Upon this model were the primitive presbyteries formed. They consisted of several presbyters possessed of equal powers, who at their meetings appointed one of their own number to discharge the office of moderator or temporary president; but to this president they gave no prelatical powers or negative voice over the deliberations of his brethren; for, as Jerome informs us, the church was then governed *communi presbyterorum concilio*, "by a common council of presbyters." It appears, however, that when an apostle, an apostolical man, or an evangelist, fixed his residence in any city, and took upon himself the pastoral care of part of the flock, his co-presbyters, from respect to his singular gifts, made him their constant and fixed moderator. Hence Timothy, during his abode at Ephesus, was moderator of the presbytery; and hence too Mark the evangelist, who resided many years in Alexandria, has been called the first bishop of that church, though he appears to have been nothing more than permanent moderator. We advance this upon the authority of Jerome, one of the most learned fathers of the Christian church, who informs us, that upon the death of the evangelist, the presbyters of Alexandria, for more than 200 years, chose their bishops from their own number, and placed them in the episcopal chair, without dreaming that they ought to be raised to a higher order by a new consecration;—*Presbyteri unum ex se electum in excelsiori gradu collocatum, episcopum nominabant.* As this practice of making the moderator of the presbytery of Alexandria a permanent officer, was thought a good expedient to guard the infant churches against schisms and divisions, those churches gradually adopted it. For, as Jerome tells us, *Postquam unusquisque eos quos baptizaverat, suos putabat esse, non Christi, in toto orbe decretum est, ut unus de presbyteris electus, superponeretur cæteris, ad quem omnis ecclesiæ cura pertineret, et schismatum semina tollerentur.*

9 According to Jerome.

The advantages which, in displaying his talents and authority, the perpetual president or speaker of any assembly has over his colleagues in office, are so obvious, that when the practice of electing their moderators for life became universal among the presbyteries of the primitive church, it is easy to conceive how ambitious men might so magnify the difficulties and importance of their station, as to introduce the custom of filling it by a new consecration of the bishop elect. But when this was done, diocesan episcopacy, with all its powers and prerogatives, would follow as a thing of course, until "by little and little (as Jerome expresses himself) the whole pastoral care of the flock was devolved upon one man."

Our limits will not permit us to trace more minutely the rise and progress of this ecclesiastical usurpation, as the Presbyterian calls it; but the reader who wishes for fuller information, after studying the remains of the four first centuries of the Christian church, may consult *An Inquiry into the Constitution, Discipline, and Worship of the Primitive Church*, said to have been written by Sir Peter King, afterwards lord chancellor of England. As an impartial lover of truth, he will do well to consult also a book entitled, *An original Draught of the Primitive Church*, which was published as an answer to the Inquiry; and he may read with much advantage to himself *A Letter from a parochial bishop to a prelatical gentleman*, with *An apology for the Church of Scotland*, both written by Mr Willison some time minister in Dundee, and both evincing considerable learning and great ingenuity in their pious author.

10 The church of Scotland.

Of the churches at present formed upon this model, we believe, that without incurring the imputation of national prejudice, we may safely affirm the church of Scotland to be by much the most respectable. Her mode of worship is simple and solemn; her established faith agreeable to the confessions of most other Protestant churches; her judicatories are calculated to maintain the rights of the people; and her pastors are confessedly men of liberal and enlightened minds. On these accounts it appears to us, that we cannot more properly conclude this article than with a short view of her constitution, as being that in which our Presbyterian readers are undoubtedly most interested.

No one is ignorant, that from the first dawn of reformation among us, till the era of the revolution, there was a perpetual struggle between the court and the people for the establishment of an Episcopal or a Presbyterian form of church government: The former model of ecclesiastical polity was patronised by the house of Stuart on account of the support which it gave to the prerogatives of the crown; the latter was the favourite of the majority of the people, perhaps not so much on account of its superior claim to apostolical institution, as because the laity are mixed with the clergy in church judicatories, and the two orders, which under episcopacy are kept so distinct, incorporated, as it were, into one body. In the Scottish church, every regulation of public worship, every act of discipline, and every ecclesiastical censure, which in other churches flows from the authority of a diocesan bishop, or from a convocation of the clergy, is the joint work of a certain number of clergymen and laymen acting together with equal authority, and deciding every question by a plurality of voices. The laymen who thus form an essential part of the ecclesiastical courts of Scotland, are called *ruling elders;* and hold the same office, as well as the same name, with those brethren * who joined with the apostles and elders at Jerusalem in determining the important question concerning the necessity of imposing upon the Gentile converts the ritual observances of the law of Moses. These lay-elders Paul enjoined Timothy † to account worthy of double honour, if they should rule well, and discharge the duties for which they were separated from the multitude of their brethren. In the church of Scotland every parish has two or three of these lay-elders, who are grave and serious persons, chosen from among the heads of families, of known orthodoxy and steady adherence to the worship, discipline, and government of the church. Being solemnly engaged to use their utmost endeavours for the suppression of vice and the cherishing of piety and virtue, and to exercise discipline faithfully and diligently, the minister, in the presence of the congregation, sets them apart to their office by solemn prayer; and concludes the ceremony, which is sometimes called ordination, with exhorting both elders and people to their respective duties.

11 Its government by clergy and laymen.

* Acts xv. † 1 Tim. v. 17.

12 The kirk-session.

The kirk-session, which is the lowest ecclesiastical judicatory, consists of the minister and those elders of the congregation. The minister is *ex officio* moderator, but has no negative voice over the decision of the session; nor indeed has he a right to vote at all, unless when the voices of the elders are equal and opposite. He

may

Presbyterians

may indeed enter his protest against their sentence, if he think it improper, and appeal to the judgment of the presbytery; but this privilege belongs equally to every elder, as well as to every person who may believe himself aggrieved by the proceedings of the session. The deacons, whose proper office it is to take care of the poor, may be present in every session, and offer their counsel on all questions that come before it; but except in what relates to the distribution of alms, they have no decisive vote with the minister and elders.

13 The presbytery.

The next judicatory is the *presbytery*, which consists of all the pastors within a certain district, and one ruling elder from each parish, commissioned by his brethren to represent, in conjunction with the minister, the session of that parish. The presbytery treats of such matters as concern the particular churches within its limits; as the examination, admission, ordination, and censuring of ministers; the licensing of probationers, rebuking of gross or contumacious sinners, the directing of the sentence of excommunication, the deciding upon references and appeals from kirk-sessions, resolving cases of conscience, explaining difficulties in doctrine or discipline; and censuring, according to the word of God, any heresy or erroneous doctrine which hath either been publicly or privately maintained within the bounds of its jurisdiction. Partial as we may be thought to our own church, we frankly acknowledge that we cannot altogether approve of that part of her constitution which gives an equal vote, in questions of heresy, to an illiterate mechanic and his enlightened pastor. We are persuaded that it has been the source of much trouble to many a pious clergyman; who, from the laudable desire of explaining the scriptures and declaring to his flock all the counsel of God, has employed a variety of expressions of the same import, to illustrate those articles of faith which may be obscurely expressed in the established standards. The fact however is, that, in presbyteries, the only prerogatives which the pastors have over the ruling elders, are the power of ordination by imposition of hands, and the privilege of having the moderator chosen from their body.

14 The provincial synod.

From the judgment of the presbytery there lies an appeal to the provincial synod, which ordinarily meets twice in the year, and exercises over the presbyteries within the province a jurisdiction similar to that which is vested in each presbytery over the several kirk-sessions within the bounds. Of these synods there are in the church of Scotland fifteen, which are composed of the members of the several presbyteries within the respective provinces which give names to the synods.

15 The general assembly.

The highest authority in the church of Scotland is the general assembly, which consists of a certain number of ministers and ruling elders delegated from each presbytery, and of commissioners from the universities and royal boroughs. A presbytery in which there are fewer than twelve parishes, sends to the general assembly two ministers and one ruling elder: if it contain between 12 and 18 ministers, it sends three of these, and one ruling elder: if it contains between 18 and 24 ministers, it sends four ministers and two ruling elders: and of 24 ministers, when it contains so many, it sends five with two ruling elders. Every royal borough sends one ruling elder, and Edinburgh two: whose election must be attested by the kirk-sessions of their respective boroughs. Every university sends one commissioner from its own body. The commissioners are chosen annually six weeks before the meeting of the assembly; and the ruling elders are often men of the first eminence in the kingdom for rank and talents. In this assembly, which meets once a-year, the king presides by his commissioner, who is always a nobleman; but he has no voice in their deliberations. The order of their proceedings is regular, though sometimes the number of members creates a confusion, which the moderator, who is chosen from among the ministers, to be, as it were, the speaker of the house, has not sufficient authority to prevent. Appeals are brought from all the other ecclesiastical courts in Scotland to the general assembly; and in questions purely religious no appeal lies from its determinations.—In the subordination of these assemblies, parochial, presbyterial, provincial, and national, the less unto the greater, consists the external order, strength, and stedfastness of the church of Scotland.

Presbyterians || Prescription.

PRESCIENCE, in *Theology*, prevision or foreknowledge; that knowledge which God has of things to come.—The doctrine of predestination is founded on the prescience of God, and on the supposition of all futurity's being present to him. See PREDESTINATION.

PRESCRIPTION, in *Law*, is a title acquired by use and time, and allowed by law; as when a man claims any thing, because he, his ancestors, or they whose estate he hath, have had or used it all the time whereof no memory is to the contrary: or it is where for continuance of time, *ultra memorium hominis*, a particular person hath a particular right against another.

There is a difference between prescription, custom, and usage. *Prescription* hath respect to a certain person, who *by intendment* may have continuance *for ever;* as for instance, he and all they *whose estate he hath* in such a thing; this is a prescription: but *custom* is *local*, and always applied to a *certain* place; as, *time out of mind there has been such a custom in such a place*, &c. And *prescription* belongeth to *one* or a *few* only; but *custom* is common to *all*. *Usage* differs from both, for it may be either to *persons* or *places;* as to *inhabitants of a town to have a way*, &c.

A custom and prescription are in the *right;* usage is in the *possession;* and a prescription that is good for the matter and substance, may be bad by the manner of setting it forth: but where that which is claimed *as a custom*, in or for many, will be good, *that* regularly will be so when claimed by *prescription* for one. *Prescription* is to be *time out of mind;* though it is not the length of time that begets the right of prescription, nothing being done by time, although every thing is done in time; *but it is a presumption in law, that a thing cannot continue so long quiet, if it was against right, or injurious to another.*

PRESCRIPTION, in *Scots Law*. See LAW, p. 675. and 702.

PRESCRIPTION, in *Theology*, was a kind of argument pleaded by Tertullian and others in the 3d century against erroneous doctors. This mode of arguing has been despised by some, both because it has been used by Papists, and because they think that truth has no need of such a support. But surely in disputed points, if it can be shown that any particular doctrine of Christianity was held in the earliest ages, even approaching the apostolic, it must have very considerable weight; and indeed that it has so, appears from the universal appeals of

Prescription.

of all parties to those early times in support of their particular opinions. Besides, the thing is in itself natural; for if a man finds a variety of opinions in the world upon important passages in scripture, where shall he be so apt to get the true sense as from cotemporary writers or others who lived very near the apostolic age? and if such a man shall find any doctrine or interpretation to have been universally believed in the first ages, or as Vincentius Lirinensis words it, *semper ubique et ab omnibus*, he will unquestionably be disposed to think such early and universal consent, or such prescription, of very considerable weight in determining his opinion.

PRESCRIPTIONS, EXTEMPORANEOUS.

Introduction.

1 Nature of a medical prescription.

A Prescription, in a medical sense, signifies much the same with what in common language is called a *receipt*, being "a form of direction for the preparation and administration of some compound medicine." These *medical receipts* are commonly called *formulæ* by physicians; and the term *prescription* is applied to what is written by a physician on seeing his patient, instructing the apothecary what medicines are to be prepared, how they are to be composed, and how administered to the patient. In this sense, a prescription may contain two or more *formulæ*.

These prescriptions are almost always written in Latin, and are expressed in a peculiar style, which, though well known to physicians and apothecaries, may require the illustration of an example. The following is a specimen of a modern prescription, as it would be written by an Edinburgh and a London physician, according to the nomenclature of their respective college Pharmacopœias.

Edinburgh Prescription.

For Mr ——.

2 Examples.

℞ Pulv. Rad. Rhei palmati gr. xxv.
Tartritis Potassæ ʒij.
Tincturæ Sennæ compositæ,
Syrupi Rosæ centifoliæ āā ʒij.
Aquæ Menthæ piperitæ ℥iss.
M. f. *Potio summo mane sumenda.*
Jan. 31. 1809.

London Prescription.

℞ Pulv. Rhei gr. xxv.
Kali Tartarisati ʒij.
Tincturæ Senæ
Syrupi Rosæ āā ʒij.
Aquæ Menthæ piperitidis ℥iss.
M. &c.

3 Parts of a prescription.

From the above examples, it will be seen that a prescription, properly so called, contains several circumstances beside the *formulæ* or *receipts*, as the name of the *patient*, for whom the prescription is written; the signature of the *physician*, as G. F. for George Fordyce, &c. and the *date of prescribing;* none of which should be omitted, as the prescriptions are carefully preserved by the apothecary, for future reference.

4 Parts of a formula.

It may be proper to explain some circumstances respecting the *formula* given in the above prescription. The ℞ with which it commences signifies *recipe* or *take;* and is prefixed to all medical receipts. Then follow the several ingredients of which the medicine is to be composed, with the quantities of each. These quantities are usually marked by peculiar characters or symbols, which will be examined hereafter; and the numbers employed are usually the Roman numerals. After the ingredients have been enumerated, and their quantities specified, there follows the title of the medicine, as *Potio* in the present instance, signifying *potion* or *purging draught*, with M. f. prefixed to it, which stand for *misce fiat*, or *misce ut fiat*, mix to make; and lastly the direction how the medicine is to be taken or administered; *summo mane sumenda;* to be taken early in the morning. In England, these directions are always written in Latin, but in Scotland it is, we believe, more common to write them in English. We shall consider the propriety of this latter mode in a future part of this article.

The ingredients of which a formula is composed have been, by writers on medical prescriptions, arranged under four heads: 1. The *basis* of the formula, which in the present instance is the rhubarb, constituting the principal ingredient, on whose action, modified where necessary, the chief success of the medicine, in fulfilling the required indication, is to depend. 2. The *adjuvant* or auxiliary, added to the basis, for the purpose of increasing its power, expediting its action, or rendering it more easily soluble in the juices of the stomach; in the above formula the *tartrate of potash* is the principal adjuvant. 3. The *corrector*, added to the basis, when we wish to moderate or delay its action, to correct some unpleasant or injurious property of it, such as its odour, taste, acrimony, &c. or to prevent it from acting on the body in a different manner from that which the indication requires: thus, in the present formula, the warm *tincture of senna* is added, rather to correct the griping quality of the rhubarb, than to increase its action, and the *syrup of roses* to correct the unpleasant taste of the medicine; and *the essential oil* in the peppermint-water contributes to both these purposes: these, therefore, are to be considered as the correctors. 4. The *constituent*, or that ingredient which serves to reduce the rest into the form which is considered as most convenient for the exhibition of the medicine; in the present case the *peppermint-water* is the constituent, serving to reduce the medicine to the form of a potion or draught.

5 Division of formulæ.

Medical *formulæ* are either *officinal*, or *extemporaneous;* the former being such as are directed by authority of some public medical college to be kept in the shops of apothecaries, and the preparation of which is described in their *pharmacopœias* or dispensatories; the latter such as are prescribed by the physician or surgeon as occasion may require.

6 Division of the subject.

Having explained the nature of a prescription, and enumerated the several circumstances which are usually comprised in it, we propose, in the present article, to consider the importance of acquiring the habit of writing prescriptions with ease, elegance, and scientific accuracy;

Importance of the Subject.

cy; the previous information required by a physician, to enable him to prescribe properly in the several cases which come under his care; the general rules which we deem it necessary to lay down for attaining the art of prescribing with neatness and accuracy; and lastly, we propose to give a brief historical view of the progress of pharmacy from the revival of literature to the present time, with a critical examination of some of the best writings on this subject.

7
Advantages of composition.

I. Before considering the importance of learning the *art* of prescribing, it may be proper to explain why such an art is required, or to point out the advantages to be expected from the composition of several simples in the same medicine. There are indeed a few drugs, which cannot be more efficacious in the generality of cases than when in their most simple state. Thus, crude *opium* in a pill, *cinchona bark* or *ipecacuan* in powder, mixed with some ordinary liquid, afford the most effectual, as well as the most simple remedies. The same may be remarked of *mustard seeds*, *white pepper*, and *garlic* swallowed whole, and so of a few others. In general, however, it is much more convenient, and in many cases it is absolutely necessary, to have recourse to composition. Many remedies cannot be taken or applied in their simple state, especially such as are used externally; while others are rendered more certain, safe, or expeditious, by being combined with others. Thus *opium* and *tartrate of antimony and potash* are both *diaphoretics*, or sweating medicines; but when combined, their effect in this way, is considerably increased. (See Kirby's Tables, *formula* 27. and 28.). So of *jalap* and *calomel* as purgatives (Ibid. *form.* 49.). Opium with many patients produces headach; but if *citric acid* (lemon juice) be added, this unpleasant symptom seldom takes place. (Tables, *formula* 137.). Chemical medicines are for the most part compound from their very nature; but even such of these as are contained in the catalogues of the *materia medica* can seldom be employed except in composition. Mercury in its native state is nearly inert, and yet how many valuable and powerful remedies are formed by its union with other bodies. *Sulphuric acid* and *alcohol* form *æther*, but æther cannot be swallowed except in combination. Thus we see, that independently of neatness and convenience, which, though they ought to have their weight, are secondary considerations, there are many positive arguments to prove the utility of composition: and if composition be of use, it must surely be of some consequence to know the scientific principles on which this is to be founded.

8
Importance of the subject.

The importance of acquiring a readiness at writing a neat and scientific prescription, seems not to be generally understood. Indeed few parts of a medical education have been more neglected than this department of pharmacy, especially in Britain. In many of the continental medical schools, there is a professor appointed to give lectures on the art of writing prescriptions, while in our colleges this subject is at most confined to a single lecture from the professor of materia medica, and the student is left to learn the art as he can, by copying the prescriptions of the physicians whose clinical practice he has an opportunity of witnessing, or by attendance in an apothecary's shop.

9
General courses of medicine insufficient for practice.

When a gentleman has passed through the usual course of education at a medical school, and has received a diploma, it is supposed that he is fully qualified to enter on his career with confidence, and proceed with success. Let us for a moment consider what are his usual qualifications. He has, we shall suppose, acquired a tolerably acurate knowledge of the structure and functions of the human body; he has been made acquainted with the nature, properties, and, so far as known, the mode of action of the various simple and compound bodies, which, as medicines, food, and poisons, exert an influence on the animal economy; he has been instructed in the general nature of disease, the various symptoms or appearances by which its presence is indicated, and the general means to be employed for their removal. He has more particularly taken a view of many of the maladies to which the human frame is subject; has seen them exerting their influence on patients, and has frequently witnessed the effects of remedies in expelling them from the system, or in alleviating the distress which they occasioned. Here, it will be said, is a complete physician, and such, to a superficial observer, he may appear. With all this knowledge, however, (and without all this no man is qualified for the active duties of the profession) many gentlemen are still deficient in a most important point, the capacity of applying this knowledge to actual practice. A physician may be able to distinguish a disease at a glance; he may be prompt and accurate in forming his indications of cure, and may be well acquainted with the general nature of the remedies by which these indications are to be fulfilled, and still, if he be not master of the form and method in which these are to be exhibited; if he be not familiar with the practice of writing prescriptions, he will often be placed in a most unpleasant predicament, and will not unfrequently expose himself to the ridicule of those who are far his inferiors in knowledge and abilities, by writing prescriptions which, though they contain the essential means of cure, yet wanting the mode and fashion of the day, will be read with a smile, or perhaps be imperfectly understood, by the apothecary or the druggist to whom they are presented.

10
Necessity of acquiring a habit of writing prescriptions.

This, however, is an inconvenience which, as it may not be attended with serious effects, is trifling in comparison of some which he will encounter.

From a want of habit in prescribing, or from a want of some medical or chemical information, which we shall presently explain, he will be often liable to jumble together substances which, though when single, they are possessed of similar medical properties, may, when combined, exert an action greater or less than he had intended to produce, or even altogether of an opposite nature.

11
Illustration.

By way of illustration let us suppose a young practitioner, at his first outset, called to a patient labouring under *tetanus*, or that disease of which a locked jaw is one of the most obvious symptoms. The patient is in the most distressing situation, and it is expected that every renewal of the spasm will end in those convulsions which most frequently bring on the fatal termination of this formidable disease. How is he to act? The remedies to be employed are evidently antispasmodics, and of these he has heard opium and mercury highly recommended in this disease. Which of these is he to employ, or is he to make a trial of both? He determines to give opium: in what form is he to order its administration? That of pill is the most obvious; but perhaps the patient cannot, in the ordinary state of his health, swallow pills, and every effort of the muscles of deglutition, increases

Importance of the Subject.

the disease. He must then prescribe it in a liquid form. Shall he order it in the form of laudanum to be given by the attendants, or shall he prescribe draughts or a mixture, with a certain proportion of *tinctura opii?* What is the dose of the opium? He knows that a person affected with this disease can bear a large dose. Is he to give this large dose at once, or is he gradually to increase it? In a short time the patient can perhaps no longer swallow even liquids. Can he administer opium in any other form? He has heard of opiate clysters. What is the best formula for them? Is the same quantity of opium as when taken by the mouth, sufficient for a clyster? Again, if the patient cannot swallow, how is he to be supported? By nutritive injections. How is the physician to prescribe a nutritive injection? Should it be large or small in quantity? and is there any mode of making the bowels retain it for a sufficient time, to draw from it the proper nourishment? We might carry this illustration, simple as it is, to a much greater length; but we forbear, that we may not be thought tedious. We need say little to persuade those who are at all acquainted with the practice of physic, that it is the duty of every physician who values the comfort and safety of his patient, or who has any regard for his own reputation and respectability, to spare no pains in enabling himself to write a prescription with facility, perspicuity, and neatness.

12 Attendance in a shop necessary, but not alone sufficient.

To those who, previous to their attending medical lectures, have been for some time in an apothecary's shop, instructions for the writing of prescriptions may be thought useless or impertinent. In the daily habit of perusing and copying formulæ from the hands of various physicians, it may be thought "custom hath made it in them a property of easiness." Certainly, with respect to form and method, doses and proportions, they can require but little information. But after all, this knowledge is merely imitative; they have learned to write prescriptions as a parrot learns to speak, and unless they have added considerable chemical knowledge to their practical information, they can only copy what they have seen, and will often find themselves very much at a loss.

This is considering the matter in the fairest point of view, taking it for granted that they have been under a master who had abilities, leisure, and inclination to give them all the necessary information; to point out to them how particular formulæ were suited to particular indications; to shew them why one is preferable to another, and how they should distinguish a scientific from an empirical prescription.

How seldom this is the case, and how easy it is for a young man to be several years in an apothecary's shop, and learn but little, we leave to the judgment of others to decide. We trust it would not be difficult to show, that many of the formulæ which they have witnessed, may be simplified or improved; that many of them are unscientific, and not a few absurd.

We would, however, by no means be understood to consider attendance on a shop as an unnecessary part of a medical education; far from it. We are of opinion that every one who intends to practise medicine, whether it be as surgeon, apothecary, or physician, should for some time accustom himself to the preparing of medicines, and the keeping of an apothecary's day-book: and we conceive that a young practitioner without this experience, will commence practice under considerable disadvantages. By perusing, copying, and preparing the formulæ of various practitioners, the student certainly acquires a readiness at prescription, which he cannot so easily and imperceptibly attain in any other way. To those who have had little opportunity of profiting in this way, and their number is by no means small, the instruction intended to be conveyed in the following observations will be peculiarly adapted; and probably such as have passed some time behind a compter, will learn something which had before escaped their notice, or will at least be convinced that the subject admits of considerable improvement by the application of recent chemical discoveries.

It may be thought, that such as have, during their residence at college, given diligent attention to hospital practice, will there have received all the information on the subject of prescription which is necessary to qualify them for private practice. But those who are familiar with both will readily agree, that what is sufficient for the one, is by no means calculated for the other. The unexperienced physician, accustomed to the hospital routine, thinks it sufficient if he prescribe the proper quantities of the proper medicines in the most simple form. Is an emetic required? He will order gr. xv. or ℈i of powdered ipecacuanha. Is a gentle diaphoretic indicated? He would prescribe ℥ij of *mistura salina* to be taken every four hours. Were his future practice to be confined to any infirmary, to the negroes of a West India plantation, or the crew of a man of war, this might be sufficient; but if he aim at extensive or genteel practice, he will find it necessary to take a much wider range.

II. The subject of extemporaneous prescription may be considered as constituting the finishing part of a physician's education; so far, at least, as we can say, that the study of a profession, for the perfect attainment of which the father of medicine has declared life too short, may admit of a completion. This is truly the practical part of a physician's duty; it is this for which all his previous studies are intended to prepare him. Having acquired a knowledge of diseases and their remedies, he is, when entering on the active duties of his profession, to apply that knowledge to the best advantage, so as to cure or relieve his patient in the easiest, safest, and most expeditious manner. It is not merely the mechanical business of penning a medical receipt, which he might copy from his memory or his *vade mecum*, that we are here considering as the practical duty of a physician. It is the adapting of the means which he possesses to the peculiar case that is under his care; the modifying his prescription according to the circumstances of the patient; the age, sex, temperament, peculiarity of constitution, season, climate, and many other circumstances; the choice of remedies, and the necessary variation of them; it is these which constitute the duty of a practical physician, so far as relates to the business of prescription.

Before a physician can attempt to prescribe for his patient, it is requisite that he possess much previous information.

In the first place, he must be well acquainted with the nature and seat of the disease, the cure or alleviation of which he is about to attempt; with the symptoms which usually appear in similar cases, and the variations which are likely to take place, with the causes, so far as known,

Previous Requisites.

known, which predispose to the disease, or which remotely or immediately have a tendency to produce it; with the probable termination of such a case, and the general indications of cure. This knowledge presupposes an acquaintance with anatomy, physiology, and pathology, without a competent share of which a physician can no more effect a cure of a disease, than an algebraist can accomplish the solution of an equation, while he is ignorant of its terms.

17 Materia Medica.

The prescriber must also be familiar with the Materia Medica and pharmacy, from which he learns the natural history, the chemical and medical properties of the various simple substances employed in medicine; their usual doses and their officinal compounds, as contained in the pharmacopœia of the country in which he resides; as it is these articles that are to form the ingredients of which the medicines he prescribes are to be composed. As without considerable practical experience few men are able to retain all the requisite information respecting each article of the Materia Medica, it would be of great advantage to the young prescriber to have by him a tabular sketch, which might, within a small compass, contain the information more immediately necessary for writing a prescription. Nothing is found to assist the memory, or to facilitate the attainment of knowledge, more than these tabular views; and so much is the learned world convinced of this, that such views are daily becoming more fashionable, and are now applied to almost every branch of science. It was with the intention of assisting the young practitioner in writing prescriptions, that Dr Kirby, a few years ago, published his tables of the Materia Medica, containing a concise view of the most material circumstances respecting the various simple and compound medicines admitted into the catalogues of the London, Edinburgh, and Dublin Pharmacopœias. In this volume the articles are arranged under 18 classes; the titles and order of which are much the same with those given in our article MATERIA MEDICA; and of each article are given the systematic name, the synonymous pharmaceutical name, the country in which it is produced, or from which it is brought; the part employed in medicine; the form in which it is commonly administered, and the usual doses of the simple, and of the several officinal compounds. In the original draught of these tables, the circumstances above mentioned were arranged in columns; but it was found, that the difficulty and consequent expence of printing the work in that form would be so great, as nearly to counterbalance the advantage which might be derived from it. We are, however, of opinion that the arrangement in columns is better adapted to strike the eye, and we shall here give a specimen of such an arrangement, taken from one of the shortest classes in the above work (A).

19 Explanation.

The above table contains eight columns. In the first are written the scientific and corresponding pharmaceutical names of the several simple substances, distributed into departments, according as they are taken from the vegetable or the mineral kingdom, and arranged alphabetically; in the second is written the name of the country where the article is found, or from which it is procured; in the third the part of the simple usually employed in medicine; in the fourth the form in which it is usually administered; in the fifth the dose of the simple. In the sixth column are arranged all the officinal preparations of each simple which properly belong to the class of expectorants, and named according to the nomenclature of the Edinburgh Pharmacopœia, with the corresponding synonymous names of the other two colleges; in the seventh are given the usual doses of these compound medicines, and in the eighth are noted the diseases to which the simple or its compound is more peculiarly adapted.

20 Use.

The use of such tables is pretty obvious. Having before him all the remedies that are suited to answer any particular indication, as in the present instance, that of promoting expectoration, the prescriber can select such articles as are best suited to the particular case in hand, or

Previous Requisites. or which can be most easily procured; and he has at once before him the circumstances respecting it which it is most necessary he should know.

21 Therapeutics. It is next required of a prescriber, that he be thoroughly acquainted with therapeutics, a part of the institutions or principles of medicine which instructs him in the nature and effects of the various classes of medicines as suited to different indications of cure.

22 Chemistry. An extensive acquaintance with the elementary parts of chemistry is also necessary, as the subject of extemporaneous prescription forms a part of pharmacy, which is essentially a chemical art. It is therefore as impossible for a physician to be a scientific prescriber without a competent share of chemical knowledge, as for the captain of a ship to be a scientific sailor, without a knowledge of astronomy and navigation. It is certainly possible for a physician to write a prescription without having studied chemistry, and for a sailor to conduct a vessel to the West Indies without being acquainted with the mathematical principles of navigation: but these men are both empirics; they have a certain mechanical way of proceeding, which they have learned by long experience, and much more severe labour than it would have cost them to acquire a knowledge of the scientific principles of the arts which they profess.

23 Rational prescription depends chiefly on chemical principles. It is of the utmost importance that a physician should be able to assign a reason for every article which he inserts in his prescriptions; that he should, as correctly as possible, know what part each will act in the composition of the medicine, and what effect the whole compound will produce on his patient; in short, that he should not prescribe a certain formula merely because he has seen it prescribed by others in similar cases, but should form his prescription on scientific principles, and from the result of reason and reflection. In the present improved state of chemistry this is more peculiarly necessary, and it is also become much more easy. Not many years ago physicians had scarcely a clue to guide them in their prescriptions, except that of experience; they saw certain results take place, and certain effects produced, but why these results took place, or how these effects were brought about, they were almost entirely ignorant. The reasoning employed by old writers on pharmacy concerning the preparation and operation of compound medicines, is to a modern chemist highly entertaining. We shall not swell this article by specimens of such reasonings, but shall refer those who wish to amuse themselves in this way, to Strother's *Lectures on the Rationale of Medicine; Quincy's Complete Dispensatory:* Fuller's *Pharmacopœia Extemporanea*, and the *Pharmaceutical* works of Dr Willis.

24 Chemical affinity. When a physician sits down to write a prescription, he should imagine the preparation going on under his eye, and should know whether or not the materials which he is ordering will act chemically on each other; and if they do, what changes will be produced. It very frequently happens that from the union of two or more substances there arises a compound possessed of very different properties, and which is likely to produce very different effects from any of the component articles. The result will sometimes be advantageous, sometimes inert, and sometimes injurious. It is the business of the prescriber to be acquainted with the advantages and disadvantages of these combinations, that he may avail himself of the former, and avoid the latter. This desirable object is to be attained only by a correct and extensive knowledge of chemical affinity. This will teach what substances are capable of combining together, or of decomposing what are already united; and will inform us whether we can derive any advantage from their action.

25 Common errors in this point. For want of this chemical knowledge many of the formulæ prescribed by some of our best practical writers, are much less simple and scientific than they might be made by an attention to chemical principles. The famous tonic remedy, commonly called *Griffith's myrrh mixture*, so much, and we believe, so justly extolled in cases of general debility, was originally composed in the following manner.

26 Griffith's myrrh mixture.

℞ Myrrhæ dr. j. *Solve terendo in mortario cum*
Aquæ Alexeteriæ simp. unc. vi. ss.
—— cujuslibet Spirituosæ dr. vi. vel unc. j.
Dein adde
Salis Absynthii, dr. ss.
—— Martis, gr. xii.
Syrupi simplicis, dr. ij. m *.

From the gravity with which the author speaks of this composition, and the various proportions he allows of the salt of wormwood and the salt of steel, together with the different methods of mixing the ingredients, it is pretty clear that he had no idea that any of them were superfluous or unnecessary, nor probably was he aware that the two salts act on each other, and undergo a mutual decomposition. It seems therefore to be quite an empirical prescription. Analysing it according to our present chemical knowledge, we know that the principal part of it consists of an emulsion of myrrh, containing in suspension a quantity of carbonate of iron, and having dissolved in it a small quantity of sulphate of potash, and perhaps a little subcarbonate of potash. Now, as there is no reason to believe that the two last are of any consequence in the medicine, it would surely be much more scientific to form a medicine of myrrh and carbonate of iron, with the addition of such cordials and syrups as may add to its tonic power, and render it palatable. A medicine of this kind is the following.

℞ Pulv. Myrrh. dr. i.
Carbonat. Ferri præcip. dr. $\frac{1}{2}$,
Syrup. Citri Aurant. unc. $\frac{1}{2}$. *Simul terc, et adde*
Aquæ Menth. piper. unc. 6.
Tinctur. Cinchon. compos. unc. i. M †.

27 In Dr Strother's 19th lecture there is noticed a medicine which was then considered as a valuable nostrum in the cure of smallpox. The principal ingredients are, spirit of salt (*muriatic acid*), and salt of hartshorn (*impure carbonate of ammonia*). A tyro in modern chemistry need not be told that this medicine contains muriate of ammonia, produced by the combination of the acid with the alkali. If, therefore, such a medicine is useful in smallpox, it would surely be much less laborious, and much more scientific, to employ the muriate of ammonia, commonly called *sal ammoniac*, which we have prepared to our hands.

28 As the secondary salts form a class of bodies which constitutes a considerable part of the materia medica, it is proper for the physician to be intimately acquainted with their nature and chemical properties. Here he will again find the advantage of systematic tables, containing

* *Griffith on Hectic Fevers.*

† *Kirby's Tables, Formal.* 106.

taining the principal circumstances respecting the composition and decomposition of such of these salts as are employed in medicine. A table of this kind is printed in Dr Kirby's Tables, and we shall here give a similar view, only divided, for the sake of convenience, into two tables, the first containing the composition of the salts, and the second the substances employed in medicine, by which they may be decomposed.

TABLE I.

Salt.	Solubility.	Composition. Base.	Acid.	Water.
1. Supersulpate of Alumina and Potash.	At 60° 20. 212°, 1.	Cryst. 12. Dry 63, 75.	17.66 36.25	70.24 0.

29 Explana-

In this first part of the table of secondary salts there are five columns, in the first of which are set down the names of most of the secondary salts employed in medicine, according to the most approved chemical nomenclature. The second column shews the degree of attraction which subsists between each salt and water, namely, how many parts of water at the temperatures of 60° and 212° of Fahrenheit are required to dissolve one part of the salt, in the state in which it is usually employed, and whether the salt be deliquescent or efflorescent. The three remaining columns point out, as far as has been ascertained, the proportional quantities of the component parts of each salt, the third column shewing how many parts in the 100 consist of base; the fourth how many of acid, and the fifth how many of water of composition. In some cases two proportions are given, and it is expressed in the third column under what state of the salt these proportions exist.

30 Explanation.

This second part of the table of secondary salts consists of three columns. In the middle column are set down the names of the secondary salts employed in medicine, in the same order as in the former table; and in the adjoining columns on each side are noted those substances employed in medicine which are capable of effecting a decomposition of each salt; those in the left-hand column being such as decompose the salt by what is called *single affinity*, in consequence of that substance having a superior attraction for the acid or the base of the salt; while the substances in the right-hand column are secondary salts, between which and the opposite salt in the middle column such an action may take place as to effect their mutual decomposition.

31 Uses of the tables.

With tables of this kind before him, a prescriber will avoid several mistakes into which he might be betrayed from a deficiency of chemical knowledge. Thus, knowing the solubility of any salt, he will not prescribe a greater quantity of it than is capable of being retained in solution in the watery part of any draught or mixture which he is to order. For instance, knowing that *sulphate of potash* requires sixteen parts of water at 60° for its solution, he will, if he proposed to prescribe a draught containing two drams of this salt, be aware that such a quantity would require at least four ounces of water; but this making the draught too large is a great objection to giving the medicine in that form. Or suppose that he wished to give half an ounce of *supertartrate of potash* (*crystals of tartar*), by way of laxative; he sees, that to dissolve this quantity it would require at least two pounds of water, and therefore that he cannot order it in the form of solution, though, when mixed up with syrup into an electuary, it affords a good and efficacious cooling laxative. Again, knowing that *sulphate of soda* effloresces in the air, and thereby loses nearly half its weight, he will take care always to prescribe it in the form of crystals; and if he is to order a laxative draught containing one ounce of this salt, he must prescribe at least three ounces of liquid.

The information conveyed in the second column respecting the deliquescence or efflorescence of certain salts, or the readiness with which they imbibe water from the atmosphere, or part with their water of crystallization, is extremely useful in pointing out the proper forms of exhibition. Seeing, for instance, that *acetate of potash* (*diuretic salt*) is a deliquescent salt, no one would think of prescribing it in the form of pills; while, on the other hand, *carbonate of soda* being efflorescent, is well adapted to that form, and accordingly has been so prescribed by Dr Beddoes; (see *Kirby's Tables, formula* 153.).

Knowing the proportional quantities of the component part of any salt, we can, by calculation, ascertain pretty nearly how much of the one is required to decompose the other, and thus employ no more of either than is necessary. Thus, suppose it were required to decompose 100 grains of *green sulphate of iron* by *carbonate of soda*, in order to procure the greatest possible quantity of *carbonate of iron*. We find by the first table, that 100 grains of the *sulphate* contain 28 grains of *oxide of iron*, and to saturate this, we find by computation, that there are required 9 grains of *carbonic acid*. Now, on examining the composition of *carbonate of soda*, we find that 100 grains of this salt contain about $14\frac{1}{7}$ grains of *carbonic acid*, and consequently, that about 60 grains of *carbonate of soda* are sufficient to decompose 100 grains of *green sulphate of iron*.

Further, knowing the substances that are capable of decomposing any particular salt, a prescriber will not order any of these substances in the same formula with that salt, unless some manifest advantage were to be the result of their mutual action. He knows that *sulphate of zinc* and *acetate of lead* decompose each other, and that the *acetate of zinc* formed by their mixture, is a better remedy in cases of ophthalmia than either of the former salts. Here then is an advantage. *Tartrate of antimony and potash* is a good remedy in fever, so is *decoction of Peruvian bark*; but we find by the tables, that this salt is decomposable by *gallic acid*, and we know that *decoction of cinchona* contains this acid, especially after having stood for some time. It would therefore be improper to prescribe these remedies in conjunction, as has sometimes been recommended, because the salt would be so much altered by the decomposition as to be no longer the medicine we propose to administer. A similar instance of unscientific prescription, arising from a want of chemical knowledge, occurs in a formula attributed to Mr Coleman, and published in the fifth edition of the *Pharmacopœia Chirurgica*, p. 58. under the title of *Collyrium hydrargyri muriati cum calce*. It is composed of a scruple of *muriate of mercury* dissolved in an English pint of boiling distilled water, with the addition of two drams of *quicklime*, and after the whole is completely mixed, we are directed to filter the clear liquor through paper. The author of this Pharmacopœia seems aware that "the different elective attractions operating in the mixture of the lime with the solution of muriate of mercury, are such as produce

Previous Requisites.

produce a new chemical arrangement, in which the activity of the ingredients is mutually diminished. The fact is, that the large quantity of lime here directed will completely decompose the muriate of mercury, so that the clear liquor will contain nothing but uncombined *lime*, and *muriate of lime*. Hence the *muriate of mercury* is an unnecessary ingredient, and if the medicine be efficacious as a collyrium, it would be better to form it at once by the addition of a small quantity of *muriate of lime* to *lime-water*.

32 Dover's powder.

A physician who is familiar with the principles of chemistry will not direct a chemical medicine to be prepared of more ingredients, or in a more operose manner, than is requisite to produce the desired effect. When Dr Dover first gave to the public the composition of his *sudorific powder*, he ordered it to be prepared in the following manner. Four ounces of *nitre*, and the same quantity of *vitriolated tartar (sulphate of potash)*, are to be thrown into a red-hot crucible, and kept stirring till the deflagration ceases. To the mixture, while hot, is to be added an ounce of sliced *opium*. The whole is then to be reduced to powder and well mixed with an ounce of powdered *ipecacuanha*, and the same quantity of powdered *liquorice root*. It is well known to the chemists of the present day, that *nitrate of potash*, when thrown on an ignited combustible body, deflagrates, and is decomposed; but that it does so when thrown into an ignited crucible, with an incombustible body, such as the *sulphate of potash*, we can scarcely conceive. If it does, the effect must be, that the *nitric acid* is carried off, and there remains the *potash*, which is an unnecessary ingredient in the composition. Again, the only use of heating the salt, would be to dry the *opium* and thus render it more easily pulverised; but as dried opium is always kept in the shops, and by means of *sulphate of potash*, is very easily reduced to powder, that part of the operation is superfluous. Accordingly, a powder equally efficacious, and much less operose, is prepared by rubbing together *sulphate of potash*, *opium*, and *ipecacuanha*, forming the present *pulvis ipecacuanhæ et opii*, Ed. or *pulvis ipecacuanhæ compositus*, Lond.

33 Burnt sponge.

From the same want of chemical knowledge, some medicines have been extolled as efficacious remedies, from not knowing their real nature. Thus burnt sponge has long been celebrated for the cure of scrofula. We do not altogether deny its efficacy in this complaint; but as burnt sponge is composed almost entirely of charcoal, with the addition of a little carbonate of soda, a powder composed of these ingredients must be equally efficacious.

34 Errors in respect to consistence.

Under this head we may notice an error which is frequently made by prescribers who have not been accustomed to see and prepare the remedies which they prescribe. We have often seen a mass for pills ordered to be prepared of such ingredients as are naturally too hard to form into pills, as for instance, extract of cinchona, and extract of liquorice, and yet there has been directed a quantity of liquorice powder, to form the mass of a proper consistence. Sometimes again, the matters directed are already too soft, or become too soft by mixture, as when aloes and extract of gentian are directed to be beaten together with a proper quantity of syrup, to form a mass for pills. See the *Edin. Phar.* edit. 1783.

35 Water.

We shall conclude this part of our subject with remarking, that it is of consequence in a chemical point of view, to prescribe as the constituent of a liquid medicine, such water as will not decompose any of the other ingredients. It is common to order the water by the name of *aqua pura*, or *aqua fontana*. Now, if this water be hard, i. e. impregnated with *sulphate of lime*, &c. it will decompose many of the secondary salts, and thus diminish their efficacy. *Acetate of lead*, for instance, is always decomposed by hard water, and a turbid liquor is thus formed, which by standing deposits a sediment. It would therefore be better in all cases to prescribe distilled water, or where this is not likely to be found, as in small country towns, soft water.

III. We have thus considered at some length the previous knowledge required by a practitioner before he can pretend to prescribe for his patient in a scientific manner. We shall now endeavour to apply the observations that have been made, and from the application deduce some general rules for extemporaneous prescription. 36

37 Practical hints.

When a practitioner is called to a patient, he will first examine into the symptoms and causes of the malady under which the patient labours, and attend to the age, sex, and peculiar habit of the patient. He will then consider whether or not a cure is probable, or whether it may be in his power only to relieve the distressing symptoms. If a cure appears to be practicable, he will proceed to form his indications, and in conformity with these he will prescribe the remedies that seem best adapted to the case. It is this method of procedure that distinguishes the scientific practitioner from the ignorant empiric. The latter, from a superficial view of the most obvious symptoms, hastily determines the nature of the complaint, which he probably contrives shall be some one of which he has witnessed many cases, or for the cure of which he is in possession of some favourite remedy. Having resolved what the disease shall be, he has nothing to do but apply his remedy, and this he does without considering whether existing circumstances may not render the administration of it improper.

To return from this digression, we shall endeavour to give an example as simple as will answer our purpose, to illustrate the above method of procedure. We shall suppose that a practitioner is sent for to a middle-aged man, in moderate circumstances, who has been for some days labouring under a tertian intermittent fever, with which he had never before been affected, but had commonly been strong and healthy. The practitioner sees nothing in the circumstances of the case which can lead to an unfavourable prognosis, and he therefore has little hesitation in pronouncing, that the fever will probably soon be removed. Considering the indications usually laid down in practical writers on intermittents, he proceeds to prescribe the remedies which appear best suited to the case in point. Thus the indications given by Dr Cullen are,

1. In the time of intermission to prevent the recurrence of paroxysms.

2. In the time of paroxysms to conduct these so as to obtain a final solution of the disease.

3. To take off certain circumstances which might prevent the fulfilling of the two first indications *.

In considering the first indication, the practitioner reflects on the effect of the usual exciting cause of an intermittent,

* Cullen's *First Lines*, § 228.

Rules for Prescriptions.

termittent, *marsh miasmata*, which he sees to be a debilitated state of the system. This he learns is to be removed by tonics; and of those the bark of the *cinchona officinalis* is justly celebrated in the cure of intermittents. This then he would immediately prescribe; but that experience has shewn it to be better to begin the administration of this medicine as soon as possible after a *paroxysm*. We shall suppose, however, that the last paroxysm took place the day before he saw the patient, and consequently may be expected to return the next day. He finds also that the patient is costive, a circumstance which must be removed according to the third indication. Now, attending to the second indication, he knows that this is generally best fulfilled by the exhibition of an emetic at the commencement of the cold fit, and of an opiate at the commencement of the hot fit; but the costiveness of the patient contraindicating the use of opium, he must endeavour to find for it a substitute which has not a tendency to excite or increase constipation. He will perhaps prescribe as follows:

38 Example of prescription.

℞. Vini ipecacuanhæ, unc. 1.
—— Tartritis antimonii (*Edin.*) unc. $\frac{1}{2}$. M. fiat haustus.

Signetur. *The emetic to be taken just as the next cold fit is coming on.*

℞. Pulveris Rhei Palmati, gr. 25.
Submuriatis Hydrargyri, gr. 3.
Succi Spissati Hyoscyami, gr. 4.
Syrupi q. s. Fiat bolus.

Signetur. *To be taken just as the next hot fit is coming on.*

℞. Pulveris Cinchonæ officinalis, scr. 2.
—— Croti Elutheriæ, gr. 10. M. f. pulvis.

Signetur. *One to be taken in a little wine and water as soon as the hot fit is gone off, and repeated every two hours till the expected return of the next cold fit.*

The analysis of this prescription will afford us some useful practical observations.

39 Arrangement of formulæ.

1. It will be observed that the *formulæ are arranged in the order in which the medicines are to be exhibited*, a circumstance to which it is always proper to attend, when the prescription is to contain more than one formula or circumstance to be directed by the practitioner. Thus when any thing is required immediately, as *bleeding*, the *application of leeches*, or of a blister, this should form the first clause in the prescription, in the following manner.

Mittatur sanguis è brachio STATIM *ad unc.* 12.; or,

Applicentur quamprimum temporibus hirudines sex; or,

Applicetur statim emplastrum vesicatorium capite raso.

40 Arrangement of ingredients.

2. *The ingredients directed in each formula should be arranged in the order in which they are to be mixed by the compounder.* This may be thought a matter of slight importance, but it is more deserving of notice than is generally supposed. For the most part, indeed, in whatever order the practitioner may arrange the ingredients in his formula, a skilful apothecary will combine them in that order which experience has shewn him to be the most convenient; but it is surely much neater that the order of preparation should be preserved in the prescription, this being considered as the guide by which the compounder is to direct his operations. Suppose we were to prescribe a medicine containing *castor oil*, *distilled water*, *mucilage of gum arabic*, *syrup of rhubarb*, and *tincture of senna*. In the preparation of this medicine the apothecary will first rub together the *oil* and *mucilage*; he will then add the *syrup*, and perhaps the *tincture*, and lastly the *water*. In this order then it would be best to express the formula. See Kirby's *Tables*, *formula* 54. In this manner the neatness of the medicine is insured, and the preparation of it rendered more easy and expeditious. It is very usual for prescribers to begin with the article that is to be most abundant in the medicine, as the water, and so gradually descend to that of least quantity; and particular care is generally taken to place in succession those ingredients that are employed in equal quantities, with the sign ($\bar{a}\bar{a}$ *singulorum*, of each) after the last. This seems rather a puerile method, and is commonly inconsistent with the practice of composition.

There are other reasons for arranging the ingredients in the order of composition. In some cases a very volatile substance forms a part of the medicine, as æther, or ammonia; and it is proper that this should be the last ingredient in the composition of the medicine, that as little as possible of it may be dissipated. It is proper, therefore, that it should stand last in the formula (see Kirby's Tables, formulæ 126, 129, and 130.). There is a formula given in the Pharmacopœia Chirurgica for an embrocation, to be composed of 2 drams of *tincture of camphor* (*camphorated spirit*), 1 dr. *water of acetated litharge* (*Goulard's extract*) and a pound of *distilled water*. We are told that the mixture of these ingredients is to take place in the order in which they are set down, otherwise the camphor will be separated *.

We have already mentioned (N° 3) the names of the several parts of which a compound medicine may be formed, as the *basis*, the *adjuvant*, the *corrector*, and *constituent*; and have explained the reasons for the addition of the three latter. There are some rules respecting these, which it will be proper to consider in this place.

41 Rules for the basis;

3. *The basis should always be single, unless some manifest advantage is expected to arise from the employment of two or more remedies of the same kind.* The reason of this rule is sufficiently obvious, as the effect of a single remedy is much more easily determined and proportioned than that of two or more employed together. The advantages of simplicity in prescription will be considered presently.

4. *If more than one basis be employed, they should be of the same nature, or such as produce the same effects.* This needs no illustration.

42 for the adjuvant;

5. With respect to the *adjuvant*, we shall remark only that one use generally assigned to it, viz. that of facilitating the solution of the basis in the stomach, appears equivocal. It is not uncommon to order resinous drugs to be made up into pills with *soap*, which is considered by many as acting in the way of promoting solution. Soap is often a good constituent, but we do not think it can produce the effect above alluded to.

43 for the corrector.

6. The use of the *corrector* requires a little more discussion. One of the first intentions of the corrector is to diminish the too violent action of the principal remedy, or to prevent its exerting an action in an improper part of the body. Thus, *mucilage* may be added to *colocynth*,

* Pharm. Chirurg. 5th edit. p. 159.

colocynth, (*bitter apple*), or given after it, to blunt or lessen the acrimony which this substance is commonly found to possess. So again, *mercury* is often combined with *opium*, when it is required to introduce a considerable quantity of the former into the system, or to speak more properly, to acquire the full benefit of its accumulated stimulus. This can scarcely be effected, if it be allowed to run off by the bowels. *Camphor* is often given after the application of a blister, to obviate the strangury which frequently attends the external application of *cantharides*. In some cases the *cinchona bark* produces sickness or purging, and here the addition of a few drops of *tincture of opium* to each dose is proper.

7. Another use of the corrector is to obviate or disguise the unpleasant taste or odour of the principal remedy. Thus, the emetic in our prescription is ordered to be prepared of the *wine* of ipecacuanha instead of the *powder*, as the wine that forms the solvent of that remedy disguises its unpleasant taste. The articles usually employed as correctors of flavour, are *syrups* and *tinctures* of various kinds, *essential aromatic oils*, &c. and the use of these has been often much abused. The addition of a large quantity of sugar, in some cases, especially in *dyspepsia* or indigestion, seldom fails of increasing the symptoms of the disease, as in a debilitated state of the stomach it quickly passes into a state of fermentation, and produces flatulence, pain, and *anorexia* or loss of appetite, the very symptoms which we are to remove. It is a common practice to add syrup to several of the neutral salts, as *sulphate of soda*, *sulphate of iron*, &c. with a view to improve their flavour; but we apprehend that whoever has tasted the nauseous mixture will scarcely agree with the prescriber that he has gained his point.

44 Abuse of tinctures.

8. The abuse of *alcohol* in the form of tinctures has been sometimes carried to a great, and, we think, a culpable excess. This has arisen sometimes from the desire of the patient to have his medicines made strong and good, and not unfrequently, perhaps, from mercenary views in the practitioner, to induce the patient to swallow a greater quantity of medicine, because it is rendered agreeable to his palate. We have no doubt that many well-meaning practitioners order a considerable dose of tincture from a mistaken complaisance to their patients, without apprehending any ill consequences from it; but in fact, the intemperate use of these tinctures is injurious to the stomach, and has, we believe, not unfrequently drawn some of the most sober persons into a habit of dram-drinking. The propensity to the use of cordials, which is now become so prevalent, has probably arisen from this source. The quantity of alcohol ordered by some prescribers is truly astonishing. A book lately came into our hands, which is called a *translation of elegant medical prescriptions for various disorders by the late Dr Hugh Smith*. For the accuracy of the translation we cannot vouch, not having seen the original; but if it be accurate, the *spirituous cinnamon water* (*spirit of cinnamon*), seems to have been a very favourite article in Dr Smith's catalogue of medicines, as it is no unusual thing to see an ounce, or 1½ ounce of it ordered in a single draught, or four ounces in an eight-ounce mixture. Did not this occur so frequently in the prescriptions of Dr Smith, we should suppose it to be some blunder of the translator or transcriber, in mistaking the character denoting dram for the symbolical character signifying ounce.

9. A third use of the corrector is to render the medicine more agreeable to the stomach. Thus, *sulphate of soda* is to many persons very nauseous, and is not unfrequently rejected by vomiting; but the addition of a small quantity of *lemon juice*, or of *supertartrate of potash*, is found to correct this unpleasant quality. The bark of *cinchona* does not agree with some stomachs, without the addition of an aromatic; the *cascarilla* ordered in the above powders, affords a useful addition, with the view of rendering it more agreeable to the stomach. 45

The unpleasant odour of a medicine is more difficult to correct than its flavour. In internal medicines this is usually best effected by regulating the form in which they are exhibited; as, in prescribing the sulphurate of potash, it is better to order it in the form of a powder to be sweetened with sugar, to be swallowed dry (see Kirby's Tables, formula 68), than by way of draught or mixture. The odour of external medicines is best corrected by the essential oils and perfumes. Thus, in using *sulphur* for cutaneous diseases, it is usual to add a quantity of *essence of bergamot* or *oil of lavender*, which, though they do not entirely destroy the odour of the sulphur, have a considerable effect in disguising it. 46

10. In ordering a corrector, the practitioner should be aware that it is not the quantity of the basis, but its quality that he is to correct. If a dose of *digitalis* or of *squill* makes the patient sick, we should not think of giving *opium* or effervescing draughts to prevent this effect, but we should lessen the quantity of the medicine at its next exhibition. We have been rather minute on the subject of the corrector, as we conceive that much will depend on the adroit management of this part of a formula, in showing the neatness and address of the prescriber. By a proper use of correctors he can often regulate the action of a medicine, and considerably relieve the feelings of his patient. 47 Quantity of a remedy to be regulated.

11. The *constituent* employed in a formula will of course vary with the form of the medicine. In the more solid compositions, as boluses, pills, and electuaries, it is generally syrup, conserve, confection or extract. In liquid medicines, it is either simple water, or some watery liquid, as *decoctions*, *infusions*, or *water distilled* from some aromatic plant. It is proper to remark, that the prescriber should consider whether a constituent ordered as such, be necessary, for it often happens, that the extracts or pilular masses kept in the shops, are already of a proper consistence for making into pills. It is obvious that the constituent, if it be not simple water, should have similar qualities with the other parts of the medicine, unless when it contains in it the corrector. 48 Remarks on the constituent.

12. In the prescription which we have given as an example, the names of the articles are written at length. We do not, however, approve of this being generally done in practice. To an apothecary's apprentice it can answer no other end than to exercise his latinity, and display the erudition of the prescriber. In fact, it may even tend to mislead him; for as the names of the articles kept in his master's shop, are always painted on the labels, or drawers, in an abbreviated form, the words at full length are not better understood by the compounder, 49 Names of ingredients need not be written at length.

Rules for Prescriptions.

compounder, and indeed they are often more intelligible in the concise form in which he is accustomed to see them. Add to this, that the writing of the words at full length may occasionally betray the practitioner into an unguarded mistake, which may call in question his grammatical accuracy. In Fox's *Formulæ Selectæ*, *calomelas* perpetually occurs as the genitive instead of *calomelanos;* and in a work on midwifery, published by Dr Pugh of Chelmsford, grammatical errors both in the names and in the directions are to be detected *passim*. The only advantage that writing at length seems to possess, is that it teaches a beginner to read a prescription, which by the way is often at first no easy matter. But practice soon renders this familiar.

50 Symbolical characters to be avoided.

13. The quantities of the ingredients in the above prescription are not expressed in the usual symbols, but we have employed the contracted forms of the words *uncia* and *drachma*, and the common Arabian figures, as recommended in the preface to Dr Kirby's Tables. The directions also are written in English. The reasons assigned in the work above referred to, are as follow. "The characters ʒ and ℥ are so similar, that they may easily be written for each other, and that they have sometimes been so written cannot be denied. The consequence is obvious; a stroke of the pen too much may kill the patient, and a stroke too little may produce a medicine of little or no efficacy. Strange! that physicians should have been so misled by an affectation of mystery or concealment, (for to what else can be attributed the use of these hieroglyphics)? as to place the safety of their patients at the mercy of a *lapsus pennæ! Unc.* and *dr.* can never be written for each other, and we see no good reason why these abbreviations should not be employed for *uncia* and *drachma*, as well as *gr.* and *gtt.* for *granum* and *gutta*. Dr Spens, in his elegant edition of the *Pharmacopœia Nosocomii Edinburgensis*, has employed these contracted words, but has retained the Roman numerals.

"The use of the Arabian figures appears calculated to insure both perspicuity and dispatch. They are more easily written, occupy less room in a prescription, and (by their familiarity) remove all possibility of mistake.

"As to the directions, they should always be written in the vernacular language. In a prescription, perspicuity is always our first object; it is not here that we are called upon to display our learning and classical elegance; and whoever considers that these are properties not always to be met with in the shop of an apothecary or a druggist, will readily wave them, in order to insure the perfect understanding of his prescriptions. It does not indeed require any great knowledge of Latin to translate the directions which usually occur in prescriptions; but as there are cases in which a long and rather complex direction is employed, we should leave nothing to the contingency of the learning or ignorance of the compounder, but by writing the directions ourselves in the received language of the country, put it out of his power to injure our reputation, or endanger the safety of the patient."

51 Rules for the doses of medicines.

The doses of medicines must, in a great measure, be determined by experience; but after having thus ascertained the medium dose proper for an adult under ordinary circumstances, and of an ordinary constitution, there are certain general considerations, according to which we may proportion the doses of the same substance to various constitutions and ages. In regulating the doses of medicine, we are to attend chiefly to the following considerations.

a. The circumstances of the disease and the vital powers of the patient.

b. The powers, mode of exhibition, and particular intention of the medicine employed.

c. The age, sex, constitution, and habits of the patient.

52 Doses regulated by the disease.

14. *The circumstances of the disease to be attended to are its nature, seat, period, and degree of violence.* There are several diseases that require Herculean remedies, and these in very large doses. It is well known that maniacs require much greater doses to produce the same effect than most other patients. If we are to administer an emetic to a person in this situation, it would be of no use to prescribe 2 or 3 grains of *tartrate of antimony and potash*, or a scruple of *ipecacuanha*, the usual doses in ordinary cases. Less than 6 grs. of the former will scarcely excite vomiting, and it is sometimes necessary to order 10 or 15 grs. If we wish to procure sleep to these wretched beings, a few grains of opium are a trifle. Dr Darwin mentions two cases of insanity, in one of which 2 scruples of solid opium were administered, and four hours after, a third scruple; while in the other, a furious maniac was rendered calm and rational in the space of a few hours by a dose of 400 drops of tincture of opium.

Again, the more violent the disease, the larger doses are generally required for its removal; but, on the other hand, the later the period or stages of several diseases, as fever, consumption, and similar affections attended with great debility, the less is the quantity required to produce the same effect; or rather the less able will the patient be to bear the usual doses. When the vital powers are much diminished, a large dose may be attended with very serious consequences. Thus, in cases of suspended animation by drowning, where the vital energy is nearly exhausted, if, when the powers of life are just returning, we were to oblige the patient to swallow a quantity of brandy, or even a glass of pure wine, we should probably smother the glimmering spark. Again, in cases of torpor from cold, if we expose the frozen limb to a sudden considerable heat, a gangrene ensues; whereas, had we in the former case given a little wine and water, and in the latter applied a moderate gradually increasing warmth, attended with gentle friction, we should probably have restored the patient, and preserved the limb.

53 By the nature and intention of the medicines.

15. *The powers, form, and intention of the medicine must be considered.* The more active remedies must be administered with greater caution than such as are of inferior efficacy. Thus, if we are to exhibit the *corrosive muriate of mercury*, the *oxide of arsenic*, the *nitrate of silver*, or other powerful and dangerous remedies, we must begin with a quantity rather below than above the medium dose, and gradually increase it according to the effect produced. On the other hand, however, we must not descend to doses that are trifling and inert. It is as ridiculous to prescribe a *scruple* of *cinchona* twice or thrice a day, to restore vigour to a debilitated system, as it would be improper to order *half an ounce* of *rhubarb* for an ordinary cathartic. A prudent practitioner will avoid both extremes of timidity and rashness, and will

Rules for Prescriptions.

will neither risk the safety of his patient by an excessive dose, nor give him lingering suspense and pain, for want of the due application of the proper remedies.

Much will depend on the form in which the medicine is to be exhibited. Thus, if we are to employ externally, or by way of blister, such medicines as are usually given by the mouth, it is necessary to order them in much larger quantity. The usual dose of tincture of opium is 25 or 30 drops; but if this is to be applied by friction, from 2 drams to half an ounce will sometimes be required for one application; and in a glyster it is usual to prescribe a dram or two. The tincture of cantharides, whether given internally, or applied by friction to the surface, is a powerful remedy; but in the former case, 20 or 30 drops are sufficient, while in the latter a dram or two is usually employed. Similar remarks might be made with respect to the use of mercury, and many other remedies.

The intention with which the medicine is administered must also be taken into consideration, as there are many substances that produce different effects, according to the quantity employed. Thus, *tartrate of antimony and potash* may be given as an *emetic*, a *diaphoretic*, an *expectorant*, or a *cathartic*, according to the magnitude or repetition of the dose. Two or three grains given at once, or a grain every 15 minutes, usually excite vomiting; but from $\frac{1}{8}$ gr. to 1 gr. given every 5 or 6 hours, generally keeps up a constant nausea without vomiting, and thus, by sympathy, the medicine acts as a diaphoretic or antispasmodic. The medicine given in the dose of a third of a grain twice or thrice a-day is a good expectorant; and in the dose of $\frac{1}{4}$ gr. every two or three hours, usually operates by the bowels. It is well known that the effect of opium varies considerably, according to the dose and the interval at which it is administered. If we wish to promote sleep, or relieve pain, we give what is called a full dose, that is, a grain or two. It thus acts as a narcotic, and an antispasmodic or a diaphoretic. Given in small repeated doses, it acts as a general stimulus, promotes absorption, and answers the purposes of diuretic and an astringent. Ten or twelve grs. of aloes exhibited at once, are cathartic; but one or two grs. given twice or thrice a day gently stimulates the rectum and neighbouring parts, and acts in particular cases as an emmenagogue.

Rules for Prescriptions.

We need scarcely remark, that when two or more articles of a similar nature are prescribed in the same formula, the dose of each must be proportionally lessened.

54 Age, &c. of the patient.

16. *We must regulate our doses according to the age, sex, constitution, and habits of the patient.*

It is evident that various ages must require various proportions; but experience shews that the required doses are not directly proportional to the ages, as might *à priori* be expected, and as the mathematical physicians in the beginning of the 18th century believed (B). Experience has enabled us to construct a table, in which may be shewn the doses proportioned to various ages, adjusted from a certain medium dose for an adult: such a table is the following.

55 Table.

Age.		Proportional dose 1.	Absolute dose, dr. 1.
Weeks,	7	$\frac{1}{15}$	grs. 4
Months,	7	$\frac{1}{12}$	grs. 5
	14	$\frac{1}{8}$	grs. 10
	28	$\frac{1}{5}$	grs. 12
Years,	$3\frac{1}{2}$	$\frac{1}{4}$	grs. 15
	5	$\frac{1}{3}$	scr. 1
	7	$\frac{1}{2}$	dr. $\frac{1}{2}$
	14	$\frac{2}{3}$	scr. 2
	21	1	dr. 1
	63	$\frac{11}{12}$	gr. 55
	77	$\frac{5}{6}$	gr. 50
	100	$\frac{4}{6}$	scr. 2

The

(B) At the time when Newton had by his discoveries rendered the study of mathematics as fashionable as it is useful, medicine partook of the general bias, and several physicians of ingenuity and erudition attempted to reduce its theory and practice under the dominion of their favourite science. Among these Dr Strother read and published a course of lectures on the rationale of medicines, which he entitles *Prelectiones Physico-mathicæ et Medico-practicæ*. In his 21st lecture he treats of the doses of medicine, and after discussing in a very philosophical manner the general mode of regulating these according to the size and shape of the particles of medicines, and their momentum as determined by their celerity multiplied by their quantity of matter, he proceeds to point out how we are to proportion the doses to various ages. He has the following question: *If a person of 30 years of age takes 60 grains of any medicine, how much must a child of 5 years of age take?* This question he of course resolves by the rule of proportion in the following manner.

$$30 : 5 :: 60 : \left(\frac{300}{30} = \right) 10$$

In order to render this generally applicable to every case, he calls in the aid of algebra, and substituting symbols for the above numbers we have

r = the greater age given
a = the less age given
t = the dose given
e = the dose required.

Then $r : a :: t : \left(\frac{at}{r} = \right) e$.

Rules for Prescriptions.

56 Explanation.

The above table may serve as a general guide to the young practitioner. The second column shows the aliquot parts of the medium dose for an adult, that are adapted to different ages from seven weeks to 100 years, supposing this medium dose to be 1; and the third column gives the absolute quantities in grains, &c. taking the medium dose at 1 dr. This table, however, will by no means apply in all cases. Thus, the dose of opium adjusted from this table, for a child of five years old, is $\frac{1}{3}$ gr. and that of submuriate of mercury or calomel, 1 gr.; but in cases of *phrenitis hydrocephalica* (water in the head), we may administer half a grain of the former, and three or four of the latter. Females in general require less doses than males; and persons of a robust and vigorous constitution, such as country labourers, the more active mechanics, servants, and those of the melancholic and phlegmatic temperaments, will, all other things being equal, require larger doses than persons of an opposite description.

57 Climate.

The climate also seems to have some influence in this respect. In America and the West Indies we are informed that much larger doses of submuriate of mercury are given than are usually prescribed in Britain. In cases where we would give three or four grains, they would order 10 or 15. We are told, too, that in some parts of India, in order to excite vomiting in a native, it is sometimes necessary to give 20 scruples of ipecacuanha. The Germans, and especially, according to Gaubius, the inhabitants of Saxony and Westphalia, require much larger doses than the inhabitants of any other country in Europe.

58 Idiosyncracy.

Peculiarities of constitution, commonly called *idiosyncrasies*, require attention on the part of the prescriber. It is therefore proper to inquire whether any circumstance of this kind occurs in any individual, especially when called for the first time.

The habits of the patient must also be regarded, as in general medicines lose some of their effect by being often repeated, and therefore require to have their dose increased. Thus, persons who are accustomed to the use of opium, will derive no benefit from the ordinary doses of that medicine, but when labouring under a complaint that requires the exhibition of opium, they must take a quantity somewhat larger than that to which they are habituated. It is well known what quantities of opium are consumed by some of the eastern nations; and the writer of this article has seen a travelling gypsy who never went to rest without taking more than half a dram of solid opium (c).

59 Perspicuity, a principal consideration.

17. Perspicuity is essentially necessary in writing a prescription, and every thing which can in any degree diminish it ought to be carefully avoided. Many of the observations already made have been directed to this point; and we have yet one or two remarks to complete this part of our subject. A prescriber should be very careful not to introduce into his prescription articles which are obsolete, or which are no longer contained in our pharmacopœias, unless he is certain that the apothecary who is to prepare the medicine keeps such articles beside him; and even then, as it is most likely that they have been long prepared, and have lost much of their efficacy, he cannot depend on their answering the end he proposes. Thus, few would now think of prescribing the *confectio paulina*, the *theriaca Andromachi*, or the *aqua alexiteria simplex*, or many other compounds, which have given place to more simple and convenient forms. 60

Obsolete or uncommon medicines to be ordered with caution.

18. The same cautions will apply, though perhaps with some limitations, to those medicines which are rarely met with, or have been newly introduced into our Pharmacopœias. Before we venture to prescribe an article of this description, we should ascertain whether or not it is to be procured in or near the place where the patient resides, or, where possible, we should give timely notice to the apothecary to provide himself with some of it. Many unpleasant circumstances may arise from not attending to this caution, especially where the patient is apprised that he is about to take a new remedy which has been found very beneficial in cases similar to his own. For instance, the *Rus Toxicodendron* has lately been much extolled in the cure of palsy. Suppose a physician in a provincial town, at a great distance from the capital, were to prescribe this medicine. The apothecary has none of it, nay, perhaps, has never heard of the medicine, and it must be procured from the capital. This occasions a delay for several days, and in the mean time the paralytic person is impatient to try the effect of the new remedy, and probably refuses to take any other. When the medicine arrives, the

(c) Before dismissing the subject of the *Doses* of Medicine, we must notice an improvement lately proposed, and which appears likely to be adopted by the London College in the intended new edition of their *Pharmacopœia*, we mean that of abolishing the usual method of measuring small doses or quantities of liquids by drops. There can be no doubt that in many cases this method of *dropping* liquids is liable to great uncertainty; the size of the drops, and of course the quantity of liquid which they contain, varying greatly according to the nature of the liquid, the size and form of the neck of the phial from which they are let fall, and even the state of the atmosphere. The dram, by measure, of *distilled water*, will afford only 60 drops from an ordinary two ounce phial with a neck of the usual diameter; whereas the same bulk of *proof spirit* may be divided into 120 drops, and some tinctures will afford many more. Considering this uncertainty, it is proposed to abolish the very name of drops (*gutt.*) in prescriptions, and to employ the small graduated measures of Lane, in which the dram is divided into 60 equal parts, which may be called *grains*. Thus, instead of ordering *gutt.* 30 of *tinct. opii*, we shall order *gr.* 15. (*fifteen grains*) or $\frac{1}{4}$ of a dram, allowing for the difference between *water* and *spirit*. This will certainly be an improvement where moderate doses are to be prescribed, but when the dose does not exceed two or three drops, as in some of the *essential oils*, *arseniate of potash*, &c. so much would be lost in the measure that the dose would be rendered very uncertain.

On the whole, we would recommend that in all cases the medicine shall be so diluted that the dose shall not be less than *half a dram*, and spoons might be made for family use that should contain that quantity, as an ordinary tea-spoon now contains a dram.

Rules for Prescriptions.

the patient has perhaps, as not unfrequently happens, lost his enthusiasm, and begins to take it with reluctance or disgust, feelings which not a little influence the success of a remedy, and thus disappoint the hopes both of the patient and physician.

Under this head of *avoiding uncommon medicines*, it may be proper to remark, that though a physician in this empire is allowed to prescribe articles from any of the national dispensatories, he should in general confine himself to that which is most used in the part of the empire where he resides, and if he mentions an article from either of the others, he should subjoin to the name of that article the initials *Ph. Ed. Ph. Lond.* or *Ph. Dub.* to prevent mistakes, thus,

R. Tincturæ Scillæ (*Ph. Lond.*) dr. 2.
R. Tincturæ Angusturæ (*Ph. Dub.*) unc. 1.
R. Solutionis muriatis Calcis (*Ph. Ed.*) dr. 1.

61 Compounds, not officinal, to be specifically described.

19. With the same view of ensuring perspicuity, we should never prescribe a compound medicine which is not officinal, merely by its usual title, without specifying the component parts, or at least the proportions of these. Thus, if we propose to order an *infusion of quassia*, or a *decoction of oak bark*, it would not be sufficient to write in the formula *infusi quassiæ*, or *decocti quercus*, but it would be proper either to prescribe the mode of preparing them at length, thus,

R. Rasuræ ligni quassiæ excelsæ, dr. 1.
Aquæ distillatæ ferventis, ℔j
Infunde per horam, et cola; or,
R. Quercus contusi, unc. 1.
Aquæ distillatæ ℔ij.
Coque ad dimidium, et cola;

And then to prescribe the proper quantity, as,

R. Infusi hujuce, unc. 7, &c. or,
R. Decocti supra præscripti, unc. 8, &c.

Or, it would at least be proper to mention within a parenthesis, the proportions to be employed in the composition, in the following manner:

R. Infusi quassiæ excelsæ (cum dr. 1. ad aquæ ℔j. &c.); or,
R. Decocti quercus (cum corticis uncia 1 ad aquæ ℔j.) &c.

Again, it would be absurd in private practice to prescribe the *citrate of potash* or of *ammonia* by the names of *mistura salina*, or *julepum neutrale;* but it would be necessary to introduce into the formula the proper quantities of lemon juice and of carbonate of potash, or carbonate of ammonia, to prepare these secondary salts. See Kirby's Tables, *formula* 13.

62 Simplicity to be studied.

20. *That we may the better avoid mistakes in composition, it is advisable to study simplicity as much as possible:* the physician is considered as the assistant of nature, and ought to follow her example in producing effects by the most simple means. Nothing looks so unscientific as a crowded formula; it bears the marks of empiricism in its very face, and always reminds us of those monuments of pharmaceutical folly, the theriaca and the mithridate to be hereafter noticed. It seems as if the prescriber said to himself, "I will put plenty of ingredients into this medicine, and the deuce is in it if some of them do'nt answer." There are many favourite recipes of old practitioners handed down from father to son, or from master to apprentice, which seem to owe their celebrity chiefly to the multitude of their ingredients. The Lisbon diet drinks have long been famous in the cure of diseases of the skin. The following is one of these, as taken from the Pharmacopœia Chirurgica.

63 Errors in point of simplicity.

R. Decoctum Lusitanicum, No. 2.
Sarsaparillæ concisæ,
Ligni santali rubri,
Ligni santali citrini, *sing.* unc. iss.;
Radicis glycyrrhizæ,
Radicis mezerei, *sing.* drach. ij.
Ligni rhodii,
Ligni guaiaci officinalis,
Ligni sassafras, *sing.* unc. ss.;
Antimonii unc. j.
Aquæ distillatæ ℔ v.

These ingredients are to be macerated for 24 hours, and afterwards boiled till the fluid is reduced to half its original quantity. From one to two pints are given daily *.

Some practitioners adhere to this form; but others, less bigotted to old customs, have recourse to a contracted form of it, retaining only the guaiacum, sassafras, and liquorice, and adding raisins, similar to the decoctum guaiaci compositum of the Pharmacopœias.

* Pharm. Chirurg. p. 66.

The following is given in Fox's Formulæ as a remedy for dropsy.

R. Succ. limon. rec. unciam,
Sal absynth. scrupulos duos,
—— corn. cerv. scrupulum,
Tinct. cinnam. et
Aceti scillit. *sing.* drachmas duas,
Tinct. cort. Peruv. semunciam,
Aq. menth. vulg. simp. et
—— puræ *sing.* unciam,
Vini antim. Huxhami guttas quadraginta,
Tinct. Theb. guttas viginti.
Fiat mistura, pro dosibus duabus.

On examining this prescription, we shall find the resulting medicine to be composed of *citrate of potash*, *acetate of ammonia*, a solution of *tartrate of antimony and potash*, and *tincture of opium*, all which are *diaphoretics;* of *squill*, which is *diuretic;* and of *cinnamon*, *Peruvian bark*, *alcohol*, and *mint water*, which are *tonic* and *stimulant*. Now, a diaphoretic, a diuretic, and a stimulant, may not form a bad compound in dropsy, but as they may be given in a much more simple form, the present medicine is absurdly complex and unscientific. It might be reduced as follows:

R. Aquæ acetitis ammoniæ, unc. 1.
Tincturæ scillæ, dr. 1.
——— lauri cinnamomi, unc. ½.
Vini tartritis antimonii, dr. 1.
Tincturæ opii, gt. 40.
Aquæ distillatæ, unc. vi. M.

We shall quote one other example of a medical farrago, taken from De Gorter's Formulæ. It is for a powder formed of vegetables; and we may remark it is in the vegetable kingdom that prescribers have most exuberantly displayed their talent at composition.

R. Rad.

℞. Rad. Imperator
Aristolochii utriusque
——— zeodar.
Siler. montan. āā dr. 1.
Zinzib. scr. 2.
Flor. Centaur. min. dr. 1.
——— Rorismar. scr. 1.
——— Gratiol. German. dr. ½.
Bacca Lauri
——— junip. āā dr. 1ss.
Thymi,
Serpylli,
Absinthiæ,
Tanaceti,
Summitat. Santon. āā. dr. 1. M. f. pulv.

Such a powder as this may vie in composition with the theriaca and mithridate of redoubted fame. As this medicine is composed of so many ingredients, possessed of various powers, it must of course be endowed with many virtues, or must be a *pulvis polychrestus*. Accordingly, its author acquaints us, in the margin, that it is resolvent, sudorific, stimulant, roborant, calefacient, aromatic, stomachic, discutient, diaphoretic, diuretic, and aperient; that it is of service in dropsy, *chlorosis*, *paralysis*, apoplexy, fever, delirium, and fifty other diseases and morbid affections, for a full detail of which we must refer our readers to the work itself.

One would think that the absurdity of these complex formulæ would be abundantly evident to every man of common sense; but the empirical prescriber will probably say, such is the medicine which I have frequently seen given with success, and how am I sure that, by omitting one of the materials, I may not destroy the efficacy of the medicine!

64
Disadvantages of complex formulæ.

The more compounded a medicine is, the more difficult it will be to ascertain and proportion the effects produced by its several parts on the human system. When several articles are employed at the same time, we cannot be certain to which of them we are to attribute the benefit which appears to result, or the noxious qualities which the compound may possess. This rage for composition has been one great obstacle to the improvement of medicine. The effects of various substances on the body have been but little attended to; and indeed the investigation is difficult, and requires a long series of careful and nice experiments, and these made, not on the inferior animals, but on man himself. The administration of medicines to the lower classes of animals, can throw but little light on their action upon the human body. Several substances which are highly injurious to man, are taken by some other animals with impunity. The old story of the origin of the name of antimony is probably well known to many of our readers. See ANTIMONY. On the contrary, some substances are poisons to many of the lower animals, but are much less injurious to man. A small quantity of *nux vomica* will destroy a garden mouse, but a man may take five or ten grains with safety, and even advantage. The doses of medicines, too, bear no proportion in the various animals. A few grains of aloes are sufficient to purge a man, but a horse requires from half an ounce to a whole ounce. It is therefore necessary that man himself should be the subject of experiment; and where great nicety is required, the enquirer should make the experiment on his own person. Innumerable are the dogs, birds, and frogs, that have been sacrificed on the altar of science. Few experimentalists have, like Pelletier and Davy, ventured to operate on themselves; and even where this has been done, the effects of prejudice and previous hypothesis have considerably diminished the value of their researches.

It is advisable that every practitioner should, from the number of his patients, select a few cases to which he may particularly attend, carefully observing and comparing the effects of the medicines prescribed. In this way he will in time collect a body of information, from which he may be able to draw some valuable conclusions. It is more peculiarly requisite to make observations on the effects of compound medicines, and compare them with those produced by the component simples, when, given separately.

65
All complex medicines not to be condemned.

It would be unfair to dismiss this part of our subject, without admitting that there are some compound medicines, the good effects of which must be acknowledged, though we cannot in the present state of medical science, explain their action. There are two medicines of this kind, which the writer of this article has often seen prescribed by physicians of whose abilities and experience he has a high opinion, with evident good effect, and which yet have much of the complex empirical air that we have been condemning. One of these is a remedy for the advanced stage of dysentery, and is prescribed nearly in the following manner.

℞. Infusi quassiæ (cum dr. 1. ad. aquæ ℔j) unc. 6.
Magnesiæ ustæ dr. 2.
Tincturæ sennæ unc. 2.
——— opii dr. 2.
Electuarii aromatici dr. 1.
Syrupi Rhei dr. 3. M.
Signetur. *Three or four table spoonsful to be taken every six hours, shaking the phial, and one spoonful after every loose stool.*

Here are a bitter, an absorbent, a stimulant, a laxative, and a narcotic, combined in the same medicine. To which of these are we to attribute the good effects which have appeared to us to result from the exhibition of the whole? Probably the slight laxative and the absorbent are here of little use, and the chief benefit is to be ascribed to the bitter and the stimuli, considering the opium in this light.

The other medicine to which we allude is considered as an antiseptic, and is frequently ordered in putrid diseases, especially in *cynanche maligna* or *scarlatina anginosa*. It is as follows.

℞. Muriatis sodæ dr. 1½.
Succini limonis. dr. 1½.
Sacchari purificati, unc. ½.
Spiritus myristic. moschati, dr. 3.
Ætheris sulphurici cum alcohole, dr. 2.
Aquæ menthæ piperitæ, unc. 6. M.
Signetur. *Three table spoonsful to be taken every four hours (and in cynanche some of it to be frequently used by way of gargle).*

What an apparent confusion of salt and sour, of sweet and strong! It is true that there is here no decomposition, and yet the medicine is certainly unscientific and empirical.

Rules for Prescriptions.

66 21. *A prescriber should adapt his prescription as far as may be to the worldly circumstances of his patient*, directing for the poorer class those forms which are least expensive, such as powders, pills, electuaries, and ingredients for teas and decoctions, with proper directions how to prepare them. To his more wealthy patients he may prescribe those forms which, by uniting neatness with convenience, will both please his patient, and allow an adequate remuneration to the apothecary, who in most places derives from his practice little profit, except what arises from the sale of his medicines. The forms best adapted to such patients are those of draughts, boluses, powders, and julep, &c.

67 Neatness to be observed.

22. *Neatness in prescription should always be regarded;* for as the effects of medicines often depend much on the feelings of the patient, we should take care that his taste, sight, and smell, be offended as little as possible, that disgust may not either prevent his taking the medicine at all, or at least prevent him from taking it with confidence. In liquid medicines, we ought as much as possible to avoid powders, and every thing which can render the liquid unpleasant to the eye; and if we prescribe a formula containing oil, we ought to take care that this be intimately mixed with the other ingredients. Thus, suppose, when about to employ opium by friction, we were to order equal parts of tincture of opium and oil of olives. Though when well shaken together, these ingredients would incorporate sufficiently to answer the purpose of opiate friction, yet when allowed to stand, they would speedily separate, and give the embrocation an unpleasant appearance. It would be better, therefore, to insure their combination by adding a little solution of ammonia.

23. In this respect much will depend on the form of the medicine; and a physician should be perfectly aware what form is best adapted to the articles he is to employ, as well as what is most agreeable to the patient. This subject of forms was sufficiently explained in the article MATERIA MEDICA, Part III. chap. 2.

68 Recapitulation.

We have now finished all that appeared most important on the general rules for extemporaneous prescriptions; but it may be proper to bring under one general view the principles which have been laid down. The great object of a practitioner is to cure his patient safely, agreeably, and expeditiously. That he may cure him safely, he is to study perspicuity and simplicity. To insure perspicuity, he should arrange his formulæ in the order of exhibition; write the words so that they may be most intelligible; arrange the articles of each formula in the mode of composition; use abbreviated words for quantities instead of symbols; employ the common numerals; write the directions in English; avoid obsolete or uncommon remedies, and order no article, not officinal, merely by its name. To insure simplicity, he must employ no more ingredients than are necessary. That he may cure his patient agreeably, he must observe neatness in his prescriptions; adapt his forms to the nature of the remedies employed, and not prescribe offensive remedies where those that are agreeable or palatable will answer the same purpose.

That he may cure his patients expeditiously, he should employ the most efficacious remedies in the proper doses, and take care they are administered in such a manner as to be most likely to produce the desired effect.

We shall now conclude these general observations on prescription with a few practical cautions, for which we are chiefly indebted to Dr Percival.

1. A practitioner should attend to the feelings and prejudices of his patient. Dr Percival ordered bleeding to a patient labouring under peripneumony, who had a great dread of the operation, and appears to have died in consequence of its having been attempted.

2. A physician, after having ascertained the nature of a disease, in considering the treatment which he means to adopt, should first reflect whether any evacuation be necessary, as bleeding, the application of leeches or of blisters, cupping, vomiting, purging, &c.

3. He should next enquire whether any particular symptom, such as hemorrhage, great pain, excessive vomiting or purging, be so violent or so distressing as to require immediate attention.

4. He is to consider whether the disease under notice is one for the cure of which any specific remedy has been discovered, such as *mercury* in *syphilis*, *cinchona* in *intermittents*, &c.

5. In chronic diseases, where the usual remedies fail of success, it is often of consequence to endeavour to rouse the system into a new action by mercury, electricity, opium, &c. This practice appears rather empirical, but the experience of many able physicians has evinced its propriety.

6. In commencing the treatment of any case, it is proper to begin with the simplest and safest method; and if this does not succeed, to try others of a more complex and bolder description.

7. A physician should not change his plan or his remedies too soon or too often.

8. The cases of new born infants require peculiar caution, as a moderate dose of a powerful medicine may prove fatal. Four drops of tincture of opium have been given to a child a few weeks old for gripes. The infant was seized with stupor and convulsions, and died. A practitioner of midwifery gave an infant two tea-spoonfuls of castor oil by way of purgative; severe vomiting and convulsions came on, and the child sunk under them.

69 Origin of modern pharmacy.

IV. Modern pharmacy may be said to commence about the middle of the 15th century, at which time it appears to have been in a most deplorable state of empirical barbarity. Though it is probable that, among the earlier practitioners of medicine, remedies were employed in their most simple forms, the art of compounding a number of simples together into one medicine had, by the time of which we are now speaking, arrived at a pitch of extravagance which has never been exceeded.

What carried this ostentation of composition to the highest excess, was the object of framing antidotes, which being previously administered, might defend against any poison whatever, that should afterwards be taken into the body. To this scheme is owing the enormous length of the celebrated mithridate and *theriaca;* for such medicines must of course recommend themselves by the number and variety of their ingredients, as they were to contain a proper antidote for every possible species of poison, and more especially as these compositions were to be farther wrought up into little less than universal remedies for all diseases to which the human body is subject.

The first of these antidotes was said to be composed

sion

Historical Sketches.

from the result of experiments made separately with all kinds of simple antidotes by the famous king whose name it bears; but as no records are left us of any of those particular experiments, we may reasonably consider this tale as fabulous. As it is not likely that this medicine and the theriaca will ever again appear in our Pharmacopœias, we shall, for the amusement of our readers, describe the composition of each, as given in the London Pharmacopœia published in 1746. The mithridate is thus composed.

70 Account of the mithridate.

"Take of cinnamon 14 drams, of myrrh 11 drams; agaric, spikenard, ginger, saffron, seeds of treacle mustard, or of mithridate mustard, frankincense, chio turpentine, of each 10 drams; camel's hay, costus, or in its stead zedoary, Indian leaf, or in its stead mace, French lavender, long pepper, seeds of hartwort, juice of the rape of cistus, strained storax, opopanax, strained galbanum, balsam of Gilead, or in its stead expressed oil of nutmegs, Russian castor, of each an ounce; poley-mountain, water-germander, the fruit of the balsam tree, or in its stead cubebs, white pepper, seeds of the carrot of Crete, bdellium strained, of each seven drams; Celtic nard, gentian root, leaves of dittany of Crete, red roses, seeds of Macedonian parsley, the lesser cardamom seeds freed from their husks, sweet fennel seeds, gum Arabic, opium strained, of each five drams; root of the sweet flag, root of wild valerian, anise-seed, sagapenum strained, of each three drams; spignel, St John's wort, juice of acacia, or in its stead Japan earth, the bellies of scinks, of each two drams and a half; clarified honey, thrice the weight of all the rest. Dissolve the opium first in a little wine, and then mix it with the honey made hot; in the mean time melt together in another vessel the galbanum, storax, turpentine, and the balsam of Gilead, or the expressed oil of nutmeg, continually stirring them round, that they may not burn; and as soon as these are melted, add to them the hot honey, first by spoonfuls, and afterwards more freely: lastly, when this mixture is nearly cold, add by degrees the rest of the species reduced to powder.

71 Account of the theriaca.

The preparation of the *Theriaca andromachi*, or Venice treacle, is thus directed.

"Take of the troches of squills, half a pound; long pepper, opium strained, dried vipers, of each three ounces; cinnamon, balm of Gilead, or in its stead expressed oil of nutmeg, of each two ounces; agaric, the root of Florentine orris, water-germander, red roses, seeds of navew, extract of liquorice, of each an ounce and a half; spikenard, saffron, ammomum, myrrh, costus, or in its stead zedoary, camel's hay, of each an ounce; the root of cinquefoil, rhubarb, ginger, Indian leaf, or in its stead mace, leaves of dittany of Crete, of horehound, and of calamint, French lavender, black pepper, seeds of Macedonian parsley, olibanum, Chio turpentine, root of wild valerian, of each six drams; gentian root, Celtic nard, spignel, leaves of poleymountain, of St John's wort, of ground pine, tops of creeping germander, with the seed, the fruit of the balsam tree, or in its stead cubebs, aniseseed, sweet fennel seed, the lesser cardamom seeds freed from their husks, seed of bishop's-weed, of hartwort, of treacle mustard or mithridate mustard, juice of the rape of cistus, acacia, or in its stead Japan earth, gum Arabic, storax strained, sagapenum strained, Lemnian earth, or in its stead bole Armenic or French bole, green vitriol calcined, of each half an ounce; root of creeping birthwort, or in its stead of the long birthwort, tops of the lesser centaury, seeds of the carrot of Crete, opopanax, galbanum strained, Russia castor, Jews pitch, or in its stead white amber prepared, root of the sweet flag, of each two drams; of clarified honey thrice the weight of all the rest. The ingredients are to be mixed in the same manner as in the mithridate.

The theriaca may be considered as a modification of the mithridate by Andromachus, though we are not informed what were his reasons for the variations, except that by the addition of the viper's flesh the medicine was rendered more useful against the bite of that animal *. The theriaca was in so great repute before the decline of the Roman empire, that even the wise Marcus Aurelius was induced to make a daily use of it, to the great prejudice of his health; for we are told by Galen, that his head was so much affected, that he dosed in the midst of business; and when on this account he omitted the opium in the composition, he could not sleep at all.

* Galen de Antidotis, lib. i. cap. i.

It is not a little amusing to observe the reasons that induced the ancient compounders of medicines to crowd their receipts with such a multitude of ingredients. Medicines were then distributed into four qualities, of *heating*, *cooling*, *drying*, and *moistening*, by the combination of which, and the structure of the substance in which they adhered, whether consisting of gross or subtle parts, was deduced another head of qualities from consequential effects they were supposed by this means to have on the body, of *inciding*, *attenuating*, *incrassating*, *relaxing*, *astringing*, and the like; by a farther prosecution of this speculation was derived from the same source a third arrangement of *cephalics*, *hepatics*, *stomachics*, *diuretics*, and others; these orders being closed by a fourth head, to comprehend such, whose effects surmounted even the acuteness of this system to explicate; these were said to operate *tota substantia*. The first of these qualities, as well as those which depended on them, were farther divided into four degrees, and each of these into three subdivisions, whereby medicines might be adapted to each case with the nicest subtilty by the rules of arithmetic. Again, when the composition was thus happily adjusted, it was farther to be enquired, whether the medicine after all might not be suspected of some noxious quality, requiring correction; and this, whether real or imaginary, was by the farther addition of some proper accompaniment to be provided for. It was also to be considered, that a medicine might be serviceable to a remote part, but exposed to be destroyed by the powers of digestion before it arrived there; then it was to be assisted by some material, by which it should be defended and conducted safely, so as neither to be acted upon, nor act, till it reached the designed part, and then be left to operate without impediment, its guide and protector being itself there opportunely consumed: some medicines were pretended to run too swiftly through the body, others to move on too sluggishly; the first of these required a curb, the others a spur: often a director was necessary, that the medicine might not stray from its destined course; every medicine was supposed to have its peculiar station, in which, left to itself, its operation would be exerted; if it were required to perform its office sooner, it was to be committed to

72 Origin of the several parts of a formula.

to the custody of some other, which might fix it to the region desired; if it were designed to proceed farther, it must have an assistant to open it a passage.

How much ingenious men have been perplexed to account for these irregularities and superfluities of the earliest pharmaceutical writers, may in some measure be conceived from Bauderon's comment on the *Aurea Alexandrina*, the first composition in the collection of Nicholaus, whom we shall presently notice. Opium, it seems, is the base whose powers are heightened by other ingredients, which require also others to correct their ill qualities. Besides these, one list of ingredients is to direct the operation to the head, another set to the breast, others to the heart, stomach, spleen, liver, kidneys, and other parts; insomuch, says the author, that this one medicine, in regard to the diseases he enumerates, may very justly be considered as a whole apothecary's shop, contained in a gallypot. Rondelet, in his remarks on the *Syrupus Hyssopi Mesuæ*, seems less disposed to admire what he did not understand, when he tells us, he long doubted with himself, under what head, whether of attenuants or incrassants, it ought to be ranged, it containing so many species of each kind; and at last has recourse to this frank reason for retaining it at all, *erit nobis usui, cum nondum erimus certi, incrassarene, an attenuare oporteat.*

73 Improvements introduced by the alchemists.

When the alchemists had extended the bounds of their art from the mere drudgery of manufacturing gold and silver, to the more noble and philosophic employment of composing an universal elixir that should secure its possessor from disease, and prolong his life to an indefinite period, pharmacy derived from their labours considerable and solid advantages. The experiments instituted by these visionaries with the metals, led to the accidental discovery of some of the most efficacious remedies which we at present employ, especially the preparations of antimony and mercury, and most of what are called the neutral or secondary salts. By calling in the aid of fire, they enabled us to produce in bodies, changes which, without the assistance of this powerful agent, we should have been unable to effect. Now, every thing was submitted to *digestion*, *calcination*, *fermentation*, *distillation*, and *sublimation*; but, as generally happens in cases of innovation or reform, these new methods of obtaining active remedies were carried to an absurd and ridiculous extent. Finding that the healing powers of many substances were eliminated or increased by the application of heat, they seemed to imagine that the simple medicine could in no case possess any medical virtue till it had been placed upon the fire, or kept for some hours in a furnace. Hence the immense number of distilled waters and spirits, essential and empyreumatic oils, with which the old pharmacopœias are crowded, and which seem in many cases to possess no other powers than what they derive from the water or the spirit that forms the bulk of the preparation. Not only plants and minerals, but animals and animal matters of all kinds, were distilled, digested, or calcined. Thus, we find a *water of snails*, a *spirit of millipedes*, an *oil of earth worms*, &c. &c. The absurd and pompous names by which the preparations were distinguished, are truly ridiculous. *Magisterial balsam*, *hierapicra*, *Ethiops mineral*, *ens veneris*, *flores martis*, *calomelas*, *aquila alba*, are a few which long retained their seat, both in public and private dispensatories. As these preparations were, from their contrivers, denominated *chemical;* the more ancient medicines, which were drawn almost entirely from the animal and vegetable kingdoms, were denominated *Galenical*, because chiefly employed by the followers of Galen. Hence the division of medicines into *Galenical* and *chemical*, a division which obtained for some hundred years, and which only a few years ago was preserved in the sale catalogues of the London druggists.

However amusing to a scientific modern chemist it may be to wander through the labyrinths of the earlier pharmaceutical writers, it is necessary for us to be brief upon the subject. These absurdities are now fast disappearing; and pharmacy, guided by the increasing brightness of her younger but more enlightened sister, has begun to assume a more scientific and a more decided character. The principles and improvements of modern chemistry have been introduced into our pharmacopœias, and the civilized nations of Europe are now vying with each other in the amelioration of these guides to the medical practitioner. In our own country, the Edinburgh college led the way to this reform. They have been followed by the Dublin physicians; and we may soon expect the completion of the revolution in our national pharmacy, by the publishing of a new edition of the London Pharmacopœia, which is, we understand, now under review. 74

75 Progress of modern pharmacy.

The progress of our present officinal pharmacy, from the time of its first introduction by the Arabians, so far as we can trace it through the obscurities attending its origin, has been as follows. Saladinus of Ascoli, an author who wrote about the middle of the 15th century, while as yet there were no pharmacopœias established by any public authority, informs us, that the books with which the apothecaries were generally furnished, were these: a book of Avicenna and another of Serapion, which treat on simples; Simon Januensis *de synonymis;* a treatise of an Arabian author under the name of *Liber Servitoris*, containing the preparations of simples, and the chemical medicines then in use; likewise two *Antidotaria*, one of Johannes Damascenus or Mesue, and another of Nicholaus de Salerno.

Some time after, Nicholaus Præpositus of Tours wrote a general dispensatory, that might supply the place of all these; in which the compositions are almost entirely taken from Mesue, and the forementioned more ancient Nicholaus. The *Thesaurus Aromatariorum* written near the same time, and the *Lumen Apothecariorum*, consist also of similar extracts; and in the *Luminare Majus* published soon after, which contains a more extensive collection, these two authors generally lead each head. The same *Antidotaria* have also been made the general basis of the modern pharmacopœias, though we know little more of their authors than that they were the favourites of those barbarous times in which they lived.

76 Mesue.

It is probable that Mesue lived about the 12th century, which is all that we can ascertain respecting a writer to whose authority such implicit submission has been paid; and even this circumstance has been disputed: for some have confounded him with a much earlier writer of the same name, who resided at the court of Bagdat.

77 Nicholaus.

Of the other father of pharmacy, Nicholaus, little more is known. From his being styled of Salerno, we might imply

imply that he resided in that school. Of his work, Saladin gives the following account: that there were two *Antidotaria* under the name of this Nicholaus, the one distinguished by the title of *Nicholaus Magnus*, and the other by that of *Nicholaus Parvus*; that the latter was in most frequent use, and was only an epitome of the former, containing but a part of the compositions, and those reduced to less quantities. Among the collections of pieces often published together as a supplement to Mesue, one is entitled *Antidotarium Nicholai*, and in this are contained the compositions which were delivered by dispensatory writers, under the name of Nicholaus. This is the lesser *antidotarium*, and there is also a copy of the greater, published under the name of Nicholaus Alexandrinus, as translated from the Greek by Nicholaus of Reggio, the first translator of Galen. In this translation, as in the former *antidotarium*, the compositions are arranged in the order of the Latin alphabet: whereas, in the original, the Greek alphabetical order seems to have been followed. Here, beside a much greater number of articles than in the other Nicholaus, those which they have in common are in greater quantities.

78 Foreign public Pharmacopœias.

The first Pharmacopœia which was set forth by public authority, was that of Valerius Cordus, published in 1542, under the sanction of the senate of Nuremberg. This consists almost entirely of collections from the two authors above mentioned, with short notes in relation to such names of plants or drugs in the compositions as were of doubtful signification. Subsequent pharmacopœias, however they might be rendered more copious by additions from other authors, also paid the like regard to Nicholaus and Mesue. This Pharmacopœia of Cordus has been made more celebrated from the comments made on it by Hoffman. In 1561, Clusius published at Antwerp a Latin translation of the *Florentine Antidotarium*. In 1581 was published at Bergamo, in Italy, the *Pharmacopœia Bergamensis*, which was followed by the *Pharmacopœia Augustana*, at Augsburg in 1601; republished at Rotterdam, with notes by Zwelfer in 1654, and again in 1666. The pharmacopœia of the faculty at Paris first appeared in 1637; and about the same time there was published at Paris a collection of Arabian formulæ, called the *Persian Pharmacopœia*. In the latter end of the 17th century, the incorporated physicians of Sweden published their Dispensatory under the title of *Phamacopœia Holmiensis*, which was republished in 1775 and 1784 by the title of *Pharmacopœia Suecica*. The Prussian Dispensatory, *Pharmacopœia Borussica*, was first published in 1799. The Pharmacopœia of Vienna was first published in 1729, and republished in 1765.

Besides these, we have seen or heard of the following:

The Dispensatory of Wirtemburg, of which the first edition is that of 1771.

Pharmacopœia Genevensis, published in 1780, republished in Italian in 1800.

Dispensatorium Lippiacum in 1792.

Pharmacopœia Bremensis in 1792.

Pharmacopœia Austriaco-provincialis, 1794.

Pharmacopœia Austriaco-castrensis, 1795.

Pharmacopœia Rossica, published at St Petersburgh first in 1798, and again in 1803.

Of the British *Pharmacopœias*, the earliest is that of the London college, which was first published in 1618. It was again published either at the close of the 17th, or beginning of the 18th century, in 18mo; again in 1746 in 4to, and last in 1791. The college is now preparing a new edition, and has circulated among its members a *specimen* of the proposed alterations. We have been favoured with a perusal of this specimen, and we have no doubt, that with respect to accuracy of preparation, and judicious selection of remedies, the new work will not be inferior to the late editions of the Edinburgh and Dublin *Pharmacopœias*. In point of nomenclature, however, we cannot help thinking, that the committee have in a great measure failed in their desire to avoid error and confusion. Should the nomenclature of the *specimen* be adopted in the *published* edition, we fear that the *novelty* of the terms will be the smallest objection to their use; but that being so perfectly different, both from the language of modern chemistry and of the late pharmacy of the London druggists and apothecaries, will occasion serious inconvenience both to prescribers and compounders. It would be indecorous for us to particularize instances, but we chiefly allude to the names of the *secondary salts*, which we consider as very objectionable. The new edition will be evidently much improved, many new articles are admitted, and not a few of such as were less efficacious, or which may be prepared extemporaneously, are omitted.

79 British public Pharmacopœias.

The college of Edinburgh first published their Pharmacopœia in 1722; and improved editions have successively appeared in 1736, 1747, 1756, 1775, 1783, 1792, 1803, and 1805, this last being little more than a new impression of the preceding. The Dublin college first published, or rather *printed*, a Pharmacopœia in 1794; and they have lately, viz. in 1807, republished it with considerable improvements. In this edition they have chiefly followed the plan of the Edinburgh Pharmacopœia, but they retain the usual pharmaceutical names of the simples, though they have in general adopted the reformed chemical nomenclature. The most material improvements will be noticed in the *appendix* to this article.

80 Foreign private Dispensatories.

Besides the Pharmacopœias printed under the authority of public colleges, a great many have been published by individuals both on the continent and in Britain. We shall notice the principal of these in chronological order.

The earliest of these that we find on record, after those of Nicholaus, is the *Antidotarium Speciale* of Wecker, which was printed in 1561. Four years after appeared the *Antidotarium* of Montagna, published at Venice; and at the same place in 1600, appeared a work by Fioraventi, entitled *Secreti Rationale Intorno Alla Medicina*. In 1608, Renodæus published at Paris his *Officina Pharmaceutica seu Antidotarium*. Mynsicht's *Armamentarium Medico-chymicum* appeared in 1631; and in 1656, Schroeder published at Leyden his *Pharmacopœia Medico-Chemica*. In 1676 Charas published his *Pharmacopée Galenique et Chemique* at Paris, and in 1684 the same work was republished in Latin at Genoa. In 1698 appeared the celebrated *Pharmacopée Universelle* of Lemery; and in the same year the *Pharmacopœia Spagyrica* of Poterius. Of those that have appeared in the 18th century, beside those mentioned in the introduction to MATERIA MEDICA, we may

Historical Sketches.

may notice as being of superior merit; Triller's *Dispensatorium Pharmaceuticum Universale*, published at Frankfort in 1764; Spielman's *Pharmacopœia Generalis* at Strasburg in 1783, and Reuss's *Dispensatorium Universale* at the same place.

81 British private Dispensatories.

In our own country, several useful works of this kind have been produced. One of the earliest (D), and among the most remarkable of these, is the *Pharmacopœia Officinalis et Extemporanea*, or *Complete English Dispensatory* of Dr Quincy, which was first published in 1718, again in 1722, and in 1739 had reached the eleventh edition, now before us. Considering the time at which it was written, this is an excellent performance, and is the more interesting, as it formed the foundation on which were composed those more accurate and scientific works the *New Dispensatory* of Lewis, and the *Edinburgh New Dispensatory*. Quincy's Dispensatory was followed by similar works, as by James's Dispensatory in 1747, Lewis's in 1753, and the *Edinburgh New Dispensatory* by Webster in 1786. At length, in 1803, Dr Andrew Duncan, Junior, published his *Edinburgh New Dispensatory*, which, from the important additions and improvements progressively introduced in four editions, must be considered as a new work, and has entirely superseded every similar publication.

82 Collections of formulæ.

Of collections of formulæ, both by continental and English writers, there is no want; but it will be difficult for an unexperienced prescriber to make a judicious selection from among them. The best we have seen in this country are, the Thesaurus Medicaminum, now admitted to be the production of Dr R. Pearson; the Pharmacopœia Chirurgica; and perhaps we may add those published in Dr Kirby's Tables of the Materia Medica. The first of these was published in 1794, and a third edition of it materially improved appeared in 1804. The Pharmacopœia Chirurgica is a valuable selection of formulæ, chiefly intended for surgeons, and drawn up principally from the practical Pharmacopœiæ of the different London hospitals. The first edition appeared, we believe, in 1794; and in 1802 there was published a fifth edition, with the addition of a synoptical table of the formulæ contained in the volume, arranged according to the order of their principal incredients. The formulæ annexed to each of the classes in Dr Kirby's Tables are intended principally to serve as examples of the method of prescribing the principal articles enumerated in the class to which they are attached. They are selected partly from the best writers on extemporaneous prescription and the practice of medicine, and are partly derived from the private experience of the author or his medical friends.

Of the older collections of formulæ, we may notice the Pharmacopœia Extemporanea of Fuller, which contains 1000 select formulæ, arranged in alphabetical order, and accompanied by practical and pharmaceutical remarks. This work went through many editions, both in England and on the Continent. The best which we have seen is that published at Paris in 1768, under the care of Theodore Baron.

83 Works on extemporaneous prescription.

We know of very few works that have been written, containing practical rules for the writing of prescriptions. In our own country, almost the only work on the subject with which we are acquainted, is *Quincy's Lectures on Pharmacy*; a work now very little known, though the principal parts of it were introduced under their proper heads, in the later editions of the complete English Dispensatory. Quincy's rules, though now a little antiquated, are for the most part very good; and allowing for the imperfect state of chemical science in the beginning of the 18th century, may still be perused with advantage. Similar rules, which were indeed little more than modifications of those given by Quincy, were laid down by Dr Lewis in his New Dispensatory.

84 Gaubius.

One of the most celebrated foreign elementary works on this subject, and that which we believe is best known in this country, is *Libellus de Methodo Concinnandi Formulas Medicamentorum*, by Gaubius, a second edition of which was published at Leyden in 1752. After laying down some general rules to be observed before prescribing, Gaubius gives an account of the nature and construction of formulæ in general, and then treats particularly of the several forms of medicines usually employed. These he divides into internal and external, reckoning among the former powders, boluses, electuaries, *eclegmata* or lynctuses, pills, lozenges, &c. which he distinguishes into *tabellæ* and *rotuli*, infusions, decoctions, expressed juices, emulsions, juleps, mixtures, and draughts or contracted mixtures. External forms he divides into injections, *adspergines* (powder sprinkled on the surface), fomentations, dry epithems, cataplasms or poultices, baths, fumigations, plasters, cerates, ointments, odoriferous balsams, liniments, epispastics or blistering plasters, frictions, *collyria* or eye-waters, errhines or snuffs, dentifrices or tooth-powders, apophlegmatisms, gargles, clysters, suppositories, and pessaries. He gives ample rules for the preparation of each of these forms, with examples. This work, however, from the antiquated style and prolixity with which it is written, and the obsolete names that every where occur throughout the examples, is of little use except as a book of reference.

85 Eberhard.

In 1754, Joannes Petrus Eberhard, professor of medicine in the university of Halle, in the duchy of Magdeburg, published his *Methodus Conscribendi Formulas Medicas*, a small pamphlet in 18mo, containing rules arranged in a tabular form. In this little work the author first treats of the nature of a medical formula, and explains the characters usually employed in prescription. He then lays down his plan of division, and lastly treats of the preparation of each particular form, with practical hints respecting the ingredients proper for each form, with their proportional doses, and the cases to which they are more particularly adapted. This work was first intended for the professor's pupils, but he published it under the conviction that it would be found of advantage by practitioners in general. On the whole, it is a useful

(D) The only Pharmacopœias worth notice in this country that preceded the Dispensatory of Quincy, were, we believe, the *Pharmacopœia Bateana*, edited by Dr Thomas Fuller, and the *Pharmacopœia Extemporanea*, drawn up by the same author, (to be presently noticed), both published early in the 18th century.

Historical Sketches. useful publication, but is as much too brief as that of Gaubius is too prolix. The rules are not illustrated by examples.

86 Grüner. The best work that we have seen on the elements of extemporaneous prescription, is entitled, *Via et Ratio Formulas Medicas conscribendi*, by Grüner, professor of medicine in the university of Jena. As we have seen only one copy of this work, belonging to the college library Edinburgh, and when this article went to press, could not procure a second perusal of it, we cannot present our readers with any analysis of its contents; but from the favourable impression we received on examining it several years ago, we consider it as a valuable work.

87 Alibert. The last writer on this subject whom we shall notice is M. Alibert, who, at the end of the second volume of his *Nouveaux Elémens de Thérapeutique et de Matiere Medicale*, has given what he calls a New Essay on the Art of Prescribing; in the first part of which he treats of the general rules of the art, and in the second explains the particular formulæ which act on the vital properties of the different organic systems of the human body. M. Alibert's arrangement is peculiar, and we shall therefore give a sketch of it. He arranges his formulæ under six sections, and divides each section into several articles. In the first section he treats of the formulæ or compound medicines which the medical art principally directs towards the vital properties of the system of the digestive organs. In the first article of this section he describes the compound medicines which are particularly directed to the muscular contractility of the stomach, in common language, emetics; in the second article, those which are particularly directed to the muscular contractility of the intestinal canal, viz. cathartics; in the third article he treats of those which are particularly adapted to the changes of the vital properties that result from the presence of worms in the stomach and intestines, namely, anthelmintics; in the fourth article, of those which are particularly directed against the effects of poisons introduced into the stomach or intestines; and in the fifth, of those compound medicines which are particularly directed to the vital properties of the larger intestines.

In the second section he treats of these medicines, which the art particularly adapts to the vital properties of the urinary passages; diuretics.

In third section he describes those that particularly refer to the vital properties of the respiratory organs, viz. expectorants and refrigerants.

In the fourth section he treats of those compound medicines which are particularly directed to the vital properties of the *dermoid system*, or the skin; namely, diaphoretics, emollients, and epispastics.

In the fifth section he notices those medicines which are particularly directed to the vital properties of the nervous system; viz. antispasmodics, narcotics, sternutatories and sialagogues.

In the sixth and last section he treats of the compound medicines that the art particularly directs toward the vital properties of the system of generation.

