly application of the theory supposes, and the whole impulse is much greater; but this is a fault in the application, not in the theory. It will not be a very difficult thing to acquire a knowledge of the motion of the water which has passed the preceding float, which, though not accurate, will yet approximate considerably to the truth; and then the ordinary theory will furnish maxims of construction which will be very serviceable. This will be attempted in its proper place; and we shall endeavour, in our treatment of all the practical questions, to derive useful information from all that has been delivered on the present occasion.

RESOLUTION of Ideas. See Logic, Part I. chap. iii.

Resolution, in Music. To resolve a discord or dissonance, says Rousseau, is to carry it according to rule into a consonance in the subsequent chord. There is for that purpose a procedure prescribed, both for the fundamental bass of the dissonant chord, and for the part by which the dissonance is formed.

There is no possible manner of resolving a dissonance which is not derived from an operation of cadence: it is then by the kind of cadence which we wish to form, that the motion of the fundamental bass is determined, (see Cadence). With respect to the part by which the dissonance is formed, it ought neither to continue in its place, nor to move by disjointed gradations; but to rise or descend distonically, according to the nature of the dissonance. Theorists say, that major dissonances ought to rise, and minor to descend; which is not however without exception, since in particular chords of harmony, a seventh, although major, ought not to rise but to descend, unless in that chord, which is, very incorrectly, called the chord of the seventh redundant. It is better then to say, that the seventh and all its derivative dissonances ought to descend; and that the sixth superadded, and all its derivative dissonances, should rise. This is a rule truly general, and without any exception. It is the same case with the rule of resolving dissonances. There are some dissonances which cannot be prepared; but there is by no means one which ought not to be resolved.

With respect to the sensible note improperly called a major dissonance, if it ought to ascend, this is less on account of the rule for resolving dissonances, than on account of that which prescribes a diatonic procedure, and prefers the shortest road; and in reality, there are cases, as that of the interrupted cadence, in which this sensible note does not ascend.

Resolution, in Chemistry, the reduction of a mixed body into its component parts or first principles, as far as can be done by a proper analysis.

Resolution, in Medicine, the disappearing of any tumor without coming to suppuration or forming an abscess.

Resolvents, in Medicine, such as are proper for dissipating tumors, without allowing them to come to suppuration.

Resonance, Resounding, in Music, &c. a sound returned by the air inclosed in the bodies of stringed instruments, such as lutes, &c. or even in the bodies of wind-instruments, as flutes, &c.

Respiration, the act of respiring or breathing the air. See Anatomy, No 118. Blood, No 29.

Respiration of Fishes. See Ichthyology.

Respites, in Law, signifies a delay, forbearance, or prolongation of time, granted to any one for the payment of a debt or the like. See Reprieve.

Respondent, in the schools, one who maintains a thesis in any art or science; who is thus called from his being to answer all the objections proposed by the opponent.

Respondentia. See Bottomry.

Response, an answer or reply. A word chiefly used in speaking of the answers made by the people to the priest, in the litany, the psalms, &c.

Resort, a French word, sometimes used by English authors to signify the jurisdiction of a court, and particularly one from which there is no appeal. Thus it is said, that the house of lords judge en dernier resort, or in the last resort.

Rest, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous bodies; and therefore is opposed to motion. See the article Motion.

Rest, in Poetry, is a short pause of the voice in reading, being the same with the caesura, which, in Alexandrine verses, falls on the sixth syllable; but in verses of 10 or 11 syllables, on the fourth. See Poetry, Part III.

Rest-Harrow, or Cammock, the Ononis Arvensis. A decoction of this plant has been much recommended to horses labouring under a stoppage of urine. It is the pest of some corn-fields; but in its younger state, before the plant has acquired its thorns, it is a most acceptable food to sheep.

Restoration, the act of re-establishing or setting a thing or person in its former good state.

Restio, a genus of plants belonging to the dioecia class. See Botany Index.

Restitution, in a moral and legal sense, is restoring a person to his right, or returning something unjustly taken or detained from him.

Restitution of Medals, or Restituted Medals, is a term used by antiquaries for such medals as were struck by the emperors, to retrieve the memory of their predecessors.

Hence, in several medals, we find the letters REST. This practice was first begun by Claudius, by his striking afresh several medals of Augustus. Nero did the same; and Titus, after his father's example, struck restitutions of most of his predecessors. Gallienus struck
Restitution of all the preceding emperors on two medals; the one bearing an altar, the other an eagle without the R.

Restoration.

RESTORATION, the same with restoration. See Restoration.

In England, the return of King Charles II. in 1660, is, by way of eminence, called the Restoration; and the 29th of May is kept as an anniversary festival, in commemoration of that event, by which the legal and episcopal government was restored.

RESTORATIVE, in Medicine, a remedy proper for restoring and retrieving the strength and vigour both of the body and animal spirits.

All under this class, says Quincy, are rather nutrimental than medicinal; and are more administered to repair the wastes of the constitution, than to alter and rectify its disorders.

RESTRICTIVE, among logicians, is limiting a term, so as to make it signify less than it usually does.

RESTRICTIVE, in Medicine, the same with astringent. See Astringents.

RESULT, what is gathered from a conference, inquiry, meditation, or the like; or the conclusion and effects thereof.

Definition.

RESURRECTION, in Theology, is a rising again from the state of the dead; and in that event, the belief of which constitutes one of the principal articles in the Christian creed.

In treating of this object of our faith, it has been usual to mention, first, the resurrection of our Blessed Lord, with the character of the witnesses, and the authenticity of the gospel history by which it has been proved, and from which, as a consequence, ours is inferred. But as most of the arguments for this resurrection are contained in the gospels, and as merely to repeat them would afford, we hope, but little information to most of our readers, we mean here to take a view of the several grounds on which the belief of a future existence is supposed to be founded; to collect together some of the sentiments of authors and nations concerning the place where departed spirits reside; concerning the nature of their present state; concerning the kinds of their future destination; that we may afterwards see how far their notions differ and agree with what we consider as the doctrines of Scripture.

Of a future state, there have sometimes been found a few wandering and obscure tribes who seemed to entertain no notion at all; though it should be remarked, that some of these were likewise observed in so low a degree of savage barbarity as not to be acquainted with the use of the bow, the dart, or the sling, and as not knowing how to wield a club, or to throw a stone, as a weapon of defence.

Wherever the human mind has been cultivated, or, properly speaking, begun to be cultivated, the opinion has likewise generally prevailed that human existence is not confined to the present scene; nay, so very general has this notion been found among mankind, that many are puzzled how to account for what they suppose to be almost next to its universality.

To explain the phenomenon, some have imagined that it is a notion derived by tradition from primeval revelation. They suppose that the first parent of mankind, as a moral agent accountable for his conduct, was informed by his Maker of every thing which it was of importance for him to know; that he must have been acquainted with this doctrine of a future state in particular; and that he could hardly fail to communicate it to his posterity. They suppose, too, that the history of the translation of Enoch must have made a great noise in the world, and that the remembrance of it must have been long retained and widely diffused; and they find in the book of Job plain intimations of a resurrection from the dead, which, from the manner in which they are introduced, they think that very ancient patriarch must have received through this channel.

It is not thought to be any objection to these suppositions, that the Most High, when delivering his laws to the children of Israel from the top of Mount Sinai, did not enforce them by the awful sanctions of a future state. The intelligent reader of the Scriptures knows that the sanctions of a future state belong to a different and more universal dispensation than was that of Moses; that the primeval revelation related to that dispensation; and that the Jewish law, with its temporal sanctions, was introduced only to preserve the knowledge and worship of the true God among a people too gross in their conceptions to have been properly influenced by the view of future rewards and punishments, of such a nature as eye hath not seen, nor ear heard, neither hath it entered into the heart of man to conceive. He saw at the same time, everywhere scattered through the Old Testament, plain indications of the Mosaic economy being no more than preparatory to the bringing in of a better hope; and he thinks it evident, that such Jews as understood any thing of the nature of that better hope, must have been convinced, that, however the ceremonial rites of their religion might be sufficiently guarded by temporal sanctions, the fundamental principles of all religion and virtue are supported by rewards and punishments to be dispensed in a state beyond the grave. See Prophecy and Theology.

That the progenitors of the human race must have been inspired by their Creator with the knowledge of their immortality, and of every thing necessary to their everlasting welfare, cannot, we should think, be questioned by any one who believes that the world had a beginning, and that it is under the government of goodness and justice. The progress from sense to science is so slow, that however capable we may suppose the earliest inhabitants of this earth to have been of making philosophical discoveries, we cannot believe that the Father of mercies left his helpless creature to discover for himself his future existence. Death, when first presented to him, must have been a ghastly object; and had he been left without any hope of redemption from it, he would undoubtedly have sunk into listless despondency.

But a prospect of immortality is so pleasing to the human mind, that if it was communicated to the first man, it would of course be cherished by his posterity; and there is no difficulty in conceiving how it might be handed down by tradition to very remote ages, among such of his descendants as were not scattered over the face of the earth in small and savage tribes.
RES [ 765 ]

...new-modelled by the ever active imagination; and at last many absurd and fantastic circumstances would doubtless be combined with the original truth, that death puts not an end to human existence.

But though we are firmly convinced that the first principles of useful knowledge, and among them the doctrine of a future state, were communicated to man by his Maker; and though this doctrine, in large and permanent societies, might certainly be conveyed more or less pure to later posterity through the channel of tradition—-we are far from attributing so much to tradition as some writers are disposed to do, or thinking it the only source from which mankind could derive the belief of their existence beyond the grave. In small tribes of savages such a tradition could hardly be preserved; and yet some indistinct notions of a future state have been found among tribes who are said to have lost all traditional notions even of the being of a God.

Others, therefore, are inclined to believe that, independent of any traditions, mankind might be led by certain phenomena to form some conjectures of a future state. They observe, that although a few individuals perhaps may, yet it seldom happens that the whole individuals of any nation are excepted from dreaming: They observe, too, and this observation is founded on experience, that the images of the dead are from the remaining impressions of memory frequently summoned up in the fancy: and that it appears from all the languages of rude nations, who pay the greatest attention to their dreams, and who speak of seeing the dead in their visions, that these images (A) have always been taken by them for realities: may, some of the learned, and the celebrated Baxter is of the number, are disposed to doubt whether these appearances be not something more than illusions of the brain: But whether they really be so or not, one thing is certain, that all nations in all countries, in the darkest ages and the rudest periods, are accustomed to dream; and whether sleeping or waking, in the stillness of the night, in the gloom of solitude, in the fondness of friendship, in the ravings of love, the delirium of fever, and the anguish of remorse, to see and converse with the shades of the departed; and Lucretius* has remarked, that even the inferior animals are not exempted from such illusions of a restless fancy.

For often sleeping racers pant and sweat, Breathe short, as if they ran their second heat; As if the barrier down with eager pace They stretch'd, as when contending for the race. And often hounds, when sleep hath clos'd their eyes, They toss, and tumble, and attempt to rise; They open often, often snuff the air, As if they prest the footsteps of the deer; And sometimes wak'd, pursue their fancy'd prey, The fancy'd deer, that seem to run away, Till quite awak'd, the follow'd shades decay.

These powers of fancy extend wide over animal creation; and it is on this general principle that necromancers and dreamers have in all ages established their trade, that the stories of goblins have at all times so very easily procured belief, and that

The village matron, round the blazing hearth, Suspends the infant audience with her tales, Breathing astonishment! Of witches' rhymes And evil spirits; of the deathbed call Of him who robb'd the widow and devour'd The orphan's portion; of unquiet souls Ris'n from the grave to ease the heavy guilt Of deeds in life conceal'd; of shapes that walk At dead of night, and clank their chains and wave The torch of hell around the murderer's head.

Mankind in general would willingly dispense with these troublesome visits of the dead. To prevent the return of the "saunder" or the ghost, some nations of Africa use many superstitious rites*; and Kolben tells us, *Voyage to that the frightened Hottentots leave in the hut where a Congo and person has died all the utensils and furniture, lest the Angola, angry ghost, incensed at their aversion, should haunt them in their dreams, and infest them in the night. Divines and moralists have laboured to show that these are merely imaginary terrors: but God and nature seem to have determined that they shall produce the same effects upon certain minds as if they were real; and that while there is any sensibility in the heart, while there is any remembrance of the past, and any conjuring power in the fancy; the ignorant, the benighted, the timid, shall often meet with the goblins of darkness, the spectres of the tomb, the apparitions that hover round the grave, and the forms of the dead in the middle dream. See Spectre.

From these phenomena, which have been so common, it is probable in all countries and in all ages, what would mankind infer naturally? Would they not infer, that there is from something in the nature of man that survives death, and dreams &c. that there is a future state of existence beyond the grave? Are not still many specimens of this reasoning preserved in the ancient poets? and is it not thus that Achilles reasons after imagining that he saw the ghost of his friend Patroclus?

'Tis true, 'tis certain, man, though dead, retains Part of himself; 'tis immortal mind remains: The form subsists without the body's aid, Aerial semblance, and an empty shade.

---

(A) These images were called by the Greeks θραύμα θηραμία; and among the Romans they had various names, as umbrae, lenures, manes, larvae, and were sometimes called occursacula noctium, bustorum formidamina, se-pulchrorum terriculamenta, animae errantes, which are all comprehended under the species mortuorum.
This night my friend, so late in battle lost,
Stood at my side a pensive plaintive ghost;
Ev'n now familiar as in life he came,
Alas! how different, yet how like the same. Pope.

* Lib. iii. * Lucretius, a studious observer of nature, though no
friend to the soul's immortality, acknowledges frankly
that these phantoms often terrify the mind, haunt us in
our sleep, and meet us while awake. He confesses, too,
that by such appearances mankind have been led to be
lieve the future existence of the soul; but aware of the
consequence,

—Ne forte animas Acheronte recurrant
Effugere, aut umbros inter vivos volitant.

he endeavours to explain these curious phenomena on
some of the odd and fantastic principles of the Epicureans.
In doing this, however, he pretends not to deny
that these images appear to be real; but candidly
acknowledges that

--------They strike and shake
The airy soul, as when we awake,
With stroke so lively, that we think we view
The absent dead, and think the image true.

Creecch.

We here see how the belief of the soul's immortality
came to be general among mankind. But for this
information we are much more indebted to the poets, who
have given us faithful transcripts of nature, than to the
philosophers who have wished to entertain us with their
own theories, or to those laborious men of erudition,
who have dared as much to examine the source of the
ancient report as the friends of Ulysses to approach the
coast of Cimmerian darkness. With them tradition is
the ultimate boundary of research: and as gorgons,
chimeras, and hydriai, have come down to us by tradition;
so they, with great sagacity, suspect that tradition
must likewise be at the bottom of the soul's immor-
tality, and occasion the visions and phantoms of the
dead.

To tradition we have allowed all that it can justly
claim; but we cannot allow it to be the only source of
this opinion: and we have felt the highest indignation
upon hearing men of learning and genius affirm, from
a false zeal for the honour of revelation, that mankind,
without this instruction, could never have acquired the
art of building huts to screen them from the cold, or
have learned the method of propagating their species!
The reader must not here suppose that we allude to
Polydore Virgil (b). We have in our eye persons now
alive, with whom we have conversed on the subject, and
who (terrified at the length to which some philosophers
have carried the doctrine of instincts, and others the rea-
ning powers of the mind) have contended, with the
utmost earnestness, that we know nothing—not even the
functions of our animal nature—but by tradition or writ-
ten revelation.

Having now seen the source of the opinion concern-
ing the future existence of the soul, and pointed out the
natural phenomena by which mankind were led to em-
brace it, we come next to review the arguments by which
the philosophers attempted to confirm it.

Pythagoras believed, with the rest of his country, that Pytha-
annihilation was never the end, and that no bitterness was ever
the beginning of anything that is. His general
discipline upon this subject was shortly expressed in very
few words, Omnia mutantur nihil interit. He afterwards
learned from Egyptian priests that the soul migrates in
to new bodies; and being, it seems, a person of a most
extraordinary and astonishing memory, he found there
was some truth in the story; for after musing, he began
to remember that he was Euphorbus, the son of Pan-
theus, that was slain by Memelaus in the Trojan war;
and upon a jaunt to Peloponnese, recollected the shield
which he had worn at the time of the siege, in one of
the temples of Juno at Argus! That none might ques-
tion the truth of his assertion, his followers presently re-
moved all doubts by the famous argument, the irre-
dixit of Egyptian origin.

As Pythagoras taught that human souls are frequent-
ly thrust into brute shapes, and, as some imagined, by the
way of punishment; it occurred to Plato, that all beings,
dies, are a sort of prisons; and that, as a
consequence of this confinement, the soul was subjected
to the rage of desire, appetite, and passion, and to all
the wretched miseries of a jail. To explain this mys-
tery, he supposed that desires and appetites belong to
a soul that is purely animal residing in the body. But
he was perplexed with another difficulty; for as he
thought highly of the goodness of Deity, he could not
imagine how he should imprison us without a crime.
He supposed, therefore, that prior to its union with the
body, the soul had existed in one of ether, which
it still retains; but that even in this ethereal body it had
felt something of impure desire; and having indulged the vicious appetite, had contracted some stains of
pollution, for which it was confined in its present body
as a house of correction to do penance and improve its
morals.

To prove this ideal pre-existence of the soul, Plato
bore out his opinion with a sort of reasoning and
observation. He thought that matter and intelligence
are coeteral (see PLATONISM); that there are various
orders of souls; that some of both the man and the
brute are parts or emanations (c) of the anima mundi,
or soul of the world; that all are fundamentally parts or
emanations of Deity itself; and that all their faculties are

(b) This writer allots part of a chapter to show, "Quis primum instituerit artem meretriciam," as being in his
opinion a traditoty practice. See Lib. iii. cap. 17. De Rerum Inventoribus.

(c) The Deity was conceived by the ancients sometimes as a solid, when inferior souls were called avorxappa,
i.e. fragments or parts broken off from him; and sometimes as a fluid, when they were considered as avorga or,
emanations: but from none of these hypotheses did they reason consequentially. Their avorxappa were often
after death reunited to the Deity; and their avorga often remained separate and distinct for a long while, with-
out flowing back as they ought to have done, and mingling with the great ocean of spirit.
that originally had sprung from the great fountain of heat and light, and our earthly bodies a sort of dungeons in which our miserable souls are benighted and debased by desires, appetites, and passions. In the magian philosophy, the Supreme Being was called Oromades; was the god of light, or was light itself, and represented by Mithras, a subordinate divinity, and the same with the sun. Another deity of very great power was Arimanes, the god of darkness, who presided over matter, and was the origin of all evil (see Polytheism).

The ancient Gnostics, who derived their tenets from this source, believed, with Pythagoras and Plato, in a great number of subordinate genii; and said, that Demiurgus, the god of matter and the soul or spirit of this world, had contrived the bodies of men and brutes; and in the former particularly, as in so many prisons, had confined a number of celestial spirits, that by exposing them to the low desires of appetite and passion, he might seduce them from their allegiance to the God of light, and render them more submissive to himself. From these prisons the Supreme Being was continually making attempts to rescue them; and in the mean time was frequently sending divine messengers to enlighten and instruct them, and to render them capable of returning to the regions of life and happiness, to which they had belonged (x).

The Stoics attempted to simplify this system, which appears ancienly to have pervaded Egypt and the east, and which would seem to be no more than variously modified by Orpheus, Pythagoras, Plato, and others of the more northerly and western nations. None of them allowed a creation out of nothing; and the shaping and modelling of matter into forms was variously explained, according as they happened to be most addicted to superstitions, to morals, or to physics. Some ascribed these operations to ancient Time, Chaos, and Darkness, and explained the future changes in nature by the genealogies of these deities; some observing attraction and repulsion, or at least a sort of agreement and discordance among bodies, were inclined to ascribe them to Friendship and Hatred, or Love and Antipathy; some observing, that while one body rose another descended, made Levity and Gravity primary agents; and some taking notice that living bodies sprung from corruption, were

(d) The general doctrine, as delivered here in these verses of Virgil, is the same with that not only of Pythagoras, but of the Stoics.

(x) Plato made the stars the native residence of inferior souls; and when these were thoroughly purified below, returned them home again: and therefore, says Virgil, alluding to his doctrine,

---

Some have taught
That bees have portions of ethereal thought,
Endued with particles of heavenly fires;
For God the whole created mass inspires:
Thro' heaven and earth, and ocean's depth, he throws
His influence round, and kindles as he goes;
Hence flocks, and herds, and men, and beasts, and fowls,
With breath are quicken'd, and attract their souls:
Hence take the forms his prescience did ordain,
And into him at length resolve again.
No room is left for death, they mount the sky,
And to their own congenial planets fly.

Dryden.
were disposed to confer the same powers on Moisture and Heat.

The physical hypotheses were what had most charms for the Stoics. From their system immaterial beings were openly excluded; all things were regulated by physical laws or inexorable fate; and all things originated in the To E'r, which was probably suggested by the Moses of Pythagoras. This To E'r appears to have been a materia præmæ devoid of all the qualities of body. In their language it was an Αέρ or first principle, not subject to change. When it was invested with the properties of body, it then became a Στιγμα or an element; and then, so far as respected its qualities, especially its form, it was subject to changes almost perpetual. The gods themselves and the souls of men were in this system only modifications of matter (f). Man was composed of their four elements, Fire, Air, Water, and Earth; and upon dissolution, every part returned to the element from which it had come, as the water of a vessel swimming in the sea unites with the ocean when the vessel is broken. This system, it is plain, cannot possibly admit of any separate consciousness of existence (c). The same may be said of the systems of Democritus and Epicurus, and all those who undertook to explain things upon physical principles (h).

The chief merit of the physical systems appears to be this: Absurd as they were, it would seem from the whimsical and the almost childish reasoning of Lucretius, that they had a tendency to lead mankind from extravagant hypotheses to something that was similar to observation.

What Aristotle thought of the separate existence of the soul after death is not very certain. The soul he calls an Eidos, and if the reader can divine the meaning of the word, he perhaps can divine the meaning of the Stagirite, and will then be a better divider than we. At other times he says, that the soul is something divine; that it resembles the element of the stars; that it is something of a fiery nature; that it is the vicegerent of God in the body; and that the acuteness of the senses, the powers of the intellect, with the various kinds of appetites and passions, depend entirely on the qualities of the blood (l). Another opinion of very old date was that of the late ingenious Mr Hunter. According to him, the living principle resides in the blood. This opinion, which is mentioned by Moses, was adopted by Critias and others of the ancients. Harvey likewise embraced it. But Mr Hunter, who always wished to be thought an original, inclines to stand at the head of the opinion, and supports it by experiments similar to those of the famed Tliasctotius in mending noses. Should any of our readers wish to extract the soul's immortality from such an opinion, we must refer them to the many resources of ingenuity, sophistry, and logic.

Among the Jews, the belief of a future and separate existence for a long time was deemed no essential article of their creed. Some thought that the soul was a spark in the moving of the heart; some imagined that it was the breath, and that upon the dissolution of the body it naturally vanished into soft air. The Sadducees denied the existence of either angel or spirit. Many believed the doctrine of ghosts, and were accustomed to invoke them at the grave. It is hence that we hear the prophets complaining that they were seeking from the living God unto dead men. Some imagined that there was a pre-existence of souls; and, in the case of a blind man, asked our Saviour, whether the manner of his parents had sinned that he was born blind? Others inclined to a revolution of soul and body, and thought that our Saviour was either Elias or one of the old prophets returned; and a great many new-modelled their opinion of the soul's immortality according to certain passages in Scripture. The inspired mother of Samuel had said, "The Lord killeth and maketh alive: he bringeth down to the grave, and bringeth up." Isaiah had exclaimed, "Thy dead shall live; together with my dead body shall they arise: Awake, and sing, ye that dwell in the dust; for thy dew is as the dew of herbs, and the earth shall cast out the dead." Daniel had declared, that many of them that sleep in the dust of the earth shall awake to everlasting life, and some to shame and everlasting contempt. In the vision of the valley of dry bones, Ezekiel had seen that "at the word of the Lord" the bones came together, bone to bone, the sinews and the flesh came upon them, and the skin covered them above; and the breath came into the bodies, and they lived and stood upon their feet. And a passage of Job led them to suppose, that at some distant and future period a particular time, which was called the last or the latter day, was appointed by heaven for the general resurrection of all those who are sleeping in their graves. "I know (says Job) my Redeemer liveth, and that he shall stand at the latter day upon the earth; and though after my skin worms destroy this body, yet in my flesh shall I see God. Whether these passages were fairly interpreted agreeably to their true and original meaning, it is not here our business to inquire. It is sufficient for us to observe, that from them many of the Jews inferred the reality of a general resurrection (k). In this persuasion, Martha, speaking of her brother Lazarus, says to our Lord, "I know that he shall rise again in the resurrection at the last day." This resurrection appears

(f) The Αέρ of the Stoics appears to be the same with the Li of the Chinese.

(c) Yet without regarding the inconsistency, many of the Stoics believed, that the soul continued separate long after death; though all in general seemed to deny a future state of rewards and punishments.

(h) In his Physical Cosmography, Plato differed but little from the Stoics; but he had another sort of cosmography, in which all things appear to have sprung from, and to be almost wholly composed of metaphysical entities, as ideas of forms, numbers, and mathematical figures. These kinds of notions were common both to him and Pythagoras; and were originally borrowed from Egypt, where calculation and geometry were half defined. See PLATO.

(l) The immortal Harvey has collected these different opinions of the Stagirite in Excercit. 52. De Generatione Animalium.

(k) At present some are for allowing only those of their own nation to share in the benefits of this resurrection;
to have been a general opinion among the Pharisees; for although it was a notion of the sest of the Saddu- cees that there was no resurrection, neither angel nor spirit, yet the Pharisees, we are told, confessed both. And this assertion is plainly confirmed by St Paul himself when his countrymen accused him before Felix. "I confess unto thee (says this eminent apostle), that after the way which they call heresy, so worship I the God of my fathers, believing all things which are written in the law and in the prophets, and having hope toward God, which they themselves also allow, that there shall be a resurrection of the dead, both of the just and unjust."

This resurrection of the dead to judgment, though not perhaps in the same sense in which the old Pharisees conceived it, is now generally and almost universally (c) maintained by Christians (n). Yet the Christians differ considerably with respect to the nature of the human soul. Some imagine that this spirit is naturally mortal, and that it is propagated along with the body from the loins of the parent. In support of this opinion, it has been observed that a great number of insects and plants transfer their lives to their posterity, and die soon after the act of propagation; that after this act the vital principle is in the most vigorous of plants and animals always found to be much exhausted; and that Tertullian a father of the church, in attempting some experiments of the kind, became subject to a momentary blindness, and felt a portion of his soul going out of him (n).

These imagine that immortality was only conditionally promised to man; that Adam forfeited this immortality by his disobedience; and that Christ has restored us to the hopes of it again by his sufferings and death: for as in Adam we have all died, so in Christ, they say, we shall all be made alive; and that now the sting is taken from death, and the victory over our souls from the grave.

Others have conceived the human soul as naturally immortal, and as setting death and the grave at defiance. Adam, they say, died only in a figure; and only from the consequences of this figure, which means sin, has our Lord saved us. In this sense Adam died on the very day in which he had sinned; or he died literally in 1000 years, which with the Lord are as one day. To these arguments their opponents reply, What then is the victory over death and the grave? You must still have recourse to a new figure, and betake yourselves to the second death; though, after all, where is your grave? To this it is answered, that the soul of itself is naturally immortal, and that it depends not either for its existence or the exercise of its faculties upon the body; that the properties of matter, as figure, magnitude, and motion, can produce nothing that is like to perception, memory, and consciousness. This is true, rejoin their opponents; but besides these few properties of matter, which are only the objects of that philosophy which lately and properly been termed mechanical, the chemical philosophy has discovered other properties of matter; has found that matter is of various kinds; that it very often does not act mechanically; that it acquires many new properties by combination; and that no man, till further experiment and observation, should venture to assert how far the soul is or is not dependent on its present organized system. The others, proceeding on their hypothesis, maintain that the soul, as being immaterial, is not divisible; and though the body of a frog may live without the head for a whole day; though the body of a tortoise may live without the head for a whole month; though a human limb may for some minutes after amputation continue to perform a vital motion, independent of a brain, a stomach, or a heart; and

* See Phil. i. 21.

¶ Body.

The sect of the Quakers explain it figuratively.

The last quoted author (Resurrection of the same Body, asserted from the traditions of the Heathens, the ancient Jews, and the primitive Church) has endeavored to show that this doctrine, in the same sense as we understand it, has been asserted by the ancient Magi, and by the present heathen Gurus of Persia, the relics of the ancient Magi; by some of the ancient Arabians; by some of the Banians of India; by the present inhabitants of the island of Ceylon, of Java, of Pegu, of Transia; by some amongst the Chinese; by the Arderians in Guiana; and by the ancient Prussians. The proofs which he brings, it must be confessed, are not however always very satisfactory. It appears, even from his own account, that some of those who had derived their notions from certain Christians, Mahometans, or Jews. But the reader may judge of the great accuracy of his ideas from his bringing old Pythagoras and the Stoics, and even Democritus and Epicurus, in support of the same or a similar opinion.

In illo ipsi volupatis ultime sæstus quo genitale virus expellitur, nomine aliquid de anima quoque seminum exire, utque adeo marcescimus et devigescimus cum lucem detrimento.

VOL. XVII. PART II. 5 E
and though the parts of a plant, a polype, or a worm, may survive their separation and become living wholes, yet the soul, they observe, is not to be compared with the vital principles of plants and animals, nor ought to be divided on reasons so slender as those of analogy. Even granting, they say, that the soul were not naturally immortal of itself; yet the justice of God, which is not remarkable for its equal distribution of rewards and punishments in the present world, is bound to make some amends in the next. And to this again their opponents answer, as to the equal distribution of justice in a future world, of that we are assured on much better grounds than any of yours: our Lord has declared it in express terms; and whether the soul be immortal or not, we can easily believe what he said is true, as we know him whom we have trusted.

These, with Plato, suppose, that the soul is here as in prison; though how or at what time it should first have come into this dungeon they have not determined. They have only agreed, that upon its enlargement all its faculties are to receive an increase of power; and "having already equipped it so exquisitely with consciousness, activity, and perception in and of itself, and put it into so complete a capacity for happiness and misery in a separate state," their hypothesis does not require them to admit the least occasion for a resurrection; which accordingly is said to have been an article of Baxter's creed (6).

A third opinion, which extends likewise to every species of plant and animal, is, that all souls were created at once with bodies of other; that these bodies, occupying only a very small space, were packed up in their first progenitors, and there left to be afterwards evolved and clothed with matter of a grosser kind by acts of generation and consequent nutrition. For the proof of this theory we are referred to the small animals seen through the microscope, and likewise to those which are supposed to escape even microscopic observation; but, above all, to the eggs of insects, which, though scarcely perceptible, yet contain in embryo a future caterpillar and all its coats, and within these a future butterfly with its legs and wings. These philosophers can perhaps account for the general taint of original sin in some other way than has hitherto been done. We have only to add, that on their scheme the resurrection is not a matter that seems to be indifferent.

The next thing that falls to be considered is the place of the dead. From a natural enough association of ideas, an opinion had very early prevailed, that the spirit continued near to the body; and the offerings therefore intended for the dead were by most nations presented at the grave; and that on which the departed spirit is supposed to rest is always placed near the grave in China.

From the dreams of the night and the natural tenency of the fancy to work and to summon spirits when the world around us is involved in darkness, it has also been imagined, that these spirits delight in night and shadow of death (P), or have been picked from enjoying the exhilarating beams of day: hence we are told,

That in the dismal regions of the dead
Th' infernal kingdom once rais'd his horrid head;
Leaps'd from his throne, lest Neptune's sword
His dark dominions open to the day,
And pour in light.

The nations, therefore, who have fancied a receptacle for the dead, have thus been induced to place it in the west (q), where the night begins and the days ends. That part of the world which, in the divine his father's dominions, fell to Pluto the infernal god, and where, according to Lactantius, Satan has his empire of darkness, the Friendly Islanders have pointed to the westward of a certain island which they call Nuku Hiva; some tribes of American Indians, in the countries beyond the western mountains; and Homer, speaking to the westward of Greece at the boundaries of the ocean,

Where in a lonely land and gloomy cells
The dusky nation of Cimmeria dwells;
The sun ne'er views th'o' uncomfortable seat
When radiant he advances nor retreats,
Unhappy race! whom endless night invades,
Clouds the dull air, and wraps them round in shades.

Another opinion entertained by the Greeks and other nations was, that the place of departed souls under the earth. This opinion is frequently noticed in Homer, in Ægopil, and alluded to by the Evangelists. As for the prophets, we know the circumstances from which they borrowed it: it was borrowed from the subterraneous vaults where their chief were buried, and which have been described by modern writers. In the sides of these caverns there is now a great number of cells; and in these cells the nations in a sort of state, with their weapons of war and swords at their head. To these kinds of Egyptian tomberies Ezekiel alludes, when he says, "that they did not lie with the mighty that are fallen of the concerisized, who are gone down to hell with their weapons of war, and they have laid their swords under their heads. And Isaiah, when thus speaking of the princes of Babylon, "Thou shalt be brought down to hell, the pit of the pit. Hell from beneath is moved for thee; at thy coming; it stirreth up the deep; the nations, even all of them, fall there; even all the chief ones of the earth, fall there from their thrones, all the kings of the nations; the kings of the nations, even all of them, lie in the grave every one in his own house."
Many of the ancient fathers of the church asserted only, that the dead are now in \textit{abdixs receptaculis}, or in certain hidden and concealed places.

Orpheus, Origen, and some others of the fathers, with the ancient Caledonian bard Osian, and the learned Dodwell among the moderns, imagined that the soul, when it left the body, went into the air, and resided somewhere between the surface of the earth and the moon.

Those who believed in a transmigration caused the soul at death only to enter a new body, and kept the departed always with the living. This creed has been found in India, in Egypt, in Mexico, and in all those countries where picture-writing has been much used. In this species of writing, the same picture is on fancied analogy transferred by metaphor to signify either a god or a man, a brute or a plant; and in those countries where it was practised, men had usually their names from animals, and were represented by their figure in writing (a). From this last stage of the process, a transmigration was easily supposed: and hence we hear of the gods of Egypt wandering about like so many vagrants in brute shapes, and of princes being translated into stars, because a star was their emblem in hieroglyphic, or stood for their name in figurative language. And, in like manner, we see, from the specimen of this character, which is still preserved on celestial globes, how the heavens at first came to be filled with bears, scorpions, and dragons, and with a variety of other animals.

The opinions concerning the state of the dead are still more numerous than those concerning the place where they reside. Rude nations have generally thought that the future state is similar to the present; that plants, animals, and inanimate things there, have their shades: and that these contribute as much to the pleasures and conveniences of the dead as their realties do to the living; that husbands have their wives (s), lovers their mistresses, warriors their battles, huntsmen their sport; and that all their passions, amusements, and business, are the same as formerly. For this reason, that the dead may not appear unprovided in the next world, like the ancient Gauls, some tribes of India, America, and Africa, bury with them in the same grave their wives, their arms, their favourite animals, and their necessary utensils.

The ancient Egyptians, who believed in transmigration, supposed that the soul was after death destined to animate every species of bird and quadruped, of reptile and insect and was not to return to a human form till after a period of 3500 years. Others have confined their transmigrations to particular animals, as the soul of man to the human form, and the soul of the brute to the bodies of the species to which it belonged. Some have changed the brute into man, and man into the brute, that man might suffer injuries similar to what he had inflicted, and the brute retaliate what he had suffered. Others have confined the human soul in plants and in stones; and Bell of Antermony mentions an Indian, who supposed that his ancestors might be in fishes.

The notions of Homer were probably those of many of the poets of his time. But these notions were dismally true. When to Homer, his hero Ulysses visited the shades, many of the ghosts seemed to retain the mangled and ghastly appearance which they had at death; and, what is worse, seemed to be all starving with hunger, innumerable multitudes, with loud shrieks, flocking to the steams of his slain victim as to a most sumptuous and delicious banquet.

For scarcely had the purple torrent flow'd,
And all the caverns smok'd with streaming blood,
When, lo! appear'd along the dusky coasts
Thin airy shaws of visionary ghosts;
Fair pensive youths, and soft enamour'd maids,
And wither'd elders, pale and wrink'd shades.
Ghastly with wounds, the forms of warriors slain,
Stalk'd with majestic port, a martial train.
These, and a thousand more, swarm'd o'er the ground,
And all the dire assembly shriek'd around.
Ulysses saw, as ghost by ghost arose,
All wailing with unutterable woes.

Alone, apart, in discontented mood,
A gloomy shade, the sullen Ajax stood;
For ever sad, with proud disdain he pin'd,
And the lost arms for ever stung his mind.

\textit{Upon Ulysses saying to Achilles,}

Alive, we hail'd thee with our guardian gods;
And, dead, thou rul'st a king in these abodes;

\textit{The shade replied:}

Talk not of ruling in this doll'rous gloom,
Nor think vain words (he cry'd) can ease my doom;
Rather I choose laboriously to bear
A weight of woes, and breathe the vital air,
A \textit{slave to some poor mind that toils for bread},
\textit{Than live a scepter'd monarch of the dead.}

In this gloomy region no one is rewarded for his virtue, nor is punished for his crimes, unless committed, like those of Sisyphus, Tantalus, and Ixion, against the gods. All indeed are classed into groups, from a certain analogy of age, sex, fate, and disposition; but all appear to be equally unhappy, having their whole heart and affections concentrated in a world to which they are fated never to return.

The Elysium of Homer is allotted only for the relations and descendants of the gods; and Meneleus goes to this country of perpetual spring (t), not as a person of

(a) A military gentleman who resided at Penobscot during the late American war, assured us that the Indians, when desired to subscribe a written agreement, drew always the picture of the object or animal whose name they bore. But for fuller information on this subject, see Clavigero's \textit{History of Mexico}.

(s) The question which the Sadducees put to our Saviour about the wife of the seven brothers, is a proof that the Pharisees thought there was a marriage and giving in marriage in the future state, and that it was somewhat similar to the present.

(t) Homer sends the ghost of Hercules to the shades, while Hercules himself is quaffing nectar with Hebe in
The conscious wretch must all his acts reveal,
Loth to confess, unable to conceal,
From the first moment of his vital breath,
To the last hour of unrepenting death.

The spirits of the dead no longer mingle together as
in the less enlightened period of Homer; the virtuous
are dismissed to a place of torments, the virtuous sent to
regions of bliss; different characters are confined to
limbs; and those who are too virtuous for hell, but too
much polluted with the stains of vice to enter heaven
even without preparation, are for some time detained in
a purgatory.

For there are various penances enjoind,
And some are hung to bleach upon the wind;
Some plung'd in waters, others purg'd in fires,
Till all the dregs are drain'd, and rust expires;
Till nothing's left of their habitual stains,
But the pure ether of the soul remains.

When thus purified, they become fitted to receive
the rewards of their past virtues, and now enter into
those regions of happiness and joy.

With eather vested, and a purple sky,
The blissful seats of happy souls below,
Stars of their own, and their own suns they know;
Where patriots live, who, for their country's good,
In fighting fields were prodigal of blood.

Priests of unhumble'd lives here make abode,
And poets worthy their inspiring god;
And searching wise, of more mechanic parts,
Who grace'd their age with new-invented arts:
Those who to worth their bounty did extend;
And those who knew that bounty to commend.

These good men are engaged in various amusements,
according to the taste and genius of each. Orpheus
is still playing on his harp, and the warriors are still
delighted with their chariots, their horses, and their
arms.

The place of torment is at some distance.
A gaping gulf, which to the centre lies,
And twice as deep as earth is distant from the skies;
From hence are heard the groans of ghosts, the pains
Of sounding lashes, and of dragging chains.
Here, those who brother's better claim disown,
Expel their parents, and usurp the throne;
Defraud their clients, and, to lure sold,
Sit brooding on unprofitable gold.
Who dare not give, and even refuse to lend,
To their poor kindred, or a wanting friend.
Vast is the throng of these; nor less the train
Of lustful youths for foul adult'ry stain.

Who hears and judges each committed crime,
Inquires into the manner, place and time.

in the skies. One soul of the hero is therefore repining with the ghosts of mortals in the regions below, while
the other is enjoying all the happiness of the gods above. (See Odyssey, book ii. near the end). Philosophers
since have improved on this hint of the poet; and men have now got rational, animal, and vegetable souls, to
which sometimes a fourth one is added, as properly belonging to matter in general. Homer insinuates, that Me-
nelus was to be translated to Elysium without tasting death. This Elysium is the habitation of men, and not
of ghosts, and is described as being similar to the seat of the gods. Compare Odyssey, iv. 1. 363, and Odyssey,
vi. 1. 43. in the Greek.
Hosts of deserters, who their honour sold,
And basely broke their faith for bribes of gold:
All these within the dungeon’s depth remain,
Despairing pardon, and expecting pain.