Some other late French writers on Pharmacy have given a number of examples of medical formulæ, especially M. Bouillon La Grange, in his *Manuel du Pharmacien*. In all these formulæ is employed the new French standard of weights and measures, commonly accompanied by the synonymous troy weights and measures, as used by the French apothecaries under the old government; but as neither of these are familiar to English readers, we shall here add two tables of the French weights and measures of capacity, reduced to English wine measures and troy and apothecary weights.

TABLE I. *A Comparison of French Grammes with Troy, French, and Nuremberg, Apothecary Grains.*

Grammes.	Troy grains.	Old French Grains	Nuremberg Grains.
1=	15.444=	18.883=	16.128
2=	30.888=	37.766=	32.256
3=	46.332=	56.649=	48.384
4=	61.776=	75.532=	64.512
5=	77.220=	94.415=	80.640
6=	92.664=	113.298=	96.768
7=	108.108=	132.181=	112.896
8=	123.552=	151.064=	129.024
9=	138.996=	169.947=	145.152
10=	154.440=	188.830=	161.280

APPENDIX.

APPENDIX.

88 THE new edition of the *Dublin Pharmacopœia* having appeared since the printing of our article MATERIA MEDICA, it becomes us to notice the principal improvements introduced by the Dublin college; and as particular circumstances prevented our doing so under PHARMACY, we have reserved them for an appendix to the present article. We shall also take this opportunity of supplying some omissions in the article MATERIA MEDICA, rendered unavoidable by the circumstance of that article coming on at the conclusion of a volume, beyond which we could not with propriety extend it, especially by the addition of a complete table of the synonymous Latin names of all the officinal compounds.

We shall notice the additions and improvements of the Dublin college in the same order which we have observed in MATERIA MEDICA, Part IV.

CHAP. I. *Animal Substances.*

2. MURIAS AMMONIÆ (E).

89 Carbonate of ammonia. Preparation *c*. CARBONAS AMMONIÆ. See MATERIA MEDICA, N° 238.

In the preparation of this salt, the Dublin college now employ carbonate of soda for decomposing the muriate of ammonia, instead of chalk. The only advantage of this seems to be that the decomposition is effected at a lower temperature.

90 Solution of carbonate of ammonia. Preparation *d*. AQUA CARBONATIS AMMONIÆ. MATERIA MEDICA, N° 239.

Here too carbonate of soda is employed in the proportion of 28 oz. to the pound of muriate of ammonia.

91 Hydrosulphuret of ammonia. Preparation *f*. HYDROSULPHURETUM AMMONIÆ. MATERIA MEDICA, N° 241.

This is now introduced into the Dublin Pharmacopœia, and is directed to be prepared much in the same manner as in the pharmacopœia of Edinburgh.

92 Aromatic ammoniated alcohol. Preparation *h*. ALCOHOL AMMONIATUM AROMATICUM. MATERIA MEDICA, N° 243.

The only change made in the preparation is, in substituting ½ oz. of nutmegs for 2 drs. of the essential oil, and distilling off the ammoniated alcohol, thus rendering the solution of the aromatic principles more complete.

5. CERVUS ELAPHUS.

93 Phosphate of lime. Preparation *a*. PHOSPHAS CALCIS. MATERIA MEDICA, N° 254.

The Dublin college order this under the name of *Pulvis cornu cervini usti*, to be prepared in the usual manner as directed by the Edinburgh Pharmacopœia.

Preparation *b*. DECOCTUM CORNU CERVINI, Dub. Decoction of hartshorn.

This is made by boiling two ounces of burnt hartshorn reduced to powder, and 3 drs. of gum arabic, in 3 pints of water to 2 pints, continually stirring, and then straining the liquor. 94 Decoction of hartshorn.

In this way a considerable quantity of the phosphate of lime is, by means of the gum arabic, suspended in the water; but we do not think this so good a method of administering the remedy as giving the powder itself, mixed with syrup or mucilage.

CHAP. II. *Vegetable Substances.*

24. ALCOHOL. MATERIA MEDICA, N° 294.

Preparation *a*. ALCOHOL. 95 Alcohol.

The new process of the Dublin college for preparing alcohol is as follows: A gallon of rectified spirit of wine is first mixed with an ounce of caustic potash in powder; then a pound of pearl ashes dried at the heat of 300° of Fahrenheit, and reduced to powder, is added while still warm, and the mixture digested for three days in a close vessel with frequent agitation. The spirit is then poured off, mixed with half a pound of dried muriate of lime (which is usually obtained from the residuum after the preparation of pure ammonia), and distilled with a moderate heat till what remains in the retort begins to grow thick.

26. ACIDUM ACETOSUM IMPURUM.

Preparation *b*. ACIDUM ACETOSUM FORTE, E. MATERIA MEDICA, N° 307.

ACIDUM ACETICUM, Dub.

This is prepared by putting into a tubulated retort, 3 ounces by weight of sulphuric acid, and adding to it gradually in small portions, 6 ounces of acetate of potash, waiting after each addition till the mixture be cold; and after the whole is mixed, distilling to dryness. What comes over is the acetic acid. 96 Acetic acid.

Preparation *d*. ACIDUM ACETOSUM CAMPHORATUM, E. MATERIA MEDICA, N° 309.

ACIDUM ACETICUM CAMPHORATUM, Dub.

Prepared much in the same manner with the Edinburgh acid, only with half the quantity of acid. 97 Camphorated acetic acid.

29. CERA. MATERIA MEDICA, N° 319.

Preparation *a*. CERA FLAVA PURIFICATA, Dub. Purified yellow wax.

Wax is purified by melting it with a moderate heat (*as in a water bath*), scumming it, and pouring off the clear fluid from the dregs. 98 Purified wax.

32. ANGUSTURA, MATERIA MEDICA, N° 331.

Preparation

(E) In the following enumerations the numbers prefixed to the simple articles correspond to those in the same situation in the arrangement of Part IV. in MATERIA MEDICA; while those which follow some of the articles refer to the paragraphs of that article as numbered in the marginal notes.

Preparation *a*. TINCTURA ANGUSTURÆ, Dub. Tincture of Angustura.

99 Tincture of angustura. This is prepared by digesting two ounces of coarsely powdered angustura bark in two pints of proof spirit for seven days, and straining.

This preparation, now first made officinal by the Dublin college, is a good form for exhibiting the angustura in small doses. Ordinary dose about 2 drs. generally in composition.

CLASS II. Order 3. DIANDRIA TRIGYNIA.

100 45. PIPER NIGRUM.

Ointment of black pepper. Preparation *a*. UNGUENTUM PIPERIS NIGRI, Dub. Ointment of black pepper. A stimulating ointment, made by mixing 4 oz. of finely powdered black pepper, with a pound of prepared hogs lard.

CLASS III. Order 1. TRIANDRIA MONOGYNIA.

48. VALERIANA OFFICINALIS, MATERIA MEDICA,
101 N° 354.

Infusion of valerian. Preparation *d*. INFUSUM VALERIANÆ, Dub. Infusion of valerian.

This is made by digesting 2 drs. of valerian root, coarsely powdered, in 7 oz. by measure of boiling water, for an hour, and draining off the liquor when cold.

This is a good antispasmodic, especially in hysteric cases, and the stomach is said to bear it better than the powder. Dose, a glassful twice or thrice a-day.

In our MATERIA MEDICA, in the names of the preparations of valerian, the genitive case of valeriana is inadvertently printed *valeriani*.

CLASS V. Order 1. PENTANDRIA MONOGYNIA.

69. HYOSCYAMUS NIGER.

102 Tincture of henbane. Preparation *b*. TINCTURA HYOSCYAMI NIGRI, MATERIA MEDICA, N° 392.

Now added by the Dublin college, and made rather stronger than the Edinburgh tincture, the proportions being $2\frac{1}{2}$ ounces of the dried leaves in coarse powder, to an English pint of proof spirit.

72. CINCHONA OFFICINALIS.

103 Infusion of cinchona. Preparation *a*. INFUSUM CINCHONÆ OFFICINALIS, E. MATERIA MEDICA, N° 402.

INFUSUM CINCHONÆ SINE CALORE, Dub.

Prepared by macerating an ounce of cinchona bark in coarse powder in 12 ounces of cold water for 24 hours; then pouring off the liquor.

Order 2. DIGYNIA.

84. ULMUS CAMPESTRIS.

104 Decoction of elm bark. Preparation *a*. DECOCTUM ULMI.

The Dublin college order this decoction to be prepared much in the same manner as that of the London pharmacopœia.

90. FERULA ASAFOETIDA.

105 Fetid clyster. Preparation *f*. ENEMA FOETIDUM, Dub. Fetid clyster.

This is made by adding to the purging clyster to be described presently, 2 drs. of tincture of asafœtida.

CLASS VI. Order 2. HEXANDRIA TRIGYNIA.

112 *. RUMEX AQUATICUS, Dub. Great water dock. The root. 106 Great water dock.

One of the new additions to the Dublin Materia Medica.

It ranks among astringents, and has been celebrated as a remedy in scurvy, diseases of the skin, and venereal complaints. It is generally given by way of infusion.

CLASS VII. Order 1. HEPTANDRIA MONOGYNIA.

113. ÆSCULUS HIPPOCASTANUM. 107

Now adopted by the Dublin college.

127. CASSIA SENNA.

Preparation *h*. SYRUPUS SENNÆ, Dub. Syrup of Senna. See SYRUPUS MANNÆ, MATERIA MEDICA, N° 795. 108 Syrup of senna.

CLASS X. Order 1. DECANDRIA MONOGYNIA.

130. SWIETENIA FEBRIFUGA. 109

Now also first adopted in the Dublin pharmacopœia.

134. QUASSIA EXCELSA.

Preparation *a*. TINCTURA QUASSIÆ, Dub. Tincture of quassia. 110 Tincture of quassia.

This is prepared by digesting an ounce of quassia shavings in 2 pints of proof spirit for 7 days, and filtering.

This forms a strong solution of the bitter principle of quassia.

137. STYRAX OFFICINALE.

Preparation *b*. PILULÆ E STYRACE, Dub. Storax pills. 111 Storax pills.

Prepared by beating well together 3 drs. of purified storax, 1 dr. of soft purified opium, and the same quantity of saffron.

This may properly be considered as a preparation of opium, of which it contains a fifth part.

CLASS XI. Order 2. DODECANDRIA DIGYNIA.

142 *. AGRIMONIA EUPATORIA, Dub. The herb. 112 Agrimony.

A slight astringent now added by the Dublin college.

CLASS XII. Order 5. ICOSANDRIA POLYGINIA.

158. GEUM URBANUM, Dub. Avens. *The root.* 113 Avens.

This has now obtained a place in the pharmacopœia of Dublin, and as a useful indigenous *tonic*, merits particular notice. Dose of the powder from *half a dram* to *a dram*.

CLASS

Appendix. CLASS XIII. Order I. POLYANDRIA MONOGYNIA.

160. PAPAVER SOMNIFERUM. Opium.

114 Opium. As the account of this important remedy given in the article Botany may not be deemed sufficiently satisfactory by our medical readers, and as in the Materia Medica we were so much confined that we could only refer to the best writers that have treated on opium, we shall here supply that deficiency, by giving a comprehensive view of the effects of opium; of the discoveries that have been made by late chemical analyses respecting the nature of its narcotic principle; shall point out the general means by which the ill effects which sometimes attend the exhibition of this medicine may be obviated, and enumerate those articles of the Materia Medica which may be most conveniently employed as substitutes for a drug now become so scarce and expensive.

Perhaps no article of the Materia Medica ranks higher in point either of antiquity or efficacy than opium. Its peculiar properties and mode of operation have, however, been long a subject of debate, both among theoretical and practical writers. The place assigned to it in systematic arrangement has been continually fluctuating; Cullen and his followers considering it as one of the most powerful sedatives which we possess, while Brown, Darwin, and the advocates for their doctrines, as strenuously contend that it ought to be ranked amongst the most active and diffusible stimuli. In fact, the parties engaged in this controversy appear chiefly to differ about words, and probably they are both partly right and partly wrong.

They agree that the effects of opium are similar to those of wine and alcohol, liquors which are generally, though indeed not universally, accounted stimulants. If opium produces similar effects with these, we see no good reason why it should not be arranged in the same class. All these substances may indeed be considered as both stimulant and sedative, according as we advert to their primary or secondary effects. If by a stimulant be meant something which increases the force and frequency of action in the muscular fibres, and possesses the power of sustaining or increasing the vital powers, which is, we believe, the generally received definition, we can surely not refuse this character to alcohol, and its modifications. Who that has ever felt the cheering influence of wine, that has experienced the exhilaration, the flow of spirits, and the energy of action, which are the usual effects of the bottle, can refuse to acknowledge the effects of the stimulating powers of this too fascinating beverage. Again, if by a sedative we are to understand something which diminishes the force and vigour of muscular action, and depresses all the vital energies, every one who has felt the effects consequent to a too free libation at the shrine of Bacchus, will readily admit that wine and alcohol are, in an eminent degree, possessed of sedative powers. Now, that opium resembles alcohol in both these circumstances, is generally admitted.

115 [Gen]eral ef[fect]s of opi[um]. When a moderate quantity of opium (we mean not more than two grains), is received into the stomach, it excites there a gentle warmth, which is gradually diffused over the whole body, attended with an itching of the skin, and usually followed by an increase of perspiration. The pulsation of the heart and arteries is at first rendered fuller and more frequent, and there is commonly a heat and flushing of the face; the eyes appear enlivened, and the spirits are exhilarated. Pain is alleviated, and all care for the time forgotten. The effects of this substance on those who swallow it as a substitute for wine, as is usual in the east, are familiar to most of our readers, and sufficiently prove its stimulating effect. Similar proofs appear to have been exhibited during the present war, among Europeans. We are told that the French soldiers are plied indifferently with opium or brandy, in order to increase their courage and ferocity; and we have been credibly informed, that some of the most celebrated performers on the London stage, particularly in tragic parts, which require peculiar self-command, or energy of expression, are accustomed to take doses of opium proportioned to the circumstances of the character which they are to perform.

The excretion of urine is sometimes increased; but as an increase of absorption is a usual consequence of opium, other excretions, except, as we have said, the perspiration, appear to be diminished. Opium also acts as a powerful stimulus to the genital organs, and excites the venereal appetite. It is said that on examining the bodies of Turks slain in battle, the penis has been often found in a state of erection, even in old men *.

After these effects have continued for a time, appearances of a different nature present themselves. At first a languor and lassitude not unpleasing come on, and are soon followed by yawning and a strong propensity to sleep. If the quantity taken has been considerable (above two gr.), the previous symptoms of excitement are more remarkable, but they generally continue for a shorter time, and are followed by a proportional depression. Considerable nausea supervenes, and sometimes a severe vomiting is excited, by which great part of the opium is expelled from the stomach. But if this should fail to take place, and often when it has to a partial degree appeared, a heavy stupor comes on, attended with giddiness and headach; the breathing becomes difficult and laborious; the person falls into a profound sleep, from which he is roused with great difficulty, and into which, if left to himself, he speedily relapses; the face becomes pale, the lips livid, the extremities cold, universal torpor seizes the limbs, and is followed by convulsions and fatal apoplexy.

116 Appearances on dissection. On examining the bodies of those animals which have fallen victims to opium, the stomach is found distended, and containing frothy mucus, its internal coat in a state of inflammation, and sometimes the pyloris contracted. The vessels of the brain are exceedingly turgid, and commonly an effusion of blood is found to have taken place.

When a person awakes after having taken opium, he usually finds himself heavy and giddy, and not unfrequently complains of headach and dimness of sight; his bowels are costive, and his appetite defective. Some people, so far from being soothed and lulled to sleep by opium, are rendered exceedingly irritable and restless; others, if they are made to sleep by the influence of this medicine, are harassed with frightful dreams, and awake unrefreshed.

Effects similar to what we have described arise from opium when injected into the rectum; but they require a larger dose. When this substance is applied to the eye, the urethra, or other sensible parts, it excites pain and redness *, which, however, do not long continue. When merely applied to the surface of the body, while the

* Murray Apparat. Medicam. tom. ii p. 282.

* Crumpe's Enquiry, p. 23.

Appendix. the cuticle is entire, it produces no change; but when the tincture of opium, or opium in fine powder, mixed with an oily substance, is rubbed on the skin, pain is alleviated, sleep induced, delirium assuaged, and other sedative effects brought on; but the stimulating effects of the medicine are, in this way, said to be less apparent.

117 Ill effects of opium. The ill effects which sometimes attend the exhibition of opium, may arise, either directly from its stimulating power, or from consequent exhaustion.

I. The ill effects which appear to be the immediate consequence of the stimulus are, excitement, increased absorption, and determination of the blood to the head. These effects render it an improper remedy in the early stages of inflammatory diseases, particularly in phrenitis, pneumonia, catarrh, and dysentery. By increasing excitement and determining to the head, opium is improper in phrenitis; and it is hurtful in the other diseases by increasing absorption, and hence lessening expectoration, and producing costiveness. In some cases of inflammation, however, where increased perspiration is desirable, as in rheumatism, if the medicine be so managed as to produce full sweating in a short time after exhibition, it may be employed with advantage.

II. The ill effects which arise from the secondary circumstances following the administration of opium, are chiefly headach, general debility, tremors, spasms, paralysis, and hypochondriasis. Of course, in cases where these symptoms and diseases are to be apprehended, it must be employed with considerable caution.

118 Analysis of opium. Opium has been analysed by several chemists, especially by Gren, Bucholtz, Josse, Proust, Dr Duncan junior, and very lately by Derosne. "By evaporating a watery solution of opium to the consistence of a syrup, Derosne obtained a precipitate, which was increased by diluting it with water. He dissolved this in hot alcohol, from which it again separated on cooling. When purified by repeated solutions, it crystallized in rectangular prisms with rhomboidal bases, had no taste or smell, was insoluble in cold water, and soluble in 400 parts of boiling water, did not affect vegetable blues, was soluble in 24 parts boiling alcohol and 110 cold; soluble in hot ether and volatile oils, and separated from them as they cooled; very soluble in all acids, and highly narcotic *.

* *Duncan's Dispensat.* 4th edit. p. 329.

A considerable proportion of the substance of opium is insoluble both in water and alcohol; and it is remarkable that the insoluble part is very different in Turkey opium from what it is in that which comes from the East Indies; being in the former a ductile, plastic, coherent mass, in the latter an incoherent, powdery matter, diffusible in water. According to Dr Duncan, the active constituent of opium appears to be of a volatile nature; and as this must be carried off by boiling or distillation, the usual processes for purifying opium tend to diminish its medical effects.

119 Means of obviating the ill effects of opium. The ill effects of opium are to be obviated or counteracted by regulating the dose according to the effect intended to be produced; by the mode of administration, whether internally, or by friction, or by combining with it some correcting substance which has the effect of counteracting its unpleasant properties, such as *lemon-juice, ammonia, tartrate of antimony and potash, submuriate of mercury*, or *aromatics*. The languor and general debility felt after having taken opium, are best relieved by wine and exercise. Appendix.

When a person has swallowed such a quantity of opium as there is reason to fear will prove fatal, if its effects are not prevented or counteracted, it is proper to exhibit an emetic as soon as convenient, in order to evacuate from the stomach as much of the opium as possible. With this view, a scruple or half a dram of sulphate of zinc dissolved in a little water, is to be given, and the action of vomiting promoted several times by proper diluting liquors. We should then administer lemon juice in considerable quantities; and if the stupor be very great, all methods are to be employed for rousing the patient, and obliging him to exert himself in moving about. If the more alarming symptoms are made to yield, we should give wine, ether, or other stimulants, in moderate doses, still taking care to keep alive the attention of the patient. Strong coffee has been highly recommended in these cases.

As opium is now become a very expensive article, it is of consequence to consider what other remedies that are likely to produce the same good effects may be substituted for it. Several of the narcotic vegetables have been employed for this purpose, especially *lactuca virosa, conium maculatum* or hemlock, *datura stramonium* or thorn apple, *atropa belladonna* or deadly nightshade, *humulus lupulus* or hop, and *hyoscyamus niger* or henbane. Of these the two last seem to be best adapted to this purpose. 120 Substitutes for opium.

Preparation *d*. EXTRACTUM OPII AQUOSUM, Dub.

The Dublin College have made some alteration in their mode of preparing this extract, though they preserve the same proportions. They direct the opium to be triturated with hot water for ten minutes, when the water is to be poured off, a fresh quantity added, and the trituration continued for the same period. This trituration to be repeated a third time. Then all the liquors are to be mixed together, suffered to stand in an open vessel for two days, strained through linen, and then inspissated to the consistence of an extract. 121 Watery extract of opium.

CLASS XIV. Order I. DIDYNAMIA GYMNOSPERMIA.

168. MENTHA VIRIDIS.

Preparation *p*. INFUSUM COMPOSITUM, Dub. Compound infusion of mint.

This is prepared by first digesting, for half an hour, in a close vessel, two drams of dried mint in as much boiling water as, when strained, may produce six ounces, and then mixing with the strained liquor, two drams of fine white sugar, and three drops of essential oil of mint, previously dissolved in half an ounce of compound tincture of cardamom. 122 Compound infusion of mint.

This forms a very grateful stomachic.

174. TEUCRIUM CHAMÆDRYS, Dub. Wall germander. *The herb*. 123 Wall germander.

An indigenous tonic, employed in domestic medicine in cases of *chlorosis, gout*, and *intermittent fever*.

Order

Appendix.

Order. 2 ANGIOSPERMIA.

180. DIGITALIS PURPUREA.

124 Tincture of digitalis.

Preparation *b*. TINCTURA DIGITALIS PURPUREÆ.

This medicine is now introduced into the Dublin Pharmacopœia, and is prepared in the same manner as directed by the Edinburgh college.

CLASS XIX. Order 2. SYNGENESIA POLYGAMIA SUPERFLUA.

216. ANTHEMIS NOBILIS.

125 Compound decoction of chamomile.

Preparation *a* *. DECOCTUM CHAMEMÆLI COMPOSITUM, Dub. Compound decoction of chamomile.

Made by boiling for a little half an ounce of chamomile flowers and two drams of sweet fennel seeds in a pint of water, and straining.
Used chiefly for clysters.

CLASS XXI. Order 8. MONOECIA POLYANDRIA.

226. QUERCUS CERRIS. *Galls.*

126 Tincture of galls.

Preparation *a*. TINCTURA GALLARUM, Dub. Tincture of galls.

Prepared by digesting four ounces of powdered galls in two pints of proof spirit for seven days, and straining.
A strong solution of the astringent principle of galls.

Order 10. MONADELPHIA.

228. PINUS ABIES. *Burgundy pitch.*

127 Calefacient plaster.

Preparation *b*. EMPLASTRUM CALEFACIENS, Dub. Calefacient plaster.

A warm stimulating plaster, made by melting together, with a moderate heat, seven parts of *Burgundy pitch* and one part of *ointment of cantharides*.

Order 12. SYNGENESIA.

236. CUCUMIS COLOCYNTHIS.

128 Compound pills of colocynth.

Preparation *b*. PILULÆ COLOCYNTHIDIS COMPOSITÆ, Dub. Compound pills of colocynth.

These are prepared by beating together half an ounce of the pith of colocynth, half an ounce of hepatic aloes, and the same quantity of scammony, all in powder, with two drams of Spanish soap, a dram of cloves, and a sufficient quantity of simple syrup, to form a mass for pills. This is a strong cathartic, and may be given in a dose of 10 or 15 grains.

244. JUNIPERUS SABINA.

129 Savine ointment.

Preparation *d*. UNGUENTUM SABINÆ, Dub. Savine ointment.

Prepared by boiling half a pound of fresh savine leaves, bruised, in two pounds of prepared hog's lard till they become crisp, then pressing out the lard and melting in it half a pound of bees wax.
A stimulating ointment, used in dressing issues, for which it is said to be preferable to cantharides ointment.

CLASS XXIV. Order 2. CRYPTOGAMIA. FUCI.

Appendix.

255 *. FUCUS VESICULOSUS, QUERCUS MARINA, Dub. Yellow bladder wrack. 130 Bladder wrack.

A common indigenous sea-weed, the charcoal from which is employed in the following preparation.

a. PULVIS QUERCUS MARINÆ, Dub. Powder of sea-wrack. 131 Powder of sea-wrack.

This is prepared by drying and cleaning any quantity of yellow bladder wrack, gathered while in fruit; then exposing it to the fire in an iron pot or crucible, covered with a perforated lid, till the volatile matters have evaporated, and the mass becomes of a dull red colour. This is to be reduced to a very fine powder, and kept in close vessels.
The medical virtues of this preparation, if it have any, are similar to those of burnt sponge, and it may be given in the same dose.

Order 3. ALGÆ.

256. LICHEN ISLANDICUS, N° 799.

Preparation *a*. DECOCTUM LICHENIS ISLANDICI, Dub. Decoction of Iceland liverwort. 132 Decoction of Iceland liverwort.

This is prepared by digesting half an ounce of Iceland liverwort in a pint of hot water for two hours, in a close vessel, then boiling for 15 minutes, and straining off the liquor while hot.

CHAP. III. *Mineral Substances.*

SECT. 2. *Inflammable Substances.*

260. SULPHUR SUBLIMATUM.

Preparation *g*. AQUA SULPHURETI KALI, Dub. Water of sulphuret of potash. 133 Water of sulphuret of potash.

This is prepared by boiling together half an ounce of sublimed sulphur with nine ounces by measure of caustic ley for 10 minutes, and straining through paper. The liquor is to be kept in vessels well closed.
The specific gravity of this liquid is assigned by the Dublin college to be to that of distilled water, as 1120 to 1000.

Preparation *h*. AQUA SULPHURETI AMMONIÆ, Dub. Water of sulphuret of ammonia. 134 Water of sulphuret of ammonia.

This is prepared by shaking four ounces of fresh-burnt lime in an earthen vessel, which is to be kept covered till the lime has fallen into powder, and become cool; when there are to be added four ounces of powdered muriate of ammonia, and two ounces of sublimed sulphur mixed together, avoiding the vapours. The whole is now to be put into a retort, and distilled with a sudden and pretty strong heat, and the liquor that comes over is to be kept in a phial well closed with a glass stopper.

SECT. 4. *Alkalies and Alkaline Salts.*

265. NITRAS POTASSÆ.

Preparation *g*. ÆTHER NITROSUS, Dub. Nitrous ether. 135 Nitrous ether.

Prepared by pouring gradually, and in different portions, upon a pound and a half of nitre, dried and coarsely powdered, in a tubulated retort, placed in a bath of cold

Appendix.

water, a pound of sulphuric acid previously mixed with 19 ounces by measure of rectified spirit of wine, the mixture having been allowed to cool. With a very slight degree of heat, such as that of tepid water, an etherial liquor will pass over from the retort, and the heat which soon spontaneously arises in the retort must be moderated by cooling with cold water. The receiver should also be cooled with ice or snow, and furnished with a proper apparatus, to carry off and condense the superabundant vapours. The etherial liquor that spontaneously comes over, is to be put into a phial with a ground glass stopper, and as much dry subcarbonate of potash added as may be sufficient to saturate the superabundant acid, which is commonly done after the addition of about a dram of the salt. The ether which now floats on the upper part of the phial, is to be separated by means of a funnel, and kept for use.

Nitrous ether is a powerful stimulus, but is seldom employed in medicine.

136 266. MURIAS SODÆ.

Oxymuriatic alkaline water.

Preparation *d*. AQUA ALKALINA OXYMURIATICA, Dub. Oxymuriatic alkaline water.

This is prepared by putting into a matrass two pounds of dried muriate of soda, and a pound of powdered manganese mixed, then pouring on two pounds of water, and gradually adding at different times two pounds of sulphuric acid, adapting a proper apparatus of tubes and recipients, that the gas which comes over may pass through a solution of four ounces of carbonate of potash, in 29 ounces by measure of water.

This preparation is a solution of *oxymuriate of potash*, a salt which was lately in great esteem as a remedy in several diseases, especially *typhus*, scurvy, and *siphilis*, from an idea that it imparted to the system the oxygen defective in these diseases. The remedy is already out of fashion in this country.

137 Oxymuriatic water.

Preparation *e*. AQUA OXYMURIATICA, Dub. Oxymuriatic water.

Made by passing the gas extricated from the mixture of muriate of soda, manganese, and sulphuric acid, in the preceding preparation, through a pound of distilled water, by which this is impregnated with *oxymuriatic acid gas*.

Forms a good bleaching liquor, but is scarcely employed in medicine.

SECT. 6. *Earths and Earthy Salts.*

272. CARBONAS CALCIS.

138 Water of muriate of lime.

Preparation *f*. SOLUTIO MURIATICA CALCIS, E. MATERIA MEDICA, N° 876. AQUA MURIATIS CALCIS, Dub. Water of muriate of lime.

The Dublin college direct this to be prepared by dissolving an ounce of chalk in coarse powder in two ounces of diluted muriatic acid, and straining.

139 Precipitated chalk.

Preparation *g*. CRETA PRÆCIPITATA, Dub. Precipitated chalk.

Prepared by precipitating the chalk from the above solution, by adding carbonate of soda, filtering and washing the precipitate.

The carbonate of lime is thus procured very pure and in a very fine powder.

273. SULPHAS MAGNESIÆ.

Appendix.

Preparation *d*. ENEMA CATHARTICUM, Dub. Purging clyster. 140

Purging clyster.

Made by dissolving an ounce of manna in 10 ounces by measure of compound decoction of chamomile, (see N° 125.), and adding an ounce of olive oil, and half an ounce of sulphate of magnesia.

SECT. 7. *Metals, and Metallic Preparations.*

275. ACIDUM ARSENIOSUM. 141

Arseniate of potash.

Preparation *a*. ARSENIAS KALI, Dub. Arseniate of potash.

The Dublin college direct this salt to be prepared by mixing together an ounce of white oxide of arsenic, and the same quantity of nitrate of potash, separately reduced to powder, putting them into a glass retort placed in a sand bath, and applying a gradual heat, till the bottom of the retort assumes an obscure red; then dissolving the residuum in four pounds of boiled distilled water, evaporating, and setting it aside to crystallize.

The use of arsenic, in the cure of many diseases of debility, has of late been much extended. It is now employed, not only in intermittents, but in protracted rheumatism, and many other cases where the vital powers are much diminished.

276. SULPHURETUM ANTIMONII.

Preparation *h*. OXIDUM ANTIMONII NITRO-MURIATICUM, olim CALX STIBII PRÆCIPITATA, Dub. (See N° 879.). Nitro-muriatic oxide of antimony. 142

Nitro-muriatic oxide of antimony.

This precipitate is now directed to be prepared by mixing together 11 ounces by measure of muriatic acid, and 1 ounce by measure of nitrous acid, taking care to avoid the fumes, and gradually adding to the mixture 2 ounces of prepared sulphuret of antimony; then digesting with a gradually increased heat, till the effervescence ceases, and boiling for an hour; filtering the liquor when cold, so that it may drop into a gallon of water. The powder which falls to the bottom is to be repeatedly washed till the water poured from it is perfectly free from acid, and is then to be dried on blotting paper.

Preparation *k*. TARTRAS ANTIMONII ET POTASSÆ. TARTARUM ANTIMONIATUM, SIVE EMETICUM. Dub. Antimoniated or emetic tartar. 143

Antimoniated tartar.

In the Dublin pharmacopœia we are directed to prepare this medicine by boiling 18 ounces by measure of distilled water in a glass vessel, and gradually throwing into it 2 ounces of nitro-muriatic oxide of antimony, and $2\frac{1}{2}$ ounces of powdered crystals of tartar, previously mixed, continuing the boiling for half an hour, then filtering the liquor, and cooling it gradually, that crystals may be formed.

277. HYDRARGYRUM.

Preparation *a*. HYDRARGYRUM CUM MAGNESIA, Dub. Mercury with magnesia. 144

Quicksilver with magnesia.

This is a new preparation, formed by first rubbing together an ounce of quicksilver with the same quantity of manna, adding now and then a few drops of water,

so

Appendix. so as to reduce the mixture to the consistence of syrup, till the whole of the mercury disappears; then still continuing the trituration, adding first a dram of magnesia, and when all are well mixed, a pint of hot water, and shaking the mixture. When the sediment has completely subsided, the liquor is to be poured off, and the washing twice repeated, so as to dissolve the whole of the manna. To the sediment, still moist, are to be added three drams more of magnesia, and the compound is to be dried on blotting paper.

This preparation is similar in its medical effects to the *hydrargyrus cum creta*, described in MATERIA MEDICA, N° 914.

145 Ammoniated submuriate of mercury. Preparation *b*. SUBMURIAS HYDRARGYRI AMMONIATUM. Dub. Ammoniated submuriate of mercury.

Prepared by adding to the liquor from which precipitated submuriate of mercury has been obtained, a quantity of caustic water of ammonia, washing the precipitate with cold distilled water, and drying on blotting paper. The same with the *calx hydrargyri alba*, London.

278. ZINCUM.

146 Tincture of acetate of zinc. Preparation *g*. TINCTURA ACETATIS ZINCI. Dub. Tincture of acetate of zinc.

Made by rubbing together an ounce of sulphate of zinc, and the same quantity of acetate of potash, then adding a pint of rectified spirit of wine, macerating for a week with frequent agitation, and filtering the tincture.

Chiefly used as an external astringent.

280*. OXIDUM MANGANESII NIGRUM. Manganesium, Dub. Black oxide of manganese.

Employed chiefly in preparing the oxymuriatic alkaline water. Appendix.

287. SULPHAS FERRI NATIVUS.

Preparation *e**. ACETAS FERRI. Dub. Acetate of iron. 147 Acetate of iron.

Made by digesting half an ounce of carbonate of iron in 3 ounces by measure of acetic acid, and filtering.

Preparation *f*. TINCTURA MURIATIS FERRI CUM OXIDO RUBRO, Dub. Tincture of muriate of iron with red oxide. 148 Tincture of muriate of iron with red oxide.

Prepared by digesting an ounce of red oxide of iron with four ounces by measure of muriatic acid for 24 hours, then boiling for half an hour, evaporating the filtered liquor to the consistence of syrup, and when cold, adding rectified spirit of wine, with frequent agitation, till the tincture acquires the specific gravity of 1050.

A modification of the tincture of muriated iron described under MATERIA MEDICA, N° 965, and is employed in similar cases.

The above appear to be the most material changes made in the new edition of the Dublin Pharmacopœia. A few articles of less consequence are omitted, and the new names of others will be seen in the following Table. In this Table we have followed the alphabetical order of the last Edinburgh Pharmacopœia, and in the third column we have caused the London names to be printed in Italics, leaving a space above each for the insertion of such new names as may occur in the new edition of their Pharmacopœia which the London College is expected soon to publish.

INDEX.

N.

Presence, Present Tense.

PRESENCE, a term of relation, used in opposition to absence, and signifying the existence of a person in a certain place.

Present Tense, in *Grammar*, the first tense of a verb, expressing the present time, or that something is now performing; as *scribo*, I write, or am writing. See Grammar.

Present Tense, Presentation.

PRESENTATION, in ecclesiastical law. See Patronage.

Presentation of the Virgin, is a feast of the Rom-ish

ish church, celebrated on the 21st of November, in memory of the Holy Virgin's being presented by her parents in the temple, to be there educated. Emanuel Comnenus, who began to reign in 1143, makes mention of this feast in his Constitutions. Some imagine it to have been established among the Greeks in the 11th century; and think they see evident proofs of it in some homilies of George of Nicomedia, who lived in the time of Photius. Its institution in the West is ascribed to Gregory XI. in 1372. Some think it was instituted in memory of the ceremony practised among the Jews for their new-born females; corresponding to the circumcision on the eighth day for males.

Presentation of our Lady also gives the title to three orders of nuns. The first, projected in 1618, by a maid named Joan of Cambray. The habit of the nuns, according to the vision she pretended to have, was to be a gray gown of natural wool, &c.; but this project was never accomplished. The second was established in France, about the year 1627, by Nicholas Sanguin, bishop of Senlis; it was approved by Urban VIII. This order never made any great progress. The third was established in 1664, when Frederic Borromeo, being apostolical visitor in the Valteline, was intreated by some devout maids at Morbegno to allow them to live in community in a retired place; which he granted, and erected them into a congregation, under the title of *congregation of our Lady*. They live under the rule of St Augustine.

PRESENTMENT, in *Law*. See Prosecution.

A presentment, generally taken, is a very comprehensive term; including not only *presentments* properly so called, but also inquisitions of office, and indictments by a grand jury. A presentment, properly speaking, is the notice taken by a grand jury of any offence from their own knowledge or observation, without any bill of indictment laid before them at the suit of the king: As the presentment of a nuisance, a libel, and the like; upon which the officer of the court must afterwards frame an indictment, before the party presented can be put to answer it. An inquisition of office is the act of a jury, summoned by the proper officer to inquire of matters relating to the crown, upon evidence laid before them. Some of these are in themselves convictions, and cannot afterwards be traversed or denied; and therefore the inquest, or jury, ought to hear all that can be alleged on both sides. Of this nature are all inquisitions of *felo de se;* of flight in persons accused of felony; of deodands, and the like; and presentments of petty offences in the sheriff's tourn or court-leet, whereupon the presiding officer may set a fine. Other inquisitions may be afterwards traversed and examined; as particularly the coroner's inquisition of the death of a man, when it finds any one guilty of homicide; for in such cases the offender so presented must be arraigned upon this inquisition, and may dispute the truth of it; which brings it to a kind of indictment, the most usual and effectual means of prosecution. See Indictment.

PRESERVATION island, a small island on the southern coast of New Holland, and one of the groupe called *Furneaux islands*, derives its name from the circumstance of the crew of a ship which was wrecked on the coast, having saved their lives, and resided for some time upon it. This island is in most places extremely barren, and is remarkable for large blocks of granite scattered on its surface in many places. But one of the most singular phenomena in the history of this island was, the discovery of a petrified wood in the midst of a patch of naked sand; and at least 100 feet above the level of the sea. Some of the stumps of the trees rose a foot and a half above the surface; some were furnished with branches, and even it is said a green leaf was seen on one of them when they were first discovered. The petrifactions were found to be of a calcareous nature. We think it probable that the trees here said to be petrified may be of the nature of corals, may have been formed as usual at the bottom of the sea, and elevated to their present situation by some convulsion.

In some parts of the island a little vegetation was observed, with some brush wood and stunted trees. Small kangaroos were found in abundance, with different kinds of birds and some noxious snakes. *Collins's Account of New South Wales*, II.

PRESERVING *Lives of Shipwrecked Persons.* In our account of life-boats, we laid before our readers every thing that seemed useful on so important a subject which was then known to us. Since that time we have met with the following description of a similar invention by a Mr Lukin of London, suggested during his casual residence at Lowestoff in Suffolk.

A boat constructed on this principle cannot be overset or sunk by any power of wind and water; in proof of which the following particulars and description of the construction are made public, with the hope of rendering more generally known the easy means of saving many valuable lives; which might certainly be done, if one or two of these boats were built at each of our ports, and every ship furnished with one (at least) in proportion to her size.

Description and Dimensions of the Lowestoff Life-Boat.

	Feet.	Inches.
Length aloft - -	40	0
——— keel - -	37	0
Breadth amidships -	10	0
Depth - - -	3	6 exclusive of
a moveable wash strake of	0	8

The form the same as the yawns of that coast; the stern post nearly upright.

External gunwales hollow, forming an oblique section of a parabola with the side of the boat, and projecting nine inches from it on each side: these gunwales are reduced a little in their projection towards their ends, and are first formed by brackets and thin boards, covered at top and bottom with one thickness of good sound cork, and the extremity or apex of the projection having two thicknesses of cork, the better to defend it from any violent blows it may meet with in hard service. The depth of these gunwales from top to bottom was 15 inches, and the whole covered with very strong canvas, laid on with strong cement to resist the water, and that will not stick to any thing laid upon it.

A false keel of wrought iron three inches deep, made of three bars rivetted together, and bolted under the common keel, which it greatly strengthens, and makes a very essential part of her ballast; being fixed so much below the floor, it has nearly double the power the same weight would have if laid on the floor, and therefore

much

Preserving || Presidial.

much preferable to any other ballast that can be used for sailing boats.

Thwarts and gang-board as usual; three masts and lug sails, and 12 short oars.

In this state, this boat is much safer than any common boat of the same dimensions, will carry more sail, and bear more weather; but to make it completely unimmergible, empty casks of about 22 inches diameter were ranged along withinside the gunwales, lashed firmly to the boat, lying even with the tops of the gunwales, and resting upon brackets fastened to the timbers for that purpose: also two such casks in the head, and two in the stern, and all removable in a short time, if desired; there were also some empty casks placed under the gang-board; these would be an addition to the buoyancy if empty, and an increase to her ballast if full.

Thus equipped, this boat was launched on the 19th of November, in a very squally day. About 20 men were launched in her, most of them pilots or seamen. They ran her immediately from the beach across the Corton sand, in the midst of the breakers, which would have been almost certain destruction to any common sailing boat, as that would have been filled and sunk immediately. They then turned to the southward along the top of the sand to its end: when they tacked and stood to the northward, pulled up the plugs in her bottom, and let in as much water as would come that way; the water rose very little above the thwarts. With all this water in it, the boat sailed better than without it. The plugs were now put in again, and water poured in by buckets, until it ran over both gunwales; and in this state it was the opinion of those on board that she would have carried 60 men without sinking, and to upset it is not possible. But it is Mr Lukin's opinion that more than 50 men should not be taken in when the boat is full of water, and all her casks empty.

It is particularly advisable that all life-boats should be built of the form most approved by the pilots or seamen on the coast where they are to be used; as no one form will suit all shores; and these principles of safety are applicable to every form.

To this description we have only to add, that Mr Lukin is said to be the inventor of the first life-boat ever built in England, and to have obtained a patent for it in the year 1785. It would appear, too, that he published a pamphlet on the subject, but this pamphlet we have had no opportunity of seeing.

PRESIDENT, PRÆSES, is an officer, created or elected to preside over a company or assembly; so called in contradistinction to the other members, who are termed *residents*.

Lord PRESIDENT *of the Council*, is a great officer of the crown, who has precedence next after the lord chancellor and lord treasurer; as ancient as the time of King John, when he was styled *consiliarius capitalis*.—His office is to attend on the king, to propose business at the council-table, and to report to the king the several transactions there. See *Privy-Council*.

PRESIDIAL, was a tribunal, or bench of judges, established (before the Revolution) in the several considerable cities of France, to judge ultimately, or in the last resort, of the several causes brought before them by way of appeal from the subaltern judges. The presidials made one company with the officers of the bailliages and seneschaussees, where they were established.

Press.

PRESS (PRELUM), in the mechanic arts, a machine made of iron or wood, serving to squeeze or compress any body very close.

The ordinary presses consist of six members, or pieces; viz. two flat smooth planks; between which the things to be pressed are laid; two screws, or worms, fastened to the lower plank, and passing through two holes in the upper; and two nuts, in form of an S, serving to drive the upper plank, which is moveable against the lower, which is stable, and without motion.

Presses used for expressing Liquors, are of various kinds; some, in most respects, the same with the common presses, excepting that the under plank is perforated with a great number of holes to let the juice expressed run through into a tub, or receiver, underneath.

A very useful machine for a press, in the process of cyder-making, has been constructed by Mr Anstice, who, with his well-known zeal for the improvement of mechanics, permits us to lay before our readers the following description of it.

AA fig. 1. two pieces of timber, 21 feet long, 12 by 6 inches, laid side by side at the distance of 12 inches, and secured in that situation by blocks placed between and bolts passing through them; this frame forms the bed of the machine. BB, two uprights, 12 feet long, 6 by 8 inches, morticed upon them, and secured in their position by pins and iron squares. CC, two uprights, five feet long, six by ten inches, morticed near the end of the under frame, and secured as before. D, a lever, 17 feet long, 12 by 13 inches, turning on a large bolt which passes through the short uprights, also through iron straps, which secure them to the bed inside, and a stirrup of iron which passes over the end of the lever, and which makes the turning point in the line of its lower side, and not through its middle. E, a lever 20 feet long, six by eight inches at its largest part and tapering towards the other end: this lever turns on a bolt in the uprights BB. F, 1, 2, 3, 4. four pieces of oak (which he calls *needles*, 10 feet long), four by two and a half inches, morticed loosely into the upper lever, and hung thereto by bolts, so as to swing perpendicularly and play in a long mortice or channel cut through the large lever to receive them. These needles have inch-holes pretty closely bored through them (in a direction crossing the machine), from the lower ends as far upwards as the great lever will reach, when it is as high as it can go. G, a bed to receive what is to be pressed. H, a frame to support a winch worked by a handle at I. At the end of the small lever two blocks or pulleys are fixed, one above, and the other below it; a rope of about half an inch diameter is then fastened to the cieling (or continuation of the uprights of the winch frame if necessary) at K; then passed through the upper block on the lever, from thence passed through a block at L, and then goes with four turns round the winch, from whence it is carried through the block under the lever, and fastens to the machine at M; by this means, if the winch be turned one way, it raises the end of the small lever if the other depresses it.

Plate CCCCXXXIX. fig. 1.

To work the machine. If we suppose the great lever bearing on the matter to be pressed, an iron pin must be put into one of the holes in the needles above the great lever; and when the small lever is worked as

 far

Press.

far as it will go, either up or down, another bolt is to be put into the hole, which comes nearest above the great lever on the other side of the uprights BB, and the winch then turned the contrary way, by which means the pressing goes on whether the small lever rises or falls. Before the resistance is very great, the needles farthest from the fulcrum of the small lever are used; after that the nearest are employed, which doubles the power of the machine. In raising the great lever, or lowering it to its bearing, the needles most distant from the fulcrum of the small lever, are used *under* instead of *over* it. As the rope is liable to stretch and get slack, he passes it, after taking two turns on the winch, through a pulley, to which is suspended a weight of half a hundred, and then takes two turns more before it is carried through the other block, by which means the slack is constantly gathered in, and the weight holds on without increasing the friction, as by hanging under the winch it counteracts the pressure upwards on its axis.

The power of this machine is very great, being as one to 1136 nearly, and capable by a trifling addition of any other proportion. It is applicable to many purposes beside cyder pressing, and is more simple, and less liable to injury, than any other which has fallen under our observation. Perhaps, however, it would be an improvement to use, instead of the ropes and pulleys, by which the lever E is moved, a small wheel or pinion of 10 or 12 teeth, on the axis of the winch W (fig. 2.), and a stiff beam *e n* down from the lever, having on its lower end an iron rack, of which the teeth take into those of the pinion. The action of these teeth would, in our opinion, be less diminished by friction and obliquity, than the pulleys are by friction and the stiffness of the rope; and the machine would retain all its other advantages.

Fig. 2.

Press used by Joiners, to keep close the pieces they have glued, especially panels, &c. of wainscot, is very simple, consisting of four members; viz. two screws, and two pieces of wood, four or five inches square, and two or three feet long; whereof the holes at the two ends serve for nuts to the screws.

Press used by Inlayers, resembles the joiner's press, except that the pieces of wood are thicker, and that only one of them is moveable; the other, which is in form of a tressel, being sustained by two legs or pillars, joined into it at each end. This press serves them for sawing and cleaving the pieces of wood required in marquetry or inlaid work.

Founder's Press, is a strong square frame, consisting of four pieces of wood, firmly joined together with tenons, &c. This press is of various sizes, according to the sizes of the moulds; two of them are required to each mould, at the two extremities of which they are placed; so as that, by driving wooden wedges between the mould and the sides of the presses, the two parts of the mould wherein the metal is to be run may be pressed close together.

Printing-Press. See *Printing-Press*.

Rolling-Press, is a machine used for taking off prints from copper-plates. It is much less complex than that of the letter-printers. See its description and use under the article *Rolling-Press Printing*.

Press, in *Coining*, is one of the machines used in striking of money; differing from the balance, in that it has only one iron bar to give it motion, and press the moulds or coins; is not charged with lead at its extreme, nor drawn by cordage. See Coining.

Press, Pressing.

Binder's Cutting-Press, is a machine used equally by book-binders, stationers, and pasteboard-makers; consisting of two large pieces of wood, in form of cheeks, connected by two strong wooden screws; which, being turned by an iron bar, draw together, or set asunder, the cheeks, as much as is necessary for the putting in the books or paper to be cut. The cheeks are placed lengthwise on a wooden stand, in the form of a chest, into which the cuttings fall. Aside of the cheeks are two pieces of wood, of the same length with the screws, serving to direct the cheeks, and prevent their opening unequally. Upon the cheeks the plough moves, to which the cutting-knife is fastened by a screw; which has its key to dismount it, on occasion, to be sharpened.

The plough consists of several parts; among the rest a wooden screw or worm, which, catching within the nuts of the two feet that sustain it on the cheeks, brings the knife to the book or paper which is fastened in the press between two boards. This screw, which is pretty long, has two directories, which resemble those of the screws of the press. To make the plough slide square and even on the cheeks, so that the knife may make an equal paring, the foot of the plough where the knife is not fixed, slides in a kind of groove, fastened along one of the cheeks. Lastly, the knife is a piece of steel, six or seven inches long, flat, thin, and sharp, terminating at one end in a point, like that of a sword, and at the other in a square form, which serves to fasten it to the plough. See *Book-Binding*.

As the long knives used by us in the cutting of books or papers, are apt to jump in the cutting of thick books, the Dutch are said to use circular knives, with an edge all round; which not only cut more steadily, but last longer without grinding.

Press, in the woollen manufactory, is a large wooden machine, serving to press cloths, serges, rateens, &c. thereby to render them smooth and even, and to give them a gloss.

This machine consists of several members; the principal whereof are the cheeks, the nut, and the worm or screw, accompanied with its bar, which serves to turn it round, and make it descend perpendicularly on the middle of a thick wooden plank, under which the stuffs to be pressed are placed. The calender is also a kind of press, serving to press or calender linens, silks, &c.

Liberty of the Press. See *Liberty of the Press*.

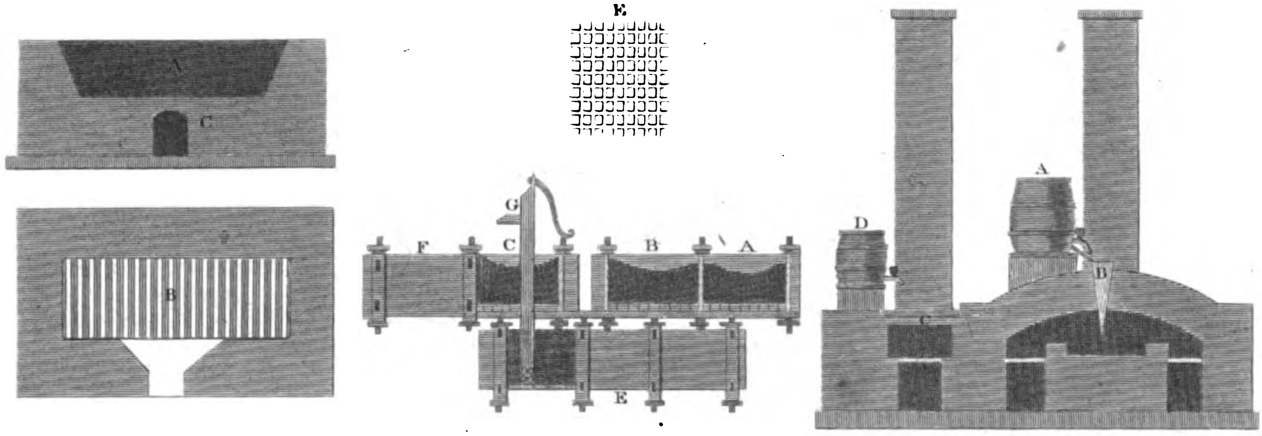
PRESSING, in the manufactures, is the violently squeezing a cloth, stuff, &c. to render it smooth and glossy.

There are two methods of pressing, viz. cold and hot.

As to the former, or cold pressing: After the stuff has been scoured, fulled, and shorn, it is folded square in equal plaits, and a skin of vellum or pasteboard put between each plait. Over the whole is laid a square wooden plank, and so put into the press, which is screwed down tight by means of a lever. After it has lain a sufficient time in the press, they take it out, removing the pasteboards, and lay it up to keep. Some only lay the stuff on a firm table after plaiting and pasteboarding, cover

POTASH. *PLATE CCCCXXXIX.*

Kiln for preparing.



PRESS Cyder.

Fig. 1.

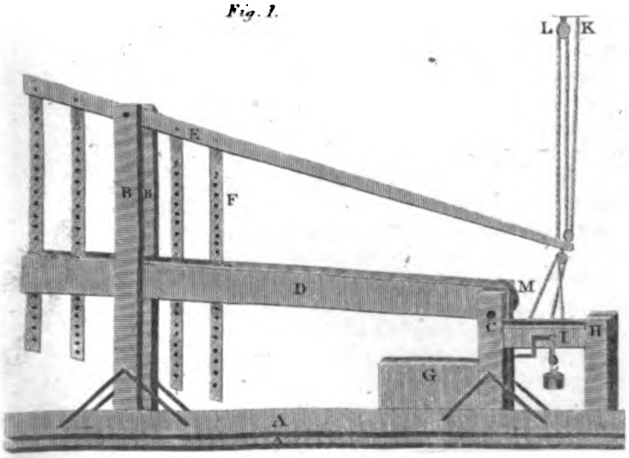


Fig. 2.

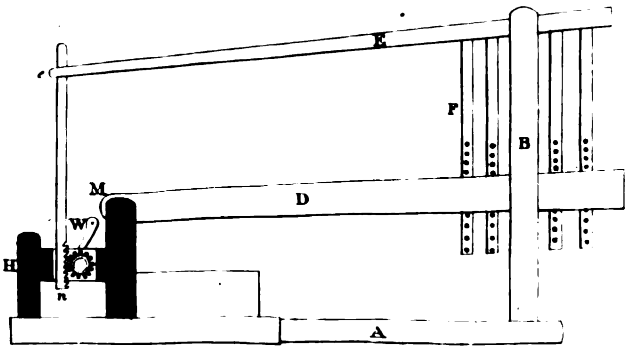

cover the whole with a wooden plank, and load it with a proper weight.

The method of pressing hot is this: When the stuff has received the above preparations, it is sprinkled a little with water, sometimes gum-water; then plaited equally, and between each two plaits are put leaves of pasteboard; and between every sixth and seventh plait, as well as over the whole, an iron or brass plate well heated in a kind of furnace. This done, it is laid upon the press, and forcibly screwed down. Under this press are laid five, six, &c. pieces at the same time, all furnished with their pasteboards and iron plates. When the plates are well cooled, the stuffs are taken out and stitched a little together to keep them in the plaits. This manner of pressing was only invented to cover the defects of the stuffs; and, accordingly, it has been frequently prohibited.

PRESSING, or *Impressing*. See IMPRESSING.

PRESSION, or PRESSURE, in the Cartesian philosophy, is a supposed impulsive kind of motion, or rather an endeavour to move, impressed on a fluid medium, and propagated through it.

PRESSURE OF AIR. See PNEUMATICS.

PRESSURE of Fluids. See HYDRODYNAMICS and PNEUMATICS.

PREST, is used for a duty in money, to be paid by the sheriff on his account, in the exchequer, or for money left or remaining in his hands: 2 & 3 Edw. VI. c. 4.

PREST-Money, is so called from the French word *prest*, that is, *promptus*, *expeditus*; for that it binds those who receive it, to be ready at all times appointed, being commonly meant of soldiers.

PRESTATION-MONEY, is a sum of money paid yearly by archdeacons and other dignitaries to their bishop, *pro exteriori jurisdictione*.

PRESTATION (*præstatio*), was anciently used for other payments: *Et quieti sint de præstatione muragii*. Chart. Hen. VII. Sometimes also for pourveyance.

PRESTEIGN is a town in Radnorshire, distant 149 miles west-north-west from London, in the direct road to Aberystwith, and throughout South Wales, in N. Lat. 52° 12′, bounded to the north and north-east by Herefordshire. It is a neat well built town, with clean and regular streets, and is the residence of many genteel families. The neighbourhood abounds with all the comforts and conveniencies of life. It is seated on a gravelly soil on the banks of the river Lug, and at the head of a very fertile vale: the mountains to the west and north-west of the town forming, as it were, an amphitheatre round it. The name of it in Welsh, is *Slan-Andras*, which is supposed to be derived from the church, which is dedicated to Saint Andrew. The town is divided into four wards, which have each a separate jurisdiction, separate officers, levies, &c. The curfew-bell of William the Conqueror still remains in this place, and is rung every night. It is a borough by prescription, and is governed by a bailiff annually elected, and sworn in by a steward appointed by the crown. The living is a rectory and vicarage united, and reported to be worth from 500l. to 600l. per annum; the parish lying in two counties. Here is an excellent free school well endowed. The county hall, the county gaol, the county bridewell, and house of correction, are kept in this place. The markets are held on Saturdays; and there are two fairs in the year. About a century and a half ago Presteign was considerably larger; had a good woollen manufactory, of which the very large buildings now standing (formerly belonging to clothiers) bear ample testimony; but a fire, succeeded by the plague, in the town, about the year 1636, reduced the same, and with it its consequence as a manufacturing town. The parish embraces a circle of at least 19 miles; and is reckoned very healthy.

PRESTER JOHN, or JEAN, an appellation formerly given to an emperor of the Tartars, who was overcome and killed by Jenghiz Khan. Since that time it has been given to the emperor of Abyssinia or Ethiopia; however, in Ethiopia itself this name is utterly unknown, the emperor being there called the *grand negus*.

PRESTER, a meteor, consisting of an exhalation thrown from the clouds downwards with such violence, as that by the collision it is set on fire. The word is Greek, πρηστηρ, the name of a kind of serpent, called also *dipsas*, to which this meteor is supposed to bear a resemblance. The prester differs from the thunderbolt in the manner of its inflammation; and in its burning and breaking every thing it touches with greater violence.

PRESTER, a word used by some to express the external part of the neck, which is usually inflated in anger.

PRESTIMONY, in *Canon Law*, is derived *à præstatione quotidiana;* and is, by some, defined to be a kind of benefice, served by a single priest. Others say, it is the incumbency of a chapel, without any title or collation; such as are most of those in castles, where prayers or mass are said; and which are mere unendowed oratories. Whence the term is also applied, in the Romish church, to certain perpetual offices bestowed on canons, religious, or others, for the saying of masses, by way of augmentation of their livings. Others think it is a lease, or concession of any ecclesiastical fund or revenue, belonging to a monastery, to be enjoyed during life. Du Moulin calls it a *profane benefice*, which, however, has a perpetual title, and an ecclesiastical office, with certain revenues attached to it; which the incumbent is allowed to sell, and which may be possessed without tonsure; such as the lay churchwardens of Notre-dame. He adds, that, in propriety, the canonries of chapels are benefices of this nature. The most probable opinion seems to be, that prestimony is a fund, or revenue, appropriated by the founder for the subsistence of a priest, without being erected into any title of benefice, chapel, prebend, or priory; and which is not subject either to the pope or to the ordinary, but whereof the patron, and those who have a right from him, are the collators, and nominate and confer *pleno jure*.

PRESTO, in the Italian music, intimates to perform quick; as *prestissimo* does extremely quick.

PRESTON, a town of Lancashire in England, seated on the river Ribble, over which there is a handsome stone bridge. Here is held a court of chancery, and other offices of justice for the county palatine of Lancaster. It is noted for the defeat of the rebels here in 1715, when they were all made prisoners, and sent up to London. It contained 17,085 inhabitants in 1811. W. Long. 2. 26. N. Lat. 53. 45.

PRESTRE. See VAUBAN.

PRETENSED or PRETENDED right, in *Law*, is where one is in possession of lands and tenements, which another, who is out, claims and sues for. Here the pretensed right is in him who so claims or sues.

PRETERITE, in *Grammar*, a tense which expresses the time past, or an action completely finished; as, *scripsi*, "I have written." See PERFECT and GRAMMAR.

PRETERITION, or PRETERMISSION, in *Rhetoric*, a figure whereby, in pretending to pass over a thing untouched, we make a summary mention thereof. *I will not say he is valiant, he is learned, he is just*, &c. The most artful praises are those given by way of preterition. See ORATORY.

PRETEXT, a colour or motive, whether real or feigned, for doing something.

TOGA PRETEXTA, among the ancient Romans, a long white gown, with a border of purple round the edges, and worn by children of quality till the age of puberty, viz. by the boys till 17, when they changed it for the *toga virilis*; and by the girls till marriage.

PRETIUM SEPULCHRI, in old law books, &c. those goods accruing to the church wherein a corpse is buried. In the Irish canons, lib. xix. cap. 6. it is ordered, that along with every body that is buried, there go his cow, horse, apparel, and the furniture of his bed; none of which may be disposed of otherwise than for the payment of debts, &c. as being familiars and domestics of the deceased.

PRETOR, a magistrate among the ancient Romans, not unlike our lord chief justices, or lord chancellor, or both in one; as being vested wtth the power of distributing justice among the citizens. At first there was only one pretor; but afterwards, another being created, the first or chief one had the title of *prætor urbanus*, or the "city pretor:" the other was called *peregrinus*, as being judge in all matters relating to foreigners. But, besides these, there were afterwards created many provincial pretors; who were not only judges, but also assisted the consuls in the government of the provinces, and even were invested with the government of provinces themselves.

PRETORIAN GUARDS, in Roman antiquity, were the emperor's guards, who at length were increased to 10,000: they had this denomination, according to some, from their being stationed at a place called *Prætorium*: their commander was styled *præfectus prætorii*.

PRETORIUM, or PRÆTORIUM, among the Romans, denoted the hall or court wherein the pretor lived, and wherein he administered justice.

It likewise denoted the tent of the Roman general, wherein councils of war, &c. were held: also a place in Rome where the Pretorian guards were lodged.

PREVARICATION, in the civil law, is where the informer colludes with the defendants, and so makes only a sham prosecution.

PREVARICATION, in our laws, is when a man falsely seems to undertake a thing, with intention that he may destroy it; where a lawyer pleads booty, or acts by collusion, &c. It signifies also the false and contradictory testimony of a witness; and denotes sometimes the secret abuse committed in the exercise of a public office, or of a commission given by a private person.

PRIAM, king of Troy, was the son of Laomedon. He was carried into Greece after the taking of that city by Hercules; but was afterwards ransomed, on which he obtained the name of *Priam*, a Greek word signifying "ransomed." At his return he rebuilt Ilium, and extended the bounds of the kingdom of Troy, which became very flourishing under his reign. He married Hecuba, the daughter of Cisseus king of Thrace, by whom he had 19 children; and among the rest Paris, who carried off Helen, and occasioned the ruin of Troy, which is supposed to have been sacked by the Greeks about 1184 B. C. when Priam was killed by Pyrrhus the son of Achilles at the foot of an altar where he had taken refuge, after a reign of 52 years. See TROY.

PRIAPISMUS, or PRIAPISM, is an erection of the penis without any concomitant pain, or the consent of other parts. It is thus called, because the person in this state resembles the lewd god Priapus. Cœlius Aurelianus says it is a palsy of the seminal vessels, and other nerves distributed to the parts about the penis, by the distension of which this disorder is produced. It is of the same nature as the satyriasis. See MEDICINE, N° 372,

PRIAPUS, in Pagan worship, the son of Bacchus and Venus, who presided over gardens and the most indecent actions. He was particularly adored at Lampsacus, a city at the mouth of the Hellespont, said to be the place of his birth; and his image was placed in gardens to defend them from thieves and birds destructive to fruit. He was usually represented naked, with a stern countenance, matted hair, and holding either a wooden sword or sickle in his hand, and with a monstrous privity; from whence downward his body ended in a shapeless trunk. The sacrifice offered to this obscene deity was the ass; either on account of the natural uncomeliness of this animal, and its propensity to venery, or from the disappointment which Priapus met with on his attempting the chastity of Vesta, while that goddess was asleep, when she escaped the injury designed her by her being awaked by the braying of old Silenus's ass.

PRICE, REV. RICHARD, D. D. L. L. D. fellow of the Royal Society of London, and of the Academy of Sciences, New England, was born at Tynton in Glamorganshire, February 22. 1723. His father was a dissenting minister at Bridgend in that county, and died in 1739. At eight years old he was placed under a Mr Simmons of Neath; and in four years removed to Pentwyn in Caermarthenshire under the Rev. Samuel Jones, whom he represented as a man of a very enlarged mind, and who first inspired him with liberal sentiments of religion. Having lived as long with him as with Mr Simmons, he was sent to Mr Griffith's academy at Talgarth in Breconshire. In 1740 he lost his mother; and on this he quitted the academy and came to London. Here he was settled at that academy, of which Mr Eames was the principal tutor, under the patronage of his uncle the Rev. S. Price, who was copastor with Dr Watts upwards of 40 years. At the end of four years he left this academy, and resided with Mr Streatfield of Stoke Newington in the quality of domestic chaplain, while at the same time he regularly assisted Dr Chandler at the Old Jewry, and occasionally assisted others. Having lived with Mr Streatfield near

Price. 13 years, on his death and his uncles's he was induced to change his situation, and in 1757 married Miss S. Blundell of Leicestershire. He then settled at Hackney, but being shortly after chosen minister at Newington Green, he lived there until the death of his wife, which was in 1786, when he returned to Hackney. He was next chosen afternoon preacher at the meeting-house in Poor Jewry-street, but this he resigned on being elected pastor of the Gravel-pit meeting Hackney, and afternoon-preacher at Newington Green. These he resigned with a farewel-sermon in February 1791. Shortly after he was attacked with a nervous fever, which disappearing, was succeeded by a disorder in his bladder, which reduced him to such a degree that, worn out with agony and disease, he died without a groan on the 19th April 1791. He left his property to a sister and two nephews.

Dr Kippis, speaking of his learning and pursuits, observes *, that "his chief aim was to lay a foundation for solid knowledge, by an application to sciences of the noblest kind. It was on the great and fundamental principles and obligations of morality, on the higher species of mathematics, on the sublimer parts of natural philosophy, on the true basis of government, and on the questions which relate to the essential welfare and dignity of man, that his studies were employed; and in the prosecution of these studies he not only enriched his own mind, but was enabled to become of eminent service to his country and to the world. In his moral writings he has laboured with distinguished ability to build the science of ethics on an immutable basis; and what he has advanced will always stand high in estimation as one of the strongest efforts of human reason in favour of the system he has adopted. For myself (adds Dr Kippis), I scruple not to say, that I regard the treatise referred to as a rich treasure of valuable information, and as deserving to be ranked among the first productions of its kind. With respect to his other ethical works, every one must admire the zeal, earnestness, and strength, with which he endeavours to lead men into pious views of God, of providence and prayer; and to promote the exercise of devout and amiable dispositions. In consequence of his profound knowledge in mathematical calculations, he was qualified at a particular crisis for being of singular utility to his fellow-citizens. A number of schemes for insurance for lives and the benefit of survivorship, promising mighty advantages, were rising up in the metropolis. These ruinous schemes would have been carried to great excess, had not Dr Price stepped forward and dispelled the delusion. Gratitude will not allow us to forget the ability and spirit with which he awakened the attention of his countrymen to the reduction of the national debt. With him it was that the scheme of the present minister for that purpose is understood to have originated. What crowned the whole of his character was, its being an assemblage of the most amiable and excellent private virtues. His piety was sincere, humble, and fervent; his soul pure and elevated; in his views disinterested and noble; and in his manners mild and gentle: the applause of his talents and virtues will be transmitted to future ages, and he will be united in the catalogue with the most eminent benefactors of mankind."

Address his neral, o.

This is the panegyric of a friend; but with few abatements it will be admitted by every candid reader. In morals Dr Price's principles were those of Cudworth and Clarke; and by many who have themselves adopted a very different theory, he is allowed to have defended those principles with greater ability than any other writer in the English language) see *Moral Philosophy*, N° 14.). In metaphysics he was perhaps too great an admirer of Plato, from whom he has borrowed a doctrine concerning ideas which we confess ourselves unable to comprehend. He was a firm believer in the immateriality of the soul; but, with Dr Law, the late learned bishop of Carlisle, he thought, that from death to the resurrection of the body it remains in a dormant or quiescent state. He contended for its indivisibility, but maintained at the same time its extension: which furnished Dr Priestley with some advantages in their celebrated controversy, which his own acuteness would never have obtained. In propagating his political principles, which were republican, he sometimes expressed himself with undue vehemence; and he was a zealous enemy to all religious establishments, which, in his opinion, encroach upon that liberty wherewith Christ has made us free. His faith respecting the Son of God was what has been called sometimes *low Arianism* and sometimes *Semi-arianism*. From a very early age he claimed the privilege of thinking for himself on every subject. His father was a rigid Calvinist, and spared no pains to instil his own theological dogmas into the tender mind of his son; but young Richard would often start his doubts and difficulties, and sometimes incur the old man's displeasure by arguing against his favourite system with an ingenuity that perplexed, and a solidity that could not be easily overturned. He had once the misfortune to be caught reading a volume of Clarke's sermons, which his father in great wrath snatched from him and threw into the fire. Perhaps he could not have taken a more effectual method to make the book a favourite, or to excite the young man's curiosity after the other works of the same author; and it is by no means improbable that this orthodox bigotry contributed more than any other circumstance to lay the foundation of his son's Arianism.

But whatever may be thought of Dr Price's speculative opinions, whether political or religious, his virtues in private life have never been called in question. Of his practical religion it is impossible to speak in terms too high. There was a fervour even in his public prayers which indicated the strongest sensibility as well as sincerity in himself, and communicated its warmth to those who joined with him. But in his family devotions he gave still fuller scope to the pious emotions of his soul, and proved to those friends who were occasionally present at them how deeply he felt religious impressions, and how happily he blended in this as well as in other things the cool decisions of the understanding with the amiable and exalted sensibilities of the heart.

But it is not in devotion only that these sensibilities were displayed. He was as exemplary in affection to his relatives as in love to his Maker. Of this he gave a striking though private instance before he first quitted his native place to try his fortune in London. His father had left to an elder brother by a former marriage a very considerable fortune; to Richard he left a mere trifle; and to each of two sisters still less. Our author divided his share between his sisters, reserving

Price.

ving to himself only a few pounds to defray the expences of his journey, and trusting for his future support to the blessing of God upon his talents and his industry. As in early life he was an affectionate and generous brother, in old age he was a loving and attentive husband. His wife, who for a considerable time before her death was almost wholly helpless, found during the last years of her life hardly any enjoyment except in a game at whist; and though our Doctor disliked cards as a waste of time, and never touched them on any other occasion, to amuse her he would sit down every evening to the card-table, and play till it was late, with a cheerfulness and good humour which charmed every person who had the happiness of viewing him in that endearing situation.

Yet, though thus attentive to the obligations of domestic life, he did not suffer his private affections to encroach upon his social duties. His talents and his labours were ever ready at the call of friendship; nay so much did his nature abound with the milk of human kindness, that he could not resist without extreme reluctance even troublesome and unreasonable solicitations. His hours of study and retirement were frequently broken in upon by applications for assistance and advice, especially in matters relating to annuities and life-insurances; and in this way he sacrificed much of his personal convenience to individuals of whom he knew but little, and from whom he would accept of no pecuniary recompense. His good nature in this respect amounted almost to a foible; and subjected him to importunities and loss of time, of which he would sometimes complain as interfering materially with more important and more generally useful studies.

Whilst he thus obliged the rich by his mental talents, he succoured the poor with his earthly substance. A fifth part of his annual income was regularly devoted to charitable purposes; and he was laudably anxious to distribute it in such a way as might produce the greatest good. In the practice of this, and indeed of all his virtues, he was utterly devoid of ostentation. Simplicity and humility were among the strong features of his character. No man was ever less sensible of his own excellence, or less elated by his own celebrity; and in no man was the dignity of artless manners and unaffected modesty more happily displayed.

His face was the true index of his mind. It beamed with philanthropy; and when lighted up in conversation with his friends, assumed an aspect peculiarly pleasing. His person was slender, and rather below the common size, but possessed of great muscular strength and remarkable activity. A habit of deep thought had given a stoop to his figure, and he generally walked a brisk pace with his eyes on the ground, his coat buttoned, one hand in his pocket, and the other swinging by his side.

It is natural to suppose that such a man as Dr Price, some of whose writings were translated into foreign languages, would be very generally respected in the republic of letters, and have many correspondents. The supposition is well founded. In 1763 or 1764 he was chosen a fellow of the Royal Society, and contributed largely to the transactions of that learned body; in 1769 he received from Aberdeen a diploma creating him DD.; and in 1783 the degree of LL.D. was conferred upon him by the college of Yale in Connecticut. As in 1770 he had refused an American degree which had been conveyed to him by Dr Franklin, his acceptance of one 13 years afterwards can be attributed only to his extravagant attachment to a republican form of government; which was the greatest defect in his character, and shows what prejudices the most vigorous mind will imbibe by thinking always on the same subjects, and in the same track. Among his correspondents, the most eminent in his own country were the late Lord Chatham, Lord Stanhope, Lord Lansdowne, the late bishops of Carlisle and St Asaph, and the present bishop of Landaff; Mr Hume, Mr Harris of Salisbury, Dr Gregory of Edinburgh, and the celebrated Mr Howard, who lived with him on terms of the greatest intimacy; in America he corresponded with Dr Franklin, Dr Chauncey, Mr Adams, and others; and in France with the celebrated Turgot, the Duke de Rochefoucault, and several of the first national assembly. One of his female correspondents sketched his character with great justness many years ago under the fictitious but well applied name of *Simplicius*; and with this character we shall close these short memoirs.

"While the vain man is painfully striving to outshine the company, and to attract their admiration by false wit, forced compliments, and studied graces, he must surely be mortified to observe how constantly Simplicius engages their attention, respect, and complacency, without having once thought of himself as a person of any consequence among them. Simplicius imparts his superior knowledge, when called upon, as easily and naturally as he would tell you what it is o'clock; and with the same readiness and good will informs the most ignorant or confers with the most learned. He is as willing to receive information as to give it, and to join the company, as far as he is able, in the most trifling conversation into which they may happen to fall, as in the most serious and sublime. If he disputes, it is with as much candour on the most important and interesting as on the most insignificant subjects; and he is not less patient in hearing than in answering his antagonist. If you talk to him of himself or his works, he accepts praise or acknowledges defects with equal meekness, and it is impossible to suspect him of affectation in either. We are more obliged by the plain unexaggerated expressions of his regard, than by the compliments and attentions of the most accomplished pattern of high breeding; because his benevolence and sincerity are so strongly marked in every look, word, and action, that we are convinced his civilities are offered for our sakes, not for his own, and are the natural effects of real kindness, not the studied ornaments of behaviour. Every one is desirous to show him kindness in return, which we know will be accepted just as it is meant. All are ready to pay him that deference which he does not desire, and to give him credit for more than he assumes, or even more than he possesses. With a person ungraceful, and with manners unpolished by the world, his behaviour is always proper, easy, and respectable; as free from constraint and servility in the highest company, as from haughtiness and insolence in the lowest. His dignity arises from his humility; and the sweetness, gentleness, and frankness of his manners, from the real goodness and rectitude of his heart, which lies open to inspection in all the fearlessness of truth, without any need of disguise or ornament."

Such

Such was Dr Price.—Of his public principles men will think differently; of his private worth there can be but one opinion. He will live in the memory of his friends till memory has lost her power. To posterity his works will be his monument. They are: A Review of the principal Questions and Difficulties in Morals, 8vo, 1758; Dissertations on Providence, &c. 8vo. 1767; Observations on Reversionary Payments, &c. 8vo. 1771; Appeal on the National Debt, &c. 8vo. 1773; Observations on the Nature of Civil Liberty, 1776: on Materialism and Necessity, in a correspondence between Dr Price and Dr Priestley, 1779; on Annuities, Assurances, Population, &c. 8vo. 1779; on the Population of England, 1780; on the Public Debts, Finances, Loans, &c. 8vo. 1783; on Reversionary Payments, 2 vols. 1783; on the importance of the American Revolution, 1784: besides Sermons, and a variety of papers in the Philosophical Transactions on astronomical and other philosophical subjects.

PRIDE, inordinate and unreasonable self-esteem, attended with insolence and rude treatment of others.—It is frequently confounded with vanity, and sometimes with dignity; but to the former passion it has no resemblance, and in many circumstance it differs from the latter. Vanity is the parent of loquacious boasting; and the person subject to it, if his pretences be admitted, has no inclination to insult the company. The proud man, on the other hand, is naturally silent, and, wrapt up in his own importance, he seldom speaks but to make his audience feel their inferiority. It is this circumstance which distinguishes pride from dignity, and constitutes its sinfulness. Every man possessed of great powers of mind is conscious of them, and feels that he holds a higher rank in the scale of existence than he whose powers are less. If he recollect, at the same time, that he has nothing which he did not receive, and that his superiority is owing to the good pleasure of Him who forms his creatures differently, as the potter forms his clay; he will be so far from insulting his inferiors, that when necessarily in company with them he will bear with their foibles, and, as far as is proper, make them lose sight of the distance which the laws of God and man have for ever placed between them and him. This condescension, however, if he be a man of dignity, will never lead him to join with them in any mean or dirty action. He will even excuse in them many things which he would condemn in himself, and give them his good wishes, after they have forfeited his esteem. Such a character is amiable and respectable, and what every man should labour to obtain. From the weakness of human nature, however, it is too apt to degenerate into pride.

To a man of great intellectual powers and various erudition, the conversation of ordinary persons affords neither instruction nor amusement; and such conversation, when often repeated, must, from the nature of things, become tedious and irksome. But it requires great command of temper and of manners to prevent uneasiness long felt from sometimes betraying itself by external symptoms, such as peevish expressions, a forbidding look, or absence of mind; and these are the infallible indications of contempt for the company, the very worst ingredient in the passion of pride. If this contempt be often excited, it will be formed into a habit; and the proud man will be so much under its influence, as to insult his inferiors, and sometimes his equals, without forming the resolution to insult either the one or the other. Such a character is hateful to every company, and is so far from indicating true dignity of mind in him to whom it belongs, that it is obviously associated with meanness, and indicates a consciousness of some radical defect. He who possesses real and conspicuous merit has no occasion to depress others for the purpose of raising himself; his superiority will be cheerfully acknowledged; but when a man of undoubted eminence in one respect, is so swollen with pride as to make him wish to appear great in all respects, he has no other means of enforcing his ill-founded claim, than displaying his acknowledged superiority, with such insolence as may drive at a distance from him every person by whom he is conscious that in many instances he might be more than rivalled. Whoever is proud of knowledge, would do well to consider how much knowledge he wants.

The same observations which we have made on pride of parts will apply to every other species of pride, such as pride of birth, office, or riches, &c. The peace and order of society require difference of rank, accompanied with different degrees of authority; and he who inherits a title or office from his ancestors, may without pride be conscious of his superiority, provided he forget not that such superiority is conferred on families and individuals, not for their own sakes, but for the good of the community. The peer who keeps this circumstance in mind, may maintain his station, and repress the forward petulance of the plebeian, without giving offence to any thinking man; but if he dwell upon his rank with too much complacency, he will in process of time be apt to consider himself and his family as superior by nature to those upon whom no title has been conferred, and then his pride will become intolerable. If we could trace our descents, says Seneca, we should find all slaves to come from princes, and all princes from slaves. To be proud of knowledge, is to be blind in the light; to be proud of virtue, is to poison ourselves with the antidote; to be proud of authority, is to make our rise our downfal. The best way to humble a proud man is to neglect him.

PRIDEAUX, Humphry, a learned clergyman of the church of England, was born at Padstow in Cornwall in 1648. He studied three years at Westminster under Dr Busby; and then was removed to Christ-church, Oxford. Here he published, in 1676, his *Marmora Oxoniensia ex Arundelianis, Seldenianis, aliique conflata, cum perpetuo Commentario.* This introduced him to the lord chancellor Finch, afterward earl of Nottingham, who in 1679 presented him to the rectory of St Clements near Oxford, and in 1681 bestowed on him a prebend of Norwich. Some years after he was engaged in a controversy with the Papists at Norwich, concerning the validity of the orders of the church of England, which produced his book upon that subject. In 1688 he was installed in the archdeaconry of Suffolk; to which he was collated by Dr Lloyd, then bishop of Norwich. In 1691, upon the death of Dr Edward Pococke, the Hebrew professorship at Oxford being vacant, was offered to Dr Prideaux, but he refused it. In 1697, he published his Life of Mahomet, and in 1702 was installed dean of Norwich. In 1710 he was cut for the stone, which interrupted his studies for

for more than a year. Some time after his return to London, he proceeded with his Connection of the History of the Old and New Testament; which he had begun when he laid aside the design of writing the History of Appropriations. He died in 1724.

Chandler's Travels in Asia Minor.

PRIENE, an ancient town of Asia Minor. It is now called *Samsun*, and *Samsun-katesi*, which do not however appear to be very recent. It was taken in 1391 by Bajazet, who subdued Ionia. It had formerly, without including the citadel, three gateways; one of which was towards Kelibesh, an adjoining village; and without it are vaults of sepulchres. The entrance was not wide. A part of the arch, consisting of a single row of massive stones, still remains: but those on which it rests are so corroded by age, broken, or distorted, as to seem every moment ready to yield and let down their load. A rugged way leads to a second opening in the wall opposite to this, and about a mile from it; beyond which are likewise vaults of sepulchres. Between these was a gate facing to the plain; and on the left hand going out of it is a hole, resembling the mouth of an oven, in the side of a square tower; and over it an inscription in small characters, exceedingly difficult to be read. It signifies, that a certain Cyprian in his sleep had beheld Ceres and Proserpine arrayed in white; and that in three visions they had enjoined the worship of a hero, the guardian of the city, and pointed out the place where, in obedience to them, he had erected the god. This was probably some local hero, whose little image was set in the wall, and whose name and memory have perished.

PRIEST, a person set apart for the performance of sacrifice, and other offices and ceremonies of religion. Before the promulgation of the law of Moses, the first-born of every family, the fathers, the princes, and the kings, were priests. Thus Cain and Abel, Noah, Abraham, Melchizedec, Job, Isaac, and Jacob, offered themselves their own sacrifices. Among the Israelites, after their exod from Egypt, the priesthood was confined to one tribe, and it consisted of three orders, the *high*-priest, *priests*, and *Levites*. The priesthood was made hereditary in the family of Aaron, and the first-born of the oldest branch of that family, if he had no legal blemish, was always the high-priest. This divine appointment was observed with considerable accuracy till the Jews fell under the dominion of the Romans, and had their faith corrupted by a false philosophy.—Then, indeed, the high-priesthood was sometimes set up to sale, and instead of continuing for life, as it ought to have done, it seems from some passages in the New Testament, to have been nothing more than an annual office. There is sufficient reason, however, to believe, that it was never disposed of but to some descendant of Aaron, capable of filling it, had the older branches been extinct. (For the consecration and offices of the Jewish priesthood, we refer our readers to the books of Moses). In the time of David, the inferior priests were divided into 24 companies, who were to serve in rotation, each company by itself, for a week. The order in which the several courses were to serve was determined by lot; and each course was in all succeeding ages called by the name of its original chief.—All nations have had their *priests*. The pagans had *priests* of Jupiter, Mars, Bacchus, Hercules, Osiris, and Isis, &c.; and some deities had *priestesses*. The Mahometans have priests of different orders, called *schiek*, and *mufti*; and the Indians and Chinese have their *bramins* and *bonzes*.

It has been much disputed, whether, in the Christian church, there be any such officer as a *priest*, in the proper sense of the word. The church of Rome, which holds the *propitiatory* sacrifice of the *mass*, has of course her proper *priesthood*. In the church of England, the word *priest* is retained to denote the second order in her hierarchy, but we believe with very different significations, according to the different opinions entertained of the Lord's supper. Some few of her divines, of great learning, and of undoubted Protestantism, maintain that the Lord's supper is a *commemorative* and *eucharistical sacrifice*. Those consider all who are authorised to administer that sacrament as in the strictest sense *priests*. Others hold the Lord's supper to be a *feast* upon the *one* sacrifice, once offered on the cross; and these too must consider themselves as clothed with some kind of priesthood. Great numbers, however, of the English clergy, perhaps the majority, agree with the church of Scotland, in maintaining that the Lord's supper is a rite of no other moral import, than the mere commemoration of the death of Christ. These cannot consider themselves as *priests* in the rigid sense of the word, but only as *presbyters*, of which the word *priest* is a contraction of the same import with *elder*. See *SUPPER of the Lord*.

PRIESTLEY, JOSEPH, LL.D. F. R. S. and member of many foreign literary societies, was born on the 24th of March 1733, at Field-head, in the parish of Bristall, in the west riding of Yorkshire. His father was a cloth-manufacturer, and both his parents were respectable among Calvinistic dissenters. A strong desire for reading was one of the first passions which this philosopher exhibited, and which probably induced his parents and friends to change their mind respecting his destination, and instead of a tradesman, to fit him for some learned profession. He acquired a knowledge of Hebrew, Greek, and Latin, in the school of an eminent teacher at Bartley, and at the age of 19 became a theological student in the academy of Daventry. When about the age of 22 he was made choice of to be assistant minister to the Independent congregation of Needham-market, in Suffolk. Having staid at Needham for about three years, he received an invitation to be pastor of a small flock at Namptwitch, in Cheshire, of which he accepted. Here he opened a day-school, in the management of which he displayed that turn for research, and that spirit of improvement, which were afterwards destined to be such prominent features of his character. His reputation as a man of extraordinary talents and diligent enquiry soon spread among his professional brethren, and when Dr Aikin was chosen to succeed the reverend Dr Taylor as tutor in divinity at Warrington, the vacant department of belles lettres was assigned to Mr Priestley.

His literary career may probably be said to have commenced at Warrington; and the extent, as well as the originality of his pursuits, were soon announced to the world by a variety of valuable publications. Much of his attention about this period was taken up with general politics, on which he delivered a number of lectures. Although it was reasonable to think that his time would be sufficiently occupied by his academical and literary employments, yet his unwearied activity and industry

Priestley.

found means to accomplish the first great work in philosophy which laid a solid foundation for his future fame.

Having long amused himself with an electrical machine, and felt himself interested in the progress of discovery in that branch of physics, he undertook a history of electricity, with an account of its present state. This work made its first appearance at Warrington in the year 1767, which was so well received by the learned world, that it went through a fifth edition in 4to in the year 1794. It is justly deemed a valuable performance, and its original experiments are allowed to be very ingenious.

About the year 1768, he was chosen pastor of a large and respectable congregation of Protestant dissenters at Leeds, which made him turn a very large share of his attention to theological subjects. His mind is said to have been strongly impressed with sentiments of piety and devotion from a child; and though he changed most of those religious sentiments in which he had been instructed, for such as he regarded to be more rational and consistent with truth, his piety and devotion never deserted him.

He was at the head of the modern Unitarians, whose leading tenet is the proper humanity of Christ, confining every species of religious worship and adoration to the one supreme. Some, we believe, have charged him with a design to subvert the Christian religion; but such an insinuation argues a total want of candour, as zeal for Christianity, as a divine dispensation, and the most valuable of all gifts bestowed upon the human race, was his ruling passion.

His History and present state of Discoveries relating to Vision, Light, and Colours, appeared in 1772, in two vols. 4to. This is allowed to be a performance of great merit, having a lucid arrangement; but it did not bring him such a large share of popularity as his History of Electricity, as it is probable that he was scarcely qualified to explain the abstruser parts of the science. In the year 1770, he quitted Leeds for a situation entirely different. His philosophical writings, and the recommendation of Dr Price had made him so favourably known to the earl of Shelburne, that this nobleman made him such advantageous proposals for residing with him, that a regard for his family would not permit them to be rejected. The domestic tuition of Lord Shelburne's sons having been previously committed to a man of merit, they received no instructions from Dr Priestley farther than some courses of experimental philosophy. He also attended his lordship in a visit to Paris, where he had an opportunity of seeing some of the most celebrated men of science in that country, whom he astonished by asserting a firm belief in revealed religion, which had been presented to their minds in such colours, that they thought no man of sense could hesitate in rejecting it as an idle fable.

In 1775, he published his examination of Dr Reid on the Human Mind; Dr Beattie on the Nature and Immutability of Truth; and Dr Oswald's Appeal to Common Sense. The design of this volume was to refute the new doctrine of *common sense*, employed as the test of truth by the metaphysicians of Scotland. He never intentionally misrepresented either the arguments or purposes of an opponent; but he measured the respect with which he treated him by that which he felt for him in his own mind. In the year 1777, he published his disquisitions relating to Matter and Spirit, in which he gave a history of the philosophical doctrine respecting the soul, and openly supported the *material* system, which makes it homogeneous with the body. This subjected him to more odium than any of his other opinions. As he materialized spirit, so he in some measure spiritualized matter, by assigning to it penetrability and some other subtle qualities. About the same period he became the champion of philosophical necessity; a doctrine not less obnoxious to many, on account of its supposed effects on morality, than the former. So astonishing was the versatility of his mind, that he at the same time carried on that course of discovery concerning aeriform bodies which has rendered his name so illustrious among philosophical chemists. A second volume was published in 1775, and a third in 1777. Some of his most memorable discoveries were those of nitrous and dephlogisticated or pure air; of the restoration of vitiated air by vegetation; of the influence of light on vegetables, and of the effects of respiration on the blood.

The name of Priestley was by these means spread through the countries of Europe, and honours were heaped upon him from scientific bodies in various parts. The term of his engagement with Lord Shelburne having expired, Dr Priestley was at liberty to choose a new situation for himself, retiring with a pension for life of 150l. a-year. He chose the vicinity of the populous town of Birmingham, as it was the residence of several men of science, such as Watt, Withering, Bolton, and Keir, whose names are well known to the public. Here he was invited to become pastor of a dissenting congregation, of which he accepted about the latter end of the year 1780. Soon after this appeared his Letters to Bishop Newcome, on the Duration of Christ's Ministry, and his History of the Corruptions of Christianity, which were afterwards followed by his History of Early Opinions.

He displayed his attachment to freedom by his Essay on the First Principles of Government; and by an anonymous pamphlet on the State of Public Liberty in this country; and had shown a warm interest in the cause of America at the time of its unfortunate quarrel with the mother country.

The celebration of the anniversary of the destruction of the Bastile, by a public dinner, on July 14th 1791, at which Dr Priestley was not present, gave the signal of those riots which have thrown lasting infamy on the town of Birmingham, and in some degree on the national character. Amidst burning houses of worship and private dwellings, Dr Priestley was the great object of popular rage; his house, library, manuscripts, and apparatus, were made a prey to the flames; he was hunted like a criminal, and experienced not only the furious outrages of a mob, but the most unhandsome treatment from some who ought to have sustained the parts of gentlemen, and the friends of good order. He now lay under a load of public odium and suspicion, and he was constantly harassed by the petty malignity of bigotry.

It was of consequence not to be wondered at, that he looked for an asylum in a country to which he had always shewn a friendly attachment, and which he supposed was in possession of all the blessings of civil and religious liberty. In the year 1794, he took leave of his

Priestley.

his native country, and embarked for North America. He took up his residence in Northumberland, a town in the interior of the state of Pennsylvania, which he selected on account of the purchase of landed property in its neighbourhood; otherwise its remoteness from the sea-ports, its want of many of the comforts of life, and of all the helps to scientific pursuit, rendered it a peculiarly undesirable abode for one of Dr Priestley's habits and employments. The loss of his amiable wife, and of a most promising son, as well as repeated attacks of disease, severely tried the fortitude and resignation of this great and good man.

In America he was received with general respect, and the angry contests of party were not able wholly to deprive him of the esteem due to his character. He was heard as a preacher by some of the most distinguished members of congress; and he was offered, but declined, the place of chemical professor of Philadelphia. It became his great object to enable himself in his retirement at Northumberland to renew that course of philosophical experiment, and especially that train of theological writing, which had occupied so many of the best years of his life. By numerous experiments on the constitution of airs, he became more and more fixed in his belief of the phlogistic theory, and in his opposition to the new French chemical system, of which he lived to be the only opponent of any celebrity. By the liberal contributions of his friends in England, he was enabled to commence the printing of two extensive works, on which he was zealously bent, a Church History, and an Exposition of the Scriptures; and through the progress of his final decline he unremittingly urged their completion.

An article in the Philadelphia Gazette speaks of him in the following honourable terms:

"Since his illness at Philadelphia, in the year 1801, he never regained his former good state of health. His complaint was constant indigestion, and a difficulty of swallowing food of any kind. But during this period of general debility, he was busily employed in printing his Church History, and in the first volume of his notes on the Scriptures, and in making new and original experiments. During this period, likewise, he wrote his pamphlet of Jesus and Socrates compared, and reprinted his Essay on Phlogiston.

"From about the beginning of November, 1803, to the middle of January, 1804, his complaint grew more serious; yet, by judicious medical treatment, and strict attention to diet, he, after some time, seemed, if not gaining strength, at least not getting worse; and his friends fondly hoped that his health would continue to improve as the season advanced. He, however considered his life as very precarious. Even at this time, besides his miscellaneous reading, which was at all times very extensive, he read through all the works quoted in his Comparison of the different Systems of Grecian Philosophers with Christianity; composed that work, and transcribed the whole of it in less than three months; so that he has left it ready for the press.

"In the last fortnight of January, his fits of indigestion became more alarming, his legs swelled, and his weakness increased. Within two days of his death he became so weak, that he could walk but a little way, and that with great difficulty. He was fully sensible that he had not long to live, yet he talked with cheerness to all who called on him. He dwelt upon the peculiarly happy situation in which it had pleased the divine Being to place him in life, and the great advantage he had enjoyed in the acquaintance and friendship of some of the best and wisest men of the age in which he lived, and the satisfaction he derived from having led an useful as well as happy life. On the 9th of February 1804, he breathed his last, so easily, that those who were sitting close to him did not immediately perceive it. He had put his hand to his face, which prevented them from observing it."

Priestley Primer Seasin.

In the constitution of Dr Priestley's mind ardour and vivacity of intellect were united with a mild and placid temper. With a zeal for the propagation of truth which nothing could subdue, he joined a calm patience, an unruffled serenity, which rendered him proof against disappointments. The rights of private judgment were rendered sacred to him by every principle of his understanding, and his heart would not have suffered him to injure his bitterest enemy. He was naturally disposed to be cheerful, and when his mind was not occupied with serious thoughts, could unbend with playful ease and negligence, in the private circle of friends. He commonly spoke little in large and mixed companies, and in the domestic relations of life was uniformly kind and affectionate. His parental feelings were those of the tenderest and best of fathers. Not even malice itself could ever fix a stain on his private conduct, or impeach his integrity.

PRIMÆ VIÆ, among physicians, denote the whole alimentary duct; including the œsophagus, stomach, and intestines, with their appendages.

PRIMAGE, in *Commerce*, a small duty at the waters-side, usually about 12d. per ton, or 6d. per bale, due to the master and mariners of a ship.

PRIMARY, first in dignity, chief, or principal.

PRIMARY Qualities of Bodies. See METAPHYSICS, Nº 152.

PRIMATE, in church-polity, an archbishop, who is invested with a jurisdiction over other bishops.

PRIME, PRIMUS, an appellation given to whatever is first in order, degree, or dignity, among several things of the same or like kind; thus we say, the prime minister, prime cost, &c.

Prime is sometimes used to denote the same with decimal, or the tenth part of an unit.

PRIME-Figure, in *Geometry*, one which cannot be divided into any other figures more simple than itself, as a triangle among planes, and the pyramid among solids.

For prime numbers, in arithmetic, see the article NUMBER.

PRIME of the Moon, is the new moon when she first appears, which is about three days after the change.

PRIME Vertical, is that vertical circle which passes through the poles of the meridian, or the east and west points of the horizon; whence dials projected on the plane of this circle are called *prime vertical*, or *north-and-south dials*.

PRIME, in the Romish church, is the first of the canonical hours succeeding to lauds.

PRIME, in *Fencing*, is the first of the chief guards. See GUARD.

PRIMER SEASIN, in *Feodal Law*, was a feodal burden, only incident to the king's tenants *in capite*, and not

not to those who held of inferior or mesne lords. It was a right which the king had, when any of his tenants *in capite* died seized of a knight's fee, to receive of the heir (provided he were of full age) one whole year's profits of the lands if they were in immediate possession, and half a year's profits if the lands were in reversion expectant on an estate for life. This seems to be little more than an additional relief (see RELIEF); but grounded upon this feodal reason, That by the ancient law of feods, immediately upon the death of a vassal the superior was entitled to enter and take seisin or possession of the land, by way of protection against intruders, till the heir appeared to claim it, and receive investiture; and for the time the lord so held it, he was entitled to take the profits; and unless the heir claimed within a year and day, it was by the strict law a forfeiture. This practice, however, seems not to have long obtained in England, if ever, with regard to tenures under inferior lords; but, as to the king's tenures *in capite*, this *prima seisina* was expressly declared, under Henry III. and Edward II. to belong to the king by prerogative, in contradistinction to other lords. And the king was entitled to enter and receive the whole profits of the land, till livery was sued; which suit being commonly within a year and day next after the death of the tenant, therefore the king used to take at an average the *first-fruits*, that is to say, one year's profits of the land. And this afterwards gave a handle to the popes, who claimed to be feodal lords of the church, to claim in like manner from every clergyman in England the first year's profits of his benefice, by way of *primitiæ*, or first-fruits.—All the charges arising by primer seisin were taken away by 12 Car. II. c. 24.

PRIMING, in *Gunnery*, the train of powder that is laid, from the opening of the vent, along the gutter or channel on the upper part of the breech of the gun: which, when fired, conveys the flame to the vent, by which it is further communicated to the charge, in order to fire the piece. This operation is only used on shipboard at the proof, and sometimes in garrison; for, on all other occasions, tubes are used for that purpose.

Priming-Wire, in *Gunnery*, a sort of iron needle employed to penetrate the vent or touch-hole of a piece of ordnance, when it is loaded: in order to discover whether the powder contained therein is thoroughly dry and fit for immediate service; as likewise to search the vent and penetrate the cartridge, when the guns are not loaded with the loose powder.

PRIMING, among painters, signifies the laying on of the first colour.

PRIMIPILUS, in antiquity, the centurion of the first cohort of a legion, who had the charge of the Roman eagle.

PRIMITIÆ, the first-fruits gathered off the earth, whereof the ancients made presents to the gods.

PRIMITIVE, in *Grammar*, is a root or original word in a language, in contradistinction to *derivative*; thus, *God* is a primitive; *godly*, a derivative; and *godlike*, a compound.

PRIMOGENITURE, the right of the first-born, has among most nations been very considerable. The first-born son in the patriarchal ages had a superiority over his brethren, and, in the absence of his father, was priest to the family. Among the Jews, he was consecrated to the Lord, had a double portion of the inheritance, and succeeded in the government of the family or kingdom. It is, however, remarkable, and unquestionably shows the connection between this institution and the birth and office of our Saviour, that if a woman's first child were a girl, neither she, nor the children that came after her, were consecrated.

In every nation of Europe, the right of primogeniture prevails in some degree at present, but it did not prevail always. The law which calls the elder-born to the crown, preferably to the others, was not introduced into France till very late; it was unknown to the first race of kings, and even to the second. The four sons of Clovis shared the kingdom equally among themselves; and Louis le Debonnaire did the same: it was not till the race of Hugh Capet, that the prerogative of succession to the crown was appropriated to the first-born.

By the ancient custom of *Gavel-kind*, still preserved in some parts of our island, primogeniture is of no account; the paternal estate being equally shared by all the sons. And it has been a matter of violent and learned dispute, whether at the death of Alexander III. Baliol or Bruce was, by the law as it then stood, heir to the crown of Scotland. The former had undoubtedly the right of primogeniture, but the latter stood in one degree of nearer relation to the deceased sovereign; and the Scottish barons, not being able to determine whose claim was best founded, referred the question to Edward I. of England, and thereby involved their country in a long and ruinous war. See SCOTLAND.

PRIMORIE, is a name given by the Slavi to that tract of sea-coast which lies between the two rivers Cettina and Narenta, the first of which is the Nestus and Tiluras, and the second the Narus, of the ancients; comprising what was properly called Dalmatia two ages before our era, and which was known to the Greeks of the low times under the name of *Paratalassia*. Appian informs us that the Ardei or Vardei possessed many cities there, part of which they seized before the invasion of the Romans, and part they built themselves. We learn also from the *Tabula Peutingeriana*, that after the conquest many of those cities remained, and were inhabited by the conquerors, who also founded new settlements. And indeed were these proofs wanting, the numerous inscriptions found near the sea, and sometimes among the hills, would render it at least probable. The coast is extremely pleasant, the soil fertile, and the situation most convenient for commerce with the inland provinces. By bad management, however, much ground has been lost near the sea, by its being covered with gravel; and by imprudent cultivation of the hills, the impetuous fury of the mountain torrents has rendered a part of it uninhabitable. Macarska is now the only town in the territory, and it appears to have risen out of the ruins of the ancient RATANEUM of Pliny. It formed a part of the Narentan state for several ages, and afterwards, together with the rest of Primorie, passed under the obedience of various Christian princes. It afterwards became subject to the Ottoman Porte, and at last voluntarily subjected itself to the Venetian republic. See DALMATIA and MACARSKA. See also Fortis's *Travels into Dalmatia*, p. 265—318.

PRIMULA, the PRIMROSE; a genus of plants belonging to the pentandria class: and in the natural method

Primula ‖ Prince

thod ranking under the 21st order, *Preciæ*. See BOTANY *Index*. This genus includes the primrose, the cowslip, the polyanthus, and the auricula; some of the earliest and most beautiful ornaments of the flower-garden. For the mode of culture, see GARDENING.

PRIMUM MOBILE, in the Ptolemaic astronomy, the ninth or highest sphere of the heavens, whose centre is that of the world, and in comparison of which the earth is but a point. This is supposed to contain within it all other spheres, and to give them motion, turning them quite round, as well as revolving itself, in 24 hours.

PRINCE, PRINCEPS, in polity, a person invested with the supreme command of a state, independent of any superior.

PRINCE also denotes a person who is a sovereign in his own territories, yet holds of some other as his superior; such are the princes of Germany, who, though absolute in their respective principalities, are bound to the emperor in certain services.

PRINCE also denotes the issue of princes, or those of the royal family. In France, before the revolution, they were called *princes of the blood*, and during the short continuance of the constitution of 1791, *French princes*. In England the king's children are called *sons and daughters of England*; the eldest son is created prince of Wales; the cadets are created dukes or earls as the king pleases; and the title of all the children is *royal highness*: all subjects are to kneel when admitted to kiss their hand, and at table out of the king's presence they are served on the knee. See *ROYAL Family*.

PRINCE of the Senate, in old Rome, the person who was called over first in the roll of senators, whenever it was renewed by the censors: he was always of consular and censorian dignity. See the article SENATE.

PRINCE's Metal, or *Pinchbeck*, an alloy of copper and zinc, which has a resemblance to gold. See CHEMISTRY, N° 2014.

PRINCETOWN. See *New JERSEY*.

PRINCE of Wales's Island, or *Pulo Penang*, is situated in the entrance of the straits of Malacca, in 100° of east longitude, and in 5° of north latitude. It is about seven leagues in length and three in breadth, and is supposed to contain about 160 square miles. Its northern extremity runs nearly parallel with the main land at a distance of about two miles, by which a fine channel is formed, where the greatest fleets might ride in perfect safety, the height of the surrounding mountains acting as a barrier against the force of the prevailing winds.

Edin. Phil. Trans. v. iii. p. 13, &c.

The purchase of this island from the king of Queddah, on the opposite Malay coast, was made on behalf of the East India Company by Mr Light, who took possession of it on the 12th of August 1786. The settlement continued to enjoy peace and security till the year 1791, when a jealousy on the part of the king of Queddah, probably arising from a collision of interests, threatened it with the calamities of war. Mr Light, however, anticipated the attack of the enemy, and carried the scene of action to his own shores. A fort constructed by the Malays at the town of Prya on the opposite shore, and only two miles distant from George Town in Prince of Wales's island, was taken by assault; and almost the whole of the prows collected in the river for the conveyance of troops to attack the British settlement, were destroyed. A new treaty was entered into, by which it was stipulated, that the Malay king should receive an annual payment of 6000 dollars. In 1800, a tract of land on the opposite shore, of 18 miles in length and three in breadth, was ceded to the company by the king of Queddah, on condition of receiving annually an additional sum of 4000 dollars. The number of inhabitants in 1797 was computed at about 12,000 persons of all descriptions.

Prince.

The climate, considering its vicinity to the equator, is remarkably mild. The thermometer on the high grounds never rises above 78°, seldom more than 74°; and falls as low as 66°; while on the plain it ranges from 76° to 90°. Its healthfulness is certainly not surpassed by that of any European settlement on the coast. Out of a garrison of 300 troops (natives of Hindostan), not one died for the space of 14 months; a singular fact to be experienced by a new settlement in an uncleared country. This great salubrity is perhaps the effect of a constant ventilation, supported by almost continued but gentle breezes, added to the dryness of the soil, the uniform but gradual elevation from the sea to the foot of the hills preventing those stagnations of water, which, in tropical latitudes, are so highly prejudicial to the health of man.

A ridge of beautiful mountains, deeply indented with valleys, and covered with evergreens, divides the island longitudinally. Flagstaff hill, nearly the highest on the island, is estimated at 2500 feet above the level of the sea. Innumerable rivulets receive their origin from these mountains, and are remarkable for the transparency and coolness of their waters. The soil, which is light and sandy near the sea, gradually changes to a rich clay as it approaches to the high lands. There the sugar-cane grows with the utmost luxuriance, and the most plentiful crops of rice are everywhere produced. The gardens have already furnished the inhabitants with cabbages and potatoes; and when industry shall have reached the tops of the mountains, it will be no surprise to see in the plantations most of the productions of Europe in their utmost perfection. Here are also produced pepper, cocoa-nuts, coffee, cotton, ginger, yams, sweet potatoes, a great variety of vegetables, and many different sorts of fruits. Among the exotics are the clove, nutmeg, cinnamon, pimento, hyapootee, colalava, and a number of other plants from the Moluccas and Eastern isles, introduced only a few years ago. In decorating the landscapes of this little island, nature has been peculiarly lavish. An assemblage of flowering trees and shrubs in perpetual blossom, and endless in the variety of their species, form the first shade. These are overtopped by forest trees of an immense height, which spread their vast branches on every side, and are covered with the richest foliage. Here strangers feel with rapture the effect of the breezes, which, from whatsoever quarter they blow, are strongly impregnated with the fragrance of the groves.

The original animal productions of this island are very limited. Of quadrupeds, the wild hog, deer, and squirrel, nearly comprehend the whole; but the absence of the tiger and leopard, whose numbers and ferocity almost render the opposite shores uninhabitable, amply compensates for this deficiency. The flying fox and squirrel are natives of this island; the former a nondescript,

descript, and a great natural curiosity. Of birds there are also but few, and only one which is remarkable for the melody of its notes. The crow and sparrow, the never-failing attendants on population, have but lately made their appearance. They are now, however, rapidly increasing and multiplying. All the domestic animals arrive here at great perfection.

The sea which surrounds the island, affords a vast variety of fish of the most delicious flavour, and its shores abundance of the finest turtle and oysters. In no situation indeed are the conveniencies and luxuries of life enjoyed in greater profusion. The advantages of the island in a political and commercial view are very considerable. There were nothing but wooden bridges on this island in the year 1800, which were perpetually liable to be injured, and which the rapid swell of the rivers frequently carried away; but four substantial bridges of brick and mortar were soon after that period completed, their foundations being of stone.

The markets are well supplied with different kinds of fish, poultry of all sorts, pork, grain, and great variety of the finest fruits and vegetables. The quality of the beef and veal is none of the best, and they import sheep from Bengal. Milk, butter, and bread, bear a high price, the two former of which are not very abundant.

Prince of Wales Island produces a great variety of timber, fit for every purpose of ship-building, and can furnish masts of any dimensions. Ships of 74 guns were provided with lower masts of one piece in the course of the late war.

There are few, if any places, more abundantly supplied with water, than this island, numerous streams of water flowing from the hills in every direction. Three or four of these streams unite, and form the Penang river, after traversing a considerable space; and it discharges itself into the sea, about a mile to the southward of the town.

This island contains mines of tin; but it is said they have never been worked.

Persons convicted of felonies, &c. in any of the British settlements in the East Indies are frequently banished to Prince of Wales Island, so that it may be considered as the Botany Bay of the East.

The following table exhibits the revenue and disbursements of the island, at several different periods, from 1789 to 1804.

	Revenue.	*Disbursements.*
	Dollars.	Dollars.
1789	2500	78,884
1790	4100	96,274
1791	11,235	108,290
1795	19,612	115,379
1796	28,000	192,598
1800	53,155	184,469
1802	74,280	176,000
1803	75,000 estimated.	180,000 estimated.

The imports of this island consist of the various natural productions of the east, as well as of a great variety of the manufactures of the industrious inhabitants of those regions.

In 1799, 95 English ships, 37 American, Portuguese, and Danish, and 36 Asiatic, arrived in this island. The total number of arrivals, in 1800, amounted to 193; and in 1802, to 241, equal nearly to 57,000 tons.

Prince William's Sound, situated on the north-west coast of America, and so named by Captain Cook in 1778. The men, women, and children of this sound are all clothed in the same manner. Their ordinary dress is a sort of close frock, or rather robe, which sometimes reaches only to the knees, but generally down to the ancles. These frocks are composed of the skins of various animals, and are commonly worn with the hairy side outwards. The men often paint their faces of a black colour, and of a bright red, and sometimes of a bluish or leaden hue; but not in any regular figure. The women puncture or stain the chin with black, that comes to a point in each of their cheeks. Their canoes are of two sorts; the one large and open, the other small and covered. The framing consists of slender pieces of wood, and the outside is composed of the skins of seals, or other sea animals, stretched over the wood. Their weapons, and implements for hunting and fishing, are the same as those used by the Greenlanders and Esquimaux. Many of their spears are headed with iron, and their arrows are generally pointed with bone. The food they were seen to eat was the flesh of some animal, either roasted or broiled, and dried fish. Some of the former that was purchased had the appearance of bear's flesh. They also eat a larger sort of fern-root, either baked or dressed in some other method. Their drink, in all probability, is water; for, in their canoes, they brought snow in wooden vessels, which they swallowed by mouthfuls. Our knowledge of the animals of this part of the American continent is entirely derived from the skins that were brought by the natives for sale. These were principally of bears, common and pine martens, sea otters, seals, racoons, small ermines, foxes, and the whitish cat or lynx. The birds found here were the halycon, or great king's-fisher, which had fine bright colours; the white-headed eagle, and the humming-bird. The fish that were principally brought to market for sale were torsk and holibut. The rocks were almost destitute of shell-fish; and the only other animal of this tribe that was observed was a reddish crab, covered with very large spines. Few vegetables of any kind were observed; and the trees that chiefly grew about this sound were the Canadian spruce pine, some of which were of a considerable size. E. Long. 115. 21. N. Lat. 59. 33.

PRINCIPAL, the chief and most necessary part of a thing. The principal of a college or hall is the master thereof.

In commerce, principal is the capital of a sum due or lent; so called in opposition to interest. See INTEREST.

It also denotes the first fund put by partners into a common stock, by which it is distinguished from the calls or accessions afterwards required.

PRINCIPAL, in *Music*. See FUNDAMENTAL, in MUSIC, and GENERATOR, in MUSIC.