The souls of babes, of unhappy lovers, and some others, seem to be placed in a paradise of fools residing in a quarter distinct from Elysium, Tartarus, and Purgatory.

It is curious to observe, how much these ideas of a future state differ from the vague and simple conjectures of rude nations; and yet from their simple and rude conjectures, we can easily trace the successive changes in the writings of Homer, Plato, and Virgil; and may easily show, that those laws which different nations have prescribed for their dead, have always borne the strongest analogy to their state of improvement, their system of opinions, and their moral attainments. Some nations, as those of India, have fancied a number of heavens and hells, corresponding to some of the principal shades in virtue and vice; and have filled each of these places respectively with all the scenes of happiness and misery, which friendship and hatred, admiration, contempt, or rancour, could suggest. But having already observed the progress of the human mind in forming the grand and leading ideas of a future state, we mean not to descend to the modifications which may have occurred to particular nations, sects, or individuals.

The belief of Christians respecting futurity demands our attention, as being founded on a different principle, namely, on express revelations from heaven. From many express declarations in Scripture, all Christians seem to be agreed, that there is a heaven appointed for the good and a hell for the wicked. In this heaven the saints dwell in the presence of God and the uninterrupted splendours of day. Those who have been wise shine as the firmament, and those who have converted many to righteousness as the stars. Their bodies are glorious, immortal, incorruptible, not subject to disease, to pain, or to death. Their minds are strangers to sorrow, to crying, to disappointment; all their desires are presently satisfied; while they are calling, they are answered; while they are speaking, they are heard. Their mental faculties are also enlarged; they no more see things obscurely, as through a cloud, but continually beholding new wonders and beauties in creation, are constantly exclaiming, “Holy, holy, holy! is the Lord of hosts; worthy is he to receive glory, honour, and thanksgiving; and to him be ascribed wisdom, and power, and might; for great and marvellous are his works, and the whole universe is filled with his glory.”

Their notions of hell differ considerably. Some understanding the Scriptures literally, have plunged the wicked into an abyss without any bottom; have made this gulf darker than night; have filled it with ravenous and malignant spirits, that are worse than furies; and have described it as full of sulphur, burning for ever. This frightful gulf has by some been placed in the bowels of the earth; by some in the sun; by some in the moon; and by some in a comet: but as the Scriptures have determined nothing on the subject, all such conjectures are idle and groundless.

Others imagine, that the fire and sulphur are here to be taken in a figurative sense. These suppose the torments of hell to be troubles of mind and remorses of conscience; and support their opinion by observing, that resurrection cannot act upon spirit; forgetting, perhaps, that at the resurrection the spirit is to be clothed with a body, and, at any rate, that it is not for man vainly to prescribe bounds to Omnipotence.

What seems to have tortured the genius of divines of the mid-much more than heaven or hell, is a middle state. On the other hand, this subject there being little revealed in Scripture, and different opinions have thought it incumbent upon them to supply notions about the defect; which they seem to have done in different ways. From the Scriptures speaking frequently of the dead as sleeping in their graves, those who imagine that the powers of the mind are dependent on the body, suppose that they sleep till the resurrection, when they are to be awakened by the trump of God, reunited to their bodies, have their faculties restored, and their sentence awarded.

This opinion they support by what St Peter says in the Acts, that David is not ascended into heaven; and that this patriarch could not possibly be speaking of himself when he said, “Thou wilt not leave my soul in hell, i.e. the place of the dead.” They observe, too, that the victory of Christ over death and the grave seems to imply, that our souls are subject to their power, sleep; and accordingly the Scripture speaks frequently of the soul’s drawing near to, of its being redeemed from, and of its descending into, the grave; that the Psalmist, however, declares, plainly, that when the breath of man goeth forth, he returneth to his earth, and that very day his thoughts perish. And should any one choose to consult Ecclesiastes, he will find, that the living know that they shall die, but that the dead know not anything, that their love, and their hatred, and their envy, are perished; and that there is no work, nor device, nor wisdom, nor knowledge, in the grave, whether they are gone.

Those who believe that the soul is not for the exercise of its faculties dependent on the body, are upon its separation at death obliged to dispose of it some other way. In establishing this theory, they usually begin with attempting to prove, from Scripture or tradition, both its active and separate existence; but with proofs from tradition we intend not to middle. Their arguments from Scripture being of more value, deserve our serious consideration; and are nearly as follow.

Abraham, they say, Isaac, and Jacob, are still living, because Jehovah is their God, and he, it is allowed, is not the God of the dead, but of the living. But their opponents reply, That this is the argument which our Saviour brought from the writings of Moses to prove a future resurrection of the dead; and that any person, who looks into the context, will see it was not meant of a middle state. From the dead living unto God, our Saviour infers nothing more than that they shall live at the resurrection; and that these gentlemen would do well in future to make a distinction between simply living and living unto God: For though Abraham, Isaac, and Jacob, be living unto God, our Saviour has assured us that Abraham is dead, and the prophets dead.

A second argument is that glimpse which St Paul had of Paradise about 14 years before he had written his Second Epistle to the Corinthians. To this argument their opponents reply, That as St Paul could not tell whether, on that occasion, he was out of the body or in the body, it is more than probable that the whole
was a vision; and, at any rate, it is no proof of a separate existence.

A third argument is, St Paul's wishing to be absent from the body, and present with the Lord. But, say their opponents, St Paul desired not to be unclothed, but to be clothed upon: and as some of those who maintain a separate existence, bring Scripture to prove that the body continues united to Christ till the resurrection; in that case, St Paul, if he wished to be present with the Lord, should have rather remained with his body than left it.

A fourth argument is, the appearance of Moses and Elias upon the mount of transfiguration. To which their opponents reply, that these saints appeared in their bodies; that Elias was never divested of his clothing; and that the account which we have of the burial of Moses, has led some of the abler critics and soundest divines to conclude, that he was likewise translated to heaven without tasting death. At any rate, say they, he might have been raised from the dead for the very purpose of being present at the transfiguration, as the bodies of other saints certainly were, to bear testimony to our Lord's resurrection and victory over the grave.

A fifth argument is, what our Saviour said to the thief: "Verily I say unto thee, to-day shalt thou be with me in paradise." The objection usually made here is, that the expression is evidently ambiguous, and that the sense depends entirely on the punctuation; for if the point be placed after to-day, the meaning will be "Verily, even now, I tell thee, thou shalt be with me in paradise." But the import of paradise in this place, say the opponents, is likewise difficult. We learn from St Peter's explanation of the 16th Psalm, that our Saviour's soul was not to be left in hell; and we know that on the day of his crucifixion he went not to heaven: for after he had risen from the place of the dead, he forbade one of the women to touch him, as he had not yet ascended to the Father. Hell, therefore, and paradise, continue they, seem to be in this passage the same thing, the place of the dead; and our Saviour's intention, they add, was not to go to heaven at that time, but to show his victory over death and the grave, to whose power all mankind had become subject by the disobedience of their first parents.

Without pretending to enter into the merits of this dispute, the ingenious Burnet, in his Theory of the Earth, endeavours to prove, upon the authority of the ancient fathers, that paradise lies between the earth and the moon; and the learned Dodwell, on the same authority, has made it the common receptacle of souls till the resurrection; but has not told us whether or not they are to be accountable for the actions of this separate existence at the latter day, or are only to be judged according to the deeds that were done in their bodies.

This notion of a common receptacle has displeased many. The state of purgation, obscurely hinted in the doctrines of Pythagoras, and openly avowed by Plato and Virgil, has been adopted by the Remish divines, who support their opinion on certain obscure passages of Scripture, which are always of a yielding and compassionate nature, may easily be twisted to any hypothesis, unlike general lovers espouse rather from interest in merit.

It has displeased others, because they are anxious that the righteous should have a fore-taste of their joys, and the wicked of their torments, immediately after death, which they infer to be certainly the case from the parable of the rich man and Lazarus (v). But to this it is objected, that the rich man is supposed to be in the place of torments, and that this punishment only is not to take place on their own hypothesis till after sentence on the resurrection.

Another argument used for the intermediate, the vision of St John in the Apocalypse. In the vision the Evangelist saw under the altar the souls of them that were slain for the word of God and for the testimony which they held. Their opponents doubt whether these visible souls were immaterial, as St John beheld them cry with a loud voice, and saw white robes put unto every one of them. If they had bodies, this circumstance might chance to prove a resurrection immediately after death, and so supersede the general resurrection at the last day.

While such conclusions as are here drawn from the parable and vision, say the opponents of an intermediate existence, imply that the dead are not raised, and are now receiving the respective rewards their virtues and their crimes; those who maintain an intermediate separate existence, who speak of the soul as a prison, and of the soul as receiving an increase of power when freed from the body, are certainly not so consistent with themselves, when they think this soul would derive an advantage from its after death with either a new system of matter or the cold air, however much altered. Baxter, they say, who first discovered the inconsistency, was disposed to reason somewhat thus:

O, Father! can it be that souls sublime
Return to visit our terrestrial clime?
Or, that the generous mind, releas'd at last
Should covet lazy limbs and mortal birth?

In no one instance, they continue, have Christ perhaps more apparently than in this argument wished the Scriptures to their own hurt; by thus rashly attempting to accommodate the sacred doctrines of religion to a preconceived philosophical hypothesis, they have kept themselves open to the ridicule of deists, and have been obliged, for the sake of consistency, either to speak slightingly of the resurrection; which certainly the surest foundation of their hope, seeing St Paul hath assured us, that if there be no resurrection of dead, then they which are fallen asleep in Christ are perished, and those who survive may eat and drink, act as they please, for to-morrow they die; and die to live never again.

Though this reproof may be rather severe, yet

(v) Whitby shows that this parable was conformable to the notions of the Jews at that time; and even the Mahometans, who believe in the resurrection of the dead, suppose likewise a state of rewards and penalties in the grave.
sorry to observe that there seems to have been sometimes too much reason for it. A certain divine whose piety was eminent, and whose memory we respect, having written "An Essay towards the proof of a separate State of Souls between Death and the Resurrection, and the Commencement of the Rewards of Virtue and Vice immediately after death," has taken this motto, "Because sentence against an evil work is not executed speedily, therefore the heart of the sons of men is fully set in them to do evil," the doctrine he says, of the resurrection of the body and the consequent states of heaven and of hell, is a guard and motive of divine force, but it is renounced by the enemies of our holy Christianity; and should we give up the recompenses of separate souls, while the deist denies the resurrection of the body, I fear, between both we should sadly enfeebled and expose the cause of virtue, and leave it too naked and defenceless."

This author, who wishes much that the punishment of crimes should follow immediately after death, is of opinion, that if heaven intended to check vice and impiety in the world, it has acted unwise, if it really has deferred the punishment of the wicked to so late a period as the resurrection. "For such, he observes, is the weakness and folly of our natures, that men will not be so much influenced and alarmed by distant prospects, nor so solicitous to prepare for an event which they suppose to be so very far off, as they would for the same event, if it commences as soon as ever this mortal life expires. The vicious man will indulge his sensualities, and lie down to sleep in death, with this comfort, I shall take my rest here for 100 or 1000 years, and perhaps in all that space my offences may be forgotten; or let the worst come that can come, I shall have a long sweet nap before my sorrows begin: and thus the force of divine terrors is greatly enervated by this delay of punishment."

Thus far our author, who thinks that his hypothesis, if not true, is at least expedient, and that from motives of expediency it ought to be inculcated as a doctrine of Scripture: but how far his reasons can be here justified we mean not to determine; we shall leave that to be settled by others, reminding them only that the distance of future rewards and punishments is not greater on the supposition of the sleep of the soul than on the contrary hypothesis. Every man who has but dipped into the science of metaphysics knows, and no man ever knew better than he who is believed to have been the author of the work before us, that time unperceived passes away as if in an instant; and that if the soul be in a state void of consciousness between death and the resurrection, the man who has lain in his grave a thousand and years will appear to himself to have died in one moment and been raised in the next. We would likewise recommend to those who may henceforth be inclined to inculcate any thing as a doctrine of scripture merely on account of its supposed expediency, always to remember that God is above, that they are below, that he is omniscient, that they are of yesterday and know little, that their words therefore should be wary and few, and that they should always speak with respect of whatever concerns the Sovereign of the universe, or relates to his government either in the natural or moral world. For wilt thou, says the Highest, disannul my judgment: Wilt thou condemn me that thou mayest be righteous? Shall he that contendeth with the Almighty instruct him? He that reproveth God let him answer it.

If, in stating these opposite opinions, we may seem to have favoured what has been called the sleep of the soul, it is not from any conviction of its truth, for there are particular texts of Scripture which appear to us to militate against it. We are satisfied, however, that it is a very harmless opinion, neither injurious to the rest of the articles of the Christian faith nor to virtuous practice; and that those who have poured forth torrents of obloquy upon such as may have held it in simplicity and godly sincerity, have either mistaken the doctrine which they condemned, or been possessed by a spirit less mild than that of the gospel (x). Whatever be the fate of the middle state, the resurrection stands on a different basis. It is repeatedly asserted in Scripture; and those grounds upon which we believe it are authenticated facts, which the affection, Scripture, the ingenuity, and the hatred of sceptics, have numberless times attempted in vain to disprove. These facts, we are now to consider, referring our readers for the character of the witnesses, the authenticity of the gospel history, and the possibility of miracles, to the parts of this work where these subjects are treated (see Miracle, Metaphysics, Part I. chap. vii. and Religion); or, should more particular information be required, to the writings of Ditton, Sherlock, and West.

Our Lord, after proving his divine mission by the miracles which he wrought, and by the completion of ancient predictions in which he was described, declared that the doctrine of a resurrection was one of those truths which he came to announce. To show that such an event was possible, he restored to life the daughter of it Jairus, a ruler of the synagogue, a young man of Nain, whose father was carried out on his bier to be buried, and his wife's relation Lazarus, whose body at the time was thought to be several have become the prey of corruption. Though the two persons first of these miracles were wrought in the presence of a number of witnesses, yet the last, owing to particular circumstances, produced a much greater noise among the Jews. It was performed on a person seemingly of some note, in the village of Bethany, not far from Jerusalem, and in the presence of a great many persons who from the metropolis had come to condole with Mary and Martha. No doubts were entertained of the reality of Lazarus's death. Our Lord was at a distance when

(x) Perhaps no man has been more culpable in this respect than the celebrated Warburton, who seems at first to have himself denied an intermediate state of conscious existence. He afterwards imagined that such a state is supposed, though not expressly asserted, in Scripture; and at last he maintained it with all the zeal and warmth of a proselyte. To prove the sincerity of his conversion, he treated his adversaries with scurrilous nicknames, banter, and abuse; a species of reasoning which seldom succeeds in recommending a bad cause, and which never confers credit on one that is good.
Resurrection.

when he expired, and his body had already been lying for some days in the grave. When he came forth at the voice of our Lord, all were astonished. Those from Jerusalem, on returning home, are impatient to relate what they had seen; those who heard of so memorable an event cannot conceal it; the report reaches the ears of the Pharisees and chief priests. They are soon made acquainted with every circumstance; and dreading the issue, they think it necessary to call a council upon the occasion, and concert the measures that ought to be pursued in a matter which was likely to be attended with so many and important consequences. In this council, it seems to be agreed, that our Lord had performed, and was still continuing to perform, many miracles: that this last miracle, as being of an extraordinary kind, would make many converts; and if measures were not speedily taken to prevent these uncommon displays of his powers, all would believe on him; the jealousy of the Romans would be excited, the rulers deposed, and the nation of the Jews deprived of its few remaining privileges. Yet notwithstanding these private concessions made in the council, the members who dreaded to let their sentiments be known to the people, affect in public to treat our Saviour as an impostor. But he who had already demonstrated the absurdity of their opinions, who supposed that his miracles were wrought by Beelzebub prince of the devils, is again ready to confute the ridiculous assertions of those who pretended to say that they were a deception. His friend Lazarus was still living at the distance of only a few miles, and many of the Jews who had gone to see him were ready to attest the truth of the report. If the rulers, apprehending the consequences of the truth, be afraid to know it, and if they are unwilling to go to Bethany, or to send for Lazarus and those who were present at his resurrection, our Lord gives them a fair opportunity of detecting his fraud, if there was any such to be found in him. To preserve their power, and remove the jealous suspicions of the Romans, it had been already determined in council to put him to death; and our Lord foretells that the third day after his death he shall rise from the grave. Here no place was reserved for deception. The sect of the Pharisees and the chief priests are openly warned and put upon their guard; and very fortunately for the cause of Christianity, this singular prediction was not heard with scorn, or indeed, if with scorn, it was only affected. We know from the sentiments expressed in the council, that our Lord was secretly dreaded by the rulers; and that his predictions, in their private opinion, were not to be slighted. The means accordingly which they employed to prevent, even in the very appearance, the completion of his prophecy, were admirably calculated to remove the scruples of the most wary and sceptical inquirers, if their object was only to search after truth. At the next festival of the passover, when the scheme of Caiaphas was put in execution, and when it was deemed expedient by the council that he should die, to save the nation from the jealousy of the Romans; as a proof of their steady loyalty to Rome he was apprehended, was tried as an enemy to her government, was at last condemned upon false evidence, and suspended on a cross until they were fully satisfied of his death. Even after his death, the spear of a soldier was thrust into his side: and the water that gushed out with the blood is a proof to those who are acquainted with the structure and economy of living bodies, that he must have been some time dead.

After he was taken down from the cross, a seal was put on the door of the sepulchre in which he was laid, as the best check against secret fraud; and a guard of soldiers was stationed around it, as the best security against open violence. In spite, however, of all these precautions, the prediction was accomplished; the angel of God, descending from heaven with a countenance like lightning, and with raiment white as snow; the watch shake, and become as dead men; the earth quakes; the stone is rolled from the mouth of the sepulchre; the angel sits on it, and our Lord comes forth.

It was in vain for the Jews to allege that his disciples came in the night, and stole him away, while the watch were asleep. One must smile at these futile assertions. How came the disciples to know that the watch were asleep; or what excuse had the watch for sleeping, and incurring a punishment which they knew to be capital in the Roman law; and how came they, in the name of wonder, to be brought as an evidence for those transactions that happened at the time when they were asleep? Whatever credit may be given by modern infidels to this ill-framed story, it is past dispute that it had some among the Jewish rulers at the time that it was current. Not long after our Saviour's resurrection, the apostles were called before the council, and threatened with death for teaching in the name of Jesus. Their boldness upon that occasion was so provoking to the rulers, that the threat would have been instantly put in execution, had not Gamaliel, a doctor of the law, of high reputation, put them in mind of other impostors who had perished in their attempts to mislead the people; and concluded a very sensible speech with these remarkable words: "And now, I say unto you, refrain from those men, and let them alone; for if this counsel, or this work, be of men, it will come to nought; but if it be of God, ye cannot overthrow it, lest haply ye be found even to fight against God." This advice the council followed. But is it possible that Gamaliel could have given it, or the council paid the least regard to it, had the story of the disciples stealing the body been then credited? Surely some among them would have observed, that a work or counsel, founded on imposture and fraud, could not be supposed to be of God, and they would unquestionably have slain the apostles.

The story of stealing the body is indeed one of the most senseless fictions that ever was invented in support of a bad cause. Our Lord was on the earth 40 days after he arose. He appeared frequently to his disciples. He ate and drank in their presence; and when some of them doubted, he bade them handle him and see that he was not a spectre, showed the mark of the spear in his side, and the prints of the nails in his feet and hands. Besides thus appearing to his disciples, he was seen by more than 500 brethren at one time; all of whom, as well as his disciples, must necessarily have known him previous to his suffering, and could therefore attest that he was the person who was once dead, but was then alive. Yet for strangers in general, who had not seen him previous to his death, and could not therefore identify his person after he arose, our Lord reserved many other proofs that were equally convincing. Before his ascension, he bade his disciples wait till they received power, by the Holy Ghost
Resurrection.

Ghost descending upon them: That then they should be witnesses with him, both in Jerusalem, and in all Judea, and in Samaria, and unto the uttermost ends of the earth; in order that the people of all these nations, observing the miracles wrought in his name, might themselves become ocular witnesses that those who preached his resurrection were warranted to do so by his authority; and that his authority, on which so numerous miracles attended, must be divine.

We intend not here to examine the minute objections and cavils that have been advanced respecting the truth of this important fact. The kinds, however, we shall mention in general. Some have doubted of our Lord's resurrection, as being an event which is not confirmed by general experience, because they imagine that what happens once should happen again, and even repeatedly, in order to be true. Some, taking their own to be preferable schemes, have objected to the way in which it happened, and to the manner in which it is narrated. Some have imagined, that possibly the gospel history may be false; that possibly the disciples were very ignorant, and might be deceived; that possibly, too, they were deep politicians, and a set of impostors; and that possibly the writings which detected their falsehoods may have been destroyed. It is difficult to reason, and worse to convince, against this evidence of possibilities: but we flatter ourselves, that to the candid reader it will appear sufficiently overturned in our article Miracle; where it is shown that neither clowns nor politicians could have acted the part that was acted by the apostles, had not the resurrection been an undoubted fact.

Some of the objectors to it have also maintained, that possibly there is nothing material without fact, that there is nothing mental within us, and that possibly the whole world is ideas. This mode of arguing we pretend not to explain; it is thought by some to proceed entirely from a perverseness of mind or disposition, in which books of medicine it is always considered as a symptom of disease, and the patient recommended to be treated in the hospital, and not in the academy.

By his raising others, and particularly by rising himself, from the dead, our Saviour demonstrated that a resurrection from the dead is possible. And on that authority, which by his miracles he proved to be divine, he declared to his followers, that there is to be a general resurrection both of the just and of the unjust, instructing his disciples to propagate this doctrine through all nations; St Paul confessing, that if there be no resurrection of the dead, preaching is vain, and our faith is vain.

As to the order of succession in which the dead are to be raised, the Scriptures are almost silent. St Paul says, that every man is to rise in his own order, and that the dead in Christ are to rise first: and St John observed in his vision, that the souls of them which were beheaded for the witness of Jesus, and for the word of God, and which had not worshipped the beast, neither his image, neither had received his mark upon their foreheads, or in their hands, lived and reigned with Christ a thousand years; but the rest of the dead lived not again until the thousand years (γ) were finished.

A question that has much oftener agitated the minds of men is, with what sort of bodies are the dead to be bodies they raised? St Paul has answered, with incorruptible and immortal bodies (ζ). And to silence the disputatious caviller of his day, he illustrated his doctrine by the growth of grain. "Thou fool (said he), that which thou sowest, thou sowerst not that body that shall be, but bare grain, it may chance of wheat or of some other grain." To us it appears very surprising, that any one who reads this passage with the slightest attention, should perplex himself, or disturb the church with idle attempts to prove the identity of the bodies with which we shall die and rise again at the last day. The apostle expressly affirms, that "flesh and blood cannot inherit the kingdom of God; that we shall all be changed, in a moment, in the twinkling of an eye, at the last trump; that there are celestial bodies and bodies terrestrial; and that the glory of the celestial is one, and the glory of the terrestrial another."

That this implies a total change of qualities, will admit of no dispute; but still it has been considered as an article of the Christian faith, that we are to rise with the same bodies in respect of substance. What is meant by the identity of substance, with quality wholly different, it is not very easy to conceive. Perhaps the meaning may be, that our incorruptible bodies shall consist of the same material particles with our mortal bodies, though these particles will be differently arranged to produce the different qualities. But as the particles of our present bodies are constantly changing, and as different particles compose the body at different times, a question has been put, With what set of particles shall we rise? Here a singular variety of opinions have been held. Some contend, that we shall rise with the original stamina of our bodies derived from our parents; some are for rising with that set of particles which they had at birth; some with the set which they are to have at death; and some with the particles which remain after maceration in water; though, God knows, that if this maceration be continued long, these may arise with few or no particles at all. Another query has given much alarm. What if any of these particles should enter a vegetable, compose its fruit, and be eaten by a man, woman, or a child? Will not a dispute, similar to that apprehended by the Sadducees about the wife of the seven brothers, necessarily follow, whose particles are they to be at the resurrection? Against this confusion, they trust that the goodness and wisdom of heaven will take all the proper and necessary measures; and they even venture to point out a way in which that may be done. A foot deep of earth, they observe, in two or three of the counties of England, supposing each person to weigh on an average about seven stones and a few pounds, would amply supply with material

(γ) These thousand years formed the happy millennium so often mentioned in the ancient fathers; and the learned Burnet, in his Theory of the Earth, has endeavoured to prove, that a similar notion prevailed among the Jews. See Millennium.

(ζ) Our Saviour rose with the same body, both as to substance and qualities; because it was necessary that his person should be known and identified after his resurrection.
RES [ 778 ] RET

Resurrection.

- See Holy's Resurrection of the Same Body Assumed.

Material bodies 600,000,000 of souls for no less a space than 20,000 years; and therefore there seems to be no necessity for the vamping up of their old materials to lodge and accommodate new souls.

But unluckily here, the question is not about the possibility of keeping the particles of different bodies separate and distinct. The question is rather, What have the Scriptures determined on the subject? Now the Scriptures say, that the spirit returns unto God who gave it. And should it be asked, in what place does he reserve it till the resurrection? the Scriptures reply, in the place of the dead; because the soul descends into the pit, is redeemed from the grave; and the sting of death, the last enemy that is to be destroyed, shall be taken away when the trumpet of God shall sound: at which time the dead that sleep in their graves shall awake, shall hear the voice, and shall come forth. There is not here so much as a word concerning the body; and therefore it was asked with what bodies are the dead to be raised? To which it was answered, the vile body is to be changed. The body which is, is not the body which shall be; for the incorruptible must put on incorruption, and that which is mortal, put on immortality.

This curious discovery of the sentiments of Scripture we owe to a layman, the celebrated Locke; who, in one of his controversies with the bishop of Worcester, etc., came to understand what he knew not before, namely, that nowhere have the Scriptures spoken of the resurrection of the same body in the sense in which it is usually conceived. The resurrection of the same person is indeed promised; and how that promise may be fulfilled, notwithstanding the constant change of the particles of the body, has been shown in another place. See Metaphysics, Part III. Chap. iii.

The advocates, therefore, for the resurrection of the mortal body, have again been obliged to betake themselves to the shifts of reasoning. It is proper, say they, that the same bodies which have been accomplies in our vices and virtues, should also share in our rewards and punishments. Now, granting they will, shall one set of particles be bound for the crimes, or be entitled to receive the rewards, of the animal system, from its first commencement to its dissolution? or shall every particle rise up successively, and receive its dividends of rewards and punishments for the vices and virtues that belonged to the system during the time that they were in union with the sentient principle? and is that the hand that fell in defending a father to be (as is supposed in some of the eastern countries) rewarded in heaven; while the other that struck him when the son became vicious, is dismissed into torments?

Finding this hypothesis supported by neither Scripture nor reason, they next appeal to the ancient fathers. And they, it is confessed, are for the resurrection of the very same flesh. But this notion is directly contrary to the Scriptures, which have said, that flesh and blood are not to inherit the kingdom of God.

But whatever be the bodies with which the dead are to be raised at the general resurrection, all mankind must appear in judgment, and receive sentence according to the deed done in the body, without regard, so far as we know, to their actions and conduct in the middle state. After this sentence, the righteous are to enter into celestial and eternal joys, and the wicked to suffer the punishments of hell. These punishments some have supposed to be everlasting; others think, that after some temporary punishment, the souls of the wicked are to be annihilated; and others imagine, that after doing penitential punishment for a while in hell, they are to be again received into favour; inclining to explain the damnation of the Almighty as a child would do the threatenings of his mother, or a lover the affected chideings of his mistress.

Resuscitation, the same with resurrection and revivification. See the preceding article and Resurrection.

The term resuscitation, however, is more particularly used by chemists for the reproducing a mixed body from its ashes; an art to which many have pretended, as to reproduce plants, &c. from their ashes.

Retail, in Commerce, is the selling of goods in small parcels, in opposition to wholesale. See Commerce.

Retainer, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

Retaining fee, the first fee given to a servant or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

Retention, among civilians, the act of returning like for like.

Retardation, in Physics, the act of diminishing the velocity of a moving body. See Gunner, Mechanics, Pneumatics, and Projectiles.

Rete mirabile, in Anatomy, a small plexus or network of vessels in the brain, surrounding the piniary gland.

Retention is defined by Mr Locke to be, a faculty of the mind, whereby it keeps or retains those simple ideas it has once received, by sensation or reflection. See Metaphysics, Part I. Chap. ii.

Retention, is also used, in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents. In this sense, retention is opposed to evacuation and excretion.

Reticula, or Reticule, in Astronomy, a contrivance for measuring very nicely the quantity of eclipses, &c. This instrument, which was introduced by the Academy of Sciences at Paris, is a little frame composed of 13 fine silken threads, parallel to, and at equal distances from each other, placed in the focus of object glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent. The diameter of the sun or moon is of consequence thus seen divided into 12 equal parts or digits; so that, in order to ascertain the quantity of the eclipse, there is nothing more to do than to number the parts that are dark, or that are luminous.

As a square Reticule is only proper for the diameter of the luminary, not for the circumference of it, it is sometimes made circular, by drawing six concentric, equidistant circles, which perfectly represents the phases of the eclipse.

But it is obvious that whether the Reticule be square or circular, it should be perfectly equal to the diameter or circumference of the sun or star, such as it appears in the focus of the glass; otherwise the division cannot be ust. Another imperfection in the Reticule is, that
But a remedy for these inconveniences has been found out by M. de la Hire, who contrived that the same Reticule may serve for all telescopes, and all magnitudes of the luminary in the same eclipse. Two object glasses applied against each other, having a common focus, and these forming an image of a certain magnitude, this image will increase in proportion as the distance between the two glasses is increased, as far as to a certain limit. If therefore a Reticule be taken of such a magnitude, as just to comprehend the greatest diameter the sun or moon can ever have in the common focus of two object glasses applied to each other, it is only necessary to remove them from each other, as the star comes to have a less diameter, to have the image still exactly comprehended in the same Reticule.

As the silken threads are apt to deviate from the parallelism, &c. by the different temperature of the air, another improvement is, to make the Reticule of a thin looking glass, by drawing lines or circles upon it with the fine point of a diamond.

RETICULAR BODY (corpus reticulare), in Anatomy, a very fine membrane, perforated, in the manner of a net, with a multitude of foramina. It is placed immediately under the cuticle; and when that is separated from the cutis, whether by art or accident, this adheres firmly to it, and is scarce possible to be parted from it, seeming rather to be its inner superficies than a distinct substance. In regard to this, we are to observe, first, the places in which it is found, being all those in which the sense of feeling is most acute, as in the palm of the hands, the extremities of the fingers, and on the soles of the feet. The tongue, however, is the part where it is most accurately to be observed: it is more easily distinguishable than anywhere else, and its nature and structure are most evidently seen there.

Its colour in the Europeans is white; but in the negroes and other black nations it is black; in the tawney it is yellowish; the skin itself in both is white; and the blackness and yellowness depend altogether on the colour of this membrane.

The uses of the corpus reticulare are to preserve the structure of the other parts of the integuments, and keep them in their determinate form and situation. Its apertures give passage to the hairs and sweat through the papillae and excretory ducts of the skin: it retains these in a certain and determinate order, that they cannot be removed out of their places, and has some share in preserving the softness of the papilae, which renders them fit for the sense of feeling. See Anatomy, No 83.

RETICULUM, is a Latin word, signifying a little or casting net. It was applied by the Romans to a particular mode of constructing their buildings. In the city of Salino (see SALINO) are still to be seen remains of some walls, evidently of Roman origin from the reticulum. This structure consists of small pieces of baked earth cut lozenge wise, and disposed with great regularity on the angles, so as to exhibit to the eye the appearance of cut diamonds; and was called reticular, from its resemblance to fishing-nets. The Romans always concealed it under a regular coating of other matter; and

Mr Houel informs us, that this was the only specimen reticulum of it which he saw in all his travels through Sicily, Malta, and Lipari. It appears to be the remains of some baths, which have been built for the convenience of sea-bathing.

RETIMO, the ancient Rhithyma of Stephen the geographer, and called by Ptolemys Rhithyma, is a fine city, lying at one end of a rich and fertile plain, on the north coast of the island of Candia. It is but a small place, containing scarce 6000 inhabitants; but it is a bivouac's see, and the harbour is defended by a citadel, where a bashaw resides. It was taken by the Turks in 1647, and has been in their hands ever since. It is about 45 miles from Candia. E. Long. 24. 45. N. Lat. 35. 22.

The citadel, which stands on a rock jutting out into the sea, would be sufficient for the defence of the city, were it not situated at the foot of a high hill, from which it might be cannonaded with great advantage. The harbour is now almost filled with sand, and is no longer accessible to shipping; nor do the Turks in any measure oppose the ravages of time, but behold with a careless eye the most valuable works in a state of ruin. The French had formerly a vice-consul at Retimo, to which ships used to repair for cargoes of oil; but they have been long unable to get into the harbour: to repair which, however, and to revive the commerce of Retimo, would be a most useful attempt. The plains around the city abound in a variety of productions. Great quantities of oil, cotton, salmon, and wax, are produced here; and they would be produced in still greater quantities if the inhabitants could export their commodities. The gardens of Retimo bear the best fruits in the island; excellent pomegranates, almonds, pistachio nuts, and oranges. The apricot-tree, bearing the michmich, the juice of which is so delicious, and its flavour so exquisite, is found here. It is a kind of early peach, but smaller and more juicy than those of France.

RETINA, in Anatomy, the expansion of the optic nerves over the bottom of the eye, where the sense of vision is first received. See Anatomy, No 142.

OPTICS (Index) at Eye and Vision.

RETINUE, the attendants or followers of a prince or person of quality, chiefly in a journey.

RETIRADE, in fortification, a kind of retreatment made in the body of a bastion, or other work, which is to be disputed, inch by inch, after the defences are dismantled. It usually consists of two faces, which make a re-entering angle. When a breach is made in a bastion, the enemy may also make a retreat or new fortification behind it.

RETIREMENT, means a private way of life or a secret habitation. "Few (says an elegant writer) are Dr Know. able to bear solitude; and though retirement is the es- tensible object of the greater part, yet, when they are enabled by success to retire, they feel themselves unhappy. Peculiar powers and elegance of mind are necessary to enable us to draw all our resources from ourselves. In a remote and solitary village the mind must be internally active in a great degree, or it will be miserable for want of employment. But in great and populous cities, even while it is passive, it will be constantly amused. It is impossible to walk the streets without finding the attention powerfully solicited on every
RETREAT

Every side. No exertion is necessary. Objects pour themselves into the senses, and it would be difficult to prevent their admittance. But, in retirement, there must be a spirit of philosophy and a store of learning, or else the fancied scenes of bliss will vanish like the colours of the rainbow. Poor Cowley might be said to be melancholy mad. He languished for solitude, and wished to hide himself in the wilds of America. But, alas! he was not able to support the solitude of a country village within a few miles of the metropolis!

"With a virtuous and cheerful family, with a few faithful and good-humoured friends, with a well-selected collection of elegant books, and with a competency, one may enjoy comforts even in the desert village, which the city, with all its diversions, cannot supply."

RETORT, in Chemistry, an oblong or globular vessel of glass or porcelain, with its neck bent, proper for distillation.

In the fifth volume of the Transactions of the London Society for the Encouragement of Arts, p. 96, we find a paper containing a method for preventing stone retorts from breaking; or stopping them when cracked, during any chemical operation without losing any of the contained subject. "I have always found it necessary (says the writer) to use a previous coating for filling up the interstices of the earth or stone, which is made by dissolving two ounces of borax in a pint of boiling water, and adding to the solution as much slaked lime as will make it into a thin paste; this, with a common painter's brush, may be spread over several retorts, which when dry are then ready for the proper preserving coating. The intention of this first coating is, that the substance thus spread over, readily vitrifying in the fire, prevent any of the distilling matters from pervading the retort, but do in no wise prevent it from cracking.

"Whenever I want to use any of the above coated retorts; after I have charged them with the substance to be distilled, I prepare a thin paste, made with common linseed oil and slaked lime well mixed, and perfectly plastic, that it may be easily spread: with this let the retorts be covered all over except that part of the neck which is to be inserted into the receiver; this is readily done with a painter's brush: the coating will be sufficiently dry in a day or two, and they will then be fit for use. With this coating I have for several years worked my stone retorts, without any danger of their breaking, and have frequently used the same retort four or five times; observing particularly to coat it over with the last-mentioned composition every time it is charged with fresh materials: Before I made use of this expedient, it was an even chance, in conducting operations in stone and earthen retorts, whether they did not crack every time; by which means great loss has been sustained. If at any time during the operation the retorts should crack, spread some of the oil Composition thick on the part, and sprinkle some powder of slaked lime on it, and it immediately stops the fissure, and prevents any of the distilling matter from pervading; even that subtle penetrating substance the solid phosphorus will not penetrate through it. It may be applied without any danger, even when the retort is red hot; and when it is made a little stiffer, is more proper for luting vessels than any other I ever have tried: because if properly mixed it will never crack, nor will it indurate so as to endanger the breaking the necks of the vessels when taken off."

RETRETS, among horsemen, pricks in a horse's feet, arising from the fault of the farrier in driving nails that are weak, or in driving them ill-pointed, or otherwise amiss.

RETREAT, in a military sense. An army or body of men are said to retreat when they turn their backs upon the enemy, or are retiring from the ground they occupied: hence every march in withdrawing from the enemy is called a retreat.

That which is done in sight of an active enemy, who pursues with a superior force, is the most important part of the subject; and is, with reason, looked upon as the glory of the profession. It is a manoeuvre the most delicate, and the properest to display the prudence, genius, courage, and address, of an officer who commands: the historians of all ages testify it; and historians have never been so lavish of eulogisms as on the subject of the brilliant retreats of our heroes. If it is important, it is no less difficult to regulate, on account of the variety of circumstances, each of which demands different principles, and an almost endless detail. Hence a good retreat is esteemed, by experienced officers, the masterpiece of a general. He should therefore be well acquainted with the situation of the country through which he intends to make it, and careful that nothing is omitted to make it safe and honourable. See War.

RETREAT, is also a beat of the drum, at the firing of the evening gun; at which the drum-major, with all the drums of the battalion, except such as are upon duty, beats from the camp-colours on the right to those on the left, on the parade of encampment: the drums of all the guards beat also; the trumpets at the same time sounding at the head of their respective troops. This is to warn the soldiers to forbear firing, and the sentinels to challenge, till the break of day that the reveille is beat. The retreat is likewise called setting the watch.

RETRANCEMENT literally signifies something cut off or taken from a thing; in which sense it is the same with subtraction, diminution, &c.

RETRANCEMENT, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gabions, barrels of earth, sand-bags, and generally all things that cover the men and stop the enemy. See FORTIFICATION AND WAR.

RETRIBUTION, a handsome present, gratuity, or acknowledgement, given instead of a formal salary or hire, to persons employed in affairs that do not so immediately fall under estimation, nor within the ordinary commerce in money.

RETRomingents, in Natural History, a class or division of animals, whose characteristic is, that they stale or make water backwards, both male and female.

RETURN (return or returns), in Law, is used in divers senses. 1. Return of writs by sheriffs and bailiffs is a certificate made by them to the court, of what they have done in relation to the execution of the writ directed to them. This is written on the back of the writ by the officer, who thus sends the writ back to the court from whence it issued, in order that it may be filed. 2. Return of a commission, is a certificate or answer.
RETZ, Cardinal de. See GONDI.

RETZIA, a genus of plants belonging to the pentandria class, and to the 29th natural order, Campanula. See BOTANY INDEX.

RETLINGEN, a handsome, and formerly a free and imperial town of Germany, in the kingdom of Wirtemberg; seated in a plain on the river Eschez, near the Neckar, adorned with handsome public buildings, and has a well frequented college. E. Long. 9. 10. N. Lat. 48. 31.