PRINCIPAL, in *Law*, is either the actor or absolute perpetrator of the crime, who is called a *principal*, in the first degree; or he who is present, aiding and abetting the fact to be done, who is denominated a *principal* in the second degree. The presence of a principal need not

not always be an actual immediate standing by, within sight or hearing of the fact; but there may be also a constructive presence, as when one commits a robbery or murder, and another keeps watch or guard at some convenient distance. And this rule has also other exceptions; for, in case of murder by poisoning, a man may be a principal felon by preparing and laying the poison, or giving it to another (who is ignorant of its poisonous quality) for that purpose; and yet not administer it himself, nor be present when the very deed of poisoning is committed. And the same reasoning will hold, with regard to other murders committed in the absence of the murderer, by means which he had prepared before-hand, and which probably could not fail of their mischievous effect. As by laying a trap or pit-fall for another, whereby he is killed; letting out a wild beast, with an intent to do mischief; or exciting a madman to commit murder, so that death thereupon ensues: in every one of these cases the party offending is guilty of murder as a principal, in the first degree. For he cannot be called an accessory, that necessarily presupposing a principal; and the poison, the pit-fall, the beast, or the madman, cannot be held principals, being only the instruments of death. As therefore he must be certainly guilty, either as principal or accessory, and cannot be so as accessory, it follows that he must be guilty as principal; and if principal, then in the first degree; for there is no other criminal, much less a superior in the guilt, whom he could aid, abet, or assist.

Blackst. Comment. b. iv. c. 3.

Principal *Point*, in *Perspective*, is a point in the perspective plane, upon which a line drawn from the eye perpendicular to the plane falls.

This point is in the intersection of the horizontal and vertical plane; and is also called the *point of sight*, and *point of the eye*. See Perspective.

Principal *Ray*, in *Perspective*, is that which passes perpendicularly from the spectator's eye to the perspective plane, or picture.

Whence the point where this ray falls on the plane, is by some also called the *principal point*, which other writers call *the centre of the picture*, and *the point of concurrence*.

PRINCIPATO, the name of a province of Italy, in the kingdom of Naples, which is divided into two parts, called by the Italians the *Principato Ultra*, and the *Principato Citra*, the Hither and Farther Principato. The Hither Principato is bounded on the north by the Farther Principato and part of the Terra-di-Lavoro, on the west and south by the Tuscan sea, and on the east by the Basilicata. It is about 60 miles in length, and 30 in breadth; the soil is fertile in wine, corn, oil, and saffron; and they have a great deal of silk, besides several mineral springs. The capital town is Salerno. The Farther Principato is bounded on the north by the county of Molese and the Terra-di-Lavoro, on the west by the Tuscan sea, on the south by the Hither Principato, and on the east by the Capitanata. It is about 37 miles in length, and 30 in breadth. The Apennine mountains render the air cold; and the soil is not very fertile either in corn or wine, but it produces chesnuts, and pastures in great plenty. Benevento is the capital town. The population of both in 1817 was 764,000.

PRINCIPLE, Principium, in general, is used for the cause, source, or origin of any thing.

Principle, in human nature. See Disposition.

Principle, in science, is a truth, admitted without proof, from which other truths are inferred by a chain of reasoning. Principles are of two kinds, *primary* and *general*; and to the last the name of *axioms* is usually given on account of their importance and *dignity*. An axiom or *general* principle, when the terms in which it is expressed are understood, must be a self-evident truth; but from its very nature it cannot be a *first* truth. Our first truths are all *particular*. A child knows that two *particular* lines, each an inch long, are equal to one another, before he has formed any *general* notions of length and equality. "Things equal to one and the same thing are equal to one another," is the first of Euclid's axioms; and an axiom it undoubtedly is, but to no man has it been a *first* truth. It is, if we may use the expression, a *genus* or *class* of truths, comprehending under it numberless individuals. Were a full-grown man introduced into the world, without a single idea in his mind, as we may suppose Adam to have been, he would instantly perceive, upon laying together three pieces of wood each a foot long, that they were all equal in length; and if he were to cut another to the same length with *any one* of them, he would find upon trial that it was of the same length with them all. After a few simple experiments of this kind, he would, by a law of human thought, infer, that all things equal in length or in any other dimension, to any *one* thing, are in that dimension equal to one another.

It was not therefore with such weakness as some have imagined, that Hobbes affirmed those propositions commonly called axioms, not to be primary but secondary principles. A primary principle deserves not the name of an axiom, as it is only a particular truth including in it no other truth. There is not one of Euclid's axioms which has not been the result of induction, though we remember not the time at which the induction was made. That the whole is greater than any of its parts is a general truth which no man of common sense can controvert; but every one discovered that truth by observing that his body was larger than his head, his foot, or his hand; that a mountain is larger than a mole-hill in the middle of it; and that a piece of timber measuring what is called a yard is longer than any one of the divisions marked upon it, and termed inches. The particular observations are made through the senses and treasured up in the memory; and the intellect, by its constitution, compares them together, marks in what they agree and disagree, and thence draws its *axioms* or *general* principles. He, therefore, who should admit the truth of an axiom, and deny the evidence of sense and perception, would act as absurdly as he who accepts payment in a bank bill, and refuses it in the individual pieces of gold or silver which that bill represents. General axioms are of infinite use in the pursuits of science; but it is not because they create new truths; they only shorten the process in the discovery of such as might be found, with labour, through the medium of particular propositions. See *Campbell's Philosophy of Rhetoric* and *Tatham's Chart and Scale of Truth*.

Principles, in *Physics*, are often confounded with elements, or the first and simplest parts whereof natural bodies are compounded, and into which they are again resolvable by the force of fire.

PRINGLE, Sir John, an eminent physician and philosopher, Pringle. philosopher, was a younger son of Sir John Pringle of Stitchel, in the shire of Roxburgh, Baronet; took the degree of M. D. at Leyden, 1730; and published there *Dissertatio Inauguralis de Marcore Senili*, 4to. After having been some years professor of moral philosophy at Edinburgh, he was in June 1745 appointed physician to the duke of Cumberland, and physician-general to the hospital of the forces in Flanders, where the earl of Stair appears to have been his patron. In February 1746, Dr Pringle, Dr Armstrong, and Dr Barker, were nominated physicians to the hospital of lame, maimed, and sick soldiers, behind Buckingham-house; and in April 1749, Dr Pringle was appointed physician in ordinary to the king. In 1750 he published "Observations on the Nature and Cure of Hospital and Gaol Fevers, in a letter to Dr Mead," 8vo (reprinted in 1755); and in 1752 he favoured the public with the result of his long experience, in an admirable treatise under the title of "Observations on the Disorders of the Army in Camp and Garrison," 8vo. On the 14th of April 1752, he married Charlotte, second daughter of Dr Oliver, an eminent physician at Bath. In 1756 he was appointed jointly with Dr Wintringham (now Sir Clifton Wintringham, Bart.) physician to the hospital for the service of the forces of Great Britain. After the accession of his present majesty, Dr Pringle was appointed physician to the queen's household, 1761; physician in ordinary to the queen in 1763, in which year he was admitted of the college of physicians in London; and on the 5th of June 1766, he was advanced to the dignity of a baronet of Great Britain. In 1772 he was elected president of the Royal Society, where his speeches for five successive years, on delivering the prize-medal of Sir Godfrey Copley, gave the greatest satisfaction. Sir John Pringle in 1777 was appointed physician extraordinary to the king. He was also a fellow of the College of Physicians at Edinburgh, and of the Royal Medical Society at Paris; member of the Royal Academies at Paris, Stockholm, Gottingen, and of the Philosophical Societies at Edinburgh and Haerlem; and continued president of the Royal Society till November 1778; after which period he gradually withdrew from the world, and in 1781 quitted his elegant house in Pall Mall (where he had long distinguished himself as the warm friend and patron of literary men of every nation and profession), and made an excursion to his native country. He returned to London in the latter end of the year; died greatly beloved and respected, January 18. 1782; and having no children, was succeeded in estate, and also (agreeably to the limitation of the patent) in title, by his nephew, Sir James Pringle, Bart. Among the worthy physician's communications to the Royal Society, the following are the principal: 1. "Some Experiments on Substances resisting Putrefaction," Phil. Trans. N° 495. p. 580; and N° 496, p. 525, 550; reprinted, with additions, in Martin's Abridgement, vol. xi. p. 1365. 2. "Account of some Persons seized with the Gaol Fever by working in Newgate, and of the manner by which the Infection was communicated to one entire Family," vol. xlviii. p. 42. At the request of Dr Hales, a copy of this useful paper was inserted in the Gentleman's Magazine, 1753, p. 71, before its appearance in the Transactions. 3. "A remarkable Case of Fragility, Flexibility, and Dissolution of the Bones, ib. p. 297. 4. "Account of the Earthquake felt at Brussels," vol. xlix. p. 546. 5. "Account of the sinking of a river near Pontypool, in Monmouthshire," ib. p. 547. 6. "Account of an Earthquake felt Feb. 18. 1756, along the coast of England, between Margate and Dover," ib. p. 579. 7. "Account of the Earthquake felt at Glasgow and Dumbarton; also of a shower of Dust falling on a Ship between Shetland and Iceland," ib. p. 509. 8. "Several Accounts of the Fiery Meteor which appeared on Sunday, November 26. 1758, between eight and nine at night, vol. l. p. 218. 9. "Account of the Virtues of Soap in dissolving the Stone, in the Case of the Reverend Mr Matthew Simson," ib. p. 221. 10. "Account of the effects of Electricity in Paralytic Cases," ib. 481. And see a letter to him on that subject from Professor Winthorp. "Some Account of the Success of the *Vitrum Ceratum Antimonii*," was printed in the Edinburgh Medical Essays, vol. v.

Pringle ‖ Printing.

PRINOS, in *Botany*, a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 43d order, *Dumosæ*. The calyx is sexfid; the corolla monopetalous, and rotaceous; the belly hexaspermous.

PRINTER, a person who composes and takes impressions from moveable characters ranged in order, by means of ink and a press.

PRINTING, the art of taking impressions from characters or figures, moveable and immoveable, on paper, linen, silk, &c. There are three kinds of printing: the one from moveable letters, for books; another from copper-plates, for pictures; and the last from blocks, in which the representation of birds, flowers, &c. are cut, for printing calicoes, linen, &c. The first is called *common* or *letter-press* printing; the second, *rolling-press* printing; and the last, *calico*, &c. printing. The principal difference between the three consists in this, that the first is cast in relievo, in distinct pieces; the second engraven in creux; and the third cut in relievo, and generally stamped, by placing the block upon the materials to be printed, and striking upon the back of it.

1 Letter-press printing.

Of the above branches, Letter-Press Printing is the most curious, and deserves the most particular notice: for to it are owing chiefly our deliverance from ignorance and error, the progress of learning, the revival of the sciences, and numberless improvements in arts, which, without this noble invention, would have been either lost to mankind, or confined to the knowledge of a few. "To the art of printing, (says an elegant essayist *), it is acknowledged we owe the reformation. It has been justly remarked, that if the books of Luther had been multiplied only by the slow process of the hand-writing, they must have been few, and would have been easily suppressed by the combination of wealth and power; but, poured forth in abundance from the press, they spread over the land with the rapidity of an inundation, which acquires additional force from the efforts used to obstruct its progress. He who undertook to prevent the dispersion of the books once issued from the press, attempted a task no less arduous than the destruction of the hydra. Resistance was vain, and religion was reformed: and we who are chiefly interested in this happy revolution must remember, amidst the praises bestowed on Luther, that

2 Utility of this art.

* Dr Knox.

Printing.

that his endeavours had been ineffectual, unassisted by the invention of Faustus.

3 Good and evil resulting from it.

"How greatly the cause of religion has been promoted by the art, must appear, when it is considered, that it has placed those sacred books in the hand of every individual, which, besides that they were once locked up in a dead language, could not be procured without great difficulty. The numerous comments on them of every kind, which tend to promote piety, and to form the Christian philosopher, would probably never have been composed, and certainly would not have extended their beneficial influence, if typography had still been unknown. By that art, the light, which is to illuminate a dark world, has been placed in a situation more advantageous to the emission of its rays: but if it has been the means of illustrating the doctrines, and enforcing the practice of religion, it has also, particularly in the present age, struck at the root of piety and moral virtue, by propagating opinions favourable to the sceptic and the voluptuary. It has enabled modern authors wantonly to gratify their avarice, their vanity, and their misanthropy, in disseminating novel systems subversive of the dignity and happiness of human nature: but though the perversion of the art is lamentably remarkable in those volumes which issue, with offensive profusion, from the vain, the wicked, and the hungry; yet this good results from the evil, that as truth is great and will prevail, she must derive fresh lustre, by displaying the superiority of her strength in the conflict with sophistry.

"Thus the art of printing, in whatever light it is viewed, has deserved respect and attention. From the ingenuity of the contrivance, it has ever excited mechanical curiosity; from its intimate connection with learning, it has justly claimed historical notice; and from its extensive influence on morality, politics, and religion, it is now become a subject of very important speculation.

4 Its good effects overbalance the bad.

"But however we may felicitate mankind on the invention, there are perhaps those who wish, that, together with its compatriot art of manufacturing gunpowder, it had not yet been brought to light. Of its effects on literature, they assert, that it has increased the number of books, till they distract rather than improve the mind; and of its malignant influence on morals, they complain, that it has often introduced a false refinement, incompatible with the simplicity of primitive piety and genuine virtue. With respect to its literary ill consequences, it may be said, that though it produces to the world an infinite number of worthless publications, yet true wit and fine composition will still retain their value, and it will be an easy task for critical discernment to select these from the surrounding mass of absurdity: and though, with respect to its moral effects, a regard to truth extorts the confession, that it has diffused immorality and irreligion, divulged with cruel impertinence the secrets of private life, and spread the tale of scandal through an empire; yet these are evils which will either shrink away unobserved in the triumphs of time and truth over falsehood, or which may, at any time, be suppressed by the legislative interposition."

5 History of the invention of printing.

Some writers have ascribed the origin of this art to the East, and affixed a very early period to its invention; particularly P. Jovius, (*Hist.* lib. xiv. p. 226. ed. Florent. 1550), from whom Osorius and many others have embraced the same opinion. But these have evidently confounded the European mode of printing with the *engraved tablets* which to this day are used in China. The invention of these tablets has been ascribed by many writers even to an earlier period than the commencement of the Christian era; but is with more probability assigned, by the very accurate Phil. Couplet, to the year 930. The *Historia Sinensis* of Abdalla, written in Persic in 1317, speaks of it as an art in very common use. MEERMAN, vol. i. p. 16. 218, 219, vol. ii. p. 186. N. Trigault asserts that the Chinese practised the art of printing five centuries before. Count Ferre Rezzonico found at Lyons plates with words and names engraven by a Nuremberger 1380.

The honour of having given rise to the European method has been claimed by the cities of *Haerlem*, *Mentz* and *Strasburg*. And to each of these it may be ascribed in a qualified sense, as they made improvements upon one another.

6 Claim of Haerlem.

I. The first testimony of the inventor is that recorded by Hadrian Junius, in his *Batavia*, p. 253, ed. Lugd. Bat. 1588; which, though it hath been rejected by many, is of undoubted authority. Junius had the relation from two reputable men; Nicholaus Galius (A), who was the schoolmaster; and Quirinius Talesius, his intimate and correspondent. He ascribes it to LAURENTIUS, the son of John (Ædituus, or Custos, of the cathedral of HAERLEM, at that time a respectable office), upon the testimony of Cornelius, some time a servant to Laurentius, and afterwards bookbinder to the cathedral, an office which had before been performed by Franciscan friars. His narrative was thus: "That, walking in a wood near the city (as the citizens of opulence use to do), he began at first to cut some letters upon the rind of a beech tree; which, for fancy's sake being impressed on paper, he printed one or two lines, as a specimen for his grand-children (the sons of his daughter) to follow. This having happily succeeded, he meditated greater things (as he was a man of ingenuity and judgment); and first of all, with his son-in-law Thomas Peter (who, by the way, left three sons, who all attained the consular dignity), invented a more glutinous writing-ink, because he found the common ink sunk and spread; and then formed whole pages of wood, with letters cut upon them; of which sort I have seen some essays, in an anonymous work, printed only on one side, entitled *Speculum nostræ salutis*: in which it is remarkable, that in the infancy

(A) Galius seems to be the same who is called *Claes Lottynsz. Gael*, Scabinus Harlemi, as it is in the Fasti of that city, in the years 1531, 1533, and 1535. Quirinus in the same Fasti is called *Mr Quiryn Dirkszoon.* He was many years amanuensis to the great Erasmus, as appears from his epistle, 23d July 1529. tom. iii. Oper. p. 1222. He was afterwards Scabinus in 1537 et seq. and consul in 1552 et seq. But in the troubles of Holland he was cruelly killed by the Spanish soldiers, May 23. 1563. There are some letters of Hadrian Junius to this Talesius, in the *Epistolæ Junianæ*, p. 198.

fancy of printing (as nothing is complete at its first invention) the back sides of the pages were pasted together, that they might not by their nakedness betray their deformity. These beechen letters he afterwards changed for leaden ones, and these again for a mixture of tin and lead [*stanneæ*] as a less flexible and more solid and durable substance. Of the remains of which types, when they were turned to waste metal, those old wine-pots were cast, that are still preserved in the family-house, which looks into the market-place, inhabited afterwards by his great-grandson Gerard Thomas, a gentleman of reputation; whom I mention for the honour of the family, and who died old a few years since. A new invention never fails to engage curiosity. And when a commodity never before seen excited purchasers, to the advantage of the inventor, the admiration of the art increased, dependents were enlarged, and workmen multiplied; the first calamitous incident! Among these was one John, whether, as we suspect, he had ominously the name of *Faustus* (B), unfaithful and unlucky to his master, or whether it was really a person of that name, I shall not much inquire; being unwilling to molest the silent shades, who suffer from a consciousness of their past actions in this life. This man, bound by oath to keep the secret of printing, when he thought he had learned the art of joining the letters, the method of casting the types, and other things of that nature, taking the most convenient time that was possible, on Christmas eve, when every one was customarily employed in lustral sacrifices, seizes the collection of types, and all the implements his master had got together, and, with one accomplice, marches off to Amsterdam, thence to Cologne, and at last settled at Mentz, as at an asylum of security, where he might go to work with the tools he had stolen. It is certain, that in a year's time, viz. in 1442, the *Doctrinale* of Alexander Galius, which was a grammar much used at that time, together with the *Tracts* of Peter of Spain, came forth there, from the same types as Laurentius had made use of at Haerlem."

Thus far the narrative of Junius, which he had frequently heard from Nicolaus Galius; to whom it was related by Cornelius himself, who lived to a great age, and used to burst into tears upon reflecting on the loss his master had sustained, not only in his substance, but in his honour, by the roguery of his servant, his former associate and bedfellow. Cornelius, as appears by the registers of Haerlem cathedral, died either in 1515, or the beginning of the following year; so that he might very well give this information to Nicolaus Galius, who was schoolmaster to Hadrian Junius.

Though this circumstance is probable as to the main fact, yet we must set aside the evidence of it in some particulars. 1. The first obvious difficulty is noticed by Scriverius; "that the types are said to be made of the *rind* of beach, which could not be strong enough to bear the impression of the press:" though this is removed, if, instead of the *bark*, we substitute a *bough* of the beech. The idea of the *bark*, when Junius wrote this, was perhaps strong in his mind, from what Virgil

Bower and Nichols's Origin of Printing.

tells us (Ecl. v. 13.) of its being usual to cut words on the *bark* of a beech; and thence he was easily led to make a wrong application of it here.

2. The letters were at first *wooden*, and are said to be afterwards exchanged for *metal* types; from which the wine-pots were formed, remaining in the time of Junius. According to tradition, printing was carried on in the same house long after the time of Laurentius: these pots might therefore be formed from the waste metal of the printing-house, after the use of *fusile types* became universal.—But Laurentius seems to have carried the art no farther than *separate wooden types*. What is a remarkable confirmation of this, Henry Spiechel, who wrote, in the 16th century, a Dutch poem entitled *Hertspiegel*, expresses himself thus: "Thou first, Laurentius, to supply the defect of wooden tablets, adaptedst *wooden types*, and afterwards didst connect them with a thread, to imitate writing. A treacherous servant surreptitiously obtained the honour of the discovery. But truth itself, though destitute of common and wide-spread fame; truth, I say, still remains." No mention in the poem of *metal types*; a circumstance which, had he been robbed of such, as well as of *wooden* ones, would scarcely have been passed over in silence.

When Laurentius first devised his rough specimen of the art, can only be guessed at. He died in 1440, after having published the *Speculum Belgicum*, and two editions of *Donatus*, all with different *wooden types*; which it is probable (considering the difficulties he had to encounter, and the many artists whom he must necessarily have had occasion to consult) cost him some years to execute; so that the first essay might be about 1430, which nearly agrees with Petrus Scriverius, who says, the invention was about 10 or 12 years before 1440. See LAURENTIUS.

3. What was the specimen he first diverted himself with in cutting, at the distance of three centuries, one would think impossible to be discovered. And yet Joh. Enschedius, a printer, thinks he was so happy as to find it, being an old parchment *Horarium*, printed on both sides, in eight pages, containing the Letters of the Alphabet, the Lord's Prayer, the Apostles Creed and three short prayers. And Mr Meerman having shown this to proper artists who were judges of these matters, they gave it as their opinion that it agreed exactly with the description of Junius. It is conformable to the first editions of the Dutch *Speculum Salvationis*, and the fragments of both *Donatus's* of Holland, both which are the works of the same Laurentius, and were preceded by this. In these types, which are certainly moveable, cut, and uneven, there is a rudeness which Mr Meerman has not observed in any other instances. There are no numbers to the pages, no signatures, no *direction-words*, no divisions at the end of the lines; on the contrary, a syllable divided in the middle is seen, thus, *Spi ritū*, in p. 8. l. 2, 3. There are neither distinctions nor points, which are seen in the other works of Laurentius; and the letter *i* is not marked with an accent, but with a dot at the top. The lines throughout

(B) *John Faust*, or *Fust*, is by many supposed to have derived his name from *faustus*, "happy;" and Dr Faustus seems to carry an air of grandeur in the appellation: but very erroneously. *John Faust*, or *Fust*, is no more than *John Hand*, whence our name *Fist*.

Printing. out are uneven. The shape of the pages not always the same; not (as they should be) rectangular, but sometimes rhomb-like, sometimes an *isoscele trapezium:* and the performance seems to be left as a specimen both of his piety, and of his ingenuity in this essay of a new invented art. Mr Meerman has given an exact engraving of this singular curiosity.

But, whatever else may appear doubtful in the narrative of Junius, it is very clear, that the first essays of the art are to be attributed to Laurentius, who used only *separate wooden types*. See the article LAURENTIUS.

Printing. II. Some of Laurentius's types were stolen from him by one of his servants (c) *John* GEINSFLEICH *senior;* who fled therewith to MENTZ. Having introduced the art from Haerlem into this his native city, he set with all diligence to carry it on; and published, in 1442, *ALEXANDRI GALLI Doctrinale*, and *PETRI HISPANI Tractatus;* two works, which, being small, best suited his circumstances; and for which, being much used in the schools, he might reasonably expect a profitable sale. They were executed with *wooden types*, cut after the model of those he had stolen.

7 Claim of Mentz.

In 1443 he hired the house Zum Jungen; and was assisted

(c) Authors differ as to the person who committed this robbery. It is clear from all accounts that his name was *John;* but what his surname was is the disputed point. Junius, after some hesitation, ascribes it to John Fust; but with injustice: for he was a wealthy man, who assisted the first printers at Mentz with money; and though he afterwards was proprietor of a printing-office, yet he never, as far as appears, performed any part of the business with his own hands, and consequently he could never have been a servant to Laurentius. Nor is the conjecture of Scriverius better founded, which fixes it upon John Gutenberg, who (as appears by authentic testimonies) resided at Strasburg from 1436 to 1444, and during all that period employed much fruitless labour and expence in endeavouring to attain this art. Mr Meerman once thought, "it might be either John Meidenbachius, (who, we are told by Seb. Munster and the author of *Chronographia Moguntinensis*, was an assistant to the first Mentz printers); or John Petersheimius (who was some time a servant to Fust and Schoeffer, and set up a printing-house at Francfort in 1459): or, lastly, some other person, who, being unable through poverty to carry on the business, discovered it to *Geinsfleich* at Mentz." But more authentic intelligence afterwards convinced him there were two persons of this name; and that John Geinsfleich senior * was the dishonest servant, who was born at Mentz, and who in the papers published by Kohlerus, we find there in the year 1441, and not before: for though he was of a good family, yet he was poor, and seems to have been obliged, as well as his brother, to seek his livelihood in a foreign country; and perhaps was content to be under Laurentius, that, when he had learned the art, he might follow it in his own. But, to leave conjecture, we may produce some certain testimonies.

1. It is what Junius himself says, that the person who stole the types did it with a view to set up elsewhere; nor is it likely that he would either make no use of an art he had seen so profitable to Laurentius, or that he would teach it to another and submit to be again a servant.

The Lambeth Record (which is printed below, from Mr Atkyns) tells us, that "Mentz gained the art by the brother of one of the workmen of Haerlem, who learned it at home of his brother, who after set up for himself at Mentz."—By the strictest examination of the best authorities, it is plain, that by these *two brothers* the two Geinsfleiches must be meant. But as the younger (*Gutenberg*) was never a servant to Laurentius, it must be the senior who carried off the types, and instructed his brother in the art; who first applied himself to the business at Strasburg, and afterwards joined his elder brother, who had in the mean time settled at Mentz.

What is still stronger, two chronologers of Strasburg, the one named *Dan Speklinus*, the other anonymous (in Meerman's *Documenta*, N° LXXXV. LXXXVI.), tell us expressly, that John Geinsfleich (viz. the senior, whom they distinguished from Gutenberg), having learned the art by being servant to its *first inventor*, carried it by theft into Mentz his native country. They are right in the fact, though mistaken in the application of it; for they make Strasburg the place of the invention, and Mentelius the inventor, from whom the types were stolen. But this is plainly an error: for Geinsfleich lived at Mentz in 1441, as appears from undoubted testimonies; and could not be a servant to Mentelius, to whom the before-mentioned writers ascribe the invention in 1440, though more ancient ones do not attempt to prove that he began to print before 1444 or 1448. Nor will the narrative agree better with Gutenberg, who was an earlier printer than Mentelius; since, among the evidences produced by him in his law-suit, 1439, no Geinsfleich senior appears, nor any other servant but Laurentius Beildek. The narration therefore of the theft of Geinsfleich, being spread by various reports through the world, and subsisting in the time of these chronologers, was applied by them (to serve the cause they wrote for) to Strasburg; but serves to confirm the truth, since no writer derives the printing spoils from any other country than Holland or Alsatia. The chronologers have likewise, instead of Fust, called Gutenberg the wealthy man; who, from all circumstances, appears to have been poor, They also call Schoeffer the son-in-law of Mentelius; when it is clear that he married the daughter of Fust.

* He was called *Geinsfleich* κατ' ἐξοχήν; the other was distinguished by the name of *Gutenberg*. They were both poor; though of a family distinguished by knighthood. They were both married men; and were most probably brothers, as it was not uncommon in that age for two brothers to have the same Christian name. These both appear in a disreputable light. The eldest robbed his master, with many aggravating circumstances. The youngest was remarkably contentious; and, after entering into a contract of marriage with Anna, a noble girl of *The Iron Gate*, refused to marry her till compelled by a judicial decree; and afterwards cared not what became of the lady, but left her behind at Strasburg when he removed to Mentz. He had not only frequent quarrels with his wife; but with *Andrew Drizehen*, *Andrew Heilmann*, and *John Riff*, all of whom were associated with him at Strasburg in his different employments of making of looking glasses, polishing of precious stones, and endeavouring to attain the art of printing; and with these he involved himself in three law-suits. See *Meerman*, vol. i. p. 163, &c. N.

Printing. assisted with money by FUST, a wealthy person, who in return had a share of the business: and about the same time *John Meidenbachius* was admitted a partner, as were some others whose names are not transmitted to our times; and in 1444 they were joined by GUTENBERG, who for that purpose quitted Strasburg. Wooden types being found not sufficiently durable, and not answering expectation in other respects, the two brothers first invented *cut metal types*. But while these were preparing, which must have been a work of time, several works were printed, both on *wooden separate types* and on *wooden blocks;* which were well adapted to small books of frequent use, such as the *Tabula Alphabetica*, the *Catholicon*, *Donati Grammatica*, and the *Confessionalia*.

From the above-mentioned printers in conjunction, after many smaller essays, the Bible was published in 1450, with *large cut metal types* (D). And it is no wonder, considering the immense labour this work cost, that it should be seven or eight years in completing. In this same year the partnership was dissolved, and a new one entered into, in August, between *Fust* and *Gutenberg;* the former supplying the money, the latter skill, for their common benefit. Various difficulties arising, occasioned a law-suit for the money which Fust had advanced; which was determined against Gutenberg. A dissolution of this partnership ensued in 1455; and in 1457 a magnificent edition of the Psalter was published by *Fust* and *Schoeffer*, with a remarkable commendation, in which they assumed to themselves the merit of a new invention (viz. of *metal types*), *ad inventionem artificiosam imprimendi ac characterizandi*. This book was uncommonly elegant, and in some measure the work of Gutenberg; as it was four years in the press, and came out but 18 months after the partnership was dissolved between him and Fust.

The latter continued in possession of the printing-office: and *Gutenberg*, by the pecuniary assistance of Conrad Humery syndic of Mentz (E), and others, opened another office in the same city; whence appeared, in 1460, without the printer's name, the *Catholicon Jo. de Janua*, with a pompous colophon in praise of its beauty, and ascribing the honour of the invention to the city of Mentz. It was a very handsome book, though inferior to the Psalter which had been published in 1457 by Fust and Schoeffer. Both the Psalter and *Catholicon* were printed on *cut metal types* (F). It may not be improper to observe here, that as the Psalter is the earliest book which is known to have a genuine date, it became a common practice, after that publication, for printers to claim their own performances, by adding their names to them.

III. The progress of the art has been thus traced through its *second* period, the invention of *cut metal types*. But the honour of completing the discovery is due to PETER SCHOFFER (G) de Gernsheim.

8 Invention of casting types. A very clear account of this final completion of the types is preserved by Trithemius (H). *Post hæc inventis successerunt subtiliora, inveneruntque modum* fundendi formas *omnium Latini alphabeti literarum, quas ipsi* matrices *nominabant: ex quibus rursum æneos sive stanneos characteres fundebant, ad omnem pressuram sufficientes, quos prius manibus sculpebant. Et revera sicuti* ante *xxx* ferme annos *ex ore Petri Opilionis de Gernsheim, civis Moguntini, qui gener erat primi artis inventoris, audivi, magnam à primo inventionis suæ hæc ars impressoria habuit difficultatem.—Petrus autem memoratus Opilio, tunc famulus postea gener, sicut diximus, inventoris primi Johannis Fust, homo ingeniosus et prudens, faciliorem modum* fundendi characteres *excogitavit, et artem, ut nunc est, complevit.*

Another ample testimony in favour of Schoeffer is given by Jo. Frid. Faustus of Aschaffenburg, from papers preserved in his family: "Peter Schoeffer of Gernsheim, perceiving his master Fust's design, and being himself ardently desirous to improve the art, found out (by the good providence of God) the method of cutting (*incidendi*) the characters in a *matrix*, that the letters might easily be singly *cast* instead of being *cut*. He privately *cut matrices* for the whole alphabet; and when he showed his master the letters cast from these matrices, Fust was so pleased with the contrivance, that he promised Peter to give him his only daughter, Christina, in marriage;

(D) Many writers have supposed that this was the edition of which some copies were sold in France, by Fust, as manuscripts, for the great price of 500 or 600 crowns, which he afterwards lowered to 60, and at last to less than 40. But it was the second and more expensive edition of 1462, that was thus disposed of, when Fust went to Paris in 1466, and which had cost 4000 florins before the third *quaternion* (or quire of four sheets) was printed. MEERMAN, vol. i. p. 6. 151, 152.

(E) At the death of Gutenberg, Conrad Humery took possession of all his printing materials; and engaged to the archbishop Adolphus, that he never would sell them to any one but a citizen of Mentz. They were, however, soon disposed of to Nicholas Bechtermuntze of Altavilla, who, in 1469, published *Vocabularium Latino-Teutonicum*, which was printed with the same types which had been used in the *Catholicon*. This very curious and scarce *Vocabulary* was shown to Mr Meerman, by Mr Bryant, in the duke of Marlborough's valuable library at Blenheim. It is in quarto, 35 lines long, contains many extracts from the *Catholicon*, and is called *Ex quo*, from the preface beginning with those words. MEERMAN, vol. ii. p. 96.

(F) Gutenberg never used any other than either *wooden* or *cut metal types* till the year 1462. In 1465 he was admitted *inter Aulicos* by the elector Adolphus, with an annual pension; and died in February 1468. His elder brother Geinsfleich died in 1462. Their epitaphs are printed by Mr Meerman, vol. ii. p. 154, 295.

(G) In German, Schoeffer; in Latin, *Opilio;* in English, *Shepherd.*——He is supposed by Mr Meerman to have been the first engraver on copperplates.

(H) *Annales Hirsaugienses*, tom. ii. ad ann. 1450.—As this book was finished in 1514, and Trithemius tells us he had the narrative from Schoeffer himself about 30 years before; this will bring us back to 1484, when Schoeffer must have been advanced in years, and Trithemius about 22 years old, who died in 1516. See *Voss.* Hist. Lat. l. 1. c. 10. *Fabr.* Med. & Infim. Æt. l. 9.

riage; a promise which he soon after performed. But there were as many difficulties at first with these letters, as there had been before with *wooden* ones; the metal being too soft to support the force of the impression: but this defect was soon remedied, by mixing the metal with a substance which sufficiently hardened it (I)."

Fust and Schoeffer concealed this new improvement, by administering an oath of secrecy to all whom they intrusted, till the year 1462; when, by the dispersion of their servants into different countries, at the sacking of Mentz by the archbishop Adolphus, the invention was publicly divulged.

The first book printed with these *improved types* was *Durandi Rationale*, in 1459; at which time, however, they seem to have had only *one size* of *cast* letters, all the larger characters which occur being *cut types*, as appears plainly by an inspection of the book. From this time to 1466, Fust and Schoeffer continued to print a considerable number of books; particularly two famous editions of *Tully's Offices*. In their earliest books, they printed more copies on *vellum* than on *paper*, which was the case both of their *Bibles* and *Tully's Offices*. This, however, was soon inverted; and *paper* introduced for the greatest part of their impressions; a few only being printed on *vellum* for curiosities, and for the purpose of being *illuminated*. How long Fust lived, is uncertain; but in 1471 we find Schoeffer was in partnership with *Conrad Henlif* and a kinsman of his master Fust. He published many books after the death of his father-in-law; the last of which that can be discovered is a third edition of the *Psalter* in 1490, in which the old *cut* types of the first edition were used.

9
Claim of Strasburg.

IV. With regard to the claim of STRASBURG: It has been already mentioned, that Gutenberg was engaged in that city in different employments; and, among others, in endeavouring to attain the art of printing. That these endeavours were unsuccessful, is plain from an authentic judicial decree of the senate of Strasburg in 1439, after the death of Andrew Drizehen (K).

But there are many other proofs that Gutenberg and his partners were never able to bring the art to perfection.

1. Wimphelingius *, the oldest writer in favour of Strasburg, tells us, that Gutenberg was the inventor of "a new art of writing," *ars impressoria*, and which might also be called a *divine benefit*, and which he happily completed at Mentz; but does not mention one book of his printing: though he adds, that Mentelius printed many volumes correctly and beautifully, and acquired great wealth; whence we may conclude that he perfected what Gutenberg had in vain essayed.

* *Epitome Rerum Germanicarum* ed. Argent. 1505, Meerman, vol. i. p. 202. vol. ii. p. 139.

2. Wimphelingius, in another book †, tells us, the art of printing was found out by Gutenberg *incomplete*; which implies, not that he practised the art in an imperfect manner (as Laurentius had done at Haerlem), but rather that he had not been able to accomplish what he aimed at.

† *Catal. Episc.* Argent. 1508. *Meerman*, ut supra.

3. Gutenberg, when he left Strasburg in 1444 or the following year, and entered into partnership with Geinsfleich senior and others, had occasion for his brother's assistance to enable him to complete the art; which shows that his former attempts at Strasburg had been unsuccessful ‡.

‡ *Meerman* ut supra.

4. These particulars are remarkably confirmed by Trithemius, who tells us, in two different places §, that Gutenberg spent all his substance in quest of this art; and met with such insuperable difficulties, that, in despair, he had nearly given up all hopes of attaining it, till he was assisted by the liberality of Fust, and by his brother's skill, in the city of Mentz.

§ *Annal. Hirsag.* ut supra, et *Chron. Sponheim.* See *Meerman*, vol. ii p. 103. 127.

5. Ulric Zell says ‖ the art was completed at Mentz; but that some books had been published in Holland earlier than in that city. Is it likely that Zell, who was a German, would have omitted to mention Strasburg, if it had preceded Mentz in printing?

‖ *Chronica Coloniæ*, 1499.

There is little doubt, therefore, that all Gutenberg's labours at Strasburg amounted to no more than a fruitless attempt, which he was at last under the necessity of relinquishing: and there is no certain proof of a single book having been printed in that city till after the dispersion of the printers in 1462, when Mentelius and Eggestenius successfully pursued the business.

In fine, the pretensions of *Strasburg* fall evidently to be set aside. And as to the other two cities, *Haerlem* and *Mentz*, the disputes between them seem easily cleared up, from the twofold invention of printing above mentioned: the first with *separate* WOODEN *types* at Haerlem, by Laurentius, about 1430, and after continued by his family; the other with *METAL types*, first *cut*, and afterwards *cast*, which were invented at Mentz, but not used in Holland till brought thither by Theodoric Martens at Alost about 1472.

From this period printing made a rapid progress in most of the principal towns of Europe. In 1490, it reached Constantinople; and, according to Mr Palmer, p. 281, &c. it was extended, by the middle of the next century, to Africa and America. It was introduced into Russia about 1560: but, from motives either of policy

(I) See *Meerman*, vol. i. p. 183. who copied this testimony from Wolfius, *Monument. Typograph*, vol. i. p. 468. et seq.

(K) Their first attempts were made about 1436 with *wooden types*. Mr Meerman is of opinion that Geinsfleich junior (who was of an enterprising genius, and had already engaged in a variety of projects) gained some little insight into the business by visiting his brother who was employed by Laurentius at Haerlem, but not sufficient to enable him to practise it. It is certain that, at the time of the law-suit in 1439, much money had been expended, without any profit having arisen; and the unfortunate Drizehen, in 1438, on his death-bed, lamented to his confessor, that he had been at great expence, without having been reimbursed a single *obolus*. Nor did Gutenberg (who persisted in his fruitless endeavours) reap any advantage from them; for, when he quitted Strasburg, he was overwhelmed in debt, and under a necessity of selling every thing he was in possession of. [MEERMAN, vol. i. p. 198—202.]. All the depositions in the law-suit abovementioned (with the judicial decree) are printed by Mr Meerman, vol. ii. p. 58.—88. N.

Printing.

policy or superstition, it was speedily suppressed by the ruling powers; and, even under the present enlightened empress, has scarcely emerged from its obscurity.—That it was early practised in the inhospitable regions of Iceland, we have the respectable authority of Mr Bryant: "Arngrim Jonas was born amidst the snows of Iceland; yet as much prejudiced in favour of his country as those who are natives of a happier climate. This is visible in his *Crymogæa*, but more particularly in his *Anatome Blefkiniana*. I have in my possession this curious little treatise, written in Latin by him in his own country, and printed *Typis Holensibus in Islandia Boreali anno* 1612. *Hola* is placed in some maps within the Arctic circle, and is certainly not far removed from it. I believe it is the farthest north of any place where arts and sciences have ever resided." *Observations and Inquiries relating to various parts of Ancient History*, 1767, p. 277.

10 Introduction of the art into Britain.

It was a constant opinion, delivered down by our historians, as hath been observed by Dr Middleton, that the Art of Printing was introduced and first practised in England by *William Caxton*, a mercer and citizen of London; who, by his travels abroad, and a residence of many years in Holland, Flanders, and Germany, in the affairs of trade, had an opportunity of informing himself of the whole method and process of the art; and by the encouragement of the great, and particularly of the abbot of Westminster, first set up a press in that abbey, and began to print books soon after the year 1471.

This was the tradition of our writers; till a book, which had scarce been observed before the Restoration, was then taken notice of by the curious, with a date of its impression from Oxford, anno 1468, and was considered immediately as a clear proof and monument of the exercise of printing in that university several years before Caxton began to deal in it.

This book, which is in the public library at Cambridge, is a small volume of 41 leaves in 4to, with this title: *Expositio Sancti Jeronimi in Simbolum Apostolorum ad Papam Laurentium*: and at the end, *Explicit expositio, &c. Impressa Oxonie et finita Anno Domini* M.CCCC.LXVIII. XVII. *die Decembris*.

11 The first printing-press set up in England, was at Oxford.

The appearance of this book has robbed Caxton of a glory that he had long possessed, of being the author of printing in this kingdom; and Oxford has ever since carried the honour of the first press. The only difficulty was, to account for the silence of history in an event so memorable, and the want of any memorial in the university itself concerning the establishment of a new art amongst them of such use and benefit to learning. But this likewise has been cleared up by the discovery of a record, which had lain obscure and unknown at Lambeth-palace, in the Register of the See of Canterbury, and gives a narrative of the whole transaction, drawn up at the very time.

An account of this record was first published in a thin quarto volume, in English; with this title: "The Original and Growth of Printing, collected out of History, and the Records of this Kingdome: wherein is also demonstrated, that Printing appertaineth to the Prerogative Royal, and is a Flower of the Crown of England. By Richard Atkyns, esq.—Whitehall, April the 25. 1664. By order and appointment of the right honourable Mr Secretary Morrice, let this be printed. Tho. Rycaut, London: Printed by John Streater, for the Author, 1664." 4to.

It sets forth in short, "That as soon as the art of printing made some noise in Europe, Thomas Bourchier, archbishop of Canterbury, moved the then king (Henry VI.) to use all possible means for procuring a printing mould (for so it was then called) to be brought into this kingdom. The king (a good man, and much given to works of this nature) readily hearkened to the motion; and taking private advice how to effect his design, concluded it could not be brought about without great secrecy, and a considerable sum of money given to such person or persons as would draw off some of the workmen of Haerlem in Holland, where John Gutenberg had newly invented it, and was himself personally at work. It was resolved, that less than 1000 merks would not produce the desired effect; towards which sum the said archbishop presented the king 300 merks. The money being now prepared, the management of the design was committed to Mr Robert Turnour, who then was master of the robes to the king, and a person most in favour with him of any of his condition. Mr Turnour took to his assistance Mr Caxton, a citizen of good abilities, who traded much into Holland; which was a creditable pretence, as well for his going, as stay in the Low Countries. Mr Turnour was in disguise (his beard and hair shaven quite off); but Mr Caxton appeared known and public. They, having received the said sum of 1000 merks, went first to Amsterdam, then to Leyden, not daring to enter Haerlem itself; for the town was very jealous, having imprisoned and apprehended divers persons who came from other parts for the same purpose. They staid till they had spent the whole thousand merks in gifts and expences: so as the king was fain to send 500 merks more, Mr Turnour having written to the king that he had almost done his work; a bargain, as he said, being struck betwixt him and two Hollanders, for bringing off one of the underworkmen, whose name was Frederick Corsells (or rather Corsellis), who late one night stole from his fellows in disguise into a vessel prepared before for that purpose; and so, the wind favouring the design, brought him safe to London. It was not thought so prudent to set him on work at London: but, by the archbishop's means (who had been vice-chancellor and afterwards chancellor of the university of Oxon), Corsellis was carried with a guard to Oxon; which guard constantly watched, to prevent Corsellis from any possible escape, till he had made good his promise in teaching them how to print. So that at Oxford, printing was first set up in England which was before there was any printing-press or printer in France, Spain, Italy, or Germany (except the city of Mentz), which claims seniority, as to printing, even of Haerlem itself, calling her city, *Urbem Moguntinam artis typographicæ inventricem primam*; though it is known to be otherwise, that city gaining the art by the brother of one of the workmen of Haerlem, who had learnt it at home of his brother, and after set up for himself at Mentz. This press at Oxon was at least ten years before there was any printing in Europe, except at Haerlem and Mentz, where it was but new-born. This press at Oxford was afterwards found inconvenient to be the sole printing-place of England; as being too far from London and the sea. Wherefore the king set up a press

Printing. press at St Alban's, and another in the city of Westminster, where they printed several books of *divinity* and *physic: for the king* (for reasons best known to himself and council) *permitted then no law-books to be printed;* nor did any printer exercise that art, but only such as were the king's sworn servants; *the king himself having the price and emoluments for printing books.*—By this means the art grew so famous, that anno primo Richard III. c. 9. when an act of parliament was made for restraint of aliens for using any handicrafts here (except as servants to natives), a special proviso was inserted, that strangers might bring in printed or written books to sell at their pleasure, and exercise the art of printing here, notwithstanding that act: so that in the space of 40 or 50 years, by the indulgence of Edward IV. Edward V. Richard III. Henry VII. and Henry VIII. the English proved so good proficients in printing, and grew so numerous, as to furnish the kingdom with books; and so skilful, as to print them as well as any beyond the seas; as appears by the act 25 Hen. VIII. c. 15. which abrogates the said proviso for that reason. And it was further enacted in the said statute, that if any person bought foreign books bound, he should pay 6s. 8d. per book. And it was further provided and enacted, that in case the said printers or sellers of books were unreasonable in their prices, they should be moderated by the lord chancellor, lord treasurer, the two lords chief justices, or any two of them, who also had power to fine them 3s. 4d. for every book whose price should be enhanced.—But when they were by charter corporated with *bookbinders, booksellers,* and *founders of letters,* 3 and 4 Philip and Mary, and called *The Company of Stationers,* they kick'd against the power that gave them life, &c.—Queen Elizabeth, the first year of her reign, grants by patent *the privilege of sole printing all books that touch or concern the common laws of England,* to Tottel a servant to her majesty, who kept it entire to his death; after him, to one Yest Weirt, another servant to her majesty; after him, to Weight and Norton; and after them, King James grants the same privilege to More, one of the signet; which grant continues to this day, &c."

12 Whether Caxton or Corsellis was the first printer.

From the authority of this record, all our later writers declare Corsellis to be the first printer in England; Mr Anthony Wood, the learned Mr Maittaire, Palmer, and one John Bagford, an industrious man, who had published proposals for An History of Printing, (Phil. Trans. for April 1707). But Dr Middleton has called in question the authenticity of this account, and has urged several objections to it, with the view of supporting Caxton's title to the precedency with respect to the introduction of the art into this country; of which we shall quote one or two, with the answers that have been made to them.

Objection 1.—" The silence of Caxton concerning a fact in which he is said to be a principal actor, is a sufficient confutation of it: for it was a constant custom with him, in the prefaces or conclusions of his works, to give an historical account of all his labours and transactions, as far as they concerned the publishing and printing of books. And, what is still stronger, in the continuation of the Polychronicon, compiled by himself, and carried down to the end of Henry the Sixth's reign, he makes no mention of the expedition in quest of a printer: which he could not have omitted had it been true; whilst in the same book he takes notice of the invention and beginning of printing in the city of Mentz."

Answer.—As Caxton makes no mention in his Polychronicon of his *expedition in quest of a printer*; so neither does he of his *bringing the art into England,* which it is as much a wonder he should omit as the other. And as to his saying that *the invention of printing was at Mentz,* he means, of printing on *fusile* separate types. In this he copies, as many others have, from the *Fasciculus Temporum;* a work written in 1470, by Wernerus Rolevinch de Laer, a Carthusian monk, a MS. copy of which was in the library of Gerard Jo. Vossius (see lib. iii. *de Histor. Latin.* c. 6.); and afterwards continued to the year 1474, when it was first printed at Cologne *typis Arnoldi ter Huernen.* It was republished in 1481 by Heinricus Wirczburgh de Vach, a Cluniac monk, without mentioning the name either of the printer or of the place of publication. It is plain that Caxton had one at least, or more probably both, of these editions before him, when he wrote his continuation of Polychronicon, as he mentions this work in his preface, and adopts the sentiments of its editor. (See MEERMAN, vol. ii. p. 37. and his *Documenta,* N° vii. xxiv. and xxv.).

Obj. 2.—" There is a farther circumstance in Caxton's history, that seems inconsistent with the record; for we find him still beyond sea, about 12 years after the supposed transactions, " learning with great charge and trouble the art of printing" (*Recule of the Histories of Troye,* in the end of the 2d and 3d books); which he might have done with ease at home, if he had got Corsellis into his hands, as the record imports, so many years before: but he probably learnt it at Cologne, where he resided in 1471, (*Recule,* &c. ibid.), and whence books had been first printed with date the year before."

Ans.—Caxton tells us, in the preface to *The History of Troye,* that he began that translation March 1. 1468, at Bruges; that he proceeded on with it at Ghent; that he finished it at Cologne in 1471; and printed it, probably, in that city with his own types. He was 30 years abroad, chiefly in Holland; and lived in the court of Margaret duchess of Burgundy, sister of Edward IV. It was therefore much easier to print his book at Cologne, than to cross the sea to learn the art at Oxford. But further, there was a special occasion for his printing it abroad. Corsellis had brought over so far the art of printing as he had learned it at Haerlem, which was the method of printing on *wooden separate* types, having the face of the letter cut upon them. But the art of *casting* metal types being divulged in 1462 by the workmen of Mentz, Caxton thought proper to learn that advantageous branch before he returned to England. This method of casting the types was such an improvement, that they looked on it as the *original* of printing; and Caxton, as most others do, ascribes that to Mentz.—Caxton was an assistant with Turnour in getting off Corsellis; but it is nowhere supposed that he came with him into England. (See MEERMAN, vol. ii. p. 34. B.).

Obj. 3.—" As the Lambeth record was *never heard of before the publication of Atkyn's book,* so it has never since been seen or produced by any man; though the registers of Canterbury have on many occasions been diligently

ligently and particularly searched for it. They were examined, without doubt, very carefully by Archbishop Parker, for the compiling his *Antiquities of the British Church*; where, in the life of Thomas Bourchier, though he congratulates that age on the noble and useful invention of printing, yet he is silent as to the introduction of it into England by the endeavours of that archbishop: nay, his giving the honour of the invention to Strasburg clearly shews that he knew nothing of the story of Corsellis conveyed from Haerlem, and that the record was not in being in his time. Palmer himself owns, "That it is not to be found there now; for that the late earl of Pembroke assured him, that he had employed a person for some time to search for it, but in vain:" (*Hist. of Printing*, p. 314.). On these grounds we may pronounce the record to be a forgery; though all the writers above mentioned take pains to support its credit, and call it an *authentic piece*.

Atkyns, who by his manner of writing seems to have been *a bold and vain man*, might possibly be *the inventor;* for he had an interest in imposing it upon the world, in order to confirm the argument of his book, that *printing was of the prerogative royal;* in opposition to to the *company of stationers*, with whom he was engaged in an expensive suit of law, in defence of the *king's patents*, under which he claimed *some exclusive powers of printing*. For he tells us, p. 3. 'That, upon considering the thing, he could not but think that a public person, more eminent than a mercer, and a public purse, must needs be concerned in so public a good: and the more he considered, the more inquisitive he was to find out the truth. So that he had formed his hypothesis before he had found his record; which he published, he says, as a friend to truth; not to suffer one man to be intitled to the worthy achievements of another; and as a friend to himself, not to lose one of his best arguments of intitling the king to this art.' But, if Atkyns was not himself the contriver, he was imposed upon at least by some more crafty man; who imagined that his interest in the cause, and the warmth that he shewed in prosecuting it, would induce him to swallow for genuine whatever was offered of the kind.

Ans.—On the other hand, is it likely that Mr Atkyns would dare to *forge* a record, to be laid before the king and council, and which his adversaries, with whom he was at law, could disprove?—(2.) He says he received this history from a person of honour, who was some time keeper of the Lambeth library. It was easy to have confuted this evidence, if it was false, when he published it, April 25. 1664.—(3.) John Bagford (who was born in England in 1651, and might know Mr Atkyns, who died in 1677), in his History of Printing at Oxford, blames those who doubted of the authenticity of the Lambeth MS.; and tells us that he knew Sir John Birkenhead had an authentic copy of it, when in 1665 [which Bagford by some mistake calls 1664, and is followed in it by Meerman] he was appointed by the house of commons to draw up a bill relating to the exercise of that art. This is confirmed by the Journals of that house, Friday Oct. 27. 1665, vol. viii. p. 622, where it is ordered, that this Sir John Birkenhead should carry the bill on that head to the house of lords for their consent.—The act was agreed to in the upper house on Tuesday Oct. 31. and received the royal assent on the same day; immediately after which the parliament was prorogued. See *Journals of the House of Lords*, vol. xi. p. 700.—It is probable, then, that after Mr Atkyns had published his book in April 1664, the parliament thought proper, the next year, to inquire into *the right of the king's prerogative;* and that Sir John Birkenhead took care to inspect the original, then in the custody of Archbishop Sheldon: and, finding it not sufficient to prove what Mr Atkyns had cited it for, made no report of the MS. to the house; but only moved that the former law should be renewed. The MS. was probably never returned to the proper keeper of it; but was afterwards burnt in the fire of London, Sept. 13. 1666.—(4.) That printing was practised at Oxford, was a prevailing opinion long before Atkyns. Bryan Twyne, in his *Apologia pro Antiquitate Academiæ Oxoniensis*, published 1608, tells us, it is so delivered down in *ancient writings:* having heard, probably, of this Lambeth MS. And King Charles I. in his letters patent to the University of Oxford, March 5. in the eleventh of his reign, 1635, mentions printing as brought to Oxford from abroad. As to what is objected, "that it is not likely that the press should undergo a ten or eleven years sleep, viz. from 1468 to 1479," it is probably urged without foundation. Corsellis might print several books without date or name of the place, as Ulric Zell did at Cologne, from 1467 to 1473, and from that time to 1494. Corsellis's name, it may be said, appears not in any of his publications; but neither does that of Joannes Petersheimius. [See MEERMAN, vol. i. p. 34.; vol. ii. p. 21—27, &c.]

Further, the famous Shakespeare, who was born in 1564, and died 1616, in the Second Part of Henry VI. act iv. sc. 7. introduces the rebel John Cade, thus upbraiding Lord Treasurer Say: "Thou has most traiterously corrupted the youth of the realm, in creating a grammar-school: and whereas, before, our forefathers had no other book but the score and the tally, thou hast caused *Printing* to be used; and, contrary to the king, his crown, and dignity, thou hast built a paper-mill."—Whence now had Shakespeare this accusation against Lord Say? We are told in the Poetical Register, vol. ii. p. 231. ed. Lond. 1724, that it was from Fabian, Pol. Vergel, Hall, Hollingshed, Grafton, Stow, Speed, &c. But not one of these ascribes printing to the reign of Henry VI. On the contrary, Stow, in his Annals, printed at London, 1560, p. 686, gives it expressly to William Caxton, 1471. "The noble science of printing was about this time found out in Germany at Magunce, by one John Guthumburgus a knight. One Conradus an Almaine brought it into Rome: William Caxton of London, mercer, brought it into England about the year 1471, and first practised the same in the abbie of St Peter at Westminster; after which time it was likewise practised in the abbies of St Augustine at Canterburie, Saint Albons, and other monasteries of England." What then shall we say, that the above is an anachronism arbitrarily put into the mouth of an ignorant fellow out of Shakespeare's head? We might believe so, but that we have the record of Mr Atkyns confirming the same in King Charles II.'s time. Shall we say, that Mr Atkyns borrowed the story from Shakespeare, and published it with some improvements of money laid out by Henry VI. from whence it might be received by Charles II. as a prerogative of the crown? But this is improbable, since Shakespeare makes Lord Treasurer

Treasurer Say the intrument of importing it, of whom Mr Atkyns mentions not a word. Another difference there will still be between Shakespeare and the Lambeth MS.; the poet placing it before 1449, in which year Lord Say was beheaded; the MS. between 1454 and 1459, when Bourchier was archbishop. We must say, then, that Lord Say first laid the scheme, and sent some one to Haerlem, though without success; but after some years it was attempted happily by Bourchier. And we must conclude, that as the generality of writers have overlooked the invention of printing at Haerlem with *wooden* types, and have ascribed it to Mentz where *metal* types were first made use of; so in England they have passed by Corsellis (or the first *Oxford Printer*, whoever he was, who printed with *wooden* types at Oxford), and only mention Caxton as the original artist who printed with *metal* types at Westminster. [See MEERMAN, vol. ii. 7, 8.]. It is strange, that the learned commentators on our great dramatic poet, who are so minutely particular upon less important occasions, should every one of them, Dr Johnson excepted, pass by this curious passage, leaving it entirely unnoticed. And how has Dr Johnson trifled, by slightly remarking, "that Shakespeare is a little *too early* with this accusation!"—The great critic had undertaken to decipher obsolete words, and investigate unintelligible phrases; but never, perhaps, bestowed a thought on Caxton or Corsellis, on Mr Atkyns or the authenticity of the Lambeth Record.

But, independent of the record altogether, the book stands firm as a monument of the exercise of printing in Oxford six years older than any book of Caxton's with a date. In order to get clear of this strong fact, Dr Middleton,

1. Supposes the date in question to have been falsified originally by the printer, either by design or mistake; and an X to have been adopted or omitted in the age of its impression. Examples of this kind, he says, are common in the history of printing. And, "whilst I am now writing, an unexpected instance is fallen into my hands, to the support of my opinion; an *Inauguration Speech of the Woodwardian Professor*, *Mr Mason*, just fresh from the press, with its date given 10 years earlier than it should have been, by the omission of an X, viz. MDCCXXIV; and the very blunder exemplified in in the last piece printed at Cambridge, which I suppose to have happened in the first from Oxford."——To this it has been very properly answered, That we should not pretend to set aside the authority of *a plain date*, without very strong and cogent reasons; and what the Doctor has in this case advanced will not appear, on examination to carry that weight with it that he seems to imagine. There may be, and have been, mistakes and forgeries in the date both of books and of records too; but this is never allowed as a reason for suspecting such as bear no mark of either. We cannot from a blunder in the last book printed at Cambridge, infer a like blunder in the first book printed at Oxford. Besides, the *type* used in this our Oxford edition seems to be no small proof of its antiquity. It is the German letter, and very nearly the same with that used by Fust [who has been supposed to be] the first printer; whereas Caxton and Rood use a quite different letter, something between his German and our old English letter, which was soon after introduced by De Worde and Pynson.

2. "For the probability of his opinion (he says), the book itself affords sufficient proof: for, not to insist on what is less material, *the neatness of the letter, and regularity of the page*, &c. above those of Caxton, it has one mark, that seems to have carried the matter beyond probable, and to make it even certain, viz. *the use of signatures*, or letters of the alphabet placed at the bottom of the page, to show the sequel of the pages and leaves of each book; an improvement contrived for the direction of the bookbinders; which yet was not practised or invented at the time when this book is supposed to be printed; for we find no signatures in the books of Faust or Schoeffer at Mentz, nor in the improved or beautiful impressions of John de Spira and Jenson at Venice till several years later. We have a book in our library, that seems to fix the very time of their invention, at least in Venice; the place where the art itself received the greatest improvements: *Baldi lectura super Codic. &c.* printed by *John de Colonia* and *Jo. Manthem de Gherretzem, anno* MCCCCLXXIIII. It is a large and fair volume in folio, *without signatures*, till about the middle of the book, in which they are first introduced, and so continued forward: which makes it probable, that the first thought of them was suggested during the impression; for we have likewise *Lectura Bartholi super Codic.* &c. in two noble and beautiful volumes in folio, printed the year before at the same place, by Vindelin de Spira, without them: yet from this time forward they are generally found in all the works of the Venetian printers, and from them propagated to the other printers of Europe. They were used at (L) Cologne, in 1475; at Paris, 1476; by Caxton, not before 1480: but if the discovery had been brought into England, and practised at Oxford 12 years before, it is not probable that he would have printed so long at Westminster without them Mr Palmer indeed tells us, p. 54, 180, that Anthony Zarot was esteemed the inventor of signatures; and that they are found in a Terence printed by him at Milan in the year 1470, in which he first printed. I have not seen that Terence; and can only say that I have observed the want of them in some later works of this

(L) Dr Middleton is mistaken in the time and place of the invention of signatures. They are to be found even in very ancient MSS. which the earliest printers very studiously imitated; and they were even used in some editions from the office of Lawrence Coster (whence Corsellis came), which consisted of wooden cuts, as in *Figuræ typicæ et antitypicæ Novi Testamenti;* and in some editions with metal types, as in *Gasp. Pergamensis epistolæ*, published at Paris, without a date, but printed A. D. 1470, (Maittaire *, Annal. vol. i. p. 25.); and in *Mammetrectus*, printed by Helias de Llouffen, at Bern in Switzerland, 1470; and in *De Tondeli visione*, at Antwerp, 1472. Venice, therefore, was not the place where they were first introduced.—They began to be used in *Baldus*, it seems, when the book was half finished. The printer of that book might not know, or did not think, of the use of them before. See *Meerman*, vol. ii. p. 18; and Phil. Trans. vol. xxiii. N° 208. p. 1509.

* See *Maittaire.*

Printing.

this as well as of other excellent printers of the same place. But, allowing them to be in the Terence, and Zarot the inventor, it confutes the date of our Oxford book as effectually as if they were of later origin at Venice; as I had reason to imagine, from the testimony of all the books that I have hitherto met with."——As to these proofs, first, the neatness of the letter, and the regularity of the page, prove, if any thing, the very reverse of what the Doctor asserts. The art of printing was almost in its infancy brought to perfection; but afterwards debased by later printers, who consulted rather the cheapness than the neatness of their work. Our learned dissertator cannot be unacquainted with the labours of Fust and Jenson. He must know, that though other printers may have printed more correctly, yet scarce any excel them, either in the neatness of the letter, or the regularity of the page. The same may be observed in our English printers. Caxton and Rood were indifferently good printers; De Worde and Pynson were worse; and those that follow them most abominable. This our *anonymous Oxford printer* excels them all; and for this very reason we should judge him to be the most ancient of all. Our dissertator lays great stress on the use of signatures. But no certain conclusion can be drawn either from the use or non-use of these lesser improvements of printing. They have in different places come in use at different times, and have not been continued regularly even at the same places. If Anthony Zarot used them at Milan in 1470, it is certain later printers there did not follow his example; and the like might happen also in England. But, what is more full to our purpose, we have in the Bodleian library an Æsop's Fables printed by Caxton. This is, it is believed, the first book which has *the leaves numbered.* But yet this improvement, though more useful than that of the signatures, was disused both by Caxton himself and other later printers in England. It is therefore not at all surprising (if true) that the signatures, though invented by our Oxford printer, might not immediately come into general use. And consequently, this particular carries with it no such certain or effectual confutation as our dissertator boasts of.

3. What the Doctor thinks farther confirms his opinion is, "That, from the time of the pretended date of this book, anno 1468, we have no other fruit or production from the press at Oxford for 11 years next following; and it cannot be imagined that a press, established with so much pains and expence, could be suffered to be so long idle and useless."—To this it may be answered, in the words of Oxonides, 1st, That his books may have been lost. Our first printers, in those days of ignorance, met with but small encouragement; they printed but few books, and but few copies of those books. In after-times, when the same books were reprinted more correctly, those first editions, which were not as yet become curiosities, were put to common uses. This is the reason that we have so few remains of our first printers. We have only four books of Theodoric Rood, who seems by his own verses to have been a very celebrated printer. Of John Lettou-William de Machlinia, and the schoolmaster of St Albans, we have scarce any remains. If this be considered, it will not appear *impossible*, that our printer should have followed his business from 1468 to 1479, and yet time have destroyed his intermediate works. But, 2dly, We may account still another way for this distance of time, without altering the date. The Civil Wars broke out in 1469: this might probably oblige our Oxford printer to shut up his press; and both himself and his readers be otherwise engaged. If this were the case, he might not return to his work again till 1479; and the next year, not meeting with that encouragement he deserved, he might remove to some other country with his types.

Dr Middleton concludes with apologizing for his "spending so much pains on an argument so inconsiderable, to which he was led by his zeal to do a piece of justice to the memory of our worthy countryman William Caxton; nor suffer him to be robbed of the glory, so clearly due to him, of having *first imported into this kingdom* an art of great use and benefit to mankind: a kind of merit, that, in the sense of all nations, gives the best title to true praise, and the best claim to be commemorated with honour to posterity."

13
The real claims of Caxton and Corsellis respectively.

The fact, however, against which he contends, but which it seems impossible to overturn, does by no means derogate from the honour of Caxton, who, as has been shown, was the first person in England that practised the art of printing with *fusile types*, and consequently the first who brought it to perfection; whereas Corsellis printed with *separate cut types in wood*, being the only method which he had learned at Haerlem. Into this detail, therefore, we have been led, not so much by the importance of the question, as on account of several anecdotes connected with it, which seemed equally calculated to satisfy curiosity and afford entertainment.

Caxton had been bred very reputably in the way of trade, and served an apprenticeship to one Robert Large a mercer; who, after having been sheriff and lord mayor of London, died in the year 1441, and left by will, as may be seen in the prerogative office, XXIIII merks to his apprentice William Caxton: a considerable legacy in those days, and an early testimonial of his good character and integrity.

From the time of his master's death, he spent the following thirty years beyond sea in the business of merchandise: where, in the year 1464, we find him employed by Edward IV. in a public and honourable negociation, jointly with one Richard Whitehill, Esq. to transact and conclude a treaty of commerce between the king and his brother-in-law the duke of Burgundy, to whom Flanders belonged. The commission styles them, *ambassiatores, procuratores, nuncios, et deputatos speciales;* and gives to both or either of them full powers to treat, &c.

Whoever turns over his printed works, must contract a respect for him, and be convinced that he preserved the same character through life, of an honest, modest, man; greatly industrious to do good to his country, to the best of his abilities, by spreading among the people such books as he thought useful to religion and good manners, which were chiefly translated from the French. The novelty and usefulness of his art recommended him to the special notice and favour of the great; under whose protection, and at whose expence, the greatest part of his works were published. Some of them are addressed to King Edward IV. his brother the duke of Clarence, and their sister the duchess of Burgundy; in whose service and pay he lived many years before he began to print, as he often acknowledges with great gratitude. He printed likewise for the use, and by the

Printing. the express order, of Henry VII. his son Prince Arthur, and many of the principal nobility and gentry of that age.

It has been generally asserted and believed, that all his books were printed in the abbey of Westminster; yet we have no assurance of it from himself, nor any mention of the place before the year 1477: so that he had been printing several years without telling us where.

There is no clear account left of Caxton's age: but he was certainly very old, and probably above fourscore, at the time of his death. In the year 1471 he complained of the infirmities of age creeping upon him, and feebling his body: yet he lived 23 years after, and pursued his business, with extraordinary diligence, in the abbey of Westminster, till the year 1494, in which he died; not in the year following, as all who write of him affirm. This appears from some verses at the end of a book, called "Hilton's Scale of Perfection," printed in the same year:

Infynite laude with thankynges many folde
  I yield to God me socouryng with his grace
This boke to finyshe which that ye beholde
  Scale of Perfection calde in every place
Whereof th' auctor Walter Hilton was
  And Wynkn de Worde this hath sett in print
In William Caxtons hows so fyll the case,
  God rest his soule. In joy ther mot it stynt.
    Impressus anno salutis MCCCCLXXXXiiii.

Though he had printed for the use of Edward IV. and Henry VII. yet there appears no ground for the notion which Palmer takes up, that the first printers, and particularly Caxton, were sworn servants and printers to the crown; for Caxton, as far as can be observed, gives not the least hint of any such character or title; though it seems to have been instituted not long after his death; for of his two principal workmen, Richard Pynson and Wynkyn de Worde, the one was made printer to the king, the other to the king's mother the lady Margaret. Pynson gives himself the first title, in The Imitation of the Life of Christ; printed by him at the commandment of the lady Margaret, who had translated the fourth book of it from the French, in the year 1504: and Wynkyn de Worde assumes the second, in The Seven Penitential Psalms, expounded by Bishop Fisher, and printed in the year 1509. But there is the title of a book given by Palmer, that seems to contradict what is here said of Pynson; viz. *Psalterium ex mandato victoriosissimi Angliæ Regis Henrici Septimi, per Gulielmum Fanque, impressorem regium*, anno MDIIII; which being the only work that has ever been found of this printer, makes it probable that he died in the very year of its impression, and was succeeded immediately by Richard Pynson. No book hath yet been discovered printed in Scotland in this period, though the English printers were able to export some of their works to other countries. See Henry's History of Great Britain, vol. v. p. 471.

14 Different characters when first used in printing.

Before 1465, the uniform character was the old *Gothic* or *German*; whence our *Black* was afterwards formed. But in that year an edition of Lactantius was printed in a kind of Semi-Gothic, of great elegance, and approaching nearly to the present *Roman* type; which last was first used at Rome in 1467, and soon after brought to great perfection in Italy, particularly by Jenson.

Towards the end of the 15th century, Aldus invented the *Italic* character which is now in use, called, from his name, *Aldine* or *cursivus*. This sort of letter he contrived, to prevent the great number of abbreviations that were then in use.

15 Of the first Greek printing.

The first essays in Greek that can be discovered are a few sentences which occur in the edition of Tully's *Offices*, 1465, at Mentz; but these were miserably incorrect and barbarous, if we may judge from the specimens Mr Maittaire has given us, of which the following is one:

Οτιcαταακαςτμακατα και τατατικα.

In the same year, 1465, was published an edition of Lactantius's *Institutes*, printed *in monasterio Sublacensi*, in the kingdom of Naples, in which the quotations from the Greek authors are printed in a very neat Greek letter. They seem to have had but *a very small quantity* of Greek types in the monastery; for, in the first part of the work, whenever a long sentence occurred, a blank was left, that it might be written in with a pen: after the middle of the work, however, all the Greek that occurs is printed.

The first printers who settled at Rome were Conrad Sweynheim and Arnold Pannartz, who introduced the present *Roman* type, in 1466, in Cicero's *Epistolæ Familiares*: in 1469 they printed a beautiful edition of *Aulus Gellius*, with the Greek quotations in a fair character, without accents or spirits, and with very few abbreviations.

The first whole book that is yet known is the Greek Grammar of Constantine Lascaris, in quarto, revised by Demetrius Cretensis, and printed by Dionysius Palavisinus, at Milan, 1476. In 1481, the Greek *Psalter* was printed here, with a Latin translation, in folio; as was Æsop's Fables in quarto.

Venice soon followed the example of Milan; and in 1486 were published in that city the *Greek Psalter* and the *Batrachomyomachia*, the former by Alexander, and the latter by Laonicus, both natives of Crete. They were printed in a very uncommon character; the latter of them with *accents* and *spirits*, and also with *scholia*.

In 1488, however, all former publications in this language were eclipsed by a fine edition of *Homer's Works* at Florence, in folio, printed by Demetrius, a native of Crete. Thus printing, says Mr Maittaire, (p. 185.) seems to have attained its ακμη of perfection, after having exhibited most beautiful specimens of Latin, Greek, and Hebrew.

In 1493, a fine edition of *Isocrates* was printed at Milan, in folio, by Henry German and Sebastian ex Pantremulo.

All the above works are prior in time to those of Aldus, who has been erroneously supposed to be the *first* Greek printer: the beauty, however, correctness, and number of his editions, place him in a much higher rank than his predecessors; and his characters in general were more elegant than any before used. He was born in 1445, and died in 1515.

Though the noble Greek books of Aldus had raised an universal desire of reviving that tongue, the French were backward in introducing it. The only pieces printed ed by them were some quotations, so wretchedly performed, that they were rather to be guessed at than read; in a character very rude and uncouth, and without accents. But Francis Tissard introduced the study of this language at Paris, by his Βίβλος ἡ γνωμαγυρικη, in 1507; and that branch of printing was afterwards successfully practised by Henry, Robert, and Henry Stephens. See the article STEPHENS.

The earliest edition of the *whole Bible* was, strictly speaking, the Complutensian Polyglott of Cardinal Ximenes; but as that edition, though finished in 1517, was not published till 1522, the *Venetian* Septuagint of 1518 may properly be called the first edition of the *whole* Greek Bible; Erasmus having published the New Testament *only* at Basil in 1516.

16 Of the first Hebrew printing.

A very satisfactory account of Hebrew printing is thus given by Dr Kennicott in his *Annual Accounts of the Collation of Hebrew MSS.* p. 112. "The method which seems to have been originally observed in printing the Hebrew Bible was just what might have been expected: 1. The Pentateuch in 1482. 2. The Prior Prophets, in 1484. 3. The Posterior Prophets, in 1486. 4. The Hagiographa, in 1487. And, after the four great parts had been thus printed separately (each with a comment), the whole text (without a comment) was printed in one volume in 1488; and the text continued to be printed, as in these first editions, so in several others for 20 or 30 years, without marginal *Keri* or *Masora*, and with greater arguments to the more ancient MSS. till about the year 1520 some of the Jews adopted later MSS. and the *Masora;* which absurd preference has obtained ever since."

Thus much for the ancient editions given by Jews.

In 1642 a Hebrew Bible was printed at Mantua under the care of the most learned Jews in Italy. This Bible had not been heard of among the Christians in this country, nor perhaps in any other; though the nature of it is very extraordinary. The text indeed is nearly the same with that in other modern editions; but at the bottom of each page are various readings, amounting in the whole to above 2000, and many of them of great consequence, collected from manuscripts, printed editions, copies of the Talmud, and the works of the most renowned Rabbies. And in one of the notes is this remark:—"That in several passages of the Hebrew Bible the differences are so many and so great, that they know not which to fix upon as the true readings."

We cannot quit this subject without observing, on Dr Kennicott's authority, that as the first printed Bibles are more correct than the latter ones; so the variations between the first edition, printed in 1488, and the edition of Vander Hooght, in 1705, at Amsterdam, in 2 vols. 8vo, amount upon the whole, to above 1200. See further *Bowyer and Nichols*, p. 112—117.

17 Anecdotes of early printing.

When the art of printing was first discovered, they only made use of one side of a page: they had not yet found out the expedient of impressing the other. When their editions were intended to be curious, they omitted to print the first letter of a chapter, for which they left a blank space, that it might be painted or illuminated at the option of the purchaser. Several ancient volumes of these early times have been found, where these letters are wanting, as they neglected to have them painted.

When the art of printing was first established, it was the glory of the learned to be correctors of the press to the eminent printers. Physicians, lawyers, and bishops themselves, occupied this department. The printers then added frequently to their names those of the correctors of the press; and editions were then valued according to the abilities of the corrector.

In the productions of early printing may be distinguished the various splendid editions they made of *Primers* or *Prayer-books.* They were embellished with cuts finished in a most elegant taste: many of them were ludicrous, and several were obscene. In one of them an angel is represented crowning the Virgin Mary, and God the Father himself assisting at the ceremony. We have seen in a book of natural history the Supreme Being represented as *reading* on the seventh day, when he rested from all his works. Sometimes St Michael is seen overcoming Satan; and sometimes St Anthony appears attacked by various devils of most hideous forms. The *Prymer of Salisbury*, 1533, is full of cuts: at the bottom of the title page there is the following remarkable prayer:

God be in my Bede,
  And in my Understandynge.
God be in my Eyen,
  And in my Lookynge.
God be in my Mouthe,
  And in my Spekynge.
God be in my Herte,
  And in my thinkinge.
God be at myn ende,
  And at my departynge.

Stereotype Printing. Different persons in different countries have claimed the merit of this invention; but from Mr Nicholls's Biographical memoirs of William Ged, it appears undeniable that he was the first by whom it was invented. Mr Tilloch, the editor of the Philosophical Magazine informs us, that he had turned his attention to the subject for a number of years, and having hit at last upon the discovery, he flattered himself that it was purely original, even feeling vexed when given to understand that he had been anticipated by Mr Ged of Edinburgh, who had printed books from plates about 50 years before. 18 History. Vol. x.

So far back as the year 1725, we find that Mr Ged had begun to prosecute plate-making. In 1727, he entered into a contract with a person who had a small capital, but who was so intimidated by the insinuations of some printer, that he expended no more than 22l. in the course of two years. In this manner he had printed both bibles and common prayer-books, but the compositors when they corrected one fault, purposely made half a dozen more; and the pressmen when the masters were absent, battered the letter to second the compositors. In consequence of these abominable proceedings, the books were suppressed by authority, and the plates sent to the King's printing-house, and from thence to the foundery.

In consequence of Mr Tilloch's invention and improvement, Stereotype printing was afterwards practised by him in conjunction with Mr Foulis, printer to the university of Glasgow, who obtained patents both for England and Scotland, as Mr Ged's invention had died with

with his son. This art, therefore, may be said to have been twice invented in Britain; after which Didot, a French printer, published several Latin classics in the same manner, and to whom some of his countrymen wished to ascribe the merit of the invention, which must be a mistake. We admit it possible that he might have discovered the secret of the art for himself; but it is not supposeable that he could be ignorant of Ged's progress and that of Mr Foulis, especially since, when patents are obtained, a specification of the process must be put upon record, of which any one may obtain an office copy at a small expence.

Neither is it at all probable that stereotype printing was the invention of a Dutchman, who is said to have practised the art even before Ged; since we are assured that Ged himself had offers from Holland repeatedly, either to go over there, or sell his invention, which could not possibly have been the case, had it been in possession of their own countrymen.

Founding of pages, on the first view of it, promises many advantages of an economical nature, and to science it holds out what can never be obtained in any other way; we mean editions of books without a single error. From books cast into solid pages, no more copies would be printed than might be wanted for immediate sale; the money thus saved from being sunk in paper, to be piled up in warehouses for years, as is the case at present, would serve as surplus capital to print other works; thus the printer, his workmen, and the booksellers, would all be benefited.

Some are of opinion, that the expence of stereotype precludes the use of it, except in the case of standard authors, whose works are sure of an extensive sale; but the very reverse of this is the truth. If there would be an advantage in applying the stereotype art to books of rapid sale, there would be a still greater one in the case of such whose sale would not be so certain, as at the worst there could only be the loss of the plates, instead of that of the paper and press-work of a whole edition, which in almost every instance would amount to a much larger sum. To the advantages already mentioned we may add a few others, as stated by Mr Wilson, Stereotype office Duke street, Lincoln's Inn Fields. The expence of Stereotype plates is not 20 per cent. of that of moveable type pages. A room that is fire-proof will hold Stereotype plates of works, of which the dead stock in printed paper would require a warehouse twenty times the size; and thus warehouse rent and insurance are saved; with the additional advantage, in case of accident by fire, that the stereotype plates may be instantly put to press, instead of going through the tedious operations of moveable type printing; and thus no loss will be sustained from the works being out of print. In stereotype, every page of the most extensive work has a separate plate; of consequence all the pages of the said work must be equally new and beautiful. The types of each sheet are distributed by the old method, by which the subsequent sheets are composed; so that, although the first few sheets of a volume may be well composed, the last part of the volume will appear to be executed in a very inferior manner. Stereotype plates admit of alteration; and it will be found that they will yield at least twice the number of impressions that moveable types are capable of producing. It seems evident upon the whole, says Mr Wilson, that a saving of from 25 to 40l. per cent. will accrue to the public in the prices of all books of standard reputation and sale, which, he believes, are pretty accurately ascertained to comprehend three-fourths of all the book printing of England, Scotland, and Ireland. It is fair to conclude, therefore, that both foreign and domestic sales will be much increased, and that the duties on paper will be proportionally productive; so that the public will reap advantage in a twofold way by the general adoption and encouragement of the stereotype art.

The advantages of this mode of printing now mentioned, are such as have been suggested by men who were competent judges; but we leave it to our readers to determine for themselves, whether the adoption of the stereotype art of printing would be more beneficial to society at large, than the publishing of books by means of moveable types.

19 Method of printing.

The workmen employed in the art of printing are of two kinds: compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author; and pressmen, who apply ink upon the same, and take off the impression. The types being cast, the compositor distributes each kind by itself among the divisions of two wooden frames, an upper and an under one, called *cases;* each of which is divided into little cells or boxes. Those of the upper case are in number 98: these are all of the same size; and in them are disposed the capitals, small capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower case, which are 54, are placed the small letters, with the points, spaces, &c. The boxes are here of different sizes, the largest being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letter oftenest wanted are nearest the compositor's hand. Each case is placed a little aslope, that the compositor may the more easily reach the upper boxes. The instrument in which the letters are set is called a *composing-stick* (fig. 1.), which consists of a long and narrow plate of brass or iron, &c. on the right side of which arises a ledge, which runs the whole length of the plate, and serves to sustain the letters, the sides of which are to rest against it; along this ledge is a row of holes, which serve for introducing the screw *a*, in order to lengthen or shorten the extent of the line, by moving the sliders *b c* farther from or nearer to the shorter ledge at the end *d*. Where marginal notes are required in a work, the two sliding-pieces *b c* are opened to a proper distance from each other in such a manner, as that while the distance between *d c* forms the length of the line in the text, the distance between the two sliding-pieces forms the length of the lines for the notes on the side of the page. Before the compositor proceeds to compose, he puts a rule or thin slip of brass-plate, cut to the length of the line, and of the same height as the letter, in the composing-stick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his stick in his left-hand, his thumb being over the slider *c;* with the right he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by pressing them to the end of the slider *c*, the other hand being constantly

Plate CCCXL. fig. 1.

stantly employed in setting in other letters: the whole being performed with a degree of expedition and address not easy to be imagined.

A line being thus composed, if it end with a word or syllable, and exactly fill the measure, there needs no further care; otherwise more spaces are to be put in, or else the distances lessened, between the several words, in order to make the measure quite full; so that every line may end even. The spaces here used are pieces of metal exactly shaped like the shanks of the letters: they are of various thicknesses, and serve to support the letters, and to preserve a proper distance between the words; but not reaching so high as the letters, they make no impression when the work is printed. The first line being thus finished, the compositor proceeds to the next; in order to which he removes the brass rule from behind the former, and places it before it, and thus composes another line against it after the same manner as before; going on thus till his stick is full, when he empties all the lines contained in it into the gally.

The compositor then fills and empties his composing-stick as before, till a complete page be formed; when he ties it up with a cord or pack-thread; and setting it by, proceeds to the next, till the number of pages to be contained in a sheet is completed; which done, he carries them to the imposing-stone, there to be ranged in order, and fastened together in a frame called a *chess*; and this is termed *imposing*. The chess is a rectangular iron frame, of different dimensions according to the size of the paper to be printed, having two cross-pieces of the same metal, called a *long* and *short cross*, mortised at each end so as to be taken out occasionally. By the different situations of these crosses the chess is fitted for different volumes: for quartos and octavos, one traverses the middle lengthwise, the other broadwise, so as to intersect each other in the centre: for twelves and twenty-fours, the short cross is shifted nearer to one end of the chess; for folios, the long cross is left entirely out, and the short one left in the middle; and for broadsides, both crosses are set aside. To dress the chess, or range and fix the pages therein, the compositor makes use of a set of furniture, consisting of slips of wood of different dimensions, and about half an inch high, that they may be lower than the letters: some of these are placed at the top of the pages, and called *head-sticks*; others between them, to form the inner margin; others on the sides of the crosses, to form the outer margin, where the paper is to be doubled; and others in the form of wedges to the sides and bottoms of the pages. Thus all the pages being placed at their proper distances, and secured from being injured by the chess and furniture placed about them, they are all united, and fastened together by driving small pieces of wood called *quoins*, cut in the wedge-form, up between the slanting side of the foot and the side-sticks and the chess, by means of a piece of hard wood and a mallet; and all being thus bound fast together, so that none of the letters will fall out, it is ready to be committed to the pressmen. In this condition the work is called a *form*; and as there are two of these forms required for every sheet, when both sides are to be printed, it is necessary the distances between the pages in each form should be placed with such exactness, that the impression of the pages in one form shall fall exactly on the back of the pages of the other, which is called *register*.

As it is impossible but that there must be some mistakes in the work, either through the oversight of the compositor, or by the casual transposition of letters in the cases; a sheet is printed off, which is called a *proof*, and given to the corrector; who reading it over and, rectifying it by the copy, making the alterations in the margin, it is delivered back to the compositor to be corrected.

The compositor then unlocking the form upon the correcting-stone, by loosening the quoins or wedges which bound the letters together, rectifies the mistakes by picking out the faulty or wrong letters with a slender sharp pointed steel-bodkin, and putting others into their places. After this another proof is made, sent to the author and corrected as before; and lastly, there is another proof called a *revise*, which is made in order to see whether all the mistakes marked in the last proof are corrected.

The pressman's business is to work off the forms thus prepared and corrected by the compositor; in doing which there are four things required, paper, ink, balls, and a press. To prepare the paper for use, it is to be first wetted by dipping several sheets together in water: these are afterwards laid in a heap over each other; and to make them take the water equally, they are all pressed close down with a weight at the top. The ink is made of oil and lamp-black; for the manner of preparing which, see *Printing-Ink*. The balls, by which the ink is applied on the forms, are a kind of wooden funnels with handles, the cavities of which are filled with wool or hair, as is also a piece of alum leather or pelt nailed over the cavity, and made extremely soft by soaking in urine, and by being well rubbed. One of these the pressman takes in each hand; and applying one of them to the ink-block, daubs and works them together to distribute the ink equally; and then blackens the form which is placed on the press, by beating with the balls upon the face of the letter.

Fig. 2.

The printing-press, represented fig. 2. is a very curious though complex machine. The body consists of two strong cheeks *a*, *a*, placed perpendicularly, and joined together by four cross-pieces, the cap *b*; the head *c*, which is moveable, being partly sustained by two iron pins or long bolts, that pass the cap; the till or shelf *d d*, by which the spindle and its apparatus are kept in their proper position; and the winter *e*, which bears the carriage, and sustains the effort of the press beneath. The spindle *f* is an upright piece of iron pointed with steel, having a male screw which goes into the female one in the head about four inches. Through the eye *g* of this spindle is fastened the bar *k*, by which the pressman makes the impression. The spindle passes through a hole in the middle of the till; and its point works into a brass pan or nut, supplied with oil, which is fixed to an iron plate let into the top of the platten. The body of the spindle is sustained in the centre of an open frame of polished iron, 1, 1, 2, 2, 3, 3, fixed to it in such a manner as, without obstructing its free play, to keep it in a steady direction; and at the same time to serve for suspending the platten. This frame consists of two parts; the upper called the *garter*, 1, 1; the under, called the *crane*, 2, 2. These are connected together

gether by two short legs or bolts, 3, 3.; which being fixed below in the two ends of the crane, pass upward, through two holes in the till, and are received at top into two eyes at the ends of the garter, where they are secured by screws. The carriage *l l* is placed a foot below the platten, having its fore-part supported by a prop called the *fore-stay*, while the other rests on the winter. On this carriage, which sustains the plank, are nailed two long iron bars or ribs; and on the plank are nailed short pieces of iron or steel called *cramp irons*, equally tempered with the ribs, and which slide upon them when the plank is turned in or out. Under the carriage is fixed a long piece of iron called the *spit*, with a double wheel in the middle, round which leather-girts are fastened, nailed to each end of the plank: and to the outside of the spit is fixed a rounce *m*, or handle to turn round the wheel. Upon the plank is a square frame or coffin, in which is inclosed a polished stone on which the form *n* is laid; at the end of the coffin are three frames, *viz.* the two tympans and frisket: the tympans *o* are square, and made of three slips of very thin wood, and at the top a piece of iron still thinner; that called the *outer tympan* is fastened with hinges to the coffin: they are both covered with parchment; and between the two are placed blankets, which are necessary to take off the impression of the letters upon the paper. The frisket *p* is a square frame of thin iron, fastened with hinges to the tympan: it is covered with paper cut in the necessary places, that the sheet, which is put between the frisket and the great or outward tympan, may receive the ink, and that nothing may hurt the margins. To regulate the margins, a sheet of paper is fastened upon this tympan, which is called the *tympan sheet*; and on each side is fixed an iron point, which makes two holes in the sheet, which is to be placed on the same points when the impression is to be made on the other side. In preparing the press for working, the parchment which covers the outer tympan is wetted till it is very soft, in order to render the impression more equable; the blankets are then put in, and secured from slipping by the inner tympan: then while one pressman is beating the letter with the balls *q*, covered with ink taken from the ink-block, the other person places a sheet of white paper on the tympan-sheet; turns down the frisket upon it, to keep the paper clean and prevent its slipping; then bringing the tympans upon the form, and turning the rounce, he brings the form with the stone, &c. weighing about 300 lbs. weight, under the platten; pulls with the bar, by which means the platten presses the blankets and paper close upon the letter, whereby half the form is printed; then easing the bar, he draws the form still forward; gives a second pull; and letting go the bar, turns back the form, takes up the tympans and frisket, takes out the printed sheet, and lays on a fresh one; and this is repeated till he has taken off the impression upon the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the press, and worked off in the same manner.

To the above description of the printing press, we shall add that of one invented by Mr Nicholson, and for which a patent was granted in 1790. This machine is recommended by the inventor as being superior to other printing presses in cheapness, accuracy, and neatness, and is adapted with some slight variations in its construction for printing on paper, linen, cotton, and woollen. Three particulars are to be attended to in the invention.

1st, The manner of preparing and placing the types, engravings, or carvings, from which the impression is to be made; *2dly*, In applying the ink or colouring matter to types or engravings; and, *3dly*, In taking off the impression.

1st, The moulds, punches, and matrices, for casting letters, are made in the same manner, and with the same materials, as other letter-founders do, excepting that, instead of leaving a space in the mould for the stem of one letter only, he leaves spaces for two, three, or more letters, to be cast at one pouring of the metal; and at the lower extremity of each of those spaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the usual way. And moreover, he brings the stem of his letters to a due form and finish, not only by rubbing it upon a stone, and scraping it when arranged in the finishing-stick, but likewise by scraping it, on one or more sides, in a finishing-stick whose hollowed part is less deep at the inner than the outer side. He calls that side of the groove which is nearest the face of the disposed letter, the outer side; and the purpose accomplished by this method of scraping is, that of rendering the tail of the letter gradually smaller the more remote it is, or farther from the face. Such letters may be firmly imposed upon a cylindrical surface, in the same manner as common letters are imposed upon a flat stone.

2dly, The ink or colouring matter is applied to the types, forms, or plates, by causing the surface of a cylinder, smeared or wetted with the colouring matter, to roll over the surfaces of the said forms or plates, or by causing the forms or plates apply themselves successively to the surface of the cylinder. The surface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton cloth. When the colour to be used is thin, as in calico-printing, and in almost every case, the covering is supported by a firm elastic stuffing, consisting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering consists of woollen cloth, the stuffing must be defended by leather or oilskin, to prevent its imbibing too much colour, and by that means losing its elasticity. It is absolutely necessary that the colouring matter be evenly distributed over the surface of the cylinder; and for this purpose, when the colour is thick and stiff, as in letter-press printing, he applies two, three, or more small cylinders, called distributing-rollers, longitudinally against the colouring cylinders, so that they may be turned by the motion of the latter; and the effect of this application is, that every lump or mass of colour which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be pressed, spread, and partly taken up, and carried by the small rollers to the other parts of the colouring cylinder; so that this last will very speedily acquire and preserve an even face of colour. But if the colouring matter be thinner, he does not apply more than one or two of these distributing-rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a straight brush, or both of these last, against the colouring cylinder, for the purpose of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or through

Printing. through the interstices of a perforated pattern, as in the manufacturing of some kinds of paper-hangings, he uses a cylinder entirely covered with hair or bristles in the manner of a brush.

3dly, The impressions, even in letter-press printing, are performed by the action of a cylinder or cylindrical surface. The following is the construction of this machine. Fig. 3. represents a printing-press, more especially applicable to the printing of books. A and E are two cylinders, running or turning in a strong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being pressed with more or less force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwise, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by straps, so as to draw it backwards and forwards by the motion of its handle L. The table is kept in the same line by grooves on its sides, which contain the cylinder A. D is a chess, containing letter set up and imposed. B is a box, containing a colouring-roller, with its distributing-rollers CC; it is supported by the arm N. O is a cylinder faced with leather, and lying across an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

Fig. 3.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has passed into the position R, a workman places or turns down a tympan with paper upon it (this tympan differs in no respect from the usual one, except that its hinge opens sidewise); it then proceeds to pass under the cylinder A, which presses it successively through its whole surface. On the other side, at S, the workman takes off the paper and leaves the tympan up. This motion causes the cylinder B to revolve continually, and consequently renders its inked surface very uniform, by the action of its distributing-rollers CC; and, when the table has passed to its extreme distance in the direction now spoken of, the arm G touches the lever P, and raises the cylinder O off the ink-block, by which means it dabs against one of the distributing-rollers, and gives it a small quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the process of printing another sheet goes on as before.

Fig. 4.

Fig. 4. is another printing-press. In this, B is the inking-roller; A is a cylinder, having the letter imposed upon its surface; and E is a cylinder, having its uniform surface covered with woollen cloth: these three cylinders are connected, either by cogs or straps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a sheet of paper to the surface of E, where it is retained, either by points in the usual manner, or by the apparatus to be described in treating of fig. 4. The paper passes between E and A, and receives an impression; after which the workman takes it off, and applies another sheet; and in the mean time the letter on the surface of A passes round against the surface of B, and receives ink during the rotation of B. The distributing-rollers CC do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raises the inking-piece G, so as to cause it to touch one of the distributing-rollers, and supply it with ink. In this way therefore the repeated printing of sheet after sheet goes on.

Fig. 5. is a printing-press, more particularly adapted to print cottons, silks, paper-hangings, or other articles which run of a considerable length. A is a cylinder covered with woollen cloth, or other soft substance. The web or piece of cotton, or other goods, is passed round this cylinder, from the carrying-roller F to the receiving-rollers GH; which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel, sewed round them; the rotation of this towel carries away the printed stuff or goods, and deposits them at I. KL is a moveable box, containing three rollers, which move against each other in rotation. The lowest roller C revolves in a mass of colour, contained in a trough or vessel in the bottom part of the box KL; the surface of this colour is represented by the line MN. The next roller B is stuffed and covered as described in section 2. The pressure of B against C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and impresses it upon the web as it passes round the cylinder A; in this way the constant and effectual action of the machine is sufficiently obvious. It must be observed, that the cylinders ADB and G are connected together by cog-wheels, straps, or other well-known equivalent contrivances; so that the handle P drives the whole, without their necessarily depending on any adhesion or friction at their surfaces. The pressure of B against D is governed by an adjustment of the axis of D, whose sockets are capable of a small motion; and the pressure of D against A is governed by the position of the whole box KL. When it is required to print more than one colour upon the same piece, it must pass two or more times through the machine; or, in those cases where the materials are liable to change their dimensions, it is necessary to apply, at one and the same time, two or more such boxes as KL, with their respective cylinders, so that the pattern cylinder of each may make its impression upon the web or material to be printed on. Printing. Fig. 5.

Fig. 6. is a printing-press, chiefly of use for books and papers. 1, 2, 3, 4, represent a long table, with ledges on each side; so that the two cylinders A and B can run backwards and forwards without any side shake. In one of these ledges is placed a strip or plate of metal cut into teeth, which lock into correspondent teeth in each cylinder; by which means the two cylinders roll along, without the possibility of changing the relative positions of their surfaces at any determinate part of the table. This may also be effected by straps, and may indeed be accomplished with tolerable accuracy, by the mere rolling of the cylinders on the smooth or flat ledges without any provision. A is the printing-cylinder, covered with woollen cloth, and B is the inking-cylinder, with its distributing-rollers. The table may be divided into four compartments marked with a thicker bounding line than the rest and numbered 1, 2, 3, 4. At 1 is placed a sheet of paper; at 2 is the form or chess, containing letter set and imposed; at 3 is an apparatus for receiving the printed sheet; and 4 is employed in no other use than as a place of standing for the carriage E, after it has passed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thrust forward by the workman, and as the roller A passes over the space numbered 1, it takes up the sheet of paper previously laid there, while the roller B runs over the form and inks the letter. The sheet of paper being wrapped Fig. 6.

round the cylinder A, is pressed against the form as that cylinder proceeds, and consequently it receives an impression. When A arrives at the space numbered 3, it lets go the sheet of paper, while the prominent part of the carriage G strikes the lever P, and raises the inking-piece, which applies itself against one of the distributing-rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another sheet of paper ready in the space numbered 1. Thus it is that the operation proceeds in the printing of one sheet after another.

The preceding description is not encumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in several ways: Fig. 11. and 12. represent one of the methods. DE is a lever, moving on the centre pin C, and having its end D pressed upwards by the action of the spring G. The shoulder which contains the pin C is fixed in another piece F, which is inserted in a groove in the surface of the cylinder A (fig. 6.), so that it is capable of moving in and out, in a direction parallel to the axis of that cylinder. As that cylinder proceeds, it meets a pin in the table; which (letter P, fig. 11.) acting on the inclined plane at the other end of the lever, throws the whole inwards, in the position represented in fig. 12.; in which case the extremity D shoots inwards, and applies itself against the side of the cylinder.

Fig. 11, 12.

Fig. 13.

In fig. 13. is a representation of part of the table; the dotted square represents a sheet of paper, and the four small shaded squares denote holes in the board, with pins standing beside them. When the lever DE (fig. 12.) shoots forward, it is situated in one of these holes, and advances under the edge of the paper, which consequently it presses and retains against the cylinder with its extremity D. Nothing more remains to be said respecting the taking up, but that the cylinder is provided with two pair of these clasps or levers, which are so fixed as to correspond with four holes represented in fig. 13. It will be easy to understand how the paper is deposited in the compartment N° 3. (fig. 6.). A pin P (fig. 12.) rising out of the platform or table, acts against a pin E, projecting sidewise out of the lever, and must of course draw the slider and its lever to the original position; the paper consequently will be let go, and its disengagement is rendered certain by an apparatus fixed in the compartment numbered 3 (fig. 6.) of exactly the same kind as that upon the cylinder, and which, by the action of a pin duly placed in the surface of the cylinder A, takes the paper from the cylinder in precisely the same manner as that cylinder originally took it up in the compartment numbered 1 (fig. 6.).

Fig. 7, 8, 9.

Fig. 7, 8, and 9, represent a simpler apparatus for accomplishing the same purpose. If A *a* B *b* (fig. 9.) be supposed to represent a thick plate of metal of a circular form, with two pins, A and B, proceeding sidewise or perpendicularly out of its plane, and diametrically opposite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A, so as to press it into the position *a* (by turning the plate on its axis or centre X), will at the same time cause the pin G to acquire the position *g*; and, on the other hand, when B is at *b*, or the dotted representation of the side-pin, if any pressure be applied to restore its original position at B, the pin *g* will return back to G. Now the figures 7 and 8 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and *p*, properly fixed in the table to re-act upon the apparatus, will cause its prominent part G either to apply to the cylinder and clasp the paper, or to rise up and let it go. The compartment numbered 3 (fig. 6.) must of course have an apparatus of the same kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumstance belonging to this machine which remains to be explained. When the carriage E (fig. 6) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, press the form of letter in their passage; but in their return back again the roller A, having no paper upon it, would itself become soiled, by taking a faint impression from the letter, if it were not prevented from touching it: the manner of effecting this may be understood from fig. 14. The apparatus there represented is fixed upon the outside of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this projects sidewise beyond the ledge of the table, except the small truck or wheel B. The irregularly-triangular piece, which is shaded by the stroke of the pen, carries this wheel, and also a catch moveable on the axis or pin E. The whole piece is moveable on the pin A, which connects it to the carriage. CD, or the part which is shaded by dotting, is a detent, which serves to hold the piece down in a certain position. It may be observed, that both the detent and the triangular piece are furnished each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harpsichord, or resembling certain pieces used in clock and watch making, as is clearly represented in the figure. These claws overhang the side of the table, and their effect is as follows: There is a pin C (fig. 6.) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 14. where GH represents the table. In the outward run of the carriage these claws strike that pin, but with no other effect than that they yield for an instant, and as instantly resume their original position by the action of their respective slender back springs. When the carriage returns, the claw of the detent indeed strikes the pin, but with as little effect as before, because its derangement is instantly removed by the action of the back spring of the detent itself; but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, so as to lift that end of the carriage, and the detent, catching on the piece at C, prevents the former position from being recovered. The consequence of this is, that the carriage runs upon the truck B (and its corresponding truck on the opposite side) instead of the cylinder A, which is too much raised to take the letter, and soil itself; but as soon as the end of the carriage has passed clear of the letter, another pin R (fig. 6.) takes the claw of the detent, and draws it off the triangular piece; at which instant the cylinder A subsides to its usual place, and performs its functions as before. This last pin R does not affect the claw of the triangular piece, because it is placed too low; and the claw of the detent is made the longest, on purpose that it may strike this pin.

Fig. 14.

Fig.

Fig. 10.

Fig. 10. represents an instrument for printing floor-cloths, paper-hangings, and the like, with a stiff paint and a brush. D is a copper or metallic cylinder fixed in a frame A, like a garden-roller; its carved part is thin, and is cut through in various places, according to the desired pattern. A strong axis passes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a vessel or box of the same kind, and answering the same purpose as the box KL in fig. 5. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P; and a third cylinder B, whose exterior surface is covered with hair, after the manner of a brush, and revolves in contact with E. This cylinder B is adjusted by its axis, in such a manner that its brush-part sweeps in the perforated parts of the metallic cylinder D. The circle C represents a cog-wheel fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any surface, its cog-wheel C drives the brush B in the contrary direction; and this brush cylinder, being connected by cogs or otherwise with E and P, causes these also to revolve and supply it with colour. As the successive openings of the cylinder D, therefore, come in contact with the ground, the several parts of the brush will traverse the uncovered part of that ground, and paint the pattern upon it. The wheel G, being kept lightly on the ground, serves to determine the line of contact, that it shall be the part opposite to B, and no other.

Chinese PRINTING, is performed from wooden planks or blocks, cut like those used in printing of callico, paper, cards, &c.

Rolling-press PRINTING, is employed in taking off prints or impressions from copperplates engraven, etched, or scraped, as in mezzotintos. See ENGRAVING.

This art is said to have been as ancient as the year 1540, and to owe its origin to Finiguerra, a Florentine goldsmith, who, pouring some melted brimstone on an engraven plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur: upon this he attempted to do the same on silver plates with wet paper, by rolling it smoothly with a roller; and this succeeded: but this art was not used in England till the reign of King James I. when it was brought from Antwerp by Speed. The form of the rolling-press, the composition of the ink used therein, and the manner of applying both in taking off prints, are as follows:

ig. 15.

The rolling-press AL, fig. 15. may be divided into two parts, the body and carriage: the body consists of two wooden cheeks PP, placed perpendicularly on a stand or foot LM, which sustains the whole press. From the foot likewise are four other perpendicular pieces, *c*, *c*, *c*, *c*, joined by other cross or horizontal ones, *d*, *d*, *d*, which serve to sustain a smooth even plank or table HIK, about four feet and a half long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DE, FG, about six inches in diameter, borne up at each end by the cheeks, whose ends, which are lessened to about two inches diameter, and called *trunnions*, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate the motion. Lastly, To one of the trunnions of the upper roller is fastened a cross, consisting of two levers AB, or pieces of wood, traversing each other, the arms of which cross serve instead of the bar or handle of the letter-press, by turning the upper roller, and when the plank is between the two rollers, giving the same motion to the under one, by drawing the plank forward and backward.

The ink used for copperplates, is a composition made of the stones of peaches and apricots, the bones of sheep and ivory, all well burnt, and called *Frankfort black*, mixed with nut-oil that has been well boiled, and ground together on a marble, after the same manner as painters do their colours.

The method of printing from copperplates is as follows: They take a small quantity of this ink on a rubber made of linen-rags, strongly bound about each other, and therewith smear the whole face of the plate as it lies on a grate over a charcoal fire. The plate being sufficiently inked, they first wipe it over with a foul rag, then with the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they rub it from time to time in whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman consists. The plate thus prepared, is laid on the plank of the press; over the plate is laid the paper, first well moistened, to receive the impression; and over the paper two or three folds of flannel. Things thus disposed, the arms of the cross are pulled, and by that means the plate with its furniture passed through between the rollers, which pinching very strongly, yet equally, press the moistened paper into the strokes of the engraving, whence it licks out the ink.

PRINTS, the impression taken from a copperplate. See the last article, and ENGRAVING.

From the facility of being multiplied, prints have derived an advantage over paintings by no means inconsiderable. They are found to be more durable; which may, however, in some degree be attributed to the different methods in which they are preserved. Many of the best paintings of the early masters have generally had the misfortune to be either painted on walls, or deposited in large and unfrequented, and consequently damp and destructive buildings; whilst a print, passing, at distant intervals, from the *porte feuille* of one collector to that of another, is preserved without any great exertion of its owner: And hence it happens, that whilst the pictures of Raphael have mouldered from their walls or deserted the canvas, the prints of his friend and cotemporary Mark Antonio Raimondi continue in full perfection to this day, and give us a lively idea of the beauties of these paintings, which, without their assistance, had been lost to us for ever; or at least, could have been only known to us, like those of Zeuxis and Apelles, by the descriptions which former writers on these subjects have left us.

Strutt's Dict of Engravers.

Independent of the advantages which prints affords us, when considered as accurate representations of paintings, and imitations of superior productions, they are no less valuable for their positive merit, as immediate representations of nature. For it must be recollected, that the art of engraving has not always been confined to the copying of other productions, but has frequently ly itself aspired to originality, and has, in this light, produced more instances of its excellence than in the other. Albert Durer, Goltzius, and Rembrandt, amongst the Dutch and Germans; Parmigiano and Della Bella amongst the Italians, and Callot amongst the French, have published many prints, the subjects of which, there is great reason to suppose, were never painted. These prints may therefore be considered as original pictures of those masters, deficient only in those particulars in which a print must necessarily be inferior to a painting.

The preceding distinction may perhaps threw some light on the proper method of arranging and classing a collection of prints, which has been a matter of no small difficulty. As an art imitating another, the principal should take the lead, and the design, composition, and drawing, in a print, being previous requisites, to the manner of execution and finishing; prints engraved after paintings should be arranged under the name of the painter; and every person who looks upon engraving only as auxilary to painting, will consequently adopt this mode of arrangement. But when engraving is considered as an original art, as imitating nature without the intervention of other methods, then it will certainly be proper to regulate the arrangement according to the names of the engravers.

Prints, method of cleaning. The following method of cleaning prints, is recommended as safe and efficacious.

"Provide a certain quantity of the common muriatic acid, for example three ounces, in a glass bottle, with a ground stopper, of such a capacity that it may be only half full. Half an ounce of minium must then be added; immediately after which the stopper is to be put in, and the bottle set in a cold and dark place. The heat, which soon becomes perceptible, shews the beginning of the new combination. The minium abandons the greatest part of its oxygen with which the fluid remains impregnated, at the same time that it acquires a fine golden yellow, and emits the detestable smell of oxygenated muriatic acid. It contains a small portion of muriate of lead; but this is not at all noxious in the subsequent process. It is also necessary to be observed, that the bottle must be strong, and the stopper not too firmly fixed, otherwise the active elastic vapour might burst it. The method of using this prepared acid is as follows:

"Provide a sufficiently large plate of glass, upon which one or more prints may be separately spread out. Near the edges let there be raised a border of soft white wax half an inch high, adhering well to the glass and flat at top. In this kind of trough the print is to be placed in a bath of fresh urine, or water containing a small quantity of ox-gall, and kept in this situation for three or four hours. The fluid is then to be decanted off, and pure warm water poured on, which must be changed every three or four hours until it passes limpid and clear. The impurities are sometimes of a resinous nature, and resist the action of pure water. When this is the case, the washed print must be left to dry, and alcohol is then to be poured on and left for a time. After the print is thus cleaned, and all the moisture drained off, the muriatic acid prepared with minium is to be poured on in sufficient quantity to cover the print; immediately after which another plate of glass is to be laid in contact with the rim of wax, in order to prevent the inconvenient exhalation of the oxygenated acid. In this situation the yellowest print will be seen to recover its original whiteness in a very short time. One or two hours are sufficient to produce the desired effect; but the print will receive no injury if it be left in the acid for a whole night. Nothing more is necessary to complete the work, than to decant off the remaining acid, and wash away every trace of acidity, by repeated effusions of pure water. The print being then left to dry (in the sun if possible) will be found white, clear, firm, and in no respect damaged, either in the texture of the paper, or the tone and appearance of the impression."

It is farther recommended to those who shall adopt the whole process for clearing prints, to make the first trial with a print of little value, and in this way he will discover what portion of water should be employed in diluting the acid to prevent the corrosive action of the latter on the paper. *Nichol. Journ.* ii. 265. 4to.

PRIOR, in general, something before or nearer the beginning than another, to which it is compared.

Prior, more particularly denotes the superior of a convent of monks, or the next under the abbot. See Abbot.

Priors are either *claustral* or *conventual*. *Conventual* are the same as abbots. *Claustral* prior, is he who governs the religious of an abbey or priory *in commendam*, having his jurisdiction wholly from the abbot.

Grand Prior, is the superior of a large abbey, where several superiors are required.

Prior, *Matthew*, an eminent English poet, was born at London in 1664. His father dying while he was very young, an uncle, a vintner, having given him some education at Westminster school, took him home in order to breed him up to his trade. However, at his leisure hours he prosecuted his study of the classics and particularly of his favourite Horace. This introduced him to some polite company who frequented his uncle's house; among whom the earl of Dorset took particular notice of him, and procured him to be sent to St John's college in Cambridge, where, in 1686, he took the degree of A. B. and afterwards became fellow of that college. Upon the revolution, Mr Prior was brought to court by the earl of Dorset; and in 1690 he was made secretary to the earl of Berkeley, plenipotentiary at the Hague; as he was afterward to the ambassador and plenipotentiaries at the treaty of Ryswick in 1697; and the year following to the earl of Portland, ambassador to the court of France. He was in 1697 made secretary of state for Ireland: and in 1700 was appointed one of the lords commissioners of trade and plantations. In 1710, he was supposed to have had a share in writing The Examiner. In 1711, he was made one of the commissioners of the customs; and was sent minister plenipotentiary to France, for the negotiating a peace with that kingdom. Soon after the accession of George I. to the throne in 1714, he presented a memorial to the court of France, requiring the demolishing of the canal and new works at Mardyke. The year following he was recalled; and upon his arrival was taken up by a warrant from the house of commons, and strictly examined by a committee of the privy-council. Robert Walpole, Esq. moved the house of commons for an impeachment against him; and Mr Prior was ordered into

into close custody. In 1717, he was excepted out of the act of grace; however, at the close of that year, he was set at liberty. The remainder of his days he spent in tranquillity and retirement, and died in 1721. His poems are well known, and justly admired. He is said to have written the following epitaph for himself:

> "Nobles and heralds, by your leave,
> Here lie the bones of Matthew Prior,
> The son of Adam and of Eve:
> Let Bourbon or Nassau go higher."

PRIORIES, Alien, were cells of the religious houses in England which belonged to foreign monasteries: for when manors or tithes were given to foreign convents, the monks, either to increase their own rule, or rather to have faithful stewards of their revenues, built a small convent here for the reception of such a number as they thought proper, and constituted priors over them.—Within these cells there was the same distinction as in those priories which were cells subordinate to some great abbey; some of these were conventual, and, having priors of their own choosing, thereby became entire societies within themselves, and received the revenues belonging to their several houses for their own use and benefit, paying only the ancient apport (A), acknowledgement, or obvention, at first the surplusage, to the foreign house; but others depended entirely on the foreign houses, who appointed and removed their priors at pleasure. These transmitted all their revenues to the foreign head houses; for which reason their estates were generally seized to carry on the wars between England and France, and restored to them again on return of peace. These alien priories were most of them founded by such as had foreign abbeys founded by themselves or by some of their family.

The whole number is not exactly ascertained; the Monasticon hath given a list of 100: Weever, p. 338. says 110.