REVE, Reeve, or Grewe, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence shire-reeve, sheriff, port-grewe, &c.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVEL, a port town of Livonia, situated at the south entrance of the gulf of Finland, partly in a plain and partly on a mountain; 133 miles south-west of Petersburg. It is a place of great trade, and holds two fairs yearly, which are visited by merchants from all countries, but particularly by those of England and Holland. It is a strong place, with a capital harbour, and had 10,600 inhabitants about 1796. It is surrounded with high walls and deep ditches, and defended by a castle. It was confirmed to the Swedes at the peace of Oliva, conquered by Peter the Great in 1710, and ceded to Russia in 1721. The conquest of it was again attempted by the Swedes in 1790. The duke of Sudermania, with the Swedish fleet, attempted to carry the harbour; but after an obstinate engagement with the Russian fleet, he was obliged to give it up; but it was but for a very short while. He retired about 10 leagues from the harbour, to repair the damage his fleet had sustained, and to prepare for a second attack before any relief could be afforded to the Russian fleet. As soon as he had refitted, he sailed for the harbour, at a league distant from which the Russian fleet was discovered, ready to dispute with the Swedes the entrance. Upon a council being held by the duke, it was resolved to attack the Russians; and the signals being given, the fleet bore down for the attack, which was maintained for near six hours with the utmost fury: at length the Swedes broke the Russian line, which threw them into much confusion; when the Swedes, taking the advantage of the general confusion into which the Russians were thrown, followed them with their whole force into the harbour, where the conflict and carnage were dreadful on both sides, though the Swedes certainly had the worst of it; but at the same time their skill and bravery are indisputable.

This valuable place was again confirmed to Russia by the peace. The government of Revel or Esthonia is one of the divisions of the Russian empire, containing five districts. 1. Revel, on the Baltic sea. 2. Baltiport, about 50 versts westward from Revel. 3. Habal, or Hapsal, a maritime town. 4. Weissenstein, on the rivulet Saida, about 50 versts from Revel. 5. Weenberg, about 100 versts from Revel, at about an equal distance from that town and Narva.

REVELATION, the act of revealing, or making a thing public that was before unknown; it is also used for,

fruits, such as apples, currants, gooseberries, and straw-
berries, which thrive in this northern climate.
Revelation. For the discoveries made by God to his prophets, and by them to the world; and more particularly for the books of the Old and New Testament. See Bible, Christianity, Miracle, Religion, and Theology.

The principal tests of the truth of any revelation, are the tendency of its practical doctrines; its consistency with itself, and with the known attributes of God; and some satisfactory evidence that it cannot have been derived from a human source.

Before any man can receive a written book as a revelation from God, he must be convinced that God exists, and that he is possessed of almighty power, infinite wisdom, and perfect justice. Now should a book teaching absurd or immoral doctrines (as many chapters of the Koran do, and as all the traditional systems of Paganism did), pretend to be revealed by a God of wisdom and justice, we may safely reject its pretensions without further examination than what is necessary to satisfy us that we have not misunderstood its doctrine. Should a book claiming this high origin, enjoin in one part of it, and forbid in another, the same thing to be done under the same circumstances, we may reject it with contempt and indignation; because a being of infinite wisdom can never act capriciously or absurdly. Still, however, as it is impossible for us to know how far the power of men may reach in the investigation or discovery of useful truth, some further evidence is necessary to prove a doctrine of divine origin, than its mere consistency with itself, and with the principles of morality; and this evidence can be nothing but the power of working miracles exhibited by him by whom it was originally revealed. In every revelation confirmed by this evidence, many doctrines are to be looked for which human reason cannot full comprehend; and these are to be believed on the testimony of God, and suffered to produce their practical consequences. At this kind of belief the shallow infidel may smile contemptuously; but it has place in arts and sciences as well as in religion. Whoever avails himself of the demonstrations of Newton, Bernoulli, and others, respecting the resistance of fluids, and applies their conclusions to the art of ship-building, is as implicit a believer, if he understand not the principles of fluxions, as any Christian; and yet no man will say that his faith is not productive of important practical consequences. He believes, however, in man, while the Christian believes in God; and therefore he cannot pretend that his faith rests on a surer foundation.

Mr. Locke, in laying down the distinct provinces of reason and faith, observes, 1. That the same truths may be discovered by revelation which are discoverable to us by reason. 2. That no revelation can be admitted against the clear evidence of reason. 3. That there are many things of which we have but imperfect notions, or none at all; and others, of whose past, present, or future existence, by the natural use of our faculties we cannot have the least knowledge: and these, being beyond the discovery of our faculties, and above reason, when revealed, become the proper object of our faith. He then adds, that our reason is not injured or disturbed; but assisted and improved, by new discoveries of truth coming from the fountain of knowledge. Whatever God has revealed is certainly true; but whether it be a divine revelation or not, reason must judge, which can never permit the mind to reject a greater evidence to embrace what is less evident. There can be no evidence that any traditional revelation is of divine original, in the words we receive it, and the sense we understand it, so clear and so certain as that of the principles of reason: and, therefore, nothing that is contrary to the clear and self-evident dictates of reason, has a right to be urged or assented to as a matter of faith, whereas reason has nothing to do.

Revelation of St. John. See Apocalypse.

Revelations, entertainments of dancing, masking, acting, comedies, farces, &c. anciently very frequent in the inns of court and in noblemen's houses, but now much disused. The officer who has the direction of the revels at court is called the Master of the Revels.

Revenge, means the return of injury for injury, and differs materially from that sudden resentment which rises in the mind immediately on being injured; which, so far from being culpable when restrained within due bounds, is absolutely necessary for self-preservation. Revenge, on the contrary, is a cool and deliberate wickedness, and is often executed years after the offence was given; and the desire of it is generally the effect of littleness, weakness, and vice; while, to do right, and to suffer wrong, is an argument of a great soul, that scorns to stoop to suggested revenges.

Revenge is but a frailty incident To craz'd and sickly minds; the poor content Of little souls, unable to surmount An injury, too weak to bear affright. Dryden.

Revenge is generally the concomitant of savage minds, of minds implacable, and capable of the most horrid barbarities; unable to set any limits to their displeasure, they can confine their anger within no bounds of reason.

Cruel revenge, which still we find The weakest frailty of a feeble mind. Degenerate passion, and for man too base, It seizes its empire in the savage race. Juvenile.

The institution of law prevents the execution of private revenge, and the growth of civilization shows its impropriety. Though in modern times a species of revenge is sanctioned by what is called the law of honour, which evades the law of God, indeed, but which is equally mean and disgraceful as the other kinds, and of consequences equally baneful. See Anger, Duelling, and Revenge.

Revenue, the annual income a person receives from the rent of his lands, houses, interest of money in the stocks, &c.

Royal Revenue, that which the British constitution hath vested in the royal person, in order to support his dignity and maintain his power; being a portion which each subject contributes of his property, in order to secure the remainder. This revenue is either ordinary or extraordinary.

1. The king's ordinary revenue is such as has either subsisted time out of mind in the crown; or else has been granted by parliament, by way of purchase or exchange for such of the king's inherent hereditary revenues as were found inconvenient to the subject. In saying that it has subsisted time out of mind in the crown, we do not mean that the king is at present in the actual possession of the whole of his revenue. Much (say the greatest
The greatest part) of it is at this day in the hands of subjects; to whom it has been granted out from time to time by the kings of England; which has rendered the crown in some measure dependent on the people for its ordinary support and subsistence. So that we must be obliged to reckon, as part of the royal revenue, what lords of manors and other subjects frequently look up to be their own absolute rights; because they and their ancestors are and have been vested in them for ages, though in reality originally derived from the grants of our ancient princes.

1. The first of the king's ordinary revenues, which may be taken notice of, is of an ecclesiastical kind, (as are also the three succeeding ones,) viz. the custody of the temporalities of bishops. See Temporalities.

2. The king is entitled to a corody, as the law calls it, out of every bishopric; that is, to send one of his chaplains to be maintained by the bishop, or to have a pension allowed him till the bishop promotes him to a benefice. This is also in the nature of an acknowledgement to the king, as founder of the see, since he had formerly the same corody or pension from every abbey or priory of royal foundation. It is supposed to be now fallen into total disuse; though Sir Matthew Hale says, that it is due of common right, and that no prescription will discharge it.

3. The king also is entitled to all the tithes arising in extraparochial places; though perhaps it may be doubted how far this article can, as well as the last, can be properly reckoned a part of the king's own royal revenue; since a corody supports only his chaplains, and these extraparochial tithes are held under an implied trust that the king will distribute them for the good of the clergy in general.

4. The next branch consists in the first-fruits and tenths of all spiritual preferments in the kingdom. See Tenth.

5. The next branch of the king's ordinary revenue (which, as well as the subsequent branches, is of a lay or temporal nature) consists in the rents and profits of the demesne lands of the crown. These demesne lands, terres dominicale regis, being either the share reserved to the crown at the original distribution of landed property, or such as came to it afterwards by purchase or other means, are of large and extensive extent; comprising divers manors, honours, and lordships; the tenants of which had very peculiar privileges, when we speak of the tenure in ancient demesne. At present they are contracted within a very narrow compass, having been almost entirely granted away to private subjects. This has occasioned the parliament frequently to interpose; and particularly after King William III. had greatly impoverished the crown, an act passed, whereby all future grants or leases from the crown for any longer term than 31 years or three lives, are declared to be void; except with regard to houses, which may be granted for 50 years. And no reversionary lease can be made, so as to exceed, together with the estate in being, the same term of three lives or 31 years; that is, when there is a subsisting lease, of which there are 20 years still to come, the king cannot grant a future interest, to commence after the expiration of the former, for any longer term than 11 years. The tenant must also be made liable to be punished for committing waste; and the usual rent must be reserved, or, where there has usually been no rent, one-third of the clear yearly value. The misfortune is, that this act was made too late, after almost every valuable possession of the crown had been granted away for ever, or else upon very long leases; but may be of benefit to posterity, when those leases come to expire.

6. Hither might have been referred the advantages which were used to arise to the king from the profits of his military tenures, to which most lands in the kingdom were subject, till the statute 12 Car. II. c. 24. which in great measure abolished them all. Hither also might have been referred the profitable prerogative of purveyance and pre-emption: which was a right enjoyed by the crown of buying up provisions and other necessaries, by the intervention of the king's purveyors, for the use of his royal household, at an appraised valuation, in preference to all others, and even without consent of the owner: and also of forcibly impressing the carriages and horses of the subject, to do the king's business on the public roads, in the conveyance of timber, baggage, and the like, however inconvenient to the proprietor, upon paying him a settled price. A prerogative which prevailed pretty generally throughout Europe during the scarcity of gold and silver, and the high estimation of money consequent thereupon. In those early times, the king's household (as well as those inferior lords) were supported by specific renders of corn, and other victuals, from the tenants of the respective demesnes; and there was also a continual market kept at the palace-gate to furnish viands for the royal use. And this answered all purposes, in those ages of simplicity, so long as the king's court continued in any certain place. But when it removed from one part of the kingdom to another (as was formerly very frequently done), it was found necessary to send purveyors before hand, to get together a sufficient quantity of provisions and other necessaries for the household: and, lest the unusual demand should raise them to an exorbitant price, the powers before-mentioned were vested in these purveyors, who in process of time greatly abused their authority, and became a great oppression to the subject though of little advantage to the crown; ready money in open market (when the royal residence was more permanent, and specie began to be plenty) being found upon experience to be the best provision any. Wherefore, by degrees, the powers of purveyance have declined, in foreign countries as well as our own; and particularly were abolished in Sweden by Gustavus Adolphus, towards the beginning of the last century. And, with us in England, having fallen into disuse during the suspension of monarchy, King Charles, at his restoration, consented, by the same statute, to resign entirely those branches of his revenue and power: and the parliament, in part of recompense, settled him; his heirs, and successors, for ever, the hereditary excise of 15d. per barrel on all beer and ale sold in the kingdom, and a proportionable sum for certain other liquors. So that this hereditary excise now forms the sixth branch of his majesty's ordinary revenue.

7. A seventh branch might also be computed to have arisen from wine licences; or the rents payable to the crown by such persons as are licensed to sell wine by retail throughout Britain, except in a few privileged places, which were first settled on the crown by the statute 12 Car. II. c. 25. and, together with the hereditary
Besides the particular reasons, given in the different laws, why the king should have the several revenues of royal fish, shipwrecks, treasure-trove, waifs, and estrays, there is also one general reason which holds for them all; and that is, because they are bona vosecesis, or goods in which no one else can claim a property. And, therefore, by the law of nature, they belong to the first occupant or finder; and so continued under the imperial law. But in settling the modern constitutions of most of the governments in Europe, it was thought proper (to prevent that strife and contention which the mere title of occupancy is apt to create and continue, and to provide for the support of public authority in a manner the least burdensome to individuals) that these rights should be annexed to the supreme power by the positive laws of the state. And so it came to pass, that, as Bracton exprest it, "hec, quae nullius in bonis sunt, et olim fuerunt inventoris de jure naturali, iam efficiunt principis de jure gentium,"

16. The next branch of the king's ordinary revenue consists in forfeitures of lands and goods for offences; bona confiscata, as they are called by the civilians, because they belonged to the fiscus or imperial treasury; or, as our lawyers term them, foris facta, that is, such whereof the property is gone away or departed from the owner. The true reason and only substantial ground of any forfeiture for crimes, consist in this; that all property is derived from society, being one of those civil rights which are conferred upon individuals, in exchange for that degree of natural freedom which every man must sacrifice when he enters into social communities. If, therefore, a member of any national community violates the fundamental contract of his association, by transgressing the municipal law, he forfeits his right to such privileges as he claims by that contract; and the state may very justly resume that portion of property, or any part of it, which the laws have before assigned him. Hence, in every offence of an atrocious kind, the laws of England have exacted a total confiscation of the moveables or personal estate; and, in many cases, a perpetual, in others only a temporary, loss of the offender's immovable or landed property; and have vested them both in the king, who is the person supposed to be offended, being the one visible magistrate in whom the majesty of the public resides. See FORFEITURE and DOWER.

17. Another branch of the king's ordinary revenue arises from escheats of lands, which happen upon the defect of heirs to succeed to the inheritance; whereupon they in general revert to and vest in the king, who is esteemed, in the eye of the law, the original proprietor of all lands in the kingdom.

18. The last branch of the king's ordinary revenue consists in the custody of idiots, from whence we shall be naturally led to consider also the custody of lunatics. See IDIOT and LUNATIC.

This may suffice for a short view of the king's ordinary revenue, or the proper patrimony of the crown; which was very large formerly, and capable of being increased to a magnitude truly formidable: for there are very few estates in the kingdom that have not, at some period or other since the Norman conquest, been vested in the hands of the king, by forfeiture, escheu, or otherwise. But, fortunately for the liberty of the subject, this hereditary landed revenue, by a series of imprudent
REV [ 785 ] REV

provident management, is sunk almost to nothing; and the casual profits, arising from the other branches of the census regalis, are likewise almost all of them alienated from the crown. In order to supply the deficiencies of which, we are now obliged to have recourse to new methods of raising money, unknown to our early ancestors; which methods consist,

II. The king's extraordinary revenue. For, the public patrimony being got into the hands of private subjects, it is but reasonable that private contributions should supply the public service. Which, though it may perhaps fall harder upon some individuals, whose ancestors have had no share in the general plunder, than upon others, yet, taking the nation throughout, it amounts to nearly the same; provided the gain by the extraordinary should appear to be no greater than the loss by the ordinary revenue. And perhaps, if every gentleman in the kingdom was to be stripped of such of his lands as were formerly the property of the crown; was to be again subject to the inconveniences of purveyance and pre-emption, the oppression of forest-laws, and the slavery of feudal tenures; and to resign into the king's hands all his royal franchises of waifs, wrecks, estrays, treasure-trove, mines, deodands, forfeitures, and the like; he would find himself a greater loser than by paying his quota to such taxes as are necessary to the support of government. The thing, therefore, to be wished and aimed at in a land of liberty, is by no means the total abolition of taxes, which would draw after it very pernicious consequences, and the very supposition of which is the height of political absurdity. For as the true idea of government and magistracy will be found to consist in this, that some few men are deputed by many others to preside over public affairs, so that individuals may the better be enabled to attend their private concerns; it is necessary that those individuals should be bound to contribute a portion of their private gains, in order to support that government, and reward that magistracy, which protects them in the enjoyment of their respective properties. But the things to be aimed at are wisdom and moderation, not only in granting, but also in the method of raising, the necessary supplies; by contriving to do both in such a manner as may be most conducive to the national welfare, and at the same time most consistent with economy and the liberty of the subject; who, when properly taxed, contributes only, as was before observed, some part of his property in order to enjoy the rest.

These extraordinary grants are usually called by the synonymous names of aids, subsidies, and supplies; and are granted by the commons of Great Britain, in parliament assembled. See Parliament and Tax.

The clear nett produce of the several branches of the revenue, after all charges of collecting and management paid, amounted in the year 1785 to about 1,397,000l. sterling, and in 1813 they amounted to 64,972,987l. of which England furnished 55,995,123l. Scotland 4,155,109l. and Ireland 4,822,864l. See National Debt and Funds.

The respective produces of the several taxes were originally separate and distinct funds; being securities for the sums advanced on each several tax, and for them only. But at last it became necessary, in order to avoid confusion, as they multiplied yearly, to reduce the number of these separate funds, by uniting and blending them together; superseding the faith of parliament for the general security of the whole. So that there are now only three capital funds of any account, the aggregate fund, and the general fund, so called from such union and addition; and the South-sea fund, being the produce of the taxes appropriated to pay the interest of such part of the national debt as was advanced by that company and its annuitants. Whereby the separate funds, which were thus united, are become mutual securities for each other; and the whole produce of them, thus aggregated, liable to pay such interest or annuitities as were formerly charged upon each distinct fund; the faith of the legislature being moreover engaged to supply any casual deficiencies.

The customs, excises and other taxes, which are to support these funds, depending on contingencies, upon exports, imports, and consumptions, must necessarily be of a very uncertain amount; but they have always been considerably more than was sufficient to answer the charge upon them. The surplusses, therefore, of the three great national funds, the aggregate, general, and South-sea funds, over and above the interest and annuities charged upon them, are directed by statute 3 Geo. I. c. 7. to be carried together, and to attend the disposition of parliament; and are usually denominated the sinking fund, because originally destined to sink and lower the national debt. To this have been since added many other entire duties, granted in subsequent years; and the annual interest of the sums borrowed on their respective credits is charged on, and payable out of the produce of the sinking fund. However, the nett surplusses and savings, after all deductions paid, amount annually to a very considerable sum. For as the interest on the national debt has been at several times reduced (by the consent of the proprietors, who had their option either to lower their interest or be paid their principal), the savings from the appropriated revenues must needs be extremely large.

But, before any part of the aggregate fund (the surplusses whereof are one of the chief ingredients that form the sinking fund) can be applied to diminish the principal of the public debt, it stands mortgaged by parliament to raise an annual sum for the maintenance of the king's household and the civil list. For this purpose, in the late reigns, the produce of certain branches of the excise and customs, the post-office, the duty on wine-licences, the revenues of the remaining crownlands, the profits arising from courts of justice, (which articles include all the hereditary revenues of the crown), and also a clear annuity of 122,000l. in money, were settled on the king for life, for the support of his majesty's household, and the honour and dignity of the crown. And, as the amount of these several branches was uncertain, (though in the last reign they were computed to have sometimes raised almost a million), if they did not rise annually to 820,000l. the parliament engaged to make up the deficiency. But his present majesty having, soon after his accession, spontaneously signified his consent that his own hereditary revenues might be so disposed of as might best conduc to the utility and satisfaction of the public, and having graciously accepted a limited sum, the said hereditary and other revenues are now carried into, and made a part of, the aggregate.
ggregate fund; and the aggregate fund is charged with the payment of the whole annuity to the crown. The limited annuity accepted by his present majesty was at first 820,000l. but it has been since augmented to 900,000l. The expences themselves, being put under the same care and management as the other branches of the public patrimony, produce more, and are better collected than heretofore; and the public is a gainer of upwards of 100,000l. per annum by this disinterested bounty of his majesty.

The sinking fund, though long talked of as the last resource of the nation, proved very inadequate to the purpose for which it was established. Ministers found pretences for diverting it into other channels; and the diminution of the national debt proceeded slowly during the intervals of peace, whilst each succeeding war increased it with great rapidity. To remedy this evil, and restore the public credit, to which the late war had given a considerable shock, Mr Pitt conceived a plan for diminishing the debt by a fund, which should be rendered unalienable to any other purpose. In the session 1786, he moved that the annual surplus of the revenue above the expenditure should be raised, by additional taxes, from 500,000l. to one million sterling, and that certain commissioners should be vested with the full power of disposing of this sum in the purchase of stock (see Funds), for the public, in their own names. These commissioners should receive the annual million by quarterly payments of 250,000l. to be issued out of tho exchequer before any other money, except the interest of the national debt itself; by these provisions, the fund would be secured, and no deficiencies in the national revenues could affect it, but such must be separately provided for by parliament.

The accumulated compound interest on a million yearly, together with the annuities that would fall into that fund, would, he said, in 28 years amount to such a sum as would leave a surplus of four millions annually, to be applied, if necessary, to the exigencies of the state. In appointing the commissioners, he should, he said, endeavour to choose persons of such weight and character as corresponded with the importance of the commission they were to execute. The speaker of the house of commons, the chancellor of the exchequer, the master of the rolls, the governor and deputy governor of the bank of England, and the accountant-general of the high court of chancery, were persons who, from their several situations, he should think highly proper to be of the number.

To the principle of this bill no objection was made, though several specious but ill-founded ones were urged against the sufficiency of the mode which the chancellor of the exchequer had adopted for the accomplishment of so great and so desirable an end. He had made it a clause in his bill, that the accumulating million should never be applied but to the purchase of stock. To this clause Mr Fox objected, and moved that the commissioners therein named should be impowered to accept so much of any future loan as they should have cash belonging to the public to pay for. This, he said, would relieve that distress the country would otherwise be under, when an account of a war, it might be necessary to raise a new loan: whenever that should be the case, his opinion was, that the minister should not only raise taxes sufficiently productive to pay the interest of the loan, but also sufficient to make good to the sinking fund whatsoever had been taken from it.

If, therefore, for instance, at any future period a loan of six millions was proposed, and there was at that time one million in the hands of the commissioners, in such case they should take a million of the loan, and the bonus or ducor therupon should be received by them for the public. Thus government would only have five millions to borrow of six; and from such a mode of proceeding, he said, it was evident great benefit would arise to the public.

This clause was received by Mr Pitt with the strongest marks of approbation, as was likewise another, moved by Mr Pulteney, enabling the commissioners named in the bill to continue purchasing stock for the public when it is above par, unless otherwise directed by parliament. With these additional clauses the bill was read a third time on the 1st of May, and passed.

The sinking fund continued to be applied to the reduction of the debt till 1819, when twelve millions, out of the fourteen to which it amounted, were applied to the services of the year, and taxes to the amount of three millions were imposed to make up the fund to five millions. The establishment of the sinking fund was really beneficial, by introducing the practice of providing a fund for the discharge of each new loan, as it was contracted; but this was the whole of its value. The idea of advantage being reaped from placing money at compound interest, instead of applying it directly to pay off debt, has been completely explained by Dr Hamilton, and is one of the most extraordinary delusions ever countenanced by public men.

The clear produce of the taxes raised on the people of this country was, in the year 1792, very near 17,000,000l.; and in the year ending 5th Jan. 1813, it amounted to the enormous sum of 64,972,987l.

Revenue, in hunting, a glossy lump formed chiefly by a cluster of whitish worms on the head of the deer, supposed to occasion the casting of the horns by gnawing them at the root.

Reverberation, in Physics, the act of a body repelling or reflecting another after its impinging thereon.

Reverberation, in Chemistry, denotes a kind of circulation of the flame by means of a reverberatory furnace.

Reverberatory, or Reverberating Furnace. See Furnace.

Reverend, a title of respect given to ecclesiastics. — The religious abroad are called reverend fathers, and abbesses, prioresses, &c. reverend mothers. In England, bishops are right reverend, and archbishops most reverend. In France, before the Revolution, their bishops, archbishops, and abbots, were all alike most reverend. In Scotland, the clergy individually are reverend, a synod is very reverend, and the general assembly is venerable.

Revere, the same with delirium, raving, or distraction. It is used also for any ridiculous, extravagant imagination, action, or proposition, a chimera, or vision. But the most ordinary use of the word among English writers, is for a deep disorderly musing or meditation.

Reversal of Judgement, in Law. A judgement may be falsified, reversed, or voided, in the first place,
REV. place, without a writ of error, for matters foreign to or dehors the record, that is, not apparent upon the face of it; so that they cannot be assigned for error in the superior court, which can only judge from what appears in the record itself; and therefore, if the whole record be not certified, or not truly certified, by the inferior court, the party injured thereby (in both civil and criminal cases) may allege a diminution of the record, and cause it to be rectified. Thus, if any judgment whatever be given by persons who had no good commission to proceed against the person condemned, it is void; and may be falsified by showing the special matter, without writ of error. As, where a commission issues to A and B, and twelve others, or any two of them, of which A or B shall be one, to take and try indictments; and any of the other twelve proceed without the interposition or presence of either A or B: in this case all proceedings, trials, convictions, and judgments, are void for want of a proper authority in the commissioners, and may be falsified upon bare suspicion, without the trouble of a writ of error; it being a high misdemeanour in the judges so proceeding, and little (if any thing) short of murder in them all, in case the person so attainted be executed and suffer death. So likewise if a man purchases land of another; and afterwards the vender is, either by outlawry, or his own confession, convicted and attainted of treason or felony previous to the sale or alienation; whereby such land becomes liable to forfeiture or escheat; now, upon any trial, the purchaser is at liberty, without bringing any writ of error, to falsify not only the time of the felony or treason supposed, but the very point of the felony or treason itself; and is not concluded by the confession or the outlawry of the vender, though the vender himself is concluded, and not suffered now to deny the fact, which he has by confession or flight acknowledged. But if such attinder of the vender was by verdict, on the oath of his peers, the alienee cannot be received to falsify or contradict the fact of the crime committed; though he is at liberty to prove a mistake in time, or that the offense was committed after the alienation, and not before.

Secondly, a judgment may be reversed, by writ of error, which lies from all inferior criminal jurisdictions to the court of king's bench, and from the king's bench to the house of peers; and may be brought for notorious mistakes in the judgment or other parts of the record: as where a man is found guilty of perjury, and receives the judgment of felony, or for other less palpable errors; such as any irregularity, omission, or want of form in the process of outlawry, or proclamation; the want of a proper addition to the defendant's name, according to the statute of additions; for not properly naming the sheriff or other officer of the court, or not duly describing where his county-court was held: for laying an offence, committed in the time of the late king, to be done against the peace of the present; and for many other similar causes, which (though allowed out of tenderness to life and liberty) are not much to the credit or advancement of the national justice.—These writs of error, to reverse judgments in case of misdemeanours, are not to be allowed of course, but on sufficient probable cause shown to the attorney-general; and then they are understood to be grantable of con-

mon right, and ex debito justitiae. But writs of error to reverse attinders in capital cases are only allowed ex gratia; and not without express warrant under the king's sign-manual, or at least by the consent of the attorney-general. These therefore can rarely be brought by the party himself, especially where he is attainted for an offence against the state: but they may be brought by his heir or executor after his death, in more favourable times; which may be some consolation to his family. But the easier and more effectual way is,

Lastly, to reverse the attinder by act of parliament. This may be and hath been frequently done upon motives of compassion, or perhaps the zeal of the times, after a sudden revolution in the government, without examining too closely into the truth or validity of the errors assigned. And sometimes, though the crime be universally acknowledged and confessed, yet the merits of the criminal's family shall after his death obtain a restitution in blood, honours, and estate, or some or one of them, by act of parliament; which (so far as it extends) has all the effect of reversing the attinder, without casting any reflections upon the justice of the preceding sentence. See ATTAINER.

The effect of falsifying or reversing an outlawry is, that the party shall be in the same plight as if he had appeared upon the copias: and, if it be before plea pleaded, he shall be put to plead to the indictment; if, after conviction, he shall receive the sentence of the law; for all the other proceedings, except only the process of outlawry for his non-appearance, remain good and effectual as before. But when judgment, pronounced upon conviction, is falsified or reversed, all former proceedings are absolutely set aside, and the party stands as if he had never been at all accused; restored in his credit, his capacity, his blood, and his estates: with regard to which last, though they be granted away by the crown, yet the owner may enter upon the grants, with as little ceremony as he might enter upon a disposer.—But he still remains liable to another prosecution for the same offence: for, the first being erroneous, he never was in jeopardy thereby.

REVERSE of a medal, coin, &c. denotes the second or back side, in opposition to the head or principal figure.

REVERSION, in Scots Law. See Law, No. clxix 1—3.

Reversion, in the law of England, has two significations: the one of which is, an estate left, which continues during a particular state in being; and the other is the returning of the land, &c. after the particular estate is ended; and it is further said to be an interest in lands, when the possession of it fails, or where the estate which was for a time parted with, returns to the granter, or their heirs. But, according to the usual definition of a reversion, it is the residue of an estate left in the granter, after a particular estate granted away ceases, continuing in the granter of such an estate.

The difference between a remainder and a reversion consists in this, that the remainder may belong to any man except the grantee; whereas the reversion returns to him who conveyed the lands, &c.

In order to render the doctrine of reversions easy, we shall give the following table; which shows the present value of one pound, to be received at the end of any
Reversion. Number of years not exceeding 40; discounting at the rate of 3, 4, or 5 per cent. compound interest.

</table>

The use of the preceding table.—To find the present value of any sum to be received at the end of a given term of years, discounting at the rate of 3, 4, or 5 per cent. compound interest. First by the above table the present value of 1l. to be received at the end of the given term; which multiply by the number of pounds proposed, (cutting off four figures from the product on account of the decimals), then the result will be the value sought: For example, the present value of 10,000l.

to be received 10 years hence, and the rate of interest being 5 per cent. is equal to 6139 × 10000 = 61390000. The present value of 10,000l. due in ten years, the rate of interest being 3 per cent. is 7441 × 10000 = 7441.

Reversion of Series, in Algebra, a kind of reversed operation of an infinite series. See Series.

Revetement, in Fortification, a strong wall built on the outside of the rampart and parapet to support the earth, and prevent its rolling into the ditch.

Revivification, in Chemistry, a term generally applied to the distillation of quicksilver from cinnabar.

Revivification, in Physiology, the recalling of animals apparently dead, to life. There are many kinds of insects which may be revivified, after all the powers of animation have been suspended for a considerable time. Common flies, small beetles, spiders, moths, bugs, &c. after being drowned in spirit of wine, and continuing apparently dead for upwards of 15 minutes, have been restored to life merely by being thrown among woodashes slightly warm.

While Dr Franklin was in France, he received a quantity of Madeira wine from America, which had been bottled in Virginia. He found a few dead flies in some of the bottles, which he exposed to the sun in the month of July; and in less than three hours these seemingly dead animals recovered life which had been so long suspended. At first they appeared as if convulsed; they then raised themselves on their legs, washed their eyes with their fore feet, dressed their wings with those behind, and in a short time began to fly about.

But the most remarkable instance of revivification we have heard of, is the following. In the warmer parts of France there is an insect very pernicious to the vine, apparently beginning its operations at the root of the plant, and gradually proceeding towards the ear. If the plant be thoroughly dried while the insect is in the root or stem, the animal is irrecoverably killed; but after it has reached the grain, the case is very different. There have been instances of these insects being brought to life in 15 minutes, by a little warm water, after the grains in which they were lodged, had been kept dry for 30 years.

What is the metaphysician to think of these phenomena, or what conclusion is he to draw from them respecting the mind? If he be a sober man he will draw no conclusion, for this reason, that he knows nothing of the sentient principle of insects, or of any animal but man. He is conscious that it is the same individual being which in himself, thinks, and wills, and feels; he knows that part of his thought is not in one place, and part of it in another; and therefore he concludes that this thinking being is not separate, while experience teaches him that it quits the material system, when that becomes unfit to discharge its functions, and cannot be recalled. Experience teaches him, on the other hand, that the sentient principle of these insects does not quit the system when unfit for its functions; and hence he must conclude that the minds of men and of insects are very different, and that the bond which unites the material and immaterial parts of an insect, is certainly different from that which unites the mind and body of man.

This is the only inference which can be fairly drawn from
REV (789) REV

Revival or

Revolution.

from these phenomena; and he who makes them the basis of materialism, must have his judgment warped by some passion or prejudice.

Commission of Review, is a commission sometimes granted, in extraordinary cases, to revise the sentence of the court of delegates, when it is apprehended they have been led into a material error. This commission the king may grant, although the statutes 24 and 25 Hen. VIII. declare the sentence of the delegates definitive; because the pope, as supreme head by the canon law, used to grant such commission of review; and such authority as the pope heretofore exercised is now annexed to the crown by statutes 26 Henry VIII. c. 1 and 2 Eliz. c. 1. But it is not matter of right, which the subject may demand ex debito justitiae; but merely a matter of favour, and which therefore is often denied.

Review, is the drawing out all or part of the army in line of battle, to be viewed by the king, or a general, that they may know the condition of the troops.

At all reviews, the officers should be properly armed, ready in their exercise, salute well, in good time, and with a good air; their uniform gentry, &c. The men should be clean and well dressed; their accoutrements well put on; very well sized in their ranks; the sergeants expert in their duty, drummers perfect in their beatings, and the fifers play correct. The manual exercise must be performed in good time, and with life; and the men carry their arms well; march, wheel, and form with exactness. All manoeuvres must be performed with the utmost regularity, both in quick and slow time. The firings are generally 36 rounds; viz. by companies; by grand divisions; by sub-divisions; obliquely, advancing, retreatting; by files; in the square; street firings, advancing and retreatting; and lastly, a volley. The intention of a review is, to know the condition of the troops, see that they are complete and perform their exercise and evolutions well.

Review is also applied to literary journals, which give a periodical view of the state of literature; as the Monthly Review, the Critical Review, the British Critic, &c. The number of works of this description in Britain has increased greatly of late years, and some of them have a very extensive circulation.

Re-Union Island, an island in the South Sea, discovered by the French on the 16th December 1773; lying, according to M. de Pages, in latitude 48° 21', and longitude 66° 49', the variation of the needle being 30° always towards north-west. The road and harbour are extremely good, and the latter from 16 to 8 fathoms deep at the very shore. The coast on each side is lofty, but green, with an abrupt descent, and swarms with a species of bustards. The penguins and sea-lions which swarmed on the sands, were nowise alarmed at the approach of those who landed; from whence M. de Pages concluded that the country was wholly uninhabited. The soil produces a kind of grass about five inches long, with a broad black leaf, and seemingly of a rich quality; but there was no vestige of a tree or human habitation. See Travels round the World, by M. de Pages, vol. iii. chaps. 8. and 9.

Revolution, in politics, signifies a change in the constitution of a state; and is a word of different import from revolt, with which it is sometimes confounded. When a people withdraw their obedience from their governors for any particular reason, without over-turning the government, or waging an offensive war against it, they are in a state of revolt; when they over-turn the government, and form a new one for themselves, they effect a revolution.

That which is termed the revolution in Britain is the change which, in 1688, took place in consequence of the forced abdication of King James II. when the Protestant succession was established, and the constitution restored to its primitive purity. Of this important transaction, which confirmed the rights and liberties of Britons, we have endeavoured to give an impartial account under another article (see Britain, N° 281, &c.) Of the rise and progress of the American revolution, which is still fresh in the memory of some of our readers, a large detail is given under the article America. By the revolution which took place in Poland about the end of the 18th century, that kingdom was dismembered and seized by Austria, Prussia and Russia. For an account of this revolution, see Poland; and for the history and progress of the French revolution, the most extraordinary of all, whether considered with regard to the events which accompanied, or the consequences which followed it, see France.

Revolution, in Geometry, the motion of rotation of a line about a fixed point or centre, or of any figure about a fixed axis, or upon any line or surface. Thus, the rotation of a given line about a fixed centre, generates a circle; and that of a right-angled triangle about one side, as an axis, generates a cone; and that of a semicircle, about its diameter, generates a sphere or globe, &c.

Revolution, in Astronomy, is the period of a star, planet, or comet, &c. or its course from any point of its orbit, till it return to the same again.

Revulsion, in Medicine, turning a flux of humours from one part to another, by bleeding, cupping, friction, sinapisms, blisters, fomentations, bathtings, issues, secons, strong purging of the bowels, &c.

Reyn, Jan de, an eminent history and portrait painter, born at Dunkirk in 1610. He had the good fortune to be a disciple of Vandyke, was the first performer in his school, and was so attached to his master that he followed him to London, where it is thought he continued as long as he lived. In these kingdoms he is mostly known by the name of Long Jun. He died in 1678: and it is imagined that the scarcity of his works is occasioned by so many of them being imputed to Vandyke; a circumstance which, if true, is beyond any thing that could be said in his praise.

Reynneau, Chevalier-Rene, commonly known by the name of Father Reynneau, a celebrated mathematician of France, was born in the year 1636, at Brissac in the province of Anjou. When 20 years of age, he connected himself with the Oratorians, a sort of religious order, the members of which lived in community without binding themselves to the observance of any vows, and turned their chief attention to the instruction of youth. He afterwards taught philosophy at Pecam, and next at Toulon, which requiring some degree of geometrical knowledge, he became extremely fond of that science, and cultivated and improved it to a great extent. He was, in consequence of his knowledge, invited to fill the mathematical chair at Angers in 1683, and he was also elected a member of the academy, in 1694.
He undertook to reduce into a body, for the benefit of his pupils, the chief theories which were scattered through the works of Newton, Des Cartes, Leibnitz, Bernoulli, the Leipsic Acts, the Memoirs of the Paris Academy, and several other works, to which he gave the name of Analyse Demonstrée, or Analyse Demonstrated, which was published in 1728, in 2 vols. 4to.

He gave to this work the name of Analysis Demonstrated, because he therein demonstrates various methods which had not been demonstrated by their authors, or at least not with sufficient accuracy and perspicuity. This work of Reyneau was very much applauded, and it became a general maxim in France, that to follow him was the best, if not the only way, to make any extraordinary progress in the study of mathematics.

Such was his ambition to be useful, that in 1714 he published his Science du Calcul des Grandeurs, intended for the benefit of such as were wholly unacquainted with the science of geometry. Of this work a very able judge was pleased to observe, that "though several books had already appeared upon the same subject, such a treatise as that before him was still wanting, as in it every thing was handled in a manner sufficiently extensive, and at the same time with all possible exactness and perspicuity." Although many branches of the mathematics had been well discussed prior to his time, no good elements were to be met with, even of practical geometry.

When the Royal Academy of Sciences at Paris gave admission to other learned and eminent men, Father Reyneau was received into the number. The works already mentioned are all he ever published, or perhaps ever composed, with the exception of a little piece upon logic; and materials for a second volume of his Science du Calcul were left behind him in manuscript. Towards the close of his life he was too much afflicted with sickness to give much application to study; and he died in 1728, at 72 years of age. His many virtues and extensive erudition made this event much regretted by all who had the pleasure of being acquainted with him. It was regarded as an honour and a happiness by the first men in France, to number him among their friends, such as the chancellor of the kingdom and Malebranche, of the latter of whom Reyneau was a faithful and zealous disciple.

REYNOLDS, SIR JOSHUA, the celebrated painter, was, on July the 16th 1723, born at Plympton, a small town in Devonshire. His father was minister of the parish, and also master of the grammar-school; and being a man of learning and philanthropy, he was beloved and respected by all to whom he was known. Such a man, it will naturally be supposed, was assiduous in the cultivation of the minds of his children, among whom his son Joshua shone conspicuous, by displaying at a very early period a superiority of genius, and the rudiments of a correct taste. Unlike other boys, who generally content themselves with giving a literal explanation of their author, regardless of his beauties or his faults, young Reynolds attended to both these, displaying a happy knowledge of what he read, and entering with ardour into the spirit of his author. He discovered likewise talents for composition, and a natural propensity to drawing, in which his friends and intimates thought him qualified to excel. Emulation was a distinguishing feature in his mind, which his father perceived with delight natural to a parent; and designing him for the church, in which he hoped that his talents might raise him to eminence, he sent him to one of the universities.

Soon after this period he grew passionately fond of painting; and, by the perusal of Richardson's theory of that art, was determined to make it his profession through life. At his own earnest request, therefore, he was removed to London; and about the year 1742 became a pupil to Mr Hudson, who, though not himself an eminent painter, was preceptor to several who afterwards excelled in the art. One of the first advice which he gave to Mr Reynolds was to copy carefully Guercino's drawings. This was done with such skill, that many of the copies are said to be now preserved in the cabinets of the curious as the originals of that very great master.

About the year 1749, Mr Reynolds went to Italy under the auspices, and in the company, of the late Lord (then Commodore) Keppel, who was appointed to the command of the British squadron in the Mediterranean. In this garden of the world, this magic seat of the arts, he failed not to visit the schools of the great masters, to study the productions of different ages, and to contemplate with unwearied attention the various beauties which are characteristic of each. His labour here, as has been observed of another painter, was "the labour of love, not the task of the hireling;" and how much he profited by it is known to all Europe.