Some of these cells were made indigenous or denizon, or endenized. The alien priories were first seized by Edward I. 1285, on the breaking out of the war between France and England; and it appears from a roll, that Edward II. also seized them, though this is not mentioned by our historians; and to these the act of restitution, 1 Edw. III. seems to refer.

In 1237, Edward III. confiscated their estates, and let out the priories themselves with all their lands and tenements, at his pleasure, for 23 years; at the end of which term, peace being concluded between the two nations, he restored their estates 1361, as appears by his latters patent to that of Montacute, county of Somerset, printed at large in Rymer, vol. vi. p. 311. and translated in Weever's *Funeral Monuments*, p. 339. At other times he granted their lands, or lay pensions out of them, to divers noblemen. They were also sequestered during Richard II.'s reign, and the head monasteries abroad had the king's licence to sell their lands to other religious houses here, or to any particular persons who wanted to endow others.

Henry IV. began his reign with showing some favour to the alien priories, restoring all the conventual ones, only reserving to himself in time of war what they paid in time of peace to the foreign abbeys.

They were all dissolved by act of parliament 2 Henry V. and all their estates vested in the crown, except some lands granted to the college of Fotheringhay. The act of dissolution is not printed in the statute book, but it is to be found entire in Rymer's *Fœdera*, ix. 283. and in the Parliament Rolls, vol. iv. p. 22. In general, these lands were appropriated to religious uses. Henry VI. endowed his foundations at Eton and Cambridge with the lands of the alien priories in pursuance of his father's design to appropriate them all to a noble college at Oxford. Others were granted in fee to the prelates, nobility, or private persons. Such as remained in the crown were granted by Henry VI. 1440, to Archbishop Chichley, &c. and they became part of his and the royal foundations. See *Some Account of Alien-Priories*, &c. in two volumes octavo.

PRIORITY, the relation of something considered as prior to another.

Priority, in *Law*, denotes an antiquity of tenure, in comparison of another less ancient.

PRISCIANUS, an eminent grammarian, born at Cæsarea, taught at Constantinople with great reputation about the year 525. Laurentius Valla calls Priscian, Donatus, and Servius, *triumviri in re grammatica*; and thinks none of the ancients who wrote after them fit to be mentioned with them. He composed a work *De arte grammatica*, which was first printed by Aldus at Venice in 1476; and another, *De naturalibus questionibus*, which he dedicated to Chosroes king of Persia: beside which, he translated Dionysius's description of the world into Latin verse. A person who writes false Latin, is proverbially said "to break Priscian's head."

PRISCILLIANISTS, in church history, Christian heretics, so called from their leader Priscillian, a Spaniard by birth, and bishop of Avila. He is said to have practised magic, and to have maintained the principal errors of the Manichees; but his peculiar tenet was, That it is lawful to make false oaths in order to support one's cause and interests.

PRISM, in *Geometry*, is a solid body, whose two ends are any plane figures which are parallel, equal, and similar; and its sides, connecting those ends, are parallelograms.

PRISMOID, is a solid body, somewhat resembling a prism, but its ends are any dissimilar parallel plane figures of the same number of sides, the upright sides being trapezoids. If the ends of the prismoid be bounded by dissimilar curves, it is sometimes called a *cylindroid*.

PRISON, a gaol, or place of confinement.

Lord Coke observes, that a prison is only a place of safe custody, *salva custodia*, not a place of punishment. If this be the case, prisons ought not to be, what they have been in most, and still are in some places of Europe,

(A) *Apportas* or *apportagium* (from *portare*), an acknowledgement, oblation, or obvention, to the mother house or church. *Du Cange*.

Prison.

rope, loathsome dungeons. Any place where a person is confined may be said to be a prison; and when a process is issued against one, he must, when arrested thereon, either be committed to prison, or be bound in a recognizance with sureties, or else give bail, according to the nature of the case, to appear at a certain day in court, there to make answer to what is alleged against him. Where a person is taken and sent to prison, in a civil case, he may be released by the plaintiff in the suit; but if it be for treason or felony, he may not regularly be discharged, until he is indicted of the fact and acquitted. See INDICTMENT.

But a prison is not only to be considered as a place of safe custody, according to its original design, but also as a place of temporary punishment for certain crimes, and perhaps this punishment might be substituted more frequently than it is, for transportation and death. Probably this is done in no country to better purpose than in Pennsylvania; and no where has imprisonment been more abused than in Venice under the old government.

By the laws of Pennsylvania, imprisonment is imposed, not merely as an expiation for past offences, but also for the reformation of the criminal's morals. The regulations of the gaol are calculated to produce this effect in the speediest manner possible, so that such a building may rather be denominated a *penitentiary house* than a *gaol*. When a criminal is committed to prison, he is made to wash; his hair is shorn, and he is furnished with clean apparel, if he has no decent clothes of his own. He is then put into a solitary cell, where he is excluded from the sight of every living being except the gaoler, whose duty is to attend to his mere necessities, but not to converse with him upon any account. If committed for an atrocious crime, he is even debarred from the light of heaven. The treatment of each prisoner varies in proportion to the nature of his crime, and his symptoms of repentance. The longest period of confinement is for a rape, which is not to be less than ten years, nor to exceed 21; and for high treason it is not to be under 6, nor above 12.

The prisoners must bathe twice in the week, having proper conveniences within the prison, and they are regularly supplied with a change of linen. Prisoners in solitary confinement subsist upon bread and water; and such as labour are allowed broth, puddings, &c. They are allowed meat in small quantities twice a week, and no beverage except water is brought into the prison. One room is set apart for shoe-makers, another for taylors, and so of every other trade. There are stone-cutters, smiths, nailers, &c. in the yards. Such a prison has all the advantages of the rasping house of Amsterdam, without any of its enormous defects.

The following account of the common prison at Venice, is given by Dr Mosely who visited this horrible place in September 1787.

"I was conducted (says he) through the prison by one of its inferior dependants. We had a torch with us. We crept along narrow passages as dark as pitch. In some of them two people could scarcely pass each other. The cells are made of massy marble; the architecture of the celebrated Sansovini.

"The cells are not only dark, and black as ink, but being surrounded and confined with huge walls, the smallest breath of air can scarcely find circulation in them. They are about nine feet square on the floor, arched at the top, and between six and seven feet high in the highest part. There is to each cell a round hole of eight inches diameter, through which the prisoner's daily allowance of twelve ounces of bread and a pot of water is delivered. There is a small iron door to the cell. The furniture of the cell is a little straw and a small tub; nothing else. The straw is renewed and the tub emptied through the iron door occasionally.

"The diet is ingeniously contrived for the perduration of punishment. Animal food, or a cordial nutritious regimen, in such a situation, would bring on disease, and defeat the end of this Venetian justice. Neither can the soul, if so inclined, steal away, wrapt up in slumbering delusion, or sink to rest; from the admonition of her sad existence, by the gaoler's daily return.

"I saw one man who had been in a cell thirty years; two who had been twelve years; and several who had been eight and nine years in their respective cells.

"By my taper's light I could discover the prisoners horrid countenances. They were all naked. The man who had been there thirty years, in face and body was covered with long hair. He had lost the arrangement of words and order of language. When I spoke to him, he made an unintelligible noise, and expressed fear and surprise; and, like some wild animals in deserts, which have suffered by the treachery of the human race, or have an instinctive abhorrence of it, he would have fled like lightning from me if he could.

"One whose faculties were not so obliterated; who still recollected the difference between day and night; whose eyes and ears, though long closed with a silent blank, still languished to perform their natural functiions—implored, in the most piercing manner, that I would prevail on the gaoler to murder him, or to give him some instrument to destroy himself. I told him I had no power to serve him in this request. He then entreated I would use my endeavours with the inquisitors to get him hanged, or drowned in the Canal' Orfano. But even in this I could not serve him: death was a favour I had not interest enough to procure for him.

"This kindness of death, however, was, during my stay in Venice, granted to one man, who had been 'from the cheerful ways of man cut off' thirteen years.

"Before he left his dungeon I had some conversation with him; this was six days previous to his execution. His transport at the prospect of death was surprising. He longed for the happy moment. No saint ever exhibited more fervour in anticipating the joys of a future state, than this man did at the thoughts of being released from life, during the four days mockery of his trial.

"It is the Canal' Orfano where vessels from Turkey and the Levant perform quarantine. This place is the watery grave of many who have committed political or personal offences against the state or senate, and of many who have committed no offences at all. They are carried out of the city in the middle of the night, tied up in a sack with a large stone fastened to it, and thrown into the water. Fishermen are prohibited, on forfeiture of of their lives, against fishing in this district. The pretence is the plague. This is the secret history of people being lost in Venice.

"The government, with age, grew feeble; was afraid of the discussion of legal process and of public executions; and navigated this rotten Bucentaur of the Adriatic by spies, prisons, assassination, and the Canal' Orfano."

PRISONER, a person restrained or kept in prison upon an action civil or criminal, or upon commendment: and one may be a prisoner on matter of record or matter of fact. A prisoner upon matter of record, is he who, being present in court, is by the court committed to prison; and the other is one carried to prison upon an arrest, whether it be by the sheriff, constable, or other officer.

PRISTIS, the SAWFISH, is generally considered as a species of the *squalus* or *shark* genus, comprehending under it several varieties. See SQUALUS, ICHTHYOLOGY *Index*. But Mr Latham is of opinion that it ought to be considered as a distinct genus, and that the characteristics of the several varieties are sufficient to constitute distinct species.

PRIVATEERS, are a kind of private men of war, the persons concerned wherein administer at their own costs a part of a war, by fitting out these ships of force, and providing them with all military stores; and they have, instead of pay, leave to keep what they take from the enemy, allowing the admiral his share, &c.

Privateers may not attempt any thing against the laws of nations; as to assault an enemy in a port or haven, under the protection of any prince or republic, whether he be friend, ally, or neuter; for the peace of such places must be inviolably kept; therefore, by a treaty made by King William and the States of Holland, before a commission shall be granted to any privateer, the commander is to give security, if the ship be not above 150 tons, in 1500l. and if the ship exceeds that burden, in 3000l. that they will make satisfaction for all damages which they shall commit in their courses at sea, contrary to the treaties with that state, on pain of forfeiting their commissions; and the ship is made liable.

Jacob's Law Dict.

Besides these private commissions, there are special commissions for privateers, granted to commanders of ships, &c. who take pay; who are under a marine discipline; and if they do not obey their orders, may be punished with death: and the wars in later ages have given occasion to princes to issue these commissions, to annoy the enemies in their commerce, and hinder such supplies as might strengthen them or lengthen out the war; and likewise to prevent the separation of ships of greater force from their fleets or squadrons.

Ships taken by privateers were to be divided into five parts; four parts whereof to go to the persons interested in the privateer, and the fifth to his majesty: and as a farther encouragement, privateers, &c. destroying any French man of war or privateer, shall receive, for every piece of ordnance in the ship so taken, 10l. reward, &c.

By a particular statute lately made, the lord admiral, or commissioners of the admiralty, may grant commissions to commanders of privateers, for taking ships, &c. which being adjudged prize, and the tenth part paid to the admiral, &c. wholly belong to the owners of the privateers and the captors, in proportions agreed on between themselves.

PRIVATION, in a general sense, denotes the absence or want of something; in which sense darkness is only the privation of light.

PRIVATIVE, in *Grammar*, a particle, which, prefixed to a word, changes it into a contrary sense. Thus, among the Greeks, the α is used as a privative; as in α-θεος, *atheist*, *acephalus*, &c.——The Latins have their privative *in*; as, *incorrigibilis*, *indeclinabilis*, &c.——The English, French, &c. on occasion borrow both the Latin and Greek privatives.

PRIVERNUM, (Livy, Virgil); a town of the Volsci, in Latium, to the east of Setia. *Privernates*, the people. Whose ambassadors being asked, What punishment they deserved for their revolt? answered, What those deserve who deem themselves worthy of liberty. And again, being asked by the Roman consul, should the punishment be remitted, What peace was to be expected with them? If you granted a good peace, you may hope to have it sincere and lasting; but if a bad one, you may well expect it of short continuance. At which answer, the Romans were so far from being displeased, that by a vote of the people they had the freedom of the city granted them. *Privernas*, *-atis*, the epithet. The town is now called *Piperno Vecchio*, situated in the Campania of Rome. E. Long. 10. 0. N. Lat. 41. 30.

PRIVET. See LIGUSTRUM, BOTANY *Index*.

PRIVILEGE, in *Law*, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law.

Privileges are said to be *personal* or *real*.

Personal privileges are such as are extended to peers, ambassadors, members of parliament, and of the convocation, &c. See LORDS, AMBASSADOR, PARLIAMENT, ARREST, &c.

A *real* privilege is that granted to some particular place; as the king's palace, the courts at Westminster, the universities, &c.

PRIVILEGES of the Clergy. See CLERGY.

PRIVY, in *Law*, is a partaker, or person having an interest, in any action or thing. In this sense they say, privies in blood: every heir in tail is privy to recover the land entailed. In old law-books, merchants privy are opposed to merchants strangers. Coke mentions four kinds of privies. Privies in blood, as the heir to his father; privies in representation, as executors and administrators to the deceased; privies in estate, as he in reversion and he in remainder, donor and donee, lessor and lessee: lastly, privy in tenure, as the lord by escheat; *i. e.* when land escheats to the lord for want of heirs.

PRIVY-Council. See COUNCIL. The king's will is the sole constituent of a privy-counsellor; and it also regulates their number, which in ancient times was about twelve. Afterwards it increased to so large a number, that it was found inconvenient for secrecy and dispatch; and therefore Charles II. in 1679, limited it to 30; whereof 15 were principal officers of state, and to be counsellors *ex officio*; and the other 15 were composed of 10 lords and five commoners of the king's choosing. Since that time, however, the number

has

has been much augmented, and now continues indefinite. At the same time also the ancient office of lord president of the council was revived, in the person of Anthony earl of Shaftesbury. Privy-counsellors are made by the king's nomination, without either patent or grant; and, on taking the necessary oaths, they become immediately privy-counsellors during the life of the king that chooses them, but subject to removal at his discretion.

Any natural born subject of England is capable of being a member of the privy-council; taking the proper oaths for security of the government, and the test for security of the church. By the act of settlement, 12 and 13 W. III. cap. 2. it is enacted, that no person born out of the dominions of the crown of England, unless born of English parents, even though naturalized by parliament, shall be capable of being of the privy-council. The duty of a privy-counsellor appears from the oath of office, which consists of seven articles. 1. To advise the king according to the best of his cunning and discretion. 2. To advise for the king's honour and good of the public, without partiality, through affection, love, meed, doubt, or dread. 3. To keep the king's counsel secret. 4. To avoid corruption. 5. To help and strengthen the execution of what shall be there resolved. 6. To withstand all persons who would attempt the contrary. And, lastly, in general, 7. To observe, keep, and do all that a good and true counsellor ought to do to his sovereign lord.

The privy-council is the *primum mobile* of the state, and that which gives the motion and direction to all the inferior parts. It is likewise a court of justice of great antiquity; the primitive and ordinary way of government in England being by the king and privy-council. It has been frequently used by all our kings for determining controversies of great importance: the ordinary judges have sometimes declined giving judgment till they had consulted the king and privy-council; and the parliament have frequently referred matters of high moment to the same, as being by long experience better able to judge of, and, by their secrecy and expedition, to transact some state affairs, than the lords and commons. At present, the privy-council takes cognizance of few or no matters except such as cannot well be determined by the known laws and ordinary courts; such as matters of complaint and sudden emergencies: their constant business being to consult for the public good in affairs of state. This power of the privy-council is to inquire into all offences against the government, and to commit the offenders to safe custody, in order to take their trial in some of the courts of law. But their jurisdiction herein is only to inquire, and not to punish; and the persons committed by them are intitled to their *habeas corpus* by statute 16 Car. I. cap. 10. as much as if committed by an ordinary justice of the peace.

In plantation or admiralty causes, which arise out of the jurisdiction of this kingdom, and in matters of lunacy and idiocy, the privy-council has cognizance, even in questions of extensive property, being the court of appeal in such causes; or, rather, the appeal lies to the king's majesty himself in council. From all the dominions of the crown, excepting Great Britain and Ireland, an appellate jurisdiction (in the last resort) is vested in this tribunal; which usually exercises its judicial authority in a committee of the whole privy-council, who hear the allegations and proofs, and make their report to his majesty in council, by whom the judgment is finally given.

Anciently, to strike in the house of a privy-counsellor, or elsewhere in his presence, was grievously punished: by 3 Hen. VII. cap. 14. if any of the king's servants of his household conspire or imagine to take away the life of a privy-counsellor, it is felony, though nothing shall be done upon it; and by 9 Ann. cap. 16. it is enacted, that any persons who shall unlawfully attempt to kill, or shall unlawfully assault, and strike, or wound, any privy counsellor in the execution of his office, shall be felons, and suffer death as such. With advice of this council, the king issues proclamations that bind the subject, provided they be not contrary to law. In debates, the lowest delivers his opinion first, the king last; and thereby determines the matter. A council is never held without the presence of a secretary of state.

The dissolution of the privy-council depends upon the king's pleasure; and he may, whenever he thinks proper, discharge any particular member, or the whole of it, and appoint another. By the common law also it was dissolved *ipso facto* by the king's demise, as deriving all its authority from him. But now, to prevent the inconveniencies of having no council in being at the accession of a new prince, it is enacted, by 6 Ann. cap. 7. that the privy-council shall continue for six months after the demise of the crown, unless sooner determined by the successor. *Blackst. Com.* book 1. p. 229, &c.

The officers of the privy-council are four clerks of the council in ordinary, three clerks extraordinary, a keeper of the records, and two keepers of the council-chamber. See President.

Privy Seal, a seal which the king uses previously to such grants, &c. as are afterwards to pass the great seal.

The privy seal is also sometimes used in matters of less consequence, which do not require the great seal.

Lord Privy Seal. See *Keeper of the Privy Seal.*

Clerks of the Privy Seal. See Clerk.

Privy Chamber. See Chamber.

PRIZE, or Prise, in maritime affairs, a vessel taken at sea from the enemies of a state, or from pirates; and that either by a man of war, a privateer, &c. having a commission for that purpose.

Vessels are looked on as prize, if they fight under any other standard than that of the state from which they have their commission; if they have no charter-party, invoice, or bill of lading abroad; if loaded with effects belonging to the king's enemies, or with contraband goods.

In ships of war, the prizes are to be divided among the officers, seamen, &c. as his majesty shall appoint by proclamation; but among privateers, the division is according to the agreement between the owners.

By stat. 13 Geo. II. c. 4. judges and officers, failing of their duty in respect to the condemnation of prizes, forfeit 500l. with full costs of suit; one moiety to the king, and the other to the informer.

PROA, Flying, in navigation, is a name given to a vessel used in the South seas, because with a brisk trade-wind trade-wind it sails near 20 miles an hour. In the construction of the proa, the head and stern are exactly alike, but the sides are very different; the side intended to be always the lee-side being flat; and the windward side made rounding, in the manner of other vessels; and, to prevent her over-setting, which, from her small breadth, and the straight run of her leeward side, would, without this precaution, infallibly happen, there is a frame laid out from her to windward, to the end of which is fastened a log, fashioned into the shape of a small boat, and made hollow. The weight of the frame is intended to balance the proa, and the small boat is by its buoyancy (as it is always in the water) to prevent her oversetting to windward; and this frame is usually called an outrigger. The body of the vessel is made of two pieces joined endwise, and sewed together with bark, for there is no iron used about her; she is about two inches thick at the bottom, which, at the gunwale, is reduced to less than one. The sail is made of matting, and the mast, yard, boom, and outriggers, are all made of bamboo. See *Anson's Voyage*, quarto, p. 341.

PROBABILITY, is a word of nearly the same import with likelihood. It denotes the appearance of truth, or that evidence arising from the preponderation of argument which produces opinion. (See OPINION). Locke classes all arguments under the heads of *demonstrative* and *probable*: Hume with greater accuracy divides them into *demonstrations*, *proofs*, and *probabilities*. Demonstration produces *science*; proof, *belief*; and probability, *opinion*.

Hardly any thing is susceptible of strict demonstration besides the mathematical sciences, and a few propositions in metaphysical theology. Physics rest upon principles, capable, some of them, of complete proof by experience, and others of nothing more than probability by analogical reasoning. What has *uniformly* happened, we expect with the fullest confidence to happen again in similar circumstances; what has *frequently* happened, we likewise expect to happen again; but our expectation is not confident. Uniform experience is proof; frequent experience is probability. The strongest man has *always* been able to lift the greatest weight; and, therefore, knowing that one man is stronger than another, we expect, with confidence, that the former will lift more than the latter. The best disciplined army has *generally* proved victorious, when all other circumstances were equal. We therefore expect that an army of veterans will, upon fair ground, defeat an equal number of new levied troops: but as sudden panics have sometimes seized the oldest soldiers, this expectation is accompanied with doubt, and the utmost that we can say of the expected event is, that it is *probable*; whereas in the competition between the two men, we look upon it as *morally certain*. (See METAPHYSICS, Part I. chap. vii. sec. 3.). When two or three persons of known veracity attest the same thing as consistent with their knowledge, their testimony amounts to *proof*, if not contradicted by the testimony of others; if contradicted, it can, at the utmost, amount only to probability. In common language we talk of *circumstantial* proofs and *presumptive* proofs; but the expressions are improper, for such evidence amounts to nothing more than probability. Of probability there are indeed various degrees, from the confines of certainty down to the confines of impossibility; and a variety of circumstances tending to the same point, though they amount not to what, in strictness of language, should be called *proof*, afford to the mind a very high degree of evidence, upon which, with the addition of one direct testimony, the laws of many countries take away the life of a man.

PROBABILITY *of an Event*, in the *Doctrine of Chances*, is greater or less according to the number of chances by which it may happen or fail. (See EXPECTATION). The *probability of life* is liable to rules of computation. In the *Encyclopedie Methodique*, we find a table of the probabilities of the duration of life, constructed from that which is to be found in the seventh volume of the *Supplemens à l'Histoire de M. de Buffon*; of which the following is an abridgement.

Of 23994 children born at the same time there will probably die

$\frac{1}{3}$	In one - -	7998
$\frac{2}{3}$	Remaining $\frac{2}{3}$ or 15996	
$\frac{1}{2}$	In eight years - -	11997
$\frac{1}{2}$	Remaining $\frac{1}{2}$ or 11997	
$\frac{2}{3}$	In thirty-eight years -	15996
$\frac{1}{3}$	Remaining $\frac{1}{3}$ or 7998	
$\frac{3}{4}$	In fifty years - -	17994
$\frac{1}{4}$	Remaining $\frac{1}{4}$ or 5998	
$\frac{5}{6}$	In sixty-one years -	19995

	Remaining $\frac{1}{10000}$ or 2.	

See *Bills of* MORTALITY.

PROBATE of a will or testament, in *Law*, is the exhibiting and proving of last wills and testaments before the ecclesiastical judge delegated by the bishop, who is ordinary of the place where the party died.

PROBATION, in the universities, is the examination and trial of a student who is about to take his degrees.

PROBATION, in a monastic sense, signifies the year of a novitiate, which a religious must pass in a convent, to prove his virtue and vocation, and whether he can bear the severities of the rule.

PROBATION, in *Scots Law*. See LAW *Index*.

PROBATIONER, in the church of Scotland, a student in divinity, who bringing a certificate from a professor in an university of his good morals, and his having performed his exercises to approbation, is admitted to undergo several trials; and, upon his acquitting himself properly in these, receives a licence to preach.

PROBATUM EST *(It is proved)*, a term frequently subjoined to a receipt for the cure of some disease.

PROBE, a surgeon's instrument for examining the circumstances of wounds, ulcers, and other cavities, searching for stones in the bladder, &c.

PROBITY means honesty, sincerity, or veracity; and consists in the habit of actions useful to society, and in the constant observance of the laws which justice and

and conscience impose on us. The man who obeys all the laws of society with an exact punctuality is not therefore a man of probity; laws can only respect the external and definite parts of human conduct, but probity respects our more private actions, and such as it is impossible in all cases to define; and it appears to be in morals what charity is in religion. Probity teaches us to perform in society those actions which no external power can oblige us to perform, and is that quality in the human mind from which we claim the performance of the *rights* commonly called *imperfect*. See MORAL PHILOSOPHY.

PROBLEM, in *Logic*, is a proposition that neither appears absolutely true nor false; and, consequently, may be asserted either in the affirmative or negative.

PROBLEM, in *Geometry*, is a proposition, wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See GEOMETRY.

PROBOSCIS, in *Natural History*, is the trunk or snout of an elephant, and some other animals and insects.

Flies, gnats, &c. are furnished with a proboscis or trunk; by means of which they suck the blood of animals, the juice of vegetables, &c. for their food.

PROBUS, MARCUS AURELIUS, was the son of a gardener, and became, by his great valour as a soldier, and his eminent virtues, emperor of Rome, to which dignity he was raised by the army. Having subdued the barbarous nations who made incursions into different parts of the empire, where they committed horrid cruelties, he managed the affairs of government with great wisdom and clemency. He was massacred in the year 282, and the 7th of his reign, by some soldiers who were weary of the public works at which he made them labour.

PROCATARCTIC CAUSE, in *Medicine*, the pre-existing, or predisposing cause or occasion of a disease.

PROCELEUSMATICUS, in the ancient poetry, a foot consisting of four short syllables, or two pyrrhychiuses; as *hominibus*.

PROCELLARIA, a genus of birds, belonging to the order of anseres. See ORNITHOLOGY *Index*. Clusius makes the procellaria pelagica or stormy petrel the Camilla of the sea.

> *Vel mare per medium fluctu suspensa tumenti*
> *Ferret iter, celeres nec tingeret æquore plantas.* VIRG.

> She swept the seas; and, as she skimm'd along
> Her flying feet unbath'd on billows hung. DRYDEN.

These birds are the *cypselli* of Pliny, which he places among the *apodes* of Aristotle; not because they wanted feet, but were κακοποδα, or had bad or useless ones; an attribute he gives to these species, on a supposition that they were almost always on the wing.

PROCESS, in *Law*, denotes the proceedings in any cause, real or personal, civil or criminal, from the original writ to the end thereof.

In a more limited sense, process denotes that by which a man is called first into any temporal court.

It is the next step for carrying on the suit, after suing out the original writ. See SUIT and WRIT.

It is the method taken by the law to compel a compliance with the original writ, of which the primary step is by giving the party notice to obey it. This notice is given upon all real *præcipes;* and also upon all personal writs for injuries not against the peace, by *summons;* which is a warning to appear in court at the return of the original writ, given to the defendant by two of the sheriff's messengers called *summoners*, either in person, or left at his house or land: in like manner as in the civil law the first process is by personal citation, *in jus vocando*. This warning on the land is given, in real actions, by erecting a white stick or wand on the defendant's grounds (which stick or wand among the northern nations is called the *baculus nunciatorius*), and by statute 31 Eliz. c. 3. the notice must also be proclaimed on some Sunday before the door of the parish-church.

Blackst. Comment.

If the defendant disobeys this verbal monition, the next process is by writ of *attachment*, or *pone;* so called from the words of the writ, *pone per vadium et salvos plegios*, "put by gage and safe pledges A. B. the defendant," &c. This is a writ not issuing out of chancery, but out of the court of common-pleas, being grounded on the non-appearance of the defendant at the return of the original writ; and thereby the sheriff is commanded to attach him, by taking *gage*, that is, certain of his goods, which he shall forfeit if he doth not appear; or by making him find *safe pledges* or sureties, which shall be amerced in case of his non-appearance. This is also the first and immediate process, without any previous summons, upon actions of trespass *vi et armis*, or for other injuries, which though not forcible, are yet trespasses against the peace, as *deceit* and *conspiracy;* where the violence of the wrong requires a more speedy remedy, and therefore the original writ commands the defendant to be at once attached, without any precedent warning.

If, after attachment, the defendant neglects to appear, he not only forfeits this security, but is moreover to be farther compelled by writ of *distringas*, or distress infinite: which is a subsequent process issuing from the court of common-pleas, commanding the sheriff to distrain the defendant from time to time, and continually afterwards, by taking his goods and the profits of his lands, which are called *issues*, and which he forfeits to the king if he doth not appear. But the issues may be sold, if the court shall so direct, in order to defray the reasonable costs of the plaintiff. In like manner, by the civil law, if the defendant absconds, so that the citation is of no effect, *mittitur adversarius in possessionem bonorum ejus*.

And here, by the common as well as the civil law, the process ended in case of injuries without force: the defendant if he had any substance, being gradually stripped of it all by repeated distresses, till he rendered obedience to the king's writ; and, if he had no substance, the law held him incapable of making satisfaction, and therefore looked upon all farther process as nugatory. And besides, upon feodal principles, the person of a feudatory was not liable to be attached for injuries merely civil, lest thereby his lord should be deprived of his personal services. But, in cases of injury accompanied with force, the law, to punish the breach of the peace and prevent its disturbance for the future, provided also a process against the defendant's person, in case he neglected to appear upon the former process of attachment, or had no substance whereby to be attached; subjecting

Process. jecting his body to imprisonment by the writ of *capias ad respondendum*. But this immunity of the defendant's person, in case of peaceable though fraudulent injuries, producing great contempt of the law in indigent wrong-doers, a *capias* was also allowed, to arrest the person in actions of account, though no breach of the peace be suggested, by the statutes of Marlbridge, 52 Hen. III. c. 23. and Westm. 2. 13. Edw. I. c. 11. in actions of debt and detinue, by statute 25 Edw. III. c. 17. and in all actions on the case, by statute 19 Hen. VII. c. 9. Before which last statute a practice had been introduced of commencing the suit by bringing an original writ of trespass *quare clausum fregit*, by breaking the plaintiff's close, *vi et armis*; which by the old common law subjected the defendant's person to be arrested by writ of *capias:* and then afterwards, by connivance of the court, the plaintiff might proceed to prosecute for any other less forcible injury. This practice (through custom rather than necessity, and for saving some trouble and expence, in suing out a special original adapted to the particular injury) still continues in almost all cases, except in actions of debt; though now, by virtue of the statutes above cited and others, a *capias* might be had upon almost every species of complaint.

If therefore the defendant, being summoned or attached, makes default, and neglects to appear; or if the sheriff returns a *nihil*, or that the defendant hath nothing whereby he may be summoned, attached, or distrained, the *capias* now usually issues: being a writ commanding the sheriff to take the body of the defendant, if he may be found in his bailiwick or county, and him safely to keep, so that he may have him in court on the day of the return, to answer to the plaintiff of a plea of debt, or trespass, &c. as the case may be. This writ, and all others subsequent to the original writ, not issuing out of chancery, but from the court into which the original was returnable, and being grounded on what has passed in that court in consequence of the sheriff's return, are called *judicial*, not *original*, writs; they issue under the privy seal of that court, and not under the great seal of England; and are *tested*, not in the king's name, but in that of the chief justice only. And these several writs being grounded on the sheriff's return, must respectively bear date the same day on which the writ immediately preceding was returnable.

This is the regular and orderly method of process. But it is now usual in practice to sue out the *capias* in the first instance, upon a supposed return of the sheriff; especially if it be suspected that the defendant, upon notice of the action, will abscond; and afterwards a fictitious original is drawn up, with a proper return thereupon, in order to give the proceedings a colour of regularity. When this *capias* is delivered to the sheriff, he by his under-sheriff grants a warrant to his inferior officers or bailiffs to execute it on the defendant. And, if the sheriff of Oxfordshire (in which county the injury is supposed to be committed and the action is laid) cannot find the defendant in his jurisdiction, he returns that he is not found, *non est inventus*, in his bailiwick: whereupon another writ issues, called a *testatum capias*, directed to the sheriff of the county where the defendant is supposed to reside, as of Berkshire, reciting the former writ, and that it is testified, *testatum est*, that the defendant lurks or wanders in his bailiwick, where he is commanded to take him, as in the former *capias*. But here also, when the action is brought in one county and the defendant lives in another, it is usual, for saving trouble, time, and expence, to make out a *testatum capias* at the first; supposing not only an original, but also a former *capias*, to have been granted; which in fact never was. And this fiction, being beneficial to all parties, is readily acquiesced in, and is now become the settled practice; being one among many instances to illustrate that maxim of law, that *in fictione juris consistit æquitas*.

Process.

But where a defendant absconds, and the plaintiff would proceed to an outlawry against him, an original writ must then be sued out regularly, and after that a *capias*. And if the sheriff cannot find the defendant upon the first writ of *capias*, and returns a *non est inventus*, there issues out an *alias* writ, and after that a *pluries*, to the same effect as the former: only after these words "we command you," this clause is inserted, "as we have formerly," or, "as we have often commanded you;"—"*sicut* alias," or, "*sicut* pluries *præcipimus*." And if a *non est inventus* is returned upon all of them, then a writ of *exigent* or *exigi facias* may be sued out, which requires the sheriff to cause the defendant to be proclaimed, required or exacted, in five county-courts successively, to render himself; and if he does, then to take him, as in a *capias:* but if he does not appear, and is returned *quinto exactus*, he shall then be outlawed by the coroners of the county. Also by statute 6 Hen. VIII. c. 4. and 31 Eliz. c. 3. whether the defendant dwells within the same or another county than that wherein the *exigent* is sued out, a *writ of proclamation* shall issue out at the same time with the *exigent*, commanding the sheriff of the county, wherein the defendant dwells, to make three proclamations thereof in places the most notorious, and most likely to come to his knowledge, a month before the outlawry shall take place. Such outlawry is putting a man out of the protection of the law, so that he is incapable to bring an action for redress of injuries; and it is also attended with a forfeiture of all one's goods and chattels to the king. And therefore, till some time after the conquest, no man could be outlawed but for felony: but in Bracton's time, and somewhat earlier, process of outlawry was ordained to lie in all actions for trespasses *vi et armis*. And since, by a variety of statutes (the same which allow the writ of *capias* before mentioned) process of outlawry doth lie in divers actions that are merely civil; providing they be commenced by original and not by bill. If after outlawry the defendant appears publicly, he may be arrested by a writ of *capias utlagatum*, and committed till the outlawry be reversed. Which reversal may be had by the defendants appearing personally in court (and in the king's bench without any personal appearance, so that he appears by attorney, according to statute 4 & 5 W. & M. c. 18.); and any plausible cause, however slight, will in general be sufficient to reverse it, it being considered only as a process to compel an appearance. But then the defendant must pay full costs, and put the plaintiff in the same condition as if he had appeared before the writ of *exigi facias* was awarded.

Such is the first process in the court of common pleas. In the king's bench they may also (and frequently do) proceed in certain causes, particularly in actions of ejectment and trespass, by *original* writ, with *attachment* and *capias* thereon; returnable, not at Westminster, where the

Process.

the common pleas are now fixed in consequence of *magna charta*, but *ubicunque fuerimus in Anglia*, wheresoever the king shall then be in England; the king's bench being removeable into any part of England at the pleasure and discretion of the crown. But the more usual method of proceeding therein is without any original, but by a peculiar species of process entitled a *bill of Middlesex;* and therefore so entitled, because the court now sits in that county; for if it sat in Kent, it would then be a bill of Kent. For though, as the justices of this court have, by its fundamental constitution, power to determine all offences and trespasses, by the common law and custom of the realm, it needed no original writ from the crown to give it cognizance of any misdemesnor in the county wherein it resides; yet as, by this court's coming into any county, it immediately superseded the ordinary administration of justice by the general commissioners of *eyre* and of *oyer and terminer*, a process of its own became necessary, within the county where it sat, to bring in such persons as were accused of committing any forcible injury. The bill of Middlesex (which was formerly always founded on a plaint of trespass *quare clausum fregit*, entered on the records of the court) is a kind of *capias*, directed to the sheriff of that county, and commanding him to take the defendant, and have him before our lord the king at Westminster on a day prefixed, to answer to the plaintiff of a plea of trespass. For this accusation of trespass it is that gives the court of king's bench jurisdiction in other civil causes, since, when once the defendant is taken into custody of the marshal, or prison-keeper of this court, for the supposed trespass, he, being then a prisoner of this court, may here be prosecuted for any other species of injury. Yet, in order to found this jurisdiction, it is not necessary that the defendant be actually the marshal's prisoner; for, as soon as he appears, or puts in bail, to the process, he is deemed by so doing to be in such custody of the marshal as will give the court a jurisdiction to proceed. And, upon these accounts, in the bill or process, a complaint of trespass is always suggested, whatever else may be the real cause of action. This bill of Middlesex must be served on the defendant by the sheriff, if he finds him in that county: but if he returns, *non est inventus*, then there issues out a writ of *latitat*, to the sheriff of another county, as Berks: which is similar to the *testatum capias* in the common pleas, and recites the bill of Middlesex and the proceedings thereon, and that it is testified that the defendant *latitat et discurrit*, lurks and wanders about in Berks; and therefore commands the sheriff to take him, and have his body in court on the day of the return. But as in the common pleas the *testatum capias* may be sued out upon only a supposed, and not an actual preceding, *capias;* so in the king's bench a *latitat* is usually sued out upon only a supposed, and not an actual, bill of Middlesex. So that, infact, a *latitat* may be called the first process in the court of king's bench, as the *testatum capias* is in the common pleas. Yet, as in the common pleas, if the defendant lives in the county wherein the action is laid, a common *capias* suffices; so in the king's bench likewise, if he lives in Middlesex, the process must still be by bill of Middlesex only.

In the exchequer the first process is by writ of *quo minus*, in order to give the court jurisdiction over pleas between party and party. In which writ the plaintiff is alleged to be the king's farmer or debtor, and that the defendant hath done him the injury complained of, *quo minus sufficiens existit*, by which he is the less able to pay the king his rent or debt. And upon this the defendant may be arrested as upon a *capias* from the common pleas.

Thus differently do the three courts set out at first, in the commencement of a suit, in order to entitle the two courts of king's bench and exchequer to hold plea in subjects causes, which by the original constitution of Westminster-hall they were not empowered to do. Afterwards, when the cause is once drawn into the respective courts, the method of pursuing it is pretty much the same in all of them.

If the sheriff had found the defendant upon any of the former writs, the *capias latitat*, &c. he was anciently obliged to take him into custody, in order to produce him in court upon the return, however small and minute the cause of action might be. For, not having obeyed the original summons, he had shown a contempt of the court, and was no longer to be trusted at large. But when the summons fell into disuse, and the *capias* became in fact the first process, it was thought hard to imprison a man for a contempt which was only supposed: and therefore, in common cases, by the gradual indulgence of the courts (at length authorised by statute 12 Geo. I. c. 29. which was amended by statute 5 Geo. II. c. 27. and made perpetual by statute 21 Geo. II. c. 3.) the sheriff or his officer can now only personally serve the defendant with the copy of the writ or process, and with notice in writing to appear by his attorney in court to defend this action; which in effect reduces it to a mere summons. And if the defendant think proper to appear upon this notice, his appearance is recorded, and he puts in sureties for his future attendance and obedience; which sureties are called *common bail*, being the same two imaginary persons that were pledges for the plaintiff's prosecution, John Doe and Richard Roe. Or, if the defendant does not appear upon the return of the writ, or within four (or in some cases eight) days after, the plaintiff may enter an appearance for him, as if he had really appeared; and may file common bail in the defendant's name, and proceed thereupon as if the defendant had done it himself.

But if the plaintiff will make affidavit, or assert upon oath, that the cause of action amounts to ten pounds or upwards, then in order to arrest the defendant, and make him put in substantial sureties for his appearance, called *special bail*, it is required by statute 13 Car. II. stat. 2. c. 2. that the true cause of action should be expressed in the body of the writ or process; else no security can be taken in a greater sum than 40l. This statute (without any such intention in the makers) had like to have ousted the king's bench of all its jurisdiction over civil injuries without force; for as the bill of Middlesex was framed only for actions of trespass, a defendant could not be arrested and held to bail thereupon for breaches of civil contracts. But to remedy this inconvenience, the officers of the king's bench devised a method of adding what is called a clause of *ac etiam* to the usual complaint of trespass; the bill of Middlesex commanding the defendant to be brought in to answer the plaintiff of a plea of trespass, *and also* to a bill of debt: the complaint or trespass giving cognizance to the court, and that of debt authorising the arrest.

rest. In imitation of which, lord chief justice North, a few years afterwards, in order to save the suitors of his court the trouble and expence of suing out special originals, directed, that in the common pleas, besides the usual complaint of breaking the plaintiff's close, a clause of *ac etiam* might be also added to the writ of *capias*, containing the true cause of action; as, "that the said Charles the defendant may answer to the plaintiff of a plea of trespass in breaking his close: and also, *ac etiam* may answer him, according to the custom of the court, in a certain plea of trespass upon the case, upon promises, to the value of 20l. &c." The sum sworn to by the plaintiff is marked upon the back of the writ; and the sheriff, or his officer the bailiff, is then obliged actually to arrest or take into custody the body of the defendant, and, having so done, to return the writ with a *cepi corpus* indorsed thereon. See ARREST.

When the defendant is regularly arrested, he must either go to prison, for safe custody; or put in *special bail* to the sheriff. For, the intent of the arrest being only to compel an appearance in court at the return of the writ, that purpose is equally answered, whether the sheriff detains his person, or takes sufficient security for his appearance, called *bail* (from the French word *bailer*, "to deliver)," because the defendant is bailed, or delivered, to his sureties, upon their giving security for his appearance; and is supposed to continue in their friendly custody instead of going to gaol. See BAIL. The method of putting in bail to the sheriff is, by entering into a bond or obligation, with one or more sureties, (not fictitious persons, as in the former case of common bail, but real, substantial, responsible bondsmen), to insure the defendant's appearance at the return of the writ; which obligation is called the *bail-bond*. The sheriff, if he pleases, *may* let the defendant go without any sureties; but that is at his own peril: for, after once taking him, the sheriff is bound to keep him safely, so as to be forthcoming in court; otherwise an action lies against him for an escape. But on the other hand, he is obliged, by statute 23 Hen. VI. c. 10. to take (if it be tendered) a sufficient bail-bond; and, by statute 12 Geo. I. c. 29. the sheriff shall take bail for no other sum than such as is sworn to by the plaintiff, and indorsed on the back of the writ.

Upon the return of the writ, or within four days after, the defendant must *appear* according to the exigency of the writ. This *appearance* is effected by putting in and justifying bail *to the action;* which is commonly called *putting in bail above*. If this be not done, and the bail that were taken by the sheriff *below* are responsible persons, the plaintiff may take an assignment from the sheriff of the bail-bond (under the statute 4 and 5 Ann. c. 16.) and bring an action thereupon against the sheriff's bail. But if the bail so accepted by the sheriff be insolvent persons, the plaintiff may proceed against the sheriff himself, by calling upon him, first to return the writ (if not already done), and afterwards to bring in the body of the defendant. And if the sheriff does not then cause sufficient bail to be put in *above*, he will himself be responsible to the plaintiff.

The bail *above*, or bail *to the action*, must be put in either in open court, or before one of the judges thereof; or else, in the country, before a commissioner appointed for that purpose by virtue of the statute 4 W. and M. c. 4. which must be transmitted to the court. These bail, who must at least be two in number, must enter into a recognizance in court, or before the judge or commissioner, whereby they do jointly and severally undertake, that if the defendant be condemned in the action, he shall pay the costs and condemnation, or render himself a prisoner, or that they will pay it for him: which recognizance is transmitted to the court in a slip of parchment, intitled a *bail-piece*. And, if required, the bail must *justify* themselves in court, or before the commissioner in the country, by swearing themselves housekeepers, and each of them to be worth double the sum for which they are bail, after payment of all their debts. This answers in some measure to the *stipulatio* or *satisdatio* of the Roman laws, which is mutually given by each litigant party to the other: by the plaintiff that he will prosecute his suit, and pay the costs if he loses his cause; in like manner as our law still requires nominal pledges of prosecution from the plaintiff: by the defendant, that he shall continue in court, and abide the sentence of the judge, much like our special bail; but with this difference, that the *fidejussores* were there absolutely bound *judicatum solvere*, to see the costs and condemnation paid at all events: whereas our special bail may be discharged, by surrendering the defendant into custody within the time allowed by law; for which purpose they are at all times entitled to a warrant to apprehend him.

Special bail is required (as of course) only upon actions of debt, or actions on the case in trover, or for money due, where the plaintiff can swear that the cause of action amounts to ten pounds: but in actions where the damages are precarious, being to be assessed *ad libitum* by a jury, as in actions for words, ejectment, or trespass, it is very seldom possible for a plaintiff to swear to the amount of his cause of action; and therefore no special bail is taken thereon, unless by a judge's order, or the particular directions of the court, in some particular species of injuries, as in cases of mayhem or atrocious battery; or upon such special circumstances as make it absolutely necessary that the defendant should be kept within the reach of justice. Also in actions against heirs, executors, and administrators, for debts of the deceased, special bail is not demandable; for the action is not so properly against them in person, as against the effects of the deceased in their possession. But special bail is required even of them, in actions for a *devastavit*, or wasting the goods of the deceased; that wrong being of their own committing.

Thus much for *process;* which is only meant to bring the defendant into court, in order to contest the suit, and abide the determination of the law. When he appears either in person as a prisoner, or out upon bail, then follow the *pleadings* between the parties. See PLEADINGS.

PROCESS upon an Indictment. See PROSECUTION. The proper process on an indictment for any petty misdemeanor, or on a penal statute, is a writ of *venire fascias*, which is in the nature of a summons to cause the party to appear. And if by the return to such *venire* it appears that the party hath lands in the county whereby he may be distrained, then a *distress infinite* shall be issued from time to time till he appears. But if the sheriff returns, that he hath no lands in his bailiwick, then (upon his non-appearance) a writ of *capias* shall issue, which commands the sheriff to take his body, and have

Process. have him at the next assizes; and if he cannot be taken upon the first *capias*, a second and a third shall issue, called an *alias* and a *pluries capias*. But, on indictments for treason or felony, a *capias* is the first process: and, for treason or homicide, only one shall be allowed to issue, or two in the case of other felonies, by statute 25 Edw. III. c. 14. though the usage is to issue only one in any felony; the provisions of this statute being in most cases found impracticable. And so in the case of misdemesnors, it is now the usual practice for any judge of the court of king's bench, upon certificate of an indictment found, to award a writ of *capias* immediately, in order to bring in the defendant. But if he absconds, and it is thought proper to pursue him to an outlawry, then a greater exactness is necessary. For, in such case, after the several writs have issued in a regular number, according to the nature of the respective crimes, without any effect, the offender shall be put in the *exigent* in order to his outlawry: that is, he shall be exacted, proclaimed, or required, to surrender at five county-courts; and if he be returned *quinto exactus*, and does not appear at the fifth exaction or requisition, then he is adjudged to be *outlawed*, or put out of the protection of the law; so that he is incapable of taking the benefit of it in any respect, either by bringing actions or otherwise.

The punishment for outlawries upon indictments for misdemesnors, is the same as for outlawries upon civil actions; viz. forfeiture of goods and chattels. But an outlawry in treason or felony amounts to a conviction and attainder of the offence charged in the indictment, as much as if the offender had been found guilty by his country. His life is, however, still under the protection of the law, as hath elsewhere been observed; (see HOMICIDE): that though anciently an outlawed felon was said to have *caput lupinum*, and might be knocked on the head like a wolf, by any one that should meet him; because, having renounced all law, he was to be dealt with as in a state of nature, when every one that should find him might slay him: yet now, to avoid such inhumanity, it is holden that no man is intitled to kill him wantonly or wilfully; but in so doing is guilty of murder, unless it happens in the endeavour to apprehend him. For any person may arrest an outlaw on a criminal prosecution, either of his own head, or by writ or warrant of *capias utlagatum*, in order to bring him to execution. But such outlawry may be frequently reversed by writ of error, the proceedings therein being (as it is fit they should be) exceedingly nice and circumstantial; and if any single minute point be omitted or misconducted, the whole outlawry is illegal, and may be reversed; upon which reversal the party accused is admitted to plead to, and defend himself against, the indictment.

Thus much for process to bring in the offender after indictment found; during which stage of the prosecution it is that writs of *certiorari facias* are usually had, though they may be had at any time before trial, to certify and remove the indictment, with all the proceedings thereon, from any inferior court of criminal jurisdiction into the court of king's bench; which is the sovereign ordinary court of justice in causes criminal. And this is frequently done for one of these four purposes; either, 1. To consider and determine the validity of appeals or indictments and the proceedings thereon; and to quash or confirm them as there is cause; or, 2. Where it is surmised that a partial or insufficient trial will probably be had in the court below, the indictment is removed, in order to have the prisoner or defendant tried at the bar of the court of king's bench, or before the justices of *nisi prius*: or, 3. It is so removed, in order to plead the king's pardon there: or, 4. To issue process of outlawry against the offender, in those counties or places where the process of the inferior judges will not reach him. Such writ of *certiorari*, when issued and delivered to the inferior court for removing any record or other proceeding, as well upon indictment as otherwise, supersedes the jurisdiction of such inferior court, and makes all subsequent proceedings therein entirely erroneous and illegal; unless the court of king's bench remands the record to the court below, to be there tried and determined. A *certiorari* may be granted at the instance of either the prosecutor or the defendant: the former as a matter of right, the latter as a matter of discretion; and therefore it is seldom granted to remove indictments from the justices of gaol-delivery, or after issue joined, or confession of the fact in any of the courts below.

At this stage of prosecution also it is, that indictments found by the grand jury against a peer, must in consequence of a writ of *certiorari*, be certified and transmitted into the court of parliament, or into that of the lord high steward of Great Britain; and that, in places of exclusive jurisdiction, as the two universities, indictments must be delivered (upon challenge and claim of cognizance) to the courts therein established by charter, and confirmed by act of parliament, to be there respectively tried and determined. See PLEA.

PROCESS, in *Chemistry*, the whole course of an experiment or series of operations, tending to produce something new.

PROCESS, in *Anatomy*, denotes any protuberance or eminence in a bone.

PROCESSION, a ceremony in the Romish church, consisting of a formal march of the clergy and people, putting up prayers, &c. and in this manner visiting some church, &c. They have also processions of the host or sacrament, &c. See HOST.

PROCHEIN AMY, in *Law*, the person next a-kin to a child in non-age, and who, in that respect, is allowed to act for him, and be his guardian, &c. if he hold land in soccage.

To sue, an infant is not allowed to make an attorney; but the court will admit his next friend as plaintiff, or his guardian as defendant.

PROCKIA, a genus of plants belonging to the polyandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

PROCLAMATION, a public notice given of any thing of which the king thinks proper to advertise his subjects.

Proclamations are a branch of the king's prerogative *; and have then a binding force, when (as Sir Edward Coke observes) they are grounded upon and enforce the laws of the realm. For though the making of laws is entirely the work of a distinct part, the legislative branch of the sovereign power, yet the manner, time, and circumstances of putting those laws in execution, must frequently be left to the discretion of the executive magistrate. And therefore his constitutions or edicts, concerning those points which we call *Proclamations*,

* See Prerogative.

Proclamations, are binding upon the subject, where they do not either contradict the old laws, or tend to establish new ones; but only enforce the execution of such laws as are already in being, in such manner as the king shall judge necessary. Thus the established law is, that the king may prohibit any of his subjects from leaving the realm: a proclamation therefore forbidding this in general for three weeks, by laying an embargo upon all shipping in time of war, will be equally binding as an act of parliament, because founded upon a prior law. But a proclamation to lay an embargo in time of peace upon all vessels laden with wheat, (though in the time of a public scarcity), being contrary to law, and particularly to statute 22 Car. II. c. 13. the advisers of such a proclamation, and all persons acting under it, found it necessary to be indemnified by a special act of parliament, 7 Geo. III. c. 7. A proclamation for disarming Papists is also binding, being only in execution of what the legislature has first ordained: but a proclamation for allowing arms to Papists, or for disarming any Protestant subjects, will not bind; because the first would be to assume a dispensing power, the latter a legislative one; to the vesting of either of which in any single person the laws of England are absolutely strangers. Indeed, by the stat. 31 Hen. VIII. c. 8. it was enacted, that the king's proclamations should have the force of acts of parliament; a statute, which was calculated to introduce the most despotic tyranny: and which must have proved fatal to the liberties of this kingdom, had it not been luckily repealed in the minority of his successor, about five years after. By a late act of parliament the king is empowered to raise regiments of Roman Catholics to serve in the present war.

PROCLUS, surnamed DIADOCUS, a Greek philosopher and mathematician, was born in Lycia, and lived about the year 500. He was the disciple of Syrianus, and had a great share in the friendship of the emperor Anastasius. It is said, that when Vitalian laid siege to Constantinople, Proclus burnt his ships with large brazen speculums. This philosopher was a Pagan, and wrote against the Christian religion. There are still extant his Commentaries on some of Plato's books, and other of his works written in Greek.

PROCONSUL, a Roman magistrate, sent to govern a province with consular authority.

The proconsuls were appointed out of the body of the senate; and usually as the year of any one's consulate expired, he was sent proconsul into some province.

The proconsuls decided cases of equity and justice, either privately in their pretorium or palace, where they received petitions, heard complaints, granted writs under their seal, and the like; or else publicly, in the common hall, with the usual formalities observed in the court of judicature at Rome. They had besides, by virtue of their edicts, the power of ordering all things relating to the tributes, taxes, contributions, and provisions of corn and money, &c. Their office lasted only a year. See CONSUL.

PROCOPIUS, a famous Greek historian, born in Cæsaria, acquired great reputation by his works in the reign of Justinian, and was secretary to Belisarius during all the wars carried on by that general in Persia, Africa, and Italy. He at length became senator, obtained the title of *illustrious*, and was made pretor of Constantinople.

PROCREATION, the begetting and bringing forth young. See GENERATION and SEMEN.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law.

PROCTOR, in the English universities. See UNIVERSITY.

PROCURATION, an act or instrument by which a person is empowered to treat, transact, receive, &c. in another person's name.

PROCURATOR. See PROCTOR.

PROCYON, in *Astronomy*, a fixed star of the second magnitude, situated in canis minor, or the little dog.

PRODIGALITY, means extravagance, profusion, waste, or excessive liberality, and is the opposite extreme to the vice of parsimony. By the Roman law, if a man by notorious prodigality was in danger of wasting his estate, he was looked upon as *non compos*, and committed to the care of curators, or tutors, by the prætor. And by the laws of Solon, such prodigals were branded with perpetual infamy.

PRODUCT, in *Arithmetic* and *Geometry*, the factum of two or more numbers, or lines, &c. into one another: thus $5 \times 4 = 20$ the product required.

PROEDRI, among the Athenians, were magistrates, who had the first seats in the public assemblies, and whose office it was to propose at each assembly the things to be deliberated upon and determined. Their office always ended with the meeting. Their number was nine, so long as the tribes were ten in number.

PROFANATION, the acting disrespectfully to sacred things.

PROFANE, a term used in opposition to *holy*; and in general is applied to all persons who have not the sacred character, and to things which do not belong to the service of religion.

PROFESSION means a calling, vocation, or known employment. In Knox's *Essays*, vol. i. page 234, we find an excellent paper on the choice of a profession, which that elegant writer concludes thus: "All the occupations of life (says he) are found to have their advantages and disadvantages admirably adapted to preserve the just equilibrium of happiness. This we may confidently assert, that, whatever are the inconveniences of any of them, they are all preferable to a life of inaction; to that wretched listlessness, which is constrained to pursue pleasure as a business, and by rendering it the object of severe and unvaried attention, destroys its very essence."

Among the Romanists profession denotes the entering into a religious order, whereby a person offers himself to God by a vow of inviolably observing obedience, chastity, and poverty.

PROFESSOR, in the universities, a person who teaches or reads public lectures in some art or science from a chair for that purpose.

PROFILE, in *Architecture*, the draught of a building, fortification, &c. wherein are expressed the several heights, widths, and thicknesses, such as they would appear were the building cut down perpendicularly from the roof to the foundation. Whence the profile is also called the *section*, sometimes *orthographical section*, and by Vitruvius also *sciagraphy*.

Profile ‖ Prognostic.

Profile, in this sense, amounts to the same with *elevation*; and stands opposed to *plan* or *ichnography*.

PROFILE is also used for the contour or outline of a figure, building, member of architecture, or the like; as a base, a cornice, &c. Hence *profiling* is sometimes used for designing, or describing the member with rule, compass, &c.

PROFILE, in sculpture and painting.—A head, a portrait, &c. are said to be in *profile*, when they are represented sidewise, or in a side-view; as, when in a portrait there is but one side of the face, one eye, one cheek, &c. shown, and nothing of the other.—On almost all medals, the faces are represented in *profile*.

PROFLUVIUM, in *Medicine*, denotes a flux, or liquid evacuation of any thing.

PROGNOSTIC, among physicians, signifies a judgement concerning the event of a disease; as whether it shall end in life or death, be short or long, mild or malignant, &c.

Prognostic ‖ Progression.

PROGRAMMA, anciently signified a letter sealed with the king's seal.

Programma is also an university term for a billet or advertisement, posted up or given into the hand, by way of invitation to an oration, &c. containing the argument, or so much as is necessary for understanding thereof.

PROGRESSION, in general, denotes a regular advancing, or going forwards, in the same course and manner.

PROGRESSION, in *Mathematics*, is either arithmetical or geometrical. Continued arithmetic proportion is, where the terms do increase and decrease by equal differences, and is called *arithmetic progression*:

$$\text{Thus}\left\{\begin{array}{l} a,\ a+d,\ a+2d,\ a+3d,\ \text{\&c. increasing} \\ a,\ a-d,\ a-2d,\ a-3d,\ \text{\&c. decreasing}\end{array}\right\}\text{by the difference } d.$$

$$\text{In numbers}\left\{\begin{array}{l} 2,\ 4,\ 6,\ 8,\ 10,\ \text{\&c. increasing} \\ 10,\ 8,\ 6,\ 4,\ \ 2,\ \text{\&c. decreasing}\end{array}\right\}\text{by the difference } 2.$$

Geometric Progression, or *Continued Geometric Proportion*, is when the terms do increase or decrease by equal ratios: thus,

$$\left.\begin{array}{r} a,\ ar,\ arr,\ arrr,\ \text{\&c. increasing} \\ a,\ \frac{a}{r},\ \frac{a}{rr},\ \frac{a}{rrr},\ \text{\&c. decreasing}\end{array}\right\}\text{from a continual}\left\{\begin{array}{l}\text{multiplication}\\ \text{division}\end{array}\right\}\text{by } r$$

$$\left.\begin{array}{r} 2,\ 4,\ 8,\ 16,\ 32,\ 64,\ \text{increasing} \\ 64,\ 32,\ 16,\ 8,\ 4,\ 2,\ \text{decreasing}\end{array}\right\}\text{from a continual}\left\{\begin{array}{l}\text{multiplication}\\ \text{division}\end{array}\right\}\text{by } 2.$$

See the articles FLUXIONS, GEOMETRY, and SERIES.

PROJECTILES.

1 Object of the science.

THIS is the name for that part of mechanical philosophy which treats of the motion of bodies anyhow projected from the surface of this earth, and influenced by the action of terrestrial gravity.

2 Effect of gravity on projected bodies.

It is demonstrated in the physical part of astronomy, that a body so projected must describe a conic section, having the centre of the earth in one focus; and that it will describe round that focus areas proportional to the times. And it follows from the principles of that science, that if the velocity of projection exceeds 36700 feet in a scond, the body (if not resisted by the air) would describe a hyperbola; if it be just 36700, it would describe a parabola; and if it be less than this, it would describe an ellipsis. If projected directly upwards, in the first case, it would never return, but proceed for ever; its velocity continually diminishing, but never becoming less than an assignable portion of the excess of the initial velocity above 36700 feet in a second; in the second case, it would never return, its velocity would diminish without end, but never be extinguished. In the third case, it would proceed till its velocity was reduced to an assignable portion of the difference between 36700 and its initial velocity; and would then return, regaining its velocity by the same degrees, and in the same places, as it lost it. These are necessary consequences of a gravity directed to the centre of the earth, and inversely proportional to the square of the distance. But in the greatest projections that we are able to make, the gravitations are so nearly equal, and in directions so nearly parallel, that it would be ridiculous affectation to pay any regard to the deviations from equality and parallelism. A bullet rising a mile above the surface of the earth loses only $\frac{1}{1000}$ of its weight, and a horizontal range of 4 miles makes only 4′ of deviation from parallelism.

Let us therefore assume gravitation as equal and parallel. The errors arising from this assumption are quite insensible in all the uses which can be made of this theory.

The theory itself will ever be regarded with some veneration and affection by the learned. It was the first fruits of mathematical philosophy. Galileo was the first who applied mathematical knowledge to the motions of free bodies, and this was the subject on which he exercised his fine genius.

3 Constant or uniform.

Gravity must be considered by us as a constant or uniform accelerating or retarding force, according as it produces the descent, or retards the ascent, of a body. A constant or invariable accelerating force is one which produces an uniform acceleration; that is, which in equal times produces equal increments of velocity, and therefore produces increments of velocity proportional to the times in which they are produced. Forces are of themselves imperceptible, and are seen only in their effects; and they have no measure but the effect, or what *measures* the effect; and every thing which we can discover with regard to those measures, we must affirm with regard to the things of which we assume them as the measures. Therefore,

The

4 **Consequences of this fact.** The motion of a falling body, or of a body projected directly downwards, is uniformly accelerated; and that of a body projected directly upwards is uniformly retarded: that is, the acquired velocities are as the times in which they are acquired by falling, and the extinguished velocities are as the times in which they are extinguished.

5 **Corollaries drawn from it.** *Cor.* 1. If bodies simply fall, not being projected downwards by an external force, the times of the falls are proportional to the final velocities; and the times of ascents, which terminate by the action of gravity alone, are proportional to the initial velocities.

2. The spaces described by a heavy body falling from rest are as the squares of the acquired velocities; and the differences of these spaces are as the differences of the squares of the acquired velocities: and, on the other hand, the heights to which bodies projected upwards will rise, before their motions be extinguished, are as the squares of the initial velocities.

3. The spaces described by falling bodies are proportional to the squares of the times from the beginning of the fall; and the spaces described by bodies projected directly upwards are as the squares of the times of the ascents.

4. The space described by a body falling from rest is one half of the space which the body would have uniformly described in the same time, with the velocity acquired by the fall.—And the height to which a body will rise, in opposition to the action of gravity, is one half of the space which it would uniformly describe in the same time with the initial velocity.

In like manner the difference of the spaces which a falling or rising body describes in any equal successive parts of its fall or rise, is one half of the space which it would uniformly describe in the same time with the difference of the initial and final velocities.

This proposition will be more conveniently expressed for our purpose thus:

A body moving uniformly during the time of any fall with the velocity acquired thereby, will in that time describe a space double of that fall; and a body projected directly upwards will rise to a height which is one half of the space which it would, uniformly continued, describe in the time of its ascent with the initial velocity of projection.

These theorems have been already demonstrated in a popular way, in the article GUNNERY. But we would recommend to our readers the 39th prop. of the first book of Newton's *Principia*, as giving the most general investigation of this subject; equally easy with these more loose methods of demonstration, and infinitely superior to them, by being equally applicable to every variation of the accelerating force. See an excellent application of this proposition by Mr Robins, for defining the motion of a ball discharged from a cannon, in the article GUNNERY, N° 15.

6 **The force of gravity in falling bodies can be ascertained.** 5. It is a matter of observation and experience, that a heavy body falls 16 feet and an inch English measure in a second of time; and therefore acquires the velocity of 32 feet 2 inches per second. This cannot be ascertained directly, with the precision that is necessary. A second is too small a portion of time to be exactly measured and compared with the space described; but it is done with the greatest accuracy by comparing the motion of a falling body with that of a pendulum. The time of a vibration is to the time of falling through half the length of the pendulum, as the circumference of a circle is to its diameter. The length of a pendulum can be ascertained with great precision; and it can be lengthened or shortened till it makes just 86,400 vibrations in a day: and this is the way in which the space fallen through in a second has been accurately ascertained.

As all other forces are ascertained by the accelerations which they produce, they are conveniently measured by comparing their accelerations with the acceleration of gravity. This therefore has been assumed by all the later and best writers on mechanical philosophy, as the unit by which every other force is measured. It gives us a perfectly distinct notion of the force which retains the moon in its orbit, when we say it is the 3600th part of the weight of the moon at the surface of the earth. We mean by this, that if a bullet were here weighed by a spring steelyard, and pulled it out to the mark 3600; if it were then taken to the distance of the moon, it would pull it out only to the mark 1. And we make this assertion on the authority of our having observed that a body at the distance of the moon falls from that distance $\frac{1}{3600}$ part of 16 feet in a second. We do not, therefore, compare the *forces*, which are imperceptible things; we compare the accelerations, which are their indications, effects, and measures.

This has made philosophers so anxious to determine with precision, the fall of heavy bodies, in order to have an exact value of the accelerating power of terrestrial gravity. Now we must here observe, that this measure may be taken in two ways: we may take the space through which the heavy body falls in a second; or we may take the velocity which it acquires in consequence of gravity having acted on it during a second. The last is the proper measure; for the last is the immediate effect on the body. The action of gravity has changed the state of the body—in what way? By giving it a determination to motion downwards, this both points out the kind and the degree or intensity of the force of gravity. The space described in a second by falling, is not an invariable measure; for, in the successive seconds, the body falls through 16, 48, 80, 112, &c. feet, but the changes of the body's state in each second is the same. At the beginning it had no determination to move with any appreciable velocity; at the end of the first second it had a determination by which it would have gone on for ever (had no subsequent force acted on it) at the rate of 32 feet per second. At the end of the second second, it had a determination by which it would have moved for ever, at the rate of 64 feet per second. At the end of the third second, it had a determination by which it would have moved for ever, at the rate of 96 feet per second, &c. &c. The difference of these determinations is a determination to the rate of 32 feet per second. This is therefore constant, and the indication and proper measure of the constant or invariable force of gravity. The space fallen through in the first second is of use only as it is one half of the measure of this determination; and as halves have the proportion of their wholes, different accelerating forces may be safely affirmed to be in the proportion of the spaces through which they uniformly impel bodies in the same time. But we should always recollect, that this is but one half of the true measure of the accelerating force. Mathematicians of the first rank have

7 **Two modes of determining the fall of heavy bodies.**

8 **Mistakes of mathematicians on this subject.**

have committed great mistakes by not attending to this; and it is necessary to notice it just now, because cases will occur in the prosecution of this subject, where we shall be very apt to confound our reasonings by a confusion in the use of those measures. Those mathematicians who are accustomed to the geometrical consideration of curvilineal motions, are generally disposed to take the *actual deflection* from the tangent as the measure of the deflecting force; while those who treat the same subject algebraically, by the assistance of fluxions, take *the change of velocity*, which is measured by *twice* the deflection. The reason is this: when a body passes through the point B of a curve ABC, fig. 1. if the deflecting force were to cease at that instant, the body would describe the tangent BD in the same time in which it describes the arch BC of the curve, and DC is the deflection, and is therefore taken for the measure of the deflecting force. But the algebraist is accustomed to consider the curve by means of an equation between the abscissæ H a, H b, H c, and their respective ordinates A a, B b, C c; and he measures the deflections by the changes made on the increments of the ordinates. Thus the increment of the ordinate A a, while the body describes the arch AB of the curve, is BG. If the deflecting force were to cease when the body is at B, the next increment would have been equal to BG, that is, it would have been EF; but in consequence of the deflection, it is only CF: therefore he takes EC for the measure of the deflection, and of the deflecting force. Now EC is ultimately twice DC; and thus the measure of the algebraist (derived solely from the nature of the differential method, and without any regard to physical considerations) happens to coincide with the true physical measure. There is therefore great danger of mixing these measures. Of this we cannot give a more remarkable instance than Leibnitz's attempt to demonstrate the elliptical motion of the planets in the Leipsic Acts, 1689. He first considers the subject mechanically, and takes the deflection or DC for the measure of the deflecting force. He then introduces his differential calculus, where he takes the difference of the increments for the measure; and thus brings himself into a confusion, which luckily compensates for the false reasoning in the preceding part of his paper, and gives his result the appearance of a demonstration of Newton's great discovery, while, in fact, it is a confused jumble of assumptions, self-contradictory, and inconsistent with the very laws of mechanics which are used by him in the investigation. Seventeen years after this, in 1706, having been criticised for his bad reasoning, or rather accused of an envious and unsuccessful attempt to appropriate Newton's invention to himself, he gives a correction of his paralogism, which he calls a correction of language. But he either had not observed where the paralogism lay, or would not let himself down by acknowledging a mistake in what he wished the world to think his own calculus (fluxions); he applied the correction where no fault had been committed, for he had measured both the centrifugal force and the solicitation of gravity in the same way, but had applied the fluxionary expression to the last and not to the first, and, by so doing, he completely destroyed all coincidence between his result and the planetary motions. We mention this instance, not only as a caution to our mathematical readers, but also as a very curious literary anecdote. This dissertation of Leibnitz is one of the most obscure of his obscure writings, but deserves the attention of an intelligent and curious reader, and cannot fail of making an indelible impression on his mind, with relation to the modesty, candour, and probity of the author. It is preceded by a dissertation on the subject which we are now entering upon, the motion of projectiles in a resisting medium. Newton's *Principia* had been published a few years before, and had been reviewed in a manner shamefully slight, in the Leipsic Acts. Both these subjects make the capital articles of that immortal work. Mr Leibnitz published these dissertations, without (says he) having seen Newton's book, in order to show the world that he had, some years before, discovered the same theorems. Mr Nicholas Fatio carried a copy of the *Principia* from the author to Hanover in 1686, where he expected to find Mr Leibnitz; he was then absent, but Fatio saw him often before his return to France in 1687, and does not say that the book was not given him. Read along with these dissertations Dr Keill's letter to John Bernoulli and others, published in the *Journal Literaire de la Hayeé* 1714, and to John Bernoulli in 1719.

Plate CCCCXLI. fig. 1.

9
Particularly of Leibnitz.

10
Newton accused of a similar mistake by J. Bernoulli.

Newton has been accused of a similar oversight by John Bernoulli, (who indeed calls it a mistake in principle) in his Proposition x. book 2. on the very subject we are now considering. But Dr Keill has shown it to be only an oversight, in drawing the tangent on the wrong side of the ordinate. For in this very proposition Newton exhibits, in the strictest and most beautiful manner, the difference between the geometrical and algebraical manner of considering the subject; and expressly warns the reader, that *his* algebraical symbol expresses the deflection only, and not the variation of the increment of the ordinate. It is therefore in the last degree improbable that he would make this mistake. He most expressly does not; and as to the real mistake, which he corrected in the second edition, the writer of this article has in his possession a manuscript copy of notes and illustrations on the whole Principia, written in 1693 by Dr David Gregory, Savilian professor of astronomy at Oxford, at the desire of Mr Newton, as preparatory for a new edition, where he has rectified this and several other mistakes in that work, and says that Mr Newton had seen and approved of the amendments. We mention these particulars, because Mr Bernoulli published an elegant dissertation on this subject in the Leipsic Acts in 1713; in which he charges Newton (though with many protestations of admiration and respect) with this mistake in principle; and says, that he communicated his correction to Mr Newton, by his nephew Nicholas Bernoulli, that it might be corrected in the new edition, which he heard was in the press. And he afterwards adds, that it appears by some sheets being cancelled, and new ones substituted in this part of the work, that the mistake would have continued, had be not corrected it. We would desire our readers to consult this dissertation, which is extremely elegant, and will be of service to us in this article; and let them compare the civil things which is here said of the *vir incomparabilis*, the *omni laude major*, the *summus Newtonus*, with what the same author, in the same year, in the Leipsic Acts, but under a borrowed name, says of him. Our readers will have no hesitation in ascribing this letter to this author. For, after praising John Bernoulli as *summus geometra*, *natus*

11
But falsely.

12
Insincerity of Bernoulli with respect to Newton.

natus ad summorum geometarum paralogismos corrigendos, summi candoris ut et modestiæ, he betrays himself by an unguarded warmth, when defending J. B.'s demonstration of the inverse problem of centripetal forces, by calling it MEAM *demonstrationem*.

Let our readers now consider the scope and intention of this dissertation on projectiles, and judge whether the author's aim was to instruct the world, or to acquire fame, by correcting Newton. The dissertation does not contain one theorem, one corollary, nor one step of argument, which is not to be found in Newton's first edition; nor has he gone farther than Newton's single proposition the xth. To us it appears an exact companion to his proposition on centripetal forces, which he boasts of having first demonstrated, although it is in every step a transcript of the 42d of the first Book of Newton's Principia, the geometrical language of Newton being changed into algebraic, as he has in the present case changed Newton's algebraic analysis into a very elegant geometrical one.

We hope to be forgiven for this long digression. It is a very curious piece of literary history, and shows the combination which envy and want of honourable principle had formed against the reputation of our illustrious countryman; and we think it our duty to embrace any opportunity of doing it justice.—To return to our subject:

13 Accurate measure of the accelerative power of gravity.

The accurate measure of the accelerative power of gravity, is the *fall* $16\frac{1}{12}$ feet, if we measure it by the space, or the *velocity* of $32\frac{1}{6}$ feet per second, if we take the velocity. It will greatly facilitate calculation, and will be sufficiently exact for all our purposes, if we take 16 and 32, supposing that a body falls 16 feet in a second, and acquires the velocity of 32 feet per second. Then, because the heights are as the squares of the times, and as the squares of the acquired velocities, a body will fall one foot in one fourth of a second, and will acquire the velocity of eight feet per second. Now let h express the height in feet, and call it the PRODUCING HEIGHT; v the velocity in feet per second, and call it the PRODUCED VELOCITY, the velocity DUE; and t the time in seconds.—We shall have the following formulæ, which are of easy recollection, and will serve, without tables, to answer all questions relative to projectiles.

14 General formulæ deduced.

$$\text{I. } v=8\sqrt{h},=8\times 4t,=32t$$

$$\text{II. } t=\frac{\sqrt{h}}{4},=\frac{v}{32}$$

$$\text{III. } \sqrt{h}=\frac{v}{8},=4t$$

$$\text{IV. } h=\frac{v^2}{64},=16t^2.$$

15 Examples of their use in falling bodies.

To give some examples of their use, let it be required,

1. To find the time of falling through 256 feet. Here $h=256$, $\sqrt{256}=16$, and $\frac{16}{4}=4$. Answer 4″.

2. To find the velocity acquired by falling four seconds. $t=4 \,.\, 32\times 4=128$ feet per second.

3. To find the velocity acquired by falling 625 feet. $h=625 \,.\, \sqrt{h}=25 \,.\, 8\sqrt{h}=200$ feet per second.

4. To find the height to which a body will rise when projected with the velocity of 56 feet per second, or the height through which a body must fall to acquire this velocity.

16 In bodies projected upwards,

$$v=56 \,.\, \frac{56}{8}=7,=\sqrt{h} \,.\, 7^2=h,=49 \text{ feet.}$$

$$\text{or } 56^2=3136 \,.\, \frac{3136}{64}=49 \text{ feet.}$$

17 and directly downwards.

5. Suppose a body projected directly downwards with the velocity of 10 feet per second; what will be its velocity after four seconds? In four seconds it will have acquired, by the action of gravity, the velocity of 4×32, or 128 feet, and therefore its whole velocity will be 138 feet per second.

6. To find how far it will have moved, compound its motion of projection, which will be 40 feet in four seconds, with the motion which gravity alone would have given it in that time, which is 256 feet; and the whole motion will be 296 feet.

7. Suppose the body projected as already mentioned, and that it is required to determine the time it will take to go 296 feet downwards, and the velocity it will have acquired.

Find the height x, through which it must fall to acquire the velocity of projection, 10 feet, and the time y of falling from this height. Then find the time z of falling through the height $296+x$, and the velocity v acquired by this fall. The time of describing the 296 feet will be $z-y$, and v is the velocity required.

From such examples, it is easy to see the way of answering every question of the kind.

18 More general formulæ.

Writers on the higher parts of mechanics always compute the actions of other accelerating and retarding forces by comparing them with the acceleration of gravity, and in order to render their expressions more general, use a symbol, such as g for gravity, leaving the reader to convert it into numbers. Agreeably to this view, the general formulæ will stand thus:

$$\text{I. } v=\sqrt{2gh}, \text{ i. e. } \sqrt{2}\sqrt{g}\sqrt{h},=gt,$$

$$\text{II. } t=\frac{v}{g}=\frac{\sqrt{4h}}{\sqrt{2g}},=\sqrt{\frac{4h}{2g}},=\sqrt{\frac{2h}{g}}$$

$$\text{IIII. } h=\frac{v^2}{2g},=\frac{gt^2}{2}.$$

In all these equations, gravity, or its accelerating power, is estimated, as it ought to be, by the change of velocity which it generates in a particle of matter in an unit of time. But many mathematicians, in their investigations of curvilineal and other varied motions, measure it by the deflection which it produces in this time from the tangent of the curve, or by the increment by which the space described in an unit of time exceeds the space described in the preceding unit. This is but one half of the increment which gravity would have produced, had the body moved through the whole moment with the acquired addition of velocity. In this sense of the symbol g, the equations stand thus:

$$\text{I. } v=2\sqrt{gh}\,|=2gt$$

$$\text{II. } t=\sqrt{\frac{h}{g}},=\frac{v}{2g}$$

$$\text{IV. } h=\frac{v^2}{4g},=gt^2, \text{ and } \sqrt{h}=\frac{v}{2\sqrt{g}}.$$

It is also very usual to consider the accelerating force of of gravity as the unit of comparison. This renders the expressions much more simple. In this way, v expresses not the velocity, but the height necessary for acquiring it, and the velocity itself is expressed by $\sqrt{v}$. To reduce such an expression of a velocity to numbers, we must multiply it by $\sqrt{2g}$, or by $2\sqrt{g}$, according as we make g to be the generated velocity, or the space fallen through in the unit of time.

19 Bodies projected obliquely.

This will suffice for the perpendicular ascents or descents of heavy bodies, and we proceed to consider their motions when projected obliquely. The circumstance which renders this an interesting subject, is, that the flight of cannon shot and shells are instances of such motion, and the art of gunnery must in a great measure depend on this doctrine.

Fig. 2.

Let a body B (fig. 2.), be projected in any direction BC, not perpendicular to the horizon, and with any velocity. Let AB be the height producing this velocity; that is, let the velocity be that which a heavy body would acquire by falling freely through AB. It is required to determine the path of the body, and all the circumstances of its motion in this path?

1. It is evident, that by the continual action of gravity, the body will be continually deflected from the line BC, and will describe a curve line BVG, concave towards the earth.

20 Describes a parabola.

2. This curve line is a parabola, of which the vertical line ABE is a diameter, B the vertex of this diameter, and BC a tangent in B.

Through any two points V, G of the curve draw VC, GH parallel to AB, meeting BC in C and H, and draw VE, GK parallel to BC, meeting AB in E, K. It follows, from the composition of motions, that the body would arrive at the points V, G of the curve in the same time that it would have uniformly described BC, BH, with the velocity of projection; or that it would have fallen through BE, BK, with a motion uniformly accelerated by gravity; therefore the times of describing BC, BH, uniformly, are the same with the times of falling through BE, BK. But, because the motion along BH is uniform, BC is to BH as the time of describing BC to the time of describing BH, which we may express thus, BC : BH $=$ T, BC : T, BH, $=$ T, BE : T, BK. But, because the motion along BK is uniformly accelerated, we have BE : BK $=$ T^2 BE : T^2, BK, $=$ BC^2 : BH^2, $=$ EV^2 : KG^2; therefore the curve BVG is such, that the abscissæ BE, BK are as the squares of the corresponding ordinates EV, KG; that is, the curve BVG is a parabola, and BC, parallel to the ordinates, is a tangent in the point B.

3. If through the point A there be drawn the horizontal line ADd, it is the directrix of the parabola.

Let BE be taken equal to AB. The time of falling through BE is equal to the time of falling through AB; but BC is described with the velocity acquired by falling through AB: and therefore by N° 4. of perpendicular descents, BC is double of AB, and EV is double of BE; therefore EV^2 $=$ 4 BE^2, $=$ 4 BE $\times$ AB, $=$ BE $\times$ 4 AB, and 4 AB is the parameter or *latus rectum* of the parabola BVG, and AB being one-fourth of the parameter, AD is the directrix.

4. The times of describing the different arches BV, VG of the parabola are as the portions BC, BH of the tangent, or as the portions AD, Ad of the directrix, intercepted by the same vertical lines AB, CV, HG; for the times of describing BV, BVG are the same with those of describing the corresponding parts BC, BH of the tangent, and are proportional to these parts, because the motion along BH is uniform; and BC, BH are proportional to AD, Ad.

Therefore the motion estimated horizontally is uniform.

5. The velocity in any point G of the curve is the same with that which a heavy body would acquire by falling from the directrix along dG. Draw the tangent GT, cutting the vertical AB in T; take the points a, f, equidistant from A and d, and extremely near them, and draw the verticals ab, fg; let the points a, f, continually approach A and d, and ultimately coincide with them. It is evident that Bb will ultimately be to gG, in the ratio of the velocity at B to the velocity at G; for the portions of the tangent ultimately coincide with the portions of the curve, and are described in equal times; but Bb is to gG as BH to TG: therefore the velocity at B is to that at G as BH to TG. But, by the properties of the parabola, BH^2 is to TG^2 as AB to dG; and AB is to dG as the square of the velocity acquired by falling through AB to the square of the velocity acquired by falling through dG; and the velocity in BH, or in the point B of the parabola, is the velocity acquired by falling along AB; therefore the velocity in TG, or in the point G of the parabola, is the velocity acquired by falling along dG.

21 The parabolic theory ingenious, but of little use in practice.

These few simple propositions contain all the theory of the motion of projectiles in vacuo, or independent on the resistance of the air; and being a very easy and neat piece of mathematical philosophy, and connected with very interesting practice, and a very respectable profession, they have been much commented on, and have furnished matter for many splendid volumes. But the air's resistance occasions such a prodigious diminution of motion in the great velocities of military projectiles, that this parabolic theory, as it is called, is hardly of any use. A musket ball, discharged with the ordinary allotment of powder, issues from the piece with the velocity of 1670 feet per second: this velocity would be acquired by falling from the height of eight miles. If the piece be elevated to an angle of 45°, the parabola should be of such extent that it would reach 16 miles on the horizontal plain; whereas it does not reach above half a mile. Similar deficiencies are observed in the ranges of cannon shot.

22 A short view of it.

We do not propose, therefore, to dwell much on this theory, and shall only give such a synoptical view of it as shall make our readers understand the more general circumstances of the theory, and be masters of the language of the art.

Fig. 3.

Let OB (fig. 3.) be a vertical line. About the centres A and B, with the distance AB, describe the semicircles ODB, AHK, and with the axis AB, and semiaxis GE, equal to AB, describe the semi-ellipse AEB: with the focus B, vertex A, diameter AB, and tangent AD, parallel to the horizon, describe the parabola APS.

Let a body be projected from B, in any direction BC

BC, with the velocity acquired by falling through AB. By what has already been demonstrated, it will describe a parabola BVPM. Then,

1. ADL parallel to the horizon is the directrix of every parabola which can be described by a body projected from B with this velocity. This is evident.

2. The semicircle AHK is the locus of all the foci of these parabolas: For the distance BH of a point B of any parabola from the directrix AD is equal to its distance BF from the focus F of that parabola; therefore the foci of all the parabolas which pass through B, and have AD for their directrix, must be in the circumference of the circle which has AB for its radius, and B for its centre.

3. If the line of direction BC cut the upper semicircle in C, and the vertical line CF be drawn, cutting the lower semicircle in F, F is the focus of the parabola BVPM, described by the body which is projected in the direction BC, with the velocity acqired by falling through BA: for drawing AC, BF, it is evident that ACFB is a rhombus, and that the angle ABF is bisected by BC, and therefore the focus lies in the line BF; but it also lies in the circumference AFK, and therefore in F.

If C is in the upper quadrant of ODB, F is in the upper quadrant of AFK; and if C be in the lower quadrant of ODB (as when BC is the line of direction) then the focus of the corresponding parabola B v M is in the lower quadrant of AHK, as at f.

4. The ellipsis AEB is the focus of the vertex of all the parabolas, and the vertex V of any one of them BVPM is in the intersection of this ellipsis with the vertical CF: for let this vertical cut the horizontal lines AD, GE, BN, in θ, λ, N. Then it is plain that Nλ is half of Nθ, and λV is half of Cθ; therefore NV is half of NC, and V is the vertex of the axis.

If the focus is in the upper or lower quadrant of the circle AHK, the vertex is in the upper or the lower quadrant of the ellipse AEG.

5. If BFP be drawn through the focus of any one of the parabolas, such as BVM, cutting the parabola APS in P, the parabola BVM touches the parabola APS in P: for drawing P$\delta$$\varkappa$ parallel to AB, cutting the directrix O$\varkappa$ of the parabola APS in $\varkappa$, and the directrix AL of the parabola BVM in δ, then PB=P$\varkappa$; but BF=BA, =AO, =$\varkappa\delta$: therefore Pδ=PF, and the point P is in the parabola BVM. Also the tangents to both parabolas in P coincide, for they bisect the angle $\varkappa$ PB; therefore the two parabolas having a common tangent, touching each other in P.

Cor. All the parabolas which can be described by a body projected from B, with the velocity acquired by falling through AB, will touch the concavity of the parabola APS, and lie wholly within it.

6. P is the most distant point of the line BP which can be hit by a body projected from B with the velocity acquired by falling through AB. For if the direction is more elevated than BC, the focus of the parabola described by the body will lie between F and A, and the parabola will touch APS in some point between P and A; and being wholly within the parabola APS, it must cut the line BP in some point within P. The same thing may be shown when the direction is less elevated than BC.

7. The parabola APS is the focus of the greatest ranges on any planes BP, BS, &c. and no point lying without this parabola can be struck.

8. The greatest range on any plane BP is produced when the line of direction BC bisects the angle OBP formed by that plane with the vertical: for the parabola described by the body in this case touches APS in P, and its focus is in the line BP, and therefore the tangent BC bisects the angle OBP.

Cor. The greatest range on a horizontal plane is made with an elevation of 45°.

9. A point M in any plane BS, lying between B and S, may be struck with two directions, BC and Bc; and these directions are equidistant from the direction Bt, which gives the greatest range on that plane: for if about the centre M, with the distance ML from the directrix AL, we describe a circle LFf, it will cut the circle AHK in two points F and f, which are evidently the foci of two parabolas BVM, BvM, having the directrix AL and diameter ABK. The intersection of the circle ODB, with the verticals FC, fc, determine the directions BC, Bc of the tangents. Draw At parallel to BS, and join tB, Cc Ff: then OBt $=\frac{1}{2}$ GBS, and Bt is the direction which gives the greatest range on the plane BS: but because Ff is the chord of the circles described round the centres B and M, Ff is perpendicular to BM, and Cc to At, and the arches Ct, ct are equal; and therefore the angles CBt, cBt are equal.

Thus we have given a general view of the subject, which shows the connection and dependence of every circumstance which can influence the result; for it is evident that to every velocity of projection there belongs a set of parabolas, with their directions and ranges; and every change of velocity has a line AB corresponding to it, to which all the others are proportional. As the height necessary for acquiring any velocity increases or diminishes in the duplicate proportion of that velocity, it is evident that all the ranges with given elevations will vary in the same proportion, a double velocity giving a quadruple range, a triple velocity giving a noncuple range, &c. And, on the other hand, when the ranges are determined beforehand (which is the usual case), the velocities are in the subduplicate proportion of the ranges. A quadruple range will require a double velocity, &c.

23 Experience principally directs the practical gunner.

On the principles now established is founded the ordinary theory of gunnery, furnishing rules which are to direct the art of throwing shot and shells, so as to hit the mark with a determined velocity.

But we must observe, that this theory is of little service for directing us in the practice of cannonading. Here it is necessary to come as near as we can to the object aimed at, and the hurry of service allows no time for geometrical methods of pointing the piece after each discharge. The gunner either points the cannon directly to the object, when within 200 or 300 yards of it, in which case he is said to shoot point blank (*pointer au blanc*, i. e. at the white mark in the middle of the gunners target); or, if at a greater distance, he estimates to the best of his judgment the deflection corresponding to his distance, and points the cannon accordingly. In this he is aided by the greater thickness at the breech of a piece of ordnance. Or lastly, when the intention is not to batter, but to rake along a line occupied

occupied by the enemy, the cannon is elevated at a considerable angle, and the shot discharged with a small force, so that it drops into the enemy's post, and bounds along the line. In all these services the gunner is directed entirely by trial, and we cannot say that this parabolic theory can do him any service.

The principal use of it is to direct the bombardier in throwing shells. With these it is proposed to break down or set fire to buildings, to break through the vaulted roofs of magazines, or to intimidate and kill troops by bursting among them. These objects are always under cover of the enemy's works, and cannot be touched by a direct shot. The bombs and carcasses are therefore thrown upwards, so as to get over the defences and produce their effect.

These shells are of very great weight, frequently exceeding 200 lbs. The mortars from which they are discharged must therefore be very strong, that they may resist the explosion of gunpowder which is necessary for throwing such a mass of matter to a distance; they are consequently unwieldy, and it is found most convenient to make them almost a solid and immoveable lump. Very little change can be made in their elevation, and therefore their ranges are regulated by the velocities given to the shell. These again are produced by the quantities of powder in the charge; and experience (confirming the best theoretical notions that we can form of the subject) has taught us, that the ranges are nearly proportional to the quantities of powder employed, only not increasing quite so fast. This method is much easier than by differences of elevation; for we can select the elevation which gives the greatest range on the given plane, and then we are certain that we are employing the smallest quantity of powder with which the service can be performed: and we have another advantage, that the deviations which unavoidable causes produce in the real directions of the bomb will then produce the smallest possible deviation from the intended range. This is the case in most mathematical maxima.

24 The moving force in theory different from that in practice.

In military projectiles the velocity is produced by the explosion of a quantity of gunpowder; but in our theory it is conceived as produced by a fall from a certain height, by the proportions of which we can accurately determine its quantity. Thus a velocity of 1600 feet per second is produced by a fall from the height of 4000 feet, or 1333 yards.

Fig. 4. The height CA (fig. 4.) for producing the velocity of projection is called, in the language of gunnery, the IMPETUS. We shall express it by the symbol h.

The distance AB to which the shell goes on any plane AB is called the AMPLITUDE of the RANGE, r.

The angle DBA, made by the vertical line and the plane AB, may be called the angle of POSITION of that plane, p.

The angle DAB, made by the axis or direction of the piece, and the direction of the object, may be called the angle of ELEVATION of the piece above the plane AB, e.

The angle ZAD, made by the vertical line, and the direction of the piece, may be called the ZENITH distance, z.

The relations between all the circumstances of velocity, distance, position, elevation, and time, may be included in the following propositions.

25 Relations between the velocity, distance, &c.

I. Let a shell be projected from A, with the velocity acquired by falling through CA, with the intention of hitting the mark B situated in the given line AB.

Make ZA=4AC, and draw BD perpendicular to the horizon. Describe on ZA an arch of a circle ZDA, containing an angle equal to DBA, and draw AD to the intersection of this circle with DB; then will a body projected from A, in the direction AD, with the velocity acquired by falling through CA, hit the mark B.

For, produce CA downwards, and draw BF parallel to AD, and draw ZD. It is evident from the construction that AB touches the circle in B, and that the angles ADZ, DBA, are equal, as also the angles AZD, DAB; therefore the triangles ZAD, ADB are similar.

$$\begin{aligned}&\text{Therefore } BD : DA = DA : AZ,\\ &\text{And } DA^2 = BD \times AZ;\\ &\text{Therefore } BF^2 = AF \times AZ, = AF \times 4AC.\end{aligned}$$

Therefore a parabola, of which AF is a diameter, and AZ its parameter, will pass through B, and this parabola will be the path of the shell projected as already mentioned.

Remark. When BD cuts this circle, it cuts it in two points D, d; and there are two directions which will solve the problem. If B′D′ only touches the circle in D′, there is but one direction, and AB′ is the greatest possible range with this velocity. If the vertical line through B does not meet the circle, the problem is impossible, the velocity being too small. When B′D′ touches the circle, the two directions AD′ and Ad coalesce into one direction, producing the greatest range, and bisecting the angle ZAB; and the other two directions AD, Ad, producing the same range AB, are equidistant from AD′, agreeably to the general proposition.

$$\begin{aligned}&\text{It is evident that } AZ : AD = S,ADZ : S,AZD, = S,DBA : S,DAB, = S,p : S,e\\ &\text{And } AD : DB = S,DBA : S,DAB, = S,p : S,e\\ &\text{And } DB : AB = S,DAB : S,ADB, = S,e : S,z\\ &\text{Therefore } AZ : AB = S^2,p \times S,e : S^2,e \times S,z; = S^2,p : S,e \times S,z\\ &\text{Or } 4h : r = S^2,p : S,e \times S,z, \text{ and } 4h \times S,e \times S,z = r \times S^2,p\end{aligned}$$

Hence we obtain the relations wanted.

Thus $h = \frac{r \times S^2,p}{4S,e \times S,z}$, and $r = \frac{4h \times S,e \times S,z}{S^2,p}$

And S, $z = \frac{r \times S^2 p}{4h \times S,e}$, and S, $e = \frac{r \times S^2,p,}{4h \times S,z}$.

The only other circumstance in which we are interested is the time of the flight. A knowledge of this is necessary for the bombardier, that he may cut the fuses of his shells to such lengths as that they may burst at the very instant of their hitting the mark.

26 To calculate the time of flight.

Now AB : DB = Sin, ADB : Sin, DAB, = S, z : S, e, and DB = $\frac{r \times S,e}{S,z}$. But the time of the flight is the

the same with the time of falling through DB, and 16 feet : DB $=1'' : t''^2$. Hence $t''^2 = \frac{r \times S,e}{16\,S,z}$, and we have the following easy rule.

From the sum of the logarithms of the range, and of the sine of elevation, subtract the sum of the logarithms of 16, and of the sine of the zenith distance, half the remainder is the logarithm of the time in seconds.

This becomes still easier in practice; for the mortar should be so elevated that the range is a maximum: in which case AB$=$DB, and then half the difference of the logarithms of AB and of 16 is the logarithm of the time in seconds.

27 The theory of gunnery compared with experiment.

Such are the deductions from the general propositions which constitute the ordinary theory of gunnery. It remains to compare them with experiment.

In such experiments as can be performed with great accuracy in a chamber, the coincidence is as great as can be wished. A jet of water, or mercury, gives us the finest example, because we have the whole parabola exhibited to us in the simultaneous places of the succeeding particles. Yet even in these experiments a deviation can be observed. When the jet is made on a horizontal plane, and the curve carefully traced on a perpendicular plane held close by it, it is found that the distance between the highest point of the curve and the mark is less than the distance between it and the spout, and that the descending branch of the curve is more perpendicular than the ascending branch. And this difference is more remarkable as the jet is made with greater velocity, and reaches to a greater distance. This is evidently produced by the resistance of the air, which diminishes the velocity, without affecting the gravity of the projectile. It is still more sensible in the motion of bombs. These can be traced through the air by the light of their fuzes; and we see that their highest point is always much nearer to the mark than to the mortar on a horizontal plane.

The greatest horizontal range on this plane should be when the elevation is 45°. It is always found to be much lower.

The ranges on this plane should be as the sines of twice the elevation.

A ball discharged at the elev.	19°. 5′	ranged	448 yards
at	9. 45		330
It should have ranged by theory			241

The range at an elevation of 45° should be twice the impetus. Mr Robins found that a musket-ball, discharged with the usual allotment of powder, had the velocity of 1700 feet in a second. This requires a fall of 45156 feet, and the range should be 90312, or 17⅛ miles; whereas it does not much exceed half a mile. A 24 pound ball discharged with 16 pounds of powder should range about 16 miles; whereas it is generally short of 3 miles.

28 ... com- ...son ...s the ...iency ...e ...y.

Such facts show incontrovertibly how deficient the parabolic theory is, and how unfit for directing the practice of the artillerist. A very simple consideration is sufficient for rendering this obvious to the most uninstructed. The resistance of the air to a very light body may greatly exceed its weight. Any one will feel this in trying to move a fan very rapidly through the air; therefore this resistance would occasion a greater deviation from uniform motion than gravity would *in that body*. Its path, therefore, through the air may differ more from a parabola than the parabola itself deviates from the straight line.

It is for such cogent reasons that we presume to say, that the voluminous treatises which have been published on this subject are nothing but ingenious amusements for young mathematicians. Few persons who have been much engaged in the study of mechanical philosophy have missed this opportunity in the beginning of their studies. The subject is easy. Some property of the parabola occurs, by which they can give a neat and systematic solution of all the questions; and at this time of study it seems a considerable essay of skill. They are tempted to write a book on the subject; and it finds readers among other young mechanicians, and employs all the mathematical knowledge that most of the young gentlemen of the military profession are possessed of. But these performances deserve little attention from the practical artillerist. All that seems possible to do for his education is, to multiply judicious experiments on real pieces of ordnance, with the charges that are used in actual service, and to furnish him with tables calculated from such experiments.

These observations will serve to justify us for having given so concise an account of this doctrine of the parabolic flight of bodies.

29 Causes of this deficiency.

But it is the business of a philosopher to inquire into the causes of such a prodigious deviation from a well-founded theory, and having discovered them, to ascertain precisely the deviations they occasion. Thus we shall obtain another theory, either in the form of the parabolic theory corrected, or as a subject of independent discussion. This we shall now attempt.

30 Effect of the atmosphere,

The motion of projectiles is performed in the atmosphere. The air is displaced, or put in motion. Whatever motion it requires must be taken from the bullet. The motion communicated to the air must be in the proportion of the quantity of air put in motion, and of the velocity communicated to it. If, therefore, the displaced air be always *similarly displaced*, whatever be the velocity of the bullet, the motion communicated to it, and lost by the bullet, must be proportional to the square of the velocity of the bullet and to the density of the air jointly. Therefore the diminution of its motion must be greater when the motion itself is greater, and in the very great velocity of shot and shells it must be prodigious. It appears from Mr Robins's experiments that a globe of 4½ inches in diameter, moving with the velocity of 25 feet in a second, sustained a resistance of 315 grains, nearly ¾ of an ounce. Suppose this ball to move 800 feet in a second, that is 32 times faster, its resistance would be 32×32 times ¾ of an ounce, or 768 ounces or 48 pounds. This is four times the weight of a ball of cast iron of this diameter; and if the initial velocity had been 1600 feet per second, the resistance would be at least 16 times the weight of the ball. It is indeed much greater than this.

31 compared with that of gravity,

This resistance, operating constantly and uniformly on the ball, must take away four times as much from its velocity as its gravity would do in the same time. We know that in one second gravity would reduce the velocity 800 to 768 if the ball were projected straight upwards. This resistance of the air would therefore reduce it in one second to 672, if it operated uniformly; but as the velocity diminishes continually by the resistance, and the resistance diminishes along with the velocity,

city, the real diminution will be somewhat less than 128 feet. We shall, however, see afterwards that in one second its velocity will be reduced fram 800 to 687. From this simple instance, we see that the resistance of the air must occasion great deviation from parabolic motion.

32 and considered as a retarding force.

In order to judge accurately of its effect, we must consider it as a retarding force, in the same way as we consider gravity. The weight W of a body is the aggregate of the action of the force of gravity g on each particle of the body. Suppose the number of equal particles, or the quantity of matter, of a body to be M, then W is equivalent to g M. In like manner, the resistance R, which we observe in any experiment, is the aggregate of the action of a retarding force R′ on each particle, and is equivalent to R′M: and as g is equal to $\frac{W}{M}$, so R′ is equal to $\frac{R}{M}$. We shall keep this distinction in view, by adding the differential mark ′ to the letter R or r, which expresses the aggregate resistance.

33 The resistance of the air not uniform.

If we, in this manner, consider resistance as a retarding force, we can compare it with any other such force by means of the retardation which it produces in similar circumstances. We would compare it with gravity by comparing the diminution of velocity which its uniform action produces in a given time with the diminution produced in the same time by gravity. But we have no opportunity of doing this directly; for when the resistance of the air diminishes the velocity of a body, it diminishes it gradually, which occasions a gradual diminution of its own intensity. This is not the case with gravity, which has the same action on a body in motion or at rest. We cannot, therefore, observe the uniform action of the air's resistance as a retarding force. We must fall on some other way of making the comparison. We can state them both as dead pressures. A ball may be fitted to the rod of a spring stillyard, and exposed to impulse of the wind. This will compress the stillyard to the mark 3, for instance. Perhaps the weight of the ball will compress it to the mark 6. We know that half this weight would compress it to 3. We account this equal to the pressure of the air, because they balance the same elasticity of the spring. And in this way we can estimate the resistance by weights, whose pressures are equal to its pressure, and we can thus compare it with other resistances, weights, or any other pressures. In fact, we are measuring them all by the elasticity of the spring. This elasticity in its different positions is supposed to have the proportions of the weights which keep it in these positions. Thus we reason from the nature of gravity, no longer considered as a dead pressure, but as a retarding force; and we apply our conclusions to resistances which exhibit the same pressures, but which we cannot make to act uniformly. This sense of the words must be carefully remembered whenever we speak of resistances in pounds and ounces.

34 Gravity and resistance compared when they are equal.

The most direct and convenient way of stating the comparison between the resistance of the air and the accelerating force of gravity, is to take a case in which we know that they are equal. Since the resistance is here assumed as proportional to the square of the velocity, it is evident that the velocity may be so increased that the resistance shall equal or exceed the weight of the body. If a body be already moving downwards with this velocity, it cannot accelerate; because the accelerating force of gravity is balanced by an equal retarding force of resistance. It follows from this remark, that this velocity is the greatest that a body can acquire by the force of gravity only. Nay, we shall afterwards see that it never can completely attain it; because as it approaches to this velocity, the remaining accelerating force decreases faster than the velocity increases. It may therefore be called the limiting or TERMINAL velocity by gravity.

Let a be the height through which a heavy body must fall, in vacuo, to acquire its terminal velocity in air. If projected directly upwards with this velocity, it will rise again to this height, and the height is half the space which it would describe uniformly, with this velocity, in the time of its ascent. Therefore the resistance to this velocity being equal to the weight of the body, it would extinguish this velocity, by its *uniform* action, in the same time, and after the same distance, that gravity would.

Now let g be the velocity which gravity generates or extinguishes during an unit of time, and let u be the terminal velocity of any particular body. The theorems for perpendicular ascents give us $g=\frac{u^2}{2a}$, u and a being both numbers representing units of space; therefore, in the present case, we have $r'=\frac{u^2}{2a}$. For the whole resistance r, or r'M, is supposed equal to the weight, or to g M; and therefore r' is equal to g, $=\frac{u^2}{2a}$, and $2a=\frac{u^2}{g}$. There is a consideration which ought to have place here. A body descends in air, not by the whole of its weight, but by the excess of its weight above that of the air which it displaces. It descends by its *specific* gravity only as a stone does in water. Suppose a body 32 times heavier than air, it will be buoyed up by a force equal to $\frac{1}{32}$ of its weight; and instead of acquiring the velocity of 32 feet in a second, it will only acquire a velocity of 31, even though it sustained no resistance from the *inertia* of the air. Let p be the weight of the body and π that of an equal bulk of air: the accelerative force of relative gravity on each particle will be $g\times\overline{1-\frac{\pi}{p}}$; and this relative accelerating force might be distinguished by another symbol γ. But in all cases in which we have any interest, and particularly in military projectiles, $\frac{\pi}{p}$ is so small a quantity that it would be pedantic affectation to attend to it. It is much more than compensated when we make $g=32$ feet instead of $32\frac{1}{12}$ which it should be.

Let e be the time of this ascent in opposition to gravity. The same theorems give us $eu=2a$; and since the resistance competent to this terminal velocity is equal to gravity, e will also be the time in which it would be extinguished by the uniform action of the resistance; for which reason we may call it the extinguishing time for this velocity. Let R and E mark the resistance and extinguishing time for the same body moving with the velocity 1.

Since the resistances are as the squares of the velocities, and the resistance to the volcity u is $\frac{u^2}{2a}$, R will be be $=\frac{1}{2a}$. Moreover, the times in which the same velocity will be extinguished by different forces, acting uniformly, are inversely as the forces, and gravity would extinguish the velocity 1 in the time $\frac{1}{g}$, $=$ (in these measures) to $\frac{1}{\frac{u^2}{2a}}$, $=\frac{2a}{u^2}$. Therefore we have the following proportion $\frac{1}{2a}(=\mathrm{R}):\frac{u^2}{2a}(=g)=\frac{2a}{u^2}:2a$, and $2a$ is equal to E, the time in which the velocity 1 will be extinguished by the uniform action of the resistance competent to this velocity.

The velocity 1 would in this case be extinguished after a motion uniformly retarded, in which the space described is one-half of what would be uniformly described during the same time with the constant velocity 1. Therefore the space thus described by a motion which begins with the velocity 1, and is uniformly retarded by the resistance competent to this velocity, is equal to the height through which *this* body must fall *in vacuo* in order to acquire *its* terminal velocity in air.

All these circumstances may be conceived in a manner which, to some readers, will be more familiar and palpable. The terminal velocity is that where the resistance of the air balances and is equal to the weight of the body. The resistance of the air to any particular body is as the square of the velocity; therefore let R be the whole resistance to the body moving with the velocity 1, and r the resistance to its motion with the terminal velocity u; we must have $r=\mathrm{R}\times u^2$, and this must be $=$W the weight. Therefore, to obtain the terminal velocity, divide the weight by the resistance to the velocity 1, and the quotient is the square of the terminal velocity, or $\frac{\mathrm{W}}{\mathrm{R}}=u^2$: And this is a very expeditious method of determining it, if R be previously known.

Then the common theorems give a, the fall necessary for producing this velocity *in vacuo* $=\frac{u^2}{2g}$, and the time of the fall $=\frac{u}{g}=e$, and $eu=2a$, $=$ the space uniformly described with the velocity u during the time of the fall, or its equal, the time of the extinction by the uniform action of the resistance r; and, since r extinguishes it in the time e, R, which is u^2 times smaller, will extinguish it in the time u^2e, and R will extinguish the velocity 1, which is u times less than u, in the time $u\,e$, that is, in the time $2a$; and the body, moving uniformly during the time $2a$, $=$E, with the velocity 1, will describe the space $2a$; and, if the body begin to move with the velocity 1, and be uniformly opposed by the resistance R, it will be brought to rest when it has described the space a; and the space in which the resistance to the velocity 1 will extinguish that velocity by its uniform action, is equal to the height through which that body must fall *in vacuo* in order to acquire its terminal velocity in air. And thus every thing is regulated by the time E in which the velocity 1 is extinguished by the uniform action of the corresponding resistance, or by $2a$, which is the space uniformly described during this time, with the velocity 1. And E and $2a$ must be expressed by the same number. It is a number of units, of time, or of length.

Having ascertained these leading circumstances for an unit of velocity, weight, and bulk, we proceed to deduce the similar circumstances for any other magnitude; and, to avoid unnecessary complications, we shall always suppose the bodies to be spheres, differing only in diameter and density. 35 The comparison made general.

First, then, let the velocity be increased in the ratio of 1 to v.

The resistance will now be $\frac{v^2}{2a}$, $=r$.

The extinguishing time will be $\frac{\mathrm{E}}{v}$, $=e$, $=\frac{2a}{v}$, and $e\,v=2a$; so that the rule is general, that the space along which *any* velocity will be extinguished by the uniform action of the corresponding resistance, is equal to the height necessary for communicating the terminal velocity to *that* body by gravity. For $e\,v$ is twice the space through which the body moves while the velocity v is extinguished by the uniform resistance.

In the 2d place, let the diameter increase in the proportion of 1 to d. The aggregate of the resistance changes in the proportion of the surface similarly resisted, that is, in the proportion of 1 to d^2. But the quantity of matter, or number of particles among which this resistance is to be distributed, changes in the proportion of 1 to d^3. Therefore the retarding power of the resistance changes in the proportion of 1 to $\frac{1}{d}$. When the diameter was 1, the resistance to a velocity 1 was $\frac{1}{2a}$. It must now be $\frac{1}{2ad}$. The time in which this diminished resistance will extinguish the velocity 1 must increase in the proportion of the diminution of force, and must now be E d, or $2\,a\,d$, and the space uniformly described during this time with the initial velocity 1 must be $2\,a\,d$; and this must still be twice the height necessary for communicating the terminal velocity w to *this* body. We must still have $g=\frac{w^2}{2\,a\,d}$; and therefore $w^2=2gad$, and $w=\sqrt{2gad}=\sqrt{2ga}\sqrt{d}$. But $u=\sqrt{2ga}$. Therefore the terminal velocity w for this body is $=u\sqrt{d}$; and the height necessary for communicating it is $a\,d$. Therefore the terminal velocity varies in the subduplicate ratio of the diameter of the ball, and the fall necessary for producing it varies in the simple ratio of the diameter. The extinguishing time for the velocity v must now be $\frac{\mathrm{E}\,d}{v}$.

If, in the 3d place, the density of the ball be increased in the proportion of 1 to m, the number of particles among which the resistance is to be distributed is increased in the same proportion, and therefore the retarding force of the resistance is equally diminished; and if the density of the air is increased in the proportion of 1 to n, the retarding force of the resistance increases in the same proportion: hence we easily deduce these *general* expressions.

The terminal velocity $=a\sqrt{d\frac{m}{n}}=\sqrt{2\,g\,a\,d\frac{m}{n}}$.

The producing fall *in vacuo* $=a\,d\,\frac{m}{n}$.

The

The retarding power of resistance to any velocity $=$

$$r', = \frac{v^2}{2\,a\,d\,\frac{m}{n}}.$$

The extinguishing time for any velocity $n = \frac{E\,d\,m}{v\,n}$.

And thus we see that the chief circumstances are regulated by the terminal velocity, or are conveniently referred to it.

36
Units necessary by which the quantities may be measured.

To render the deductions from these premises perspicuous, and for communicating distinct notions or ideas, it will be proper to assume some convenient units, by which all these quantities may be measured; and, as this subject is chiefly interesting in the case of military projectiles, we shall adapt our units to this purpose. Therefore, let a second be the unit of time, a foot the unit of space and velocity, an inch the unit of diameter of a ball or shell, and a pound avoirdupois the unit of pressure, whether of weight or of resistance; therefore g is 32 feet.

The great difficulty is to procure an absolute measure of r, or u, or a; any one of these will determine the others.