Having remained about two years in Italy, and studied the language as well as the arts of the country with great success, he returned to England, improved by travel and refined by education. On the road to London from the port where he landed, he accidentally found in the inn where he lodged Johnson's life of Savage; and was so taken with the charms of composition, and the masterly delineation of character displayed in that performance, that, having begun to read it while leaning with his arm on the chimney-piece, he continued in that attitude insensible of pain till he was hardly able to raise his hand to his head. The admiration of the work naturally led him to seek the acquaintance of its author, who continued one of his sincerest admirers and warmest friends, till 1784, when they were separated by the stroke of death.

The first thing that distinguished him after his return to his native country, was a full length portrait of Commodore Keppel; which in the polite circles was spoken of in terms of the highest eulogium, and testified to what a degree of eminence he had arrived in his profession. This was followed by a portrait of Lord Edgecumbe, and a few others, which at once introduced him to the first business in portrait painting; and that branch of the art he cultivated with such success as will for ever establish his fame with all descriptions of refined society. Having painted some of the first-rate beauties of the age, the polite world flocked to see the graces and the charms of his pencil; and he soon became the most fashionable painter, not only in England, but in all Europe. He has indeed preserved the resemblance of so many illustrious characters, that we feel the less regret for his having left behind him so few historical
Reynolds, historical paintings; though what he has done in that way shows (A) him to have been qualified to excel in both departments. The only landscape, perhaps, which he ever painted, except those beautiful and chaste ones which compose the back grounds of many of his portraits, is "A View on the Thames from Richmond," which in 1784 was exhibited by the Society for Promoting Painting and Design in Liverpool.

In 1764 Mr. Reynolds had the merit of being the first promoter of that club, which, having long existed without a name, became at last distinguished by the appellation of the Literary Club. Upon the foundation of the Royal Academy of Painting, Sculpture, and Architecture, he was appointed president; and his acknowledged excellence in his profession made the appointment acceptable to all the lovers of art. To add to the dignity of this new institution, his majesty conferred on the president the honour of knighthood; and Sir Joshua delivered his first discourse at the opening of the Academy on January 2, 1760. The merit of that discourse has been universally admitted among painters; but it contains some directions respecting the proper mode of prosecuting their studies, to which every student of every art would do well to pay attention. "I would chiefly recommend (says he), that an implicit obedience to the rules of art, as established by the practice of the great masters, should be exacted from the young students. That those models, which have passed through the approbation of ages, should be considered by them as perfect and infallible guides; as subjects for their imitation, not their criticism. I am confident, that this is the only efficacious method of making a progress in the arts; and that he who sets out with doubting, will find life finished before he becomes master of the rudiments. For it may be laid down as a maxim, that he who begins by presuming on his own sense, has ended his studies as soon as he has commenced them. Every opportunity, therefore, should be taken to discountenance that false and vulgar opinion, that rules are the fitters of genius. They are fitters only to men of no genius; as that armour which, upon the strong, becomes an ornament and a defence, upon the weak and misshapen turns into a load, and cripples the body which it was made to protect."

Each succeeding year, on the distribution of the prizes, Sir Joshua delivered to the students a discourse of equal merit with this: and perhaps we do not hazard too much when we say, that, from the whole collected, the lover of belles lettres and the fine arts will acquire juster notions of what is meant by taste in general, and better rules for acquiring a correct taste, than from multitudes of those volumes which have been professionally written on the subject.

In the autumn of 1785 he went to Brussels, where he expended about 1000l. on the purchase of paintings, which, having been taken from the different monasteries and religious houses in Flanders and Germany, were then exposed to sale by the command of the emperor Joseph I. Gainsborough and he had engaged to paint each other's portrait; and the canvas for both being actually stretched, Sir Joshua gave one sitting to his distinguished rival; but, to the regret of every admirer of the art, the unexpected death of the latter prevented all further progress.

In 1792 he was anxiously desirous to procure the vacant professorship of perspective in the academy for Mr. Bononi, an Italian architect; but that artist not having been yet elected an associate, was of course no academicians, and it became necessary to raise him to those situations, in order to qualify him for being a professor. Mr. Gilpin being his competitor for the associaethip; the numbers on the ballot proved equal, when the president by his casting vote decided the election in favour of his friend, who was thereby advanced so far towards the professorship. Soon after this, an academic seat being vacant, Sir Joshua exerted all his influence to obtain it for Mr. Bononi; but finding himself outvoted by a majority of two to one, he quoted the chair with great dissatisfaction, and next day sent to the secretary of the academy a formal resignation of the office, which for twenty-one years he had filled with honour to himself and his country. His indignation, however, subiding.

(A) As the lovers of painting may wish to have a catalogue of this great master's historical pieces, we subjoin the following from the European Magazine, which we have good reason to believe accurate, as the editors of that miscellany grudge neither trouble nor expense to procure authentic information. Sir Joshua's principal historical pieces, then, are the following: Hope nursing Love; Venus chastising Cupid for having learned to cast accounts; Count Ugolino in the dungeon; the calling of Samuel; Ariadne; a Captain of banditti; Beggar Boy; A Lady in the character of St. Agnes; Thais; Dionysius the Areopagite; an infant Jupiter; Master Crewe in the character of Henry VIII.; the death of Dido; a Child asleep; Cupid sleeping; Covent Garden Cupid; Cupid in the Clouds; Cupids painting; Boy laughing; Master Herbert in the character of Bacchus; Hebe; Miss Meyer in the character of Behe; Madoni, a head; the Black-guard Mercury; a little boy (Samuel) praying; an old Man reading; Love loosing the zone of Beauty; the Children in the Wood; Cleopatra dissolving the Pearl; Garrick in the character of Kitely; Garrick between Tragedy and Comedy; Mrs. Abingdon in the character of Comedy; a Child surrounded by Guardian Angels; Miss Beauciere in the character of Spencer's Uns; Resignation; the Duchess of Manchester in the character of Diana; Lady Blake in the character of June; Mrs. Sheridan in the character of St. Cecilia; Edwin, from Beattie's Minstrel; the Nativity, Four Cardinal Virtues, and Faith, Hope, and Charity, for the window of New College Chapel, Oxford; the Studious Boy; a Bacchante; a daughter of Lord W. Gordon as an Angel; the Holy Family; the Cottagers, from Thomson; the Vestal; the Careful Shepherdess; a Gypsy telling Fortunes; the infant Hercules strangling the Serpent; the Mouse-trap girl; Venus; Cornelia and her Children; the Bird; Melancholy; Mrs. Siddons in Tragedy; Head of Lear; Mrs. Talmarsh in the character of Miranda, with Prospero and Caliban; Robin Goodfellow; Death of Cardinal Beaufort; Macbeth, with the Caldron of the Witches.
Finding a disease of languor, occasioned by an enlargement of the liver, to which he had for some time been subject, increase upon him, and daily expecting the total loss of sight, he wrote a letter to the academy, intimating his intention to resign the office of president on account of bodily infirmities, which disabled him from executing the duties of it to his own satisfaction. The academicians received this intelligence with the respectful concern due to the talents and virtues of their president; and either then did enter, or designed to enter, into a resolution, honourable to all parties, namely, that a deputation from the whole body of the academy should wait upon him, and inform him of their wish, that the authority and privileges of the office of president might be his during his life; declaring their willingness to permit the performance of any of its duties which might be irksome to him by a deputy.

From this period Sir Joshua never painted more. The last effort of his pencil was the portrait of the Honourable Charles James Fox, which was executed in his best style, and shows that his fancy, his imagination, and his other great powers in the art which he professed, remained unabated to the end of his life. When the last touches were given to this picture,

"The hand of Reynolds fell, to rise no more."

On Thursday February the 23d 1792, the world was deprived of this amiable man and excellent artist, at the age of 68 years; a man than whom no one, according to Johnson, had passed through life with more observation of men and manners. The following character of him is said to be the production of Mr Burke.

"His illness was long, but borne with a mild and cheerful fortiude, without the least mixture of any thing irritable or querulous, agreeably to the placid and even tenor of his whole life. He had from the beginning of his malady a distinct view of his dissolution, which he contemplated with that entire composure which nothing but the innocence, integrity, and usefulness of his life, and an unaffected submission to the will of Providence, could bestow. In this situation he had every consolation from family tenderness, which his tenderness to his family had always merited.

"Sir Joshua Reynolds was, on very many accounts, one of the most memorable men of his time: He was the first Englishman who added the praise of the elegant arts to the other glories of his country. In taste, in grace, in facility, in happy invention, and in the richness and harmony of colouring, he was equal to the great masters of the renowned ages. In portrait he went beyond them; for he communicated to that description of the art in which English artists are the most engaged, a variety, a fancy, and a dignity, derived from the higher branches, which even those who

professed them in a superior manner did not always preserve when they delineated individual nature. His portraits remind the spectator of the invention of history and the amenity of landscape. In painting portraits he appears not to be raised upon that platform, but to descend to it from a higher sphere. His paintings illustrate his lessons, and his lessons seem to be derived from his paintings.

"He possessed the theory as perfectly as the practice of his art. To be such a painter, he was a profound and penetrating philosopher.

"In full happiness of foreign and domestic fame, admired by the expert in art, and by the learned in science, courted by the great, caressed by sovereign powers, and celebrated by distinguished poets, his native humility, modesty, and candour, never forsook him, even on surprise or provocation; nor was the least degree of arrogance or assumption visible to the most scrutinizing eye in any part of his conduct or discourse.

"His talents of every kind—powerful from nature, and not meanly cultivated in letters—his social virtues in all the relations and all the habits of life, rendered him the centre of a very great and unparalleled variety of agreeable societies, which will be dissipated by his death. He had too much merit not to excite some jealousy, too much innocence to provoke any enmity. The loss of no man of his time can be felt with more sincere, general, and unmixed sorrow."

REZAN, or REZANSKII, an ancient town of Russia, and capital of a duchy of the same name, with an archbishop's see. It was formerly considerable for its extent and riches; but it was almost ruined by the Tartars in 1568. The country is populous, and was formerly governed by its own princes. F. Long. 42. 37. N. Lat. 54. 54.

RHABDOLOGY, or RABDOLOGY, in arithmetic, a name given by Napier to a method of performing some of the more difficult operations of numbers by means of square little rods. Upon these are inscribed the simple numbers; then by shifting them according to certain rules, those operations are performed by simply adding or subtracting the numbers as they stand upon the rods.

RHADAMANTHUS, a severe judge, and king of Lydia; the poets make him one of the three judges of hell.

RHAGADES in Medicine, denotes chaps or clots in any part of the body. If seated in the anus, and recent, the patient must sit still, and sit over the steam of warm water. The epulotic cerite may also be applied. If the lips of these fissures are callous, they must be cut or otherwise treated as to become new ulcerations.

RHAMA, or RAMA, an incarnate deity of the first rank, in Indian mythology. Sir William Jones believes he was the Dionysus (A) of the Greeks, whom they named Bromius, without knowing why; and Bucegni, when

(A) The learned president, whose death will be lamented by every scholar, by the orientalist and the divine especially, imagines, that this would fully appear from comparing, together, the Dionysius of Noonus and the Ramayana of Valmics, the first poet of the Hindoos. He adds, that, in his opinion, Rhama was the sun of Cush, and that he might have established the first regular government in that part of Asia, in which his exploits are said to have been performed.
when they represented him horned, as well as Lyana and Eleutherios the deliverer, and Tryambos or Dythyrambos the triumphant. "Most of those titles (says Sir William) were adopted by the Romans, by whom he was called Bruna, Taurosiris, Liber, and Triumphus; and both nations had records or traditional accounts of his giving laws to men and deciding their contests, of his improving navigation and commerce, and, what may appear yet more observable, of his conquering India and other countries with an army of satyrs, commanded by no less a personage than Pan; whom Lilius Gyraldus, on what authority I know not, asserts to have resided in Iberia when he had returned, says the learned mythologist, from the Indian war, in which he accompanied Bacchus." It were superfluous in a mere essay to run any length in the parallel between this European god and the sovereign of Ayodhya, whom the Hindoos believe to have been an appearance on earth of the preserving power; to have been a conqueror of the highest renown, and the deliverer of nations from tyrants, as well as of his consort Sita from the giant Ravan king of Lanka; and to have commanded in chief a numerous and intrepid race of those large monkeys, which our naturalists, or some of them, have denominated Indian satyrs: his general, the prince of satyrs, was named Hamnasot, or "with high cheek bones;" and, with workmen of such agility, he soon raised a bridge of rocks over the sea, part of which, say the Hindoos, yet remains; and it is probably the series of roads to which the Mussulmans or Portuguese have given the foolish name of Adam's (it should be called Rama's) bridge. Might not this army of satyrs have been only a race of mountaineers, whom Rama, if such a monarch ever existed, had civilised? However that may be, the large breed of Indian apes is at this moment held in high veneration by the Hindoos, and fed with devotion by the Brahmins, who seem in two or three places on the banks of the Ganges to have a regular endowment for the support of them: they live in tribes of three or four hundred, are wonderfully gentle (I speak as an eye-witness), and appear to have some kind of order and subordination in their little sylvan polity." The festival of Rhamas is held on the 9th day of the new moon of Chaitra, on which the war of Lanka is dramatically represented, concluding with an exhibition of the fire- ordeal, by which the victor's wife Sita gave proof of her connubial fidelity. Among the Hindoos there is a variety of very fine dramas of great antiquity on the story of Rhamas.

There are three Rhamas mentioned in the Indian mythology, who, together with Chisnus, the darling god of the Indian women, are described as youths of perfect beauty. The third Rhamas is Chisnus's elder brother, and is considered as the eighth Avatar (A), invested with an emanation of his divine radiance. Like all the Avatars, Rhamas is painted with gemmed Ethiopian or Parthian coronets; with rays encirling his head, jewels in his ears, two necklaces, one straight and one pendant on his bosom, with dropping gems; garlands of well-disposed many-coloured flowers, or collars of pearls, hanging down below his waist; loose mantles of golden tissue or dyed silk, embroidered on the hems with flowers, elegantly thrown over one shoulder, and folded like ribbands across the breast: with bracelets, two on one arm and on each wrist: all the Avatars are naked to the waist, and uniformly with dark azure flesh, in allusion to the tint of that primordial fluid on which Narayan moved in the beginning of time; but their skirts are bright yellow, the colour of the curious pericarpium in the centre of the water-lily.

RHAMNUS, the Buckthorn, a genus of plants belonging to the pantandria class; and in the natural method ranking under the 43d order, Diumus. See Botany and Materia Medica Index.

The paliurus, or thorn of Christ, a deciduous shrub or tree, belongs to this genus, and is a native of Palestine, Spain, Portugal, and Italy. It grows to nearly the height of 14 feet, and is armed with sharp thorns, two of which are at each joint, one of which is about half an inch long, straight, and upright; the other is scarcely half that length, and bent backward; and between them is the bud for next year's shoot. June is the time of flowering, and the flowers are succeeded by a small fruit, surrounded by a membrane. "This plant (says Hanbury) is undoubtedly the sort of which the crown of thorns for our blessed Saviour was composed. The branches are very pliant, and the spines of it are at every joint strong and sharp. It grows naturally about Jerusalem, as well as in many parts of Judea; and there is no doubt that the barbarous Jews would make choice of it for their cruel purpose. But what farther confirms the truth of these thorns being then used, are the ancient pictures of our blessed Saviour's crucifixion. The thorns on the crown of his head exactly answer to those of this tree; and there is great reason to suppose these were taken from the earliest paintings of the Lord of Life: and even now our moderate painters copy from them, and represent the crown as composed of these thorns. These plants, therefore, should principally have a share in those parts of the plantation that are more peculiarly designed for religious retirement; for they will prove excellent monitors, and conducing to due reflection on and gratitude to 'Him who hath loved us, and has washed us from our sins,' &c.

RHAMPHASTOS, a genus of birds belonging to the order of Picae. See Ornithology Index.

RHAPIS, a genus of plants belonging to the hexandria class; and in the natural method ranking under the first order Palmæ. See Botany Index.

RHAPSODI, Rhapsodists, in Antiquity, persons who made a business of singing pieces of Homer's poems.

(A) Avatar means the descent of the deity in his capacity of preserver. The three first of these descents relate to some stupendous convulsion of our globe from the fountains of the deep, and the fourth exhibits the miraculous punishment of pride and impiety, appearing to refer to the deluge. Three of the others were ordained for the overthrow of tyrants or plants. Of these Avatars, we have mentioned in the text that Rhamas is the eighth; Buddha, who appears to have been a reformer of the doctrines contained in Vedas, is the ninth: the tenth Avatar, we are told, is yet to come, and is expected to appear mounted (like the crowned conqueror in the Apocalypse) on a white horse, with a scimitar blazing like a comet, to mow down all incorrigible and impudent offenders who shall then be on the earth.

Vol. XVII. Part II.
RHE [ 794 ]

poems. It has been said, that the Rhapsodi were
clothed in red when they sung the Iliad, and in blue
when they sung the Odyssey. They performed on
the theatres, and sometimes strove for prizes in contests of
poetry, singing, &c. After the two antagonists had
finished their parts, the two pieces or papers they were
written in were soon joined together again: whence the
name, viz. from ἄρσπος, συγγραφέας, and σατυρικά: but there
seem to have been other Rhapsodi of more antiquity
than these people, who composed heroic poems or songs
in praise of heroes and great men, and sung their own
compositions from town to town for a livelihood; of
which profession Homer himself is said to have been.
See BARD.

RHAPSODOMANCY, an ancient kind of divina-
tion performed by pitching on a passage of a poet at
hazard, and reckoning on it as a prediction of what was
to come to pass. There were various ways of practi-
cising this rhapsodomancy. Sometimes they wrote sev-
eral papers or sentences of a poet on so many pieces of
wood, paper, or the like, shook them together in an urn,
and drew out one which was accounted the lot: some-
times they cast dice on a table wherein verses were
written, and that wherein the die lodged contained the
prediction. A third manner was by opening a book,
and pitching on some verse at first sight. This method
they particularly called the sartes Præsanetiae; and af-
fterwards, according to the poet, made use of sartes Ho-
ericæ, sartes Virgilianæ, &c. See SORTES.

RHAPSODY, in Antiquity, a discourse in verse sung
or rehearsed by a rhapsodist. Others will have rhapsody
to signify a collection of verses, especially those of Ho-
mer, which having been a long time dispersed in pieces
and fragments, were at length by Priestatus's order di-
gested into books called rhapsoctes, from ἄρσπος, συγγραφέας,
and σατυρικά. Hence, among moderns, rhapsody is also
used for an assemblage of passages, thoughts, and au-
thorities, raked together from divers authors, to compose
some new piece.

RHE, or REE, a little island in the bay of Biscay,
early the coast of Annis in France. It was taken during
the war with France which ended in 1763, in the expedi-
tion commanded by Hawke and Mordaunt.

RHEA AMERICANA. The American ostrich of au-
thors has been frequently mentioned, but till of late
years very imperfectly known. See ORNITHOLOGY
INDEX.

RHEEDIA, a genus of plants belonging to the poly-
andria class, and in the natural method ranking with those
of which the order is doubtful. See BOTANY INDEX.

RHEGIUM, in Ancient Geography, so very ancient
a city as to be supposed to take its name from the violent
bursting of the coast of Italy from Sicily, thought to
have been formerly conjoined (Mela, Virgil). A city of the Brutii, a colony of Chalcidians from Euboea:
a strong barrier opposed to Sicily (Strabo); mentioned
by Luke; surnamed Julium (Polishms), from a fresh
supply of inhabitants sent hither by Augustus, after
driving Sextus Pompeius out of Sicily (Strabo); and
thus was in part a colony, retaining still the right of a
municipium (Inscription). The city is now called Re-
ggio, in the Farther Calabria.

RHEIMS, a city of France, in the department of
Marne, which contained 31,295 inhabitants in 1800. It
is one of the most ancient and celebrated places in the
kingdom, had an archbishop's see, whose archbishop was
a duke and peer of France. It is about four miles in
circumference, and contains several fine squares, well-
built houses, and magnificent churches. It had a mint,
an university, and five abbeys, the most famous of which
is that of St Remi. There are also several triumphant
arches and other monuments of the Romans. It is seat-
ed on the river Vesle, surrounded by hills, which pro-

RHENISH WINE, that produced on the hills about
Rheims. This wine is much used in medicine as a
solvent of iron, for which it is well calculated on ac-
count of its acidity. Dr Percival observes, that it is
the best solvent of Peruvian bark; in which, how-
ever, he thinks its acidity has no share, because an ad-
dition of vinegar to water does not augment its solvent
power.

RHETORES, amongst the Athenians, were ten in
number, elected by lot to plead public causes in the
senate house or assembly. For every cause in which they
were retained, they received a drachm out of the public
money. They were sometimes called συντριβων and their
fee συντριβον. No man was admitted to this office
before he was 40 years of age, though others say 30.
Valour in war, piety to their parents, prudence in their
affairs, frugality, and temperance, were necessary quali-
fications for this office, and every candidate underwent
an examination concerning these virtues, previous to the
election. The orators at Rome were not unlike the
Athenian rhetoricians. See ORATOR.

RHETORIANS, a sect of heretics in Egypt, so
denominated from Rhetorius their leader. The dis-
guisie[]
The rhubarb, Rheum, heart-shaped somewhat lobed, sharply indented, smooth leaves, and an upright large stem, five or six feet high, garnished with leaves singly, and branching above; having all the branches terminated by nodding panicles of white flowers. This has been supposed to be the true rhubarb; which, however, though of superior quality, is not the same sort, is accounted inferior to the rheum palmatum.

4. The undulatum, undulated, or waved-leaved Chinese rhubarb, hath a thick, branching, deep-striking root, yellow within; crowned with large, oblong, undulate, somewhat hairy leaves, having equal foot-stalks, and an upright firm stem, four feet high; garnished with leaves single, and terminated by long loose spikes of white flowers.

5. The Arabian ribs, or currant rhubarb of Mount Libanus, has a thick fleshy root, very broad leaves, full of granulated protuberances, and with equal foot-stalks, and upright firm stems, three or four feet high, terminated by spikes of flowers, succeeded by berry-like seeds, being surrounded by a purple pulp. All these plants are perennial in root, and the leaves and stalks are annual. The roots being thick, fleshy, generally divided, strike deep into the ground; of a brownish colour without and yellow within; the leaves rise in the spring, generally come up in a large head folded together, gradually expanding themselves, having thick foot-stalks; and grow from one to two feet high, or more in length and breadth, spreading all around: amidst them rise the flower-stems, which are garnished at each joint by one leaf, and are of strong and expeditious growth, attaining their full height in June. When they flower; and are succeeded by large triangular seeds, ripening in August. Some plants of each sort merit culture in gardens for variety; they will effect a singularity with their luxuriant foliage, spikes, and flowers; and as medical plants, they demand culture both for private and public use.

They are generally propagated by seeds sown in autumn soon after they are ripe, or early in the spring, in any open bed of light deep earth; remarking, those intended for medical use should generally be sowed where they are to remain, that the roots, being not disturbed by removal, may grow large. Scatter the seeds thinly, either by broadcast all over the surface, and rake well in; or in shallow drills a foot and a half distance, covering them near an inch deep. The plants will rise in the spring, but not flower till the second or third year; when they, however, are come up two or three inches high, thin them to eight or ten inches, and clear out all weeds; though those designed always to stand should afterwards be hoed out to a foot and a half or two feet distance. Observing, if any are required for the pleasure ground, &c. for variety, they should be transplanted where they are to remain in autumn, when their leaves decay, or early in spring, before they shoot: the others remaining where sowed, must have the ground kept clean between them; and in autumn, when the leaves and stalks decay, cut them down, and slightly dig the ground between the rows of plants, repeating the same work every year. The roots remaining, they increase in size annually; and in the second or third year many of them will shoot up stalks, flower, and perfect seeds; and in three or four years the roots will be arrived to a large size; though older roots are generally preferable for medical use.

In Mr Bell’s Travels we have an account of some curious particulars relating to the culture of rhubarb. He tells us, that the best rhubarb grows in that part of Eastern Tartary called Mongolia, which now serves as a boundary between Russia and China. The marmots contribute greatly to the culture of the rhubarb. Whenever you see 10 or 20 plants growing, you are sure of finding several burrows under the shade of their broad-spreading leaves. Perhaps they may sometimes eat the leaves and roots of this plant; however, it is probable the manure they leave about the roots contributes not a little to its increase; and their casting up the earth, makes it shoot out young buds and multiply. This plant does not run, and spread itself, like docks and others of the same specie; but grows in tufts, at uncertain distances, as if the seeds had been dropped with design. It appears that the Mongols never accounted it worth cultivating; but that the world is obliged to the marmots for the quantities scattered, at random, in many parts of this country: for whatever part of the ripe seed happens to be blown among the thick grass, can very seldom reach the ground, but must there wither and die; whereas, should it fall among the loose earth thrown up by the marmots, it immediately takes root and produces a new plant.

After digging and gathering the rhubarb, the Mongols cut the large roots into small pieces, in order to make them dry more readily. In the middle of every piece they scoop a hole, through which a cord is drawn, in order to suspend them in any convenient place. They hang them, for the most part, about their tents, and sometimes on the horns of their sheep. This is a most pernicious custom, as it destroys some of the best part of the root; for all about the hole is rotten and useless, whereas, were people rightly informed how to dig and dry this plant, there would not be one pound of refuse in a hundred; which would save a great deal of trouble and expense, that much diminish the profits on this commodity. At present, the dealers in this article think these improvements not worthy of their attention, as their gains are more considerable on this than on any other branch of trade. Perhaps the government may hereafter think it proper to make some regulations with regard to this matter.

Two sorts of rhubarb are met with in the shops. The first is imported from Turkey and Russia, in roundish pieces freed from the bark, with a hole through the middle of each; they are externally of a yellowish colour, and on cutting appear variegated with lively reddish streaks. The other, which is less esteemed, comes immediately from the East Indies in longish pieces, harder, heavier, and more compact than the foregoing. The first sort, unless kept very dry, is apt to grow mouldy and worm-eaten; the second is less subject to these inconveniences. Some of the more industrious artists are said to fill up the worm holes with certain mixtures, and to colour the outside of the damaged pieces with powder of the finer sorts of rhubarb, and sometimes with cheaper materials: this is often so nicely done, as effectually to impose upon the buyer, unless he be very carefully examines each piece.

The Turkey rhubarb is, among us, universally preferred to the East India sort, though this last is for some purposes at least equal to the other; it is manifestly more astringent, but has somewhat less of an aromatic
RHE [ 796 ]

In the year 1794 the Society adjudged the gold medal to Mr. William Hayward of Hanbury, Oxfordshire, for propagating rhubarb by offsets taken from the crowns of large plants, instead of seeds, for the purpose of bringing it to perfection in a shorter time, which fully answered his expectations. Mr. Hayward was a candidate in the year 1789 for the gold medal; but having misunderstood their rules, he was not entitled to it; though with great propriety they voted to him the silver medal; in consequence of which he sent them his method of culture and cure. His method of cultivating Turkey rhubarb from seed is thus explained in the Society: "I have usually sown the seed about the beginning of February, on a bed of good soil (if rather sandy the better), exposed to an east or west aspect, in preference to the south; observing a full sun to be prejudicial to the vegetation of the seeds, and to the plants whilst young. The seeds are best sown moderately thick (broadcast), treading them gently into, as is usual with pursneys and other light seeds, and then raking the ground smooth. I have sometimes, when the season has been wet, made a bed for sowing the rhubarb seeds upon, about two feet thick, with new dung from the stable, covering it near one foot thick with good soil. The interior of this bed is kept for the sake of warmth, but solely to prevent the rising of earth-worms, which, in a moist season, will frequently destroy the young crop. If the seed is good, the plants often rise too thick; if so, when they have attained six leaves they should be taken carefully up (where too close), leaving the standing crop eight or ten inches apart: those taken up may be planted at the same distance, in a fresh spot of ground, in order to furnish other plantations. When the plants in general are grown to the size that cabbage plants are usually set out for a standing crop, they are best planted where they are to remain, in beds four feet wide, one row along the middle of the bed, leaving two yards distance between the plants, allowing an alley between the beds about a foot wide, for convenience of weeding the plants. In the autumn, when the decayed leaves are removed, if the shovellings of the alleys are thrown over the crowns of the plants, it will be found of service.

His mode of cultivating the same plant by offsets is thus given: "On taking up some plants the last spring, I slipped off several offsets from the heads of large plants: those I set with a dibble about a foot apart, in order, if I found them thrive, to remove them into other beds. On examining them in the autumn, I was surprised to see the progress they had made, and pleased to be able to furnish my beds with 40 plants in the most thriving state. Though this was my first experiment of its kind, I do not mean to arrogate the discovery to myself, having known it recently tried by others, but without being informed of their success. I have reason to think this valuable drug will, by this method, be brought much sooner to perfection than from seed."

His method of curing rhubarb is thus described: "The plants may be taken up either early in the spring, or in autumn, when the leaves are decayed, in dry weather if possible, when the roots are to be cleared from dirt (without washing): let them be cut into pieces, and with a sharp knife freed from the outer coat, and exposed to the sun and air for a few days, to render the outside a little dry. In order to accelerate the curing
of the largest pieces, a hole may be scooped out with a penknife: these and the smaller parts are then to be
strung on a thread, and hung up in a warm room (I
have always had the convenience of such a one over a
baker's oven), where it is to remain till perfectly dry.
Each piece may be rendered more sightly by a common
file, fixing it in a small vice during that operation:
afterwards rub it over with a very fine powder, which the small
roots furnish in beautiful perfection, for this and every
other purpose where rhubarb is required."

In the year 1704, too, the society adjudged the gold
medal to Mr. Ball for his method of curing the true rhubarb,
which is as follows: "I take the roots up when
I find the stalks withering or dying away, clean them
from the earth with a dry brush, cut them in small pieces
of about four or five inches in breadth, and about two in
depth, taking away all the bark, and make a hole in
the middle, and string them on a thread, keeping
every piece apart; and every morning, if the weather is
clear and fine, I place them in the open part of the
garden, on stages, erected by fixing small posts about six
feet high in the ground, and six feet asunder, into which
I fix horizontal pegs, about a foot apart, beginning at
the top; and the rhubarb being strung crosswise on
small poles, I place them on these pegs; so that if
it should rain, I could easily remove each pole with the
suspended pieces, into any covered place. I never suf-
fer them to be out at night, as the damp at this season
would be apt to mould them; and if at any time I per-
ceive the least mark of mould, I rub it off with a dry
cloth. In some of the pieces of rhubarb which I have
cured this year, I have made holes about half an inch
diameter in the middle, for the free passage of air, and
have found that every one of these pieces dried better
than the others where no such holes were made; and
have likewise hung several strings in the kitchen, and
ever exposed them in the open air, and found them to
dry exceedingly well, and much better than those in
the open air. Some years since I dried a quantity of
rhubarb on a malt-kiln, keeping up the thermometer to
80 degrees, which answered well, but I think rather
dried too quick: the roots which I have cured this
year are a part of the plantation of 1789, and for
which the Society was so kind as to give me a me-
dal."

RHEXIA, a genus of plants belonging to the oc-
tandria class; and in the natural method ranking
with those of the 17th order, Calycanthemae. See BOTANY
Index.

RHINANTHUS, a genus of plants belonging to the
dilymnia class; and in the natural method ranking
under the 40th order, Personatae. See BOTANY
Index.

RHINE, a large river of Germany, famous both in
ancient and modern history. It rises among the Alps
Leptontes, or Grisons; and first traversing the Lactus
Acruminus, divides the Rheti and Vindelicis from the
Helvetii, and then the Germans from the Gauls and
Belge; and running from south to north for the grea-
est part of its way, and at length bending its course
west, it empties itself at several mouths (Cesar); at
three mouths into the German ocean, (Pliny); viz. the
western, or Helius; the eastern, or Fleuvus; and the
middle between both these, which retains the original
name, Rheus; and in this Ptolemy agrees.—Mela
and Tacitus mention two channels, and as many most
the right and left; the former running by German
and the latter by Gallia Belgica: and thus also Asini
Pollio, and Virgil; the cut or trench of Drusus not
being made in their time, whereby the middle channe
was much drained and reduced, and therefore overlook-
ning made by Tacitus and Mela; and which Pliny calls the
Scanty. To account for Cesar's seven mouths, is a
matter of no small difficulty with the commentators;
and they do it no otherwise than by admitting that the
Rhine naturally formed small drains or rivulets from it-
self; the cut of Drusus being long posterior to him; in
whose time Asinus Pollio, quoted by Strabo, who
agrees with him therein, affirmed that there were but
two mouths, finding fault with those who made them
more; and he must mean the larger mouths, which
emitted larger streams. The Romans, especially
the poets, used the term Rheus for Germany, (Marzial).

At present, the river, after entering the Netherlands
at Schenkinquaus, is divided into several channels, the
two large of which obtain the names of the Lach and
the Iual, which running through the United Pro-
vinces, falls into the German ocean below Rotter-
dam.

RHINE, Lower, a department in the east of France,
consisting chiefly of the lower part of the ancient
Alsace. It is extremely fertile, and produces corn of
all kinds, maize, rapseseed, hemp, flax, tobacco, chestnuts,
vines, excellent pasturage, and wood in abundance.
Agriculture is more improved here than in most other
parts of France. Fallow are now dispersed. Potatoes
were introduced here earlier, and are cultivated more
extensively, than in the other departments. The horses
are good—black cattle numerous,—but there are few
sheep. There are mines of iron and coal, and quarries
of building stone. The manufactures consist of fus-
tians, tapestry, cutlery, &c. The extent of this de-
partment was 495,075 hectares, of which, about one-
eighth part was cut off by the treaty of Paris in 1815.
Its population in 1830 was 444,848; but in 1815, after
the cessions, it was only 304,642. Its contributions
in 1822 amounted to 3,609,442. Strasbourg is the chief
town.

RHINE, Upper, a department in the east of France,
consisting of the higher part of the ancient Alsace.
The soil is unequal, and in many places poor. It pro-
duces wheat, barley, rye, flax, madder, wine, and
legumes. There are mines of silver, copper, lead, iron,
and coal. The manufactures are woolen and cotton
cloths, hosiery, ribbons, cotton-yarn, iron and steel
ware, powder, and watches. The extent of this de-
partment in 1800 was 549,627 hectares, and the popu-
lation 392,285; but about one-fifth of its surface
having been disjoined from it and annexed to Switzer-
land in 1815, its population in 1817 was only 318,577.
Its contributions in 1822 amounted to 2,837,963 francs.
Colmar is the chief town.

Lower Circle of the RHINE, consisted of the palat-
nate of the Rhine, and the three ecclesiastical electo-
rates, viz., those of Cologne, Mentz, and Triers, now
belonging to Prussia.

Upper Circle of the RHINE, consisted of the landgraves
of Alsace and Hesse, comprehending the Wette-
raw;
Rhine
||
Rhinegau

RHINEBERG, a town of Germany, in the circle of the Lower Rhine, and diocese of Cologne, now belonging to Prussia. It is seated on the Rhine, in E. Long. 6° 39'. N. Lat. 51° 30'.

RHINECK, a town of Germany, in the archbishopric of Cologne, seated on the Rhine, E. Long. 7° 53'. N. Lat. 50° 27'.—There is another town of the same name in Switzerland, capital of Rintaln, seated on the Rhine, near the lake of Constance, with a good castle. E. Long. 9° 53'. N. Lat. 47° 38'.

RHINFELD, a small but strong town of Germany, formerly belonging to Austria, but now to the grand duchy of Baden. It has been often taken and retaken in the German wars; and is seated on the Rhine, over which there is a handsome bridge. E. Long. 7° 53'. N. Lat. 47° 40'.

RHINEGAGU, a beautiful district of the electorate of Mentz, is situated on the Rhine, about three miles from the city of Mentz, and is so populous that it looks like one entire town intermixed with gardens and vineyards. The Rhine here grows astonishingly wide, and forms a kind of sea, near a mile broad, in which are several well wooded little islands. The Rhinegau forms an amphitheatre, the beauties of which are beyond all description. At Walluf, the very high hill comes nearly down to the river side; from thence they recede again into the country, forming a kind of half circle, the other end of which is 15 miles on Rudesheim, on the banks of the Rhine. The banks of the river, the hills which form the circles, and the slopes of the great mountains, are thick sown with villages and hamlets. The white appearance of the buildings, and the fine blue slatted roofs of the houses playing amidst the various green of the landscape, have an admirable effect. In the space of every mile, as you sail down the river, you meet with a village which in any other place would pass for a town. Many of the villages contain from 300 to 400 families; and there are 36 of them in a space of 15 miles long and six miles broad, which is the width of this beautiful amphitheatre. The declivities of all the hills and mountains are planted thick with vineyards and fruit trees, and the thick wooded tops of the hills cast a gloomy horror over the otherwise cheerful landscape. Every now and then a row of rugged hills run directly down to the shore, and dominate majestically over the lesser hills under them. On one of these great mountains, just about the middle of the Rhinegau, you meet Johannisberg, a village which produces some of the best Rhenish. Before this village is a pretty little rising, and near the banks of the river there is a very fine old castle, which gives unspeakable majesty to the whole landscape. Indeed, in every village, you meet with some or other large building, which contributes very much to the decoration of the whole. This country is indented for its riches to this semicircular hill, which protects it from the cold winds of the east and north, at the same time that it leaves room enough for the sun to exercise its benign influences. The groves and higher slopes of the hills make excellent pastures, and produce large quantities of dung, which, in a country of this sort, is of inestimable value.

The bank of the Rhine, opposite to the Rhinegau, is exceedingly barren, and heightens the beauty of the Rhine prospect on the other side by the contrast it exhibits; on this side, you hardly meet above three or four villages, and these are far distant from each other. The great interval between them is occupied by heaths and meadows, only here and there a thick bush affords some shade, and a few corn fields among the villages enliven the gloomy landscape. The back ground of this country is the most picturesque part of it. It is formed by a narrow gullet of mountains, which diminish in perspective between Rudesheim and Bingen. Perpendicular mountains and rocks hang over the Rhine in this place, and seem to make it the dominion of eternal night. At a distance, the Rhine seems to come out of this landscape through a hole under ground; and it appears to run tediously, in order to enjoy its course through a pleasant country the longer. Amidst the darkness which covers this back ground, the celebrated Mouse tower seems to swim upon the river. In a word, there is not any thing in this whole tract that does not contribute something to the beauty and magnificence of the whole; or, if I may be permitted the expression, to make the paradise more welcome. As you sail along the Rhine, between Mentz and Bingen, the banks of the river form an oval amphitheatre, which makes one of the richest and most picturesque landscapes to be seen in Europe. The inhabitants of these regions are some of them extremely rich, and some extremely poor. The happy middle state is not for countries the chief product of which is wine; for, besides that the cultivation of the vineyard is infinitely more troublesome and expensive than agriculture, it is subjected to revolutions, which in an instant reduce the holder of land to the condition of a day-labourer. It is a great misfortune for this country, that, though restrained by law, the nobility are, through connivance of the elector, allowed to purchase as much land as they please. The peasant generally begins by running in debt for his vineyard; so that if it does not turn out well, he is reduced to day-labour, and the rich man extends his possessions to the great detriment of the country. There are several peasants here, who having incomes of 30,000 50,000 or 100,000 guilders a-year, have laid aside the peasant, and assumed the wine-merchant; but splendid as their situation is, it does not compensate, in the eyes of the humane man, for the sight of so many poor people with which the villages swarm. In order to render a country of this kind prosperous, the state should appropriate a fund to the purpose of maintaining the peasant in bad years, and giving him the assistance which his necessities, and his want of ready money, may from time to time make convenient.

The inhabitants of the Rhinegau are a handsome and uncommonly strong race of men. You see at the very first aspect that their wine gives them merry hearts and sound bodies. They have a great deal of natural wit, and a vivacity and jocoseness, which distinguishes them very much from their neighbours. You need only compare them with some of these, to be convinced that the drinker of wine excels the drinker of beer and water, both in body and mind, and that the inhabitant of the south is much stouter than he who lives in the north; for though the wine-drinker may not have quite as much flesh as he who drinks only beer, he has better
Rhineland, a name given to a part of South Holland, which lies on both sides of the Rhine, and of which Leyden is the capital town.

RHINOCEROS, a genus of quadrupeds belonging to the order of bison. See Mammalia Index.

RHINOCEROS-Bird. See Bucerius, Ornithology Index.

RHITYMNA. See Retimo.

RHIZOBALUS, a genus of plants, belonging to the polyandria class; and in the natural method ranking under the 23d order, Trihitae. Of this there is only one species, viz. Pekia. The nuts are sold in the shops as American nuts; they are flat, tuberculated, and kidney-shaped, containing a kernel of the same shape, which is sweet and agreeable. Clusius gives a good figure of the nut, and Aublet has one of the whole plant.