37
Sir Isaac Newton's endeavours in this way

Sir Isaac Newton has attempted to determine r by theory, and employs a great part of the second book of the *Principia* in demonstrating, that the resistance to a sphere moving with any velocity, is to the force which would generate or destroy its whole motion in the time that it would uniformly move over $\frac{8}{3}$ of its diameter with this velocity, as the density of the air is to the density of the sphere. This is equivalent to demonstrating that the resistance of the air to a sphere moving through it with any velocity, is equal to half the weight of a column of air having a great circle of the sphere for its base, and for its altitude the height from which a body must fall in *vacuo* to acquire this velocity. This appears from Newton's demonstration; for, let the specific gravity of the air be to that of the ball as 1 to m; then, because the times in which the same velocity will be extinguished by the uniform action of different forces are inversely as the forces, the resistance to this velocity would extinguish it in the time of describing $\frac{8}{3}\,m\,d$, d being the diameter of the ball. Now 1 is to m as the weight of the displaced air to the weight of the ball, or as $\frac{2}{3}$ of the diameter of the ball to the length of a column of air of equal weight. Call this length a; a is therefore equal to $\frac{2}{3}\,m\,d$. Suppose the ball, to fall from the height a in the time t, and acquire the velocity u. If it moved uniformly with this velocity during this time, it would describe a space $=2a$, or $\frac{4}{3}\,m\,d$. Now its weight would extinguish this velocity, or destroy this motion, in the same time, that is, in the time of describing $\frac{4}{3}\,m\,d$; but the resistance of the air would do this in the time of describing $\frac{8}{3}\,m\,d$; that is, in twice the time. The resistance therefore is equal to half the weight of the ball, or to half the weight of the column of air whose height is the height producing the velocity. But the resistances to different velocities are as the squares of the velocities, and therefore, as their producing heights; and, in general, the resistance of the air to a sphere moving with any velocity, is equal to the half weight of a column of air of equal section, and whose altitude is the height producing the velocity. The result of this investigation has been acquiesced in by all Sir Isaac Newton's commentators. Many faults have indeed been found with his reasoning, and even with his principles; and it must be acknowledged that although this investigation is by far the most ingenious of any in the *Principia*, and sets his acuteness and address in the most conspicuous light, his reasoning is liable to serious objections, which his most ingenious commentators have not completely removed. However, the conclusion has been acquiesced in, as we have already stated, but as if derived from other principles, or by more logical reasoning. We cannot, however, say that the reasonings or assumptions of these mathematicians are much better than Newton's: and we must add, that all the causes of deviation from the duplicate ratio of the velocities, and the causes of increased resistance, which the latter authors have valued themselves for discovering and introducing into their investigations, were pointed out by Sir Isaac Newton, but purposely omitted by him, in order to facilitate the discussion *in re difficillima*. (See *Schol.* prop. 37. book ii.).

38
His result just, but his reasoning erroneous.

It is known that the weight of a cubic foot of water is $62\frac{1}{2}$ pounds, and that the medium density of the air is $\frac{1}{840}$ of water; therefore, let a be the height producing the velocity (in feet), and d the diameter of the ball (in inches), and π the periphery of a circle whose diameter is 1; the resistance of the air will be $= \frac{62\frac{1}{2}}{840} \times \frac{\pi}{4} \times \frac{1}{144} \times \frac{a}{2} \times d^2 = \frac{a\,d^2}{4928\frac{1}{2}}$ pounds, very nearly, $= \frac{v^2}{4928\frac{1}{2} \times 64}a^2, = \frac{v^2\,d^2}{315417}$ pounds.

We may take an example. A ball of cast iron weighing 12 pounds, is $4\frac{1}{2}$ inches in diameter. Suppose this ball to move at the rate of $25\frac{1}{10}$ feet in a second (the reason of this choice will appear afterwards). The height which will produce this velocity in a falling body is $9\frac{7}{8}$ feet. The area of its great circle is 0.11044 feet, or $\frac{11044}{100000}$ of one foot. Suppose water to be 840 times heavier than air, the weight of the air incumbent on this great circle, and $9\frac{7}{8}$ feet high, is 0.081151 pounds: half of this is 0.0405755 or $\frac{405755}{10000000}$, or nearly $\frac{1}{25}$ of a pound. This should be the resistance of the air to this motion of the ball.

39
Necessity of experiment.

In all matters of physical discussion, it is prudent to confront every theoretical conclusion with experiment. This is particularly necessary in the present instance, because the theory on which this proposition is founded is extremely uncertain. Newton speaks of it with the most cautious diffidence, and secures the justness of the conclusions by the conditions which he assumes in his investigation. He describes with the greatest precision the state of the fluid in which the body must move, so as that the demonstrations may be strict, and leaves it to others to pronounce, whether this is the real constitution of our atmosphere. It must be granted that it is not; and that many other suppositions have been introduced by his commentators and followers, in order to suit his investigation (for we must assert that little or nothing has been added to it) to the circumstances of the case.

40
Newton's experiments.

Newton himself, therefore, attempted to compare his propositions with experiment. Some were made by dropping balls from the dome of St Paul's cathedral; and all these showed as great a coincidence with his theory as they did with each other: but the irregulari-

ties

ties were too great to allow him to say with precision what was the resistance. It appeared to follow the proportion of the squares of the velocities with sufficient exactness; and though he could not say that the resistance was equal to the weight of the column of air having the height necessary for communicating the velocity, it was always equal to a determinate part of it; and might be stated $= n\,a$, n being a number to be fixed by numerous experiments.

One great source of uncertainty in his experiments seems to have escaped his observation: the air in that dome is almost always in a state of motion. In the summer season there is a very sensible current of air downwards, and frequently in winter it is upwards: and this current bears a very great proportion to the velocity of the descents. Sir Isaac takes no notice of this.

He made another set of experiments with pendulums; and has pointed out some very curious and unexpected circumstances of their motions in a resisting medium. There is hardly any part of his noble work in which his address, his patience, and his astonishing penetration, appear in greater lustre. It requires the utmost intenseness of thought to follow him in these disquisitions; and we cannot enter on the subject at present; some notice will be taken of these experiments in the article *Resistance of fluids*. Their results were much more uniform, and confirmed his general theory; and as we have said above, it has been acquiesced in by the first mathematicians of Europe.

41 **Inutility of the theory in practice.**

But the deductions from this theory were so inconsistent with the observed motions of military projectiles, when the velocities are prodigious, that no application could be made which could be of any service for determining the path and motion of cannon shot and bombs;

42 **The attempts of various mathematicians, &c.**

and although Mr John Bernoulli gave, in 1718, a most elegant determination of the trajectory and motion of a body projected in a fluid which resists in the duplicate ratio of the velocities (a problem which even Newton did not attempt), it has remained a dead letter. Mr Benjamin Robins, equally eminent for physical science and mathematical genius, was the first who suspected the true cause of the imperfection of the usually received theories; and in 1737 he published a small tract, in which he showed clearly, that even the Newtonian theory of resistance must cause a cannon ball, discharged with a full allotment of powder, to deviate farther from the parabola, in which it would move *in vacuo*, than the parabola deviates from a straight line. But he farther asserted, on the authority of good reasoning, that in such great velocities the resistance must be much greater than this theory assigns; because, besides the resistance arising from the *inertia* of the air which is put in motion by the ball, there must be a resistance arising from a condensation of the air on the anterior surface of the ball, and a rarefaction behind it: and there must be a third resistance, arising from the statical pressure of the air on its anterior part, when the motion is so swift that there is a vacuum behind. Even these causes of disagreement with the theory had been foreseen and mentioned by Newton (see the Scholium to prop. 37. book ii. *Princip.*); but the subject seems to have been little attended to. The eminent mathematicians had few opportunities of making experiments; and the professional men, who were in the service of princes, and had their countenance and aid in this matter, were generally too deficient in mathematical knowledge to make a proper use of their opportunities. The numerous and splendid volumes which these gentlemen have been enabled to publish by the patronage of sovereigns are little more than prolix extensions of the same theory of Galileo. Some of them, however, such as St Remy, Antonini, and Le Blond, have given most valuable collections of experiments, ready for the use of the profound mathematician.

43 **Observations of Mr Robins on velocity and resistance,**

Two or three years after this first publication, Mr Robins hit upon that ingenious method of measuring the great velocities of military projectiles, which has handed down his name to posterity with great honour. And having ascertained these velocities, he discovered the prodigious resistance of the air, by observing the diminution of velocity which it occasioned. This made him anxious to examine what was the real resistance to any velocity whatever, in order to ascertain what was the law of its variation; and he was equally fortunate in this attempt. His method of measuring the resistance has been fully described in the article Gunnery, N° 9, &c.

It appears (Robins's *Math. Works*, vol. i. page 205.) that a sphere of $4\frac{1}{2}$ inches in diameter, moving at the rate of $25\frac{1}{3}$ feet in a second, sustained a resistance of 0.04914 pounds, or $\frac{4914}{100000}$ of a pound. This is a greater resistance than that of the Newtonian theory, which gave $\frac{405755}{10000000}$ in the proportion of 1000 to 1211, or very nearly in the proportion of five to six in small numbers. And we may adopt as a rule in all moderate velocities, that the resistance to a sphere is equal to $\frac{61}{100}$ of the weight of a column of air having the great circle of the sphere for its base, and for its altitude the height through which a heavy body must fall *in vacuo* to acquire the velocity of projection.

This experiment is peculiarly valuable, because the ball is precisely the size of a 12 pound shot of cast iron; and its accuracy may be depended on. There is but one source of error. The whirling motion must have occasioned some whirl in the air, which would continue till the ball again passed through the same point of its revolution. The resistance observed is therefore probably somewhat less than the true resistance to the velocity of $25\frac{1}{3}$ feet, because it was exerted in a relative velocity which was less than this, and is, in fact, the resistance competent to this relative and smaller velocity.

44 **and of Mr Rouse and De Borda.**

—Accordingly, Mr Smeaton, a most sagacious naturalist, places great confidence in the observations of a Mr Rouse of Leicestershire, who measured the resistance by the effect of the wind on a plane properly exposed to it. He does not tell us in what way the velocity of the wind was ascertained; but our deference for his great penetration and experience disposes us to believe that this point was well determined.

45 **They differ widely in their conclusions.**

The resistance observed by Mr Rouse exceeds that resulting from Mr Robins's experiments nearly in the proportion of 7 to 10. Chevalier de Borda made experiments similar to those of Mr Robins, and his results exceed those of Robins in the proportion of 5 to 6. These differences are so considerable, that we are at a loss what measure to abide by. It is much to be regretted, that in a subject so interesting both to the philosopher and the man of the world, experiments have not been multiplied. Nothing would tend so much to perfect the science of of gunnery; and indeed till this be done, all the labours of mathematicians are of no avail. Their investigations must remain an unintelligible cipher, till this key be supplied. It is to be hoped that Dr Charles Hutton of Woolwich, who has so ably extended Mr Robins's Examination of the Initial Velocities of Military Projectiles, will be encouraged to proceed to this part of this subject. We should wish to see, in the first place, a numerous set of experiments for ascertaining the resistances in moderate velocities; and, in order to avoid all error from the resistance and inertia of the machine, which is necessarily blended with the resistance of the ball, in Mr Robins's form of the experiment, and is separated with great uncertainty and risk of error, we would recommend a form of experiment somewhat different.

46 A new form of experiment recommended.

Let the axis and arm which carries the ball be connected with wheelwork, by which it can be put in motion, and gradually accelerated. Let the ball be so connected with a bent spring, that this shall gradually compress it as the resistance increases, and leave a mark of the degree of compression; and let all this part of the apparatus be screened from the air except the ball. The velocity will be determined precisely by the revolutions of the arm, and the resistance by the compression of the spring. The best method would be to let this part of the apparatus be made to slide along the revolving arm, so that the ball can be made to describe larger and larger circles. An intelligent mechanician will easily contrive an apparatus of this kind, held at any distance from the axis by a cord, which passes over a pulley in the axis itself, and is then brought along a perforation in the axis, and comes out at its extremity, where it is fitted with a swivel, to prevent it from snapping by being twisted. Now let the machine be put in motion. The centrifugal force of the ball and apparatus will cause it to fly out as far as it is allowed by the chord; and if the whole is put in motion by connecting it with some mill, the velocity may be most accurately ascertained. It may also be fitted with a bell and hammer like Gravesande's machine for measuring centrifugal forces. Now by gradually veering off more cord, the distance from the centre, and consequently the velocity and resistance increase, till the hammer is disengaged and strikes the bell.

Another great advantage of this form of the experiment is, that the resistance to very great velocities may be thus examined, which was impossible in Mr Robins's way. This is the great desideratum, that we may learn in what proportion of the velocities the resistances increase.

In the same manner, an apparatus, consisting of Dr Lynd's Anemometer, described in the article PNEUMATICS, N° 311, &c. might be whirled round with prodigious rapidity, and the fluid on it might be made clammy, which would leave a mark at its greatest elevation, and thus discover the resistance of the air to rapid motions.

Nay, we are of opinion that the resistance to very rapid motions may be measured directly in the conduit pipe of some of the great cylinder bellows employed in blast furnaces: the velocity of the air in this pipe is ascertained by the capacity of the cylinder and the strokes of the piston. We think it our duty to point out, to such as have the opportunities of trying them, methods which promise accurate results for ascertaining this most desirable point.

47 The result of Robins's experiments as yet most to be depended on.

We are the more puzzled what measure to abide by, because Mr Robins himself, in his practical propositions, does not make use of the result of his own experiments, but takes a much lower measure. We must content ourselves, however, with this experimental measure, because it is as yet the only one of which any account can be given, or well-founded opinion formed.

48 Applied to the formulæ.

Therefore, in order to apply our formulæ, we must reduce this experiment, which was made on a ball of $4\frac{1}{2}$ inches diameter, moving with the velocity of $25\frac{1}{5}$ feet per second, to what would be the resistance to a ball of one inch, having the velocity 1 foot. This will evidently give us $R = \frac{0.04914}{4,5^2 \times 25.2^2}$, being diminished in the duplicate ratio of the diameter and velocity. This gives us $R = 0,00000381973$ pounds, or $\frac{3.81973}{1000000}$ of a pound. The logarithm is 4.58204. The resistance here determined is the same whatever substance the ball be of; but the retardation occasioned by it will depend on the proportion of the resistance to the *vis insita* of the ball; that is, to its quantity of motion. This in similar velocities and diameters is as the density of the ball. The balls used in military service are of cast iron or of lead, whose specific gravities are 7,207 and 11,37 nearly, water being 1. There is considerable variety in cast iron, and this density is about the medium. These data will give us

		For Iron.	For Lead
W, or weight of a ball 1 inch in diameter - -	lbs.	0.13648	0.21533
Log. of W - -		9.13509	9.33310
E″ - - -		1116″.6	1761″.6
Log. of E - - -		3.04790	3.24591
u, or terminal velocity -		189.03	237.43
Log. u - - - -		2.27653	2.37553
a, or producing height -		558.3	880.8

These numbers are of frequent use in all questions on this subject.

Mr Robins gives an expeditious rule for readily finding a, which he calls F (see the article GUNNERY), by which it is made 900 feet for a cast iron ball of an inch diameter. But no theory of resistance which he professes to use will make this height necessary for producing the terminal velocity. His F therefore is an *empirical* quantity, analogous indeed to the producing height, but accommodated to his theory of the trajectory of cannon-shot, which he promised to publish, but did not live to execute. We need not be very anxious about this; for all our quantities change in the same proportion with R, and need only a correction by a multiplier or divisor, when R shall be accurately established.

We may illustrate the use of these formulæ by an example or two.

49 Examples of their use.

1. Then, to find the resistance to a 24 pound ball moving with the velocity of 1670 feet in a second, which is nearly the velocity communicated by 16lbs. of powder. The diameter is 5,603 inches.

Log.

Log. R - - -	$+\bar{4}.58204$
Log. d^2 - - -	$+1.49674$
Log. 1670^2 - - -	$+6.44548$
Log. 334.4 lbs.$=r$ - -	2.52426

But it is found, by unequivocal experiments on the retardation of such a motion, that it is 504 lbs. This is owing to the causes often mentioned, the additional resistance to great velocities, arising from the condensation of the air, and from its pressure into the vacuum left by the ball.

2. Required the terminal velocity of this ball?

Log. R - - -	$+4.58204$
Log. d^2 - - -	$+1.49674$
Log. resist. to veloc. 1 - -	$6.07878=a$
Log. W. - - -	$1.38021=b$
Diff. of a and b,$=$log. u^2 -	5.30143
Log. 447.4 $=u$ - -	2.65071

50 Table of terminal velocity according to Newton and Robins.

As the terminal velocity u, and its producing height a, enter into all computations of military projectiles, we have inserted the following Table for the usual sizes of cannon-shot, computed both by the Newtonian theory of resistance, and by the resistances observed in Robin's experiments.

Lb. Ball.	Newton.		Robins.		Diam: Inch.
	u Term Vel.	2 a.	Term. Vel.	2 a.	
1	289.9	2626.4	263.4	2168.6	1.94
2	324.9	3298.5	295.2	2723.5	2.45
3	348.2	3788.2	316.4	3127.9	2.80
4	365.3	4170.3	331.9	3442.6	3.08
6	390.8	4472.7	355.1	3940.7	3.52
9	418.1	5463.5	379.9	4511.2	4.04
12	438.6	6010.6	398.5	4962.9	4.45
18	469.3	6883.3	426.5	5683.5	5.09
24	492.4	7576.3	447.4	6255.7	5.61
32	512.6	8024.8	465.8	6780.4	6.21
	540.5	9129.9	491.5	7538.3	6.75

51 Mr Muller's theory altogether erroneous.

Mr Muller, in his writings on this subject, gives a much smaller measure of resistance, and consequently a much greater terminal velocity: but his theory is a mistake from beginning to end (See his *Supplement to* his *Treatise of Artillery*, art. 150, &c.). In art. 148. he assumes an algebraic expression for a principle of mechanical argument; and from its consequence draws erroneous conclusions. He makes the resistance of a cylinder one third less than Newton *supposes* it; and his reason is false. Newton's measure is demonstrated by his commentators Le Seur and Jaquier to be even a little too small, upon his own principles, (Not. 277. Prop. 36. B. II.). Mr Muller then, without any seeming reason, introduces a new principle, which he makes the chief support of his theory, in opposition to the theories of other mathematicians. The principle is false, and even absurd, as we shall have occasion to show by and by. In consequence, however, of this principle, he is enabled to compare the results with many experiments, and the agreement is very flattering. But we shall soon see that little dependence can be had on such comparisons. We notice these things here, because Mr Muller being head of the artillery school in Britain, his publications have become a sort of text-books. We are miserably deficient in works on this subject, and must have recourse to the foreign writers.

52 The motions considered through their whole course.

We now proceed to consider these motions through their whole course; and we shall first consider them as affected by the resistance only; then we shall consider the perpendicular ascents and descents of heavy bodies through the air; and, lastly, their motion in a curvilineal trajectory, when projected obliquely. This must be done by the help of the abstruser parts of fluxionary mathematics. To make it more conspicuous, we shall, by way of introduction, consider the simply resisted rectilineal motions geometrically, in the manner of Sir Isaac Newton. As we advance, we shall quit this track, and prosecute it algebraically, having by this time acquired distinct ideas of the algebraic quantities.

53 Preliminary observations.

We must keep in mind the fundamental theorems of varied motions.

1. The momentary variation of the velocity is proportional to the force and the moment of time jointly, and may therefore be represented by $\pm\dot{v}=f\dot{t}$, where $\dot{v}$ is the momentary increment or decrement of the velocity v, f the accelerating or retarding force, and $\dot{t}$ the moment or increment of the time t.

2. The momentary variation of the square of the velocity is as the force, and as the increment or decrement of the space jointly; and may be represented by $\pm v\dot{v}=f\dot{s}$. The first proposition is familiarly known. The second is the 39th of Newton's *Principia*, B. I. It is demonstrated in the article OPTICS, and is the most extensively useful proposition in mechanics.

54 The motions as affected by resistance only. Fig. 5.

These things being premised, let the straight line AC (fig. 5) represent the initial velocity V, and let CO, perpendicular to AC, be the time in which this velocity would be extinguished by the uniform action of the resistance. Draw through the point A an equilateral hyperbola A e B, having OF, OCD for its assymptotes; then let the time of the resisted motion be represented by the line CB, C being the first instant of the motion. If there be drawn perpendicular ordinates κc, gf, DB, &c. to the hyperbola, they will be proportional to the velocities of the body at the instants κ, g, D, &c. and the hyperbolic areas ACκe, ACgf, ACDB, &c. will be proportional to the spaces described during the times Cκ, Cg, CB, &c.

For, suppose the time divided into an indefinite number of small and equal moments, Cc, Dd, &c. draw the ordinates ac, bd, and the perpendiculars $b\beta$, $a\alpha$. Then, by the nature of the hyperbola, AC : ac=Oc : OC; and AC$-ac$: ac=O$c-$OC : OC, that is, Aα : ac=Cc : OC, and Aα : Cc=ac : OC=AC$\cdot ac$: AC$\cdot$OC; in like manner, Bβ : Dd=BD$\cdot bd$: BD$\cdot$OD. Now Dd=Cc, because the moments of time were taken equal, and the rectangles AC$\cdot$CO, BD$\cdot$DO, are equal, by the nature of the hyperbola; therefore Aα : Bβ=AC$\cdot ac$: BD$\cdot bd$: but as the points c, d continually approach, and ultimately coincide with C, D, the ultimate ratio of AC$\cdot ac$ to BD$\cdot bd$ is that of AB^2 to BD^2; therefore the momentary decrements of AC

AC and BD are as AC^2 and BD^2. Now, because the resistance is measured by the momentary diminution of velocity, these diminutions are as the squares of the velocities; therefore the ordinates of the hyperbola and the velocities diminish by the same law; and the initial velocity was represented by AC: therefore the velocities at all the other instants x, g, D, are properly represented by the corresponding ordinates. Hence,

1. Since the abscissæ of the hyperbola are as the times, and the ordinates are as the velocities, the areas will be as the spaces described, and AC$x e$ is to Acgf as the space described in the time Cx to the space described in the time Cg (1st Theorem on varied motions).

2. The rectangle ACOF is to the area ACDB as the space formerly expressed by $2a$, or E to the space described in the resisting medium during the time CD: for AC being the velocity V, and OC the extinguishing time e, this rectangle is $=e$ V, or E, or $2a$, of our former disquisitions; and because all the rectangles, such as ACOF, BDOG, &c. are equal, this corresponds with our former observation, that the space uniformly described with any velocity during the time in which it would be uniformly extinguished by the corresponding resistance is a constant quantity, viz. that in which we always had $cv=$ E, or $2a$.

3. Draw the tangent Ax; then, by the hyperbola Cx=CO: now Cx is the time in which the resistance to the velocity AC would extinguish it; for the tangent coinciding with the elemental arc Aa of the curve, the first impulse of the uniform action of the resistance is the same with the first impulse of its varied action. By this the velocity AC is reduced to ac. If this operated uniformly like gravity, the velocities would diminish uniformly, and the space described would be represented by the triangle ACx.

This triangle, therefore, represents the height through which a heavy body must fall in vacuo, in order to acquire the terminal velocity.

4. The motion of a body resisted in the duplicate ratio of the velocity will continue without end, and a space will be described which is greater than any assignable space, and the velocity will grow less than any that can be assigned; for the hyperbola approaches continually to the assymptote, but never coincides with it. There is no velocity BD so small, but a smaller ZP will be found beyond it; and the hyperbolic space may be continued till it exceeds any surface that can be assigned.

5. The initial velocity AC is to the final velocity BD as the sum of the extinguishing time and the time of the retarded motion, is to the extinguishing time alone: for AC : BD=OD (or OC+CD) : OC; or V : $v=e : e+t$.

6. The extinguishing time is to the time of the retarded motion as the final velocity is to the velocity lost during the retarded motion: for the rectangles AFOC, BDOG are equal; and therefore AVGF and BVCD are equal, and VC : VA=VG : VB; therefore $t=e\frac{V-v}{v}$, and $e=t\frac{v}{V-v}$.

7. Any velocity is reduced in the proportion of m to n in the time $e\frac{m-n}{n}$. For, let AC : BD=$m:n$; then DO : CO=$m:n$, and DC : CO=$m-n:n$, and DC=$\frac{m-n}{n}$CO, or $t=e\frac{m-n}{n}$. Therefore any velocity is reduced to one half in the time in which the initial resistance would have extinguished it by its uniform action.

Thus may the chief circumstances of this motion be determined by means of the hyperbola, the ordinates and abscissæ exhibiting the relations of the times and velocities, and the areas exhibiting the relations of both to the spaces described. But we may render the conception of these circumstances infinitely more easy and simple, by expressing them all by lines, instead of this combination of lines and surfaces. We shall accomplish this purpose by constructing another curve LKP, having the line ML∂, parallel to OD, for its abscissa, and of such a nature, that if the ordinates to the hyperbola AC, ex, fg, BD, &c. be produced till they cut this curve in L, p, n, K, &c. and the abscissa in L, s, h, ∂, &c. the ordinates sp, h, n, ∂K, &c. may be proportional to the hyperbolic areas eACx, fACg, ∂AcK. Let us examine what kind of curve this will be. Another mode of determining this motion.

Make OC : Ox=Ox : Og; then (Hamilton's *Conics*, IV. 14. Cor.), the areas ACxe, $exgf$ are equal: therefore drawing ps, nt perpendicular to OM, we shall have (by the assumed nature of the curve LpK), M$s=st$; and if the abscissa OD be divided into any number of small parts in geometrical progression (reckoning the commencement of them all from O), the axis Vi of this curve will be divided by its ordinates into the same number of equal parts; and this curve will have its ordinates LM, ps, nt, &c. in geometrical progression, and its abscissæ in arithmetical progression.

Also, let KN, MV touch the curve in K and L, and let OC be supposed to be to Oc, as OD to Od, and therefore Cc to Dd as OC to OD; and let these lines Cc, Dd be indefinitely small; then (by the nature of the curve) Lo is equal to Kr: for the areas aACc, bBDd are in this case equal. Also ko is to kr, as LM to KI, because cC : dD=CO : DO:

Therefore IN : IK=rK : rk
IK : ML=rk : ol
ML : MV=ol : oL
and IN : MN=rK : oL

That is, the subtangent IN, or MV, is of the same magnitude, or is a constant quantity in every part of the curve.

Lastly, the subtangent IN, corresponding to the point K of the curve, is to the ordinate K∂ as the rectangle BDOG or ACOF to the parabolic area BDCA.

For let $fghn$ be an ordinate very near to BD∂K; and let hn cut the curve in n, and the ordinate KI in q; then we have

Kq : qn=KI : IN, or
Dg : qn=DO : IN;
but BD : AC=CO : DO;
therefore B D . Dg : AC . qn=CO : IN.

Therefore the sum of all the rectangles BD . Dg is to the sum of all the rectangles AC . qn, as CO to IN: but

but the sum of the rectangles BD . Dg is the space ACDB; and, because AC is given, the sum of the rectangles AC . $q\,n$ is the rectangle of AC and the sum of all the lines $q\,n$; that is, the rectangle of AC and RL: therefore the space ACDB : AC . RL = CO : IN, and ACDB × IN = AC . CO . RL; and therefore IN : RL = AC . CO : ACDB.

Hence it follows that QL expresses the area BVA, and in general, that the part of the line parallel to OM, which lies between the tangent KN and the curve LpK, expresses the corresponding area of the hyperbola which lies without the rectangle BDOG.

And now, by the help of this curve, we have an easy way of convincing and computing the motion of a body through the air. For the subtangent of our curve now represents twice the height through which the ball must fall in vacuo, in order to acquire the terminal velocity; and therefore serves for a scale on which to measure all the other representatives of the motion.

56 The whole reduced to simple arithmetical computation.

But it remains to make another observation on the curve L p K, which will save us all the trouble of graphical operations, and reduce the whole to a very simple arithmetical computation. It is of such a nature, that when MI is considered as the abscissa, and is divided into a number of equal parts, and ordinates are drawn from the points of division, the ordinates are a series of lines in geometrical progression, or are continual proportionals. Whatever is the ratio between the first and second ordinate, there is the same between the second and third, between the third and fourth, and so on; therefore the number of parts into which the abscissa is divided is the number of these equal ratios which is contained in the ratio of the first ordinate to the last: For this reason, this curve has got the name of the *logistic* or *logarithmic* curve; and it is of immense use in the modern mathematics, giving us the solution of many problems in the most simple and expeditious manner, on which the genius of the ancient mathematicians had been exercised in vain. Few of our readers are ignorant, that the numbers called *logarithms* are of equal utility in arithmetical operations, enabling us not only to solve common arithmetical problems with astonishing dispatch, but also to solve others which are quite inaccessible in any other way. Logarithms are nothing more than the numerical measures of the abscissa of this curve, corresponding to ordinates, which are measured on the same or any other scale by the natural numbers; that is, if ML δ be divided into equal parts, and from the points of division lines be drawn parallel to MI, cutting the curve L p K, and from the points of intersection ordinates be drawn to MI, these will divide MI into portions, which are in the same proportion to the ordinates that the logarithms bear to their natural numbers.

In constructing this curve we were limited to no particular length of the line LR, which represented the space ACDB; and all that we had to take care of was, that when OC, Ox, O g were taken in geometrical progression, M s, M t should be in arithmetical progression. The abscissæ having ordinates equal to ps, $n\,t$, &c. might have been twice as long, as is shown in the dotted curve which is drawn through L. All the lines which serve to measure the hyperbolic spaces would then have been doubled. But NI would also have been doubled, and our proportions would have still held good; because this subtangent is the scale of measurement of our figure, as E or $2a$ is the scale of measurement for the motions.

Since then we have tables of logarithms calculated for every number, we may make use of them instead of this geometrical figure, which still requires considerable trouble to suit it to every case. There are two sets of logarithmic tables in common use. One is called a table of hyperbolic or natural logarithms. It is suited to such a curve as is drawn in the figure, where the subtangent is equal to that ordinate $\pi\,\upsilon$ which corresponds to the side π O of the square $\pi\,\theta\,\lambda$ O inserted between the hyperbola and its assymptotes. This square is the unit of surface, by which the hyperbolic areas are expressed; its side is the unit of length, by which the lines belonging to the hyperbola are expressed; $\pi\,\upsilon$ is $=1$, or the unit of numbers to which the logarithms are suited, and then IN is also 1. Now the square $\theta\pi$Oλ being unity, the area BACD will be some number; πO being also unity, OD is some number: Call it x. Then, by the nature of the hyperbola, OB : O π = $\pi\,\theta$: DB: That is, $x : 1 = 1 : \frac{1}{x}$, so that DB is $\frac{1}{x}$. Now calling D $d\,\dot{x}$, the area BD $d\,b$, which is the fluxion (ultimately) of the hyperbolic area, is $\frac{\dot{x}}{x}$. Now in the curve L p K, MI has the same ratio to NI that BACD has to $\theta\lambda$Oπ: Therefore, if there be a scale of which NI is the unit, the number on this scale corresponding to MI has the same ratio to 1 which the number measuring BACD has to 1; and I i, which corresponds to BD $d\,b$, is the fluxion (ultimately) of MI: Therefore, if MI be called the logarithm of x, $\frac{\dot{x}}{x}$ is properly represented by the fluxion of MI. In short the line MI is divided precisely as the line of numbers on a Gunter's scale, which is therefore a line of logarithms; and the numbers called logarithms are just the lengths of the different parts of this line measured on a scale of equal parts. Therefore, when we meet with such an expression as $\frac{\dot{x}}{x}$ viz. the fluxion of a quantity divided by the quantity itself, we consider it as the fluxion of the logarithm of that quantity, because it is really so when the quantity is a number; and it is therefore strictly true that the fluent of $\frac{\dot{x}}{x}$ is the hyperbolic logarithm of x.

Certain reasons of convenience have given rise to another set of logarithms; these are suited to a logistic curve whose subtangent is only $\frac{43429}{100000}$ of the ordinate $\pi\,\upsilon$, which is equal to the side of the hyperbolic square, and which is assumed for the unit of number. We shall suit our applications of the preceding investigation to both these, and shall first use the common logarithms whose subtangent is 0,43429.

The whole subject will be best illustrated by taking an example of the different questions which may be proposed. 57 Illustrated by examples.

Recollect that the rectangle ACOF is $=2\,a$, or $\frac{v^2}{g}$, or

E,

E, for a ball of cast-iron one inch diameter, and if it has the diameter d, it is $\frac{u^2 d}{g}$, or $2\,a\,d$, or E d.

I. It may be required to determine what will be the space described in a given time t by a ball setting out with a given velocity V, and what will be its velocity v at the end of that time.

Here we have NI : MI=ACOF : BDCA ; now NI is the subtangent of the logistic curve ; MI is the difference between the logarithms of OD and OC ; that is, the difference betweeen the logarithms of $e+t$ and e ;

ACOF is $2\,a\,d$, or $\frac{u^2 d}{g}$, or E d.

Therefore by common logarithms 0,43429 : log. $e+t$—log. $e=2ad$: S, = space described,

or 0,43429 : log. $\frac{e+t}{e}=2ad$: S,

and $S.=\frac{2ad}{0{,}43429}\times \text{log.}\frac{e+t}{e}$,

by hyperbolic logarithms $S=2ad\times\text{log.}\frac{e+t}{e}$.

Let the ball be a 12 pounder, and the initial velocity be 1600 feet, and the time 20 seconds. We must first find e, which is $\frac{2ad}{V}$.

Therefore, log. 2 a	+3.03236
log. d (4,5)	+0.65321
log. V. (1600)	—3.20415
Log. of 3″,03,=e	0.48145
And $e+t$ is 23″03, of which the log. is	1.36229
from which take the log. of e	0.48145
remains the log. of $\frac{e+t}{e}$	0.88084

This must be considered as a common number by which we are to multiply $\frac{2ad}{0.43429}$.

Therefore add the logarithms of $2\,a\,d$	+ 3.68557
log. $\frac{e+t}{e}$	+ 9.94490
log. 0.43429	— 9.63778
Log. S. 9833 feet	3.99269

For the final velocity,

OD : OC=AC : BD, or $e+t$: e=V : v.

23″,03 : 3″,03=1600 : $210\frac{1}{7}$, =v.

The ball has therefore gone 3278 yards, and its velocity is reduced from 1600 to 210.

It may be agreeable to the reader to see the gradual progress of the ball during some seconds of its motion.

6″	5294	569	537	67

The first column is the time of the motion, the second is the space described, the third is the differences of the spaces, showing the motion during each successive second ; the fourth column is the velocity at the end of the time t ; and the last column is the differences of velocity, showing its diminution in each successive second. We see that at the distance of 1000 yards the velocity is reduced to one half, and at the distance of less than a mile it is reduced to one-third.

II. It may be required to determine the distance at which the initial velocity V is reduced to any other quantity v. This question is solved in the very same manner, by substituting the logarithms of V and v for those of $e+t$ and e; for AC : BD=OD : OC, and therefore log. $\frac{AC}{BD}$=log. $\frac{OD}{OC}$, or log. $\frac{V}{v}$= log. $\frac{e+t}{e}$.

Thus it is required to determine the distance in which the velocity 1780 of a 24 pound ball (which is the medium velocity of such a ball discharged with 16 pounds of powder) will be reduced to 1500.

Here d is 5.68, and therefore the logarithm of $2ad$ is	+3.78671
Log. $\frac{V}{v}$=0.07433, of which the log. is	+8.87116
Log. 0.43429	—9.63778
Log. 1047.3 feet, or 349 yards	3.02009

This reduction will be produced in about $\frac{7}{8}$ of a second.

III. Another question may be to determine the time which a ball, beginning to move with a certain velocity, employs in passing over a given space, and the diminution of velocity which it sustains from the resistance of the air.

We may proceed thus :

$2ad$: S=0,43429 : log. $\frac{e+t}{e}$, =t. Then to log. $\frac{e+t}{e}$ add log. e, and we obtain log. $e+t$, and $e+t$; from which if we take e we have t. Then to find v, say $e+t$: e =V : v.

We shall conclude these examples by applying this last rule to Mr Robins's experiment on a musket bullet of $\frac{3}{4}$ of an inch in diameter, which had its velocity reduced from 1670 to 1425 by passing through 100 feet of air. This we do in order to discover the resistance which it sustained, and compare it with the resistance to a velocity of 1 foot per second. 58 Application of an experiment of Mr Robins. See Robins's Math. Works, vol. i p. 135.

We must first ascertain the first term of our analogy. The ball was of lead, and therefore $2a$ must be multiplied by d and by m, which expresses the ratio of the density of lead to that of cast iron. d is 0.75, and m is $\frac{11.37}{7.21}=1.577$. Therefore

log.	$2\,a$	3.03236
	d	9.87506
	m	0.19782
Log.	$2adm$	3.10524

and $2adm$=1274.2

Now 1274.2 : 100=0.43429 : 0.03408=log. $\frac{e+t}{e}$.

But $e=\frac{2adm}{V}$=0.763, and its logarithm =9.88252, which, added to 0.03408, gives 9.91660, which is the log. of $e+t$, =0.825, from which take e, and there remains

remains $t=$, $0''.062$, or $\frac{62}{1000}$ of a second, for the time of passage. Now, to find the remaining velocity, say $825 : .763 = 1670 : 1544, = v$.

But in Mr Robins's experiment the remaining velocity was only 1425, the ball having lost 245; whereas by this computation it should have lost only 126. It appears, therefore, that the resistance is double of what it would have been if the resistance increased in the duplicate proportion of the velocity. Mr Robins says it is nearly triple, But he supposes the resistance to slow motions much smaller than his own experiment, so often mentioned, fully warrants.

The time e, in which the resistance of the air would extinguish the velocity is $0''.763$. Gravity, or the weight of the bullet, would have done it in $\frac{1670}{32}$ or $52''$; therefore the resistance is $\frac{52}{0.763}$ times, or nearly 68 times its weight, by this theory, or 5.97 pounds. If we calculate from Mr Robins's experiment, we must say log. $\frac{V}{v} : 0.43429 = 100 : e\,V$, which will be 630.23, and $e = \frac{630.23}{1670} = 0''.3774$, and $\frac{52}{0.3774}$ gives 138 for the proportion of the resistance to the weight, and makes the resistance 12.07 pounds, fully double of the other.

It is to be observed that with this velocity, which greatly exceeds that with which the air can rush into a void, there must be a statical pressure of the atmosphere equal to $6\frac{1}{4}$ pounds. This will make up the difference, and allows us to conclude that the resistance arising solely from the motion communicated to the air follows very nearly the duplicate proportion of the velocity.

The next experiment, with a velocity of 1690 feet, gives a resistance equal to 157 times the weight of the bullet, and this bears a much greater proportion to the former than 1690^2 does to 1670^2, which shows, that although these experiments clearly demonstrate a prodigious augmentation of resistance, yet they are by no means susceptible of the precision which is necessary for discovering the law of this augmentation, or for a good foundation of practical rules; and it is still greatly to be wished that a more accurate mode of investigation could be discovered.

59 Recapitulation.

Thus we have explained, in great detail, the principles and the process of calculation for the simple case of the motion of projectiles through the air. The learned reader will think that we have been unreasonably prolix, and that the whole might have been comprised in less room by taking the algebraic method. We acknowledge that it might have been done even in a few lines. But we have observed, and our observation has been confirmed by persons well versed in such subjects, that in all cases where the fluxionary process introduces the fluxion of a logarithm, there is a great want of distinct ideas to accompany the hand and eye. The solution comes out by a sort of magic or legerdemain, we cannot tell either *how* or *why*. We therefore thought it our duty to furnish the reader with distinct conceptions of the things and quantities treated of. For this reason, after showing, in Sir Isaac Newton's manner, how the spaces described in the retarded motion of a projectile followed the proportion of the hyperbolic areas, we shewed the nature of another curve, where lines could be found which increase in the very same manner as the path of the projectile increases; so that a point describing the abscissa MI of this curve moves precisely as the projectile does. Then, discovering that this line is the same with the line of logarithms on a Gunter's scale, we shewed how the logarithm of a number really represents the path or space described by the projectile.

Having thus, we hope, enabled the reader to conceive distinctly the quantities employed, we shall leave the geometrical method, and prosecute the rest of the subject in a more compendious manner.

60 Of the perpendicular ascents of heavy projectiles.

We are, in the next place, to consider the perpendicular ascents and descents of *heavy* projectiles, where the resistance of the air is combined with the action of gravity: and we shall begin with the descents.

Let u, as before, be the terminal velocity, and g the accelerating power of gravity: When the body moves with the velocity u, the resistance is equal to g; and in every other velocity v, we must have $u^2 : v^2 = g : \frac{g\,v^2}{u^2}, = r$, for the resistance to that velocity. In the descent the body is urged by gravity g, and opposed by the resistance $\frac{g\,v^2}{u^2}$: therefore the remaining accelerating force, which we shall call f, is $g - \frac{g\,v^2}{u^2}$, or $\frac{g\,u^2 - g\,v^2}{u^2}$, or $\frac{g(u^2 - v^2)}{u^2}, = f$.

Now the fundamental theorem for varied motions is $f\dot{s} = u\dot{v}$, and $\dot{s} = \frac{v\dot{v}}{f}, = \frac{u^2}{g} \times \frac{v\dot{v}}{u^2 - v^2}$, and $s = \frac{u^2}{g} \times \int \frac{v\dot{v}}{u^2 - v^2} + C$. Now the fluent of $\frac{v\dot{v}}{u^2 - v^2}$ is $= -$ hyperb. log. of $\sqrt{u^2 - v^2}$. For the fluxion of $\sqrt{u^2 - v^2}$ is $\frac{-v\dot{v}}{\sqrt{u^2 - v^2}}$, and this divided by the quantity $\sqrt{u^2 - v^2}$, of which it is the fluxion, gives precisely $\frac{u\dot{v}}{u^2 - v^2}$, which is therefore the fluxion of its hyperbolic logarithm. Therefore $S = -\frac{u^2}{g} \times L\sqrt{u^2 - v^2} + C$. Where L means the hyperbolic logarithm of the quantity annexed to it, and λ may be used to express its common logarithm. (See article Fluxions).

The constant quantity C for completing the fluent is determined from this consideration, that the space described is o, when the velocity is o: therefore $C - \frac{u^2}{g} \times L\sqrt{u^2} = o$, and $C = \frac{u^2}{g} \times L\sqrt{u^2}$, and the complete fluent $S = \frac{u^2}{g} \times \overline{L\sqrt{u^2} - L\sqrt{u^2 - v^2}}$, $= \frac{u^2}{g} \times L\sqrt{\frac{u^2}{u^2 - v^2}}, = \frac{u^2}{0.43429\,g} \times \lambda\sqrt{\frac{u^2}{u^2 - v^2}}$, or (putting M for 0.43429, the modulus or subtangent of the common logistic curve) $= \frac{u^2}{Mg} \times \lambda\sqrt{\frac{u^2}{u^2 - v^2}}$.

This

This equation establishes the relation between the space fallen through, and the velocity acquired by the fall. We obtain by it $\frac{gS}{u^2}=L\sqrt{\frac{u^2}{u^2-v^2}}$, and $\frac{2gS}{u^2}=L.\frac{u^2}{u^2-v^2}$, or, which is still more convenient for us, $\frac{M\times 2gS}{u^2}=\lambda\frac{u^2}{u^2-v^2}$, that is, equal to the logarithm of a certain number: therefore having found the natural number corresponding to the fraction $\frac{M\times 2gS}{u^2}$, consider it as a logarithm, and take out the number corresponding to it: call this n. Then, since n is equal to $\frac{u^2}{u^2-v^2}$, we have $nu^2-nv^2=u^2$, and $nu^2-u^2=nv^2$, or $nv^2=u^2\times\overline{n-v}$, and $v^2=\frac{u^2\times\overline{n-1}}{n}$.

To expedite all the computations on this subject, it will be convenient to have multipliers ready computed for $M\times 2g$, and its half,

viz. 27,794, whose log. is	- -	1.44396
and 13,897	- - - -	1.14293.

But v may be found much more expeditiously by observing that $\sqrt{\frac{u^2}{u^2-v^2}}$ is the secant of an arch of a circle whose radius is u, and whose sine is v, or whose radius is unity and sine $=\frac{v}{u}$: therefore, considering the above fraction as a logarithmic secant, look for it in the tables, and then take the sine of the arc of which this is the secant, and multiply it by u; the product is the velocity required.

We shall take an example of a ball whose terminal velocity is $689\frac{1}{3}$ feet, and ascertain its velocity after a fall of 1848 feet. Here,

$u^2=475200$	and its log. -	$=5.67688$
$u=689\frac{1}{3}$	- - - -	2.83844
$g=32$	- - - - -	1.50515
$S=1848$	- - - -	3.26670
Then log. 27,794	- - -	$+$ 1.44396
log. S	- - -	$+$ 5.26670
log. u^2	- - -	$-$ 5.67688
Log. of 0,10809 = log. n	- -	9.03378

0,10809 is the logarithm of $1,2826=n$, and $n-1=0,2826$, and $\frac{u^2\times\overline{n-1}}{n}=323,6^2$, $=v^2$, and $v=323,6$.

In like manner, 0,054045 (which is half of 0,10809) will be found to be the logarithmic secant of 28°, whose sine 0,46947 multiplied by $689\frac{1}{3}$ gives 324 for the velocity.

The process of this solution suggests a very perspicuous manner of conceiving the law of descent; and it may be thus expressed:

M is to the logarithm of the secant of an arch whose sine is $\frac{v}{u}$, and radius 1, as $2a$ is to the height through which the body must fall in order to acquire the velocity v. Thus, to take the same example.

1. Let the height h be sought which will produce the velocity 323,62 the terminal velocity of the ball being 689,44. Here $2a$, or $\frac{u^2}{g}$ is 14850, and $\frac{323,62}{689,34}=$ 0,46947, which is the sine of 28°. The logarithmic secant of this arch is 0,05407. Now M or 0,43429 : 0,05407 = 14850 : 1848, the height wanted.

2. Required the velocity acquired by the body by falling 1848 feet. Say 14850 : 1848 = 0,43429 : 0,05407. Look for this number among the logarithmic secants. It will be found at 28°, of which the logarithmic sine is

garithmic sine is	- - -	9.67161
Add to this the log. of u	- -	2.83844
The sum	- - -	2.51005

is the logarithm of 323,62, the velocity required.

We may observe, from these solutions, that the acquired velocity continually approaches to, but never equals, the terminal velocity. For it is always expressed by the sine of an arch of which the terminal velocity is the radius. We cannot help taking notice here of a very strange assertion of Mr Muller, late professor of mathematics and director of the royal academy at Woolwich. He maintains, in his Treatise on Gunnery, his Treatise of Fluxions, and in many of his numerous works, that a body cannot possibly move through the air with a greater velocity than this; and he makes this a fundamental principle, on which he establishes a theory of motion in a resisting medium, which he asserts with great confidence to be the only just theory; saying, that all the investigations of Bernoulli, Euler, Robins, Simpson, and others, are erroneous. We use this strong expression, because, in his criticisms on the works of those celebrated mathematicians, he lays aside good manners, and taxes them not only with ignorance, but with dishonesty; saying, for instance, that it required no small dexterity in Robins to confirm by his experiments a theory founded on false principles; and that Thomas Simpson, in attempting to conceal his obligations to him for some valuable propositions, by changing their form, had ignorantly fallen into gross errors.

61 Erroneous assertion of Mr Muller.

Nothing can be more palpably absurd than this assertion of Mr Muller. A blown bladder will have but a small terminal velocity; and when moving with this velocity, or one very near it, there can be no doubt that it will be made to move much swifter by a smart stroke. Were the assertion true, it would be impossible for a portion of air to be put into motion through the rest, for its terminal velocity is nothing. Yet this author makes this assertion a principle of argument, saying, that it is impossible that a ball can issue from the mouth of a cannon with a greater velocity than this; and that Robins and others are grossly mistaken, when they give them velocities three or four times greater, and resistances which are 10 or 20 times greater than is possible; and by thus compensating his small velocities by still smaller resistances, he confirms his theory by many experiments adduced in support of the others. No reason whatever can be given for the assertion. Newton, or perhaps Huygens, was the first who observed that there was a limit to the velocity which gravity could communicate to a body; and this limit was found by his commentators to be a term to which it was vastly convenient to refer all its other motions. It therefore became

became an object of attention; and Mr Muller, through inadvertency, or want of discernment, has fallen into this mistake, and with that arrogance and self-conceit which mark all his writings, has made this mistake a fundamental principle, because it led him to establish a novel set of doctrines on this subject. He was fretted at the superior knowledge and talents of Mr Simpson, his inferior in the academy, and was guilty of several mean attempts to hurt his reputation. But they were unsuccessful.

62 Motion of a body projected downwards.

We might proceed to consider the motion of a body projected downwards. While the velocity of projection is less than the terminal velocity, the motion is determined by what we have already said: for we must compute the height necessary for acquiring this velocity in the air, and suppose the motion to have begun there. But if the velocity of projection be greater, this method fails. We pass it over (though not in the least more difficult than what has gone before), because it is of mere curiosity, and never occurs in any interesting case. We may just observe, that since the motion is swifter than the terminal velocity, the resistance must be greater than the weight, and the motion will be retarded. The very same process will give us for the space described $S = \frac{u^2}{g} \times L\sqrt{\frac{V^2-u^2}{v^2-u^2}}$, V being the velocity of projection, greater than u. Now as this space evidently increases continually (because the body always falls), but does not become infinite in any finite time, the fraction $\frac{V^2-u^2}{v^2-u^2}$ does not become infinite; that is, v^2 does not become equal to u^2: therefore although the velocity V is continually diminished, it never becomes so small as u. Therefore u is a limit of diminution as well as of augmentation.

63 Relation between the time of descent and space described, &c.

We must now ascertain the relation between the time of the descent and the space described, or the velocity acquired. For this purpose we may use the other fundamental proposition of varied motions $f\dot{t} = \dot{v}$, which, in the present case, becomes $g\frac{u^2-v^2}{u^2}\dot{t} = \dot{v}$; therefore $\dot{t} = \frac{u^2}{g} \times \frac{\dot{v}}{u^2-v^2}, = \frac{u}{g} \times \frac{u\dot{v}}{u^2-v^2}$, and $t = \frac{u}{g} \times \int \frac{u\dot{v}}{u^2-v^2}$. Now (article FLUXIONS) $\int \frac{u\dot{v}}{u^2-v^2} = L\sqrt{\frac{u+v}{u-v}}$. Therefore $t = \frac{u}{g} \times L\sqrt{\frac{u+v}{u-v}}, = \frac{u}{Mg} \times \lambda\sqrt{\frac{u+v}{u-v}}$. This fluent needs no constant quantity to complete it, or rather $C = o$; for t must be $= o$ when $v = o$. This will evidently be the case: for then $L\sqrt{\frac{u+v}{u-v}}$ is $L\sqrt{\frac{u}{u}}, = L\,1, = o$.

But how does this quantity $\frac{u}{Mg} \times \lambda\sqrt{\frac{u+v}{u-v}}$ signify a time? Observe, that in whatever numbers, or by whatever units of space and time, u and g are expressed, $\frac{u}{g}$ expresses the number of units of time in which the velocity u is communicated or extinguished by gravity; and $L\sqrt{\frac{u+v}{u-v}}$, or $\frac{\lambda}{M}\sqrt{\frac{u+v}{u-v}}$, is always an abstract number, multiplying this time.

We may illustrate this rule by the same example. In what time will the body acquire the velocity 323,62? Here $u + v = 1012{,}96$, $u - v = 365{,}72$; therefore $\lambda\sqrt{\frac{u+v}{u-v}} = 0.22122$, and $\frac{u}{g}$ (in feet and seconds) is $21'',542$. Now, for greater perspicuity, convert the equation $t = \frac{u}{Mg} \times \lambda\sqrt{\frac{u+v}{u-v}}$ into a proportion: thus $M : \lambda\sqrt{\frac{u+v}{u-v}} = \frac{u}{g} : t$, and we have $0{,}43429 : 0{,}22122 = 21'', 542 : 10'',973$ the time required.

This is by far the most distinct way of conceiving the subject; and we should always keep in mind that the numbers or symbols which we call logarithms are really parts of the line MI in the figure of the logistic curve, and that the motion of a point in this line is precisely similar to that of the body. The Marquis Poleni, in a dissertation published at Padua in 1725, has with great ingenuity constructed logarithmics suited to all the cases which can occur. Herman, in his *Phoronomia*, has borrowed much of Poleni's methods, but has obscured them by an affectation of language geometrically precise, but involving the very obscure notion of abstract ratios.

It is easy to see that $\sqrt{\frac{u+v}{u-v}}$ is the cotangent of the $\frac{1}{2}$ complement of an arch, whose radius is 1, and whose sine is $\frac{v}{u}$: For let KC (fig. 6.) be $= u$, and BE $= v$; then KD $= u + v$, and DA $= u - v$. Join KB and BA, and draw CG parallel to KB. Now GA is the tangent of $\frac{1}{2}$ BA, $= \frac{1}{2}$ complement of HB. Then, by similarity of triangles, GA : AC $=$ AB $=$: BK $=$ $\sqrt{AD} : \sqrt{DK} = \sqrt{u-v} : \sqrt{u+v}$ and $\frac{AC}{GA}$ ($=$ cotan. $\frac{1}{2}$BA) $= \sqrt{\frac{u+v}{u-v}}$; therefore look for $\frac{v}{u}$ among the natural sines, or for log. $\frac{v}{u}$ among the logarithmic sines, and take the logarithmic cotangent of the half complement of the corresponding arch. This, considered as a common number, will be the second term of our proportion. This is a shorter process than the former. Fig. 6.

By reversing this proportion we get the velocity corresponding to a given time.

64 Fall of a body in air compared with that of one in vacuo.

To compare this descent of 1848 feet in the air with the fall of the body *in vacuo* during the same time, say $\overline{21'',542}^2 : \overline{10'',973}^2 = 1848 : 1926{,}6$, which makes a difference of 79 feet.

Cor. 1. The time in which the body acquires the velocity u by falling through the air, is to the time of acquiring the same velocity by falling *in vacuo*, as u. $L\sqrt{\frac{u+v}{u-v}}$ to v; for it would acquire this velocity *in vacuo*

vacuo during the time $\frac{v}{g}$, and it acquires it in the air in the time $\frac{u}{g}\mathrm{L}\sqrt{\frac{u+v}{u-v}}$.

2. The velocity which the body acquires by falling through the air in the time $\frac{u}{g}\mathrm{L}\sqrt{\frac{u+v}{u-v}}$, is to the velocity which it would acquire *in vacuo* during the same time, as v to $u\,\mathrm{L}\sqrt{\frac{u+v}{u-v}}$: For the velocity which it would acquire *in vacuo* during the time $\frac{u}{g}$ $\mathrm{L}\sqrt{\frac{u+v}{u-v}}$ must be $u\,\mathrm{L}\sqrt{\frac{u+v}{u-v}}$ (because in any time $\frac{w}{g}$ the velocity w is acquired).

65 Time of the ascent of a body projected perpendicularly.

In the next place, let a body, whose terminal velocity is u, be projected perpendicularly upwards, with any velocity V. It is required to determine the height to which it ascends, so as to have any remaining velocity v, and the time of its ascent; as also the height and time in which its whole motion will be extinguished.

We have now $\frac{g(u^2+v^2)}{u^2}$ for the expression of f; for both gravity and resistance act now in the same direction, and retard the motion of the ascending body: therefore $\frac{g(u^2+v^2)}{u^2}\dot{s}=-v\dot{v}$, and $\dot{s}=-\frac{u^2}{g}\times\frac{v\dot{v}}{u^2+v^2}$, and $s=-\frac{u^2}{g}\times\int\frac{v\dot{v}}{u^2+v^2}+\mathrm{C}, =-\frac{u^2}{g}\times\mathrm{L}\sqrt{u^2+v^2}+$ C (see art. FLUXIONS). This must be $=o$ at the beginning of the motion, that is, when $v=\mathrm{V}$, that is $-\frac{u^2}{g}\times\mathrm{L}\sqrt{u^2+\mathrm{V}^2}+\mathrm{C}=o$, or $\mathrm{C}=\frac{u^2}{g}\times\mathrm{L}\sqrt{u^2+v^2}$, and the complete fluent will be $s=\frac{u^2}{g}\times\mathrm{L}\sqrt{u^2+\mathrm{V}^2}-$ $\mathrm{L}\sqrt{u^2+v^2})=\frac{u^2}{g}\times\mathrm{L}\sqrt{\frac{u^2+\mathrm{V}^2}{u^2+v^2}}=\frac{u^2}{\mathrm{M}g}\times\lambda\sqrt{\frac{u^2+\mathrm{V}^2}{u^2+v^2}}$.

Let h be the greatest height to which the body will rise. Then $s=h$ when $v=o$; and $h=\frac{u^2}{g}\times$ $\mathrm{L}\sqrt{\frac{u^2+\mathrm{V}^2}{u^2}}=\frac{u^2}{\mathrm{M}g}\times\lambda\sqrt{\frac{u^2+\mathrm{V}^2}{u^2}}$. We have $\lambda\sqrt{\frac{u^2+\mathrm{V}^2}{u^2+v^2}}=s\frac{mg}{u^2}$; therefore $\lambda\left(\frac{u^2+\mathrm{V}^2}{u^2+v^2}\right)=\frac{2\mathrm{M}gs}{u^2}$. Therefore let n be the number whose common logarithm is $\frac{2\mathrm{M}gs}{u^2}$; we shall have $n=\frac{u^2+\mathrm{V}^2}{u^2+v^2}$, and $v^2=\frac{u^2+\mathrm{V}^2}{n}$ $-u^2$; and thus we obtain the relation of s and v, as in the case of descents: but we obtain it still easier by observing that $\sqrt{u^2+\mathrm{V}^2}$ is the secant of an arch whose radius is u, and whose tangent is V, and that $\sqrt{u^2+v^2}$ is the secant of another arch of the same circle, whose tangent is v.

Let the same ball be projected upwards with the velocity 411,05 feet per second. Required the whole height to which it will rise?

Here $\frac{\mathrm{V}}{u}$ will be found the tangent of 30.48½, the logarithmic secant of which is 0,06606. This, multiplied by $\frac{u^2}{\mathrm{M}g}$, gives 2259 feet for the height. It would have risen 2640 feet in a void.

Suppose this body to fall down again. We can 66 Velocity of projection compared with that with which it reaches the ground.
compare the velocity of projection with the velocity with which it again reaches the ground. The ascent and descent are equal: therefore $\sqrt{\frac{u^2+\mathrm{V}^2}{u^2}}$, which multiplies the constant factor in the ascent, is equal to $\sqrt{\frac{u^2}{u^2-v^2}}$, the multiplier in the descent. The first is the secant of an arch whose tangent is V; the other is the secant of an arch whose sine is v. These secants are equal, or the arches are the same; therefore the velocity of projection is to the final returning velocity as the tangent to the sine, or as the radius to the cosine of the arch. Thus suppose the body projected with the terminal velocity, or $\mathrm{V}=u$; then $v=\frac{u}{\sqrt{2}}$. If $\mathrm{V}=689$, $v=487$.

We must in the last place ascertain the relation of the space and the time.

Here $\frac{g(u^2+v^2)}{u^2}\dot{t}=-\dot{v}$, and $\dot{t}=-\frac{u^2}{g}\times\frac{\dot{v}}{u^2+v^2}$, $=$ $-\frac{u}{g}\times\frac{u\dot{v}}{u^2+v^2}$, and $t=\frac{-u}{g}\times\int\frac{u\dot{v}}{u^2+v^2}+\mathrm{C}$. Now (art. FLUXIONS) $\int\frac{u\dot{v}}{u^2+v^2}$ is an arch whose tangent $=\frac{v}{u}$ and radius 1; therefore $t=-\frac{u}{g}\times\text{arc. tan.}\frac{v}{u}+\mathrm{C}$. This must be $=o$ when $v=\mathrm{V}$, or $\mathrm{C}-\frac{u}{g}\times\text{arc. tan.}$ $\frac{\mathrm{V}}{u}=o$, and $\mathrm{C}=\frac{u}{g}\times\text{arc. tan.}\frac{\mathrm{V}}{g}$, and the complete fluent is $t=\frac{u}{g}\times\left(\text{arc. tan.}\frac{\mathrm{V}}{u}-\text{arc. tan.}\frac{v}{u}\right)$. The quantities within the brackets express a portion of the arch of a circle whose radius is unity; and are therefore abstract numbers, multiplying $\frac{u}{g}$, which we have shown to be the number of units of time in which a heavy body falls *in vacuo* from the height a, or in which it acquires the velocity u.

67 Time of ascent limited.

We learn from this expression of the time, that however great the velocity of projection, and the height to which this body will rise, may be, the time of its ascent is limited. It never can exceed the time of falling from the height a *in vacuo* in a greater proportion than that of a quadrantal arch to the radius, nearly the proportion of 8 to 5. A 24 pound iron ball cannot continue rising above 14 seconds, even if the resistance to quick motions did not increase faster than the square of the velocity. It probably will attain its greatest height in less than 12 seconds, let its velocity be ever so great.

In the preceding example of the whole ascent, $v=o$, and

and the time $t = \frac{u}{g} \times$ arc. tan. $\frac{V}{u}$, or $\frac{u}{g}$ arc. $30^{\circ}.\ 48'$. Now $30^{\circ}.\ 48' = 1848'$, and the radius 1 contains 3438; therefore the arch $= \frac{1848}{3438}, = 0{,}5376$; and $\frac{u}{g} = 21'',54$. Therefore $t = 21'',54 \times 0{,}5376, = 11'',58$, or nearly $11\frac{1}{2}$ seconds. The body would have risen to the same height in a void in $10\frac{1}{4}$ seconds.

68 This time compared in bodies projected in air and in vacuo.

Cor. 1. The time in which a body, projected in the air with any velocity V, will attain its greatest height, is to that in which it would attain its greatest height *in vacuo*, as the arch whose tangent expresses the velocity is to the tangent; for the time of the ascent in the air is $\frac{u}{g} \times$ arch; the time of the ascent *in vacuo* is $\frac{V}{g}$. Now $\frac{V}{g}$ is $=$ tan. and $V = u \times$ tan. and $\frac{V}{g} = \frac{u}{g} \times$ tan.

Fig. 6.

It is evident, by inspecting fig. 6. that the arch AI is to the tangent AG as the sector ICA to the triangle GCA; therefore the time of attaining the greatest height in the air is to that of attaining the greatest height *in vacuo* (the velocities of projection being the same), as the circular sector to the corresponding triangle.

If therefore a body be projected upwards with the terminal velocity, the time of its ascent will be to the time of acquiring this velocity *in vacuo* as the area of a circle to the area of the circumscribed square.

2. The height H to which a body will rise in a void, is to the height h to which it would rise through the air when projected with the same velocity V as $M \cdot V^2$ to $u^2 \times \lambda \frac{u^2 + V^2}{u^2}$: for the height to which it will rise *in vacuo* is $\frac{V^2}{2g}$, and the height to which it rises in the air is

$$\frac{u^2}{Mg} \lambda \sqrt{\frac{u^2 + V^2}{u^2}}; \text{ therefore } H : h = \frac{V^2}{2g} : \frac{u^2}{Mg} \lambda \sqrt{\frac{u^2 + V^2}{u^2}}, = V^2 : \frac{u^2}{M} \times 2\lambda \sqrt{\frac{u^2 + V^2}{u^2}}, = V^2 : \frac{u^2}{M} \times \lambda \frac{u^2 \times V^2}{u^2}, = M \cdot V^2 : u^2 \times \lambda \frac{u^2 + V^2}{u^2}.$$

Therefore if the body be projected with its terminal velocity, so that $V = u$, the height to which it will rise in the air is $\frac{30103}{43429}$ of the height to which it will rise *in vacuo*, or $\frac{5}{7}$ in round numbers.

We have been thus particular in treating of the perpendicular ascents and descents of heavy bodies through the air, in order that the reader may conceive distinctly the quantities which he is thus combining in his algebraic operations, and may see their connection in nature with each other. We shall also find that, in the present state of our mathematical knowledge, this simple state of the case contains almost all that we can determine with any confidence. On this account it were to be wished that the professional gentlemen would make many experiments on these motions. There is no way that promises so much for assisting us in forming accurate notions of the air's resistance. Mr Robins's method with the pendulum is impracticable with great shot; and the experiments which have been generally resorted to for this purpose, viz. the ranges of shot and shells on a horizontal plane, are so complicated in themselves, that the utmost mathematical skill is necessary for making any inferences from them; and they are subject to such irregularities, that they may be brought to support almost any theory whatever on this subject. But the perpendicular flights are affected by nothing but the initial velocity and the resistance of the air; and a considerable deviation from their intended direction does not cause any sensible error in the consequences which we may draw from them for our purpose.

69 [N]ecessity [of] further [ex]peri[me]nts.

70 Of oblique projection.

But we must now proceed to the general problem, to determine the motion of a body projected in any direction, and with any velocity. Our readers will believe beforehand that this must be a difficult subject, when they see the simplest cases of rectilineal motion abundantly abstruse: it is indeed so difficult, that Sir Isaac Newton has not given a solution of it, and has thought himself well employed in making several approximations, in which the fertility of his genius appears in great lustre. In the tenth and subsequent propositions of the second book of the *Principia*, he shows what state of density in the air will comport with the motion of a body in any curve whatever: and then, by applying this discovery to several curves which have some similarity to the path of a projectile, he finds one which is not very different from what we may suppose to obtain in our atmosphere. But even this approximation was involved in such intricate calculations, that it seemed impossible to make any use of it. In the second edition of the *Principia*, published in 1713, Newton corrects some mistakes which he had committed in the first, and carries his approximations much farther, but still does not attempt a direct investigation of the path which a body will describe in our atmosphere. This is somewhat surprising. In prop. 14. &c. he shows how a body, actuated by a centripetal force, in a medium of a density varying according to certain laws, will describe an eccentric spiral, of which he assigns the properties, and the law of description. Had he supposed the density constant, and the difference between the greatest and least distances from the centre of centripetal force exceedingly small in comparison with the distances themselves, his spiral would have coincided with the path of a projectile in the air of uniform density, and the steps of his investigation would have led him immediately to the complete solution of the problem. For this is the real state of the case. A heavy body is not acted on by equal and parallel gravity, but by a gravity inversely proportional to the square of the distance from the centre of the earth, and in lines tending to that centre nearly; and it was with the view of simplifying the investigation, that mathematicians have adopted the other hypothesis.

71 This problem not solved by Newton.

72 Disputes among British and foreign mathematicians.

Soon after the publication of this second edition of the *Principia*, the dispute about the invention of the fluxionary calculus became very violent, and the great promoters of that calculus upon the continent were in the habit of proposing difficult problems to exercise the talents of the mathematician. Challenges of this kind frequently passed between the British and foreigners.

Dr

Dr Keill of Oxford had keenly espoused the claim of Sir Isaac Newton to this invention, and had engaged in a very acrimonious altercation with the celebrated John Bernoulli of Basle. Bernoulli had published in the *Acta Eruditorum Lipsiæ* an investigation of the law of forces, by which a body moving in a resisting medium might describe any proposed curve, reducing the whole to the simplest geometry. This is perhaps the most elegant specimen which he has given of his great talents. Dr Keill proposed to him the particular problem of the trajectory and motion of a body moving through the air, as one of the most difficult. Bernoulli very soon solved the problem in a way much more general than it had been proposed, viz. without any limitation either of the law of resistance, the law of the centripetal force, or the law of density, provided only that they were regular, and capable of being expressed algebraically. Dr Brook Taylor, the celebrated author of the Method of Increments, solved it at the same time, in the limited form in which it was proposed. Other authors since that time have given other solutions. But they are all (as indeed they must be) the same in substance with Bernoulli's. Indeed they are all (Bernoulli's not excepted) the same with Newton's first approximations, modified by the steps introduced into the investigation of the spiral motions mentioned above; and we still think it most strange that Sir Isaac did not perceive that the *variation of curvature*, which he introduced in that investigation, made the whole difference between his approximations and the complete solution. This we shall
73 Bernoulli's solution. point out as we go along. And we now proceed to the problem itself, of which we shall give Bernoulli's solution, restricted to the case of uniform density and a resistance proportional to the square of the velocity. This solution is more simple and perspicuous than any that has since appeared.

PROBLEM. To determine the trajectory, and all the circumstances of the motion of a body projected
Fig. 7. through the air from A (fig. 7.) in the direction AB, and resisted in the duplicate ratio of the velocity.

Let the arch AM be put$=z$, the time of describing it t, the abscissa AP$=x$, the ordinate PM$=y$. Let the velocity in the point M$=v$, and let MN$=\dot{z}$, be described in the moment $\dot{t}$; let r be the resistance of the air, g the force of gravity, measured by the velocity which it will generate in a second; and let a be the height through which a heavy body must fall *in vacuo* to acquire the velocity which would render the resistance of the air equal to its gravity: so that we have $r=\frac{v^2}{2a}$; because, for any velocity u, and producing height h, we have $g=\frac{u^2}{2h}$.

Let M m touch the curve in M; draw the ordinate p N m, and draw M o, N n perpendicular to N p and M m. Then we have MN $=\dot{z}$, and M $o=\dot{x}$, also $m\,o$ is ultimately $=\dot{y}$ and M m is ultimately$=$MN or $\dot{z}$.
74 Action of gravity in a given time. Lastly, let us suppose $\dot{x}$ to be a constant quantity, the elementary ordinates being supposed equidistant.

The action of gravity during the time $\dot{t}$ may be measured by m N, which is half the space which it would cause the body to describe uniformly in the time $\dot{t}$ with the velocity which it generates in that time. Let this be resolved into n N, by which it deflects the body into a curvilineal path, and $m\,n$, by which it retards the ascent and accelerates the descent of the body along the tangent. The resistance of the air acts solely in retarding the motion, both in ascending and descending, and has no deflective tendency. The whole action of gravity then is to its accelerating or retarding tendency as m N to $m\,n$, or (by similarity of triangles) as m M to $m\,o$. Or $\dot{z}:\dot{y}=g:\frac{g\dot{y}}{\dot{z}}$, and the whole retardation in the ascent will be $r+\frac{g\dot{y}}{\dot{z}}$. The same fluxionary symbol will express the retardation during the descent, because in the descent the ordinates decrease, and $\dot{y}$ is a negative quantity.

The diminution of velocity is $-\dot{v}$. This is proportional to the retarding force and to the time of its action jointly, and therefore $-\dot{v}=\overline{r+\frac{g\dot{y}}{\dot{z}}}\times\dot{t}$; but the time $\dot{t}$ is as the space $\dot{z}$ divided by the velocity v; therefore $-\dot{v}=\overline{r+\frac{g\dot{y}}{\dot{z}}}\times\frac{\dot{z}}{v},=-\frac{r\dot{z}+g\dot{y}}{v}$, and $-v\dot{v}=-r\dot{z}-g\dot{y}=\frac{v^2\dot{z}}{2a}-g\dot{y}$. Because m N is the deflection by gravity, it is as the force g and the square of the time $\dot{t}$ jointly (the momentary action being held as uniform), We have therefore m N, or $-\ddot{y}=g\dot{t}^2$. (Observe that m N is in fact only the half of$-\ddot{y}$; but g being twice the fall of a heavy body in a second, we have $-\ddot{y}$ strictly equal to $g\dot{t}^2$). But $\dot{t}^2=\frac{\dot{z}^2}{v^2}$; therefore $-\ddot{y}=\frac{g\dot{z}^2}{v^2}$, and $v^2=\frac{g\dot{z}^2}{-\ddot{y}}$ and $-v^2\ddot{y}=g\dot{z}^2$. The fluxion of this equation is $-v^2\dddot{y}-2v\ddot{y}\dot{v}=2g\dot{z}\ddot{z}$; but, because $\dot{z}:\dot{y}=m$ M $:m\,o,=m$ N $:m\,n,=\ddot{y}:\ddot{z}$, we have $\dot{z}\ddot{z}=\dot{y}\ddot{y}$. Therefore $2g\dot{y}\ddot{y}=2g\dot{z}\ddot{z},=-v^2\dddot{y}-2v\ddot{y}\dot{v}$, and $-2v\dot{v}\ddot{y}=v^2\dddot{y}-2g\dot{y}\ddot{y}$, and $-v\dot{v}=\frac{v^2\dddot{y}}{2\ddot{y}}-g\dot{y}$. But we have already $-v\dot{v}=\frac{v^2\dot{z}}{2a}-g\dot{y}$; therefore $\frac{v^2\dddot{y}}{\ddot{y}}=\frac{v^2\dot{z}}{a}$, and finally $\frac{\dddot{y}}{\ddot{y}}=\frac{\dot{z}}{a}$, or $a\dddot{y}=\dot{z}\ddot{y}$, for the fluxionary equation of the curve.

If we put this into the form of a proportion, we have $a:\dot{z}=\ddot{y}:\dddot{y}$. Now this evidently establishes a relation between the length of the curve and its variation of curvature; and between the curve itself and its evoluta, which are the very circumstances introduced by Newton 75 Relation between the length of the curve and its variation of curvature.

Newton into his investigation of the spiral motions. And the equation $\frac{\dot{z}}{a}=\frac{\dddot{y}}{\ddot{y}}$ is evidently an equation connected with the logarithmic curve and the logarithmic spiral. But we must endeavour to reduce it to a lower order of fluxions, before we can establish a relation between z, x, and y.

Let p express the ratio of $\dot{y}$ to $\dot{x}$, that is, let p be $=\frac{\dot{y}}{\dot{x}}$, or $p\,\dot{x}=\dot{y}$. It is evident that this expresses the inclination of the tangent at M to the horizon, and that p is the tangent of this inclination, radius being unity. Or it may be considered merely as a number, multiplying $\dot{x}$, so as to make it $=\dot{y}$. We now have $\dot{y}^2=p^2\dot{x}^2$, and since $\dot{z}^2=\dot{x}^2+\dot{y}^2$, we have $\dot{z}^2=\dot{x}^2+p^2\dot{x}^2$, $=\overline{1+p^2}\times\dot{x}^2$, and $\dot{z}=\dot{x}\sqrt{1+p^2}$.

Moreover, because we have supposed the abscissa x to increase uniformly, and therefore $\dot{x}$ to be constant, we have $\ddot{y}=\dot{x}\,\dot{p}$, and $\dddot{y}=\dot{x}\,\ddot{p}$. Now let q express the ratio of $\dot{p}$ to $\dot{x}$, that is, make $\frac{\dot{p}}{\dot{x}}=q$, or $q\,\dot{x}=\dot{p}$. This gives us $\dot{x}\,\dot{q}=\ddot{p}$, and $\dot{x}^2\dot{q}=\dot{x}\,\ddot{p}$, $=\dddot{y}$.

By these substitutions our former equation $a\,\dddot{y}=\dot{z}\,\ddot{y}$ changes to $a\,\dot{x}^2\dot{q}=\dot{x}\sqrt{\overline{1+p^2}}\,\dot{x}\,\dot{p}$, or $a\,\dot{q}=\dot{p}\sqrt{1+p^2}$, and, taking the fluent on both sides, we have $a\,q=\int\dot{p}\sqrt{1+p^2}+C$, C being the constant quantity required for completing the fluent according to the limiting conditions of the case. Now $\dot{x}=\frac{\dot{p}}{q}$, and $\frac{1}{q}=$

$$\int,\frac{a}{\dot{p}\sqrt{\overline{1+p^2}}+C}.\ \text{Therefore}\ \dot{x}=\int,\frac{a\,\dot{p}}{\dot{p}\sqrt{\overline{1+p^2}}+C}.$$

Also, since $\dot{y}=p\,\dot{x}$, $=\frac{p\dot{p}}{q}$, we have $\dot{y}=$

$$\int,\frac{a\,p\,\dot{p}}{\dot{p}\sqrt{\overline{1+p^2}}+C}.$$

Also $\dot{z}=\dot{x}\sqrt{\overline{1+p^2}}=\frac{a\,\dot{p}\sqrt{\overline{1+p^2}}}{\int,\dot{p}\sqrt{\overline{1+p^2}}+C}.$

The values of $\dot{x}$, $\dot{y}$, $\dot{z}$, give us

$$x=\int,\frac{a\,\dot{p}}{\int,\dot{p}\sqrt{\overline{1+p^2}}+C},=a\int\frac{\dot{p}}{\int\dot{p}\sqrt{\overline{1+p^2}}+C}.$$

$$y=\int\frac{a\,p\,\dot{p}}{\int,\dot{p}\sqrt{\overline{1+p^2}}+C},=a\int\frac{p\,\dot{p}}{\int\dot{p}\sqrt{\overline{1+p^2}}+C}.$$

$$z=\int,\frac{a\sqrt{\overline{1+p^2}}\,\dot{p}}{\int,\dot{p}\sqrt{\overline{1+p^2}}+C},=a\int\frac{\dot{p}\sqrt{\overline{1+p^2}}}{\int,\dot{p}\sqrt{\overline{1+p^2}}+C}.$$

The process therefore of describing the trajectory is, 1st, to find q in terms of p by the area of the curve whose abscissa is p and the ordinate is $\sqrt{1+p^2}$.

2d, We get x by the area of another curve whose abscissa is p, and the ordinate is $\frac{1}{q}$.

3d, We get y by the area of a third curve whose abscissa is p, and the ordinate is $\frac{p}{q}$.

The problem of the trajectory is therefore completely solved, because we have determined the ordinate, abscissa, and arch of the curve for any given position of 76
its tangent. It now only remains to compute the magnitudes of these ordinates and abscissæ, or to draw them by a geometrical construction. But in this consists the difficulty. The areas of these curves, which express the lengths of x and y, can neither be computed nor exhibited geometrically, by any accurate method *yet* discovered, and we must content ourselves with approximations. These render the description of the trajectory exceedingly difficult and tedious, so that little advantage has as yet been derived from the knowledge we have got of its properties. It will however greatly assist our conception of the subject to proceed some length in this construction; for it must be acknowledged that very few distinct notions accompany a mere algebraic operation, especially if in any degree complicated, which we confess is the case in the present question.

To compute the magnitude of the ordinate and abscissa.

Let B m NR (fig. 8.) be an equilateral hyperbola, of which B is the vertex, BA the semitransverse axis, which we shall assume for the unity of length. Let AV be the semiconjugate axis = BA, = unity, and AS the assymptote, bisecting the right angle BAV. Let PN, $p\,n$ be two ordinates to the conjugate axis, exceedingly near to each other. Join BP, AN, and draw Bβ, Nν perpendicular to the assymptote, and BC parallel to AP. It is well known that BP is equal to NP. Therefore $PN^2=BA^2+AP^2$. Now since BA=1, if we make AP=p of our formulæ, PN is $\sqrt{1+p^2}$, and Pp is $=\dot{p}$, and the area BAPNB$=\int,\dot{p}\sqrt{\overline{1+p^2}}$: That is to say, the number $\int,\dot{p}\sqrt{1+p^2}$ (for it is a number) has the same proportion to unity of number that the area BAPNB has to BCVA, the unit of surface. This area consists of two parts, the triangle APN, and the hyperbolic sector ABN. APN $=\frac{1}{2}$ AP $\times$ PN, $=\frac{1}{2}p\sqrt{1+p^2}$, and the hyperbolic sector ABN=BN$\nu\beta$, which is equivalent to the hyperbolic logarithm of the number represented by Aν when Aβ is unity. Therefore it is equal to $\frac{1}{2}$ the logarithm of $p+\sqrt{1+p^2}$. Hence we see by the bye that $\int,\dot{p}\sqrt{1+p^2}=\frac{1}{2}p\sqrt{1+p^2}+\frac{1}{2}$ hyperbolic logarithm $\overline{p+\sqrt{1+p^2}}$.

Plate CCCCXLII. fig. 8.

Now let AMD be another curve, such that its ordinates V m, PD, &c. may be proportional to the areas AB m V, ABNP and may have the same proportion to AB, the unity of length, which these areas have to ABCV, the unity of surface. Then VM : VC = V m BA : VCBA, and PD : P ɔ = PNBA : VCBA, &c. These ordinates will now represent $\int,\dot{p}\sqrt{\overline{1+p^2}}$ with reference to a linear unit, as the areas to the hyperbola represented it in reference to a superficial unit.

Again,

Again, in every ordinate make $PD : P\delta = P\delta : PO$, and thus we obtain a reciprocal to PD, or to $\int, \dot{p}\sqrt{1+p^2}$, or equivalent to $\int, \frac{1}{\dot{p}\sqrt{1+p^2}}$. This will evidently be $\frac{\dot{x}}{a\dot{p}}$, and $POop$ will be $\frac{\dot{x}}{a}$, and the area contained between the lines AF, AW, and the curve GEOH, and cut off by the ordinate PO, will represent $\frac{x}{a}$.

Lastly, make $PO : PQ = AV : AP, = 1 : p$; and then $PQqp$ will represent $\frac{\dot{y}}{a}$, and the area ALEQP will represent $\frac{y}{a}$.

But we must here observe, that the fluents expressed by these different areas require what is called the *correction* to accommodate them to the circumstances of the case. It is not indifferent from what ordinate we begin to reckon the areas. This depends on the initial direction of the projectile, and that point of the abscissa AP must be taken for the commencement of all the areas which gives a value of p suited to the initial direction. Thus, if the projection has been made from A (fig. 7.) at an elevation of 45°, the ratio of the fluxions $\dot{x}$ and $\dot{y}$ is that of equality; and therefore the point E of fig. 8. where the two curves intersect and have a common ordinate, evidently corresponds to this condition. The ordinate EV passes through V, so that AV or $p = AB, = 1, =$ tangent 45°, as the case requires. The values of x and of y corresponding to any other point of the trajectory, such as that which has AP for the tangent of the angle which it makes with the horizon, are now to be had by computing the areas VEOP, VEQP.

Fig. 7.

Fig. 8.

Another curve might have been added, of which the ordinates would exhibit the fluxions of the arch of the trajectory $\dot{z} = \frac{a\dot{p}\sqrt{1+p^2}}{\int, \dot{p}\sqrt{1+p^2}|+C}$, and of which the area would exhibit the arch itself. And this would have been very easy, for it is $\dot{z} = a\frac{\dot{p}\sqrt{1+p^2}}{\int, \dot{p}\sqrt{1+p^2}|+C}$, which is evidently the fluxion of the hyperbolic logarithm of $\int, \dot{p}\sqrt{1+p^2}|$. But it is needless, since $\dot{z} = \dot{x}\sqrt{1+p^2}$, and we have already got $\dot{x}$. It is only increasing PO in the ratio of BA to BP.

77 Consequences of knowing the form of the trajectory.

And thus we have brought the investigation of this problem to considerable length, having ascertained the *form* of the trajectory. This is surely done when the ratio of the arch, abscissa, and ordinate, and the position of its tangent, is determined in every point. But it is still very far from a solution, and much remains to be done before we can make any practical application of it. The only general consequence that we can deduce from the premises is, that in every case where the resistance in any point bears the same proportion to the force of gravity, the trajectory will be similar. Therefore, two balls, of the same density, projected in the same direction, will describe similar trajectories if the velocities are in the subduplicate ratio of the diameters. This we shall find to be of considerable practical importance. But let us now proceed to determine the velocity in the different points of the trajectory; and the time of describing its several portions.

78 To determine the velocity in different points.

Recollect, therefore, that $v^2 = \frac{-g\dot{x}^2}{\ddot{y}}$, and that $\dot{z}^2 = \dot{x}^2\overline{1+p^2}$ and $\ddot{y} = \dot{x}\dot{p}$. This gives $v^2 = \frac{-g\dot{x}\overline{1+p^2}}{\dot{p}}$. But $\dot{p} = q\dot{x}$. Therefore $v^2 = \frac{-g\times\overline{1+p^2}}{q}, = \frac{-ag\overline{1+p^2}}{\int, \dot{p}\sqrt{1+p^2}|+C}$, and $v = \sqrt{\frac{-g\overline{1+p^2}}{q}}, = \frac{\sqrt{a}\sqrt{-g}\sqrt{1+p^2}}{\sqrt{\int\dot{p}\sqrt{1+p^2}|+C}}$.

Also $\dot{t}$ was found $= \frac{\dot{z}}{v}, = \frac{\dot{x}\sqrt{1+p^2}}{v}, = \frac{\dot{p}\sqrt{1+p^2}}{qv}$. If we now substitute for v its value just found, we obtain $\dot{t} = \frac{\dot{p}}{\sqrt{-gq}}$, and $t = \int\frac{\dot{p}}{\sqrt{-gq}}, = \int\frac{\dot{p}\sqrt{a}}{\sqrt{-g\int\dot{p}\sqrt{1+p^2}|+C}}, = \frac{\sqrt{a}}{\sqrt{-g}}\times \int\frac{\dot{p}}{\sqrt{\int\dot{p}\sqrt{1+p^2}|+C}}$.

79 Difficulty of accommodating the formulæ to particular cases.

The greatest difficulty still remains, viz. the accommodating these formulæ, which appear abundantly simple, to the particular cases. It would seem at first sight, that all trajectories are similar; since the ratio of the fluxions of the ordinate and abscissa corresponding to any particular angle of inclination to the horizon seems the same in them all: but a due attention to what has been hitherto said on the subject will show us that we have as yet only been able to ascertain the velocity in the point of the trajectory, which has a certain inclination to the horizon, indicated by the quantity p, and the time (reckoned from some assigned beginning) when the projectile is in that point.

To obtain absolute measures of these quantities, the term of commencement must be fixed upon. This will be expressed by the constant quantity C, which is assumed for completing the fluent of $\dot{p}\sqrt{1+p^2}$, which is the basis of the whole construction. We there found $q = \frac{\int, \dot{p}\sqrt{1+p^2}}{a}$. This fluent is in general $q = \frac{C+\int, \dot{p}\sqrt{1+p^2}}{a}$, and the constant quantity C is to be accommodated to some circumstances of the case. Different authors have selected different circumstances. Euler, 80 Euler, in his Commentary on Robins, and in a dissertation in the Memoirs of the Academy of Berlin published in 1753, takes the vertex of the curve for the beginning of his abscissa and ordinate. This is the simplest method of any, for C must then be so chosen that the whole fluent may vanish when $p=o$, which is the case in the vertex of the curve, where the tangent is parallel to the horizon. We shall adopt this method.

Euler's method the simplest.

Fig. 9. Therefore, let AP (fig. 9.) $=x$, PM $=y$, AM $=z$. Put the quantity C which is introduced into the fluent equal to $\frac{n}{a}$. It is plain that n must be a number; for it must be homologous with $\dot p\sqrt{1+p^2}$, which is a number. For brevity's sake let us express the fluent of $\dot p\sqrt{1+p^2}$ by the single letter P; and thus we shall have $x=a\times\int\frac{\dot p}{n+\mathrm{P}}$, $y=a\times\int\frac{p\dot p}{n+\mathrm{P}}$, $z=a\times\int\frac{\dot p\sqrt{1+p^2}}{n+\mathrm{P}}$. And $v^2=\frac{-ag(1+p^2)}{n+\mathrm{P}}$. Now the height h necessary for communicating any velocity v is $\frac{v^2}{2g}=\frac{-ag(1+p^2)}{2g(n+\mathrm{P})},=\frac{-\frac{1}{2}a(1+p^2)}{n+p}$. And lastly, $t=\frac{\sqrt{}}{\sqrt{g}}\int\frac{\dot p}{\sqrt{n+\mathrm{P}}}$.

These fluents, being all taken so as to vanish at the vertex, where the computation commences, and where p is $=o$ (the tangent being parallel to the horizon), we obtain in this case $h=\frac{\frac{1}{2}a}{n}=\frac{a}{2n}$, and $n=\frac{a}{2h}$.

Hence we see that the circumstance which modifies all the curves, distinguishing them from each other, is the velocity (or rather its square) in the highest point of the curve. For h being determined for any body whose terminal velocity is u, n is also determined; and this is the modifying circumstance. Considering it geometrically, it is the area which must be cut off from the area DMAP of fig. 8. in order to determine the ordinates of the other curves.

We must further remark, that the values now given relate only to that part of the area where the body is descending from the vertex. This is evident; for, in order that y may increase as we recede from the vertex, its fluxion must be taken in the opposite sense to what it was in our investigation. *There* we supposed y to increase as the body ascended, and then to diminish during the descent; and therefore the fluxion of y was first positive and then negative.

The same equations, however, will serve for the ascending branch CNA of the curve, only changing the sign of P; for if we consider y as decreasing during the ascent, we must consider q as expressing $\frac{\dot p}{\dot x}$, and therefore P, or $\int\dot p\sqrt{1+p^2}$, which is $=\frac{q}{a}$, must be taken negatively. Therefore, in the ascending branch, we have AQ or x (increasing as we recede from A)— $a\times\int\frac{\dot p}{n-\mathrm{P}}$, QN or $y=a\times\int\frac{p\dot p}{n-p}$, AN or $z=a\times\int\frac{\dot p\sqrt{1+p^2}}{n-\mathrm{P}}$, $t=\frac{\sqrt{a}}{\sqrt{g}}\times\int\frac{\dot p}{\sqrt{1-\mathrm{P}}}$, and the height producing the velocity at N$=\frac{\frac{1}{2}a(1+p^2)}{n-\mathrm{P}}$.

Hence we learn by the bye, that in no part of the ascending branch can the inclination of the tangent be such that P shall be greater than n; and that if we suppose P equal to n in any point of the curve, the velocity in that point will be infinite. That is to say, there is a certain assignable elevation of the tangent which cannot be exceeded in a curve which has this velocity in the vertex. The best way for forming a conception of this circumstance in the nature of the curve, is to invert the motion, and suppose an accelerating force, equal and opposite to the resistance, to act on the body in conjunction with gravity. It must describe the same curve, and this branch ANC must have an assymptote LO, which has this limiting position of the tangent. For, as the body descends in this curve, its velocity increases to infinity by the joint action of gravity and this *accelerating* force, and yet the tangent never approaches so near the perpendicular position as to make P$=n$. This remarkable property of the curve was known to Newton, as appears by his approximations, which all lead him to curves of a hyperbolic form, having one assymptote inclined to the horizon. Indeed it is pretty obvious: For the resistance increasing faster than the velocity, there is no velocity of projection so great but that the curve will come to deviate so from the tangent, that in a finite time it will become parallel to the horizon. Were the resistance proportional to the velocity, then an infinite velocity would produce a rectilineal motion, or rather a deflection from it less than any that can be assigned. 81

Remarkable property of the curve or trajectory.

We now see that the particular form and magnitude of this trajectory depends on two circumstances, a and n. a affects chiefly the magnitude. Another circumstance might indeed be taken in, viz. the diminution of the accelerating force of gravity by the statical effect of the air's gravity. But, as we have already observed, this is too trifling to be attended to in military projectiles. 82

On what its form and magnitude depends.

$\frac{\dot y}{\dot x}$ was made equal to p. Therefore the radius of curvature, determined by the ordinary methods, is $\frac{\dot x(1+p^2)(\sqrt{1+p^2})}{\dot p}$ *, and, because $\frac{\dot x}{\dot p}$ is $=\frac{a}{n+\mathrm{P}}$ for the descending branch of the curve, the radius of curvature at M is $\frac{a\times\overline{1+p^2}\times\sqrt{1+p^2}}{n+\mathrm{P}}$, and, in the ascending branch at N, it is $\frac{a\times\overline{1+p^2}\times\sqrt{1+p^2}}{n-\mathrm{P}}$.

* Simpson's Fluxions, § 68, &c.

On both sides, therefore, when the velocity is infinitely great, and P by this means supposed to equal or exceed n, the radius of curvature is also infinitely great. We also see that the two branches are unlike each other, and that when p is the same in both, that is, when the tangent is equally inclined to the horizon, the radius of curvature, the ordinate, the absciss, and the arch, are all greater in the ascending branch. This is pretty obvious.

vious. For as the resistance acts entirely in diminishing the velocity, and does not affect the deflection occasioned by gravity, it must allow gravity to incurvate the path so much the more (with the same inclination of its line of action) as the velocity is more diminished. The curvature, therefore, in those points which have the same inclination of the tangent, is greatest in the descending branch, and the motion is swiftest in the ascending branch. It is otherwise in a void, where both sides are alike. Here u becomes infinite, or there is no terminal velocity; and n also becomes infinite, being $= \frac{a}{2h}$.

It is therefore in the quantity P, or $\int \dot{p}\sqrt{1+p^2}$, that the difference between the trajectory in a void and in a resisting medium consists; it is this quantity which expresses the accumulated change of the ratio of the increments of the ordinate and absciss. In vacuo the second increment of the ordinate is constant when the first increment of the abscissa is so, and the whole increment of the ordinate is as $1+p$. And this difference is so much the greater as P is greater in respect of n. P is nothing at the vertex, and increases along with the angle M'TP; and when this is a right angle, P is infinite. The trajectory in a resisting medium will come therefore to deviate infinitely from a parabola, and may even deviate farther from it than the parabola deviates from a straight line. That is, the distance of the body in a given moment from that point of its parabolic path where it would have been in a void, is greater than the distance between that point of the parabola from the point of the straight line where it would have been, independent of the action of gravity. This must happen whenever the resistance is greater than the weight of the body, which is generally the case in the beginning of the trajectory in military projectiles; and this (were it now necessary) is enough to show the inutility of the parabolic theory.

83 **Several properties of it ascertained.**

Although we have no method of describing this trajectory, which would be received by the ancient geometers, we may ascertain several properties of it, which will assist us in the solution of the problem. In particular, we can assign the absolute length of any part of it by means of the logistic curve. For because P $=\int \dot{p}\sqrt{1+p^2}$, we have $\dot{p}\sqrt{1+p^2} = \dot{P}$, and therefore z, which was $= a \times \int \frac{\dot{p}\sqrt{1+p^2}}{\int \dot{p}\sqrt{1+p^2}} + C$, or $= a \times \int \frac{\dot{P}}{n+P}$, may be expressed by logarithms; or $z = a \times$ hyp. log. of $\frac{n+P}{n}$, since at the vertex A, where z must be $= o$, P is also $= o$.

Being able, in this way, to ascertain the length AM of the curve (counted from the vertex), corresponding to any inclination p of the tangent at its extremity M, we can ascertain the length of any portion of it, such as Mm, by first finding the length of the part Am, and then of the part AM. This we do more expeditiously thus. Let p express the position of the tangent in M, and q its position at m; then AM $= a \times$ log. $\frac{n+P}{n}$ and Am $= a \times$ log. $\frac{n+Q}{n}$, and therefore Mm is $= a \times$ log. $\frac{n+Q}{n+P}$. Thus we can find the values of a great number of small portions and the inclination of the tangents at their extremities. Then to each of these portions we can assign its proportion of the abscissa and ordinate, without having recourse to the values of x and y. For the portion of absciss corresponding to the arch Mm, whose middle point is inclined to the horizon in the angle b, will be Mm $\times$ cosine b, and the corresponding portion of the ordinate will be Mm $\times$ sin. b. Then we obtain the velocity in each part of the curve by the equation $h = \frac{1}{2}a \times \frac{\overline{1+p^2}}{n+p}$; or, more directly the velocity v at M will be $= \sqrt{ag\frac{\sqrt{1+p^2}}{\sqrt{n+P}}}$. Lastly, divide the length of the little arch by this, and the quotient will be the time of describing Mm very nearly. Add all these together, and we obtain the whole time of describing the arch AM, but a little too great, because the motion in the small arch is not perfectly uniform. The error, however, may be as small as we please, because we may make the arch as small as we please; and for greater accuracy, it will be proper to take the p by which we compute the velocity, a medium between the p for the beginning and that for the end of the arch.

84 **Euler's method preferred.**

This is the method followed by Euler, who was one of the most expert analysts, if not the very first, in Europe. It is not the most elegant, and the methods of some other authors, who approximate directly to the areas of the curves which determine the values of x and y, have a more scientific appearance; but they are not ultimately very different: For, in some methods, these areas are taken piecemeal, as Euler takes the arch; and by the methods of others, who give the value of the areas by Newton's method of describing a curve of the parabolic kind through any number of given points, the ordinates of these curves, which express $\dot{x}$ and $\dot{y}$, must be taken singly, which amounts to the same thing, with the great disadvantage of a much more complicated calculus, as any one may see by comparing the expressions of $\dot{x}$ and $\dot{y}$ with the expressions of $\dot{z}$. As to those methods which approximate directly to the areas or values of x and y by an infinite series, they all, without exception, involve us in most complicated expressions, with coefficients of sines and tangents, and ambiguous signs, and engage us in a calculation almost endless. And we know of no series which converges fast enough to give us tolerable accuracy, without such a number of terms as is sufficient to deter any person from the attempt. The calculation of the arches is very moderate, so that a person tolerably versant in arithmetical operations may compute an arch with its velocity and time in about five minutes. We have therefore no hesitation in preferring this method of Euler's to all that we have seen, and therefore proceed to determine some other circumstances which render its application more general.

If

85 If there were no resistance, the smallest velocity would be at the vertex of the curve, and it would immediately increase by the action of gravity conspiring (in however small degree) with the motion of the body. But in a resisting medium, the velocity at the vertex is diminished by a quantity to which the acceleration of gravity in that point bears no assignable proportion. It is therefore diminished, upon the whole, and the point of smallest velocity is a little way beyond the vertex. For the same reasons, the greatest curvature is a little way beyond the vertex. It is not very material for our present purpose to ascertain the exact positions of those points.

Its application made more general.

The velocity in the descending branch augments continually: but it cannot exceed a certain limit, if the velocity at the vertex has been less than the terminal velocity; for when the curve is infinite, p is also infinite, and $h=\frac{\frac{1}{2}ap^2}{P}$, because n in this case is nothing in respect of P, which is infinite; and because p is infinite, the number hyp. log. $p\times\sqrt{1+p^2}$, though infinite, vanishes in comparison with $p\times\sqrt{1+p^2}$; so that in this case $P=\frac{1}{2}p^2$, and $h=a$, and $v=$ the terminal velocity.

If, on the other hand, the velocity at the vertex has been greater than the terminal velocity, it will diminish continually, and when the curve has become infinite, v will be equal to the terminal velocity.

In either case we see that the curve on this side will have a perpendicular assymptote. It would require a long and pretty intricate analysis to determine the place of this assymptote, and it is not material for our present purpose. The place and position of the other assymptote LO is of the greatest moment. It evidently distinguishes the kind of trajectory from any other. Its position depends on this circumstance, that if p marks the position of the tangent, $n-P$, which is the denominator of the fraction expressing the square of the velocity, must be equal to nothing, because the velocity is infinite: therefore, in this place, $P=n$, or $n=\frac{1}{2}p\sqrt{1+p^2}+\frac{1}{2}\log.\,p+\sqrt{1+p^2}$. In order, therefore, to find the point L, where the assymptote LO cuts the horizontal line AL, put $P=n$, then will $AL=x-\frac{y\dot{x}}{\dot{y}},=a\times\left(\int\frac{\dot{p}}{n-P}-\frac{1}{p}\int\frac{p\dot{p}}{n-P}\right)$.

Through the whole of this article $\int$ means fluent.

It is evident that the logarithms used in these expressions are the natural or hyperbolic. But the operations may be performed by the common tables, by making the value of the arch M m of the curve $=\frac{a}{M}\times\log.\frac{n+Q}{n+P}$, &c. where M means the subtangent of the common logarithms, or 0,43429; also the time of describing this arch will be expeditiously had by taking a medium μ between the values of $\frac{\sqrt{1+p^2}}{\sqrt{n+P}}$ and $\frac{\sqrt{1+q}}{\sqrt{n+Q}}$, and making the time $=\frac{\sqrt{a}}{M\mu\sqrt{g}}\times\log.\frac{n+Q}{n+P}$.

86 Such then is the process by which the form and magnitude of the trajectory, and the motion in it, may be determined. But it does not yet appear how this is to be applied to any question in practical artillery. In this process we have only learned how to compute the motion from the vertex in the descending branch till the ball has acquired a particular direction, and the motion to the vertex from a point of the ascending branch where the ball has another direction, and all this depending on the greatest velocity which the body can acquire by falling, and the velocity which it has in the vertex of the curve. But the usual question is, "What will be the motion of the ball projected in a certain direction with a certain velocity?"

Mode of applying this process to practice.

The mode of application is this: Suppose a trajectory computed for a particular terminal velocity, produced by the fall a, and for a particular velocity at the vertex, which will be characterized by n, and that the velocity at that point of the ascending branch where the inclination of the tangent is 30° is 900 feet per second. Then, we are certain, that if a ball, whose terminal velocity is that produced by the fall a, be projected with the velocity of 900 feet per second, and an elevation of 30°, it will describe this very trajectory, and the velocity and time corresponding to every point will be such as is here determined.

Now this trajectory will, in respect to form, answer an infinity of cases: for its characteristic is the proportion of the velocity in the vertex to the terminal velocity. When this proportion is the same, the number n will be the same. If, therefore, we compute the trajectories for a sufficient variety of these proportions, we shall find a trajectory that will nearly correspond to any case that can be proposed: and an approximation sufficiently exact will be had by taking a proportional medium between the two trajectories which come nearest to the case proposed.

Accordingly, a set of tables or trajectories have been computed by the English translator of Euler's Commentary on Robins's Gunnery. They are in number 18, distinguished by the position of the assymptote of the ascending branch. This is given for 5°, 10°, 15°, &c. to 85°, and the whole trajectory is computed as far as it can ever be supposed to extend in practice. The following table gives the value of the number n corresponding to each position of the assymptote. 87

Computed tables or trajectories.

OLB	n	OLB	n
1	0,00000	45	1,14779
5	0,08760	50	1,43236
10	0,17724	55	1,82207
15	0,27712	60	2,39033
20	0,37185	65	3,29040
25	0,48269	70	4,88425
30	0,60799	75	8,22357
35	0,75382	80	17,54793
40	0,92914	85	67,12291

Since the path of a projectile is much less incurvated, and more rapid in the ascending than in the descending branch, and the difference is so much the more remarkable in great velocities; it must follow, that the range on a horizontal or inclined plane depends most on the ascending branch: therefore the greatest range will not be made with that elevation which bisects the angle of position, but with a lower elevation; and the deviation from the bisecting elevation will be greater as the initial velocities

velocities are greater. It is very difficult to frame an exact rule for determining the elevation which gives the greatest range. We have subjoined a little table which gives the proper elevation (nearly) corresponding to the different initial velocities.

It was computed by the following approximation, which will be found the same with the series used by Newton in his Approximation.

Let e be the angle of elevation, a the height producing the terminal velocity, h the height producing the initial velocity, and c the number whose hyperbolic logarithm is 1 (i. e. the number 2,718). Then,

$$y = x \times \left(\tan. e + \frac{a}{2h. \cos. e}\right) - \frac{a^2}{2h}\left(C^{\frac{x}{a \cos. e.}} - 1\right),$$

&c. Make $y = v$, and take the maximum by varying e, we obtain $\frac{1}{\text{Sin.}^2 e + \frac{a \sin. e}{2h}} =$ hyperbol. log. $\left(1 + \frac{2h}{a \text{ sine } e}\right)$, which gives us the angle e.

The numbers in the first column, multiplied by the terminal velocity of the projectile, give us the initial velocity; and the numbers in the last column, being multiplied by the height producing the terminal velocity, and by 2,3026, give us the greatest ranges. The middle column contains the elevation. The table is not computed with scrupulous exactness, the question not requiring it. It may, however, be depended on within one part of 2000.

To make use of this table, divide the initial velocity by the terminal velocity u, and look for the quotient in the first column. Opposite to this will be found the elevation giving the greatest range; and the number in the last column being multiplied by $2,3026 \times a$ (the height producing the terminal velocity) will give the range.

Table of Elevations giving the greatest Range.

Initial vel. / u	Elevation.	Range. / 2,3026 a
0,6909	43°.40	0,1751
0,7820	43 .20	0,2169
0,8645	42 .50	0,2548
1,3817	41 .40	0,4999
1,5641	40 .20	0,5789

4,8631	31 .50	1,5341

88 Advantage to be derived from the solution of the problem.

Such is the solution which the present state of our mathematical knowledge enables us to give of this celebrated problem. It is exact in its principle, and the application of it is by no means difficult, or even operose. But let us see what advantage we are likely to derive from it.

In the first place it is very limited in its application. There are few circumstances of general coincidence, and almost every case requires an appropriated calculus. Perhaps the only general rules are the two following:

1. Balls of equal density, projected with the same elevation, and with velocities which are as the square roots of their diameters, will describe similar curves.—This is evident, because, in this case, the resistance will be in the ratio of their quantities of motion. Therefore all the homologous lines of the motion will be in the proportion of the diameters.

2. If the initial velocities of balls projected with the same elevation are in the inverse subduplicate ratio of the whole resistances, the ranges, and all the homologous lines of their track, will be inversely as those resistances.

These theorems are of considerable use: for by means of a proper series of experiments on one ball projected with different elevations and velocities, tables may be constructed which will ascertain the motions of an infinity of others.

89 Shown from various considerations to be very little.

But when we take a retrospective view of what we have done, and consider the conditions which were assumed in the solution of the problem, we shall find that much yet remains before it can be rendered of great practical use, or even satisfy the curiosity of the man of science The resistance is all along supposed to be in the duplicate ratio of the velocity; but even theory points out many causes of deviation from this law, such as the pressure and condensation of the air, in the case of very swift motions; and Mr Robins's experiments are sufficient to show us that the deviations must be exceedingly great in such cases. Mr Euler and all subsequent writers have allowed that it may be three times greater, even in cases which frequently occur; and Euler gives a rule for ascertaining with tolerable accuracy what this increase and the whole resistance may amount to. Let H be the height of a column of air whose weight is equivalent to the resistance taken in the duplicate ratio of the velocity. The whole resistance will be expressed by $H + \frac{H^2}{28845}$. This number 28845 is the height in feet of a column of air whose weight balances its elasticity. We shall not at present call in question his reasons for assigning this precise addition. They are rather reasons of arithmetical conveniency than of physical import. It is enough to observe, that if this measure of the resistance is introduced into the process of investigation, it is totally changed; and it is not too much to say, that with this complication it requires the knowledge and address of a Euler to make even a partial and very limited approximation to a solution.—Any law of the resistance, therefore, which is more complicated than what Bernoulli has assumed, namely, that of a simple power of the velocity, is abandoned by all the mathematicians, as exceeding their abilities; and they have attempted to avoid the error arising from the assumption of the duplicate ratio of the velocity, either by supposing the resistance throughout the whole trajectory to be greater than what it is in general, or they have divided the trajectory into different portions, and assigned different resistances to each, which vary

vary, through the whole of that portion, in the duplicate ratio of the velocities. By this kind of patchwork they make up a trajectory and motion which corresponds, in some tolerable degree, with what? With an accurate theory? No; but with a series of experiments. For, in the first place, every theoretical computation that we make, proceeds on a supposed initial velocity; and this cannot be ascertained with any thing approaching to precision, by any theory of the action of gunpowder that we are yet possessed of. In the next place, our theories of the resisting power of the air are entirely established on the experiments on the flights of shot and shells, and are corrected and amended till they tally with the most approved experiments we can find. We do not learn the ranges of a gun by theory, but the theory by the range of the gun. Now the variety and irregularity of all the experiments which are appealed to are so great, and the acknowledged difference between the resistance to slow and swift motions is also so great, that there is hardly any supposition which can be made concerning the resistance, that will not agree in its results with many of those experiments. It appears from the experiments of Dr Hutton of Woolwich, in 1784, 1785, and 1786, that the shots frequently deviated to the right or left of their intended track 200, 300, and sometimes 400 yards. This deviation was quite accidental and anomalous, and there can be no doubt but that the shot deviated from its intended and *supposed* elevation as much as it deviated from the intended vertical plane, and this without any opportunity of measuring or discovering the deviation. Now, when we have the whole range from one to three to choose among for our measure of resistance, it is evident that the confirmations which have been drawn from the ranges of shot are but feeble arguments for the truth of any opinion. Mr Robins finds his measures fully confirmed by the experiments at Metz and at Minorca. Mr Muller finds the same. Yet Mr Robins's measure both of the initial velocity and of the resistance are at least treble of Mr Muller's; but by compensation they give the same results. The Chevalier Borda, a very expert mathematician, has adduced the very same experiments in support of his theory, in which he abides by the Newtonian measure of the resistance, which is about $\frac{1}{3}$ of Mr Robins's, and about $\frac{2}{3}$ of Muller's.

90 Cause of its inutility. What are we to conclude from all this? Simply this, that we have hardly any knowledge of the air's resistance, and that even the solution given of this problem has not as yet greatly increased it. Our knowledge consists only in those experiments, and mathematicians are attempting to patch up some notion of the motion of a body in a resisting medium, which shall tally with them.

There is another essential defect in the conditions assumed in the solution. The density of the air is supposed uniform; whereas we are certain that it is less by one-fifth or one-sixth towards the vertex of the curve, in many cases which frequently occur, than it is at the beginning and end of the flight. This is another latitude given to authors in their assumptions of the air's resistance. The Chevalier de Borda has, with considerable ingenuity, accommodated his investigation to this circumstance, by dividing the trajectory into portions, and, without much trouble, has made one equation answer them all. We are disposed to think that his solution of the problem (in the Memoirs of the Academy of Paris for 1769) corresponds better with the physical circumstances of the case than any other. But this process is there delivered in too concise a manner to be intelligible to a person not perfectly familiar with all the resources of modern analysis. We therefore preferred John Bernoulli's, because it is elementary and rigorous.

After all, the practical artillerist must rely chiefly on the records of experiments contained in the books of practice at the academies, or those made in a more public manner. Even a perfect theory of the air's resistance can do him little service, unless the force of gunpowder were uniform. This is far from being the case even in the same powder. A few hours of a damp day will make a greater difference than occurs in any theory; and, in service it is only by trial that every thing is performed. If the first shell fall very much short of the mark, a little more powder is added; and, in cannonading, the correction is made by varying the elevation. 91 Necessity of attending to experiments.

We hope to be forgiven by the eminent mathematicians for these observations on their theories. They by no means proceed from any disrespect for their labours. We are not ignorant of the almost insuperable difficulty of the task, and we admire the ingenuity with which some of them have contrived to introduce into their analysis reasonable substitutions for those terms which would render the equations intractable. But we must still say, upon their own authority, that these are but ingenious guesses, and that experiment is the touchstone by which they mould these substitutions; and when they have found a coincidence, they have no motive to make any alteration. Now, when we have such a latitude for our measure of the air's resistance, that we may take it of any value, from one to three, it is no wonder that compensations of errors should produce a coincidence; but where is the coincidence? The theorist *supposes* the ball to set out with a certain velocity, and his theory gives a certain range; and this range agrees with observation—but how? Who knows the velocity of the ball in the experiment? This is concluded from a theory incomparably more uncertain than that of the motion in a resisting medium.

The experiments of Mr Robins and Dr Hutton show, in the most incontrovertible manner, that the resistance to a motion exceeding 1100 feet in a second, is almost *three times* greater than in the duplicate ratio to the resistance to moderate velocities. Euler's translator, in his comparison of the author's trajectories with experiment, supposes it to be *no* greater. Yet the coincidence is very great. The same may be said of the Chevalier de Borda's. Nay, the same may be said of Mr Robins's own practical rules: for he makes his F, which corresponds to our *a*, almost double of what these authors do, and yet his rules are confirmed by practice. Our observations are therefore well founded.

But it must not be inferred from all this, that the physical theory is of no use to the practical artillerist. It plainly shows him the impropriety of giving the projectile an enormous velocity. This velocity is of no effect after 200 or 300 yards at farthest, because it is so rapidly reduced by the prodigious resistance of the air. Mr Robins has deduced several practical maxims of the greatest importance from what we already know of this subject, and which could hardly have been even conjectured without this knowledge. See GUNNERY. 92 The theory is still of some use in practice.

And

93 And it must still be acknowledged, that this branch of physical science is highly interesting to the philosopher; nor should we despair of carrying it to a greater perfection. The defects arise almost entirely from our ignorance of the law of variation of the air's resistance. Experiments may be contrived much more conducive to our information here than those commonly resorted to. The oblique flights of projectiles are, as we have seen, of very complicated investigation, and ill fitted for instructing us; but numerous and well contrived experiments on the perpendicular ascents are of great simplicity, being affected by nothing but the air's resistance. To make them instructive, we think that the following plan might be pursued. Let a set of experiments be premised for ascertaining the initial velocities. Then let shells be discharged perpendicularly with great varieties of density and velocity, and let nothing be attended to but the height and the time; even a considerable deviation from the perpendicular will not affect either of these circumstances, and the effect of this circumstance can easily be computed. The height can be ascertained with sufficient precision for very valuable information by their light or smoke. It is evident that these experiments will give *direct* information of the air's retarding force; and every experiment gives us two measures, viz. the ascent and descent: and the comparison of the times of ascent and descent, combined with the observed height in one experiment made with a great initial velocity, will give us more information concerning the air's resistance than 50 ranges. If we should suppose the resistance as the square of the velocity, this comparison will give in each experiment an exact determination of the initial and final velocities, which no other method can give us. These, with experiments on the *time* of horizontal flights, with known initial velocities, will give us more instruction on this head than any thing that has yet been done; and till something of this kind is carefully done, we presume to say that the motion of bodies in a resisting medium will remain in the hands of the mathematicians as a matter of curious speculation. In the mean time, the rules which Mr Robins has delivered in his Gunnery are very simple and easy in their use, and seem to come as near the truth as any we have met with. He has not informed us upon what principles they are founded, and we are disposed to think that they are rather empirical than scientific. But we profess great deference for his abilities and penetration, and doubt not but that he had framed them by means of as scientific a discussion as his knowledge of this new and difficult subject enabled him to give it.

and may be brought to greater perfection.

94 We shall conclude this article, by giving two or three tables, computed from the principles established above, and which serve to bring into one point of view the chief circumstances of the motion in a resisting medium. Although the result of much calculation, as any person who considers the subject will readily see, they must not be considered as offering any very accurate results; or that, in comparison with one or two experiments, the differences shall not be considerable. Let any person peruse the published registers of experiments which have been made with every attention, and he will see such enormous irregularities, that all expectations of perfect agreement with them must cease. In the experiments at Woolwich in 1735, which were continued for several days, not only do the experiments of one day differ among themselves, but the mean of all the experiments of one day differs from the mean of all the experiments of another no less than one-fourth of the whole. The experiments in which the greatest regularity may be expected, are those made with great elevations. When the elevation is small, the range is more affected by a change of velocity, and still more by any deviation from the supposed or intended direction of the shot.

Tables calculated on the preceding principles.

The first table shows the distance in yards to which a ball projected with the velocity 1600 will go, while its velocity is reduced one-tenth, and the distance at which it drops 16 feet from the line of its direction. This table is calculated by the resistance observed in Mr Robins's experiments. The first column is the weight of the ball in pounds. The second column remains the same whatever be the initial velocity; but the third column depends on the velocity. It is here given for the velocity which is very usual in military service, and its use is to assist us in directing the gun to the mark.—If the mark at which a ball of 24 pounds is directed is 474 yards distant, the axis of the piece must be pointed 16 feet higher than the mark. These deflections from the line of direction are nearly as the squares of the distances.

4	121	428
9	159	456
18	200	470
32	272	479

The next table contains the ranges in yards of a 1 pound shot, projected at an elevation of 45°, with the different velocities in feet per second, expressed in the first column. The second column contains the distances to which the ball would go in vacuo in a horizontal plane; and the third contains the distances to which it will go through the air. The fourth column is added, to show the height to which it rises in the air; and the fifth shows the ranges corrected for the diminution of the air's density as the bullet ascends, and may therefore be called the *corrected range*.

95 Use of the last table.

The initial velocities can never be pushed as far as we have calculated for in this table; but we mean it for a table of more extensive use than appears at first sight. Recollect, that while the proportion of the velocity at the vertex to the terminal velocity remains the same, the curves will be similar: therefore, if the initial velocities are as the square-roots of the diameters of the balls, they will describe similar curves, and the ranges will be as the diameters of the balls.

Therefore, to have the range of a 12 pound shot, if projected at an elevation of 45, with the velocity 1500; suppose the diameter of the 12-pounder to be d, and that of the 24-pounder D; and let the velocities be v and V: Then say, $\sqrt{d}:\sqrt{D}=1500$, to a fourth proportional V. If the 24-pounder be projected with the velocity V, it will describe a curve similar to that described by the 12-pounder, having the initial velocity 1500. Therefore find (by interpolation) the range of the 24-pounder, having the initial velocity V. Call this R. Then $D:d=R:r$, the range of the 12-pounder which was wanted, and which is nearly 3380 yards.

We see by this table the immense difference between the motions through the air and in a void. We see that the ranges through the air, instead of increasing in the duplicate ratio of the initial velocities, really increase slower than those velocities in all cases of military service; and in the most usual cases, viz. from 800 to 1600, they increase nearly as the square-roots of the velocities.

A set of similar tables, made for different elevations, would almost complete what can be done by theory, and would be much more expeditious in their use than Mr Euler's Trajectories, computed with great labour by his English translator.

The same table may also serve for computing the ranges of bomb-shells. We have only to find what must be the initial velocity of the 24 pound shot which corresponds to the proposed velocity of the shell. This must be deduced from the diameter and weight of the shell, by making the velocity of the 24-pounder such, that the ratio of its weight to the resistance may be the same as in the shell.

That the reader may see with one glance the relation of those different quantities, we have given this table, expressed in a figure (fig. 10.). The abscissa, or axis DA, is the scale of the initial velocities in feet per second, measured in a scale of 400 equal parts in an inch. The ordinates to the curve ACG express the yards of the range on a scale containing 800 yards in an inch. The ordinates to the curve $A\,x\,y$ express (by the same scale) the height to which the ball rises in the air.

Fig. 10. 96 Relation of the different quantities in it.

The ordinate BC (drawn through the point of the abscissa which corresponds to the initial velocity 2000) is divided on the points 4, 9, 12, 18, 24, 32, 42, in the ratio of the diameters of cannon-shot of different weights; and the same ordinate is produced on the other side of the axis, till BO be equal to BA; and then BO is divided in the subduplicate ratio of the same diameters. Lines are drawn from the point A, and from any point D of the abscissa, to these divisions.

We see distinctly by this figure how the effect of the initial velocity gradually diminishes, and that in very great velocities the range is very little increased by its augmentation. The dotted curve APQR, shows what the ranges in vacuo would be.

By this figure may the problems be solved. Thus, to find the range of the 12-pounder, with the initial velocity 1500. Set off 1500 from B to F; draw FH parallel to the axis, meeting the line 12 A in H; draw the ordinate HK, draw HL parallel to the axis, meeting 24 B in L; draw the ordinate LM, cutting 12 B in N. MN is the range required.

If curves, such as ACG, were laid down in the same manner for other elevations, all the problems might be solved with great dispatch, and with much more accuracy than the theory by which the curves are drawn can pretend to.

Note, that fig. 10. as given on Plate CCCCXLII, *is one-half less than the scale according to which it is described; but the practical mathematician will find no difficulty in drawing the figure on the enlarged scale to correspond to the description.*

PROJECTION OF THE SPHERE.

Stereographic Projection of the Sphere.

THE PROJECTION of the SPHERE is a perspective representation of the circles on the surface of the sphere; and is variously denominated according to the different positions of the eye and plane of projection.

There are three principal kinds of projection; the *stereographic*, the *orthographic*, and *gnomic*. In the tereographic projection the eye is supposed to be placed on the surface of the sphere; in the orthographic it is supposed to be at an infinite distance; and in the gnomic projection the eye is placed at the centre of the sphere. Other kinds of projection are, the *globular*, *Mercator's*, *scenographic*, &c. for which see the articles GEOGRAPHY, NAVIGATION, PERSPECTIVE, &c.

DEFINITIONS.

1. The plane upon which the circles of the sphere are described, is called the *plane of projection*, or the *primitive circle*. The pole of this circle is the *pole of projection*, and the place of the eye is the *projecting point*.

2. The *line of measures* of any circle of the sphere is that diameter of the primitive, produced indefinitely, which passes through the centre of the projected circle.

AXIOM.

The projection, or representation of any point, is where the straight line drawn from it to the projecting point intersects the plane of projection.

SECTION I.

Of the Stereographic Projection of the Sphere.

IN the stereographic projection of the sphere, the eye

Stereographic Projection of the Sphere.

eye is placed on the surface of the sphere in the pole of the great circle upon which the sphere is to be projected. The projection of the hemisphere opposite to the eye falls within the primitive, to which the projection is generally limited; it, however, may be extended to the other hemisphere, or that wherein the eye is placed, the projection of which falls without the primitive.

As all circles in this projection are projected either into circles or straight lines, which are easily described, it is therefore more generally understood, and by many preferred to the other projections.

Proposition I. Theorem I.

Every great circle which passes through the projecting point is projected into a straight line passing through the centre of the primitive; and every arch of it, reckoned from the other pole of the primitive, is projected into its semitangent.

Plate CCCCXLIII. fig. 1.

Let ABCD (fig. 1.) be a great circle passing through A, C, the poles of the primitive, and intersecting it in the line of common section BED, E being the centre of the sphere. From A, the projecting point, let there be drawn straight lines AP, AM, AN, AQ, to any number of points P, M, N, Q, in the circle ABCD: these lines will intersect BED, which is in the same plane with them. Let them meet it in the points p, m, n, q; then p, m, n, q, are the projections of P, M, N, Q: hence the whole circle ABCD is projected into the straight line BED, passing through the centre of the primitive.

Again, because the pole C is projected into E, and the point M into m; therefore the arch CM is projected into the straight line Em, which is the semitangent of the arch CM to the radius AE. In like manner, the arch CP is projected into its semitangent, Ep, &c.

Corollaries.

1. Each of the quadrants contiguous to the projecting point is projected into an indefinite straight line, and each of these that are remote into a radius of the primitive.

2. Every small circle which passes through the projecting point is projected into that straight line which is its common section with the primitive.

3. Every straight line in the plane of the primitive, and produced indefinitely, is the projection of some circle on the sphere passing through the projecting point.

4. The projection of any point in the surface of the sphere, is distant from the centre of the primitive, by the semitangent of the distance of that point from the pole opposite to the projecting point.

Proposition II. Theorem II.

Every circle on the sphere which does not pass through the projecting point is projected into a circle.

If the given circle be parallel to the primitive, then a straight line drawn from the projecting point to any point in the circumference, and made to revolve about the circle, will describe the surface of a cone; which being cut by the plane of projection parallel to the base, the section will be a circle. See *Conic-Sections*.

Fig. 2.

But if the circle MN (fig. 2.) be not parallel to the primitive circle BD, let the great circle ABCD, passing through the projecting point, cut it at right angles in the diameter MN, and the primitive in the diameter BD. Through M, in the plane of the great circle, let MF be drawn parallel to BD; let AM, AN be joined, and meet BD in m, n. Then, because AB, AD are quadrants, and BD, MF parallel, the arch AM is equal to AF, and the angle AMF or Amn is equal to ANM. Hence the conic surface described by the revolution of AM about the circle MN is cut by the primitive in a subcontrary position; therefore the section is in this case likewise a circle.

Corollaries.

1. The centres and poles of all circles parallel to the primitive have their projection in its centre.

2. The centre and poles of every circle inclined to the primitive have their projections in the line of measures.

3. All projected great circles cut the primitive in two points diametrically opposite; and every circle in the plane of projection, which passes through the extremities of a diameter of the primitive, or through the projections of two points that are diametrically opposite on the sphere, is the projection of some great circle.

4. A tangent to any circle of the sphere, which does not pass through the projecting point, is projected into a tangent to that circle's projection; also, the circular projections of tangent circles touch one another.

5. The extremities of the diameter, on the line of measures of any projected circle, are distant from the centre of the primitive by the semitangents of the least and greatest distances of the circle on the sphere, from the pole opposite to the projecting point.

6. The extremities of the diameter, on the line of measures of any projected great circle, are distant from the centre of the primitive by the tangent and cotangent of half the great circle's inclination to the primitive.

7. The radius of any projected circle is equal to half the sum, or half the difference of the semitangents of the least and greatest distances of the circle from the pole opposite to the projecting point, according as that pole is within or without the given circle.

Proposition III. Theorem III.

An angle formed by two tangents at the same point in the surface of the sphere, is equal to the angle formed by their projections.

Fig. 3.

Let FGI and GH (fig. 3.) be the two tangents, and A the projecting point; let the plane AGF cut the sphere in the circle AGL, and the primitive in the line BML. Also, let MN be the line of common section of the plane AGH with the primitive: then the angle FGH=LMN. If the plane FGH be parallel to the primitive BLD, the proposition is manifest. If not, through any point K in AG produced, let the plane FKH, parallel to the primitive, be extended to meet FGH in the line FH. Then, because the plane AGF meets the two parallel planes BLD, FKH, the lines of common section LM, FK are parallel; therefore

Stereographic Projection of the Sphere.

for the angle AML=AKF. But since A is the pole BLD, the chords, and consequently the arches AB AL, are equal, and the arch ABG is the sum of the arches AL, BG; hence the angle AML is equal to an angle at the circumference standing upon AG, and therefore equal to AGI or FGK; consequently the angle FGK=FKG, and the side FG=FK. In like manner HG=HK: hence the triangles GHF, KHF are equal, and the angle FGH=FKH=LMN.

Corollaries.

1. An angle contained by any two circles of the sphere is equal to the angle formed by their projections. For the tangents to these circles on the sphere are projected into straight lines, which either coincide with, or are tangents to, their projections on the primitive.

2. An angle contained by any two circles of the sphere is equal to the angle formed by the radii of their projections at the point of intersection.

Proposition IV. Theorem IV.

The centre of a projected great circle is distant from the centre of the primitive; the tangent of the inclination of the great circle to the primitive, and its radius, is the secant of its inclination.

Fig. 4. Let MNG (fig. 4.) be the projection of a great circle, meeting the primitive in the extremities of the diameter MN, and let the diameter BD, perpendicular to MN, meet the projection in F, G. Bisect FG in H, and join NH. Then, because any angle contained by two circles of the sphere is equal to the angle formed by the radii of their projections at the point of intersection; therefore the angle contained by the proposed great circle and the primitive is equal to the angle ENH, of which EH is the tangent, and NH the secant, to the radius of the primitive.

Corollaries.

1. All circles which pass through the points M, N, are the projections of great circles, and have their centres in the line BG; and all circles which pass through the points F, G, are the projections of great circles, and have their centres in the line HI, perpendicular to BG.

2. If NF, NH be continued to meet the primitive in L, F; then BL is the measure of the great circle's inclination to the primitive; and MT=2BL.

Proposition V. Theorem V.

The centre of projection of a less circle perpendicular to the primitive, is distant from the centre of the primitive, the secant of the distance of the less circle from its nearest pole; and the radius of projection is the tangent of that distance.

Fig. 5. Let MN (fig. 5.) be the given less circle perpendicular to the primitive, and A the projecting point. Draw AM, AN to meet the diameter BD produced in G and H; then GH is the projected diameter of the less circle: bisect GH in C, and C will be its centre; join NE, NC. Then because AE, NI are parallel, the angle INE=NEA; but NEA=2NMA =2NHG=NCG: hence ENC=INE+INC=NCG+INC = a right angle; and therefore NC is a tangent to the primitive at N; but the arch ND is the distance of the less circle from its nearest pole D: hence NC is the tangent, and EC the secant of the distance of the less circle from its pole to the radius of the primitive.

Proposition VI. Theorem VI.

The projection of the poles of any circle, inclined to the primitive, are, in the line of measures, distant from the centre of the primitive, the tangent, and cotangent, of half its inclination.

Fig. 6. Let MN (fig. 6.) be a great circle perpendicular to the primitive ABCD, and A the projecting point; then P, *p* are the poles of MN, and of all its parallels *m n*, &c. Let AP, A*p* meet the diameter BD in F*f*, which will therefore be the projected poles of MN and its parallels. The angle BEM is the inclination of the circle MEN, and its parallels, to the primitive: and because BC and MP are quadrants, and MC common to both; therefore PC=BM: and hence PEC is also the inclination of MN and its parallels. Now EF is the tangent of EAF, or of half the angle PEC the inclination; and E*f* is the tangent of the angle EA*f*; but EA*f* is the complement of EAF, and E*f* is the cotangent of half the inclination.

Corollaries.

1. The projection of that pole which is nearest to the projecting point is without the primitive, and the projection of the other within.

2. The projected centre of any circle is always between the projection of its nearest pole and the centre of the primitive; and the projected centres of all circles are contained between the projected poles.

Proposition VII. Theorem VII.

Equal arches of any two great circles of the sphere will be intercepted between two other circles drawn on the sphere through the remote poles of those great circles.

Fig. 7. Let AGB, CFD (fig. 7.) be two great circles of the sphere, whose remote poles are E, P; through which draw the great circle PBEC, and less circle PGE, intersecting the great circles AGB, CFD in the points B, G, and D, F; then the arch BG is equal to the arch DF.

Because E is the pole of the circle AGB, and P the pole of CFD, therefore the arches EB, PD are equal; and since BD is common to both, hence the arch ED is equal to the arch PB. For the same reason, the arches EF, PG are equal; but the angle DEF is equal to the angle BPG: hence these triangles are equal, and therefore the arch DF is equal to the arch BG.

Proposition VIII. Theorem VIII.

If from either pole of a projected great circle, two straight lines be drawn to meet the primitive and the projection, they will intercept similar arches of these circles.

Stereographic Projection of the Sphere.

On the plane of projection AGB (fig. 7.) let the great circle CFD be projected into *cfd*, and its pole P into *p*; through *p* draw the straight lines *pd*, *pf*, then are the arches GB, *fd* similar.

Since *pd* lies both in the plane AGB and APBE, it is in their common section, and the point B is also in their common section; therefore *pd* passes through the point B. In like manner it may be shown that the line *pf* passes through G. Now the points D, F are projected into *d*, *f*: hence the arches FD, *fd* are similar; but GB is equal to FD, therefore the intercepted arch of the primitive GB is similar to the projected arch *fd*.

Corollary.

Hence, if from the angular point of a projected spherical angle two straight lines be drawn through the projected poles of the containing sides, the intercepted arch of the primitive will be the measure of the spherical angle.

Proposition IX. Problem I.

To describe the projection of a great circle through two given points in the plane of the primitive.

Let P and B be given points, and C the centre of the primitive.

Fig. 8. 1. When one point P (fig. 8.) is the centre of the primitive, a diameter drawn through the given points will be the great circle required.

Fig. 9. 2. When one point P (fig. 9.) is in the circumference of the primitive. Through P draw the diameter PD; and an oblique circle described through the three points P, B, D, will be the projection of the required great circle.

3. When the given points are neither in the centre nor circumference of the primitive. Through either of Fig. 10. the given points P (fig. 10.) draw the diameter ED, and at right angles thereto draw the diameter FG. From F through P draw the straight line FPH, meeting the circumference in H: draw the diameter HI, and draw the straight line FIK, meeting ED produced in K; then an arch, terminated by the circumference, being described through the three points, P, B, K, will be the great circle.

Proposition X. Problem II.

To describe the representation of a great circle about any given point as a pole.

Let P be the given pole, and C the centre of the primitive.

1. When P (fig. 8.) is in the centre of the primitive, then the primitive will be the great circle required.

Fig. 11. 2. When the pole P (fig. 11.) is in the circumference of the primitive. Through P draw the diameter PE, and the diameter AB drawn at right angles to PE will be the projected great circle required.

3. When the given pole is neither in the centre nor circumference of the primitive. Through the pole P

Plate CCCCXLIV. (fig. 12.) draw the diameter AB, and draw the diameter DE perpendicular to AB; through E and P draw the straight line EPF, meeting the circumference in F. Make FG equal to FD; through E and G draw the straight line EGH, meeting the diameter AB produced if necessary in H; then from the centre H, with the radius HE, describe the oblique circle DIE, and it will be the projection of the great circle required.

Or, make DK equal to FA; join EK, which intersects the diameter AB in I; then through the three points, D, I, E, describe the oblique circle DIE.

Proposition XI. Problem III.

To find the poles of a great circle.

1. When the given great circle is the primitive, its centre is the pole.

2. To find the pole of the right circle ACB (fig. 11.). Draw the diameter PE perpendicular to the given circle AB; and its extremities P, E are the poles of the circle ACB.

3. To find the pole of the oblique circle DEF (fig. 13.). Join DF, and perpendicular thereto draw the diameter AB, cutting the given oblique circle DEF in E. Draw the straight line FEG, meeting the circumference in G. Make GI, GH, each equal to AD; then FI being joined, cuts the diameter AB in P, the lower pole; through F and H draw the straight line FH*p*, meeting the diameter AB produced in *p*, which will be the opposite or exterior pole. Fig. 13.

Proposition XII. Problem IV.

To describe a less circle about any given point as a pole, and at any given distance from that pole.

1. When the pole of the less circle is in the centre of the primitive; then from the centre of the primitive, with the semitangent of the distance of the given circle from its pole, describe a circle, and it will be the projection of the less circle required.

2. If the given pole is in the circumference of the primitive, from C (fig. 14.) the centre of the primitive, Fig. 14. set off CE the secant of the distance of the less circle from its pole P; then from the centre E, with the tangent of the given distance, describe a circle, and it will be the less circle required. Or, make PG, PF each equal to the chord of the distance of the less circle from its pole. Through B, G draw the straight line BGD meeting CP produced in D: bisect GD in H, and draw HE perpendicular to GD, and meeting PD in E; then E is the centre of the less circle.

3. When the given pole is neither in the centre nor circumference of the primitive. Through P (fig. 15.), Fig. 15. the given pole, and C the centre of the primitive, draw the diameter AB, and draw the diameter DE perpendicular to AB; join EP, and produce it to meet the primitive in *p*; make *p*F, *p*G, each equal to the chord of the distance of the less circle from its pole; join EF which intersects the diameter AB in H; from E through G draw the straight line EGI, meeting the diameter AB produced in I; bisect HI in K: Then a circle described from the centre K, at the distance KH or KI, will be the projection of the less circle.

Proposition XIII. Problem V.

To find the poles of a given less circle.

The poles of a less circle are also those of its parallel great

Stereographic Projection of the Sphere.

great circle. If therefore the parallel great circle be given, then its poles being found by Prob. III. will be those of the less circle. But if the parallel great circle be not given, let HMIN (fig. 15.) be the given less circle. Through its centre, and C the centre of the primitive, draw the line of measures IAHB; and draw the diameter DE perpendicular to it, also draw the straight line EHF meeting the primitive in F; make Fp equal to the chord of the distance of the less circle from its pole: join Ep, and its intersection P with the diameter AB is the interior pole. Draw the diameter p CL through E and L, draw ELq meeting the diameter AB produced in q; then q is the external pole. Or thus: Join EI intersecting the primitive in G; join also EH, and produce it to meet the primitive in F; bisect the arch GH in p; from E to p draw the straight line EPp, and P is the pole of the given less circle.

Fig. 15.

Proposition XIV. Problem. VI.

To measure any arch of a great circle.

1. Arches of the primitive are measured on the line of chords.

2. Right circles are measured on the line of semitangents, beginning at the centre of the primitive. Thus, the measure of the portion AC (fig. 16.) of the right circle DE, is found by applying it to the line of semitangents. The measure of the arch DB is found by subtracting that of BC from 90°: the measure of the arch AF, lying partly on each side of the centre, is obtained by adding the measures of AC and CF. Lastly, To measure the part AB, which is neither terminated at the centre or circumference of the primitive, apply CA to the line of semitangents; then CB, and the difference between the measures of these arches, will be that of AB.

Fig. 16.

Or thus: Draw the diameter GH perpendicular to DE; then from either extremity, as D, of this diameter, draw lines through the extremities of the arch intended to be measured; and the intercepted portion of the primitive applied to the line of chords will give the measure of the required arch. Thus IK applied to the line of chords will give the measure of AB.

3. To measure an arch of an oblique circle: draw lines from its pole through the extremities of the arch to meet the primitive, then the intercepted portion of the primitive applied to the line of chords will give the measure of the arch of the oblique circle. Thus, let AB (fig. 17.), be an arch of an oblique circle to be measured, and P its pole; from P draw the lines PAD, PBE meeting the primitive in B and E; then the arch DE applied to the line of chords will give the measure of the arch of the oblique circle AB.

Fig. 17.

Proposition XV. Problem VII.

To measure any arch of a less circle.

Let DEG (fig. 18.) be the given less circle, and DE the arch to be measured: find its internal pole P; and describe the circle AFI parallel to the primitive, and whose distance from the projecting point may be equal to the distance of the given less circle from its pole P: then join PD, PE, which produce to meet the parallel circle in A and F. Now AF applied to a line of chords will give the measure of the arch DE of the given less circle.

Fig. 18.

Proposition XVI. Problem VIII.

To measure any spherical angle.

1. If the angle is at the centre of the primitive, it is measured as a plane angle.

2. When the angular point is in the circumference of the primitive; let A (fig. 19.) be the angular point, and ABE an oblique circle inclined to the primitive. Through P, the pole of ABE, draw the line APp meeting the circumference in p: then the arch E p is the measure of the angle BAD, and the arch AFp is the measure of its supplement BAF: also p F is the measure of the angle BAC, and p ED that of its supplement.

Fig. 19.

3. If the angular point is neither at the centre nor circumference of the primitive. Let A (fig. 20.) be the angular point, and DAH, or GAF, the angle to be measured, P the pole of the oblique circle DAF, and p the pole of GAH: then from A, through the points Pp, draw the straight lines APM, A p N, and the arch MN will be the measure of the angle DAH; and the supplement of MN will be the measure of the angle HAF or DAG.

Fig. 20.

Proposition XVII. Problem IX.

To draw a great circle perpendicular to a projected great circle, and through a point given in it.

Find the pole of the given circle, then a great circle described through that pole and the given point will be perpendicular to the given circle. Hence if the given circle be the primitive, then a diameter drawn through the given point will be the required perpendicular. If the given circle is a right one, draw a diameter at right angles to it; then through the extremities of this diameter and the given point describe an oblique circle, and it will be perpendicular to that given. If the given circle is inclined to the primitive, let it be represented by BAD (fig. 21.), whose pole is P, and let A be the point through which the perpendicular is to be drawn: then, by Prob. I. describe a great circle through the points P and A, and it will be perpendicular to the oblique circle BAD.

Fig. 21.

Proposition XVIII. Problem X.

Through a point in a projected great circle, to describe another great circle to make a given angle with the former, provided the measure of the given angle is not less than the distance between the given point and circle.

Let the given circle be the primitive, and let A (fig. 19.) be the angular point. Draw the diameter AE, DF perpendicular to each other; and make the angle CAG equal to that given, or make CG equal to the tangent of the given angle; then from the centre G, with the distance GC, describe the oblique circle ABE, and it will make with the primitive an angle equal to that given.

If the given circle be a right one, let it be APB (fig. 22.) and let P be the given point. Draw the diameter GH

Fig. 22.

GH perpendicular to AB; join GP, and produce it to *a*; make H *b* equal to twice A *a*: and G *b* being joined intersects AB in C. Draw CD perpendicular to AB, and equal to the cotangent of the given angle to the radius PC; or make the angle CPD equal to the complement of that given: then from the centre D, with the radius DP, describe the great circle FPE, and the angle APF, or BPE, will be equal to that given.

Fig. 23. If APB (fig. 23.) is an oblique circle. From the angular point P, draw the lines PG, PC through the centres of the primitive and given oblique circle. Through C, the centre of APB, draw GCD at right angles to PG; make the angle GPD equal to that given; and from the centre D, with the radius DP, describe the oblique circle FPE, and the angle APF, or BPE, will be equal to that proposed.

Proposition XIX. Problem XI.

Any great circle cutting the primitive being given, to describe another great circle which shall cut the given one in a proposed angle, and have a given arch intercepted between the primitive and given circles.

Plate CCCCXLV fig. 24. If the given circle be a right one, let it be represented by APC (fig. 24.); and at right angles thereto draw the diameter BPM; make the angle BPF equal to the complement of the given angle, and PF equal to the tangent of the given arch; and from the centre of the primitive with the secant of the same arch describe the arch G*g*. Through F draw FG parallel to AC, meeting G*g* in G; then from the centre G, with the tangent PF, describe an arch *n o*, cutting APC in I, and join GI. Through G, and the centre P, draw the diameter HK; draw PL perpendicular to HK, and IL perpendicular to GI, meeting PL in L; then L will be the centre of the circle HIK, which is that required.

Fig. 25. But if the given great circle be inclined to the primitive, let it be ADB (fig. 25.), and E its centre: make the angle BDF equal to the complement of that given, and DF equal to the tangent of the given arch, as before. From P, the centre of the primitive, with the secant of the same arch, describe the arch G*g*, and from E, the centre of the oblique circle, with the extent EF, describe an arch intersecting G*g* in G. Now G being determined, the remaining part of the operation is performed as before.

When the given arch exceeds 90°, the tangent and secant of its supplement are to be applied on the line DF the contrary way, or towards the right; the former construction being reckoned to the left.

Proposition XX. Problem XII.

Any great circle in the plane of projection being given, to describe another great circle, which shall make given angles with the primitive and given circles.

Fig. 26. Let ADC (fig. 26.) be the given circle, and Q its pole. About P the pole of the primitive, describe an arch *m n*, at the distance of as many degrees as are in the angle which the required circle is to make with the primitive. About Q the pole of the circle ADC, and at a distance equal to the measure of the angle which the required circle is to make with the given circle ADC, describe an arch *o n*, cutting *m n* in *n*. Then about *n* as a pole, describe the great circle EDF, cutting the primitive and given circle in E and D, and it will be the great circle required.

Scholium.

It will hence be an easy matter to construct all the various spherical triangles. The reader is, however, referred to the article *Spherical* Trigonometry, for the method of constructing them agreeably to this projection; and also for the application to the resolution of problems of the sphere. For the method of projecting the sphere upon the plane of the meridian, and of the horizon, according to the stereographic projection, see the article Geography.

SECTION II.

Of the Orthographic Projection of the Sphere.

The orthographic projection of the sphere, is that in which the eye is placed in the axis of the plane of projection, at an infinite distance with respect to the diameter of the sphere; so that at the sphere all the visual rays are assumed parallel, and therefore perpendicular to the plane of projection.

Hence the orthographic projection of any point is where a perpendicular from that point meets the plane of projection; and the orthographic representation of any object is the figure formed by perpendiculars drawn from every point of the object to the plane of projection.

This method of projection is used in the geometrical delineation of eclipses, occultations, and transits. It is also particularly useful in various other projections, such as the analemma. See Geography, &c.

Proposition I. Theorem I.

Every straight line is projected into a straight line. If the given line be parallel to the plane of projection, it is projected into an equal straight line; but if it is inclined to the primitive, then the given straight line will be to its projection in the ratio of the radius to the cosine of inclination.

Let AB (fig. 27.) be the plane of projection, and let CD be a straight line parallel thereto: from the extremities C, D of the straight line CD, draw the lines CE, DF perpendicular to AB; then by 3. of xi. of Eucl. the intersection EF, of the plane CEFD, with the plane of projection, is a straight line: and because the straight lines CD, EF are parallel, and also CE, DF; therefore by 34. of i. of Eucl. the opposite sides are equal; hence the straight line CD, and its projection EF, are equal. Again, let GH be the proposed straight line, inclined to the primitive; then the lines GE, HF being drawn perpendicular to AB, the intercepted portion EF will be the projection of GH. Through G draw GI parallel to AB, and the angle IGH will be equal to the inclination of the given line to the plane of projection. Now GH being the radius, GI, or its equal EF, will be the cosine of IGH; hence the given line GH is to its projection EF as radius to the cosine or inclination. Fig. 27.

Corollaries.

Orthographic projection of the Sphere.

COROLLARIES.

1. A straight line perpendicular to the plane of projection is projected into a point.

2. Every straight line in a plane parallel to the primitive is projected into an equal and parallel straight line.

3. A plane angle parallel to the primitive is projected into an equal angle.

4. Any plane rectilineal figure parallel to the primitive is projected into an equal and similar figure.

5. The area of any rectilineal figure is to the area of its projection as radius to the cosine of its inclination.

PROPOSITION II. THEOREM II.

Every great circle, perpendicular to the primitive, is projected into a diameter of the primitive; and every arch of it, reckoned from the pole of the primitive, is projected into its sine.

Fig. 28. Let BFD (fig. 28.) be the primitive, and ABCD a great circle perpendicular to it, passing through its poles A, C; then the diameter BED, which is their line of common section, will be the projection of the circle ABCD. For if from any point, as G, in the circle ABC, a perpendicular GH fall upon BD, it will also be perpendicular to the plane of the primitive: therefore H is the projection of G. Hence the whole circle is projected into BD, and any arch AG into EH equal to GI its sine.

COROLLARIES.

1. Every arch of a great circle, reckoned from its intersection with the primitive, is projected into its versed sine.

2. Every less circle perpendicular to the primitive is projected into its line of common section with the primitive, which is also its own diameter: and every arch of the semicircle above the primitive, reckoned from the middle point, is projected into its sine.

3. Every diameter of the primitive is the projection of a great circle; and every chord the projection of a less circle.

4. A spherical angle at the pole of the primitive is projected into an equal angle.

PROPOSITION III. THEOREM III.

A circle parallel to the primitive is projected into a circle equal to itself, and concentric with the primitive.

Fig. 29. Let the less circle FIG (fig. 29.) be parallel to the plane of the primitive BND. The straight line HE, which joins their centres, is perpendicular to the primitive; therefore E is the projection of H. Let any radii HI and IN perpendicular to the primitive be drawn. Then IN, HE being parallel, are in the same plane; therefore IH, NE, the lines of common section of the plane IE, with two parallel planes, are parallel; and the figure IHEN is a parallelogram. Hence NE= IH, and consequently FIG is projected into an equal circle KNL, whose centre is E.

COROLLARY.

The radius of the projection is the cosine of the distance of the parallel circle from the primitive, or the sine of its distance from the pole of the primitive.

PROPOSITION IV. THEOREM IV.

An inclined circle is projected into an ellipse, whose transverse axis is the diameter of the circle.

1. Let ELF (fig. 30.) be a great circle inclined to the primitive EBF, and EF their line of common section. From the centre C, and any other point K, in EF, let the perpendicular CB, KI be drawn in the plane of the primitive, and CL, KN, in the plane of the great circle, meeting the circumference in L, N. Let LG, ND be perpendicular to CB, KI; then G, D are the projections of L, N. And because the triangles LCG, NKD are equiangular, $CL^2 : CG^2 :: NK^2 : DK^2$; or $EC^2 : CG^2 :: EKF : DK^2$: therefore the points G, D are in the curve of an ellipse, of which EF is the transverse axis, and CG the semiconjugate axis. Fig. 30.

COROLLARIES.

1. In a projected great circle, the semiconjugate axis is the cosine of the inclination of the great circle to the primitive.

2. Perpendiculars to the transverse axis intercept corresponding arches of the projection and the primitive.

3. The eccentricity of the projection is the sine of the inclination of the great circle to the primitive.

Case 2. Let AQB (fig. 31.) be a less circle, inclined to the primitive, and let the great circle LBM, perpendicular to both, intersect them in the lines AB, LM. From the centre O, and any other point N in the diameter AB, let the perpendiculars TOP, NQ, be drawn in the plane of the less circle, to meet its circumference in T, P, Q. Also from the points A, N, O, B, let AG, NI, OC, BH, be drawn perpendicular to LM; and from P, Q, T, draw PE, QD, TF, perpendicular to the primitive; then G, I, C, H, E, D, F, are the projections of these points. Because OP is perpendicular to LMB, and OC, PE, being perpendicular to the primitive, are in the same plane, the plane COPE is perpendicular to LBM. But the primitive is perpendicular to LBM; therefore the common section EC is perpendicular to LBM, and to LM. Hence CP is a parallelogram, and EC=OP. In like manner, FC, DI, are proved perpendicular to LM, and equal to OT, NQ. Thus ECF is a straight line, and equal to the diameter PT. Let QR, DK be parallel to AB, LM; then RO=NQ=DI=KC, and $PR \times RT = EK \times KF$. But AO : CG :: NO : CI; therefore $AO^2 : CG^2 :: QR^2 : DK^2$; and $EC^2 : CG^2 :: EKF : DK^2$. Fig. 31.

COROLLARIES.

1. The transverse axis is to the conjugate as radius to the cosine of the circle's inclination to the primitive.

2. Half the transverse axis is the cosine of half the sum of the greatest and least distances of the less circle from the primitive.

3. The extremities of the conjugate axis are in the line of measures, distant from the centre of the primitive by the cosines of the greatest and least distances of the less circle from the primitive.

4. If

Orthographic Projection of the Sphere.

4. If from the extremities of the conjugate axis of any elliptical projection perpendiculars be drawn (in the same direction if the circle do not intersect the primitive, but if otherwise in opposite directions), they will intersect an arch of the primitive, whose chord is equal to the diameter of the circle.

Proposition V. Theorem V.

The projected poles of an inclined circle are in its line of measures distant from the centre of the primitive the sine of the inclination of the circle to the primitive.

Fig. 32. Let ABCD (fig. 32.) be a great circle, perpendicular both to the primitive and the inclined circle, and intersecting them in the diameters AC, MN. Then ABCD passes through the poles of the inclined circle: let these be P, Q; and let P p, Q q, be perpendicular to AC; p, q are the projected poles; and it is evident that p O = sine of BP, or MA, the inclination.

Corollaries.

1. The centre of the primitive, the centre of the projection, the projected poles, and the extremities of the conjugate axis, are all in one and the same straight line.

2. The distance of the centre of projection from the centre of the primitive, is to the cosine of the distance of the circle from its own pole, as the sine of the circle's inclination to the primitive is to the radius.

Proposition VI. Problem I.

To describe the projection of a circle perpendicular to the primitive, and whose distance from its pole is equal to a given quantity.

Fig. 33. Let PA p B (fig. 33.) be the primitive circle, and P, p the poles of the right circle to be projected. Then if the circle to be projected is a great circle, draw the diameter AB at right angles to the axis P p, and it will be that required. But if the required projection is that of a less circle, make PE, PF each equal to the chord of the distance of the less circle from its pole; join EF, and it will be the projection of the less circle required.

Proposition VII. Problem II.

Through a given point in the plane of the primitive to describe the projection of a great circle, having a given inclination to the primitive.

1. When the given inclination is equal to a right angle, a straight line drawn through the centre of the primitive, and the given point, will be the projection required.

2. When the given inclination is less than a right angle, and the given point in the circumference of the primitive. Let R (fig. 34). be a point given in the circumference of the primitive, through which it is required to draw the projection of a great circle, inclined to the primitive in an angle measured by the arch QP of the primitive. Fig. 34.

Through the given point R draw the diameter RCS, and draw GC g at right angles to it. Make the arch GV of the primitive equal to QP, and draw VA at right angles to GC; and in G g towards the opposite parts of C, take CB equal to AC; then, with the greater axis RS, and less axis AB, describe an ellipse, and it will be the projection of the oblique circle required.

3. When the distance of the given point from the primitive is equal to the cosine of the given inclination.

Every thing remaining as in the preceding case; let A be the given point, and AC the cosine of an arch GV, equal to the given arch QP; then drawing the diameter RCS at right angles to ACB, the ellipse described with the given axis RS, AB will be the projection of the inclined circle.

4. When the distance of the given point from the centre of the primitive is less than the semidiameter of primitive, but greater than the cosine of the given inclination.

Let D be the given point, through which draw the diameter IC i; and at the point D draw DL perpendicular to DC meeting the primitive in L; also draw LK, making with LD the angle DLK equal to the complement of the given inclination. Let LK meet DC in K; then will DK be less than DC. On DC as a diameter describe a circle, and make DH equal to DK; through H draw a diameter of the primitive RCS, and describe an ellipse through the points R, D, S, and it will be the projection of the inclined circle. Walker on the Sphere, p. 159.

Proposition VIII. Problem III.

Through two given points in the plane of the primitive to describe the projection of a great circle.

1. If the two given points and the centre of the primitive be in the same straight line, then a diameter of the primitive being drawn through these points will be the projection of the great circle required.

2. When the two given points are not in the same straight line with the centre of the primitive; and one of them is in the circumference of the primitive.

Let DR (fig. 34.) be the two given points, of which R is in the circumference of the primitive. Draw the diameters RCS, and GC g, FDH perpendicular to it, meeting the primitive in G g F. Divide GC, g C, in A, B, in the same proportion as FH is divided in D; and describe the ellipse whose axes are RS, AB, and centre C; and it will be the projection required.

3. When the given points are within the primitive, and not in the same straight line with its centre.

Let D, E (fig. 35.) be the two given points; through C the centre of the primitive draw the straight lines ID, KE i; draw DL perpendicular to I i, and EO perpendicular to K k, meeting the primitive in L, O. Through E, and towards the same parts of C, draw EP parallel to DC, and in magnitude a fourth proportional to LD, DC, OE. Draw the diameter CP meeting the primitive in R, S, and describe an ellipse through the points D and R, or S, and it will also pass through E. This ellipse will be the projection of the proposed inclined circle. Fig. 35.

Proposition IX. Problem IV.

To describe the projection of a less circle parallel to the primitive, its distance from the pole of the primitive being given.

From

Orthographic Projection of the Sphere.

From the pole of the primitive, with the sine of the given distance of the circle from its pole, describe a circle, and it will be the projection of the given less circle.

Proposition X. Problem V.

About a given point as a projected pole to describe the projection of an inclined circle, whose distance from its pole is given.

Fig. 36. Let P (fig. 36.) be the given projected pole, through which draw the diameter G *g*, and draw the diameter H *b* perpendicular thereto. From P draw PL perpendicular to GP meeting the circumference in L; through which draw the diameter L *l*. Make LT, LK each equal to the chord of the distance of the less circle from its pole, and join TK, which intersects L *l*, in Q. From the points T, Q, K, draw the lines FA, QS, KB, perpendicular to G *g*; and make OR, OS, each equal to QT, or QK. Then an ellipse described through the points A, S, B, R will be the projection of the proposed less circle.

Proposition XI. Problem VI.

To find the poles of a given projected circle.

1. If the projected circle be parallel to the primitive, the centre of the primitive will be its pole.

2. If the circle be perpendicular to the primitive, then the extremities of a diameter of the primitive drawn at right angles to the straight line representing the projected circle, will be the poles of that circle.

3. When the projected circle is inclined to the primitive.

Fig. 37. Let ARBS (fig. 36, 37.) be the elliptical projection of any oblique circle; through the centre of which, and C the centre of the primitive, draw the line of measures CBA, meeting the ellipse in B, A, and the primitive in G, *g*. Draw CH, BK, AT perpendicular to G *g*, meeting the primitive in H, K, T. Bisect the arch KT in L, and draw LP perpendicular to G *g*; then P will be the projected pole of the circle, of which ARBS is the projection.

Proposition XII. Problem VII.

To measure any portion of a projected circle, and conversely.

1. When the given projection is that of a great circle.

Fig. 38. Let ADBE (fig. 38.) be the given great circle, either perpendicular or inclined to the primitive, of which the portion DE is to be measured, and let M *m* be the line of measures of the given circle. Through the points D, E, draw the lines EG, DF parallel to M *m*; and the arch FG of the primitive will be the measure of the arch DE of the great circle, and conversely.

2. When the projection is that of a less circle parallel to the primitive.

Plate CCCCXLVI. fig. 39. Let DE (fig. 39.) be the portion to be measured, of the less circle DEH parallel to the primitive. From the centre C draw the lines CD, CE, and produce them to meet the primitive in the points B, F. Then the intercepted portion BF of the primitive will be the measure of the given arch DE of the less circle DEH.

3. If the given less circle, of which an arch is to be measured, is perpendicular to the primitive.

Fig. 40. Let ADEB (fig. 40.) be the less circle, of which the measure of the arch DE is required. Through C, the centre of the primitive, draw the line of measures M *m*, and from the intersection O of the given right circle, and the line of measures, with the radius OA, or OB, describe the semicircle AFGB; through the points D, E, draw the lines DF, EG parallel to the line of measures, and the arch FG will be the measure of DE, to the radius AO. In order to find a similar arch in the circumference of the primitive, join OF, OG, and at the centre C of the primitive, make the angle *m* CH equal to FOG, and the arch *m* H to the radius C *m* will be the measure of the arch DE.

4. When the great projection is of a less circle inclined to the primitive.

Fig. 41. Let RDS (fig. 41.) be the projection of a less circle inclined to the primitive, and DE a portion of that circle to be measured. Through O the centre of the projected circle, and C the centre of the primitive, draw the line of measures M *m*; and from the centre O, with the radius OR, or OS, describe the semicircle RGFS; through the points D, E, draw the lines DF, EG parallel to the line of measures, and FG will be the measure of the arch DE to the radius OR, or OS. Join OF, OG, and make the angle *m* CH equal to FOG, and the arch *m* H of the primitive will be the measure of the arch DE of the inclined circle RDS.

The converse of this proposition, namely, to cut off an arch from a given projected circle equal to a given arch of the primitive, is obvious.

The above operation would be greatly shortened by using the line of signs in the sector.

It seems unnecessary to insist farther on this projection, especially as the reader will see the application of it to the projection of the sphere on the planes of the *Meridian*, *Equator*, and *Horizon*, in the article Geography; and to the delineation of *Eclipses* in the article Astronomy. The *Analemma*, Plate CCXXXV. in the article Geography, is also according to this projection; and the method of applying it to the solution of astronomical problems is there exemplified.

SECTION III.

Of the Gnomonic Projection of the Sphere.

In this projection the eye is in the centre of the sphere, and the plane of projection touches the sphere in a given point parallel to a given circle. It is named *gnomonic*, on account of its being the foundation of dialling: the plane of projection may also represent the plane of a dial, whose centre being the projected pole, the semiaxis of the sphere will be the stile or gnomon of the dial.

As the projection of great circles is represented by straight lines, and less circles parallel to the plane of projection are projected into concentric circles: therefore many problems of the sphere are very easily resolved. Other problems, however, become more intricate on account of some of the circles being projected into ellipses, parabolas, and hyperbolas.

Proposition

Gnomonic Projection of the Sphere.

Proposition I. Theorem I.

Every great circle is projected into a straight line perpendicular to the line of measures; and whose distance from the circle is equal to the cotangent of its inclination, or to the tangent of its nearest distance from the pole of the projection.

Fig. 42. Let BAD (fig. 42.) be the given circle, and let the circle CBED be perpendicular to BAD, and to the plane of projection; whose intersection CF with this last plane will be the line of measures. Now since the circle CBED is perpendicular both to the given circle BAD and to the plane of projection, the common section of the two last planes produced will therefore be perpendicular to the plane of the circle CBED produced, and consequently to the line of measures: hence the given circle will be projected into that section; that is, into a straight line passing through d, perpendicular to C d. Now C d is the cotangent of the angle C d A, the inclination of the given circle, or the tangent of the arch CD to the radius AC.

Corollaries.

1. A great circle perpendicular to the plane of projection is projected into a straight line passing through the centre of projection: and any arch is projected into its correspondent tangent.

2. Any point, as D, or the pole of any circle, is projected into a point d, whose distance from the pole of projection is equal to the tangent of that distance.

3. If two great circles be perpendicular to each other, and one of them passes through the pole of projection, they will be projected into two straight lines perpendicular to each other.

4. Hence if a great circle be perpendicular to several other great circles, and its representation pass through the centre of projection; then all these circles will be represented by lines parallel to one another, and perpendicular to the line of measures, for representation of that first circle.

Proposition II. Theorem II.

If two great circles intersect in the pole of projection, their representations will make an angle at the centre of the plane of projection, equal to the angle made by these circles on the sphere.

For since both these circles are perpendicular to the plane of projection, the angle made by their intersections with this plane is the same as the angle made by these circles.

Proposition III. Theorem III.

Any less circle parallel to the plane of projection is projected into a circle whose centre is the pole of projection, and its radius is equal to the tangent of the distance of the circle from the pole of projection.

Let the circle PI (fig. 42.) be parallel to the plane GF, then the equal arches PC, CI are projected into the equal tangents GC, CH; and therefore C the point of contact and pole of the circle PI and of the projection, is the centre of the representation G, H.

Corollary.

If a circle be parallel to the plane of projection, and 45 degrees from the pole, it is projected into a circle equal to a great circle of the sphere; and therefore may be considered as the primitive circle, and its radius the radius of projection.

Proposition IV. Theorem IV.

A less circle not parallel to the plane of projection is projected into a conic section, whose transverse axis is in the line of measures; and the distance of its nearest vertex from the centre of the plane of projection is equal to the tangent of its nearest distance from the pole of projection; and the distance of the other vertex is equal to the tangent of the greatest distance.

Any less circle is the base of a cone whose vertex is at A (fig. 43.); and this cone being produced, its intersection with the plane of projection will be a conic section. Thus the cone DAF, having the circle DF for its base, being produced, will be cut by the plane of projection in an ellipse whose transverse diameter is df; and C d is the tangent of the angle CAD, and Cf the tangent of CAF. In like manner, the cone AFE, having the side AE parallel to the line of measures df; being cut by the plane of projection, the section will be a parabola, of which f is the nearest vertex, and the point into which E is projected is at an infinite distance. Also the cone AFG, whose base is the circle FG, being cut by the plane of projection, the section will be a hyperbola; of which f is the nearest vertex; and GA being produced gives d the other vertex. Fig. 43.

Corollaries.

1. A less circle will be projected into an ellipse, a parabola or hyperbola, according as the distance of its most remote point is less, equal to, or greater than, 90 degrees.

2. If H be the centre, and K k, l the focus of the ellipse, hyperbola, or parabola; then $HK=\frac{A\,d-Af}{2}$ for the ellipse; $H\,k=\frac{A\,d+Af}{2}$ for the hyperbola; and $f\,n$ being drawn perpendicular to AE $f\,l=\frac{n\,E+F\,f}{2}$ for the parabola.

Proposition V. Theorem V.

Let the plane TW (fig. 44.) be perpendicular to the plane of projection TV, and BCD a great circle of the sphere in the plane TW. Let the great circle BED be projected into the straight line $b\,e\,k$. Draw CQS perpendicular to $b\,k$, and C m parallel to it and equal to CA, and make QS equal to Q m; then any angle QS t is the measure of the arch Q t of the projected circle. Fig. 44.

Join AQ: then because C m is equal to C A, the angle QC m equal to QCA, each being a right angle, and the side QC common to both triangles; therefore Q m, or its equal QS, is equal QA. Again, since the plane ACQ is perpendicular to the plane TV, and b Q to

Gnomonic Projection of the Sphere

to the intersection CQ; therefore b Q is perpendicular both to AQ and QS: hence, since AQ and QS are equal, all the angles at S cut the line b Q in the same points as the equal angles at A. But by the angles at A the circle BED is projected into the line b Q. Therefore the angles at S are the measures of the parts of the projected circle b Q; and S is the dividing centre thereof.

Corollaries.

1. Any great circle b Q t is projected into a line of tangents to the radius SQ.

2. If the circle b C pass through the centre of projection, then the projecting point A is the dividing centre thereof, and C b is the tangent of its correspondent arch CB to CA the radius of projection.

Proposition VI. Theorem VI.

Fig. 44. Let the parallel circle GLH (fig. 44.) be as far from the pole of projection C as the circle FNI is from its pole; and let the distance of the poles C, P be bisected by the radius AO: and draw b AD perpendicular to AO; then any straight line b Q t drawn through b will cut off the arches h l, F n equal to each other in the representations of these equal circles in the plane of projection.

Let the projections of the less circles be described. Then, because BD is perpendicular to AO, the arches BO, DO are equal; but since the less circles are equally distant each from its respective pole, therefore the arches FO, OH are equal; and hence the arch BF is equal to the arch DH. For the same reason the arches BN, DL are equal; and the angle FBN is equal to the angle LDH; therefore, on the sphere, the arches FN, HL are equal. And since the great circle BNLD is projected into the straight line b Q n l, &c. therefore n is the projection of N, and l that of L; hence f n, h l, the projections of FN, HL respectively, are equal.

Proposition VII. Theorem VII.

Fig. 45. If F n k, h l g, (fig. 45.) be the projections of two equal circles, whereof one is as far from its pole P as the other from its pole C, which is the centre of projection; and if the distance of the projected poles C, p be divided in o, so that the degrees in C o, o p be equal, and the perpendicular o S be erected to the line of measures g h. Then the line p n, C l drawn from the poles C, p, through any point Q in the line o S, will cut off the arches F n, h l equal to each other, and to the angle Q C p.

The great circle A o perpendicular to the plane of the primitive is projected into the straight line o S perpendicular to g h, by Prop. i. cor. 3. Let Q be the projection of q; and since p Q, CQ are straight lines, they are therefore the representations of the arches P q, C q of great circles. Now since P q C is an isosceles spherical triangle, the angles PCQ, CPQ are therefore equal; and hence the arches P q, C q produced will cut off equal arches from the given circles FI, GH, whose representations F n, h l are therefore equal: and since the angle QC p is the measure of the arch h l, it is also the measure of its equal F n.

Corollary.

Hence, if from the projected pole of any circle a perpendicular be erected to the line of measures, it will cut off a quadrant from the representation of that circle.

Proposition VIII. Theorem VIII.

Let F n k (fig. 45.) be the projection of any circle FI, and p the projection of its pole P. If C g be the cotangent of CAP, and g B perpendicular to the line of measures g C, let CAP be bisected by A o, and the line o B drawn to any point B, and also p B cutting F n k in d; then the angle g o B is the measure of the arch F d. Fig. 45.

The arch PG is a quadrant, and the angle g o A= P A+o A P=g A C+o A P=g A C+C A o=g A o; therefore g A=g o; consequently o is the dividing centre of g B, the representation of GA; and hence, by Prop. v. the angle g o B is the measure of g B. But since p g represents a quadrant, therefore p is the pole of g B; and hence the great circle p d B passing through the pole of the circles g B and F n will cut off equal arches in both, that is F d=g B=angle g o B.

Corollary.

The angle g o B is the measure of the angle g p B. For the triangle g p B represents a triangle on the sphere, wherein the arch which g B represents is equal to the angle which the angle p represents; because g p is a quadrant; therefore g o B is the measure of both.

Proposition IX. Theorem I.

To draw a great circle through a given point, and whose distance from the pole of projection is equal to a given quantity.

Let ADB (fig. 46.) be the projection, C its pole or centre, and P the point through which a great circle is to be drawn: through the points P, C draw the straight line PCA, and draw CE perpendicular to it: make the angle CAE equal to the given distance of the circle from the pole of projection C; and from the centre C, with the radius CE, describe the circle EFG: through P draw the straight line PIK, touching the circle EFG in I, and it will be the projection of the great circle required. Fig. 46.

Proposition X. Problem II.

To draw a great circle perpendicular to a great circle which passes through the pole of projection, and at a given distance from that pole.

Let ADB (fig. 46.) be the primitive, and CI the given circle: draw CL perpendicular to CI, and make the angle CLI equal to the given distance: then the straight line KP, drawn through I parallel to CL, will be the required projection.

Proposition XI. Problem III.

At a given point in a projected great circle, to draw another great circle to make a given angle with the former; and, conversely, to measure the angle contained between two great circles.

Let P (fig. 47.) be the given point in the given great circle Fig. 47.

Gnomonic Projection of the Sphere.

circle PB, and C the centre of the primitive: through the points P, C draw the straight line PCG; and draw the radius of the primitive CA perpendicular thereto; join PA; to which draw AG perpendicular: through G draw BGD at right angles to GP, meeting PB in B; bisect the angle CAP by the straight line AO; join BO, and make the angle BOD equal to that given; then DP being joined, the angle BPD will be that required.

If the measure of the angle BPD be required, from the points B, D draw the lines BO, DO, and the angle BOD is the measure of BPD.

Proposition XII. Problem IV.

To describe the projection of a less circle parallel to the plane of projection, and at a given distance from its pole.

Fig. 46. Let ADB (fig. 46.) be the primitive, and C its centre: set the distance of the circle from its pole, from B to H, and from H to D; and draw the straight line AED, intersecting CE perpendicular to BC, in the point E: with the radius CR describe the circle EFG, and it is the projection required.

Proposition XIII. Problem V.

To draw a less circle perpendicular to the plane of projection.

Plate CCCCXLVII. fig. 48. Let C (fig. 48.) be the centre of projection, and TI a great circle parallel to the proposed less circle: at C make the angles ICN, TCO each equal to the distance of the less circle from its parallel great circle TI; let CL be the radius of projection, and from the extremity L draw LM perpendicular thereto; make CV equal to LM; or GF equal to CM: then with the vertex V and assymptotes CN, CO describe the hyperbola WVK *; or, with the focus F and CV describe the hyperbola, and it will be the perpendicular circle described.

* See *Conic Sections.*

Proposition XIV. Problem VI.

To describe the projection of a less circle inclined to the plane of projection.

Fig. 49. Draw the line of measures *dp* (fig. 49.); and at C, the centre of projection, draw CA perpendicular to *d p*, and equal to the radius of projection: with the centre A, and radius AC, describe the circle DCFG; and draw RAE parallel to *d p*: then take the greatest and least distances of the circle from the pole of projection, and set them from C to D and F respectively, for the circle DF; and from A, the projecting point, draw the straight lines AF*f*, and AD*d*; then *d f* will be the transverse axis of the ellipse; but if D fall beyond the line RE, as at G, then from G draw the line GAD*d*, and *d f* is the transverse axis of an hyperbola: and if the point D fall in the line RE, as at E, then the line AE will not meet the line of measures, and the circle will be projected into a parabola whose vertex is *f*: bisect *d f* in H, the centre, and for the ellipse take half the difference of the lines A*d*, A*f*, which laid from H will give K the focus: for the hyperbola, half the sum of A*d*, A*f* being laid from H, will give *k* its focus: then with the transverse axis *d f*, and focus K, or *k*, describe the ellipse *d* M *f*, or hyperbola *f m*, which will be the projection of the inclined circle: for the parabola, make EQ equal to F*f*, and draw *f n* perpendicular to AQ, and make *f k* equal to one half of *n* Q: then with the vertex *f*, and focus *k*, describe the parabola *f m*, for the projection of the given circle FE.

Proposition XV. Problem VII.

To find the pole of a given projected circle.

Let DMF (fig. 50.) be the given projected circle whose line of measures is DF, and C the centre of projection; from C draw the radius of projection CA, perpendicular to the line of measures, and A will be the projecting point: join AD, AF, and bisect the angle DAF by the straight line AP; hence P is the pole. If the given projection be an hyperbola, the angle *f* AG (fig. 49.), bisected, will give its pole in the line of measures; and in a parabola, the angle *f* AE bisected will give its pole. Fig. 50.

Proposition XVI. Problem VIII.

To measure any portion of a projected great circle, or to lay off any number of degrees thereon.

Let EP (fig. 51.) be the great circle, and IP a portion thereof to be measured: draw ICD perpendicular to IP; let C be the centre, and CB the radius of projection, with which describe the circle EBD; make IA equal to IB; then A is the dividing centre of EP; hence AP being joined, the angle IAP is the measure of the arch IP. Fig. 51.

Or, if IAP be made equal to any given angle, then IP is the correspondent arch of the projection.

Proposition XVII. Problem IX.

To measure any arch of a projected less circle, or to lay off any number of degrees on a given projected less circle.

Let F *n* (fig. 52.) be the given less circle, and P its pole: from the centre of projection C draw CA perpendicular to the line of measures GH, and equal to the radius of projection; join AP, and bisect the angle CAP by the straight line AO, to which draw AD perpendicular: describe the circle G *l* H, as far distant from the pole of projection C as the given circle is from its pole P; and through any given point *n*, in the projected circle F *n*, draw D *n l*, then H *l* is the measure of the arch F *n*. Fig. 52.

Or let the measure be laid from H to *l*, and the line D *l* joined will cut off F *n* equal thereto.

Proposition XVIII. Problem X.

To describe the gnomonic projection of a spherical triangle, when three sides are given; and to find the measures of either of its angles.

Let ABC (fig. 53.) be a spherical triangle whose three sides are given: draw the radius CD (fig. 54.) perpendicular to the diameter of the primitive EF; and at the point D make the angles CDA, CDG, ADI, equal respectively to the sides AC, BC, AB, of the spherical triangle ABC (fig. 53.), the lines DA, DG intersecting the diameter EF, produced if necessary in the points A and G: make DI equal to DG; then from the centre C, with the radius CG, describe an arch; and from A, with the distance AI, describe another arch, intersecting the former in B; join AB, CB, and ACB will be the projection of the spherical triangle (fig. 53.); and the rectilineal angle ACB is the measure of the spherical angle ACB (fig. 53.). Fig. 53. Fig. 54.

Proposition

Gnomonic Projection of the Sphere.

PROPOSITION XIX. PROBLEM XI.

The three angles of a spherical triangle being given, to project it, and to find the measures of the sides.

Fig. 55. Let ABC (fig. 55.) be the spherical triangle of which the angles are given: construct another spherical triangle EFG, whose sides are the supplements of the given angles of the triangle ABC; and with the sides of this supplemental triangle describe the gnomonic projection, &c. as before.

It may be observed, that the supplemental triangle EFG has also a supplemental part EF g; and when the sides GE, GF, which are substituted in place of the angles A, B, are obtuse, their supplements g E, g F are to be used in the gnomonic projection of the triangle.

PROPOSITION XX. PROBLEM XII.

Given two sides, and the included angle of a spherical triangle, to describe the gnomonic projection of that triangle, and to find the measures of the other parts.

Fig 56. Let the sides AC, CB, and the angle ACB (fig. 53.), be given; make the angles CDA, CDG (fig. 56.) equal respectively to the sides AC, CB (fig. 53.); also make the angle ACB (fig. 56.) equal to the spherical angle ACB (fig. 53.), and CB equal to CG, and ABC will be the projection of the spherical triangle.

To find the measure of the side AB: from C draw CL perpendicular to AB, and CM parallel thereto, meeting the circumference of the primitive in M; make LN equal to LM; join AN, BN, and the angle ANB will be the measure of the side AB.

To find the measure of either of the spherical angles, as BAC: from D draw DK perpendicular to AD, and make KH equal to KD: from K draw KI perpendicular to CK, and let AB produced meet KI in I, and join HI: then the rectilineal angle KHI is the measure of the spherical angle BAC. By proceeding in a similar manner, the measure of the other angle will be found.

PROPOSITION XXI. PROBLEM XIII.

Two angles and the intermediate side given, to describe the gnomonic projection of the triangle; and to find the measures of the remaining parts.

Let the angles CAB, ACB, and the side AC of the spherical triangle ABC (fig. 53.), be given: make the angle CDA (fig. 56.) equal to the measure of the given side AC (fig. 53.); and the angle ACB (fig. 56.) equal to the angle ACB (fig. 53.); produce AC to H, draw DK perpendicular to AD, and make KH equal to KD; draw KI perpendicular to CK, and make the angle KHI equal to the spherical angle CAB: from I, the intersection of KI, HI, to A draw IA, and let it intersect CB in B, and ACB will be the gnomonic projection of the spherical triangle ACB (fig. 53.). The unknown parts of this triangle may be measured by last problem.

PROPOSITION XXII. PROBLEM XIV.

Two sides of a spherical triangle, and an angle opposite to one of them given, to describe the projection of the triangle; and to find the measure of the remaining parts.

Let the sides AC, CB, and the angle BAC of the spherical triangle ABC (fig. 53.) be given: make the angles CDA, CDG (fig. 56.) equal respectively to the measures of the given sides AC, BC: draw DK perpendicular to AD, make KH equal to DK, and the angle KHI equal to the given spherical angle BAC: draw the perpendicular KI, meeting HI in I; join AI; and from the centre C, with the distance CG, describe the arch GB, meeting AI in B; join CB, and ABC will be the rectilineal projection of the spherical triangle ABC (fig. 53.) and the measures of the unknown parts of the triangle may be found as before.

PROPOSITION XXIII. PROBLEM XV.

Given two angles, and a side opposite to one of them, to describe the gnomonic projection of the triangle, and to find the measures of the other parts.

Let the angles A, B, and the side BC of the triangle ABC (fig. 55.) be given: let the supplemental triangle EFE be formed, in which the angles E, F, G, are the supplements of the sides BC, CA, AB, respectively, and the sides EF, FG, GE, the supplements of the angles C, A, B. Now at the centre C (fig. 56.) make the angles CDA, CDK equal to the measures of the sides GE, GF respestively, being the supplements of the angles B and A; and let the lines DA, DK intersect the diameter of the primitive EF in the points A and K: draw DG perpendicular to AD, make GH equal to DG, and at the point H make the angle GHI equal to the angle E, or to its supplement; and let EI, perpendicular to CH, meet HI in I, and join AI: then from the centre C, with the distance CG, describe an arch intersecting AI in B; join CB, and ABC will be the gnomonic projection of the given triangle ABC (fig. 55.): the supplement of the angle ACB (fig. 56.) is the measure of the side AB, (fig. 55.); the measures of the other parts are found as before.

It has already been observed, that this method of projection has, for the most part, been applied to dialling only. However, from the preceding propositions, it appears that all the common problems of the sphere may be more easily resolved by this than by either of the preceding methods of projection; and the facility with which these problems are resolved by this method has given it the preference in dialling. It may not perhaps be amiss in this place, to give a brief illustration of it in this particular branch of science.

In an horizontal dial, the centre of projection Z (fig. 57.) represents the zenith of the place for which Fig. 57. the dial is to be constructed; ZA the perpendicular height of the style: the angle ZPA, equal to the given latitude, determines the distance ZP of the zenith from the pole; and AP the edge of the style, which by its shadow gives the hour: the angle ZAP, equal also to the latitude, gives the distance of the equator EQ from the zenith: let E a be equal to EA, and a will be the dividing point of the equator. Hence if the angles E a I, E a II, &c. E a XI, E a X, &c. be made equal to 15°, 30°, &c. the equator will be divided into hours; and

Gnomonic Projection of the Sphere.

and lines drawn from P to these points of division will be hour lines.

If the dial is either vertical, or inclined to the horizon, then the point Z will be the zenith of that place whose horizon is parallel to the plane of the dial: ZE will be that latitude of the place; and the hours on the former dial will now be changed into others, by a quantity equal to the difference of longitude between the given place and that for which the dial is to be constructed. Thus, if it is noon when the shadow of the style falls on the line *PX*, then the difference of meridians is the angle E *a* X, or 30°. Hence, when a dial is to be constructed upon a given plane, either perpendicular or inclined to the horizon, the declination and inclination of that place must be previously found.

In an erect direct south dial, its zenith Z is the south point of the horizon, ZP is the distance of this point from the pole, and ZE its distance from the equator. If the dial is directed to the north, Z represents the north point of the horizon; PZ the distance of Z from the pole under the horizon; and ZE the elevation of the equator above the horizon.

If the dial is an erect east or west dial, the zenith Z is the east or west points of the horizon, accordingly, and the pole P is at an infinite distance, for the angle ZAP is a right angle; and therefore the line AP will not meet the meridian PZ. The line ZA produced is the equator, and is divided into hours by lines perpendicular to it.

If the plane of the dial is parallel to the equator, its zenith Z coincides with one of the poles of the equator P; and hence the hour lines of this dial are formed by drawing lines from the point Z, containing angles equal to 15°.

In the preceding methods of projection of the sphere, equal portions of a great circle on the sphere are represented by unequal portions in the plane of projection, and this inequality increases with the distance from the centre of projection. Hence, in projections of the earth, those places towards the circumference of the projection are very much distorted. In order to avoid this inconveniency, M. de la Hire* proposed, that the eye should be placed in the axis produced at the distance of the sine of 45° beyond the pole: In this case arches of the sphere and their projections are very nearly proportional to each other. Hence in a map of the earth agreeable to this construction, the axis, instead of being divided into a line of semitangents, is divided equally, in like manner as the circumference. The map of the world is constructed agreeable to this method of projection.

* Hist. de l'Academie Royal des Scien. 1701. See the article Geography.

P R O

Projection || Prolate.

PROJECTION, in *Perspective*, denotes the appearance, or representation of an object on the perspective plane.

The projection of a point is a point through which an optic ray passes from the objective point through the plane to the eye; or it is the point wherein the plane cuts the optic ray.

And hence may be easily conceived what is meant by the projection of a line, a plane, or a solid.

Projection, in *Alchemy*, the casting of a certain imaginary powder, called *powder of projection*, into a crucible, or other vessel, full of some prepared metal, or other matter; which is to be hereby presently transmuted into gold.

Powder of Projection, or of the philosophers stone, is a powder supposed to have the virtue of changing any quantity of an imperfect metal, as copper or lead, into a more perfect one, as silver or gold, by the admixture of a little quantity thereof.

The mark to which alchemists directed all their endeavours, was to discover this powder of projection. See *Philosophers Stone*, and Chemistry, *History of*.

PROJECTURE, in *Architecture*, the outjetting and prominency, or embossing, which the mouldings and other members have beyond the naked wall, column, &c.

PROLAPSUS, in *Surgery*, a prolapsion or falling out of any part of the body from its natural situation: thus we say, *prolapsus intestini*, "a prolapsion of the intestine," &c. See Surgery.

PROLATE, in *Geometry*, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its larger diameter. See Spheroid.

Prolegomena | Prolific.

PROLEGOMENA, in *Philology*, certain preparatory observations or discourses prefixed to a book, &c. containing something necessary for the reader to be apprised of, to enable him the better to understand the book, or to enter deeper into the science, &c.

PROLEPSIS, a figure in *Rhetoric*, by which we anticipate or prevent what might be objected by the adversary. See Oratory, N° 80.

PROLEPTIC, an epithet applied to a periodical disease which anticipates, or whose paroxysm returns sooner and sooner every time; as is frequently the case in agues.

PROLIFER flos, (*proles*, "an offspring;" and *fero*, "to bear);" a prolific flower, or a flower which from its own substance produces another; a singular degree of luxuriance, to which full flowers are chiefly incident. See Botany.

PROLIFIC, something that has the qualities necessary for generating.

The prolific powers of some individuals among mankind are very extraordinary.—Instances have been found where children, to the number of six, seven, eight, nine, and sometimes sixteen, have been brought forth after one pregnancy. The wife of Emmanuel Gago, a labourer near Valladolid, was delivered, the 14th of June 1779, of five girls, the two first of whom were baptized: the other three were born in an hour after; two of them were baptized; but the last, when it came into the world, had every appearance of death. The celebrated Tarsin was brought to bed in the seventh month of her pregnancy, at Argenteuil near Paris, 17th July 1779, of three boys, each 14 inches and a half long, and of a girl 13 inches: they were all four baptized, but did not live 24 hours.

W. Archibald Sculp.

The public papers for the month of June 1779, made mention of one Maria Ruiz, of the district of Lucena in Andalusia, who was successively delivered of 16 boys, without any girls; and seven of them were still alive on the 17th of August thereafter. The following, though a recent fact, is almost incredible: In the year 1755, a Muscovite peasant, named *James Kyrloff*, and his wife, were presented to the empress of Russia. This peasant had been twice married, and was then 70 years of age. His first wife was brought to bed 21 times; namely, four times of four children each time; seven times of three, and ten times of two; making in all 57 children, who were then alive. His second wife, who accompanied him, had already been delivered seven times, once of three children, and six times of twins, which made 15 children for her share. Thus the Muscovite patriarch had already had 72 children by two marriages. We are assured that the sultan Mustapha III. had issue by his concubines 580 male children. What number of female children he had, and whether there were twins of both sexes, we are not informed. These facts suppose great fecundity; and whatever credit is given them, we must consider as entirely fabulous what is reported concerning a countess of Holland, who was delivered of 365 children, of a very small size.

PROLIXITY in discourse, the fault of entering into too minute a detail, or being too long, precise, and circumstantial, even to a degree of tediousness.

PROLOCUTOR of the convocation, the speaker or chairman of that assembly. See CONVOCATION.

PROLOGUE, in dramatic poetry, a discourse addressed to the audience before the drama or play begins. The original intention was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action, and sometimes to make an apology for the poet.

PROMETHEUS, the son of Japetus, supposed to have been the first discoverer of the art of striking fire by flint and steel; which gave rise to the fable of his stealing fire from heaven: A renowned warrior; but whose history is involved in fable. He flourished about 1687 B. C. The poetical account is, that he formed a man of clay of such exquisite workmanship, that Pallas, charmed with his ingenuity, offered him whatever in heaven could contribute to finish his design; and for this purpose took him up with her to the celestial mansions, where he stole some fire from the chariot of the sun, which he used to animate his image. At this theft Jupiter was so enraged, that he ordered Vulcan to chain him down on Mount Caucasus, and sent an eagle or vulture to prey on his liver; which every night was renewed in proportion to the quantity eaten up in the daytime, until at last he was delivered by Hercules, who killed the vulture.

PROMETHEUS, in *Ancient Astronomy*, was the name of a constellation of the northern hemisphere, now called *Hercules Eugonasin*. See ASTRONOMY.

1 Promise defined.

PROMISE, in ordinary cases, is a declaration of some intention to be put in execution; but in morals is a solemn asseveration by which one pledges his veracity that he shall perform, or cause to be performed, the thing which he mentions.

As such a declaration excites expectations in the minds of those to whom it is made; and as to frustrate these expectations might rouse indignation, and be followed by consequences injurious to the person, the character, or interest, of him who made it—it becomes a matter of prudence in the promiser to keep his word. And farther, as a certain degree of confidence is found necessary to the very existence of civil society, and as others may have acted on the faith of his promise, it is now not a matter of prudence only to keep his word—it is a duty which he owes to all who have spent their time, their money, or their labour, in consequence of those expectations which he has warranted them to entertain.

2 How it comes to be binding.

It, then, being consonant to sound reason, necessary to the existence of civil society, and in general the interest of both the promiser and promisee, that the words of the promise should be fulfilled, it has become a maxim in morals that a man is obliged to perform his promise.

3 Interpretation of a promise sometimes difficult.

In many instances, the great difficulty concerning a promise is, how to explain it; for although the grounds of its obligation be those expectations which it has raised, a question will occur, Is the promiser bound to answer fully all the expectations to which the different constructions of his words may have given birth? Should I, for instance, desire a man to run with a letter to such a place, and engage to satisfy him upon his return; and if on his return I gave him double of the usual hire in like cases; but if he be not satisfied with less than the triple of such a sum, am I obliged to grant his demands? This will lead us to consider the rules by which a promise should be interpreted.

4 Whether the meaning of the promiser or promisee ought to be taken.

If a promise were always to be deemed obligatory in the sense in which the promisee receives it, a man would not know what he had promised; the promisee, from a difference of views, associations, and interests, might conceive a sense of which the promiser had never dreamed; might suppose engagements which were never intended, which could not be foreseen, and, although foreseen, could not be performed. For these reasons it is natural to think that the sense of the promiser should rather direct the interpretation. He knows precisely what it is he has undertaken, and is unquestionably the best judge of what meaning he affixed to his words. His explanation should therefore be admitted, if information alone could give him a title to decide in the affair.

But something more than mere information, or a knowledge of the cause, is expected from a judge, as integrity is equally essential to his character. Doubts may arise when the words will admit of various meanings, whether the promiser will be so candid as impartially to own the precise meaning which he had actually annexed to his expressions: At any rate, if he wishes to deceive, he might purposely use an ambiguous phraseology, and perform the promise in a sense of his own, without satisfying the reasonable hopes of the promisee.

When the daughter of Tarpeius bargained with Tatius to betray the citadel for what he and his Sabines wore on their left hands, meaning their rings and their golden bracelets, Tatius probably performed his promise in the way which he intended, when he caused her to be buried under their shields, which they carried also on their left hands. But who will say that here were not treachery and a dishonourable abuse of that confidence which had been reposed in him?

It

Promise.

5 In doubtful cases the interpretation of neither is to be trusted.

It must therefore be obvious, that the import of a promise, where its meaning is disputed, is not to be determined by the sense of the promiser nor by the expectations of the promisee; and if it was said that the obligation of a promise arose from those expectations which had been raised by it, the assertion now must be limited to those expectations which were intentionally raised by the promiser, or those which to his knowledge the promisee was induced to entertain in consequence of that declaration which had been made to him. Should there still be a doubt about what expectations were intentionally raised, and what should have been reasonably entertained, recourse must be had to the judgment of those who are allowed to be persons of candour, and who are acquainted with the characters of the men, and with those circumstances in which the promise was made.

6 Cases where a promise is not binding.

The following are some of the cases in which a promise is not binding. As the obligation to perform the promise arises from those expectations which are intentionally raised by the promiser; it is plain that no promise can be binding before acceptance, before the promise has been communicated to the promisee, and before he has entertained hopes of its performance. The case is similar where a promise is released, that is, where the performance is dispensed with by the promisee, and where he entertains no expectations on account of any

7 When it is released by the promisee.

thing than the promiser has said to him. Should a third person entertain hopes on account of the promise, he is to cherish these hopes at his own hazard, having no encouragement from the promiser to do so: yet if this person has been warranted to hope by the promisee, the promisee has renounced his privilege of releasing the promise, and along with the promiser becomes bound for its performance.

8 Where its performance is unlawful.

A promise is not binding where the performance is unlawful; and the performance is unlawful where it is contrary to former promises, or to any moral and religious precept, which from the beginning to the end of time is of perpetual and unalterable obligation. Thus no man is bound by his promise to give to me what he has already promised to another; and no man is bound by his promise to blaspheme God, to commit murder, or to criminate the innocent. Such promises are unlawfully made, and cannot be otherwise than unlawfully performed.

9 A case where doubts have arisen.

Some have even carried their scruples so far as to doubt, whether any promise unlawfully made, can be lawfully performed. Should a man, during the lifetime of his wife, happen to promise marriage to another, such a man (they say) by the Christian religion has already committed adultery in his heart: and should he afterwards become a widower, he is not bound, and he even ought not, to fulfil his engagements, as this would be putting his criminal intention into execution. This species of reasoning, we must confess, is to us unintelligible.—As the wife is dead, what now should prevent the man from marrying the object of his affections? Why, say the casuists, he already is under a promise to marry her, and his promise was made at a time when it should not have been made. It is true, the performance, considered by itself, is opposed by no law human or divine; but then it originated in what was wrong; and however much the Supreme Being and the bulk of the creation may be out of the secret, we have discovered by the ingenious logic of casuistry, that evil can never spring out of good, nor good out of evil; but that the means and the end, the motive and the action, are always of the same complexion in morals.

10 Erroneous promises.

When a promise is made, the particular circumstances in which it is to be deemed obligatory are sometimes mentioned. "I promise (for instance) to lend my friend 200 pounds within three days, provided a certain creditor which I name do not make a demand on me before that time. In other cases no circumstance is foreseen by the promiser to prevent the fulfilling of his engagement; and hence we have erroneous promises, which proceed on the supposition that things are true, possible, and lawful, which are not so. An erroneous promise, which proceeds on the false representation of the promisee, is not binding.

A London gentleman lately purchased an estate in the south of England at a public sale, believing the description which he saw in the newspapers, and which likewise was given by the auctioneer, to be true; but finding afterwards that the estate nowise corresponded to the description, the law freed him from his engagement, because the seller had evidently been guilty of a breach of promise in not satisfying those expectations which he had intentionally and even studiously excited in the buyers.

11 A promise not binding when the performance is impossible.

An erroneous promise, whose performance is impossible, is not binding. Before the conclusion of the late war, a planter of Tobago, promised to send to his friend in England 12 hogsheads of sugar from the next year's produce of his estate; but before that time Tobago fell into the hands of the French, and the West Indian found it impossible to answer the expectations of his friend in England.

12 nor when it is unlawful.

An erroneous promise, whose performance is unlawful, or, to speak more precisely, whose performance is contrary to a prior promise, or to any moral or religious obligation, is not binding. A father, believing the accounts from abroad of his son's death, soon after bequeathes his fortune to his nephew: but the son, the report of whose death had been false, returns home, and the father is released from the promise to his nephew, because it was contrary to a prior promise, which he had tacitly come under to his son. This prior promise was implied in the whole of the father's conduct, and was expressed in signs as emphatic and as unequivocal as those of language. It had all the effect too of the most solemn promise on the son, who, to his father's knowledge, was induced in consequence of this promise to entertain the most sanguine hopes of succeeding to his father, if he survived. The world likewise could bear testimony that these expectations were not rashly cherished. He was brought into existence by means of his father, who was thereby understood to love him affectionately; he was ushered into society as the representative of his family, and was therefore supposed to be the heir of its wealth. Religion itself supported his pretensions, pronouncing the father worse than an infidel who neglects to show that attention to his children which the world naturally expects from a parent.—That the father's promise was not released from the mere circumstance that the mistake was known to his nephew the promisee, will appear plain from the following circumstance. Suppose the father a landed proprietor, that the lease of one of his farms has expired, and that he has long been expecting

Promise.

to let it at 200l.; suppose that this sum is refused, and that he agrees with the present tenant to grant a new lease at 150l.—the obligation here to perform his promise is not dissolved by an after offer of 200l. though the tenant knew that 200l. had been expected, and that only from despairing of that sum his landlord had granted the new lease at 150l.: the promise is binding, because the performance is every way lawful, contrary to no prior engagement, and opposed to no principle in morals. The law of the land, were the proprietor reluctant, would enfore the obligation, and exact obedience in the tone of authority; because breaches of faith, were they permitted in such cases, would destroy all confidence, and annihilate the bonds of social union:

> Men live and prosper but in mutual trust;
> A confidence of one another's truth. *Oroonoko.*

13
Utility no criterion whereby to judge of the validity of promises.

The great difficulty which many have to encounter in determining when errroneous promises ought or ought not to be kept, arises from their proceeding on a principle of whose consequences they do not seem to be always aware. There is seldom, they perceive, a virtuous action that is not attended with some happy effects; and it will, perhaps, be generally allowed, that the comparative merit of similar virtues may safely be estimated by their utility: But to make utility, as some do, the criterion of virtue, and pronounce an action vicious or virtuous merely on account of those consequences which they see may flow from it, is a dangerous maxim. Evil has often sprung out of good, and good out of evil; and good and evil have frequently sprung from the same action. In Mandeville's *Hive*,

14
This principle would give a sanction to vice and falsehood.

> That root of evil Avarice,
> That damn'd ill-natur'd baneful vice,
> Was slave to Prodigality,
> That noble sin; whilst Luxury
> Employ'd a million of the poor,
> And odious Pride a million more.
> Envy itself and Vanity
> Were ministers of Industry:
> That darling folly, Fickleness,
> In diet, furniture, and dress,
> That strange ridiculous vice, was made
> The very wheel that turn'd the trade.

The description here is not altogether false; and these indeed may be some of the consequences that flow from avarice, luxury, pride, vanity, and envy: but these are not all.—To see at once all the consequences that spring from an action, the good and the bad, the particular and general, the immediate and remote, would require sometimes the foresight of Omniscience, and at all times a knowledge superior to what is human. In the Fable of the Bees, the author's object was to show that private vices are public benefits; and he therefore was naturally led by his argument to consider only such consequences of vice as favoured his hypothesis. He wanted candour. And that artifice which runs through his Fable happens to remind us, that while the remote and the general effects of an action may not be seen, the particular and immediate, which fall within our notice, are apt to be viewed through the medium of passion, interest, or opinion. For these reasons, it appears surprising how any person should ever imagine that the obligation to perform a promise should depend entirely upon the ideas which the promiser apprehended of its utility.

The best refutation of such an opinion are the singular conclusions to which it leads.

15
The consequences that flow from it ridiculous and absurd.

A late writer on political justice, who appears to have embraced it, gets into reasoning not very common. In a part of his system he looks on morals as an article of trade: virtue and vice, in his Chapter of *Promises*, are but antiquated terms for profit and loss; and right and wrong are used to express what is beneficial and what is hurtful, in his apprehension, to himself and the community.—With respect to veracity, those "rational and intelligent beings," by whom he wishes the affairs of the world to be carried on, may, while they act as rational and intelligent, break or perform their promises at pleasure. He thinks it "essential to various circumstances of human intercourse, that we should be known to bestow a steady attention upon the quantities of convenience or inconvenience, of good or evil, that might arise to others from our conduct." After this attention, the disappointment of the promise is not to be minded, though the expectations excited by these "rational and intelligent beings" may have "altered the nature of his situation, and engaged him in undertakings from which he would otherwise have abstained." What the promiser takes to be the general utility and the fitness of things is to be his guide. And a breach of promise will be attended with the following advantages: "The promisee, and all other men, will be taught to depend more upon their own exertions, and less upon the assistance of others, which caprice may refuse or justice withhold. He and all others will be taught to acquire such merit and to engage in such pursuits, as shall oblige any honest man to come to their succour if they should stand in need of assistance. This breach of promise, with a view to the general utility, will, so far from being criminal, form a part of that resolute execution of justice which would in a thousand ways increase the independence, the energies, and the virtue of mankind *."

Such are the views which determined this author to consider "the validity of promises" as "inconsistent with justice," and as "foreign to general good." From one, however, who relies with so much confidence on the promiser, it would certainly be desirable to know, whether the person, who violates his faith for the public utility, is always to be candid. Where breach of faith promotes his own interest, ought he alone to decide on the validity of his promise? or where promises are broken for the general good, is he to be guided by his own visionary schemes of utility? Is he to act as trustee for the public without any delegated power? and shall the community submit to his decisions without so much as putting the question, Who hath made thee a ruler over us? When a writer thus deviates so far from the path of reason, it is natural to ask, what was the *ignis fatuus* that misled him? In the present case it is pretty obvious. Being something of opinion with the celebrated Turgot †, that romances are the only books in which moral principles are treated in an impartial manner, this gentleman, in his Chapter of *Promises*, seems to have borrowed a part of his morality from

* *Godwin's Inquiry concerning Political Justice,* book iii. chap. 3.

16
A private individual has no right to intrude his schemes of utility on the public.

† See Note book iii. chap. 6.

Promise.

from the doggerels of Butler; and having adopted, though from different motives, the political principles of Sir Hudibras's squire, that obedience to civil government is not due because it is promised, he has come to exactly the same conclusion with respect to the obligation of keeping one's word. But Ralph has reasoned with more ingenuity; and has shewn not only that the public good, but the glory of the Lord, may be sometimes promoted by a breach of faith.

The saints*, whom oaths and vows oblige,
Know little of their privilege;
Farther, I mean, than carrying on
Some self-advantage of their own:
For if the dev'l, to serve his turn,
Can tell truth, why the saints should scorn,
When it serves theirs, to swear and lie,
I think there's little reason why:
Else h' has a greater pow'r than they,
Which 'twere impiety to say:
W' are not commanded to forbear,
Indefinitely, at all to swear;
But to swear idly, and in vain,
Without self-interest and gain;
For breaking of an oath and lying
Is but a kind of self-denying,
A saint-like virtue; and from hence
Some have broke oaths by Providence:
Some, to the glory of the Lord,
Perjur'd themselves and broke their word:——
For saints may do the same thing by
The spirit, in sincerity,
Which other men are tempted to,
And at the devil's instance do.

HUDIBRAS, *Canto II.*

* The saints are Godwin's rational and intelligent beings.

Here are new views of utility; which, were they to be considered as of any weight, would increase the difficulty of determining when an erroneous promise ought to be kept.

17
Views of utility an unsafe guide in morals.

But should views of utility be laid aside, and should it be made an invariable rule that truth is on no account to be violated, that deceit is never to be practised, and that moral obligations are not to be dissolved for the prospect of any physical advantage; those doubts which arise concerning the validity of erroneous promises will soon disappear. Disagreeable perhaps and ridiculous consequences may sometimes arise to a few individuals from an honest and conscientious adherence to their promise; but will any assert that the general good, *that burden of the song*, will ever be endangered by too much veracity.

So numerous inconveniences arise daily from the regular operation of those great physical laws, which are under the immediate direction of Providence, that those philosophers who have adopted the principle of utility, and are much surprised to see the universe so awkwardly planned for the ease and comfort of them and their species, have been under the necessity of imputing many events in nature to the malignity of some evil independent being; or of allowing that things have degenerated since they first came from the hands of the Creator, and that they must now be exceedingly altered from what they had been when He chose to pronounce them all very good. Thus, absurdity or impiety must always be the consequence of judging of the vice and virtue of an action by its utility, and of estimating its utility by our limited views and erroneous conceptions.

As for extorted promises, it is curious to observe how this question should always be started, whether or not they ought to be kept? and another question should seldom be thought of, whether or not they ought to be made? Fortitude was one of the cardinal virtues among the ancients; and is deemed of such importance in the Christian system, that the fearful are classed with the unbelievers, and are thought unworthy of the favour of the Deity, as being incapable of supporting those trials to which heaven exposes the faithful as the truest test of Christian virtue.—If a person should want the necessary fortitude to be virtuous, it will be a poor excuse for his baseness, that he has added deceit to his cowardice: and surely it is not the business of morality, when it has found him guilty of one crime, to grant him a dispensation for committing two. The laws of jurisprudence, it will readily be allowed, cannot favour the claims of the promisee; because they ought never to lend their support to oppression and violence. But their acquital, should he violate his faith, will by no means vindicate the character of the promise. Their acquitting a woman from the charge of adultery, goes a short way in restoring the fair reputation of her innocence.

18
Extorted promises.

19
Whether binding or not.

Let jurisprudence decide as it will, the man of honour and the generous patriot can never be brought to respect the person who, struck with a panic, could betray either himself or his friends. The magnanimous spirits who could die for the truth will view with contempt his pitiful deceit. Those unfortunate men who may suffer from that very distrust which the breach of his faith has begotten, will always detest him as a traitor and enemy; and heaven itself cannot be supposed to reward that soldier who deserts her cause, and relinquishes the post which she has assigned him, at the sight of danger.

If we once begin to accommodate morality to the dispositions and humours of mankind, it is hard to say where this species of complaisance will end The degrees of timidity are so various, and some tempers by nature so yielding, that repeated importunity or an earnest request will extort a promise.

20
The laws of morality are not to be accommodated to the humours and interests of mankind.

A young lady was frequently pressed by her dying husband to grant him a promise that she would not marry after his death. For some time she was able to resist with becoming spirit his absurd request; but upon his declaring oftener than once that he could not otherwise die in peace, she complied and promised. Too young, however, for this effort of continence, she afterwards listened to the addresses of a second lover, and found her heart insensibly engaged before she adverted to the impropriety of a new attachment. But proposals of marriage could scarcely fail to remind her of her promise and awaken her scruples. These she soon communicated to her lover, with her firm resolution to remain a widow, if the contrary measure, which she greatly preferred, and on which her earthly happiness depended, were not removed by some spiritual counsellor.

Upon this declaration it was agreed to take the advice of their own minister, who was an eminent dissenting clergyman

clergyman in the diocese of Oxford: but this gentleman, unwilling to decide in a matter of such importance, proposed to refer it to Dr Secker, who was then bishop of that see. This prelate too declined to give any judgement in the case; but, as was his way, mustered up a number of arguments on each side of the question, and committed them to a letter, which a learned gentleman of our acquaintance had some time ago an opportunity of seeing in manuscript.

If the sentiments to which the bishop was inclined could have been inferred from his statement of arguments, he seemed to think that the promise was binding. In our opinion, he ought to have a given positive decision. It was no matter whether the promise was extorted or not: the promise was made; and the question was now, whether or not was the performance lawful? That it was lawful appears evident. The lady was under a moral obligation to remain a widow; and no moral obligation, so far as we know, required her to marry.

To be fruitful and multiply, indeed, is declared in Scripture, and is found, to the woful experience of many, to be one of the general laws of our nature. But of all those laws intended by nature to regulate the conduct of inferior intelligences, the moral, which were meant to be checks and correctors of those abuses to which
21 Moral laws superior to physical in point of obligation.
the physical are apt to be carried, are certainly the most sacred and obligatory. To procreate his species, a man is not then to be guilty of adultery, or of fornication, or to listen to the lewd calls of incontinency. St Paul's observation, that it is better to marry than burn, cannot be allowed in this instance to have much weight. He has not defined what degree of amorous inflammation constitutes burning, nor in what cases this burning would be a sufficient warrant for marrying. In the present instance he does not even consider marriage as a duty; he compares it with burning, and thinks it only the least of the two evils. Not that marriage is evil of itself; for he that marrieth doth well: but there are circumstances in which it would be inconvenient to marry, and in which he that marrieth not is said to do better. But if those inconveniences be reasons sufficient to deter from marrying, is that person to be held excusable who, in order to gratify an animal passion, somewhat refined, should violate an oath, and trample on a sacred moral obligation?

The young lady might indeed declare that her earthly happiness was at an end if she were not permitted to marry again: but what circumstance prevented her from marrying? It was not the opinion of her own pastor, or the bishop of Oxford: the truth is, it was certain scruples of her own, which being unable of herself to overcome, she had piously solicited the assistance of others. It is certainly a misfortune that a devotional and amorous turn should always be so closely connected in the females. Both, however, cannot always be indulged. Who will say, that the motive is rational which inclines one to cherish a passion which conscience disapproves? The virtue of continency might indeed have borne hard on this lady's constitution, and in her way to immortal happiness might have formed a gate so strait and narrow as it might be difficult for her to pass through: but after all, her case was not harder than that of nuns, who take the vows of perpetual chastity, and endure sufferings of a similar nature, and in some instances even perhaps greater than hers; yet doing it cheerfully, from the supposition that the Omniscient is well acquainted with the nature of the great sacrifice which they make, and that after death he will study to requite them; and bestow on them something like an equivalent, which in their opinion can scarcely be less than a happiness in heaven as ample as their wishes and as lasting as their souls.

Every promise, therefore, which is not released, nor fraudulently obtained by the promisee, is to be held binding if the performance be lawful and possible. 22

A promise of a similar nature with an oath.
The Christian cannot, and a man of honour will scarcely venture to reject this maxim, that a good man ought not to change though he swear to his hurt. Yet a simple promise and a promissory oath are not very different in point of obligation. Most people know, and where any moral duty is concerned, they ought particularly to reflect, that this world is governed by an Almighty Being, who knows all things, who lives always, and who is just to reward and to punish. The person who makes a promissory oath does it avowedly under an immediate sense of these truths; the person who makes a simple promise, though he certainly ought, yet may not reflect on these at the time. The former, when he violates his oath, exhibits, only to outward appearance, a greater contempt of the Divine power, knowledge, and justice, than he who violates a simple promise under an impression of the same truths. To Him who knows the secrets of the heart, the breach of the promise must appear as criminal as the breach of the oath. See ASSUMPSIT and OATH.

PROMONTORY, in *Geography*, a high point of land or rock projecting into the sea; the extremity of which towards the sea is called a *cape* or *headland*. See GEOGRAPHY *Index*.

PROMPTER, in the drama, an officer posted behind the scenes, whose business it is to watch attentively the actors speaking on the stage, in order to suggest and put them forward when at a stand, to correct them when amiss, &c. in their parts.

PROMULGATED, or PROMULGED, something published or proclaimed, and generally applied to a law, to denote the publishing or proclaiming it to the people.

PRONAOS, in ancient architecture, a porch to a church, palace, or other spacious building. See the article PORCH.

PRONATION, among anatomists. The radius of the arm has two kinds of motion, the one called *pronation*, the other *supination*. Pronation is that whereby the palm of the hand is turned downwards; and supination, the opposite motion thereto, is that whereby the back of the hand is turned downwards. The peculiar muscles whereby pronation is performed, are called *pronatores*, as those by which supination is performed are termed *supinatores*. See ANATOMY, *Table of the Muscles*, and *Plates*.

PRONG-HOE, in husbandry, a term used to express an instrument used to hoe or break the ground near and among the roots of plants.

The ordinary contrivance of the hoe is very defective, it being only made for scraping on the surface; but the great use of hoeing being to break and open the ground, beside the killing of the weeds, which the ancients, and many among us, have thought the only use of the hoe, this

this dull and blunt instrument is by no means calculated for the purposes it is to serve. The prong-hoe consists of two hooked points of five or seven inches long, and when struck into the ground will stir and remove it the same depth as the plough does, and thus answer both the ends of cutting up the weeds and opening the land. It is useful even in the horse-hoeing husbandry, because the hoe-plough can only come within three or four inches of the rows of the corn, turnips and the like; whereas this instrument may be used afterwards, and with it the land may be raised and stirred even to the very stalk of the plant. See Agriculture.

PRONOUN, Pronomen, in *Grammar*, a declinable part of speech, which being put instead of a noun, points out some person or thing. See Grammar.

PRONUNCIATION, in *Grammar*, the manner of articulating or sounding the words of a language.

Pronunciation makes the most difficult part of written grammar; in regard that a book expressing itself to the eyes, in a manner that wholly concerns the ears, seems next akin to that of teaching the blind to distinguish colours: hence it is that there is no part so defective in grammar as that of pronunciation, as the writer has frequently no term whereby to give the reader an idea of the sound he would express; for want of a proper term, therefore, he substitutes a vicious and precarious one. To give a just idea of the pronunciation of a language, it seems necessary to fix as nearly as possible all the several sounds employed in the pronunciation of that language. Cicero tells us, that the pronunciation underwent several changes among the Romans: and indeed it is more precarious in the living languages, being, as Du Bos tells us, subservient to fashion in these. The French language is clogged with a difficulty in pronunciation from which most others are free; and it consists in this, that most of their words have two different pronunciations, the one in common prose, the other in verse.

As to the pronunciation of the English language, the ingenious Mr Martin, in his Spelling-Book of Arts and Sciences, lays down the following rules: 1. The final (*e*) lengthens the sound of the foregoing vowel; as in *can, cane; rob, robe; tun, tune*, &c. 2. The final (*e*), in words ending in *re*, is sounded before the *r* like *u*; as *massacre, massa-cur; lucre, lu-cur*, &c. 3. The Latin diphthongs *æ*, *œ*, are sounded like *e*; as *Ætna, Etna; œconomy, economy*, &c.: but at the end of the words *oe* sounds like *o*; as in *toe, foe*, &c. 4. Also the English improper diphthongs, *ea, eo, eu, ue*, sound only the *e* and *u*; as *tea* or *te; feoffee*, or *feffee; due* or *du; true* or *tru*, &c. though sometimes *eo* and *ea* are pronounced like *ee*, as in *people, fear, near*, &c. 5. Sometimes the diphthong (*ie*) is pronounced like *e* in *ceiling*, like *ee* in *field*, and, at the end of words, always like *y*, as in *lie*, &c.; and *ei* is pronounced either like *e* or *ai*, as in *deceit, reign*, &c. 6. The triphthong *eau* is pronounced like *o*, in *beau* and *jet d'eau*; and *ieu* sounds like *u* in *lieu, adieu*, &c. The sound of *c* is hard before the vowels *a, o, u*, as in *call, cold, cup*, &c.; also sometimes before *h*, as in *chart, chord*, &c.; and before *l* and *r*, as in *clear, creep*, &c. It is otherwise generally soft, as in *city, cell, cyder, child*, &c. 8. In French words *ch* is sounded like *sh*, as in *chagreen, machine;* and sometimes like *qu*, as in *choir*. 9. The sound of *g* is hard before *a, o, u, l, r*, as in *gall, go, gum, glean, grope;* also before *ui*, as in *guilt, guild*, &c.; and before *h*, as in *ghost;* sometimes before *i*, as in *gibbous, gibberish*. It is also generally hard before *e*, as in *get, geld*, &c.; but soft in many words derived from the Greek and Latin, as in *geometry, genealogy, genus*, &c. Two *gg* are always hard, as in *dagger*, &c. The sound of *g*, when soft, is like that of *j*. 10. In any part of a word, *ph* sounds like *f*, as in *philosophy*, &c. 11. The sound of *qu*, at the end of French words, is like *k*, as in *risque*, &c. 12. The syllables *ti* and *ci*, if followed by a vowel, sound like *si* or *shi;* as in *fiction, logician*, &c. 13. When *cc* occurs before *i*, the first is hard and the latter is soft; as in *flaccid*, &c. 14. The letter *p* is not pronounced at the beginning of syllables before *s* and *t;* as in *psalm, ptarmics*, &c. As to other peculiarities regarding the pronunciation of single letters, many of them have been taken notice of at the beginning of each, in the course of this work.

But it is not enough to know the just pronunciation of single letters, but also of words: in order to which, the accenting of words ought to be well understood; since nothing is more harsh and disagreeable to the ear, than to hear a person speak or read with wrong accents. And indeed in English the same word is often both a noun and a verb, distinguished only by the accent, which is on the first syllable of the noun, and on the last of the verb, as *fèrment* and *fermènt; rècord* and *recòrd*, &c. We are to observe also, that in order to a just expression of words, some require only a single accent on the syllable, as in *tòrment*, &c.; but in others it should be marked double, as in *anˈˈmal*, because it is pronounced as if the letter was wrote double, viz. *anni-mal*.

Mr Sheridan's Dictionary will be found extremely useful as a directory in acquiring the pronunciation of the English language; but care must be taken to avoid his provincial brogue, which has certainly misled him in several instances. Mr Walker's Pronouncing Dictionary, lately published, will likewise deserve the student's attention. It is a work of great labour and merit, and is highly useful. It has indeed some faults and inaccuracies, but it is notwithstanding, in all probability, the best of the kind.

Pronunciation is also used for the fifth and last part of rhetoric, which consists in varying and regulating the voice agreeably to the matter and words, so as most effectually to persuade and touch the hearers. See Oratory, Part IV.

PROOF, in *Law* and *Logic*, is that degree of evidence which carries conviction to the mind. It differs from demonstration, which is applicable only to those truths of which the contrary is inconceivable. It differs likewise from probability, which produces for the most part nothing more than opinion, while proof produces belief. See Probability.

The *proof* of crimes was anciently effected among our ancestors divers ways; viz. by duel or combat, fire, water, &c. See Duel and Ordeal.

Proof *of Artillery and Small Arms*, is a trial whether they stand the quantity of powder allotted for that purpose. The rule of the board of ordnance is, that all guns, under 24-pounders, be loaded with powder as much as their shot weighs; that is, a brass 24-pounder with 21 lb. a brass 32-pounder with 26 lb. 12 oz. and a 42-pounder with 31 lb. 8 oz.; the iron 24-pounder with 18 lb. the 32-pounder with 21 lb. 8 oz. and the 42-pounder with 25 lb.

The

Proof.

The brass light field-pieces are proved with powder that weighs half as much as their shot, except the 24-pounder which is loaded with 10 lb. only.

Government allows 11 bullets of lead in the pound for the proof of muskets and 14,5, or 29 in two pounds, for service; 17 in the pound for the proof of carabines, and 20 for service; 28 in the pound for the proof of pistols, and 34 for service.

When guns of a new metal, or of lighter construction, are proved; then, besides the common proof, they are fired 200 or 300 times, as quick as they can be, loaded with the common charge given in actual service. Our light 6-pounders were fired 300 times in 3 hours 27 minutes, loaded with 1 lb. 4 oz. without receiving any damage.

Proof of Powder, is in order to try its goodness and strength. See Gunpowder.

Proof of Cannon, is made to ascertain their being well cast, their having no cavities in their metal, and, in a word, their being fit to resist the effort of their charge of powder. In making this proof, the piece is laid upon the ground, supported only by a piece of wood in the middle, of about 5 or 6 inches thick, to raise the muzzle a little; and then the piece is fired against a solid butt of earth.

Tools used in the Proof of Cannon, are as follows:

Searcher, an iron socket with branches, from 4 to 8 in number, bending outwards a little, with small points at their ends: to this socket is fixed a wooden handle, from 8 to 12 feet long, and 1½ inch in diameter. This searcher is introduced into the gun after each firing, and turned gently round to discover the cavities within: if any are found, they are marked on the outside with chalk; and then the

Searcher with one point is introduced: about which point a mixture of wax and tallow is put, to take the impression of the holes; and if any are found of one-fourth of an inch deep, or of any considerable length, the gun is rejected as unserviceable to the government.

Reliever, is an iron ring fixed to a handle, by means of a socket, so as to be at right angles; it serves to disengage the first searcher, when any of its points are retained in a hole, and cannot otherwise be got out. When guns are rejected by the proof-masters, they order them to be marked × thus, which the contractors generally alter *WP* thus; and after such alteration, dispose of them to foreign powers for Woolwich proof.

The most curious instrument for finding the principal defects in pieces of artillery, was lately invented by Lieutenant-general Desaguliers, of the royal regiment of artillery. This instrument, grounded on the truest mechanical principles, is no sooner introduced into the hollow cylinder of the gun, than it discovers its defects, and more particularly that of the piece not being truly bored; which is a very important one, and to which most of the disasters happening to pieces of artillery are in a great measure to be imputed; for, when a gun is not truly bored, the most expert artillerist will not be able to make a good shot.

Proof of Mortars and Howitzers, is made to ascertain their being well cast, and of strength to resist the effort of their charge. For this purpose the mortar or howitzer is placed upon the ground, with some part of their trunnions or breech sunk below the surface, and resting on wooden billets, at an elevation of about 70 degrees.

Proof, Propagation.

The mirror is generally the only instrument to discover the defects in mortars and howitzers. In order to use it, the sun must shine; the breech must be placed towards the sun, and the glass over-against the mouth of the piece: it illuminates the bore and chamber sufficiently to discover the flaws in it.

Proof of Foreign Brass-Artillery. 1st, The Prussians. Their battering-train and garrison artillery are proved with a quantity of powder equal to $\frac{1}{7}$ the weight of the shot, and fired 75 rounds as fast as in real service; that is, 2 or 3 rounds in a minute. Their light field-train, from a 12-pounder upwards, are proved with a quantity of powder = 1-3d of the weight of the shot, and fired 150 rounds, at 3 or 4 rounds in a minute. From a 12-pounder downwards, are proved with a quantity of powder = 1-5th of the shot's weight, and fired 300 rounds, at 5 or 6 rounds each minute, properly spunged and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible.

2d, The Dutch prove all their artillery by firing each piece 5 times; the two first rounds with a quantity of powder = 2-3ds of the weight of the shot; and the three last rounds with a quantity of powder = $\frac{1}{7}$ the weight of the shot.

3d, The French the same as the Dutch.

Proof, in brandy and other spirituous liquors, is a little white lather which appears on the top of the liquor when poured into a glass. This lather, as it diminishes, forms itself into a circle called by the French the *chapelet*, and by the English the *bead* or *bubble*.

Proofs of Prints, were anciently a few impressions taken off in the course of an engraver's process. He proved a plate in different states, that he might ascertain how far his labours had been successful, and when they were complete. The excellence of such early impressions, worked with care, and under the artist's eye, occasioning them to be greedily sought after, and liberally paid for, it has been customary among our modern print-sellers to take off a number of them, amounting perhaps, to hundreds, from every plate of considerable value; and yet their want of rareness has by no means abated their price. On retouching a plate, it has been also usual, among the same conscientious fraternity, to cover the inscription, which was immediately added after the first proofs were obtained, with slips of paper, that a number of secondary proofs might also be created. *Nichols's Life of Hogarth.*

Proof, in the sugar trade. See Sugar.

Proofs, in printing. See Printing.

PROPAGATION, the act of multiplying the kind. See Generation.

Propagation of Plants. The most natural and the most universal way of propagating plants is by seeds. See Plants. But they may also be propagated by *sets*, *pieces*, or *cuttings*, taken from the parent plant. Willows are very easily propagated by sets: such as rise to be considerable timber trees being raised from sets seven or eight feet long, sharpened at their larger ends, which are thrust into the ground by the sides of ditches, on the banks of rivers, or in any moist soil. The sallow trees are raised from sets only three feet long. The plane tree, mint, &c. may be propagated in the same way. In providing

Propagation ‖ Property.

viding the slips, sprigs, or cuttings, however, care must be taken to cut off such branches as have knots or joints two or three inches beneath them: small top sprigs of two or three years growth are the best for this operation. Plants are also propagated by parting their roots, each part of which, properly managed, sends out fresh roots. Another mode of propagating plants is by layering or laying the tops of the branches in the ground.

The method of layering is this: Dig a ring-trench round the stool, of a depth suitable to the nature of the plant; and having pitched upon the shoots to be layered, bend them to the bottom of the trench (either with or without plashing, as may be found most convenient), and there *peg* them fast; or, putting some mould upon them, *tread* them hard enough to prevent their springing up again—fill in the mould—place the top of the layer in an upright posture, treading the mould hard behind it; and cut it carefully off above the first, second or third eye. Plants are also propagated by their bulbs.

The number of vegetables that may be propagated from an individual is very remarkable, especially in the most minute plants. The annual product of one seed even of the common mallow has been found to be no less than 200,000; but it has been proved, by a strict examination into the more minute parts of the vegetable world, that the common wall moss produces a much more numerous offspring. In one of the little heads of this plant there have been counted 13,824 seeds. Now allotting to a root of this plant eight branches, and to each branch six heads, which appears to be a very moderate computation, the produce of one seed is $6 \times 13824 = 82944$; and 8×82944 gives 663,552 seeds as the annual produce of one seed, and that so small that 13824 of them are contained in a capsule, whose length is but one-ninth of an inch, its diameter but one 23d of an inch, and its weight but the 13th part of a grain.

For the propagation or culture of particular plants, see AGRICULTURE.

PROPER, something natural and essentially belonging to any thing.

PROPERTIUS, SEXTUS AURELIUS, a celebrated Latin poet, born at Mevania, a city of Umbria, now called *Bevagna*, in the duchy of Spoletto. He went to Rome after the death of his father, a Roman knight, who had been put to death by order of Augustus, for having followed Antony's party during the triumvirate. Propertius in a short time acquired great reputation by his wit and abilities, and had a considerable share in the esteem of Mæcenas and Cornelius Gallus. He had also Ovid, Tibullus, Bassus, and the other ingenious men of his time for his friends. He died at Rome 19 B. C. He is printed with almost all the editions of Tibullus and Catullus: but the best edition of him is that which was given separately by Janus Brouckhusius at Amsterdam, 1702, in 4to, and again in 1714, 4to, *cum curis secundis ejusdem*. We have four books of his Elegies or Amours with a lady called *Hostia*, or *Hostilia*, to whom he gave the name of *Cynthia*.

PROPERTY, in a general sense, is a particular virtue or quality which nature has bestowed on some things exclusive of all others: thus, colour is a property of light; extension, figure, divisibility, and impenetrability, are properties of body.

Property.

PROPERTY, in *Law*, is described to be the highest right which a person has or can have to any thing.

1 Definition.

There is nothing which so generally strikes the imagination, and engages the affections of mankind, as the right of property; or that sole and despotic dominion which one man claims and exercises over certain external things of the world, in total exclusion of the right of any other individual in the universe. And yet there are very few that will give themselves the trouble to consider the original and foundation of this right. Pleased as we are with the possession, we seem afraid to look back to the means by which it was acquired, as if fearful of some defect in our title; or at best we rest satisfied with the decision of the laws in our favour, without examining the reason or authority upon which those laws have been built. We think it enough that our title is derived by the grant of the former proprietor, by descent from our ancestors, or by the last will and testament of the dying owner: not caring to reflect, that (accurately and strictly speaking) there is no foundation in nature or in natural law, why a set of words upon parchment should convey the dominion of land; why the son should have a right to exclude his fellow creatures from a determinate spot of ground, because his father had done so before him; or why the occupier of a particular field or of a jewel, when lying on his death-bed and no longer able to maintain possession, should be entitled to tell the rest of the world which of them should enjoy it after him. These inquiries, it must be owned, would be useless and even troublesome in common life. It is well if the mass of mankind will obey the laws when made, without scrutinizing too nicely into the reasons of making them. But when law is to be considered not only as a matter of practice, but also as a rational science, it cannot be improper or useless to examine more deeply the rudiments and grounds of these positive constitutions of society.

2 The original foundation of the right to property not generally considered.

3 This right arises from a divine grant.

In the beginning of the world, we are informed by holy writ, that the all-bountiful Creator gave to man "dominion over all the earth; and over the fish of the "sea, and over the fowl of the air, and over every li-"ving thing that moveth upon the earth." This is the only true and solid foundation of man's dominion over external things, whatever airy metaphysical notions may have been started by fanciful writers upon this subject. The earth, therefore, and all things therein, are the general property of all mankind, exclusive of other beings, from the immediate gift of the Creator. And, while the earth continued thinly inhabited, it is reasonable to suppose, that all was in common among them, and that every one took from the public stock to his own use such things as his immediate necessities required.

4 The state of property in the early ages of the world.

These general notions of property were then sufficient to answer all the purposes of human life; and might perhaps still have answered them, had it been possible for mankind to have remained in a state of primæval simplicity: as may be collected from the manners of many American nations, when first discovered by the Europeans; and from the ancient method of living among the first Europeans themselves, if we may credit either the memorials of them preserved in the golden age of the poets, or the uniform accounts given by historians of those times wherein *erant omnia communia et indivisa omnibus, veluti unum cunctis patrimonium esset*. Not that this communion of goods seems ever to have been applicable,

Blackst. Comment.

even

Property. even in the earliest ages, to aught but the *substance* of the thing; nor could it be extended to the *use* of it. For, by the law of nature and reason, he who first began to use it, acquired therein a kind of transient property, that lasted so long as he was using it, and no longer: or, to speak with greater precision, the *right* of possession continued for the same time only that the *act* of possession lasted. Thus the ground was in common, and no part of it was the permanent property of any man in particular; yet whoever was in the occupation of any determinate spot of it, for rest, for shade, or the like, acquired for the time a sort of ownership, from which it would have been unjust, and contrary to the law of nature, to have driven him by force; but the instant that he quitted the use or occupation of it, another might seize it without injustice. Thus also a vine or other tree might be said to be in common, as all were equally entitled to its produce; and yet any private individual might gain the sole property of the fruit, which he had gathered for his own repast. A doctrine well illustrated by Cicero, who compares the world to a great theatre, which is common to the public, and yet the place which any man has taken is for the time his own.

5 Rise of permanent property in various things.

But when mankind increased in number, craft, and ambition, it became necessary to entertain conceptions of more permanent dominion; and to appropriate to individuals, not the immediate *use* only, but the very *substance* of the thing to be used: otherwise innumerable tumults must have arisen, and the good order of the world been continually broken and disturbed, while a variety of persons were striving who should get the first occupation of the same thing, or disputing which of them had actually gained it. As human life also grew more and more refined, abundance of conveniencies were devised to render it more easy, commodious, and agreeable; as habitations for shelter and safety, and raiment for warmth and decency. But no man would be at the trouble to provide either, so long as he had only an usufructuary property in them, which was to cease the instant that he quitted possession;—if, as soon as he walked out of his tent, or pulled off his garment, the next stranger who came by would have a right to inhabit the one and to wear the other. In case of habitations in particular, it was natural to observe, that even the brute creation, to whom every thing else was in common, maintained a permanent property in their dwellings, especially for the protection of their young; that the birds of the air had nests, and the beasts of the field had caverns, the invasion of which they esteemed a very flagrant injustice, and would sacrifice their lives to preserve them. Hence a property was soon established in every man's house and home-stall; which seem to have been originally mere temporary huts or moveable cabins, suited to the design of Providence for more speedily peopling the earth, and suited to the wandering life of their owners, before any extensive property in the soil or ground was established. And there can be no doubt, but that moveables of every kind became sooner appropriated than the permanent substantial soil: partly because they were more susceptible of a long occupancy, which might be continued for months together without any sensible interruption, and at length by usage ripen into an established right; but principally because few of them could be fit for use, till improved and meliorated by the bodily labour of the occupant; which bodily labour, bestowed upon any subject which before lay in common to all men, is universally allowed to give the fairest and most reasonable title to an exclusive property therein. Property.

6 In food and other necessary articles.

The article of food was a more immediate call, and therefore a more early consideration. Such as were not contented with the spontaneous product of the earth sought for a more solid refreshment in the flesh of beasts, which they obtained by hunting. But the frequent disappointments incident to that method of provision induced them to gather together such animals as were of a more tame and sequacious nature; and to establish a permanent property in their flocks and herds, in order to sustain themselves in a less precarious manner, partly by the milk of their dams, and partly by the flesh of the young. The support of these their cattle made the article of *water* also a very important point. And therefore the book of Genesis (the most venerable monument of antiquity, considered merely with a view to history) will furnish us with frequent instances of violent contentions concerning wells; the exclusive property of which appears to have been established in the first digger or occupant, even in such places where the ground and herbage remained yet in common. Thus we find Abraham, who was but a sojourner, asserting his right to a well in the country of Abimelech, and exacting an oath for his security, "because he had digged that well." And Isaac, about 90 years afterwards, reclaimed this his father's property; and, after much contention with the Philistines, was suffered to enjoy it in peace.

7 Nature of patriarchal property.

All this while the soil and pasture of the earth remained still in common as before, and open to every occupant: except perhaps in the neighbourhood of towns, where the necessity of a sole and exclusive property in lands (for the sake of agriculture) was earlier felt, and therefore more readily complied with. Otherwise, when the multitude of men and cattle had consumed every convenience on one spot of ground, it was deemed a natural right to seize upon and occupy such other lands as would more easily supply their necessities. This practice is still retained among the wild and uncultivated nations that have never been formed into civil states, like the Tartars and others in the east; where the climate itself, and the boundless extent of their territory, conspire to retain them still in the same savage state of vagrant liberty, which was universal in the earliest ages, and which Tacitus informs us continued among the Germans till the decline of the Roman empire. We have also a striking example of the same kind in the history of Abraham and his nephew Lot. When their joint substance became so great, that pasture and other conveniencies grew scarce, the natural consequence was, that a strife arose between their servants; so that it was no longer practicable to dwell together. This contention Abraham endeavoured to compose: "Let there be no strife, I pray thee, between thee and me. Is not the whole land before thee? Separate thyself, I pray thee, from me: if thou wilt take the left hand, then I will go to the right; or if thou depart to the right hand, then I will go to the left." This plainly implies an acknowledged right, in either, to occupy whatever ground he pleased, that was not pre-occupied by other tribes. "And Lot lifted up his eyes, and beheld all the plain of Jordan, that it was well watered every where, even as the garden of the Lord. Then Lot chose him all the plain of Jordan, and journeyed east; and Abraham dwelt in the land of Canaan."

Property.

Upon the same principle was founded the right of migration, or sending colonies to find out new habitations, when the mother-country was overcharged with inhabitants; which was practised as well by the Phœnicians and Greeks, as the Germans, Scythians, and other northern people. And, so long as it was confined to the stocking and cultivation of desert uninhabited countries, it kept strictly within the limits of the law of nature.

8 Necessity of property and of laws respecting it.

But as the world by degrees grew more populous, it daily became more difficult to find out new spots to inhabit, without encroaching on former occupants; and by constantly occupying the same individual spot, the fruits of the earth were consumed, and its spontaneous produce destroyed, without any provision for a future supply or succession. It therefore became necessary to pursue some regular method of providing a constant subsistence; and this necessity produced, or at least promoted and encouraged, the art of agriculture. And the art of agriculture, by a regular connection and consequence, introduced and established the idea of a more permanent property in the soil than had hitherto been received and adopted. It was clear that the earth would not produce her fruits in sufficient quantities without the assistance of tillage; but who would be at the pains of tilling it, if another might watch an opportunity to seize upon and enjoy the product of his industry, art, and labour? Had not therefore a separate property in lands, as well as moveables, been vested in some individuals, the world must have continued a forest, and men have been mere animals of prey; which, according to some philosophers, is the genuine state of nature. Whereas now (so graciously has Providence interwoven our duty and our happiness together) the result of this very necessity has been the ennobling of the human species, by giving it opportunities of improving in *rational* faculties, as well as of exerting its *natural*. Necessity begat property: and in order to insure that property, recourse was had to civil society, which brought along with it a long train of inseparable concomitants; states, government, laws, punishments, and the public exercise of religious duties. Thus connected together, it was found that a part only of society was sufficient to provide, by their manual labour, for the necessary subsistence of all; and leisure was given to others to cultivate the human mind, to invent useful arts, and lay the foundation of science.

9 Property acquired first by occupancy.

The only question remaining is, How this property became actually vested; or what it is that gave a man an exclusive right to retain in a permanent manner that specific land which before belonged generally to every body, but particularly to nobody? And as we before observed, that *occupancy* gave the right to the temporary *use* of the soil; so it is agreed upon all hands, that occupancy gave also the original right to the permanent property in the *substance* of the earth itself, which excludes every one else but the owner from the use of it. There is indeed some difference among the writers on natural law, concerning the reason why occupancy should convey this right, and invest one with this absolute property: Grotius and Puffendorf insisting, that this right of occupancy is founded upon a tacit and implied assent of all mankind, that the first occupant should become the owner; and Barbeyrac, Titius, Mr Locke, and others, holding that there is no such implied assent, neither is it necessary that there should be; for that the very act of occupancy, alone, being a degree of bodily labour, is from a principle of natural justice, without any consent or compact, sufficient of itself to gain a title. A dispute that savours too much of nice and scholastic refinement. However, both sides agree in this, that occupancy is the thing by which the title was in fact originally gained; every man seizing to his own continued use such spots of ground as he found most agreeable to his own convenience, provided he found them unoccupied by any one else.

10 By what means it is preserved or lost.

Property, both in lands and moveables, being thus originally acquired by the first taker, which taking amounts to a declaration, that he intends to appropriate the thing to his own use, it remains in him, by the principle of universal law, till such time as he does some other act which shows an intention to abandon it; for then it becomes naturally speaking, *publici juris* once more, and is liable to be again appropriated by the next occupant. So if one is possessed of a jewel, and casts it into the sea or a public highway, this is such an express dereliction, that a property will be vested in the first fortunate finder that shall seize it to his own use. But if he hides it privately in the earth, or other secret place, and it is discovered, the finder acquires no property therein; for the owner had not by this act declared any intention to abandon it, but rather the contrary: and if he loses or drops it by accident, it cannot be collected from thence that he designed to quit the possession; and therefore in such cases the property still remains in the loser, who may claim it again of the finder. And this, we may remember, is the doctrine of the English law with relation to *Treasure-Trove*.

But this method of one man's abandoning his property, and another seizing the vacant possession, however well-founded in theory, could not long subsist in fact. It was calculated merely for the rudiments of civil society, and necessarily ceased among the complicated interests and artificial refinements of polite and established governments. In these it was found, that what became inconvenient or useless to one man, was highly convenient and useful to another; who was ready to give in exchange for it some equivalent that was equally desirable to the former proprietor. This mutual convenience introduced commercial traffic, and the reciprocal transfer of property by sale, grant, or conveyance: which may be considered either as a continuance of the original possession which the first occupant had; or as an abandoning of the thing by the present owner, and an immediate successive occupancy of the same by the new proprietor. The voluntary dereliction of the owner, and delivering the possession to another individual, amount to a transfer of the property; the proprietor declaring his intention no longer to occupy the thing himself, but that his own right of occupancy shall be vested in the new acquirer. Or, taken in the other light, if I agree to part with an acre of my land to Titius, the deed of conveyance is an evidence of my intending to abandon the property; and Titius, being the only or first man acquainted with such my intention, immediately steps in and seizes the vacant possession: thus the consent expressed by the conveyance gives Titius a good right against me; and possession or occupancy confirms that right against all the world besides.

11 How it goes on the death of the occupant.

The most universal and effectual way of abandoning property is by the death of the occupant: when, both the actual possession and intention of keeping possession

Property. sion ceasing, the property, which is founded upon such possession and intention, ought also to cease of course. For, naturally speaking, the instant a man ceases to be, he ceases to have any dominion: else, if he had a right to dispose of his acquisitions one moment beyond his life, he would also have a right to direct their disposal for a million of ages after him; which would be highly absurd and inconvenient (A). All property must therefore cease upon death, considering men as absolute individuals, and unconnected with civil society: for then, by the principles before established, the next immediate occupant would acquire a right in all that the deceased possessed. But as, under civilized governments, which are calculated for the peace of mankind, such a constitution would be productive of endless disturbances, the universal law of almost every nation (which is a kind of secondary law of nature) has either given the dying person a power of continuing his property, by disposing of his possessions by will; or, in case he neglects to dispose of it, or is not permitted to make any disposition at all, the municipal law of the country then steps in, and declares who shall be the successor, representative, or heir of the deceased; that is, who alone shall have a right to enter upon this vacant possession, in order to avoid that confusion which its becoming again common would occasion. And farther, in case no testament be permitted by the law, or none be made, and no heir can be found so qualified as the law requires, still, to prevent the robust title of *occupancy* from again taking place, the doctrine of escheats is adopted in almost every country; whereby the sovereign of the state, and those who claim under his authority, are the ultimate heirs, and succeed to those inheritances to which no other title can be formed.

12 Of the right of inheritance.

The right of inheritance, or descent to the children and relations of the deceased, seems to have been allowed much earlier than the right of devising by testament. We are apt to conceive at the first view that it has nature on its side; yet we often mistake for nature what we find established by long and inveterate custom. It is certainly a wise and effectual, but clearly a political, establishment; since the permanent right of property, vested in the ancestor himself, was no *natural*, but merely a *civil*, right. It is true, that the transmission of one's possessions to posterity has an evident tendency to make a man a good citizen and a useful member of society: it sets the passions on the side of duty, and prompts a man to deserve well of the public, when he is sure that the reward of his services will not die with himself, but be transmitted to those with whom he is connected by the dearest and most tender affections. Yet, reasonable as this foundation of the right of inheritance may seem, it is probable that its immediate original arose not from speculations altogether so delicate and refined, and, if not from fortuitous circumstances, at least from a plainer and more simple principle. A man's children or nearest relations are usually about him on his death-bed, and are the earliest witnesses of his decease. They became therefore generally the next immediate occupants, till at length in process of time this frequent usage ripened into general law. And therefore also in the earliest ages, on failure of children, a man's servants born under his roof were allowed to be his heirs; being immediately on the spot when he died. For we find the old patriarch Abraham expressly declaring, that "since God had given him no seed, his steward Eliezer, one born in his house, was his heir." Property.

13 Last wills or testaments

While property continued only for life, testaments were useless and unknown; and when it became inheritable, the inheritance was long indefeasible, and the children or heirs at law were incapable of exclusion by will. Till at length it was found, that so strict a rule of inheritance made heirs disobedient and headstrong, defrauded creditors of their just debts, and prevented many provident fathers from dividing or charging their estates as the exigence of their families required. This introduced pretty generally the right of disposing of one's property, or a part of it, by *testament;* that is, by written or oral instructions properly *witnessed* and authenticated, according to the *pleasure* of the deceased; which we therefore emphatically style his *will*. This was established in some countries much later than in others. In England, till modern times, a man could only dispose of one-third of his moveables from his wife and children; and in general, no will was permitted of lands till the reign of Henry VIII. and then only of a certain portion; for it was not till after the Restoration that the power of devising real property became so universal as at present.

14 are creatures of the civil or municipal laws.

Wills, therefore, and testaments, rights of inheritance, and successions, are all of them creatures of the civil or municipal laws, and accordingly are in all respects regulated by them; every distinct country having different ceremonies and requisites to make a testament completely valid; neither does any thing vary more than the right of inheritance under different national establishments. In England particularly, this diversity is carried to such a length, as if it had been meant to point out the power of the laws in regulating the succession to property, and how futile every claim must be that has not its foundation in the positive rules of the state. In personal estates, the father may succeed to his children; in landed property, he never can be their immediate heir by any the remotest possibility: in general, only the eldest son, in some places only the youngest, in others all the sons together, have a right to succeed to the inheritance: In real estates, males are preferred to females, and the eldest male will usually exclude the rest; in the division of personal estates, the females of equal degree are admitted together with the males, and no right of primogeniture is allowed. *Blackst. Comment.*

15 Scruples respecting heritable property removed.

This one consideration may help to remove the scruples of many well-meaning persons, who set up a mistaken conscience in opposition to the rules of law. If a man disinherits his son, by a will duly executed, and leaves his estate to a stranger, there are many who consider this proceeding as contrary to natural justice; while others so scrupulously adhere to the supposed intention of the deed, that if a will of lands be attested by only *two* witnesses instead of *three*, which the law requires,

---

(A) This right, inconvenient as it certainly is, the law of Scotland gives to every man over his *real* estate, by authorising him to entail it on his heirs for ever. See LAW, clxxx. 9, 10, 11. and TAILZIE.

Property.

requires, they are apt to imagine that the heir is bound in conscience to relinquish his title to the devisee. But both of them certainly proceed upon very erroneous principles: as if, on the one hand, this son had by nature a right to succeed to his father's lands; or as if, on the other hand, the owner was by nature entitled to direct the succession of his property after his own decease. Whereas the law of nature suggests, that on the death of the possessor, the estate should again become common, and be open to the next occupant, unless otherwise ordered, for the sake of civil peace, by the positive law of society. The positive law of society, which is with us the municipal laws of England and Scotland, directs it to vest in such person as the last proprietor shall by will, attended with certain requisites, appoint; and, in defect of such appointment, to go to some particular person, who from the result of certain local constitutions, appears to be the heir at law. Hence it follows, that, where the appointment is regularly made, there cannot be a shadow of right in any one but the person appointed; and, where the necessary requisites are omitted, the right of the heir is equally strong, and built upon as solid a foundation, as the right of the devisee would have been, supposing such requisites were observed.

16
Of things that are still in common.

But, after all, there are some few things, which notwithstanding the general introduction and continuance of property, must still unavoidably remain in common; being such wherein nothing but an usufructuary property is capable of being had: and therefore they still belong to the first occupant, during the time he holds possession of them, and no longer. Such (among others) are the elements of light, air, and water; which a man may occupy by means of his windows, his gardens, his mills, and other conveniences; such also are the generality of those animals which are said to be *feræ naturæ*, or of a wild and untameable disposition; which any man may seize upon and keep for his own use or pleasure. All these things, so long as they remain in possession, every man has a right to enjoy without disturbance; but if once they escape from his custody, or he voluntarily abandons the use of them, they return to the common stock, and any other man has an equal right to seize and enjoy them afterwards.

17
Of similar things which have been appropriated.

Again, there are other things in which a permanent property may subsist not only as to the temporary use, but also the solid substance; and which yet would be frequently found without a proprietor, had not the wisdom of the law provided a remedy to obviate this inconvenience. Such are forests and other waste grounds, which were omitted to be appropriated in the general distribution of lands: such also are wrecks, estrays, and that species of wild animals, which the arbitrary constitutions of positive law have distinguished from the rest by the well-known appellation of *game*. With regard to these and some others, as disturbances and quarrels would frequently arise among individuals contending about the acquisition of this species of property by first occupancy, the law has therefore wisely cut up the root of dissension, by vesting the things themselves in the sovereign of the state; or else in his representatives appointed and authorised by him, being usually the lords of manors. And thus our legislature has universally promoted the grand ends of civil society, the peace and security of individuals, by steadily pursuing that wise and orderly maxim, of assigning to every thing capable of ownership a legal and determinate owner.

Property. Prophecy.

18
The reasoning of those who contend for an equalization of property.

In this age of paradox and innovation, much has been said of *liberty* and *equality*; and some few have contended for an equalization of property. One of the wildest declaimers on this subject, who is for abolishing property altogether, has (inadvertently we suppose) given a complete confutation, not only of his own arguments, but also of the arguments of all who have written, or, we think, can write, on the same side of the question. After labouring to prove that it is gross injustice in any man to retain more than is absolutely necessary to supply him with food, clothes, and shelter, this zealous reformer states an objection to his theory, arising from the well-known allurements of sloth, which, if the accumulation of property were not permitted, would banish industry from the whole world. The objection he urges fairly, and answers it thus: "It may be observed, that the equality for which we are pleading is an equality that would succeed to a state of great intellectual improvement. So bold a revolution cannot take place in human affairs, till the general mind has been highly cultivated. The present age of mankind is greatly enlightened; but it is to be feared is not yet enlightened enough. Hasty and undigested tumults may take place, under the idea of an equalization of property; but it is only a calm and clear conviction of justice, of justice mutually to be rendered and received, of happiness to be produced by the *desertion of our most rooted habits*, that can introduce an invariable system of this sort. Attempts without this preparation will be productive only of confusion. Their effect will be momentary, and a new and more barbarous inequality will succeed. Each man with unaltered appetite will watch his opportunity to gratify his love of power, or his love of distinction, by usurping on his inattentive neighbours."

19
The effect of ignorance of human nature.

These are just observations, and such as we have often made to ourselves on the various proposed reformations of government. The illumination which the author requires before he would introduce his abolition of property, would constitute men more than angels; for to be under the influence of no passion or appetite, and to be guided in every action by unmixed benevolence and pure intellect, is a degree of perfection which we can attribute to no being inferior to God. But it is the object of the greater part of this writer's book to prove that all men must arrive at such perfection before his ideal republic can contribute to their happiness; and therefore every one who is conscious of being at any time swayed by passion, and who feels that he is more attached to his wife or children than to strangers, will look without envy to the present inequalities of property and power, if he be an intelligent disciple of Mr Godwin.

Literary PROPERTY. See COPY-RIGHT.

1
Definition.

PROPHECY is a word derived from προφαίνω, and in its original import signifies the prediction of future events.

2
Prophecy proves a supernatural communion with the Deity.

As God alone can perceive with certainty the future actions of free agents, and the remote consequences of those laws of nature which he himself established, prophecy, when clearly fulfilled, affords the most convincing evidence of an intimate and supernatural communion between

between God and the person who uttered the prediction. Together with the power of working miracles, it is indeed the only evidence which can be given of such a communion.

3
The professors of all religions have pretended to it.

Hence among the professors of every religious system, except that which is called the religion of nature, there have been numberless pretenders to the gift of prophecy. The Pagan nations of antiquity had their oracles, augurs, and soothsayers. Modern idolaters have their necromancers and diviners; and the Jews, Christians, and Mahometans, have their seers and prophets.

The ill-founded pretensions of paganism, ancient and modern, have been exposed under various articles of this work. (See Divination, Magic, Necromancy, and Mythology). And the claims of the Arabian impostor are examined under the articles Alcoran and Mahometanism; so that at present we have only to consider the use, intent, and truth, of the Jewish and Christian prophecies.

4
The word in Scripture has various meanings.

Previous to our entering on this investigation, it may be proper to observe, that in the Scriptures of the Old and New Testaments, the signification of the word prophecy is not always confined to the foretelling of future events. In several instances it is of the same import with preaching, and denotes the faculty of illustrating and applying to present practical purposes the doctrines of prior revelation. Thus in Nehemiah it is said, "Thou hast appointed prophets to preach *;" and whoever speaketh unto men to edification, and exhortation, and comfort, is by St Paul called a *prophet* †. Hence it was that there were schools of prophets in Israel, where young men were instructed in the truths of religion, and fitted to exhort and comfort the people.

* Ch. vi. ver. 7.

† 1 Cor. ch. xiv. ver. 3.

In this article, however, it is chiefly of importance to confine ourselves to that kind of prophecy which, in declaring truths either past, present, or future, required the immediate inspiration of God.

5
Science and religion gradually acquired.

Every one who looks into the history of the world must observe, that the minds of men have from the beginning been gradually opened by a train of events still improving upon, and adding light to each other; as that of each individual is, by proceeding from the first elements and seeds of science, to more enlarged views, and a still higher growth. Mankind neither are nor ever have been capable of entering into the depths of knowledge at once; of receiving a whole system of natural or moral truths together; but must be let into them by degrees, and have them communicated by little and little, as they are able to bear it. That this is the case with respect to human science, is a fact which cannot be questioned; and there is as little room to question it with respect to the progress of religious knowledge among men, either taken collectively or in each individual. Why the case is thus in both, why all are not adult at once in body and mind, is a question which the religion of nature is equally called upon with revelation to answer. The fact may not be easily accounted for, but the reality of it is incontrovertible.

6
The revelations of Old Testament gradual.

Accordingly, the great object of the several revelations recorded in the Old Testament was evidently to keep alive a sense of religion in the minds of men, and to train them by degrees for the reception of those simple but sublime truths by which they were to be saved. The notions which the early descendants of Adam entertained of the Supreme Being, and of the relation in which they stood to him, were probably very gross; and we see them gradually refined by a series of revelations or prophecies, each in succession more explicit than that by which it was preceded, till the advent of him who was the way, the truth, and the life, and who brought to light life and immortality.

7
Prophecy always accompanied by miracles,

When a revelation was made of any important truth, the grounds of which the mind of man has not faculties to comprehend, that revelation, though undoubtedly a prophecy, must have been so far from confirming the truth of revealed religion in general, that it could not gain credit itself, but by some extrinsic evidence that it came indeed from God. Hence we find Moses, after it was revealed to him from the burning bush that he should deliver his countrymen from Egyptian bondage, replying, "Behold, they will not believe me, nor hearken to my voice; for they will say, the Lord hath not appeared unto thee." This revelation certainly constituted him a prophet to Israel; and there cannot be a doubt but that he perfectly knew the divine source from which he received it: but he very naturally and reasonably concluded, that the children of Israel would not believe that the Lord had appeared to him, unless he could give them some other proof of this preternatural appearance than his own simple affirmation of its reality. This proof he was immediately enabled to give, by having conferred upon him the power of working miracles in confirmation of his prophecy. Again, when Gideon was called to the deliverance of Israel, the angel of the Lord came and said unto him, "The Lord is with thee, thou mighty man of valour: go in this thy might, and thou shalt save Israel from the hand of the Midianites. Have not I sent thee?" Here was a prophecy delivered by the angel of the Lord to encourage Gideon's undertaking: but he, being probably afraid of some illusion of sense or imagination, demanded a sign that he was really an angel who talked with him. A sign is accordingly given him, a miraculous sign, with which he is satisfied, and undertakes the work appointed him.

8
and of itself can be no proof of a revelation.

From these and many similar transactions recorded in the Old Testament, it appears that prophecy was never intended as evidence of an original revelation. It is indeed, by its very nature, totally unfit for such a purpose; because it is impossible, without some extrinsic proof of its divine origin, to know whether any prophecy be true or false, till the era arrive at which it ought to be fulfilled. When it is fulfilled, it affords complete evidence that he who uttered it spake by the spirit of God, and that the doctrines which he taught of a religious nature, were all either dictated by the same spirit, or at least are true, and calculated to direct mankind in the way of their duty.

9
It was intended to preserve a sense of religion among men.

The prophecies vouchsafed to the patriarchs in the most early periods of the world, were all intended to keep alive in their minds a sense of religion, and to direct their views to the future completion of that first and greatest prophecy which was made to Adam immediately on his fall: but in order to secure credit to those prophecies themselves, they were always accompanied by some miraculous sign that they were indeed given by the God of truth, and not the delusions of fanaticism or hypocrisy. Prophecy, in the proper sense of the word, commenced with the fall; and the first instance of it is implied in the sentence denounced upon the

the original deceiver of mankind; "I will put enmity between thee and the woman, and between thy seed and her seed: It shall bruise thy head, and thou shalt bruise his heel."

10
Probable effects of the first prophecy on our first parents.

This prophecy, though one of the most important that ever was delivered, when considered by itself, is exceedingly obscure. That Adam should have understood it, as some of his degenerate sons have pretended to do, in a literal sense, is absolutely impossible. He knew well that it was the great God of heaven and earth who was speaking, and that such a Being was incapable of trifling with the wretchedness of his fallen creature. The sentence denounced upon himself and his wife was awful and severe. The woman was doomed to sorrow in conception; the man to sorrow and travel all the days of his life. The ground was cursed for his sake; and the end of the judgment was, "Dust thou art, and to dust thou shalt return." Had our first parents been thus left, they must have looked upon themselves as rejected by their Maker, delivered up to trouble and sorrow in the world, and as having no hope in any other. With such impressions on their minds they could have retained no sense of religion; for religion, when unaccompanied by hope, is a state of frenzy and distraction: yet it is certain that they could have no hope from any thing expressly recorded by Moses, except what they might draw from this sentence passed on their deceiver. Let us then endeavour to ascertain what consolation it could afford them.

At that awful juncture, they must have been sensible that their fall was the victory of the serpent, whom by experience they had found to be an enemy to God and to man. It could not therefore but be some comfort to them to hear this enemy first condemned, and to see that, however he had prevailed against them, he had gained no victory over their Maker. By this condemnation they were secured from thinking that there was any malignant being equal to the Creator in power and dominion; an opinion which, through the prevalency of evil, gained ground in after times, and was destructive of all true religion. The belief of God's supreme dominion being thus preserved, it was still necessary to give them such hopes as might induce them to love as well as to fear him; and these they could not but conceive when they heard from the mouth of their Creator and Judge, that the serpent's victory was not complete even over themselves; that they and their posterity should be enabled to contest his empire; and that though they were to suffer much in the struggle, they should yet finally prevail, bruise the serpent's head, and deliver themselves from his power and dominion.

This prophecy therefore was to our first parents a light shining in a dark place. All that they could certainly conclude from it was, that their case was not desperate; that some remedy, some deliverance from the evil they were under, would in time appear; but *when* or *where*, or by *what means* they were to be delivered, they could not possibly understand, unless the matter was further revealed to them, as probably it was at the institution of sacrifice (see SACRIFICE). Obscure, however, as this promise or prophecy was, it served after the fall as a foundation for religion, and trust and confidence towards God in hopes of deliverance in time from the evils of disobedience: and this appears to have been the sole purpose for which it was given, and not, as some well-meaning though weak advocates for Christianity have imagined, as a prediction pointing *directly* to the cross of Christ.

As this prophecy was the first, so is it the only considerable one in which we have any concern from the creation to the days of Noah. It was proportioned to the then wants and necessities of the world, and was the grand charter of God's mercy after the fall. Nature had no certain help for sinners; her rights were lost with her innocence. It was therefore necessary either to destroy the offenders, or to raise them to a capacity of salvation, by giving them such hopes as might enable them to exercise a reasonable religion. So far the light of this prophecy extended. By what *means* God intended to work their salvation, he did not expressly declare: and who has a right to complain that he did not, or to prescribe to him rules in dispensing his mercy to the children of men?

11
The curse removed from the ground.

Upon the hopes of mercy which this prophecy gives in very general terms, mankind rested till the birth of Noah. At that period a new prophecy was delivered by Lamech, who foretels that his son should comfort them concerning the work and toil of their hands, "because of the *earth which the Lord had cursed.*" We are to remember that the curse pronounced upon the earth was part of the sentence passed upon our first parents; and when that part was remitted, if it ever was remitted, mankind would acquire new and more lively hopes that in God's good time they should be freed from the whole. But it has been shown by Bishop Sherlock*, that this declaration of Lamech's was a prediction, that during the life of his son the curse should be taken off from the earth: and the same prelate has proved with great perspicuity, and in the most satisfactory manner, that this happy revolution actually took place after the flood. The limits prescribed to an article of this kind will not permit us even to abridge his arguments. We shall only observe, that the truth of his conclusion is manifest from the very words of scripture; for when God informs Noah of his design to destroy the world, he adds, "But with thee will I establish my covenant:" and as soon as the deluge was over, he declared that he "would not again curse the ground any more for man's sake; but that while the earth should remain, seed-time and harvest, and cold and heat, and summer and winter, and day and night, should not cease." From this last declaration it is apparent that a curse *had* been on the earth, and that seed-time and harvest had often failed; that the curse was now taken off; and that in consequence of this covenant, as it is called, with Noah and his seed and with every living creature, mankind should not henceforth be subjected to toil so severe and so generally fruitless.

* *Use and Intent of Prophecy.*

12
A future life not then explicitly revealed.

It may seem surprising perhaps to some, that after so great a revolution in the world as the deluge made, God should say nothing to the remnant of mankind of the punishments and rewards of another life, but should make a new covenant with them relating merely to fruitful seasons and the blessings of the earth. But in the scriptures we see plainly a gradual working of providence towards the redemption of the world from the curse of the fall; that the temporal blessings were first restored as an earnest and pledge of better things to follow; and that the covenant given to Noah had, strictly speaking, nothing to do with the hopes of futurity, Prophecy. ty, which were reserved to be the matter of another covenant, in another age, and to be revealed by him, whose province it was to "bring life and immortality to light through the gospel." But if Noah and his forefathers expected deliverance from the whole curse of the fall, the actual deliverance from one part of it was a very good pledge of a further deliverance to be expected in time. Man himself was cursed as well as the ground; he was doomed to dust: and fruitful seasons are but a small relief compared to the greatness of his loss. But when fruitful seasons came, and one part of the curse was evidently abated, it gave great assurance that the other should not last for ever, but that by some means, still unknown to them, they should be freed from the whole, and finally bruise the serpent's head, who, at the deluge, had so severely bruised man's heel.

Upon this assurance mankind rested for some generations, and practised, as we have every reason to believe, a rational worship to the one God of the universe. At last, however, idolatry was by some means or other introduced (see POLYTHEISM), and spread so universally through the world, that true religion would in all probability have entirely failed, had not God visibly interposed to preserve such a sense of it as was necessary for

13 Promise to Abraham.

the accomplishment of his great design to restore mankind. This he did by calling Abraham from amidst his idolatrous kindred, and renewing to him the word of prophecy: "Get thee out of thy country (said he), and from thy kindred, and from thy father's house, unto a land that I will shew thee. And I will make of thee a great nation, and I will bless thee, and make thy name great; and thou shalt be a blessing. And I will bless them that bless thee, and curse him that curseth thee; and in thee shall all the families of the earth be blessed." These magnificent promises are several times repeated to the father of the faithful, with additional circumstances of great importance, such as, "that he should be multiplied exceedingly; that he should be a father of many nations; that kings should come out of him;" and above all, that God would establish an *everlasting covenant* with him and his seed, to give him and them all the land of Canaan for an *everlasting possession*, and to be *their God*."

Upon such of these promises, as relate to temporal blessings we need not dwell. They are much of the same nature with those which had been given before to Lamech, Noah, Shem, and Japheth; and all the world knows how amply and literally they have been fulfilled. There was, however, so little probability in nature of their accomplishment at the time when they were made, that we find the patriarch asking, "Whereby he should *know* † that he should inherit such an extent of country?" And as the promises that he should inherit it were found to be a foundation for religion and confidence in God, a miraculous sign was given him that they came indeed from the spirit of truth. This removed from his mind every doubt, and made him give the fullest credit, not only to them, but also to that other promise, "that in his seed should all the nations of the earth be blessed."

† Genesis xv. 8. &c.

What distinct notion he had of this blessing, or in what manner he hoped it should be effected, we cannot pretend to say. "But that he understood it to be a promise of restoring mankind, and delivering them from the remaining curse of the fall, there can be no doubt. He knew that death had entered by sin; he knew that God had promised victory and redemption to the seed of the woman. Upon the hopes of this restoration the religion of his ancestors was founded; and when God, from whom this blessing on all men was expected, did expressly promise a blessing on all men, and in this promise founded his everlasting covenant—what could Abraham else expect but the completion in his seed of that ancient promise and prophecy concerning the victory to be obtained by the woman's seed? The curse of the ground was expiated in the flood, and the earth restored with a blessing, which was the foundation of the temporal covenant with Noah; a large share of which God expressly grants to Abraham and his posterity particularly, together with a promise to bring, by their means, a new and further blessing upon the whole race of men. If we lay these things to heart, we cannot suppose that less could be expected from the new promise or prophecy given to Abraham than a deliverance from that part of the curse still remaining on men: *Dust thou art, and to dust thou shalt return.* In virtue of this covenant Abraham and his posterity had reason to expect that the time would come when man should be called from his dust again. For this expectation they had his assurance who gave the covenant, that he would be their God for ever. Well might our Saviour then tell the sons of Abraham, that even Moses at the bush showed the resurrection of the dead, when he called the Lord the God of Abraham, and the God of Isaac, and the God of Jacob *."

* Sherlock's *Use and Intent of Prophecy*.

14 To Isaac and Jacob.

These promises made to Abraham were renewed to Isaac and Jacob; to the last of whom it was revealed, not only that all the nations of the earth should be blessed in his seed, but that the blessing should spring from his son Judah. It is, however, by no means evident that any one of those patriarchs knew precisely by what *means* (A) the curse of the fall was to be entirely removed, and all men called from their dust again. It was enough that they were convinced of the fact in general terms, since such conviction was a sufficient foundation of a rational religion; and the descendants of Abraham had no other foundation upon which to rest their

(A) This they certainly could not know from the promises expressed in the very general terms in which they are recorded in the book of Genesis. It is, however, not improbable that those promises, as they immediately received them, were conceived in terms more precise and particular; and, at all events, Dr Warburton has proved to the full conviction of every man who is not a determined unbeliever, that Abraham was commanded to sacrifice his son Isaac, not only as a trial of his obedience, but also that God might give him what he earnestly desired, a scenical representation of the means by which mankind were to be redeemed from death. The learned writer thinks, and his reasoning compels us to think with him, that to this transaction our Saviour alludes when he says, "Your father Abraham rejoiced to see my *day*, and he saw it and was glad."

Prophecy. their hopes, and pay a cheerful worship to the God of their fathers, till the giving of the law to Moses. Then

15
The law of Moses and the succeeding prophets.

indeed they were incorporated into a society with municipal laws of their own, and placed under a theocratic government; the temporal promises made to their fathers were amply fulfilled; religion was maintained among them by rewards and punishments equally distributed in this world (see THEOLOGY): and a series of prophets succeeding one another pointed out with greater and greater clearness, as the fulness of time approached, the person who was to redeem mankind from the power of death; by what means he was to work that great redemption, and at what precise period he was to make his appearance in the world. By these supernatural interpositions of divine providence, the principles of pure theism and the practice of true religion were preserved among the children of Israel, when all other nations were sunk in the grossest idolatry, and wallowed in the most abominable vices; when the far-famed Egyptians, Greeks, and Romans, fell down with adoration to stocks and stones and the vilest reptiles; and when they had no well-grounded hope of another life, and were in fact without God in the world.

16
Were all intended to keep alive a sense of religion.

From this short deduction, we think ourselves intitled to conclude, that the *primary* use and intent of prophecy, under the various dispensations of the Old Testament, was not, as is too often supposed, to establish the divine mission of Jesus Christ, but to keep alive in the minds of those to whom it was given, a sense of religion, and a hope of future deliverance from the curse of the fall. It was, in the expressive language of St Peter, "a light that shone in a dark place, unto which men did well to take heed until the day dawned and the day-star arose in their hearts." But though this was certainly the original intent of prophecy (for Christ, had he never been foretold, would have proved himself to be the son of God with power by his astonishing miracles, and his resurrection from the dead), yet it cannot be denied, that a long series of prophecies, given in different and far distant ages, and having all their completion in the life, death, and resurrection, of Jesus, concur very forcibly with the evidence of miracles to prove that he was the seed of the woman ordained to bruise the head of the serpent, and restore man to his forfeited inheritance. To the Jews the force of this evidence must have been equal, if not superior, to that of miracles themselves; and therefore we find the Apostles and first preachers of the gospel, in their addresses to them, constantly appealing to the law and the prophets, whilst they urged upon the Gentiles the evidence of miracles.

17
The prophecies to be considered in connection.

In order to form a right judgment of the argument for the truth of Christianity drawn from the sure word of prophecy, we must not consider the prophecies given in the Old Testament as so many *predictions* only independent of each other; for if we do, we shall totally lose sight of the purpose for which they were originally given, and shall never be able to satisfy ourselves when confronted by the objections of unbelievers. It is easy for men of leisure and tolerable parts to find difficulties in particular predictions, and in the application of them made by writers, who lived many hundred years ago, and who had many ancient books and records of the Jewish church, from which they drew many passages, and perhaps some prophecies; which books and records we have not to enable us to understand, and to justify their applications. But it is not so easy a matter to show, or to persuade the world to believe, that a chain of prophecies reaching through several thousand years, delivered at different times, yet manifestly subservient to one and the same administration of providence from beginning to end, is the effect of art and contrivance and religious fraud. In examining the several prophecies recorded in the Old Testament, we are not to suppose that each of them *expressly* pointed out and *clearly* characterized Jesus Christ. Had they done so, instead of being a support to religion in general, the purpose for which they were originally intended, they would have had a very different effect, by making those to whom they were given repine at being placed under dispensations so very inferior to that of the gospel. We are therefore to inquire only whether all the notices, which, in general and often metaphorical terms, God gave to the fathers of his intended salvation, are perfectly answered by the coming of Christ; and we shall find that nothing has been promised with respect to that subject which has not been performed in the amplest manner. If we examine the prophecies in this manner, we shall find that there is not one of them, which the Apostles have applied to the Messiah, that is not applicable in a rational and important sense to something in the birth, life, preaching, death, resurrection, and ascension of Jesus of Nazareth; that as applied to him they are all consistent with each other; and that though some few of them may be applied without absurdity to persons and events under the Jewish dispensation, Christ is the only person that ever existed in whom they all meet as in a centre. In the limits prescribed us, it is impossible that we should enter upon a particular proof of this position. It has been proved by numberless writers, and, with respect to the most important prophecies, by none with greater success than Bishop Sherlock in his Use and Intent of Prophecy in the several ages of the World; a work which we recommend to our readers as one of the most valuable on the subject in our own or any other language.

18
Objection from the obscurity of prophecy.

But admitting that it would have been improper, for the reason already hinted at, to have given a clear and precise description of Christ, and the Christian dispensation, to men who were ordained to live under dispensations less perfect, how, it may be asked, comes it to pass that many of the prophecies applied by the writers of the gospel to our Saviour and his actions are still dark and obscure, and so far from belonging evidently to him and to him only, that it requires much learning and sagacity to show even now the connection between some prophecies and the events?

19
Answered.

In answer to these questions, the learned prelate just referred to observes, "That the obscurity of prophecy does not arise from hence, that it is a relation or description of something *future*; for it is as easy to speak of things future plainly, and intelligibly, as it is of things past or present. It is not, therefore, of the nature of prophecy to be obscure; for it may easily be made, when he who gives it thinks fit, as plain as history. On the other side, a figurative and dark description of a future event will be figurative and dark still when the event happens; and consequently will have all the obscurity of a figurative and dark description as well after as before the event. The prophet Isaiah describes the peace

peace of Christ's kingdom in the following manner: 'The wolf shall dwell with the lamb, and the leopard shall lie down with the kid, and the calf and the young lion, and the fatling, together, and a little child shall lead them.' Nobody, some modern Jews excepted, ever understood this literally; nor can it now be *literally* applied to the state of the gospel. It was and is capable of different interpretations: it may mean temporal peace, or that internal and spiritual peace—that tranquillity of mind, which sets a man at peace with God, himself, and the world. But whatever the true meaning is, this prophecy does no more obtrude one determinate sense upon the mind since the coming of Christ than it did before. But then we say, the state of the gospel was very properly prefigured in this description, and is as properly prefigured in a hundred more of the like kind; and since they all agree in a fair application to the state of the gospel, we strongly conclude, that this state was the thing foretold under such expressions. So that the argument from prophecy for the truth of Christianity does not rest on this, that the event has necessarily limited and ascertained the particular sense and meaning of every prophecy; but in this, that every prophecy has in a proper sense been completed by the coming of Christ. It is absurd, therefore, to expect clear and evident conviction from every single prophecy applied to Christ; the evidence must arise from a view and comparison of all together." It is doubtless a great mistake to suppose that prophecy was intended solely or chiefly for their sakes in whose time the events predicted are to happen. What great occasion is there to lay in so long beforehand the evidence of prophecy to convince men of things that are to happen in their own times; the truth of which they may, if they please, learn from their own senses? Yet some people are apt to talk as if they thought the truth of the events predicted depended very much on the evidence of prophecy: they speak, for instance, as if they imagined the certainty and reality of our Saviour's resurrection were much concerned in the clearness of the prophecies relating to that great and wonderful event, and seem to think that they are confuting the truth of his resurrection when they are pointing out the absurdity of the prophecies relating to it. But can any thing be more absurd? For what ground or pretence is there to inquire whether the prophecies foretelling that the Messiah should die and rise again do truly belong to Christ, unless we are first satisfied that Christ died and rose again?

The part which unbelievers ought to take in this question, if they would make any use of prophecy, should be, to show from the prophets that Christ was necessarily to rise from the dead; and then to prove that in fact Jesus never did rise. Here would be a plain consequence. But if they like not this method, they ought to let the prophecies alone; for if Christ did not rise, there is no harm done though the prophets have not foretold it. And if they allow the resurrection of Christ, what do they gain by discrediting the prophets? The event will be what it is, let the prophets be what they will.

These considerations show how far the gospel is *necessarily* concerned in prophetical evidence, and how clear the prophecies should be. Christ claims to be the person foretold in the law and the prophets; and as truth must ever be consistent with itself, this claim must be true as well as all others. This is the part then to be tried on the evidence of prophecy: Is Christ that person described and foretold under the Old Testament or not? Whether all the prophecies relating to him be plain or not plain, it matters little; the single question is, Are there enough plain to show us that Christ is the person foretold under the Old Testament? If there be, we are at an end of our inquiry, and want no farther help from prophecy; especially since we have seen the day dawn and enjoyed the marvellous light of the gospel of God.

20 Objections from the clearness of some prophecies,

But so unreasonable are unbelievers, that whilst some of them object to the obscurity of the prophecies, others have rejected them altogether on account of their clearness, pretending that they are histories and not predictions. The prophecies against which this objection has been chiefly urged are those of Daniel, which were first called in question by the famous Porphyry. He affirmed that they were not composed by Daniel, whose name they bear, but by some author who lived in Judea about the time of Antiochus Epiphanes; because all to that time contained true history, but that all the facts beyond that were manifestly false.

21 answered;

This method of opposing the prophecies, as a father of the church rightly observes, is the strongest testimony of their truth: for they are so exactly fulfilled, that to infidels the prophet seemed not to have foretold things future, but to have related things past. To an infidel of this age, if he has the same ability and knowledge of history that Porphyry had, all the subsequent prophecies of Daniel, except those which are still fulfilling, would appear to be history and not prophecy;

22 from what has happened since the objection was first started,

for it entirely overthrows the notion of their being written in the days of *Antiochus Epiphanes*, or of the *Maccabees*, and establishes the credit of Daniel as a prophet beyond contradiction, that there are several of those prophecies which have been fulfilled since that period as well as before; nay, that there are prophecies of Daniel which are fulfilling at this very time in the world.

Our limits will not permit us to enter into the objections which have been made to this prophet by the author of the Literal Scheme of Prophecy considered; nor is there occasion that we should enter into them. They have been all examined and completely answered by Bishop Chandler in his Vindication of his Defence of Christianity, by Mr Samuel Chandler in his Vindication of the Antiquity and Authority of Daniel's Prophecies, and by Bishop Newton in his excellent Dissertations on the Prophecies. To these authors we refer the reader; and shall conclude the present article with a view of some prophecies given in very remote ages, which are in this age receiving their accomplishment.

23 and from facts of the present age.

Of these the first is that of Noah concerning the servitude of the posterity of Canaan. In the greater part of original manuscripts, and in our version of the holy scriptures, this prophecy is thus expressed: "Cursed be Canaan; a servant of servants shall he be unto his brethren:" but in the Arabic version, and in some copies of the Septuagint, it is, "Cursed be *Ham* the father of Canaan; a servant of servants shall he be to his brethren." Whether the curse was really pronounced upon Ham, which we think most probable, or only upon his son Canaan, we shall find the prediction remarkably

ably fulfilled, not barely ages after the book of Genesis was very generally known, but also at this very day. It is needless to inform any man who has but looked into the Old Testament, that when the ancient patriarchs pronounced either a curse or a blessing upon any of their sons, they meant to declare the future fortunes, not of that son individually, but of his descendants as a tribe or a nation. Let us keep this in mind, and proceed to compare with Noah's prophecy *first* the fortunes of the descendants of Canaan, the fourth son of Ham, and then the fortunes of the posterity of Ham by his other sons.

With the fate of the Canaanites every reader is acquainted. They were conquered by Joshua several centuries after the delivery of this prophecy; and such of them as were not exterminated were by him and Solomon reduced to a state of the lowest servitude to the Israelites, the posterity of Shem the brother of Ham. The Greeks and Romans, too, who were the descendants of Japheth, not only subdued Syria and Palestine, but also pursued and conquered such of the Canaanites as were anywhere remaining, as for instance the Tyrians and Carthaginians, of whom the former were ruined by Alexander and the Grecians, and the latter by Scipio and the Romans. Nor did the effects of the curse stop there. The miserable remainder of that devoted people have been ever since slaves to a foreign yoke; first to the Saracens who are descended from Shem, and afterwards to the Turks who are descended from Japheth; and under the Turkish dominion they groan at this day.

If we take the prophecy as it stands in the Arabic version, its accomplishment is still more remarkable. The whole continent of Africa was peopled principally by the posterity of Ham. And for how many ages have the better parts of that country lain under the dominion first of the Romans, then of the Saracens, and now of the Turks? In what wickedness, ignorance, barbarity, slavery, and misery, live most of its inhabitants? and of the poor negroes how many thousands are every year sold and bought like beasts in the market, and conveyed from one quarter of the world to do the work of beasts in another; to the full accomplishment indeed of the prophecy, but to the lasting disgrace of those who are from the love of gain the instruments of fulfilling it. Nothing can be more complete than the execution of the sentence as well upon Ham as upon Canaan; and the hardiest infidel will not dare to say that it was pronounced after the event.

The next prophecy which we shall notice is that of Abraham concerning the multitude of his descendants; which every one knows is still fulfilled in the Jews even in their dispersed state, and therefore cannot have been given after the event of which it speaks.

Of the same kind are the several prophecies concerning Ishmael; of which some have been fulfilled, and others are at present fulfilling in the most astonishing manner. Of this son of Abraham it was foretold, that "he should be a wild man; that his hand should be against every man, and every man's hand against him; that he should dwell in the presence of all his brethren; that he should be multiplied exceedingly, beget twelve princes, and become a great nation." The sacred historian who records these prophecies adds, that "God was with the lad, and he grew, and dwelt in the wilderness, and became an archer."

To show how fully and literally all these prophecies have been accomplished, would require more room than we have to bestow; and to the reader of history the labour would be superfluous. We shall therefore only request the unbeliever to attend to the history of the Arabs, the undoubted descendants of Ishmael; and to say how it comes to pass, that though they have been robbers by land and pirates by sea for time immemorial, though their hands have been against every man, and every man's hand against them, they always have dwelt, and at this day dwell, in the presence of their brethren, a free and independent people. It cannot be pretended that no attempt has ever been made to conquer them; for the greatest conquerors in the world have all in their turns attempted it: but though some of them made great progress, not one was ever crowned with success. It cannot be pretended that the inaccessibleness of their country has been their protection; for their country has been often penetrated, though it never was entirely subdued. When in all human probability they have been on the brink of ruin, they were signally and providentially delivered. Alexander was preparing an expedition against them, when he was cut off in the flower of his age. Pompey was in the career of his conquests when urgent affairs called him elsewhere. Ælius Gallus had penetrated far into their country, when a fatal disease destroyed great numbers of his men, and obliged him to return. Trajan besieged their capital city, but was defeated by thunder and lightning and whirlwinds. Severus besieged the same city twice, and was twice repelled from before it. The Turks, though they were able to wrest from them their foreign conquests, have been so little able to subdue the Arabs themselves, or even to restrain their depredations, that they are obliged to pay them a sort of annual tribute for the safe passage of the pilgrims who go to Mecca to pay their devotions. On these facts we shall not exclaim. He who is not struck upon comparing the simple history of this singular people with the prophecies so long ago delivered of them and their great ancestor, whose love of liberty is compared to that of the wild ass, would rise wholly unmoved from our exclamations. 14

The dispersion of the Jews plainly foretold.

A fourth prophecy of this kind, which cannot be alleged to have been uttered after the event, is the denunciation of Moses against the children of Israel in case of their disobedience; which is so literally fulfilled, that even at this moment it appears rather a history of the present state of the Jews, than a remote prediction of their apostasy and punishment. "And the Lord shall scatter thee among all people from the one end of the earth even unto the other. And among these nations shalt thou find no ease, neither shall the sole of thy foot have rest; but the Lord shall give thee there a trembling heart and falling of eyes, and sorrow of mind. And thy life shall hang in doubt before thee; and thou shalt fear day and night, and shall have none assurance of thy life," (Deut. xxviii. 64, 65, 66.). "And thou shalt become an astonishment, a proverb, and a bye-word, among all nations, whither the Lord shall lead you." (Deut. xxviii. 37.).

Similar to this denunciation, but attended with some circumstances still more wonderful, is the following prediction of the prophet Hosea: "The children of Israel shall abide many days without a king, and without a prince, and without a sacrifice, and without an image,

and

and without an ephod, and without teraphim. Afterwards shall the children of Israel return, and seek the Lord their God, and David their king; and shall fear the Lord and his goodness in the latter days (B)." In this passage we find the state of the Jews for the last 1700 years clearly and distinctly described with all its circumstances. From the time that they rejected their Messiah all things began to work towards the destruction of their politics both civil and religious; and within a few years from his death, their city, temple, and government, were utterly ruined; and they themselves not carried into a gentle captivity, to enjoy their laws, and live under governors of their own, as they did in Babylon, but they were sold like beasts in a market, and became slaves in the strictest sense; and from that day to this have had neither prince nor chief among them. Nor will any one of them ever be able, after all their pretences, to prove his descent from Aaron, or to say with certainty whether he is of the tribe of Judah or of the tribe of Levi, till he shall discover that unknown country where never mankind dwelt, and where the apocryphal Esdras has placed their brethren of the ten tribes. This being the case, it is impossible they can have either an altar, or a sacrifice, or a priesthood, according to the institution of Moses, but are evidently an outcast people living under laws which cannot be fulfilled.

25 nd the ause of it.

The cause of this deplorable condition is likewise assigned with the same perspicuity: They are scattered over the face of the earth, because they do not acknowledge Christ for the Messiah; because they do not submit to their own king, the true David. In the prophetic writings the name of David is frequently given to the Messiah, who was to descend from that prince. Thus Ezekiel, speaking of the kingdom of Christ, says, "I will set up one Shepherd over them, and he shall feed them, even my servant David; he shall feed them, and he shall be their shepherd." And Jeremiah says, "They shall serve the Lord their God, and David their king, whom I will raise up unto them."

That in these places, as well as in the passage under consideration, the Messiah is meant, is undeniable; for David the son of Jesse was dead long before any of the three prophets was born; and by none of them it is said "afterwards David their king shall come again;" but "afterwards the children of Israel *shall* return to David their king," they shall recover from their blind infatuation, and seek him whom they have not yet known. By their not receiving Jesus for their Christ, they have forfeited all claim to the divine favour, and are, of consequence, "without a king, and without a chief, and without a sacrifice, and without an altar, and without a priesthood."

26 eir re- n also ;told.

The time, however, will come, when they shall return and seek "the Lord their God and David their king;" when they shall tremble before him whom their fathers crucified, and honour the son even as they honour the father. That this part of the prophecy will in time be as completely fulfilled as the other has been, may be confidently expected from the wonderful preservation of the Jews for so many ages. Scattered as they are over the whole earth, and hated as they are by all nations, it might naturally be thought, that in process of time they would have coalesced with their conquerors, and have been ultimately absorbed and annihilated by their union, so that no trace of them should now have remained; yet the fact is, that, dispersed as they have ever since been over the whole face of the globe, they have never, in a single instance, in any country, lost their religious or natural distinctions; and they are now generally supposed to be as numerous as they were under the reigns of David and Solomon. This is contrary to all history, and all experience of the course of human affairs in similar cases; it has been boldly and justly styled a standing miracle. Within 1000 or 1200 years back, a great variety of extraordinary and important revolutions have taken place among the nations of Europe. In the southern part of this island the Britons were conquered by the Saxons, the Saxons by the Danes, and the Danes and Saxons by the Normans; but in a few centuries these opposite and hostile nations were consolidated into one indistinguishable mass. Italy, about the same time that Britain was subdued by the Saxons, was conquered by the Goths and Vandals: and it is not easy to conceive a more striking contrast than that which subsisted between the polished inhabitants of that delightful country and their savage invaders; and yet how soon did all distinction cease between them! In France, the Roman colonies gradually assimilated with the ancient Gauls; and in Spain, though the Moors continued for several ages, and till their final expulsion, a distinct people, yet after they were once reduced to a state of subjection, their numbers very sensibly diminished; and such of them as were suffered to remain after their last overthrow have been long since so blended with the Spaniards that they cannot now be distinguished. But with regard to the Jews, the wonder is, that though they do not in any country where they are settled bear any proportion to the natural inhabitants, though they are universally reduced to a state of the lowest subjection, and even exposed to hatred, contempt, and persecution; yet in no instance does there seem to be the least appearance or probability of their numbers being diminished, in no instance do they discover any decay of attachment to their religious principles. Whence then comes it that this people alone, who, having no form of government or a republic anywhere subsisting, are without the means by which other people are kept united and distinct, should still be preserved amongst so many different nations? How comes it, when they have been thus scattered into so many distant corners, like dust which cannot be perceived, that they should still so long survive the dissolution of their own state, as well as that of so many others! To these questions the answer is obvious: They are

(B) Such is our translation of this remarkable prophecy; but the Greek version of the Seventy has it, perhaps more properly, thus: "The children of Israel shall abide many days without a king, and without a chief, and without a sacrifice, and without an altar, and without a priesthood, and without prophecies. Afterwards," &c.

Prophecy, Prophet. are preserved, that, as a nation, "they may return and seek the Lord their God and David their king, and fear the Lord and his goodness in the latter days."

27
Of prophecies respecting the Christian church.

We might here subjoin many prophecies both from the Old and the New Testament, and especially from the writings of St Paul and St John, which so clearly describe the various fortunes of the Christian church, her progress to that state of general corruption under which she was sunk three centuries ago, and her gradual restoration to her primitive purity, that they cannot be supposed to proceed from the cunning craftiness of men, or to have been written after the events of which they speak. To do justice to these, however, would require a volume, and many excellent volumes have been written upon them. The reader who wishes for satisfaction on so interesting a subject will do well to consult the writings of Mr Mede and Sir Isaac Newton, together with Bishop Newton's Dissertations, and the Sermons of Hurd, Halifax, and Bagot, preached at Warburton's lecture. We shall only observe, that one of the ablest reasoners that Great Britain ever produced, after having paid the closest attention to the predictions of the New Testament, hath been bold enough to put the truth of revealed religion itself upon the reality of that prophetic spirit which foretold the desolation of Christ's church and kingdom by antichrist. "If (says he), IN THE DAYS OF ST PAUL AND ST JOHN, there was any footstep of such a sort of power as this in the world; or if there HAD BEEN any such power in the world; or if there WAS THEN any appearance or probability that could make it enter into the heart of man to imagine that there EVER COULD BE any such kind of power in the world, much less in the *temple* or *church of God;* and if there be not NOW such a power actually and conspicuously exercised in the world; and if any picture of this power, DRAWN AFTER THE EVENT, can now describe it more plainly and exactly than it was originally described in the words of the prophecy—then may it, with some degree of plausibility, be suggested, that the prophecies are nothing more than enthusiastic imaginations."

Upon the whole, we conclude with Bishop Sherlock, that the various prophecies recorded in the Holy Scriptures were given, not to enable man to foresee with clearness future events, but to support the several dispensations of religion under which they were respectively promulgated. The principal prophecies recorded in the Old Testament led mankind to hope for a complete deliverance from the curse of the fall; and therefore tended to fill their minds with gratitude, and to enforce a cheerful obedience to that God who in the midst of judgment remembereth mercy. The prophecies, whether in the Old or New Testament, that pourtray the present state of the Jews, and the various fortunes of the Christian church, as they are daily fulfilling in the presence of all men, are the strongest possible proof of the divinity of our holy religion, and supply to us in the latter-days the place of miracles, by which it was at first established.

PROPHET, in general, a person who foretels future events; but is particularly applied to such inspired persons among the Jews as were commissioned by God to declare his will and purposes to that people. Among the canonical books of the Old Testament we have the writings of 16 prophets, four of whom are denominated the *greater prophets*, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length and extent of their writings, which exceed those of the others, viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Haggai, Zechariah, and Malachi, who are called the *lesser prophets*, from the shortness of their writings. The Jews do not place Daniel among the prophets, because, they say, he lived the life of a courtier rather than that of a prophet. An account of the several writings of the prophets may be seen each under its particular head. See the article ISAIAH, &c.

Sons of the PROPHETS, in scripture history, an appellation given to young men who were educated in the schools or colleges under a proper master, who was commonly, if not always, an inspired prophet, in the knowledge of religion and in sacred music, and thus were qualified to be public preachers; which seems to have been part of the business of the prophets on the Sabbath days and festivals. It is probable that God generally chose the prophets, whom he inspired, out of these schools. See PROPHECY.

PROPITIATION, in *Theology*, a sacrifice offered to God to assuage his wrath and render him propitious. Among the Jews there were both ordinary and public sacrifices, as holocausts, &c. offered by way of thanksgiving; and extraordinary ones, offered by particular persons guilty of any crime, by way of propitiation. The Romish church believe the mass to be a sacrifice of propitiation for the living and the dead. The reformed churches allow of no propitiation but that one offered by Jesus Christ on the cross. See SACRIFICE.

PROPITIATORY, any thing rendering God propitious; as we say *propitiatory* sacrifices, in contradistinction to sacrifices which were *eucharistical*. Among the Jews the propitiatory was the cover or lid of the ark of the covenant; which was lined both within and withoutside with plates of gold, insomuch that there was no wood to be seen. This propitiatory was a type or figure of Christ, whom St Paul calls the propitiatory ordained from all ages. See *Ark of the Covenant*.

PROPOLIS, the name of a certain substance more tenacious than wax, with which the bees stop up all the holes or cracks in the side of their hives. See BEE, N° 13.

PROPONTIS, or SEA of MARMORA, a part of the Mediterranean, dividing Europe from Asia; it has the Hellespont or canal of the Dardanelles to the south-west, whereby it communicates with the Archipelago, and the ancient Bosphorus of Thrace, or strait of Constantinople, to the north-east, communicating with the Black or Euxine sea. It has two castles: that on the Asia side is on a cape, where formerly stood a temple of Jupiter. The castle of Europe is on an opposite cape, and had anciently a temple of Serapis. It is 120 miles long, and in some places upwards of 40 miles broad.

PROPORTION, the identity or similitude of two ratios. Hence quantities that have the same ratio between them are said to be proportional; *e. gr.* if A be to B as C to D, or 8 be to 4 as 30 to 15; A, B, C, D, and 8, 4, 30, and 15, are said to be in proportion, or are simply called proportionals. Proportion is frequently confounded with ratio; yet have the two in reality very different ideas, which ought by all means to be distinguished. Ratio is properly the relation or habitude

tude of two things, which determines the quantity of one from the quantity of another, without the intervention of any third: thus we say the ratio of 5 and 10 is 2, the ratio of 12 and 24 is 2. Proportion is the sameness or likeness of two such relations; thus the relations between 5 and 10 and 12 and 24 being the same, or equal, the four terms are said to be in proportion. Hence ratio exists between two numbers, but proportion requires at least three. Proportion, in fine, is the habitude or relation of two ratios when compared together; as ratio is of two quantities. See ALGEBRA, ARITHMETIC, and GEOMETRY.

Arithmetical and Geometrical PROPORTION. See PROGRESSION.

Inordinate PROPORTION, is where the order of the terms compared is disturbed or irregular. As, for example, in two ranks of numbers, three in each rank,

viz. in one rank, - - 2, 3, 9,
and in the other, - - 8, 24, 36,

which are proportional, the former to the latter, but in a different order, viz. - 2 : 3 : : 24 : 36,
and - - - 3 : 9 : : 8 : 24,
then; casting out the mean terms in each rank it is concluded that - - 2 : 9 : : 8 : 36,
that is, the first is to the third in the first rank, as the first is to the third in the second rank.

Harmonical or *Musical* PROPORTION, is a kind of numeral proportion formed thus: of three numbers, if the first be to the third as the difference of the first and second to the difference of the second and third; the three numbers are in harmonical proportion.

Thus 2, 3, 6, are harmonical, because 2 : 6 : : 1 : 3. So also four numbers are harmonical, when the first is to the fourth as the difference of the first and second to the difference of the third and fourth.

Thus 24, 16, 12, 9, are harmonical, because 24 : 9 : : 8 : 3. By continuing the proportional terms in the first case, there arises an harmonical progression or series.

1. If three or four numbers in harmonical proportion be multiplied or divided by the same number; the products or quotients will also be in harmonical proportion: thus, if 6, 8, 12, which are harmonical, be divided by 2, the quotients 3, 4, 6, are also harmonical; and reciprocally the products by 2, viz. 6, 8, 12.

2. To find an harmonical mean between two numbers given; divide double the product of the two numbers by their sum, the quotient is the mean required; thus suppose 3 and 6 the extremes, the product of these is 18, which doubled gives 36; this divided by 9 (the sum of 3 and 6) gives the quotient 4. Whence 3, 4, 6, are harmonical.

3. To find a third harmonical proportion to two numbers given.

Call one of them the first term, and the other the second; multiply them together, and divide the product by the number remaining after the second is subtracted from double the first; the quotient is a third harmonical proportional: thus, suppose the given terms 3, 4, their product 12 divided by 2 (the remainder after 4 is taken from 6, the double of the first), the quotient is 6, the harmonical third sought.

4. To find a fourth harmonical proportion to three terms given; multiply the first into the third, and divide the product by the number remaining after the middle or second is subtracted from double the first; the quotient is a third harmonical proportion; thus supposing the numbers 9, 12, 16, a fourth will be found by the rule to be 24.

5. If there be four numbers disposed in order, whereof one extreme and the two middle terms are in arithmetical proportion; and the same middle terms with the other extreme are in harmonical proportion; the four are in geometrical proportion; as here 2 : 3 : : 4 : 6, which are geometrical; whereof 2, 3, 4, are arithmetical, and 3, 4, 6, are harmonical.

6. If betwixt any two numbers you put an arithmetical mean, and also an harmonical one, the four will be in geometrical proportion: thus betwixt 2 and 6 an arithmetical mean is 4, and an harmonical one 3; and the four 2 : 3 : : 4 : 6, are geometrical.

We have this notable difference between the three kinds of proportion, arithmetical, harmonical, and geometrical; that from any given number we can raise a continued arithmetical series increasing *in infinitum*, but not decreasing: the harmonical is decreasable *in infinitum*, but not increasable; the geometrical is both.

PROPORTION, or *Rule of Three*. See ARITHMETIC.

Reciprocal PROPORTION. See RECIPROCAL.

PROPORTION is also used for the relation between unequal things of the same kind, whereby their several parts correspond to each other with an equal augmentation or diminution.

Thus, in reducing a figure into little, or in enlarging it, care is taken to observe an equal diminution or enlargement through all its parts; so that if one line, *e. gr.* be contracted by one-third of its length, all the rest shall be contracted in the same proportion.

PROPORTION, in *Architecture*, denotes the just magnitude of the members of each part of a building, and the relation of the several parts of the whole; *e. gr.* of the dimensions of a column, &c. with regard to the ordonnance of the whole building.

One of the greatest differences among architects, M. Perrault observes, is in the proportion of the heights of entablatures with respect to the thickness of the columns, to which they are always to be accommodated.

In effect, there is scarcely any work, either of the ancients or moderns, wherein this proportion is not different; some entablatures are even near twice as high as others:—yet it is certain this proportion ought of all others to be most regulated; none being of greater importance, as there is none in which a defect is sooner seen, nor any in which it is more shocking.

Compass of PROPORTION, a name by which the French, and after them some English, authors call the SECTOR.

PROPORTIONAL, relating to proportion. Thus we say, proportional compasses, parts, scales, spirals, &c.

PROPORTIONALS, in *Geometry*, are quantities, either linear or numeral, which bear the same ratio or relation to each other.

PROPOSITION, in *Logic*, part of an argument, wherein some quality, either negative or positive, is attributed to a subject.

PROPOSITION, in *Mathematics*, is either some truth advanced and shown to be such by demonstration, or some operation proposed and its solution shown. If the proposition

proposition be deduced from several theoretical definitions compared together, it is called a *theorem*; if from a praxis, or series of operations, it is called a *problem*. See the articles THEOREM and PROBLEM.

PROPOSITION, in *Oratory*. See ORATORY, N° 28. 124.

PROPOSITION, in *Poetry*, the first part of a poem, wherein the author proposes briefly, and in general, what he is to say in the body of his work. It should comprehend only the matter of the poem, that is, the action and persons that act. Horace prescribes modesty and simplicity in the proposition, and would not have the poet promise too much, nor raise in the reader too great ideas of what he is going to relate.

PROPREFECT, among the Romans, the prefect's lieutenant, or an officer whom the prefect of the pretorium commissioned to do part of his duty in his place.

PROPRETOR, a Roman magistrate, who, having discharged the office of pretor at home, was sent into a province to command there with his former pretorial authority. It was also an appellation given to those who, without having been pretors at Rome, were sent extraordinarily into the provinces to administer justice with the authority of pretors.

PROPRIETOR, or PROPRIETARY, is he who possesses any thing as his own in the utmost degree. Such monks were called *proprietary* as had reserved goods and effects to themselves, notwithstanding their formal renunciation of all at the time of their profession. They are frequently mentioned in the *Monast. Anglic.* &c. and were to be very severely dealt with; to be excommunicated, deprived of burial, &c. *Monachi proprietarii excommunicentur ab abbatibus: et, si in morte proprietarius inventus fuerit, ecclesiastica careat sepultura*, &c. Addit. ad Matt. Par.

PRO RATA, in commerce, a term sometimes used by merchants for *in proportion;* as, each person must reap the profit or sustain the loss, *pro rata* to his interest, that is, in proportion to his stock.

PROROGATION, the act of prolonging, adjourning, or putting off, to another time. The difference between a prorogation and an adjournment of parliament is, that by prorogation the session is ended, and such bills as passed in either house, or both houses, and had not the royal assent, must at the next assembly begin again.

PROSCRIPTION, a publication made in the name of the chief or leader of a party, whereby he promises a reward to any one who shall bring him the head of one of his enemies.

Sylla and Marius by turns proscribed each others adherents.—Under the triumvirate great part of the best and bravest of the Romans fell by proscription.

The term took its rise from the practice of writing down a list of the persons names, and posting it in public; from *pro* and *scribo*, "I write."

PROSE, the natural language of mankind, loose and unconfined by poetical measures, rhymes, &c. In which sense it stands opposed to verse.

There is, however, a species of prose which is measured, such as that in which epitaphs and other inscriptions are generally written; and indeed every man who has formed for himself a style writes in uniform periods regularly recurring. It has been much disputed whether a poem can be written in prose. We enter not into that dispute, as we have said enough on the subject elsewhere. See NOVEL.

The word *prose* comes from the Latin *prosa*, which some will have derived from the Hebrew *poras*, which signifies *expendit:* others deduce it from the Latin *prorsa*, of *prorsus*, "going forwards:" by way of opposition to *versa*, or "turning backwards," as is necessary in writing.

PROSECUTION, in the criminal law. The next step towards the punishment of offenders after COMMITMENT, is their prosecution, or the manner of their formal accusation. And this, in the English law, is either upon a previous finding of the fact by an inquest or grand jury; or without such previous finding.

The former way is either by PRESENTMENT or INDICTMENT. See these articles.

The remaining methods of prosecution are without any previous finding by a jury, to fix the authoritative stamp of verisimilitude upon the accusation. One of these, by the common law, was when a thief was taken *with the mainour*, that is, with the thing stolen upon him, *in manu*. For he might, when so detected, *flagrante delicto*, be brought into court, arraigned, and tried, without indictment: as by the Danish law he might be taken and hanged upon the spot without accusation or trial. But this proceeding was taken away by several statutes in the reign of Edward III. though in Scotland a similar process remains to this day. So that the only species of proceeding at the suit of the king, without a previous indictment or presentment by a grand jury, now seems to be that of INFORMATION; which see.

These are all the methods of prosecution at the suit of the king. There yet remains another, which is merely at the suit of the subject, and is called an APPEAL. See that article.

But of all the methods of prosecution, that by indictment is the most general. See INDICTMENT.

PROSECUTOR, in *Law*, he that pursues a cause in another's name.

PROSELYTE, a new convert to some religion or religious sect.

PROSERPINACA, a genus of plants belonging to the triandria class, and in the natural method ranking under the 15th order, *Inundatæ*. See BOTANY *Index*.

PROSERPINE, in fabulous history, the daughter of Jupiter and Ceres, was carried off by Pluto as she was gathering flowers with her companions. Ceres, disconsolate for the loss of her daughter, after having long sought her, heard where she was, and intreated Jupiter to let her return from hell. This request Jupiter granted, on condition she had tasted nothing in Pluto's dominions. Ceres therefore went to fetch her; but when her daughter was preparing to return, Ascalaphus gave information that he had seen Proserpine eat some grains of a pomegranate she had gathered in Pluto's garden; on which she was sentenced to continue in Tartarus in quality of Pluto's spouse, and the queen of those gloomy regions: but to mitigate the grief of Ceres for her disappointment, Jupiter granted that her daughter should only spend six months together in hell with her husband, and the other six on earth with her mother.

Some mythologists imagine that the latter part of the fable

fable alludes to the corn, which must remain all the winter hid in the earth, in order to sprout forth in the spring, and produce the harvest.

PROSEUCHE, in antiquity, properly signifies *prayer;* but it is taken for the places of prayer of the Jews, and was pretty near the same as their synagogues. But the synagogues were originally in the cities, and were covered places: whereas, for the most part, the proseuches were out of the cities, and on the banks of rivers; having no covering except perhaps the shade of some trees or covered galleries. The word is Greek, προσευχη, prayer.

PROSLAMBANOMENE, the name of a musical note in the Greek system.

As the two tetrachords of the Greeks were conjunctive, or, in other words, as the highest note of the first served likewise for the lowest note of the second, it is plain that a complete octave could not be formed. To remedy this deficiency, therefore, one note beneath the lowest tetrachord was added, as an octave to the highest of the last tetrachord. Thus, if we suppose the first to have begun on B, the last must have ended upon A, to which one note subjoined immediately beneath the lowest B in the diatonic order must have formed an octave. This note was called *proslambanomene.* But it appears from authors who have scrutinized antiquity with some diligence, and perhaps with as much success as the data upon which they proceeded could produce, that the names of the notes in the Greek system, which originally signified their natural station in the scale of ascending or descending sounds, were afterwards applied to their positions in the lyre. *Higher* or *lower*, then, according to this application, did not signify their degrees of acuteness or gravity, but their higher or lower situation upon this instrument.

Burney's History of Music, Dissert. i.

PROSODY, that part of grammar which treats of the quantities and accents of syllables, and the manner of making verses.

The English prosody turns chiefly on two things, numbers and rhyme. See POETRY, N° 66—76. and Part III.

PROSOPIS, in *Botany*, a genus of the monogynia order, belonging to the dodecandria class of plants. The calyx is hemispherical and quadridentate; the stigma is simple; the legumen inflated and monospermous. See BOTANY *Index*.

PROSOPOPOEIA, a figure in oratory, whereby we raise qualities of things inanimate into persons. See ORATORY.

PROSTATÆ, in *Anatomy*, a gland, generally supposed to be two separate bodies, though in reality but one, situated just before the neck of the bladder, and surrounding the beginning of the urethra. See ANATOMY *Index*.

PROSTYLE, in *Architecture*, a range of columns in the front of a temple.

PROTAGORAS, a famous Greek philosopher, was born at Abdera. In his youth, his poverty obliged him to submit to the servile office of frequently carrying logs of wood from the neighbouring fields to Abdera. It happened that as he was one day going on briskly towards the city under one of these loads, he was met by Democritus, who was particularly struck with the neatness and regularity of the bundle. Desiring him to stop and rest himself, Democritus examined more closely the structure of the load, and found that it was put together with mathematical exactness; upon which he asked the youth whether he himself had made it up. Protagoras assured him that he had; and immediately taking it to pieces, with great ease replaced every log in the same exact order as before. Democritus expressed much admiration of his ingenuity; and said to him, "Young man, follow me, and your talents shall be employed upon greater and better things." The youth consented, and Democritus took him home, maintained him at his own expence, and taught him philosophy, which qualified him for the office of legislator of the Thurians. He was more subtle than solid in his reasonings; however, he taught at Athens with great reputation, but was at length banished from thence for the impiety of his doctrines. He then travelled, and visited the islands in the Mediterranean, where it is said that he was the first philosopher who taught for money. He died in a voyage to Sicily, in a very advanced age. He commonly reasoned by dilemmas, and left the mind in suspense with respect to all the questions he proposed. His moral principles were adopted by Hobbes. (See MORAL PHILOSOPHY). Plato wrote a dialogue against him. He flourished 400 years B. C.

Enfield's History of Philosophy, vol. i.

PROTASIS, in the ancient drama, the first part of a comic or tragic piece, wherein the several persons are shown, their characters intimated, and the subject of the piece proposed and entered upon.

It might reach as far as our two first acts; and where it ended the epitasis commenced. See the article EPITASIS.

PROTEA, the SILVER-TREE, a genus of plants, belonging to the tetrandria class; and in the natural method ranking under the 47th order, *Stellatæ.* See BOTANY *Index*.

PROTECTOR, a person who undertakes to shelter and defend the weak, helpless and distressed.

Every Catholic nation, and every religious order, has a protector residing at the court of Rome, who is a cardinal, and is called the *cardinal protector.*

Protector is also sometimes used for a regent of a kingdom, made choice of to govern it during the minority of a prince.

Cromwell assumed the title and quality of *lord protector of the commonwealth of England.*

PROTESILAI TURRIS, the sepulchre of Protesilaus, with a temple, at which Alexander sacrificed, (Arian); situated at the south extremity of the Hellespont, near the Chersonesus Thracia. Protesilaus was the first Greek who landed on the coast of Troy, and the first Greek slain by the Trojans, (Homer, Ovid). His wife Laodamia, to assuage her grief, begged the gods for a sight of his shade; and obtaining her request, she expired in his embraces, (Hyginus). Protesilaus was also called *Phylacides*, from Phylace, a town of Thessaly.

PROTEST, in *Law*, is a call of witness, or an open affirmation that a person does, either not at all, or but conditionally, yield his consent to any act, or to the proceeding of any judge in a court in which his jurisdiction is doubtful, or to answer upon his oath farther than he is bound by law.

Any of the lords in parliament have a right to protest their dissent to any bill passed by a majority: which protest is entered in form. This is said to be a very ancient privilege. The commons have no right to protest. See PARLIAMENT.

PROTEST, in *Commerce*, a summons written by a notary-public to a merchant, banker, or the like to accept or discharge a bill of exchange drawn on him, after his having refused either to accept or pay it. See *BILL of Exchange*.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529 they protested against a decree of the emperor Charles V. and the diet of Spires; declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin; and is now become a common denomination for all those of the reformed churches.

PROTEUS, in *Heathen Mythology*. See EGYPT, N° 6.

PROTHONOTARY, a term which properly signifies *first notary*, and which was anciently the title of the principal notaries of the emperors of Constantinople.

Prothonotary, with us, is used for an officer in the court of king's bench and common pleas; the former of which courts has one, and the latter three. The prothonotary of the king's bench records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the common pleas enter and enrol all declarations, pleadings, assizes, judgments, and actions: they also make out all judicial writs, except writs of *habeas corpus*, and *distringas jurator*, for which there is a particular office, called the *habeas corpora office*; they likewise enter recognizances acknowledged, and all common recoveries; make exemplifications of records, &c.

In the court of Rome there is a college of 12 prelates, called *apostolical prothonotaries*, empowered to receive the last wills of cardinals, to make all informations and proceedings necessary for the canonization of saints; and all such acts as are of great consequence to the Papacy: for which purpose they have the right of admission into all consistories, whether public or half public. They also attend on the pope whenever he performs any extraordinary ceremony out of Rome.

PROTO, a Greek term, frequently used in composition of priority: thus proto-collum, in the ancient jurisprudence, signifies the first leaf of a book; protomartyr, the first martyr; proto-plast, the first man formed, &c.

PROTOGENES, a celebrated ancient painter, was born at Caunas, a city of Caria, subject to the Rhodians, and flourished 300 years before the birth of our Saviour. He was first obliged to paint ships for his livelihood; but afterwards acquired the highest reputation for history-painting; though Apelles blamed him for finishing his pieces too highly, and not knowing when to have done. The finest of his pictures was that of Jalisus, which is mentioned by several ancient authors, though none of them give any description of it. He worked seven years on this picture; during which time he lived entirely upon lupines and water, being of opinion that this light and simple nourishment left him greater freedom of fancy. Apelles, on seeing this picture, was struck with such admiration, that he was unable to speak, or to find words sufficient to express his idea of its beauty. It was this picture that saved the city of Rhodes when besieged by Demetrius king of Macedon; for being able to attack it only on that side where Protogenes worked, which he intended to burn, he chose rather to abandon his design than to destroy so fine a piece. Pliny says, that Apelles asking him what price he had for his pictures, and Protogenes naming an inconsiderable sum, Apelles concerned at the injustice done to the beauty of his productions, gave him 50 talents, about 10,000l. for one picture only, declaring publicly, that he would sell it for his own. This generosity made the Rhodians sensible of the merit of Protogenes; and they were so eager to purchase the picture Apelles had bought, that they paid him a much greater price for it than he had given.

PROTOTYPE, is the original or model after which a thing was formed; but chiefly used for the patterns of things to be engraved, cast, &c.

PROTRACTOR, an instrument for laying down and measuring angles upon paper with accuracy and dispatch; and by which the use of the line of chords is superseded. This instrument is variously formed, as semicircular, rectangular, or circular; and constructed of different materials, as brass, ivory, &c. It is necessary in laying down those surveys or other plans where angles are concerned.

The rectangular protractor is constructed in form of a right-angled parallelogram, which, when applied to a case of mathematical instruments, is substituted in place of the semicircular protractor and scale of equal parts. Fig. 1. is a representation of it: the manner of using it is exactly similar to that of the semicircular one. Plate cccclviii. fig. 1.

The circular protractor, as its name implies, is a complete circle, and is superior by far to either of the former, both in point of accuracy and dispatch, especially when several angles are to be formed at the same point. The limb of this instrument is divided into 360 degrees, and each degree in some protractors is halved: it has a subdividing scale or vernier, by which an angle may be laid down or measured to a single minute. In the centre of the protractor is a fine mark, which, when an angle is to be protracted or measured, is to be laid upon the angular point, and o, or zero on the limb, upon the given line forming one side of the angle.

Fig. 2. represents a circular protractor whose limb is divided as above described, and the dividing scale on the index, which moves round the limb of the protractor on a conical centre, gives every minute of a degree. That part of the index beyond the limb has a steel point fixed at the end, in a direct line with the centre of the protractor, and whose use is to prick off the proposed angles. Fig. 2.

Fig. 3. is another circular protractor, a little differently constructed from the former. The central point is formed by the intersection of two lines crossing each other at right angles, which are cut on a piece of glass. The limb is divided into degrees and half degrees, having an index with a vernier graduated to count to a single minute, and is furnished with a tooth and pinion, by means of which the index is moved round by turning a small nut. It has two pointers, one at each end of the index, furnished with springs for keeping them suspended while they are bringing to any angle; and Fig. 3.

Protractor ‖ Proverb. being brought, applying a finger to the top of the pointer, and pressing it down, pricks off the angle. There is this advantage in having two pointers, that all the bearings round a circuit may be laid or pricked off, although the index traverses but one-half of the protractor.

Another circular protractor, different from either of the former, is represented at fig. 4. The centre is also formed by the intersection of two lines at right angles to each other, which are cut on glass, that all parallax may thereby be avoided. The index is moved round by a tooth and pinion. The limb is divided into degress and half degrees, and subdivided to every minute by the vernier. The pointer may be set at any convenient distance from the centre, as the socket which carries it moves upon the bar BC, and is fixed thereto by the nut D, at right angles to the bar BC, and moveable with it. There is another bar EF: On this bar different scales of equal parts are placed; so that by moving a square against the inner edge thereof, angles may be transferred to any distance within the limits, from the centre containing the same number of degrees marked out by the index.

Fig. 4.

It would indeed be superfluous to describe any more of these circular protractors, especially as the little alterations in them depend very much upon the fancy of the artist. Suffice it however to say, that we have seen others still differently constructed, one of which we shall briefly describe. The divisions upon the limb of this instrument are similar to those already described; but the index is a straight bar continued to some considerable distance each way beyond the limb of the instrument, and has a vernier to show minutes as usual; a mark upon one of the edges of the index, always coincides with the centre of the instrument. Instead, therefore, of pricking down the angle as in the former, part of the line containing the angle may be drawn, which, although perhaps not so accurate as a point, is more conspicuous, and the line is easily completed upon removal of the protractor. The common dimensions of the circular part of these instruments is from six to ten inches diameter; and they are made of brass.

PROTUBERANCE, in *Anatomy*, is any eminence, whether natural or preternatural, that projects or advances out beyond the rest.

PROVEDITOR, an officer in several parts of Italy, particularly at Venice, who has the direction of matters relating to policy.

PROVENCE, a province or government of France, bounded by Dauphiné on the north, by Piedmont on the east, by the Mediterranean on the south, and by the river Rhone, which separates it from Languedoc, on the west: it is about 100 miles long, and near as many broad.

PROVEND, or PROVENDER, originally signified a kind of vessel containing the measure of corn daily given to a horse, or other beast of labour, for his subsistence; but is now generally used to signify the food for cattle; whatever it is.

PROVERB, according to Camden, is a concise, witty, and wise speech, grounded upon experience, and for the most part containing some useful instruction.

Book of PROVERBS, a canonical book of the Old Testament, containing a part of the proverbs of Solomon the son of David king of Israel. The first 24 chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his proverbs made by order of King Hezekiah; and the two last seem to have been added, though belonging to different and unknown authors, Agur the son of Jakeh, and King Lemuel.

Proverb, Providence.

In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, children, &c.

PROVIDENCE, the superintendence and care which God exercises over creation. 1 Definition.

That there exists a divine providence which attends to the affairs of this world, and directs their course, has been a received opinion among the human race in every country and in every period of history. Every altar that is erected, every prayer and every sacrifice that is offered up, affords a proof of this belief. So fully have men been convinced of the sincerity of each other's faith upon this subject, that in one form, that of an appeal to the Divine Ruler of the world, by the solemnity of an oath, they have introduced it both into the most ordinary and the most important business of life. 2 Belief of a providence universal.

This universal conviction of men of all degrees of knowledge, from the most profound philosopher to the rudest barbarian, is probably to be traced to some primæval tradition, never totally effaced from any nation under heaven. The truth itself, however, is susceptible of the most complete proof from principles of science. If the world had a beginning, it may obviously have an end, and can be continued in existence only by the constant energy of that power by which it was at first created. He therefore who acknowledges a creation and denies a providence, involves himself in this palpable contradiction—"that a system, which of itself had not an original and momentary existence, may yet of itself have a perpetual existence; or that a being which cannot of itself exist for a second of time, may yet, of itself, exist for thousands of years!" Or should we be so complaisant, as for a moment to suppose, with certain theists, ancient and modern, that the *matter* of the universe is self-existent and eternal, and that the power of God was exerted, not in creating substances, but in reducing the original matter from a state of chaos into that beautiful order in which we see it arranged; the constant energy of providence must still be admitted as necessary to preserve the forms and to continue the motions which were originally impressed upon the chaotic mass. From late experiments it appears extremely doubtful whether any two atoms of the most solid body be in actual contact; and that they are not *all* in contact is certain. (See METAPHYSICS, N° 176. and OPTICS, N° 45, p. 185.). Yet it requires a very considerable degree of force to carry to a greater distance from one another the parts of a stone or of a bar of iron. By what power then are those parts kept contiguous? It cannot be by their own; because nothing can act where it is not present, and because our best philosophy has long taught us that the atoms of matter are essentially inactive. Again, it requires a very great degree of force to bring two bodies, however small, into *apparent* contact (see OPTICS, *ubi supra*); and therefore it follows that they must be kept asunder by some foreign power. Every attempt to solve these phenomena by the intervention 3 Existence of providence may be proved on scientific principles.

Providence. vention of a subtle fluid is vain; for the question recurs, what keeps the parts of the fluid itself contiguous, and yet separated from each other?

The cohesion therefore of the parts of matter, and that which is called their repulsive power, demonstrate, through the whole system, the immediate energy of something which is not matter, and by which every body small and great is preserved in its proper form. It has been elsewhere shown (see METAPHYSICS, Part II. chap. 5. and MOTION, N° 19, 20.), that the various motions which are regularly carried on through the universe, by which animals and vegetables grow and decay, and by which we have day and night, summer and winter, cannot be accounted for by any laws of mere mechanism, but necessarily imply the constant agency of something which is itself distinct from matter. But the forms of bodies are preserved, and their natural motions carried on, for purposes obviously planned by Wisdom. The power therefore which effects these things must be combined with intelligence: but power and intelligence preserving the order of the universe constitute all that is meant by a general providence; which is therefore as certainly administered as the sun daily rises and sets, or as bodies are kept solid by what is termed cohesion and repulsion.

4
Reasoning of the Bramins of Hindostan.

Abstracted and metaphysical as this reasoning may appear, it is by no means peculiar to the philosophers of Europe. Its force has been felt from time immemorial by the Bramins of Hindostan, who, as Sir William Jones informs us *, "being unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of supreme goodness was left a moment to itself, imagine that the Deity is ever present to his work, not in substance, but in spirit and in energy." On this rational and sublime conception they have indeed built numberless absurd superstitions; but their holding the opinion itself, shows that they believe in the reality of providence upon philosophical principles: and what truth is there on which the mind of man has not ingrafted marks of its own weakness?

* *Asiatic Researches*, vol. i.

Few nations, however, except the ancient Greeks, have had philosophers equally subtile with the Bramins of India; and therefore though all mankind have in general agreed in the belief of a superintending Providence, they have in different ages and countries admitted that truth upon different kinds of evidence, and formed very different notions concerning the mode in which the Divine superintendence is exerted.

5
Idea of providence in rude ages.

While societies are still in a rude and unpolished state, while individuals possess little security and little leisure for the exertion of their rational powers, every important or singular appearance in nature becomes an object of wonder or of terror. In this state of ignorance, men see not the universe as it is, a great collection of connected parts, all contributing to form one grand and beautiful system. Every appearance seems to stand alone; they know that it must have a cause, but what that cause is they are ignorant. The phenomena exhibited by nature are so complicated and so various, that it never occurs to them that it is possible for one Being to govern the whole. Hence arose the different systems of polytheism that have appeared in the world. Nature was divided into different regions, and a particular invisible power was assigned to each department: one conducted the flaming chariot of the sun, another wielded the terrible thunderbolt, and others were employed in diffusing plenty, and introducing the useful arts among men. Thus, although the various systems of polytheism in general acknowledged one Supreme Ruler, the father of gods and men, yet they at the same time peopled not only the regions above, the air and the heavens, but they also filled the ocean and the land, every grove, and every mountain, with active but invisible natures. Having arisen from the same causes, these systems of polytheism, which are so many hypotheses concerning Divine providence, are all extremely similar; and we have a very favourable specimen of them in the elegant mythology of Greece and Rome, which gave to every region of nature a guardian genius, and taught men in the deep recesses of the forest, or in the windings of the majestic flood, to expect the presence of protecting and friendly powers. See POLYTHEISM.

6
The doctrine has had opponents in almost every age.

Notwithstanding this universal reception, in some form or other, of the doctrine of a divine providence, it has in every age met with some opponents. The most ancient of these were Democritus and Leucippus. They denied the existence of a Deity—asserted that all things were mechanically necessary, and that thought and sense were only modifications of matter. This is atheism in the strictest sense, and the only form of it that has ever been consistently supported. Epicurus followed upon the same principles; but he rendered the system altogether absurd, by confessing the freedom of the human will. To avoid the imputation of atheism, he asserted the existence of God; but declared that he resided above the heavens, and interfered not in human affairs. One of his maxims was, that "the blessed and immortal Being neither hath any employment himself, nor troubles himself with others." Maximus Tyrius * justly observes, that this is rather a description of a Sardanapalus than of a Deity. And some of the moralists † of antiquity remarked, that they knew many men among themselves possessed of active and generous minds, whose characters they valued more highly than that of Epicurus's god. Some of the ancients also appear to have entertained the following strange notion: They acknowledged the existence of a Supreme and of many inferior deities; but at the same time, they supposed that there is a certain fate which rules over all, and is superior to the gods themselves. See NECESSITY in Mythology.

* *Max. Tyr. Diss. art.* 19.

† *Cicero de finibus* lib. i. and *De Natura Deorum*, lib. ii.

The providence exerted by the Author of nature over his works is usually divided into two branches: a *general*, referring to the management of the universe at large; and a *particular* providence, chiefly regarding particular men.

7
General providence.

Upon the first of these, in *The Religion of Nature delineated*, the question is stated somewhat in the following manner: The world may be said to be governed, or at least cannot be said to fluctuate fortuitously, if there are laws or rules by which natural causes act; if the several phenomena in it succeed regularly, and in general the constitution of things is preserved; if there are rules observed in the production of herbs, trees, and the like; if the several kinds of animals are furnished with faculties proper to determine their actions in the different stations which they hold in the general economy of the world; and lastly, if rational beings are taken care of in such a manner as will at last agree best with reason. By the providence of God we ought to understand

 understand his governing the world by *such* laws as these now mentioned: so that if there are such, there must be a Divine providence.

8 as it respects inanimate objects With regard to *inanimate objects*, the case agrees precisely with the above supposition. The whole of that universe which we see around us is one magnificent and well regulated machine. The world that we inhabit is a large globe, which, conducted by an invisible power, flies with a rapidity of which we have no conception, through an extent of space which sets at defiance every power of fancy to embody it into any distinct image. A large flaming orb stands immoveable in the heavens; around which this, and other worlds of different magnitudes, perform their perpetual revolutions. Hence arise the expected returns of day and night, and the regular diversity of seasons. Upon these great operations a thousand other circumstances depend. Hence, for example, the vapours ascend from the ocean, meet above in clouds, and after being condensed, descend in showers to cover the earth with fertility and beauty. And these appearances are permanent and regular. During every age since men have been placed upon the earth, this astonishing machine continued steadily to perform its complicated operations. Nothing is left to chance. The smallest bodies are not less regular than the largest, and observe continually the same rules of attraction, repulsion, &c. The apparent variations of nature proceed only from different circumstances and combinations of things, acting all the while under their ancient laws. We ourselves can calculate the effects of the laws of gravitation and of motion. We can render them subservient to our own purposes, with entire certainty of success if we only adhere to the rules established by nature, that is to say, by providence.

9 vegetables, *Vegetables* also live and flourish according to prescribed methods. Each sort is produced from its proper seed; has the same texture of fibres, is at all times nourished by the *same* kind of juices, digested and prepared by the *same* vessels. Trees and shrubs receive annually their peculiar liveries, and bear their proper fruits: so regular are they in this last respect, that every species may be said to have its profession or trade appointed to it, by which it furnishes a certain portion of manufacture, or of food, to supply the wants of animals: being created for the purpose of consumption, all vegetables produce great quantities of seed to supply the necessary waste. Here too, then, there is evidently a *regulation* by which the several orders are preserved, and the ends of them answered according to their first establishment.

10 animals, With regard to *animals*, they too, in structure of their form, are subject to laws similar to those which govern the vegetable world. In the sentient part of their constitution they are no less subject to rule. The lion is always fierce, the fox is crafty, and the hare is timid. Every species retains from age to age its appointed place and character in the great family of nature. The various tribes are made and placed in such a manner as to find proper means of support and defence. Beasts, birds, fishes, and insects, are all possessed of organs and faculties adapted to their respective circumstances, and opportunities of finding their proper food and prey.

11 and man. *Man* is subject to the ordinary laws which other material and animal substances obey; but he is left more at large in the determination of his actions. Yet even here things do not fluctuate at random. Individuals do indeed rise and perish according to fixed rules, and nations themselves have only a temporary endurance. But the species advances with a steady progress to intellectual improvement. This progress is often interrupted; but it appears not to be less sure at the long-run than even the mechanical laws which govern the material part of our constitution. Amidst the convulsion of states and the ruin of empires, the useful arts, when once invented, are never lost. These, in better times, render subsistence easy, and give leisure for reflection and study to a greater number of individuals. Tyre and Sidon have passed away, Athens itself has become the prey of barbarians, and the prosperity of ancient Egypt is departed, perhaps for ever; but the ship, the plough, and the loom, remain, and have been perpetually improving. Thus every new convulsion of society does less mischief than the last; and it is hoped that by the assistance of printing the most polished arts and the most refined speculations have now become immortal.

The world is not then left in a state of confusion: it is reduced into order, and methodised for ages to come; the several species of beings having their offices and provinces assigned them. Plants, animals, men, and nations, are in a state of continual change; but successors are appointed to relieve them, and to carry on the *scheme of Providence*.

12 Difficulty of accounting for particular providence. But the great difficulty is, how to account for that providence which is called *particular*: For rational beings, and free agents, are capable of doing and deserving well or ill; and the safety or danger, that happiness or unhappiness of a man here, must depend upon many things that seem scarcely *capable* of being determined by Providence. Besides *himself* and his own conduct, he depends upon the conduct of *other men*; whose actions, as we naturally suppose, cannot, consistently with their free will, be controuled for the advantage of another individual. The actions of numbers of men proceeding upon their private freedom, with different degrees of ability, as they cross and impede, or directly oppose each other, must produce very different effects upon men of different characters, and thus in a strange manner embarrass and entangle the general plan. And as to the *course of nature*, it may justly be asked, is the force of gravitation to be suspended till a good man pass by an infirm building? (See PRAYER). Add to this, that some circumstances appear absolutely irreconcileable. The wind which carries one into port drives another back to sea: and the rains that are just sufficient upon the hills may drown the inhabitants of the valleys. In short, may we expect *miracles*? or can there be a particular Providence that foresees and prepares for the several cases of individuals, without force frequently committed upon the laws of nature and the freedom of intelligent agents?

13 No good argument against its existence. In whatever way it is brought about, there is little doubt that something of this kind *must* take place. For as the Deity *does* direct, as already mentioned, the great and general progress of things in this world, he must also manage those of less importance. Nations are composed of individuals. The progress of individuals is the progress of the nation, and the greatest events usually depend upon the history and the most trifling actions

Providence.

actions of private persons. The difficulty is to conceive how the superintendence and management of all this can be brought about. But as the ways and the thoughts of the Omnipotent Spirit whose influence pervades, and rules, and animates nature, resemble not the limited operations of men, we can only form conjectures concerning the means by which his government is conducted.

14
The Deity may easily foresee the actions of men;

1. In the first place, then, it is not impossible that the Deity should foresee the future actions of intelligent beings. Many of these actions depend upon the mechanism of the material world, which was formed by himself, and must be entirely known to him. Many men among ourselves possess much sagacity in discerning the future actions of others, from attending to their known characters, and the circumstances in which they are placed. If superior natures do exist, and minds more perfect than the human, they must possess this penetration in a more eminent degree in proportion to the excellence of their intellectual powers. But if this discernment be in God proportionable to his nature, as in lower beings it is proportionable to theirs, it then becomes altogether unlimited, and the future actions of free agents are at once unlocked and exposed to his view. Add to this, that the Author of nature is well acquainted with the creatures that he has made; he knows the mechanism of our bodies, the nature and extent of our understandings, and all the circumstances by which we are surrounded. With all these advantages, it is making no great stretch to suppose him capable of discerning the line of conduct which we will pursue; and this even setting aside the infinity of his nature, to which a thousand years are as one day, and supposing him to reason from probabilities in the imperfect manner that we do.

15
and may thence fit them for their situations in life.

2. There is no impossibility at least, that men, whose characters and actions are thus foreknown, may be introduced into the world in such times and places as that their acts and behaviour may not only coincide with the general plan of things, but may also answer many private cases. The celestial bodies are so placed that their jarring attractions make out a splendid system. Why then may there not be in the Divine mind something like a projection of the future history of mankind, as well as of the motions of the heavenly bodies? And why should it not be thought possible for men, as well as for them, by some secret law, or rather by the management of an unseen power, to be brought into their places in such a manner as that, by the free use of their faculties, the conjunctions and oppositions of their interests and inclinations, the natural influence of their different degrees of talents, power, and wealth, they may conspire to make out the great scheme of human affairs? There is no absurdity in this supposition: it is not beyond the power of an almighty and perfect Being; and it is worthy of him. Let us take from the Jewish history, as most generally known, an example of what may be supposed to happen daily. It was the intention of providence to place David the son of Jesse upon the throne of the Hebrews. The country is invaded by a foreign enemy: the hostile armies meet, and lie encamped upon opposite mountains. A man comes forth from the army of the invaders, as was extremely common in those times, and defies the Hebrew host to send forth a champion to meet him in single combat.

16
The possibility of this exemplified.

Terrified by the gigantic bulk and mighty force of Goliah, no man would risk the unequal conflict. David, who was too young to carry arms, had been sent to the camp with provisions for his brothers, and heard the challenge. In defence of his flock he had killed some beasts of prey in the wilderness, and he was an excellent marksman with the sling. He thought it might probably be as easy to kill a man as a wild beast; at all events, he knew that a stone well directed would prove no less fatal to a giant than to a dwarf: he therefore resolved to try his skill; and he tried it with success. Here no man's free will was interrupted, and no miracle was accomplished: Yet by this *train* of circumstances thus *brought* together, a foundation was laid for the future fortunes of the son of Jesse, for the greatness of his country, and for accomplishing the purposes of Providence. According to Seneca, "Hoc dico, fulmina non mitti à Jove, sed sic omnia disposita, ut ea etiam quæ ab illo non fiunt, tamen sine ratione non fiunt; quæ illius est.—Nam etsi Jupiter illa nunc non facit, fecit ut fierent."—*I say, that the lightning comes not directly from the hand of Jove, but things are properly disposed for the indirect execution of his will; for he acts not immediately, but by the intervention of means.*

17
Secret influences on the mind are far from impossible.

3. Lastly, it is *not impossible* that many things may be accomplished by secret influence upon the human mind, either by the Deity himself, or by the intervention of agents possessed of powers superior to those which belong to us. "For instance, if the case should require that a particular man be delivered from some threatening *ruin*, or from some *misfortune*, which would certainly befal him if he should go such a way at such a time, as he intended: upon this occasion some *new* reasons may be presented to his mind why he should not go *at all*, or not *then*, or not *by that road*; or he may forget to go. Or, if he is to be delivered from some dangerous *enemy*, either some new turn given to his thoughts may divert him from going where the *enemy* will be, or the enemy may be after the same manner diverted from coming where *he* shall be, or his resentment may be *qualified*; or some proper method of *defence* may be suggested to the person in danger. After the same manner advantages and successes may be conferred on the deserving; as, on the other side, men, by way of punishment for their crimes, may incur mischiefs and calamities. These things, and such as these (says Mr Wollaston*), *may be*. For since the motions and actions of men, which depend upon their wills, do also depend upon their judgments, as these again do upon the *present appearances* of things in their minds; if a new prospect of things can be any way produced, the lights by which they are seen *altered*, new forces and directions impressed upon the spirits, passions *exalted* or *abated*, the power of judging *enlivened* or *debilitated*, or the attention taken off without any suspension or alteration of the standing laws of nature,—then, without that, *new* volitions, designs, measures, or a cessation of thinking, may also be produced; and thus many things prevented that otherwise would *be*, and many brought about that would *not*. That there may possibly be such inspirations of new thoughts and counsels (continues our author), may perhaps appear farther from this, that we frequently find thoughts arising in our heads, into which we are led by no discourse, nothing we read, no clue of reasoning, but they surprise and come upon us from we know not

* *Religion of Nature delineated*, sect. 5.

Providence.

not what quarter. If they proceeded from the mobility of spirits straggling out of order, and fortuitous affections of the brain, or were they of the nature of *dreams*, why are they not as wild, incoherent, and extravagant as they are?" Is it not much more reasonable to imagine that they come by the order and direction of an all-seeing and all-gracious God, who continually watches over us, and disposes every thing in and about us for the good of ourselves or others? not to speak of the agreeableness of this notion to the opinions of the best and wisest men in all ages (A). "If this, then, be the case, as it seems to be, that men's minds are susceptible of such *insinuations* and *impressions*, as frequently, by ways unknown, do affect them, and give them an inclination towards this or that; how many things (asks our author) may be brought to pass by these means without *fixing* and *refixing* the laws of nature, any more than they are unfixed when one man alters the opinion of another by throwing in his way a book proper for that purpose?"

18 And may be effected by beings superior to us, or by the Deity.

All this may be effected either by the immediate interposition of God himself, or by that of beings *invisible*, and in nature superior to us, who act as the ministers of his providence. That there are such beings we can hardly doubt, as it is in the highest degree improbable that such imperfect beings as men are at the top of the scale of created existence. And since we ourselves, by the use of our limited powers, do often alter the course of things within our sphere from what they would be if left to the ordinary laws of motion and gravitation, without being said to alter those laws; why may not superior beings do the same as instruments of divine providence? This idea of the intervention of superior natures is beautifully illustrated by Thomson in the following passage:

These are the haunts of meditation, these
The scenes where ancient bards th' inspiring breath,
Ecstatic, felt; and from this world retir'd,
Convers'd with angels and immortal forms,
On gracious errands bent: to save the fall
Of virtue struggling on the brink of vice;
In waking whispers, and repeated dreams,
To hint pure thought, and warn the favour'd soul
For future trials fated to prepare.

We agree, however, with Mr Wollaston, in thinking the power of these beings not so large as to alter or suspend the general laws of nature (see MIRACLE); for the world is not like a bungling piece of clock-work, which requires to be often set backwards or forwards. We are likewise perfectly satisfied, that they cannot change their condition, to ape us or inferior beings; and consequently we are not apt hastily to credit stories of *portents*, &c. such as cannot be true, unless the nature of things and their manner of existence were occasionally reversed. Yet as men may be so placed as to become, even by the free exercise of their own powers, *instruments* of God's particular providence to other men; so may we well suppose that these higher beings may be so *distributed* through the universe, and subject to such an economy, unknown to us, as may render *them also* instruments of the same providence; and that they may, in proportion to their greater abilities, be capable, *consistently with the laws of nature*, of influencing human affairs in proper places.

19 Objections to the doctrine of Providence

We shall next proceed to state some of the chief objections which in ancient or modern times have been brought against the opinion, that the world is governed by a Divine providence.

20 from the imperfections of nature,

1. The first of these is this, that the system of nature contains many imperfections which it ought not to do if it be the work of a perfectly wise and good Being. To avoid the force of this objection, some modern writers have deserted the ground of supreme and absolute goodness, which the ancient theists always occupied, and have asserted that the divine perfection consists in unlimited power and uncontrouled supremacy of will; that consequently the Deity does not always that which is best, but merely what he himself pleases; and that for no other reason but because he *wills* to do so. But this is no better than atheism itself. For it is of no importance to us whether the universe is governed by blind fate or chance, that is to say, by nothing at all; or whether it is governed by an arbitrary sovereign will that is directed by chance, or at least by no principle of beneficence.

21 answered.

The true answer to this objection is, that no created system can have every perfection, because it must necessarily be destitute of self-existence and independence; and therefore if being destitute of some perfections be better than nothing, it was worthy of infinite power and perfect goodness to create such beings. In our present state, we mortals stand upon too low ground to take a commanding view of the whole frame of things. We can only reason concerning what is unknown from the little that is within our reach. In that little, we can see that wisdom and goodness reign; that nature always aims to produce perfection; that many salutary effects result even from the thunder and the storm: and we doubt not that a view of the whole structure of the universe would afford an additional triumph to the goodness and skill of its great Architect.

We see a regular ascent in the scale of beings from mere lifeless matter up to man; and the probability is, that the scale continues to ascend as far above man in perfection as created beings can possibly be raised.—The sole purpose of God in creating the world must have been to produce happiness: but this would be most effectually done by creating, in the first place, as many of the most perfect class of beings as the system could contain; and afterwards other classes less and less perfect, till the whole universe should be completely full. We do not positively assert such a scheme of creation,

Where

(A) That such was the general belief of the Greeks in the days of Homer, is plain from that poet's constantly introducing his deities into the narrative of his poems, and telling us that Minerva, or some other god, altered the minds of his heroes. "By this," says Plutarch, "the poet does not mean to make God *destroy* the will of man, but only move him to will: nor does he miraculously produce the appetites themselves in men, but only causes such imaginations as are capable of exciting them."

Providence.

Where all must fall, or not coherent be;
And all that rises, rise in due degree,

was actually in the divine Architect's intention; but that it is possible, is sufficiently obvious. No man will pretend to say, that this earth could afford a comfortable subsistence to a greater number of the human race, were all the inferior animals annihilated, than it could at present, swarming as every element is with life.—Suppose then, that as many men had been placed at first upon the earth as it could possibly support, and that matters had been so constituted, as that the number should never have been either increased or diminished; we beg leave to ask, whether, since there would have been evidently room for inferior animals, it would have been most worthy of infinite goodness to leave the whole globe to men, or to introduce into it different orders of less perfect beings, which, while they could not incommode this principal inhabitant, would each find pleasure in its own existence? To this question different answers cannot surely be given. Let the reader then extend his view, and consider the universe, which, however vast, cannot be positively infinite, as one system as much united as the several parts of this globe; let him suppose that there were at first created as many of the highest order of beings as it could have contained had creation there stopt; let him remember that happiness in many different degrees is valuable;—and he will not surely think it any imputation on the goodness of God that there are in the universe many beings far from perfection. The most imperfect of these are by themselves better than nothing; and they all contribute to make up a system which, considered as a whole, we have every reason to believe to be as perfect as any thing not self-existent can possibly be.

22 Objection from the introduction of evil.

2. If the world is conducted by a benevolent providence, how came evil to be introduced into it? This question has perplexed mankind in all ages. The ancient Persians resolved it, by asserting the existence of two gods, Oromasdes the author of good, and Arimanius the author of evil. From them the Christian heretics called *Manichees* borrowed their doctrine of two opposite co-eternal principles. Both the Platonists and Stoics ascribed the origin of evil to the perverseness or imperfection of matter, which they thought the Deity could not alter: and Pythagoras imagined a state of pre-existence, in which the souls of men had committed offences, for which they are here suffering the punishment. But these hypotheses are, some of them impious, and all unsatisfactory.

23 answered.

Taking the expression in its most extensive sense, the evils to which the human race are exposed may be reduced to *pain*, *uneasiness*, *disappointment of appetites*, and *death;* of which not one could have been wholly prevented without occasioning greater evils, inconsistent with the perfect goodness of the Creator. As long as we have solid bodies capable of motion, supported by food, subject to the influence of the atmosphere, and divisible, they must necessarily be liable to dissolution or death: But if a man could suffer death, or have his limbs broken, without feeling pain, the human race had been long ago extinct. A fever is a state of the body in which the fluids are in great disorder. Felt we no uneasiness from that disorder, we should have no inducement to pay the proper attention to our state, and should certainly die unawares, without suspecting ourselves to be in danger; whereas, under the present administration of divine providence, the pain and sickness of the disease compel us to have recourse to the remedies proper for restoring us to soundness and to health. Of the uneasinesses to which we are liable, and which are not the effect of immediate pain, the greatest has been sometimes said to arise from the apprehension of death, which constantly stares us in the face, and frequently embitters all our pleasures even in the hour of perfect health.—But this dread of death is implanted in our breasts for the very best of purposes. Had we no horror at the apprehension of death, we should be apt, whenever any misfortune befel us, to quit this world rashly, and rush unprepared into the presence of our Judge: but the horror which attends our reflections on our own dissolution, arising not from any apprehensions of the pain of dying, but from our anxiety concerning our future state of existence, tends strongly to make us act, while we are here, in such a manner as to ensure our happiness hereafter. Add to this, that the fear of death is the greatest support of human laws. We every day see persons breaking through all the regulations of society and good life, notwithstanding they know death to be the certain consequence, and feel all the horrors of it that are natural to man: and therefore were death divested of these horrors, how insignificant would capital punishments be as guardians of the law, and how insecure would individuals be in civil society?

With regard to the unavoidable misfortunes and anxieties of our present state, so far from being truly hurtful in themselves, they are proofs of divine beneficence. When we see men displeased with their situation, when we hear them complain of the difficulties, the miseries, and the cares of life, of the hardships which they have undergone, and the labours which still lie before them: instead of accounting them unfortunate, we ought to regard them as active beings, placed in the only situation that is fit for the improvement of their nature. That discontent, these restless wishes to improve their condition, are so many sure indications that their faculties will not languish. They who are in the least degree accustomed to observe the human character, know well the influence which pleasure and repose have in enfeebling every manly principle, and how capable they are of attaching us even to a sordid and dishonourable existence.

Happy indeed it is for the human race, that the number of those men is small whom providence has placed in situations in which personal activity is unnecessary. By far the greater number are compelled to exert themselves, to mix and to contend with their equals, in the race of fortune and of honour. It is thus that our powers are called forth, and that our nature reaches its highest perfection. It is even perhaps a general truth, that they who have struggled with the greatest variety of hardships, as they always acquire the highest energy of character, so if they have retained their integrity, and have not sunk entirely in the contest, seldom fail to spend their remaining days respectable and happy, superior to passion, and secured from folly by the possession of a wisdom dearly earned.

24 Physical evil the cause of moral good.

But the benefits of physical evils have been set in a still stronger light by a great master of moral wisdom, who was himself subject to many of those evils. That

Providence. man is a moral agent, sent into this world to acquire habits of virtue and piety to fit him for a better state, is a truth to which no consistent theist will for a moment refuse his assent. But almost all the moral good which is left among us, is the apparent effect of physical evil.

Johnson's Idler, No. 89. "Goodness is divided by divines into soberness, righteousness, and godliness. Let it be examined how each of these duties would be practised if there were no physical evil to enforce it.

"Sobriety or temperance is nothing but the forbearance of pleasure; and if pleasure was not followed by pain, who would forbear it? We see every hour those in whom the desire of present indulgence overpowers all sense of past, and all foresight of future misery. In a remission of the gout, the drunkard returns to his wine, and the glutton to his feast; and if neither disease nor poverty were felt or dreaded, every one would sink down in idle sensuality, without any care of others, or of himself. To eat and drink, and lie down to sleep, would be the whole business of mankind.

"Righteousness, or the system of social duty, may be subdivided into justice and charity. Of justice, one of the heathen sages has shown, with great acuteness, that it was impressed upon mankind only by the inconveniences which injustice had produced. 'In the first ages (says he) men acted without any rule but the impulse of desire; they practised injustice upon others, and suffered it from others in their turn; but in time it was discovered, that the pain of suffering wrong was greater than the pleasure of doing it; and mankind, by a general compact, submitted to the restraint of laws, and resigned the pleasure to escape the pain.'

"Of charity, it is superfluous to observe, that it could have no place if there were no want; for of a virtue which could not be practised, the omission could not be culpable. Evil is not only the occasional but the efficient cause of charity; we are incited to the relief of misery by the consciousness that we have the same nature with the sufferer; that we are in danger of the same distresses, and may some time implore the same assistance.

"Godliness or piety is elevation of the mind towards the Supreme Being, and extension of the thoughts to another life. The other life is future, and the Supreme Being is invisible. None would have recourse to an invisible power, but that all other subjects had eluded their hopes. None would fix their attention upon the future, but that they are discontented with the present. If the senses were feasted with perpetual pleasure, they would always keep the mind in subjection. Reason has no authority over us but by its power to warn us against evil.

"In childhood, while our minds are yet unoccupied, religion is impressed upon them; and the first years of almost all who have been well educated are passed in a regular discharge of the duties of piety: But as we advance forward into the crowds of life, innumerable delights solicit our inclinations, and innumerable cares distract our attention. The time of youth is passed in noisy frolics; manhood is led on from hope to hope, and from project to project; the dissoluteness of pleasure, the inebriation of success, the ardour of expectation, and the vehemence of competition, chain down the mind alike to the present scene: nor is it remembered how soon this mist of trifles must be scattered, and the bubbles that float upon the rivulet of life be lost for ever in the gulf of eternity. To this consideration scarce any man is awakened but by some pressing and resistless evil; the death of those from whom he derived his pleasures, or to whom he destined his possessions, some disease which shows him the vanity of all external acquisitions, or the gloom of age which intercepts his prospects of long enjoyment, forces him to fix his hopes upon another state; and when he has contended with the tempests of life till his strength fails him, he flies at last to the shelter of religion.

"That misery does not make all virtuous, experience too certainly informs us; but it is no less certain, that of what virtue there is, misery produces far the greater part. Physical evil may be therefore endured with patience, since it is the cause of moral good; and patience itself is one virtue by which we are prepared for that state in which evil shall be no more."

The calamities and the hardships of our present state, then, are so far from being real evils, of which providence ought to be accused, that in every point of view in which we can consider them, they afford the surest proofs of the wisdom of its administration, and of its goodness to man.

25 Objections from the permission of moral guilt,

The most serious difficulty lies in accounting for the permission of moral evil or guilt, in a system governed by infinite benevolence and wisdom. Those who in a consistent manner hold the doctrine of the absolute necessity of human actions in its full extent, and acknowledge all its consequences, find it easy to elude this difficulty. They very fairly deny the existence of any such thing as moral evil in the abstract; and assert, that what we call a *crime*, is nothing more than an action which we always regard with a painful sensation: that these apparent evils endure only for a time; and that all will at last terminate in the perfection and happiness of every intelligent being.

26 answered.

Upon the system of liberty, the shortest answer seems to be this: that some things are absolutely impossible, not from any weakness in the Deity, but because they infer absurdity or contradiction. Thus it is impossible for twice two to be any thing else than four; and thus it is impossible for Omnipotence itself to confer self-approbation upon an intelligent being who has never deserved it; that is to say, it is impossible for a man of sense to be pleased with himself for having done a certain action, while he himself is conscious that he never did that action. But self-approbation constitutes the highest, the most unmingled, and permanent felicity, of which our nature is capable. It is not in the power of Omnipotence itself, then, to bestow the highest and most permanent felicity of our nature; it must be *earned* and deserved before it can be obtained. In the same manner good desert, virtue or merit, cannot be *conferred;* they must be *acquired.* To enable us to acquire these, we must be exposed to difficulties, and must suffer in a certain degree. If these difficulties had no influence upon our conduct and feelings, if they exposed us to no real danger, no fabric of merit and of self-approbation could be reared upon them. All that the Supreme Being could do for us, was to confer such an original constitution and character as would enable us to do well if we should exert our utmost powers. The universe

universe is not ruled by favour, but by justice. Complete felicity must be purchased. Guilt is an abuse of our freedom, a doing ill where we could have done well, and is entirely the work of man. Heaven could not avoid permitting its existence, and exposing us to danger; for temptation is necessary to virtue, and virtue is the perfection of our nature, our glory, and our happiness.

27
By Simplicius.

The permission of moral evil has been so ably accounted for by Simplicius, a Pagan writer, and therefore not biassed by any partiality to the Jewish or Christian Scriptures, that we cannot deny ourselves the pleasure of laying his reasoning before our readers. He asks *, "Whether God may be called the author of sin, because he permits the soul to use her liberty? and answers the question thus:

* *Simplic. Com. in Epict.* p. 186, 187. ed. *Salmas.*

"He who says that God should not permit the exercise of its freedom to the soul, must affirm one of these two things; either that the soul, though by nature capable of indifferently choosing *good* or *evil*, should yet be constantly prevented from choosing evil; or else that it should have been made of such a nature as to have no *power* of choosing *evil*.

"The former assertion (continues he) is irrational and absurd; for what kind of liberty would that be in which there should be no freedom of choice? and what choice could there be, if the mind were constantly restrained to one side of every alternative? With respect to the second assertion, it is to be observed (says he), that no evil is in itself desirable, or can be chosen *as evil*. But if this power of determining itself either way in any given case must be taken from the soul, it must either be as something not good, or as some great evil. But whoever saith so, does not consider how many things there are which, though accounted good and desirable, are yet never put in competition with this freedom of will: for without it we should be on a level with the brutes; and there is no person who would rather be a brute than a man. If God then shows his goodness in giving to inferior beings such perfections as are far below this, is it incongruous to the divine nature and goodness to give man a self-determining power over his actions, and to permit him the free exercise of that power? Had God, to prevent man's sin, taken away the liberty of his will, he would likewise have destroyed the foundation of all virtue, and the very nature of man; for there could be no virtue were there not a possibility of vice; and man's nature, had it continued rational, would have been divine, because impeccable. Therefore (continues he), though we attribute to God, as its author, this self-determining power, which is so necessary in the order of the universe; we have no reason to attribute to him that evil which comes by the abuse of liberty: For God doth not cause that aversion from good which is in the soul when it sins; he only gave to the soul such a power as might turn itself to evil, out of which he produces much good, which, without such a power, could not have been produced by Omnipotence itself." So consonant to the doctrine of our scriptures is the reasoning of this opponent of the writings of Moses! *Fas est et ab hoste doceri.*

28
Objection from the apparent confusion of human affairs,

The last objection to the belief of a divine providence arises from the apparent confusion of human affairs, that all things happen alike to all, that bad men are prosperous, and that a total want of justice appears to attend the divine administrations. Even the best men have at times been shaken by this consideration.—But there are many reasons for rendering this world a mixed scene: it would become unfit for a state of trial and of education to virtue were it otherwise. 29

answered,

It has been shown already, that physical evil is the parent of moral good; and therefore it would be absurd to expect that the virtuous should be entirely exempted from that evil. For the occasional prosperity of the wicked, many reasons have been assigned even by those who, in their disquisitions, were not guided by that revelation which has brought to light life and immortality. "God (says Plutarch) spares the wicked, that he may set to mankind an example of forbearance, and teach them not to revenge their injuries too hastily on each other. He spares some wicked men from early punishment, in order to make them instruments of his justice in punishing others. And he spares all for a time, that they may have leisure for repentance; for men (says the same excellent moralist) look at nothing further, in the punishments which they inflict, than to satisfy their revenge and malice, and therefore they pursue those who have offended them with the utmost rage and eagerness; whereas God, aiming at the cure of those who are not utterly incurable, gives them μεταβαλλεσθαι χρονον, "time to be converted."

30
by Plutarch

But this objection receives the best solution from the doctrine of the immortality of the human soul.

31
The immortality of the soul the best answer to this objection

——————And see!
'Tis come, the glorious morn! the second birth
Of heav'n and earth! awakening nature hears
The *new creating word*, and starts to life,
In every height'ned form, from pain and death
For ever free. *The great eternal scheme*,
Involving all, and in a *perfect whole*
Uniting, as the prospect wider spreads,
To reason's eye refin'd clears up apace.
Ye vainly wise! Ye blind presumptuous! now,
Confounded in the dust, adore that Pow'r
And Wisdom oft arraign'd; see now the cause,
Why unassuming worth in secret liv'd
And died neglected: why the good man's share
In life was gall and bitterness of soul:
Why the lone widow and her orphans pin'd
In starving solitude; while luxury,
In palaces, lay straining her low thought,
To form unreal wants: why heav'n-born truth,
And moderation fair, wore the red marks
Of superstition's scourge; why licenc'd pain,
That cruel spoiler, that embosom'd foe,
Imbitter'd all our bliss. Ye good distrest!
Ye noble few! who here unbending stand
Beneath life's pressure, yet bear up a while,
And what your bounded view, which only saw
A little part, deem'd evil, is no more:
The storms of wintry time will quickly pass,
And one unbounded spring encircle all."

THOMSON'S *Winter*.

PROVIDENCE-Plantation, a colony of New England, which, with Rhode-island, formerly constituted a charter government. Its chief town is Newport.

PROVIDENCE, one of the least of the Bahama islands in the American ocean, but the best of those planted and fortified by the English. It is seated on the east

side

side of the gulf of Florida. W. Long. 77. 35. N. Lat. 25. 0.

PROVINCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command of annual governors sent from Rome; being commonly obliged to pay such taxes and contributions as the senate thought fit to demand.

Of these countries, that part of France next the Alps was one, and still retains the name *Provence.*

Nicod derives the word *à procul vivendo*, "living afar off;" but it is better deduced from *pro* and *vinco*, "I overcome."

PROVINCE, in *Geography*, a division of a kingdom or state, comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

The church distinguishes its provinces by archbishoprics; in which sense, England is divided into two provinces, Canterbury and York.

The United Provinces are seven provinces of the Netherlands, who, revolting from the Spanish dominion, made a perpetual alliance, offensive and defensive, at Utrecht, anno 1579. See *UNITED Provinces*.

PROVINCIAL, something relating to a province. It also denotes, in Romish countries, a person who has the direction of the several convents of a province.

PROVISIONS, in a military sense, implies all manner of eatables, food or provender, used in an army, both for man and beast.

PROVOST of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Paris, &c. being much the same with mayor in other places. He presides in city-courts, and together with the bailies, who are his deputies, determines in all differences that arise among citizens.

The provost of Edinburgh is called *lord*, and the same title is claimed by the provost of Glasgow. The former calls yearly conventions of the royal boroughs to Edinburgh by his missives, and is, *ex officio*, president to the convention when met.

PROVOST, or *Prevot-Royal*, a sort of inferior judge formerly established throughout France, to take cognizance of all civil, personal, real, and mixed causes, among the people only.

Grand PROVOST of France, or *of the Household*, had jurisdiction in the king's house, and over the officers therein; looked to the policy thereof, the regulation of provisions, &c.

Grand PROVOST of the Constable, a judge who manages processes against the soldiers in the army who have committed any crime.

He has four lieutenants distributed throughout the army, called *provosts of the army*, and particular provosts in the several regiments.

PROVOST Marshal of an Army, is an officer appointed to seize and secure deserters, and all other criminals. He is to hinder soldiers from pillaging, to indict offenders, and see the sentence passed on them executed. He also regulates the weights and measures, and the price of provisions, &c. in the army. For the discharge of his office, he has a lieutenant, a clerk, and a troop of marshal-men on horseback, as also an executioner.

There is also a provost-marshal in the navy, who has charge over prisoners, &c.

The French also had a provost-general of the marines, whose duty it was to prosecute the marines when guilty of any crime, and to make report thereof to the council of war; besides a marine provost in every vessel, who was a kind of gaoler, and took the prisoners into his care, and kept the vessel clean.

PROVOSTS of the Marshals, were a kind of lieutenants of the marshals of France; of these there were 180 seats in France; their chief jurisdiction regarded highwaymen, footpads, house-breakers, &c.

PROVOST of the Mint, a particular judge instituted for the apprehending and prosecuting of false coiners.

PROVOST, or *Prevot*, in the king's stables; his office is to attend at court, and hold the king's stirrup when he mounts his horse. There are four provosts of this kind, each of whom attends in his turn, monthly.

PROW, denotes the head or fore-part of a ship, particularly in a galley; being that which is opposite to the poop or stern.

PROXIMITY, denotes the relation of nearness, either in respect of place, blood, or alliance.

PRUDENCE, in ethics, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, *De Officiis*, lib. i. cap. 43. prudence is the knowledge of what is to be desired or avoided. Accordingly, he makes *prudentia* (*De Legibus*, lib. i.) to be a contraction of *providentia*, or foresight. Plato (*De Legibus*, lib. iii.) calls this the leading virtue; and Juvenal, Sat. x. observes,

Nullum numen abest si sit prudentia.

The idea of prudence includes ευβουλια, or due consultation; that is, concerning such things as demand consultation in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and συνεσις, or a faculty of discerning proper means when they occur: and to the perfection of prudence, these three things are farther required, viz. δεινοτης, or a natural sagacity; αγχινοια, presence of mind, or a ready turn of thought; and εμπειρια, or experience. The extremities of prudence are craft or cunning on the one hand, which is the pursuit of an ill end by direct and proper though not honest means; and folly on the other, which is either a mistake, both as to the end and means, or prosecuting a good end by foreign and improper means. Grove's *Moral Philosophy*, vol. ii. chap. ii.

PRUDENTIUS, or AURELIUS PRUDENTIUS CLEMENS, a famous Christian poet, under the reign of Theodosius the Great, who was born in Spain in the year 348. He first followed the profession of an advocate, was afterwards a judge, then a soldier, and at length had an honourable employment at court. We have a great number of his poems, which, from the choice of his subject, may be termed *Christian poems*; but the style is barbarous, and very different from the purity of the Augustan age. The most esteemed editions of Prudentius's works are that of Amsterdam, in 1667, with Heinsius's Notes, and that of Paris in 1687, *in usum Delphini.*

PRUNELLA, a genus of plants belonging to the didynamia class; and in the natural method ranking under

under the 12th order, *Holoraceæ*. See BOTANY *Index*.

PRUNES, are plums dried in the sunshine, or in an oven.

PRUNING, in *Gardening* and *Agriculture*, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

Pruning, though an operation of very general use, is nevertheless rightly understood by few; nor is it to be learned by rote, but requires a strict observation of the different manners of growth of the several sorts of fruit-trees; the proper method of doing which cannot be known without carefully observing how each kind is naturally disposed to produce its fruit: for some do this on the same year's wood, as vines; others, for the most part, upon the former year's wood, as peaches, nectarines, &c.; and others upon spurs which are produced upon wood of three, four, &c. to fifteen or twenty years old, as pears, plums, cherries, &c. Therefore, in order to the right management of fruit-trees, provision should always be made to have a sufficient quantity of bearing wood in every part of the trees; and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years.

The reasons for pruning of fruit-trees, are, 1. To preserve them longer in a vigorous bearing-state; 2. To render them more beautiful; and, 3. To cause the fruit to be larger and better tasted.

The general instructions for pruning are as follow. The greatest care ought to be taken of fruit-trees in the spring, when they are in vigorous growth; which is the only proper season for procuring a quantity of good wood in the different parts of the tree, and for displacing all useless branches as soon as they are produced, in order that the vigour of the tree may be entirely distributed to such branches only as are designed to remain. For this reason trees ought not to be neglected in April and May, when their shoots are produced: however, those branches which are intended for bearing the succeeding year should not be shortened during the time of their growth, because this would cause them to produce two lateral shoots from the eyes below the place where they were stopped, which would draw much of the strength from the buds of the first shoot: and if the two lateral shoots are not entirely cut away at the winter-pruning, they will prove injurious to the tree. This is to be chiefly understood of stone-fruit and grapes; but pears and apples, being much harder, suffer not so much, though it is a great disadvantage to those also to be thus managed. It must likewise be remarked, that peaches, nectarines, apricots, cherries, and plums, are always in the greatest vigour when they are least maimed by the knife; for where large branches are taken off, they are subject to gum and decay. It is therefore the most prudent method to rub off all useless buds when they are first produced, and to pinch others, where new shoots are wanted to supply the vacancies of the wall; by which management they may be so ordered as to want but little of the knife in winter-pruning. The management of pears and apples is much the same with these trees in summer; but in winter they must be very differently pruned: for as peaches and nectarines, for the most part, produce their fruit upon the former year's wood, and must therefore have their branches shortened according to their strength, in order to produce new shoots for the succeeding year; so, on the contrary, pears apples, plums, and cherries, producing their fruit upon spurs, which come out of the wood of five, six, and seven years old, should not be shortened, because thereby those buds which were naturally disposed to form these spurs, would produce wood branches; by which means the trees would be filled with wood, but would never produce much fruit. The branches of standard-trees should never be shortened unless where they are very luxuriant, and, by growing irregularly on one side of the trees, attract the greatest part of the sap, by which means the other parts are either unfurnished with branches, or are rendered very weak; in which case the branch should be shortened down as low as is necessary, in order to obtain more branches to fill up the hollow of the tree: but this is only to be understood of pears and apples, which will produce shoots from wood of three, four, or more years old; whereas most sorts of stone-fruit will gum and decay after such amputations: whenever this happens to stone-fruit, it should be remedied by stopping or pinching those shoots in the spring, before they have obtained too much vigour, which will cause them to push out side-branches; but this must be done with caution. You must also cut out all dead or decaying branches, which cause their heads to look ragged, and also attract noxious particles from the air: in doing of this, you should cut them close down to the place where they were produced, otherwise that part of the branch which is left will also decay, and prove equally hurtful to the rest of the tree; for it seldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced, and if permitted to remain long uncut, often infects some of the other parts of the tree. If the branches cut off are large, it will be very proper, after having smoothed the cut part exactly even with a knife, chissel, or hatchet, to put on a plaster of grafting clay, which will prevent the wet from soaking into the tree at the wounded part. All such branches as run across each other, and occasion a confusion in the head of the tree, should be cut off; and as there are frequently young vigorous shoots on old trees, which rise from the old branches near the trunk, and grow upright into the head, these should be carefully cut out every year, lest, by being permitted to grow, they fill the tree too full of wood.

As to the pruning of forest-trees, if they be large, it is best not to prune them at all; yet, if there be an absolute necessity, avoid taking off large boughs as much as possible. And, 1. If the bough be small, cut it smooth, close and sloping. 2. If the branch be large, and the tree old, cut it off at three or four feet from the stem. 3. If the tree grow crooked, cut it off at the crook, sloping upward, and nurse up one of the most promising shoots for a new stem. 4. If the tree grow top-heavy, its head must be lightened, and that by thinning the boughs that grow out of the main branches. But if you would have them spring, rub off the buds, and shroud up the side-shoots. 5. If the side-bough still break out, and the top be able to sustain itself, give the boughs that put forth in spring a pruning after Midsummer, cutting them close.

It

It has been observed, that trees are subject to gum and decay, in consequence of pruning; to prevent these injurious effects, a remedy has been proposed by Mr Bucknall, which on trial, it is said, has been succesful. By this method the branches to be removed are to be cut close to the place of separation from the trunk, smoothed well with a knife, and the wound is to be smeared over with medicated tar, laid on with a painter's brush. The following is the composition of this medicated tar. One quarter of an ounce of corrosive sublimate reduced to fine powder, by beating it with a wooden hammer, is introduced into a three pint earthen pipkin, with about a glassful of gin or other spirit. The mixture is to be well stirred till the sublimate is dissolved. The pipkin is then gradually filled with vegetable or common tar, and constantly stirred, till the mixture be blended together as intimately as possible; and this quantity will at any time be sufficient for 200 trees. To prevent danger, let the corrosive sublimate be mixed with the tar as quickly as possible after it is purchased; for being of a very poisonous nature to all animals, it should not be suffered to lie about a house, for fear of mischief to some part of the family.

By applying this composition, Mr Bucknall can, without the least danger, use the pruning hook on all sorts of trees, much more freely than by the use of any article hitherto recommended. The following remarks by the author on pruning in general, seem worthy of notice, and we give them in his own words. "I give no attention (says he) to fruit branches, and wood branches; but beg, once for all, that no branch shall ever be shortened unless for the figure of the tree, and then constantly taken off close to the separation, by which means the wound soon heals. The more the range of the branches shoots circularly, a little inclining upwards, the more equally will the sap be distributed, and the better will the tree bear; for, from that circumstance, the sap is more evenly impelled to every part. Do not let the ranges of branches be too near each other; for, remember all the fruit and the leaves should have their full share of the sun; and where it suits, let the middle of the tree be free from wood, so that no branch shall ever cross another, but all the extreme ends point upwards."

PRUNUS, a genus of plants belonging to the icosandria class; and in the natural method ranking under the 36th order, *Pomaceæ*. See BOTANY *Index*.

PRUSA, in *Ancient Geography*, a town situated at Mount Olympus in Mysia, built by Prusias, who waged war with Crœsus, (Strabo); with Cyrus, (Stephanus); both cotemporary princes. Now called *Bursa* or *Prusa*, capital of Bithynia, in Asia Minor. E. Long. 29. 5. N. Lat. 39. 22.

PRUSIAS, the name of several kings of Bithynia.

PRUSIAS, a town of Bithynia, anciently called *Cios*, from a cognominal river, and giving name to the Sinus Cianus of the Propontis; rebuilt by Prusias the son of Zela, after having been destroyed by Philip the son of Demetrius: it stood on the Sinus Cianus, at the foot of Mount Arganthonius. This is the Prusias who harboured Hannibal after the defeat of Antiochus.—Of this place was Asclepiades, surnamed *Prusicus*, the famous physician.

PRUSSIA, a modern, but deservedly celebrated kingdom of Europe, whose monarch, along with Prussia Proper, possesses also the electorate of Brandenburg, and some other territories of considerable extent. The district properly called *Prussia* is of great extent, and divided into the Ducal and Regal Prussia, the latter belonging to the republic of Poland till the late partition of the Polish territories. Both together are of great extent; being bounded on the north by the Baltic, on the south by Poland and the duchy of Mazovia, on the west by Pomerania, and on the east by Lithuania and Samogitia. The name is by some thought to be derived from the *Borussi*, a tribe of the Sarmatians, who, migrating from the foot of the Riphæan mountains, were tempted by the beauty and fertility of the country to settle there. Others think that the name of this country is properly *Porussia; Po* in the language of the natives signifying *near*, and *Porussia* signifying *near Russia*. To the latter etymology we find the king of Prussia himself assenting in the treatise intitled *Memoirs of the House of Brandenburg*. However, it must be owned, that these or any other etymologies of the word are very uncertain, and we find nothing like it mentioned by historians before the tenth century.

See Map of Poland and Prussian States. Plate CCCCXXXIV.

1 Etymology of the name.

2 Extreme barbarity of the ancient inhabitants.

The ancient state of Prussia is almost entirely unknown. However, the people are said to have been very savage and barbarous; living upon raw flesh, and drinking the blood of horses at their feasts, according to Stella, even to intoxication (A). Nay, so extremely savage were this people, that they were even unacquainted with the method of constructing huts, and took up their dwelling in caves and cavities of rocks and trees, where they protected themselves and children from the inclemencies of the weather. Among such a people it is vain to expect that any transactions would be recorded, or indeed that any thing worthy of being recorded would be transacted. We shall therefore begin our history of Prussia with the time when the Teutonic knights first got footing in the country. (See TEUTONIC *Knights*).

3 Teutonic knights first get footing in the country.

On the expulsion of the Christians from the Holy Land by Saladin, a settlement was given to the Teutonic knights in Prussia by Conrade duke of Mazovia, the competitor of Boleslaus V. for the crown of Poland. Their first residence in this country was Culm; to which territory they were confined by the conditions of the donation, excepting what they could conquer from their pagan neighbours, all which the emperor granted to them in perpetuity.

Encouraged by this grant, the knights conquered the greatest

(A) This author does not mention any particular method by which they communicated an inebriating quality to the blood of animals. Possibly, however, the vital fluid may have a property of this kind, though unknown in our days where such barbarous customs are disused. Drunkenness from drinking blood is frequently mentioned in Scripture, but whether literally or metaphorically must be decided by the learned.

Prussia. greatest part of the country which now goes by the name of *Prussia*; and, not content with this, became very troublesome to Poland, insomuch that the monarchs of that kingdom were sometimes obliged to carry on dangerous and bloody wars with them; for an account of which we refer to the article POLAND, N° 61, 67, &c.

The Teutonic order continued in Prussia till the year 1531. Their last grand-master was Albert marquis of Brandenburg, and nephew to Sigismund I. king of Poland. He was preferred to this dignity, in hopes that his affinity to Sigismund might procure a restitution of some of the places which had been taken from the order during the former unsuccessful wars with Poland; but in this the fraternity were disappointed. Albert, however, was so far from endeavouring to obtain any favour from his uncle by fair means, that he refused to do homage to him, and immediately began to make preparations for throwing off his dependence altogether, and recovering the whole of Prussia and Pomerania by force of arms. In this he was so far from succeeding, that, being foiled in every attempt, he was forced to resign the dignity of grand-master; in recompense for which, his uncle bestowed on him that part of Prussia

4 Expelled. now called *Ducal*, in quality of a secular duke. It was now the interest of the house of Brandenburg to assist in the expulsion of the fraternity; and accordingly, being at last driven out of Prussia and Pomerania, they transferred their chapter to Mariendal in Franconia; but in that and other provinces of the empire where they settled, little more than the name of the order, once so famous, now remains.

5 History of Brandenburg. The other most considerable part of his Prussian majesty's dominions is the electorate of Brandenburg. Like other parts of Germany, it was anciently possessed by barbarians, of whom no history can be given. These were subdued by Charlemagne, as is related under the article FRANCE *; but being on every occasion ready to revolt, in 927 Henry the Fowler established margraves, or governors of the frontiers, to keep the barbarians in awe. The first margrave of Brandenburg was Sigefroy, brother-in-law to the above-mentioned emperor; under whose administration the bishoprics of Brandenburg and Havelberg were established by Otho I. From this Sigefroy, to the succession of the house of Hohenzollern, from whom the present elector is descended, there are reckoned eight different families, who have been margraves of Brandenburg; namely, the family of the Saxons, of Walbeck, Staden, Plenck, Anhalt, Bavaria, Luxemberg, and Misnia. The margraves of the four first races had continual wars with the Vandals and other barbarous people; nor could their ravages be stopped till the reign of Albert surnamed *the Bear*, the first prince of the house of Anhalt. He was made margrave by the emperor Conrad III. and afterwards raised to the dignity of elector by Frederic Barbarossa, about the year 1100. Some years afterwards the king of the Vandals dying without issue, left the Middle Marche by his last will to the elector, who was besides possessed of the Old Marche, Upper Saxony, the country of Anhalt, and part of Lusace. In 1332 this line became extinct, and the electorate devolved to the empire. It was then given by the emperor Louis of Bavaria to his son Louis, who was the first of the sixth race. Louis the Roman succeeded his brother; and as he also died without children, he was succeeded by Otho, his third brother, who sold the electorate to the emperor Charles IV. of the house of Luxemburg, for 200,000 florins of gold. Charles IV. gave the Marche to his son Winceslaus, to whom Sigismund succeeded. This elector, being embarrassed in his circumstances, sold the New Marche to the knights of the Teutonic order. Josse succeeded Sigismund; but aspiring to the empire, sold the electorate to William duke of Misnia; who, after he had possessed it for one year, sold it again to the emperor Sigismund. In 1417, Frederic VI. burgrave of Nuremberg, received the investiture of the country of Brandenburg at the diet of Constance from the hands of the emperor Sigismund; who, two years before, had conferred upon him the dignity of elector, and arch-chamberlain of the Holy Roman empire.

* N° 27, &c.

This prince, the first of the family of Hohenzollern, found himself possessed of the Old and Middle Marche, but the dukes of Pomerania had usurped the Marche Ukraine. Against them, therefore, the elector immediately declared war, and soon recovered the province. As the New Marche still continued in the hands of the Teutonic knights, to whom it had been sold, as we have already mentioned, the elector, to make up for this, took possession of Saxony, which at that time happened to be vacant by the death of Albert the last elector of the Anhalt line. But the emperor, not approving of this step, gave the investiture of Saxony to the duke of Misnia; upon which Frederic voluntarily desisted from his acquisitions. This elector made a division of his possessions by will. His eldest son was deprived of his right on account of his having too closely applied himself to search for the philosopher's stone; so he left him only Voigtland. The electorate was given to his second son Frederic; Albert, surnamed *Achilles*, had the duchies of Franconia; and Frederic, surnamed the *Fat*, had the Old Marche; but by his death it returned to the electorate of Brandenburg.

Frederic I. was succeeded by his son, called also *Frederic*, and surnamed *Iron-tooth* on account of his strength. He might with as great reason have been surnamed *the Magnanimous*, since he refused two crowns, viz. that of Bohemia, which was offered him by the pope, and the kingdom of Poland to which he was invited by the people; but Frederic declared he would not accept of it unless Casimir brother to Ladislaus the late king refused it. These instances of magnanimity had such an effect on the neighbouring people, that the states of Lower Lusatia made a voluntary surrender of their country to him. But as Lusatia was a fief of Bohemia, the king of that country immediately made war on the elector, in order to recover it. However, he was so far from being successful, that, by a treaty of peace concluded in 1462, he was obliged to yield the perpetual sovereignty of Corbus, Peits, Sommerfeld, and some other places, to the elector. Frederic then, having redeemed the New Marche from the Teutonic order for the sum of 100,000 florins, and still further enlarged his dominions, resigned the sovereignty in 1469 to his brother Albert, surnamed *Achilles*. 6 Exploits of Albert surnamed Achilles.

Albert was 57 years old when his brother resigned the

Prussia.

the electorate to him. Most of his exploits, for which he had the surname of *Achilles*, had been performed while he was burgrave of Nuremberg. He declared war against Lewis duke of Bavaria, and defeated and took him prisoner. He gained eight battles against the Nurembergers, who had rebelled and contested his rights to the burgraviate. In one of these he fought singly against 16 men, till his people came up to his assistance. He made himself master of the town of Grieffenburg in the same manner that Alexander the Great took the capital of the Oxydracæ, by leaping from the top of the walls into the town, where he defended himself singly against the inhabitants till his men forced the gates and rescued him. The confidence which the emperor Frederic III. placed in him, gained him the direction of almost the whole empire. He commanded the Imperial armies against Lewis the Rich duke of Bavaria; and against Charles the Bold duke of Burgundy, who had laid siege to Nuis, but concluded a peace at the interposition of Albert. He gained the prize at 17 tournaments, and was never dismounted.

7
Prussia and Brandenburg united.

All these exploits, however, had been performed before Albert obtained the electorate. From that time we meet with no very important transactions till the year 1594, when John Sigismund of Brandenburg, having married Anne the only daughter of Albert duke of Prussia, this united that duchy to the electorate, to which it has continued to be united ever since; and obtained pretensions to the countries of Juliers, Berg, Cleves, Marck, Ravensburg, and Ravenstein, to the succession of which Anne was heiress.

8
Unfortunate reign of the elector George William.

Sigismund died in 1619, and was succeeded by his son George William; during whose government the electorate suffered the most miserable calamities. At this time it was that the war commenced between the Protestants and Catholics, which lasted 30 years. The former, although leagued together, were on the point of being utterly destroyed by the Imperialists under the command of Count Tilly and Wallenstein, when Gustavus Adolphus of Sweden turned the scale in their favour, and threatened the Catholic party with utter destruction *. But by his death at the battle of Lutzen, the fortune of war was once more changed. At last, however, peace was concluded with the emperor; and, in 1640, the elector died, leaving his dominions to his son Frederic William, surnamed the *Great*.

* See *Sweden*.

9
Reign of Frederic William the Great.

This young prince, though only 20 years of age at the time of his accession, applied himself with the utmost diligence to repair the losses and devastations occasioned by the dreadful wars which had preceded. He received the investiture of Prussia personally from the king of Poland, on condition of paying 100,000 florins annually, and not making truce or peace with the enemies of that crown. His envoy likewise received the investiture of the electorate from the emperor Ferdinand III. The elector then thought of recovering his provinces from those who had usurped them. He concluded a truce for 20 years with the Swedes, who evacuated the greatest part of his estates. He likewise paid 140,000 crowns to the Swedish garrisons, which still possessed some of his towns; and he concluded a treaty with the Hessians, who delivered up a part of the duchy of Cleves; and obtained of the Hollanders the evacuation of some other cities.

In the mean time, the powers of Europe began to be weary of a war which had continued for such a length of time with such unrelenting fury. The cities of Osnaburg and Munster being chosen as the most proper places for negociation, the conferences were opened in the year 1645; but, by reason of the multiplicity of business, they were not concluded till two years after. France, which had espoused the interests of Sweden, demanded that Pomerania should be ceded to that kingdom as an indemnification for the expences which the war had cost Gustavus Adolphus and his successors. Although the empire and the elector refused to give up Pomerania, it was at last agreed to give up to the Swedes Hither Pomerania, with the isles of Rugen and Wollin, also some cities; in return for which cession, the bishoprics of Halberstadt, Minden, and Camin, were secularized in favour of the elector, of which he was put in possession, together with the lordships of Hochenstein and Richenstein, with the reversion of the archbishopric of Magdeburg. Thus was the treaty of Westphalia concluded in 1648, and which serves as a basis to all the possessions and rights of the German princes. The elector then concluded a new treaty with the Swedes, for the regulation of limits, and for the acquittal of some debts, of which Sweden would only pay a fourth; and next year the electorate, Pomerania, and the duchies of Cleves, were evacuated by the Swedes.

10
Treaty of Westphalia concluded.

11
The elector succeeds against the Swedes.

Notwithstanding all these treaties, however, the Swedes soon after invaded Pomerania, but were entirely defeated by the elector near the town of Fehrbellin. Three thousand were left dead on the spot, among whom were a great number of officers; and a great many were taken prisoners. The elector then pursued his victory, gained many advantages over the Swedes, and deprived them of the cities of Stralsund and Gripswald. On this the Swedes, hoping to oblige the elector to evacuate Pomerania, which he had almost totally subdued, invaded Prussia, from Livonia, with 16,000 men; and advancing into the country, they burned the suburbs of Memel, and took the cities of Tilse and Insterburg. The elector, to oppose the invaders, left Berlin on the 10th of January 1679, at the head of 9000 men. The Swedes retired at his approach, and were greatly harassed by the troops on their march. So successful indeed was the elector on this occasion, that the Swedes lost almost one half of their army killed or taken prisoners. At last, having crossed the bay of Frisch-haff and Courland on the ice, he arrived on the 19th of January, with his infantry, within three miles of Tilse, where the Swedes had their head-quarters. The same day, his general, Trefenfeldt, defeated two regiments of the enemy near Splitter; and the Swedes who were in Tilse abandoned that place, and retired towards Courland. They were pursued by General Gortz, and entirely defeated with such slaughter, that scarce 3000 of them returned to Livonia. Yet, notwithstanding all these victories, the elector, being pressed on the other side by the victorious generals of France, M. Turenne and the prince of Conde, was obliged to make peace with the Swedes. The conditions were,

12
Is obliged to conclude a treaty of peace with them.

Prussia. that the treaty of Westphalia should serve for a basis to the peace; that the elector should have the property of the customs in all the ports of Further Pomerania, with the cities of Camin, Gartz, Grieffenburg, and Wildenbruck: on his part, he consented to give up to the Swedes all that he had conquered from them, and to give no assistance to the king of Denmark, upon condition that France delivered up to him his provinces in Westphalia, and paid him 300,000 ducats, as an indemnification for the damages done by the French to his states. This treaty was styled *the peace of St Germain*.

13 A strange embassy from the cham of Tartary.

With the treaty of St Germain terminated the military exploits of Frederic William, who passed the last years of his administration in peace. His great qualities had rendered him respected by all Europe, and had even been heard of in Tartary. He received an embassy from Murad Geray, cham of the Tartars, courting his friendship. The barbarian ambassador appeared in such tattered clothes as scarce covered his nakedness, so that they were obliged to furnish him with other clothes before he could appear at court. His interpreter had a wooden nose and no ears. In 1684, Frederic received into his dominions great numbers of Protestants who fled out of France from the persecutions of Louis XIV. after he had revoked the edict of Nantz. Twenty thousand of them are said to have settled at this time in the electorate, where they introduced new arts and manufactures, that were of the utmost benefit to the country. By this, however, he disobliged Louis XIV. for which reason he concluded an alliance with the emperor; and having furnished him with 8000 troops against the Turks in Hungary, the emperor yielded to him the circle of Schwibus in Silesia, as an equivalent for all his rights in that province.

14 Frederic III. obtains the title of king of Prussia.

In 1688, the elector Frederic William died, and was succeeded by his son Frederic III. This prince was remarkably fond of show and ceremony, which, during the course of his government, involved him in much expence. The regal dignity seemed to be the greatest object of his ambition. To obtain this, he joined with the emperor in the alliance against France, in which he was engaged by William III. king of Britain. He also yielded up the circle of Schwibus, which had been given to his predecessor; and, in 1700, obtained from the emperor that dignity which he had so earnestly desired. The terms on which it was obtained were, 1. That Frederic should never separate from the empire those provinces of his dominions which depended on it. 2. That he should not, in the emperor's presence, demand any other marks of honour than those which he had hitherto enjoyed. 3. That his Imperial majesty, when he wrote to him, should only give him the title of *Royal Dilection*. 4. That nevertheless the ministers which he had at Vienna should be treated like those of other crowned heads. 5. That the elector should maintain 6000 men in Italy at his own expence, in case the emperor should be obliged to make war on account of the succession of the house of Bourbon to the crown of Spain. 6. That those troops should continue there as long as the war lasted.

Thus was the kingdom of Prussia established through the friendship of the emperor, with whom Frederic I. so called as being the first king of Prussia, continued all his life in strict alliance. Indeed he was a pacific prince; and though contemptible in his person, and incapable of achieving great things, had this merit, that he always preserved his dominions in peace, and thus consulted the true interest of his subjects much more than those monarchs who have dazzled the eyes of the world by their military exploits. He was indeed vain, and fond of show, as we have already observed; but had a good heart, and is said never to have violated his conjugal vow; though it does not appear that he was greatly beloved by his royal consorts (of whom he had three) on that or any other account.

15 Frederic II. of Prussia a martial prince.

Frederic I. died in the beginning of 1713, and was succeeded by Frederic William. He was in almost every thing the reverse of his father. His dispositions were altogether martial; so that he applied himself entirely to the augmentation of his army, and perfecting them in their exercise, by which means they became the most expert soldiers in Europe. His foible was an ambition of having his army composed of men above the ordinary size; but as these could not be procured, he composed a regiment of the tallest men he could find; and as his officers made no scruple of picking up such men wherever they could find them for his majesty's use, the neighbouring states were frequently offended, and a war was often likely to ensue even from this ridiculous cause. However, his Prussian majesty was never engaged in any martial enterprise of consequence: but having put his army on the most respectable footing of any in the world, and filled his coffers, for he was of a very saving disposition, he put it in the power of his son to perform those exploits which have been matter of astonishment to all Europe.

16 Enmity between Prussia and Austria.

It was in this king's reign that Prussia first perceived her natural enemy and rival to be the house of Austria, and not France as had been formerly supposed. Hence frequent bickerings took place between these two powers, for which the persecution of the Protestants by some of the Catholic states of the empire afforded a pretence; and though a war never actually took place, yet it was easy to see that both were mortal enemies to each other. But when Frederic William died in 1740, this enmity broke out in full force. The empress queen was then left in a very disagreeable situation, as has been observed under the article BRITAIN, N° 410, &c. Of this Frederic III. took the advantage to do himself justice, as he said, with regard to Silesia, of which his ancestors had been unjustly deprived. This province he seized at that time: but it cost him dear; for the empress having at last overcome all difficulties, formed against him the most terrible combination that ever was known in Europe.

17 Frederic III. seizes Silesia.

18 Combination against him.

The treaty was hardly concluded with the king of Prussia, by which she reluctantly yielded up the province of Silesia, and with it a clear revenue of 800,000l. a year, before she entered into another with the court of Petersburg, which was concluded May 22. 1746. This treaty, as far as it was made public, was only of a defensive nature; but six secret and separate articles were added to it. By one of these it was provided, that in case his Prussian majesty should attack the empress queen, or the empress of Russia, or even the republic of Poland, it should be considered as a breach of the treaty of Dresden, by which Silesia was given up. It was also stipulated, that, notwithstanding that treaty (which indeed had been dictated by the king of Prussia himself), the

Prussia.

the right of the empress-queen to Silesia still continued, and for the recovery of that province the contracting powers should mutually furnish an army of 60,000 men. To this treaty, called the treaty of *Petersburg*, the king of Poland was invited to accede; but he, being in a manner in the power of the king of Prussia, did not think proper to sign it: however, he verbally acceded to it in such a manner, that the other parties were fully convinced of his design to cooperate with all their measures; and in consideration of this intention, it was agreed that he should have a share in the partition of the king of Prussia's dominions, in case of a successful event of their enterprises.

In consequence of these machinations, every art was used to render the king of Prussia personally odious to the empress of Russia; the queen of Hungary made vast preparations in Bohemia and Moravia; and the king of Poland, under pretence of a military amusement, drew together 16,000 men, with whom he occupied a strong post at Pirna. The queen of Hungary, still further to strengthen herself, concluded a treaty with the court of France at Versailles, dated May 1. 1756. But in the mean time, the king of Prussia having understood by his emissaries what was going forward, resolved to be beforehand with his enemies, and at least

19 He invades Saxony,

to keep the war out of his own country; and therefore entered Saxony with a considerable army. At first he affected only to demand a free passage for his troops, and an observance of the neutrality professed by the king of Poland; but, having good reasons to doubt this neutrality, he demanded, as a preliminary, that these Saxon troops should immediately quit the strong post they occupied, and disperse themselves. This demand was refused; on which his Prussian majesty blockaded the Saxon camp at Pirna, resolving to reduce it by famine, since its strong situation rendered an attack very dangerous. At that time there were in Bohemia two Saxon armies, one under the command of M. Brown, and the other under M. Picolomini. To keep these in awe, the king had sent M. Schwerin with an army into Bohemia from the country of Glatz, and M. Keith had penetrated into the same kingdom on the side of Misnia. But still the king of Prussia did not entirely confide in these dispositions;

20 and takes 16,000 Saxons prisoners.

and therefore fearing lest M. Brown might afford some assistance to the Saxons, he joined his forces under Keith, and on December 1. attacked and defeated the Austrian general, so that the latter found it impossible to relieve the Saxons, who, after a vain attempt to retire from their post, were all taken prisoners. The king of Poland quitted his dominions in Germany, and the Prussians took up their winter quarters in Saxony. Here they seized on the revenues, levied exorbitant contributions, and obliged the country to furnish them with recruits. The king of Prussia at this time made himself master of the archives of Dresden, by which means he procured the originals of those pieces above mentioned, which, when produced to the world, gave a full proof of the combination that had been formed against him, and consequently justified the measures he had taken for his own defence.

21 He is prosecuted in the Aulic council, and put to the ban of the empire.

No sooner had the king entered Saxony, in the manner already related, than a process was commenced against him in the emperor's Aulic council, and before the diet of the empire, where he was soon condemned for contumacy, and put to the ban of the empire.—The various circles of the empire were ordered to furnish their contingents of men and money to put this sentence in execution; but these came in so slowly, that, had it not been for the assistance of the French under the prince de Soubise, the army would probably have never been in a condition to act. The Austrians, in the mean time, made great preparations, and raised 100,000 men in Bohemia, whom they committed to the care of Prince Charles of Lorrain, assisted by M. Brown. The Czarina sent a body of 60,000 men under M. Apraxin, to invade the Ducal Prussia; whilst a strong fleet was equipped in the Baltic, in order to co-operate with that army. The king of Sweden also acceded to the confederacy, in hopes of recovering the possessions in Pomerania which his ancestors had enjoyed; and the duke of Mecklenburg took the same party, promising to join the Swedish army with 6000 men as soon as it should be necessary. On the king of Prussia's side appeared nobody excepting an army of between 30,000 and 40,000 Hanoverians commanded by the duke of Cumberland; and these were outnumbered and forced to yield to a superior army of French commanded by M. d'Etrees.

22 Prodigious preparations against him.

23 He invades Bohemia, and totally defeats the Austrian army.

In the mean time, his Prussian majesty, finding that he must depend for assistance solely on his own abilities, resolved to make the best use of his time. Accordingly, in the spring 1757, his armies poured into Bohemia from two different quarters, while the king himself prepared to enter it from a third. M. Schwerin entered from Silesia; the prince of Bevern from Lusatia, where he defeated an army of 28,000 Austrians that opposed his passage. As the intentions of the king himself were not known, the Austrians detached a body of 20,000 men from their main army to observe his motions. This was no sooner done than the king cut off all communication between the detachment and the main body: and having joined his two generals with incredible celerity, he engaged the Austrians near Prague, totally defeated them, took their camp, military chest, and cannon; but lost the brave General Schwerin, who was killed at the age of 82, with a colonel's standard in his hand. On the Austrian side, M. Brown was wounded, and died in a short time, though it is supposed more from the chagrin he suffered, than from the dangerous nature of the wound itself.

24 Besieges and bombards Prague.

About 40,000 of the Austrian army took refuge in Prague, while the rest fled different ways. The city was instantly invested by the king, and all succours were cut off. The great number of troops which it contained rendered an attack unadvisable, but seemed to render the reduction of it by famine inevitable; however, the king, to accomplish his purpose the more speedily, prepared to bombard the town. On the 29th of May, after a most dreadful storm of thunder and lightning, four batteries began to play on the city. From these were thrown, every 24 hours, 288 bombs, besides a vast number of red-hot balls, so that it was soon on fire in every quarter. The garrison made a vigorous defence, and one well-conducted sally; but had the misfortune to be repulsed with great loss. The magistrates, burghers, and clergy, seeing their city on the point of being reduced

Prussia.

reduced to an heap of rubbish, supplicated the commander in the most earnest manner to capitulate; but he was deaf to their intreaties, and drove 12,000 of the most useless mouths out of town, who were quickly driven in again by the Prussians.

25
Count Daun takes the command of the Austrian army.

Thus the affairs of the empress queen seemed verging to destruction, when Leopold count Daun took upon him the command of the remains of M. Brown's army. This general had arrived within a few miles of Prague the day after the great battle. He immediately collected the scattered fugitives with the greatest diligence, and retired with them to a strong post in the neighbourhood, from whence he gave the troops in Prague hopes of a speedy relief. It was now the king of Prussia's business, either to have attempted to make himself master of the city by one desperate effort, or entirely to have abandoned the enterprise, and driven Count Daun from his post before his troops had recovered from the terror of their late defeat; but, by attempting to do both, he rendered himself incapable of doing either. Though the army of Count Daun already amounted to 60,000 men, and though they were strongly entrenched, and defended by a vast train of artillery, his majesty thought proper to send no more than 32,000 men. This body made the arduous attempt on the 18th of June; but though they did all that human courage and conduct could do, and though the king himself at last charged at the head of his cavalry, the Prussians were driven out of the field with great loss. This engagement was named *the battle of Colin.*

26
Defeats the Prussians at Colin.

27
Siege of Prague raised.

The first consequence of the battle of Colin was, that the king of Prussia was obliged to raise the siege of Prague; soon after which, he was obliged to quit Bohemia, and take refuge in Saxony. The Austrians harassed him as much as possible; but, notwithstanding their great superiority, their armies were not in a condition to make any decisive attempt upon him, as the frontiers of Saxony abounded with situations easily defended. In the mean time the Russians, who had hitherto been very dilatory in their motions, began to exert themselves, and entered Ducal Prussia, under M. Apraxin and Fermor, where they committed innumerable cruelties and excesses. A large body of Austrians entered Silesia, and penetrated as far as Breslau. Then they made a turn backwards, and besieged Schweidnitz. Another body entered Lusatia, and made themselves masters of Zittau. An army of 22,000 Swedes entered Prussian Pomerania, took the towns of Anclam and Demmein, and laid the whole country under contribution. The French, too, being freed from all restraint by the capitulation of the duke of Cumberland at Closter Seven *, made their way into Halberstadt and the Old March of Brandenburg, first exacting contributions, and then plundering the towns. The army of the empire, being reinforced by that of the prince de Soubise, after many delays, was on full march to enter Saxony, which left the Austrians at liberty to exert the greatest part of their force in the reduction of Silesia. General Haddick penetrated through Lusatia, passed by the Prussian armies, and suddenly appeared before the gates of Berlin, which city he laid under contribution. He retired on the approach of a body of Prussians; yet he still found means to keep such a post as interrupted the king's communication with Silesia. The destruction of the king of Prussia therefore now seemed inevitable. Every exertion which he had made, though brave and well-conducted, had been unsuccessful. His general Lehwald, who opposed the Russians, had orders to attack them at all events. He obeyed his orders; and with 30,000 men attacked 60,000 of the enemy strongly entrenched at a place called *Norkitten*. The Prussians behaved with the greatest valour; but after having killed five times more of the enemy than they themselves lost, they were obliged to retire, though more formidable after their defeat than the Russians after their victory. The king, in the mean time, exerted himself on every side, and his enemies fled everywhere before him; but whilst he pursued one body, another gained upon him in some other part, and the winter came on fast, while his strength decayed, and that of his adversaries seemed to increase on every quarter.

* See Britain, N° 441.

28
Berlin laid under contribution.

29
Lehwald's Prussian general defeated by the Russians.

The Prussian monarch, however, though distressed, did not abandon himself to despair, or lose that wonderful presence of mind which has so eminently distinguished him in all his military enterprises. He industriously delayed a decisive action till the approach of winter; but at last, after various movements, on November 5. 1757, he met at Rosbach with the united army of his enemies commanded by the prince of Saxe Hilburghausen and the prince de Soubise. The allied army amounted to 50,000 men complete; but most of the troops of the Circles were new raised, and many of them not well affected to the cause. The Prussians did not exceed 25,000 men; but they were superior to any troops in the world, and were inspired, by the presence of their king, with the most enthusiastic valour. The Austrians were defeated with the loss of 3000 killed, eight generals, 250 officers of different ranks, and 6000 private soldiers, taken prisoners, while night alone prevented the total destruction of the army.

30
The king gains a great victory at Rosbach.

By this battle the king was set free on one side; but this only gave him an opportunity of renewing his labours on another. The Austrians had a great force, and now began to make a proportionable progress in Silesia. After a siege of 16 days, they had reduced the strong fortress of Schweidnitz, and obliged the Prussian garrison of 4000 men to surrender prisoners of war. Hearing then of the victory at Rosbach, and that the king of Prussia was in full march to relieve Silesia, they resolved to attack the prince of Bevern in his strong camp under the walls of Breslau. They attacked the prince's army on November 22d; but their attack was sustained with the greatest resolution. The slaughter of the Austrians was prodigious. A great part of the enemy had retired from the field of battle, and the rest were preparing to retire, when all at once the Prussian generals took the same resolution. Their army had suffered much in the engagement, and they became apprehensive of a total defeat in case their intrenchments should be forced in any part; for which reason they quitted their strong post, and retired behind the Oder. Two days after, the prince of Bevern, going to reconnoitre without escort, attended only by a groom, was taken prisoner by an advanced party of Croats, a small body of whom had crossed the Oder.

On

Prussia

33 Breslau taken by the Austrians.

On this the town of Breslau immediately surrendered; where, as well as at Schweidnitz, the Austrians found great quantities of provisions, ammunition, and money. All Silesia was on the point of falling into their hands, and the Prussian affairs were going into the utmost distraction, when the king himself by a most rapid march passed through Thuringia, Misnia, and Lusatia, in spite of the utmost efforts of the generals Haddick and Marshal, who were placed there to oppose him; and, entering Silesia on the 2d of December, joined the prince of Bevern's corps, who repassed the Oder to meet him. The garrison of Schweidnitz, who, as we have already observed, had been made prisoners of war, also joined the king's army unexpectedly; and their presence contributed not a little, notwithstanding the smallness of their number, to raise the spirits of the whole army. They had submitted to the capitulation with the greatest reluctance; but as the Austrians were conducting them to prison, they happened to receive intelligence of the victory at Rosbach: on which they immediately rose on the escort that conducted them, and entirely dispersed it; and afterwards marched in such a direction as they thought might most readily lead them to their king, they accidentally fell in with his army.

34 Garrison of Schweidnitz recover their liberty.

35 Count Daun defeated by the king of Prussia at Leuthen.

His Prussian majesty now approached Breslau; on which the Austrians, confiding in their superiority, (for they exceeded 70,000, while the Prussians scarce amounted to 36,000), abandoned their strong camp, the same which the prince of Bevern had formerly occupied, and advanced to give him battle. The king did not intend by any means to disappoint them, but advanced on his part with the greatest celerity. The two armies met on December 5th, near the village of Leuthen. Count Daun made the best dispositions possible. The ground occupied by his army was a plain, with small eminences in some parts. These eminences they surrounded with artillery; and as the ground was also interspersed with thickets, they sought to turn these likewise to their advantage. On their right and left were hills, on which they planted batteries of cannon. The ground in their front was intersected by many causeways; and to make the whole more impracticable, the Austrians had felled a great number of trees, and scattered them in the way. It was almost impossible at the beginning of the engagement for the Prussian cavalry to act, on account of these impediments; but, by a judicious disposition made by the king himself, all difficulties were overcome. His majesty had placed four battalions behind the cavalry of his right wing; foreseeing that General Nadasti, who was placed on the enemy's left with a corps de reserve, designed to attack him in flank. It happened as he had foreseen: that general's cavalry attacked the Prussian right wing with great fury; but he was received with such a severe fire from the four battalions, that he was obliged to retire in disorder. The king's flank then, well covered and supported, was enabled to act with such order and vigour as repulsed the enemy. The Austrian artillery was also silenced by that of the Prussians; however, the Austrians continued to make a gallant resistance during the whole battle. After having been once thrown into disorder, they rallied all their forces about Leuthen, which was defended on every side by entrenchments and redoubts. The Prussians attacked them with the utmost impetuosity, and at last became masters of the post; on which the enemy fled on all sides, and a total rout ensued. In this battle the Austrians lost 6000 killed on the spot, 15,000 taken prisoners, and upwards of 200 pieces of cannon.

36 Breslau retaken.

The consequences of this victory were very great. Breslau was immediately invested, and surrendered on December 29th; the garrison, amounting to 13,000 men, were made prisoners of war. The blockade of Schweidnitz was formed as closely as the season of the year would permit; while detached Prussian parties overran the whole country of Silesia, and reduced every place of less importance. The Russians, who had ravaged and destroyed the country in such a manner that they could not subsist in it, thought proper to retire out of the Prussian dominions altogether. Thus General Lehwald was left at liberty to act against the Swedes; and them he quickly drove out of Prussian Pomerania, the whole of which country he not only recovered, but also some part of Swedish Pomerania. Thus the duchy of Mecklenburg being left quite exposed, the king took ample vengeance on it by exacting the most severe contributions of men and money. To complete this monarch's good fortune also, the French, who had retired after the battle of Rosbach, were now opposed by the Hanoverians under Prince Ferdinand, who kept them so well employed, that, during the rest of the war, the king of Prussia had no more trouble from them. See Britain, N° 442.

37 Swedes driven out of Pomerania.

38 Schweidnitz retaken.

The beginning of the year 1758 was favourable to the arms of his Prussian majesty. On the 3d of April he commenced his operations against Schweidnitz, and pushed the siege so vigorously, that the place surrendered in 13 days. He then disposed his forces in such a manner as might best guard his dominions against his numerous enemies. For this purpose Count Dohna commanded a body of troops on the side of Pomerania; another considerable body was posted between Wohlau and Glogau, in order to cover Silesia from the Russians, in case they should make their inroad that way. An army, in a little time after, was formed in Saxony, commanded by the king's brother Prince Henry. This army consisted of 30 battalions and 45 squadrons, and was designed to make head against the army of the empire; which, by great efforts made during the winter, and the junction of a large body of Austrians, was again in a condition to act. Between all these armies a ready communication was kept up by a proper choice of posts. After the reduction of Schweidnitz, the king having made a show of invading Bohemia, suddenly burst into Moravia, where in a short time he made himself master of the whole country, and on the 27th of May laid siege to Olmutz the capital. Of this M. Daun was no sooner informed, than he took his route to Moravia through Bohemia: and though he was not in a condition to risk a battle, nor indeed would have done so unless he had had a very considerable advantage; yet, by placing himself in a strong situation where he could not be attacked, by harassing the king's troops and cutting off their convoys, he at last obliged him to abandon the enterprise. The king, however, who frequently owed a good part of his success to the impenetrable secrecy with which he covered all his designs, gave not the least hint of his intention to raise the siege of Olmutz.

39 The king besieges Olmutz without success.

On

Prussia. On the contrary, the very day before the siege was raised, the firing continued as brisk as ever; but in the night (July 1.) the whole army took the road to Bohemia in two columns, and gained an entire march upon the Austrians. Thus, notwithstanding the utmost efforts of his enemies, the Pussian army reached Bohemia with very little molestation. Here he seized upon a large magazine at Lieutomissel; defeated some corps of Austrians who had attempted to interrupt his progress; and arrived at Konigsgratz, of which he took possession, after driving from it 7000 Austrians who were intrenched there. This city and several other districts he laid under contribution: but soon after entered Silesia, and marched with the utmost rapidity to encounter the Russians, who had at that time united their forces under generals Brown and Fermor, entered the New Marche of Brandenburg, and laid siege to Custrin.

40 The Russians besiege Custrin.

The king arrived at this city at a very critical period. The Russians had laid siege to it on the 15th of August; and though they were not well skilled in managing artillery, yet, by furious and unremitting discharges at random, they threw in such a number of bombs and red-hot balls, that the town was soon on fire in every quarter. Some of the wretched inhabitants were burned; others buried in the ruins of their houses, or killed by the balls which fell like hail in the streets; while many of the survivors abandoned their habitations, and fled out of the town on that side where it was not invested. The governor did every thing for the defence of the place; but as the walls were built after the old manner, it was impossible that the town could have made a defence for any length of time, especially as the principal magazine of the besieged had been blown up. The avenger of all these injuries, however, was now at hand. The king came in sight of the Russians on the 25th of August, after a march of 56 days, and beheld the country everywhere desolated, and the villages in flames by the depredations of his cruel enemy, who had raised the siege at his approach, and retired towards a neighbouring village named *Zorndorff*. At nine o'clock in the morning, a most terrible fire of cannon and mortars poured destruction on the right wing of the Russian army for two hours without intermission. The slaughter was such as might have been expected; but the Russians kept their ground with astonishing resolution, new regiments still pressing forward to supply the places of those that fell. When the first line had fired away all their charges, they rushed forward on the Prussians with their bayonets; and all at once these brave troops, though encouraged by the presence of their king, gave way and fled before an enemy already half defeated. The Russian generals ought now to have attacked with their cavalry the disordered infantry of their enemies, which would have completed the defeat, and in all probability given the finishing stroke to the king of Prussia's affairs. This opportunity, however, they lost: but the king was not so negligent; for, by a very rapid and masterly motion, he brought all the cavalry of his right wing to the centre, and falling on the Russian foot uncovered by their horse, and even disordered by their own success, they pushed them back with most miserable slaughter, at the same time that the repulsed battalions of infantry, returning from the charge, and exasperated at their late disgrace, rendered the victory no longer doubtful. The Russians were now thrown into the most dreadful confusion. The wind blew the dust and smoke into their faces, so that they could not distinguish friends from foes; they fired on each other, plundered their own baggage which stood between the lines, and intoxicated themselves with brandy: the ranks fell in upon one another; and, being thus crammed together into a narrow space, the fire of the Prussians had a full and dreadful effect, while their enemies kept up only a scattered and ineffectual fire, generally quite over their heads. Yet even in this dismal situation the Russians did not fly; but suffered themselves to be slaughtered till seven at night, when their generals having caused an attack to be made on the Prussian right wing, the attention of the enemy was drawn to that quarter, and they had time to retire a little from the field of battle to recover their order.

41 But are defeated at Zorndorff.

In this engagement, which was called the *battle of Zorndorff*, the Russians lost 21,529 men, while that of the Prussians did not exceed 2000. A vast train of artillery was taken, together with the military chest, and many officers of high rank. The consequence was, that the Russian army retreated as far as Landsperg on the frontiers of Poland, and the king was left at liberty to march with his usual expedition to the relief of Prince Henry in Saxony.

42 Operations of Count Daun,

The prince was at this time sorely pressed by M. Daun. As soon as the king had left Bohemia in the manner already related, M. Daun, considering that it would have been to no purpose to follow him, resolved to turn his arms towards Saxony. Towards that country, therefore, he took his route through Lusatia, by Zittau, Gorlitz, and Bautzen. On the 3d of September he invested the strong fortress of Sonnestein; which unaccountably surrendered, after a single day's resistance, to one of his generals named *Macguire*. He then began to favour the operations of General Laudohn, who had advanced through the Lower Lusatia to the confines of Brandenburg; and, by drawing the attention of the Prussian forces which were left in Silesia to the northward of that duchy, he facilitated the progress of the generals Harsch and De Ville in the southern parts. He then proposed that Prince Henry should be attacked by the army of the empire, while that of the Austrians should pass the Elbe, and falling at the same time on the Prussians, second the attack of the Imperialists, and cut off the retreat of their enemies from Dresden. The sudden appearance of the king of Prussia, however, put an end to his plan; General Laudohn abandoned all his conquests in Lower Lusatia, and retired towards M. Daun, while that general himself retired from the neighbourhood of Dresden as far as Zittau. The army of the empire only kept its ground; possessing itself of the strong post at Pirna, formerly mentioned, but did not undertake any thing. As for the Swedes, who had directed their motions by those of the Russians, they no sooner heard of the victory of Zorndorff, than they retreated with much more expedition than they had advanced.

43 rendered abortive by the king of Prussia;

Thus the king of Prussia's affairs seemed to be pretty well retrieved, when by one fatal piece of negligence he was brought to the verge of ruin. M. Daun had possessed himself of an advantageous camp at Stolphen, by which he preserved a communication with the army of

Prussia.

of the empire. On the other hand, the king of Prussia, having taken possession of an important post at Bautzen, extended his right wing to the village of Hochkirchen, by which he preserved a communication with his brother Prince Henry, protected Brandenburg, and was better situated than he could be anywhere else for throwing succours into Silesia. The two armies kept a watchful eye on the motions of each other; and as the principal aim of M. Daun was to cut off the king's communication with Silesia, and of the king to cut off M. Daun's communication with Bohemia, a battle seemed inevitable, though great danger seemed to await that party who should begin the attack.

44
Who is surprised and defeated at Hochkirchen.

In this critical posture of affairs, the Austrian general formed a design of attacking the Prussian camp in the night. In what manner he came to surprise such a vigilant enemy has never been accounted for; but that such a surprise was actually accomplished on the 14th of October, is certain. In the dead of the preceding night, the Austrian army began to march in three columns towards the camp of the king of Prussia; and though the night was exceedingly dark, and they had a considerable way to go, they all arrived at the same time, in safety, without being discovered, aud without the least confusion; and at five in the morning began a regular and well-conducted attack. The Prussians were in a moment thrown into confusion; Marshal Keith, one of their best generals, received two musket-balls, and fell dead on the spot. Prince Francis of Brunswick had his head shot off by a cannon-ball as he was mounting his horse; and every thing seemed to announce the total destruction of the army. Still, however, the king preserved his wonderful presence of mind, which indeed he never appears to have lost on any occasion. He ordered some detachments from his left to support his right wing; but the moment that these orders were received, the left itself was furiously attacked. General Ketzow, who commanded in that quarter, repulsed the Austrians with difficulty, and was not able to afford any considerable assistance to the right; which alone was obliged to sustain the weight of the grand attack. The Austrians, in the beginning of the engagement, had driven the Prussians out of the village of Hochkirchen; and as the fate of the day depended on the possession of that post, the hottest dispute was there. The Prussians made three bloody and unsuccessful attacks on the village; on the fourth they carried it; but the Austrians continually pouring in fresh troops, at last drove them out with prodigious slaughter on all sides. The king then ordered a retreat, which was conducted in good order, without being pursued; however, this bloody action cost him 7000 men, together with a great number of cannon. The Austrians computed their own loss at 5000.

His Prussian majesty, having thus happily escaped such imminent danger, took every possible measure to prevent the enemy from gaining any considerable advantage from his defeat. Perceiving that the only advantage they wished to derive from it was to cover the operations of their armies in Silesia, and that he had now nothing to fear on the side of Saxony, he largely reinforced his own army from that of Prince Henry, and hastened into Silesia, in order to raise the siege of Neiss, which had been completely invested on the 4th of October. On the 24th of that month, therefore, he quitted his camp, and making a great compass to avoid obstructions from the enemy, arrived in the plains of Gorlitz. A body of the Austrians had in vain attempted to secure this post before him, and some who arrived after him were defeated with the loss of 800 men. From this place the king pursued his march with the utmost diligence; but was followed by General Laudohn, at the head of 24,000 men, who constantly hung on his rear, and harassed his army. The king, however, knowing the importance of his expedition, continued his march without interruption, and suffered his antagonist to obtain many little advantages without molestation. Daun, however, not content with the opposition given by Laudohn, sent a large body of horse and foot by another route to reinforce the generals Karsch and De Ville, who had formed the siege of Neiss and the blockade of Cosel, while he himself passed the Elbe, and advanced towards Dresden.

All these precautions, however, were of little avail. The generals Karsch and De Ville, notwithstanding their reinforcement, no sooner heard of the king of Prussia's approach, than they raised the siege of both places, and retired, leaving behind them a considerable quantity of military stores. The end of the Prussian monarch's march being thus accomplished, he instantly returned by the same way he came, and hastened to the relief of Saxony, the capital of which (Dresden) was in great danger from Marshal Daun. The place was but indifferently fortified, and garrisoned only by 12,000 men; so that it could not promise to hold out long against a numerous and well-appointed army. It was besides commanded by a large suburb, of which, if once the enemy got possession, all defence of the city must then be vain. For this reason M. Schmettau, the Prussian governor, determined to set these suburbs on fire, which was actually done November 10th, with an incredible loss to the inhabitants, as in the suburbs were carried on most of those valuable manufactures which render the city of Dresden remarkable. This disappointed the designs of M. Daun; but, though the action was agreeable to the laws of war, and had been executed with all the caution and humanity of which such an action was capable, yet the Austrians exclaimed against it as a piece of the most unprovoked and wanton cruelty recorded in history.

45
Suburbs of Dresden burnt.

46
Saxony oppressed by the king of Prussia.

After the king of Prussia had approached Dresden, all the Austrian armies retired into Bohemia, where they took up their winter-quarters, as the king of Prussia did in Saxony. This unhappy country he said he would now consider as his own by right of conquest. But instead of treating the conquered people as his lawful subjects, he oppressed them in all possible ways, by levying the most severe and exorbitant contributions, surrounding the exchange with soldiers, and confining the merchants in narrow lodgings on straw-beds, till they drew upon their correspondents for such sums as he wanted.

In 1759, as early as the 23d of February, the Prussians commenced their military operations. General Wobersow marched with a body of troops into Poland, where he destroyed several very large magazines belonging to the Russians, and returned into Silesia without any loss on the 18th of April. In the mean time, by some movements of the king of Prussia himself, the greatest part of the Austrian troops had been drawn

drawn towards the frontiers of Silesia. Prince Henry immediately took advantage of this opening, and on the 15th of April entered Bohemia with his army divided into two columns. One, commanded by himself, marched towards Peterswade; the other, under General Hulsen, passed by the towns of Pasberg and Commottau. That commanded by Prince Henry himself penetrated as far as Loboschutz and Leitmeritz; the enemy flying everywhere before them, and burning or abandoning the vast magazines which they had amassed in these parts. The body under General Hulsen had a more active employment. A strong pass at Pasberg was defended by a considerable body of Austrians. General Hulsen, having conducted his cavalry by another way in such a manner as to fall directly on their rear, attacked them in front with his infantry, drove them out of their intrenchments, and totally defeated them with the loss of a great number killed, and 2000 taken prisoners, while that of the Prussians did not exceed 70 in killed and wounded. After this exploit they returned into Saxony, with hostages for the contributions which they had largely exacted during the course of their expedition.

47 Bohemia invaded by Prince Henry.

48 A body of Austrians defeated by General Hulsen.

Some other successes obtained by Prince Henry cleared the country of Franconia of his enemies; but now the approach of the Russians seemed once more to bring the affairs of the king of Prussia to a crisis. Notwithstanding the destruction of their magazines, they had continued to advance into Silesia, where they were opposed by Count Dohna; but as the troops he had with him were very far inferior to his enemies, he found it impossible to do more, at least with any appearance of success, than to observe their motions and harass them on their march. But this was so displeasing to the king, that he disgraced his general, and appointed Wedel to succeed him, with orders to attack the Russians at all events. To enable him, however, in some measure to comply with this desperate order, he sent him some reinforcements, which brought his army up to near 30,000. With these, on the 23d of July 1759, General Wedel attacked 70,000 Russians posted in the most advantageous manner at Zulichau, and defended by a numerous artillery. Though the Prussians marched on to certain destruction and disgrace, they sustained the attack for a long time with unparalleled resolution. At last, however, they gave way, and were obliged to retire with the loss of 4700 killed or taken prisoners, and 3000 wounded.

49 Prussians defeated at Zulichau.

50 The Russians take Crossen and Frankfort on the Oder.

The consequences of this victory were, that the Russians penetrated into the king's territories, and took possession of the towns of Crossen and Frankfort on the Oder, which made it absolutely necessary for the king to come in person to oppose them. Accordingly, on the 4th of August, he joined Wedel with a considerable body of forces, having left the greatest part of his army in Saxony under Prince Henry. But as Marshal Daun had sent a body of 12,000 horse and 8000 foot under General Laudohn to the assistance of the Russians, the king still found himself unable to fight them; as, with this and some other reinforcements, their army now amounted to upwards of 90,000. He therefore recalled General Finck, whom he had sent into Saxony with 9000 men; but with all his reinforcements, it was found impossible to augment his army to 50,000 complete. His situation, however, was now so critical that a battle was unavoidable; and therefore, on the 12th of August, with this inferiority of number, the king attacked his enemies strongly intrenched, and defended by a prodigious number of cannon. In this action, his principal effort was against the left wing of the Russian army. He began the attack, according to custom, with a heavy cannonade; which having produced the desired effect, he attacked that wing with several battalions disposed in columns. The Russian intrenchments were forced with great slaughter, and 72 pieces of cannon were taken. But still there was a defile to be passed, and several redoubts which covered the village of Cunnersdorf to be mastered. These were attacked with the same resolution, and taken one after another. The enemy made another stand at the village, and endeavoured to preserve their ground there by pushing forward several battalions of horse and foot: but this also proved unsuccessful; they were driven from post to post quite to the last redoubts. For upwards of six hours the Prussians were successful, and everywhere broke the enemy with prodigious slaughter; drove them from almost all the ground they had occupied before the battle, took more than half their artillery, and scarce any thing seemed wanting to make the victory complete. In these circumstances, the king wrote the following billet to the queen: "Madam, we have beat the Russians from their intrenchments. In two hours expect to hear of a glorious victory." Of this victory, however, he deprived himself, by an excessive eagerness for conquest. The enemy, defeated almost in every quarter, found their left wing, shattered as it was, to be more entire than any other part of their army. Count Soltikoff, the Russian general, therefore, assembled the remains of his right wing, and, gathering as many as he could from his centre, reinforced the left, and made a stand at a redoubt which had been erected on an advantageous eminence in a placed called *the Jews burying-ground*. All the king's generals are said to have been of opinion that he ought to allow the Russians the peaceable possession of this post. Their army had already suffered so much, that it would have been impossible for them to have attempted any enterprise of consequence after the battle; but their artillery was still numerous, the post very strong, and the Prussian troops greatly fatigued. These reasons for a few moments had some weight with the king; but the natural impetuosity of his temper getting the better of his reason, he led on his wearied troops again and again; till at last, when their strength was in a manner totally exhausted, they were attacked and utterly routed by the Austrian and Russian cavalry, the former of which had hitherto remained quite inactive, and were therefore quite fresh, and irresistible by the enfeebled Prussians. The night, and the prudent use of some eminences, prevented the total destruction of the army; however, their loss amounted to 20,000 men killed and wounded. The king, when he found the victory totally lost, sent another billet to the queen, expressed in the following manner: "Remove from Berlin with the royal family; let the archives be carried to Potsdam; the town may make conditions with the enemy."

51 King of Prussia defeated by the Russians at Cunnersdorf.

Immediately after this defeat, the king set himself about repairing his losses with the utmost diligence. In a few days every thing was again put in order in his camp.

Prussia.

camp. He replaced his artillery from Berlin; recalled General Kliest with 5000 men from Pomerania; detached 6000 from his own army to the defence of Saxony; and with the remainder put himself between the Russsians and Great Glogau, covering that city which had been the chief object of their designs; and in short, notwithstanding their victory, obliged them to return to Poland without accomplishing any thing besides the carnage at Cunnersdorff.

The misfortunes of the Prussian monarch, however, were not at an end. Prince Henry, indeed, by a most extraordinary and well-conducted march, entered Saxony, which was now totally overrun by the armies of the enemy. At the same time, strong detachments having been sent into that country under generals Finck and Wunsch, the whole was in a short time recovered except Dresden. Towards this place Marshal Daun retired, and in all probability would soon have been obliged to leave Saxony entirely. But the king's impatience could not be satisfied without cutting off his retreat, and forcing him to a battle; for which purpose he sent General Finck with upwards of 12,000 men according to the Prussian account, but 20,000 according to the Austrians, to seize some passes through which M. Daun could only take his route towards Bohemia.

This commission was executed with great exactness; but the Prussian general, having probably advanced too far into these defiles, and neglected to preserve a communication with the main army, gave his enemy an opportunity of surrounding him, and at last forcing him and his whole army to surrender prisoners of war. This disaster was soon after followed by another. General Durceke was posted at the right of the Elbe, opposite to Messen; but on the approach of a large body of Austrians, they prepared to retreat over the river into a place where they hoped to be more secure. But having been obliged by an hard frost to withdraw their bridge of boats, a thaw supervened, when they attempted to lay a bridge of pontoons, so that they were again obliged to have recourse to their boats. In this situation, their rear-guard was attacked with great fury by the Austrians, and all the soldiers who composed it killed or taken. The loss of the Prussians on this occasion was computed at 3000 men.

The year 1760 showed the Prussian monarch in a more dangerous situation than he had ever yet experienced.

53
sperate
ation of
king of
ssia.

Indeed his affairs now seemed to be altogether desperate. His losses were not to be measured by the number of the killed or prisoners, but by armies destroyed or taken. Forty generals had died or been killed in his service since the beginning of October 1756, exclusive of those who were wounded or taken prisoners. This of itself would have been an irreparable loss, had not the very wars which destroyed these furnished others equally capable of filling their places. But another deficiency, which could not be remedied, still remained.—The king had, by his indefatigable industry and exertions, supplied all the deficiencies of men in his armies, but they were not the same men as before. The hardy veterans, with whom he had originally taken the field, were now no more, and their places were supplied by others who had neither the same experience nor discipline; so that now he was obliged to supply this deficiency by his own genius and heroism.

But whatever abilities the Prussian monarch might possess, and though he undoubtedly exerted them to the utmost, it seemed only to be contending against fate, and his enemies gained still greater and greater advantages. General Laudohn, with whom none but the king himself seems to have been able to cope, by a series of artful movements, drew into a disadvantageous situation M. Fouquet, one of the Prussian generals, with a strong body of forces. Perceiving it impossible for them to escape, Laudohn then made a violent attack on their entrenchments in the dead of the night of June 23d. The Prussians made a gallant defence, but at last were all killed or taken prisoners except about 300. Of the Prussians were killed 4000, and 7000 taken prisoners; 58 pieces of cannon, and a great number of colours, were also lost. The victory, however, was dear bought; for the Austrians lost above 12,000 men in killed and wounded; whom, however, they could better spare than the Prussians, on account of their numbers.—This action was called the *battle of Landshut*.

54
Prussians
defeated at
Landshut.

Baron Laudohn failed not to improve this victory to the utmost. He instantly turned back from Landshut, and fell upon the city of Glatz; which he took in a very short time, with the garrison who defended it, consisting of 2000 men. In this place were found 101 pieces of brass cannon, with immense quantities of provisions and military stores. From thence he marched against Breslau, and immediately invested it. But, in the mean time, the king of Prussia, whose motions had been all this time counteracted by M. Daun in Saxony, marched with his usual rapidity towards Silesia. By this means he drew M. Daun out of Saxony; and indeed the Austrian general used such expedition, that he gained two full days on the king. This was no sooner known to his Prussian majesty, than he returned with the same expedition that he had advanced, and sat down before Dresden. Of this M. Daun soon received intelligence, and returned also. In the mean time, however, the buildings of the city were terribly shattered by the king's cannon and bombs which continually played on it. His endeavours, however, proved ineffectual to reduce it before the arrival of M. Daun. The siege had been begun on the 13th of July, and on the 19th M. Daun appeared within a league of Dresden. The Prussians then redoubled their efforts. They had that day received reinforcements of heavy cannon and mortars, with which they battered the place incessantly. The cathedral church, New Square, several principal streets and some palaces, and the noble manufactory of porcelain, were entirely destroyed. The siege was continued till the 22d; but, on the night of the 21st, M. Daun had thrown 16 battalions into the city; which rendered it impossible for the king to continue longer before it with any prospect of success. He therefore raised the siege, and retired without molestation, though there were three considerable armies of the enemy in the neighbourhood. Breslau was fiercely bombarded by Laudohn, but the approach of Prince Henry obliged him to desist from his enterprise on the 5th of August.

55
Glatz taken by the Austrians.

56
Dresden besieged, but without success, by the king of Prussia.

But, in the mean time, the fortune of the king seemed likely to be terminated by one fatal stroke. Finding it impossible for him to carry on a defensive war, he marched towards Silesia with such astonishing rapidity,

Prussia.

57 Three Austrian generals join their forces against him.

pidity, that before the middle of August he had advanced 200 miles, leaving Marshal Daun with his army far behind him. This expedition he undertook in order to engage General Laudohn before he could have time to effect a junction with Daun and Lacy, another Austrian general; which triple union seemed to threaten him with unavoidable destruction at once. This, however, he found it impossible to prevent: and the three armies, when joined, formed a most tremendous line of encampments, extending no less than 30 English miles; at the same time that every one of their posts was strong, and the communication between them easy. The king was strongly encamped at Lignitz; and for several days employed all his military skill in attempting to induce one of the bodies to detach itself from the rest, or to attack them at some disadvantage; but without effect. At last, the Austrian generals, having maturely weighed all circumstances, resolved to attack the king's camp itself, strong as it was; and Marshal Daun, remembering the advantage he had gained at Hochkirchen by an attack in the night-time, resolved to follow the same plan now. The plan therefore was laid in the following manner. The whole army, as soon as it should begin to grow dark, was to march from their several posts to such situations as were marked out for each corps: they were to strike their tents, but yet to keep up the fires in their camps, and to have the drums beat the tattoo as usual, by which means they had a probability of surprising the enemy; or if not, they judged it absolutely impossible for him to escape them, though he should be ever so much on his guard. In what manner the king of Prussia became acquainted with this plan, is not known. His friends attributed it to his own penetration and knowledge of the stratagems of war; the Austrians, to intelligence given him by deserters. But, in whatever way he became acquainted with this design, it is certain that he took the most effectual methods of preventing it. As the Austrian plan was to surround his camp, and this could not be done without the division of their army which he had so long desired, he resolved to intercept one of the parties; and if that should be disabled from acting, he could then more easily deal with the other two. Therefore, in the very evening calculated for the decisive attack on his camp, he quitted it with the utmost privacy, and took an advantageous post on the road through which General Laudohn was to pass. The nature of this post was such, that at the same time that it stopped the progress of Laudohn in front, Daun would lie under great difficulties if he should attempt his rear; at the same time that, for his further security, the king strengthened the rear with several batteries. As soon as his army was drawn up, he divided it; leaving his right on the ground where it had been formed, to observe Marshal Daun, and to maintain that post; whilst with his left he turned in order to fall on the corps under General Laudohn. In the mean time, that commander, ignorant of the fate which was awaiting him, advanced with the utmost expedition towards the place which had been assigned him, in order to share in the glory of destroying the Prussian monarch; when, at three in the morning, on the 15th of August, a thick fog which covered the ground, suddenly clearing up, discovered, like the opening of a great scene, the dreadful front of the Prussian army regularly embattled, and advantageously posted. Laudohn, though surprised, made the best dispositions that circumstances would admit of, and an obstinate engagement ensued; in which, however, he was at last obliged to yield to the superior skill of his adversary, with the loss of 10,000 killed, wounded, and prisoners, 82 pieces of cannon, and 23 pair of colours.

Prussia.

58 He defeats General Laudohn and intimidates the Russians.

The victory, though complete, gave but a partial relief to the king of Prussia. The most essential service it did was the preventing of the Russians from joining those enemies which he already had. Count Czernichew had been advancing with 24,000 men, and had even passed the Oder; but was so intimidated by this news, that he instantly repassed that river on the same bridges which he had lately built, even though M. Daun sent him a strong body of troops in order to encourage him to advance. Soon after this battle, the king joined his brother Prince Henry at New Marche, and marched against Daun, who had begun to form the blockade of Schweidnitz; fell upon a corps under General Beck, made two battalions of Croats prisoners, and dispersed the rest, which obliged the enemy to abandon the enterprise they had just undertaken. About the same time, General Hulsen gained a considerable advantage over the Imperial army in Saxony, with very trifling loss on his part, by which he effectually prevented them fnom cutting off his communication with the city of Torgau.

By these successes the affairs of his Prussian majesty seemed to revive: but there was no end of his enemies. The late manœuvres had drawn him so far into Silesia, that his communication with Brandenburg was almost wholly cut off. The Russian army, which after it had repassed the Oder began to move out of Silesia, sent forward a powerful detachment under Count Czernchew towards the marche of Brandenburg. A body of 15,000 Austrians, under the generals Lacy and Brentano, and the whole united body of Austrians and Imperialists which acted in Saxony, began their march in concert with the Russians, and proposed to unite at the gates of Berlin. These armies amounted to 40,000 men. To oppose this formidable power, General Hulsen called to his assistance General Werner, who had been sent with a body of troops into Pomerania; but, after being joined by him, their united forces were found not to exceed 15,000 or 16,000 men. To attempt a defence of the capital with this force would have been little short of madness: and therefore these commanders were obliged to leave Berlin to its fate;

59 Berlin taken by the Austrians and Russians.

which indeed, considering the barbarity of the Russians and the animosity of the Austrians, seemed to be a dreadful one. However, by the powerful mediation of several foreign ministers, the town obtained terms which were not altogether intolerable; but the magazines, arsenals, and founderies were destroyed, and an immense quantity of military stores seized, with a number of cannon and other arms. The city was first obliged to pay 800,000 guilders, after which a contribution of 1,900,000 crowns was laid on: yet, notwithstanding this, many violences were committed, and the king's palace was plundered and the furniture abused in a scandalous army.

The combined armies staid in Berlin only four days; dreading the severe vengeance of the king of Prussia, who

Prussia.

60 Extreme embarrassment of the king.

who they heard was advancing towards that place with great expedition. But so great were the embarrassments which now attended that monarch, that it seemed almost beyond human power to retrieve his affairs. The Imperialists, on their return from Berlin, having no army to oppose them, made themselves masters of Leipsic, Torgau, Meissen, and Wirtemberg; (in which last city they found the grand magazine of the Prussians immensely stored with provisions, ammunition, &c. M. Stainville also, with a detachment from Broglio the French general's army, laid the city and duchy of Halberstadt under contribution. In Eastern Pomerania, the Russians had besieged Colberg by sea and land. In the Western Pomerania, the Swedes advanced with great celerity, hoping to share in the plunder of Berlin. In Silesia, the king no sooner began his march to the northward, than Laudohn advanced, and laid siege to the important fortress of Cosel; and, to complete this distress and embarrassment, the king himself was attended at every step by Count Daun with a superior army well prepared to take every advantage.

In this desperate situation the king, being joined by his generals Hulsen and Prince Eugene of Wirtemberg with the corps under their command, advanced up the Elbe, while M. Daun fell back to cover Leipsic and Torgau, but the latter finding that the Prussians directed their march towards the Elbe, encamped within reach of Torgau; one part of his army extending to the Elbe, by which he was covered on that side, whilst on the other he was covered by hills and woods, so that it was impossible to choose a more advantageous situation. The Prussian army did not amount to 50,000 men, whilst that of the Austrians exceeded 86,000: yet such were the unfortunate circumstances of the king, that he was obliged to fight under all these disadvantages; and therefore he caused his army to be informed, that he was now to lead them to a most desperate attempt, that his affairs required it, and that he was determined to conquer or die. His soldiers unanimously declared that they would die with him.

61 He defeats Count Daun at Torgau.

The 3d of November 1760 was the day on which this important affair was decided. The king divided his forces into three columns. General Hulsen was to take post with one in a wood that lay on the left of the Austrian army, and had orders not to move until he found the rest of the Prussians engaged. General Ziethen was to charge on the right; and the great attack in front was to be conducted by the king in person. His forces were disposed in such a manner, that either his right or left must take the enemy in rear and close them in, so as to disable them from undertaking any thing against the part where he intended to effect his principal attack. On the other hand, M. Daun perceiving the king to be serious in his design of fighting, to prevent confusion, sent all his baggage over the Elbe, across which he threw three bridges in case a retreat should be necessary. At the same time he caused Torgau to be evacuated; and then, extending his first line to a village called *Zinne* on the left, he stretched it to another called *Croswitz* on the right; supporting the right of his second line upon the Elbe. In this disposition he was found, when, about two o'clock in the afternoon, the king began his attack. He was received by the fire of 200 pieces of cannon, which, were disposed along the Austrian front. The Prussians were thrice led on to the attack; but were every time repulsed and broken with terrible slaughter. The king at length commanded a fresh body of cavalry to advance, which at first compelled the Austrians to retire; but new reinforcements continually coming in, this cavalry was in its turn obliged to fall back, and the Prussians maintained themselves with extreme difficulty, until General Ziethen, with the right wing, attacked the enemy in the rear, repulsed them, and possessed himself of some eminences which commanded the whole Austrian army. Encouraged by this success, the Prussian infantry once more advanced, mastered several of the enemy's intrenchments, and made way for a new attack of their cavalry, which broke in with irresistible fury on the Austrians, and threw several bodies of them into irreparable disorder. It was now about 9 o'clock, and of consequence both armies were involved in thick darkness; yet the fire continued without intermission, and the battalions with a blind rage discharged at one another without distinguishing friend from foe. M. Daun received a dangerous wound in the thigh, and was carried from the field, which probably hastened the defeat of his troops. The command then devolved on Count O'Donnel; who, finding the greatest part of his troops in disorder, the night advanced, and the enemy possessed of some eminences which commanded his camp, and from which it was in vain to think of driving them, ordered a retreat, which was conducted with wonderful order and exactness; none were lost in passing the bridges, and by far the greater part of their artillery was preserved. The loss of the Prussians was estimated at 10,000 killed and wounded, and 3000 taken prisoners. That of the Austrians in killed and wounded is not known; but 8000 were taken prisoners, with 216 officers, among whom were four generals.

62 All Saxony except Dresden recovered.

The consequence of the victory of Torgau was, that the king recovered all Saxony except Dresden; and in the mean time General Werner having marched into Pomerania, the Russians raised the siege of Colberg, and retired into Poland, without having effected any thing further than wasting the open country. Werner then flew to the assistance of Western Pomerania, where he defeated a body of Swedes, and at last drove them totally out of the country. General Laudohn too abruptly raised the blockade of Cosel; and afterwards, abandoning Landshut, he retired into the Austrian Silesia, leaving the Prussian part entirely in quiet. M. Daun placed one part of his army in Dresden, and the other in some strong posts which lie to the south and west of it, by which he commanded the Elbe, and preserved his communication with Bohemia. The army of the empire retired into Franconia, and placed its headquarters at Bamberg.

Though these successes had, to appearance, retrieved the king's affairs in some measure, yet his strength seemed now to be wholly exhausted; and in the campaign of 1761, he made no such vigorous efforts as he had formerly done. The Russians, dividing themselves into two bodies, invaded Silesia and Pomerania. In the former country they laid siege to Breslau, and in the latter to Colberg. Tottleben also, who had commanded the Russian armies, was now removed on a suspicion that he had corresponded with the king of Prussia, and General Romanzow put in his place; by which it was

 expected

expected that the Russian operations would be more brisk this year than formerly.

The king continued strongly encamped near Schweidnitz; where he was so closely watched by generals Daun and Laudohn, that he could attempt nothing. However, he defeated the designs of the Russians against Breslau, by sending General Platen to destroy their magazines; which he accomplished with great success, at the same time cutting off a body of 4000 of their troops. But this only brought the more sure destruction upon Colberg; to which place that body of Russians immediately marched, cruelly wasting the country as they went along. The king of Prussia could do nothing but send detachments of small parties, which, though they could not oppose their enemies in the field, yet he hoped, by cutting off the convoys of the enemy, might distress them to such a degree as to oblige them to abandon the siege, or at least protract it till the severity of the winter should render it impossible for them to carry on their operations. Thus he weakened his own army so much, that it was found requisite to draw 4000 men out of Schweidnitz in order to reinforce it; and no sooner was this done, than General Laudohn suddenly attacked and took that fortress by a coup de main. Colberg made a brave defence; but the troops sent to its relief being totally unable to cope with the Russian army, consisting of 50,000 men, it was obliged to surrender on the 3d of December; and thus the fate of the Prussian monarch seemed to be decided, and almost every part of his dominions lay open to the invaders.

63
Schweidnitz and Colberg retaken.

64
Empress of Russia dies.

In the midst of these gloomy appearances the empress of Russia, the king's most inveterate and inflexible enemy, died on the 2d of January 1762. Her successor, Peter III. instead of being the king's enemy, was his most sanguine friend. As early as the 23d of February, in a memorial delivered to the ministers of the allied courts, he declared, that, "in order to the establishment of peace, he was ready to sacrifice all the conquests made in this war by the arms of Russia, in hopes that the allied courts will on their parts equally prefer the restoration of peace and tranquillity, to the advantages which they might expect from the continuance of the war, but which they cannot obtain but by a continuance of the effusion of human blood."—This address was not so well relished by the allies: however, they were very willing to make peace, provided it was for their own interest; but they recommended to his attention fidelity to treaties, which constitutes a no less valuable part of the royal character, than humanity and disinterestedness. This answer made no impression on the czar; a suspension of hostilities took place on the 16th of March, which was followed by a treaty of alliance on the 5th May. In this treaty the czar stipulated nothing in favour of his former confederates; on the contrary, he agreed to join his troops to those of the king of Prussia, in order to act against them. Sweden, which had for a long time acted under the direction of Russian counsels, now followed the example of her mistress, and concluded a peace with Prussia on the 22d of May.

65
Peace between Russia, Sweden, and Prussia.

66
Successes of the king of Prussia.

It is not to be supposed that the king of Prussia would remain long inactive after such an unexpected turn in his favour. His arms were now everywhere attended with success. Prince Henry drove the Imperialists from some important posts in Saxony, by which he secured all that part which the Prussians possessed; and though the Austrians frequently attempted to recover these posts, they were constantly repulsed with great slaughter. The king was not joined by his new allies till the latter end of June; after which he drove M. Daun before him to the extremity of Silesia, leaving the town of Schweidnitz entirely uncovered, and which the king immediately prepared to invest. In the mean time, different detachments of Prussians, some on the side of Saxony, and others on that of Silesia, penetrated deep into Bohemia, laid many parts of the country under contribution, and spread an universal alarm. A considerable body of Russian irregulars also made an irruption into Bohemia, where they practised on the Austrians the same cruelties which they had long been accustomed to practise on the Prussians.

67
A new revolution in Russia.

But while the king was thus making the best use of his time, he was all at once threatened with a fatal reverse of fortune by a new revolution in Russia. The emperor was deposed, and his deposition was soon after followed by his death. The empress, who succeeded him, suspected that her husband had been misled by the counsels of his Prussian majesty, against whom, therefore, she entertained a mortal enmity. She could not, however, in the very beginning of her reign, undertake again a war of so much importance as that which had been just concluded. She therefore declared her intention of observing the peace concluded by the late emperor; but, at the same time, of recalling her armies from Silesia, Prussia, and Pomerania; which indeed the unsettled state of the kingdom now made in some degree necessary. At the same time a discovery was made with regard to the king of Prussia himself, which turned the scale greatly in his favour. The Russian senate, flaming with resentment against this monarch, and against their late unfortunate sovereign; and the empress, full of suspicion, that the conduct of the latter might have been influenced by the counsels of the former, searched eagerly amongst the papers of the late emperor for an elucidation or proofs of this point. They found indeed many letters from the Prussian monarch, but in a strain absolutely different from what they had expected. The king had, as far as prudence would permit, kept a reserve and distance with regard to the too rash advances of this unhappy ally; and, in particular, counselled him to undertake nothing against the empress his consort. The hearing of these letters read is said to have had such an effect upon the empress, that she burst into tears, and expressed her gratitude towards the Prussian monarch in the warmest terms. Still, however, the Russian army was ordered to separate from the Prussians; but all the important places which the former had taken during the whole war were faithfully restored.

The king, finding that the Russians were no more to take an active part in his favour, resolved to profit by their appearance in his camp; and, therefore, the very day after the order for their return had arrived, he attacked the Austrian army, and drove their right wing from some eminences and villages where they were advantageously posted; by which means he entirely cut off their communication with Schweidnitz, so that nothing could be attempted for its relief. Prince Henry kept them in continual alarms for Bohemia; and a

great

Prussia.

68 General Laudohn utterly defeated.

great part of their attention, and no small part of their forces, were engaged on that side. Marshal Daun, now finding himself rendered almost incapable of undertaking any thing, detached General Laudohn, with a force very much superior, to attack the prince of Bevern, and drive him from the advantageous post he occupied. But the prince defended himself with such resolution, that all the efforts of Laudohn could not succeed before the king had time to come to his assistance. The Austrians, being then put between two fires, were routed and pursued with terrible slaughter; after which, the king met with no more disturbance in his preparations for the siege, and the trenches were opened on the 18th of July. Marshal Daun made no attempts to relieve the place; but the garrison being very strong, it held out for near two months from the opening of the trenches. It is said that the attack was conducted, and the defence made, by two engineers who had written on the subject of the attack and defence of fortified places; and they were now practically engaged to prove the superiority of their systems. At last, however, the garrison, to the number of 8000 men, surrendered prisoners of war; and the whole body, except nine, were soon after drowned at the mouth of the Oder, on their passage to their intended confinement in Konigsberg.

69 The total defeat of the Austrians at Freyberg produces a peace.

The king of Prussia, now become master of Schweidnitz, turned his attention towards Saxony, where he considerably reinforced his brother's army, and made preparations for laying siege to Dresden. In this country the Austrians had lately met with some success, and driven Prince Henry as far back as Freyberg; but on the 29th of October, they were attacked by the Prussian army thus reinforced, and totally routed. Great numbers were slain, and near 6000 taken prisoners. This victory proved decisive: and the empress-queen, finding herself deserted by all her allies, was glad to conclude a treaty, the substance of which was, that a mutual restitution and oblivion should take place, and both parties sit down at the end of the war in the same situation in which they began it. This treaty is called the *peace of Hubertsburg*.

The war was no sooner concluded than the king of Prussia turned his attention to domestic policy, and the recovery of his dominions from those innumerable calamities which had befallen them during the war. He immediately distributed lands to his disbanded soldiers, and gave them the horses of his artillery to assist them in their cultivation. By his wise and prudent management, the horrors of war were soon forgotten; and the country was quickly in as flourishing a state as ever. Notwithstanding this pacific disposition, however, the king never slackened his endeavours for the defence of his country, by keeping a respectable army on foot; which might be able to act on the least emergency.

70 A new war commences, but produces no memorable event.

In the year 1778, a new difference with the house of Austria took place, concerning the duchy of Bavaria. But though the most enormous warlike preparations were made on both sides, and immense armies brought into the field, nothing of consequence was effected. What little advantage there was, seems to have been on the Prussian side, since they made themselves masters of several towns, and kept the war in the enemy's country. However, the emperor acted with so much caution, and showed so much skill in a defensive war, that all the manœuvres of his Prussian majesty could gain no material advantage; as, on the other hand, his adversary was too wise to venture an engagement. A peace therefore was very soon concluded, and since that time the history of Prussia, during the remainder of the great Frederic's reign, affords no remarkable event which we have not mentioned in the life of that hero, and the article POLAND. He left his crown to his nephew, whose character was not then much developed; and it was easily seen that a new kingdom, which had risen suddenly to such unexampled power and greatness as to excite the jealousy or apprehension of all its neighbours, would require great abilities to preserve it from dismemberment.

71 The great Frederic succeeded by his nephew.

72 State of the nation, and behaviour of the new king.

The late king had indeed bequeathed the most effectual securities to his successor for the preservation of his dominions, that human wisdom could provide or devise; by leaving him a full treasury, the finest army in the world, and a people enthusiastically attached to his memory and government. The new monarch, with these advantages, was not wanting to himself. The late king's predilection for the French language and French literature were not grateful to his subjects. The present sovereign began his reign with declaring in council, "Germans we are, and Germans I mean we shall continue;" giving directions, at the same time, that their native language should resume its natural rank and station, from which for near half a century it had been degraded by the French. This was a very popular measure, and it was followed by another still more so. Observing that he had marked with great concern the progress of impiety and profaneness on the one hand, and of enthusiasm on the other, he declared, that he would not have his subjects corrupted either by fanatics or atheists, and strictly prohibited all publications tending to excite a contempt or indifference for religion.

73 He assists the stadtholder against the states of Holland.

Such, on his immediate accession to the throne, was the pacific conduct of the monarch, which endeared him to his subjects, and commanded the approbation of all good men. An opportunity soon occurred, in which he was thought to have displayed such talents in negociation and in military arrangements, as proclaimed him in every respect a worthy successor of his uncle. The states of Holland, who had long been jealous of the power of the stadtholder, and inclined to a republican government without any permanent chief, had gained such an ascendency in the states general, that in 1786 and 1787 they in effect divested the Prince of Orange of all his prerogatives, (see UNITED *Provinces*). They proceeded even to the seizure and imprisonment of the princess, sister to the king of Prussia; and depending upon support from France, treated with insolence every power connected with them in Europe. The court of Berlin did not witness these proceedings without indignation; and the king formed his plan for restoring the power of the stadtholder with such secrecy and prudence, that perhaps nothing could surpass it but the bravery and military skill of the duke of Brunswick, by whom it was carried into execution. In the short space of one month, that accomplished general led 18,000 Prussians to Amsterdam, and restored the just prerogatives of the prince of Orange.

The affairs of Prussia during the early period of the French revolution, and the active but unsuccessful part which that monarch took against it, are interwoven with the

Prussia. the historical details of that period under the articles FRANCE and BRITAIN, to which we refer our readers. For a number of years he acted the prudent part of standing clear of hostilities as much as possible; and when he did at last interfere, we find little in his conduct which is intitled to the praise either of consistency or honour. Indeed it may perhaps be admitted, that on many occasions he acted rather from necessity than choice; and finding that a contest with France was both absurd and ruinous, he chose to sacrifice a less evil to a greater good. Whether by consent or compulsion is not certainly known, the king of Prussia ceded to France the duchies of Cleves and Berg, March 1806, which were to be governed by Prince Murat, the brother-in-law of Bonaparte, under the title of Joachim, duke of Cleves and Berg.

The king of Prussia likewise took possession of the Hanoverian states 30th October 1806, at the time when Great Britain had no reason to apprehend any such mysterious conduct from that quarter. He entered into a secret treaty with France for the purpose of shutting the northern ports; a measure which gave such offence to this country, that the British minister thought proper to take his leave of Berlin. At one period he came to a final determination to make no separate treaty with the French government, and proposed a treaty of peace and alliance between his court and that of Britain. To give this as much effect as possible, the Prussian princes of the blood began to raise volunteer regiments in Poland and Silesia, the loyalty of the peasantry in these countries far exceeding the most sanguine expectations.

So low, however, were the king of Prussia's finances at the time of Lord Hutchinson's arrival at Memel, March 1807, that his lordship found it necessary to advance 80,000l. for the support of his family and domestic household. This being intimated to the British ministers, his majesty recommended it to parliament to enable him to implement the agreement. Yet not long after this period he actually entered into a treaty of peace with the emperor of France, by virtue of which his territories were so dreadfully mutilated, as to leave him little more of a sovereign than the name. He was required to renounce the whole of his dominions situated between the Rhine and the Elbe; the circle of Cotbus in Lower Lusatia; nearly all the provinces which formerly constituted part of the kingdom of Poland; the city of Dantzic; and he was laid under the necessity of shutting all the ports and harbours of his whole dominions against the trade and navigation of Great Britain. Not above 18 months prior to this treaty, the king of Prussia might have been said to hold the fate of Europe in his hands; but by means of it he was reduced to the very lowest rank among the powers of Europe. Had he taken a decided part against France before the battle of Austerlitz, he might have been able to secure the independence of Europe; but, having suffered this auspicious moment to pass unimproved, the consequences were exactly such as might have been predicted, without any pretensions to uncommon sagacity.

The king of Prussia being thus degraded by means of his own imprudence and want of sound policy, endeavoured to ease the burdens of his remaining subjects by reducing his civil and military establishments. The army was reduced to 24,000 men, and General Knoblesdorf was sent to Paris to procure a diminution of the contributions exacted from him, or to crave that payments might be accepted of by instalments; and, in the mean time, the troops belonging to France were not to be withdrawn from the impoverished kingdom of Prussia. Every decree issued in Holland against the commerce of Great Britain, this humbled monarch was obliged to adopt, and to order the publication of them in every part of his mutilated dominions. Prussia.

In this state of degradation the Prussian monarchy continued till the extraordinary events of 1812. When Bonaparte made his irruption into Russia, Prussia was compelled to furnish a body of troops for the service, who formed part of the army under Macdonald. After the disastrous retreat of the French, the king made his escape from Potsdam, and retired to Silesia. He immediately called on his subjects to rise in arms for the defence of their country, without at first disclosing against whom he was to act. Great numbers of all ages joyfully obeyed the call. On the 22d February 1813, he entered into a treaty of alliance with Russia. The battle of Lutzen, however, on the 2d, and of Bautzen on the 20th May, threw discouragement on the rising hopes of the allies. But in August they were strengthened by the junction of Austria. The battle of Dresden was lost on the 26th of August; but from this time their affairs began to improve, and the victory of Leipsic, on the 16th October, turned the scale entirely in their favour. Prussia was now delivered entirely from French oppression; and her armies took a part in all the events that followed, to the peace of Paris in May 1814. When the war broke out again on Bonaparte's return, the Prussian armies performed essential services. The advance of Blucher in the afternoon gave a decisive turn to the battle of Waterloo.

By these successes Prussia not only recovered her former losses, but gained large additions of territory and population. She recovered the province of Posen in Poland, all her territories between the Elbe and the Rhine; and obtained besides, about one half of the king of Saxony's territories, and extensive districts on the south side of the Rhine. She acquired also Swedish Pomerania; and ceded East Friesland with some other districts to Hanover, and Anspach and Bayreuth to Bavaria. After these acquisitions and cessions, Prussia contained in 1819, 106,000 square English miles, and 10,065,000 inhabitants.

74 Air, soil, and population of Prussia.

The air of Prussia is wholesome, and the soil fruitful in grain; affording, besides, plenty of pitcoal and other fuel. The rivers and lakes are well stored with fish; and amber is found on its coast towards the Baltic. The principal rivers are the Vistula, Bregel, Memel, the Passarge, and the Elbe; all of which frequently do damage by their inundations.

Since the year 1719 it is computed that about 34,000 colonists have removed to Prussia from France, Switzerland, and Germany; of which number one half were Saltzburghers. These emigrants have built 400 small villages, 11 towns, 50 new churches, and founded 1000 village-schools. The manners of the people differ but little from those of the Germans. The established religions are those of Luther and Calvin, but chiefly the former; though almost all other sects are tolerated.

75 Commerce and manufactures.

The late king of Prussia, by the assistance of an excellent police, brought the commerce and manufactures of of this country to a very flourishing state, which during his life were daily improving. The manufactures of Prussia consist in glass, iron-work, paper, gunpowder, copper and brass-mills, manufactures of cloth, camblet, linen, silk, gold and silver lace, stockings, and other articles. The inhabitants export variety of naval stores, amber, lint-seed and hemp-seed, oat-meal, fish, mead, tallow, and caviar; and it is said that 500 ships are loaded with those commodities every year, chiefly from Koningsberg.

76 Constitution.

His Prussian majesty is absolute through all his dominions; but the late king was too wise to oppress his subjects, though he availed himself to the full of his power. The government of this kingdom is by a regency of four chancellors of state, viz. 1. The great-master; 2. The great-burgrave; 3. The great-chancellor; and, 4. The great-marshal. There are also some other councils, and 37 bailiwicks. The states consist, 1. Of counsellors of state; 2. Of deputies from the nobility; and, 3. From the commons. Besides these institutions, the late king erected a board for commerce and navigation.

77 Revenues.

His Prussian majesty, by means of the happy situation of his country, its inland navigation, and the excellent regulations of his predecessor, derives an amazing revenue from this country, which, about a century and a half ago, was the seat of boors and barbarism. It is said, that amber alone brings him in 26,000 dollars annually. His other revenues arise from his demesnes, his duties of customs and tolls, and the subsidies yearly granted by the several states. In 1815 the whole revenues of Prussia were estimated at seven millions sterling. See EUROPE, SUPPLEMENT.

78 Military strength.

The military regulations introduced by the late king had a wonderfully quick operation in forming his troops and recruiting his armies. Every regiment has a particular district assigned it, where the young men proper for bearing arms are registered; and when occasion offers, they join their regiment, and being incorporated with veterans they soon become well disciplined troops. The Prussian army, in the time of peace, consists of 250,000 of the best disciplined troops in the world; and during the last war, that force was augmented to 300,000 men.

79 Royal arms, &c.

The royal arms of Prussia are argent, an eagle displayed sable, crowned, or, for Prussia: azure, the Imperial sceptre, or, for Courland: argent, an eagle displayed, gules, with semicircular wreaths, for the marquisate of Brandenburg: to these are added the respective arms of the several provinces subject to the Prussian crown.

There are two orders of knighthood; the first, that of the Black Eagle, instituted by Frederic I. on the day of his coronation at Koningsberg, with this motto, *Suum cuique*. The sovereign is always grand-master; and the number of knights, exclusive of the royal family, is limited to 30. Next to this is the order of Merit, instituted by his late majesty; the motto is, *Pour le merite*.

PRUSSIAN BLUE. See PRUSSIATE OF IRON, CHEMISTRY *Index*.

PRUSSIC ACID. See CHEMISTRY *Index*.

PRYNNE, WILLIAM, an English lawyer, much distinguished in the civil commotions under Charles I. was born at Swainswick in Somersetshire in 1600. His *Histriomastix*, written against stage-plays in 1632, containing some reflections that offended the court, he was sentenced by the star-chamber to pay a fine of 5000l. to stand in the pillory, to lose his ears, and to perpetual imprisonment. During his confinement, he wrote several more books; particularly, in 1637, one entitled *News from Ipswich*, which reflecting severely on the bishops, he was again sentenced by the star-chamber to another fine of 5000l. to lose the remainder of his ears in the pillory, to be branded on both cheeks with S. L. for seditious libeller, and to be perpetually imprisoned in Caernarvon castle. Nothing but cutting off his hands could have prevented Prynne from writing: he wrote still; and in 1640, being set at liberty by the house of commons, he entered London in a kind of triumph, was elected into parliament for Newport in Cornwall, and opposed the bishops with great vigour, being the chief manager of Archbishop Laud's trial. In the long parliament he was zealous in the Presbyterian cause; but when the Independents gained the ascendency, he opposed them warmly, and promoted an agreement with the king. When the army garbled the house and refused him entrance, he became a bitter enemy to them and their leader Cromwell, and attacked them with his pen so severely, that he was again imprisoned: but he pleaded the liberty of the subject so successfully, that he was enlarged, to write more controversial books. Being restored to his seat after Cromwell's death, with the other secluded members, he assisted in promoting the restoration, and was appointed keeper of the Tower records; a place excellently well calculated for him, and where he was very useful by the collections he published from them. He presented 40 volumes of his works, in folio and 4to, to Lincoln's-inn library, of which society he was a member; and, dying in 1669, was buried under the chapel.

PRYTANES, in Grecian antiquity, were the presidents of the senate, whose authority consisted chiefly in assembling the senate; which, for the most part, was done once every day.

The senate consisted of 500, 50 senators being elected out of each tribe: after which, lots were cast to determine in what order the senators of each tribe should preside; which they did by turns, and during their presidentship were called *prytanes*. However, all the 50 prytanes of the tribes did not govern at once, but one at a time, viz. for seven days; and after 35 days, another tribe came into play, and presided for other five weeks; and so of the rest.

PSALM, a divine song or hymn; but chiefly appropriated to the 150 Psalms of David, a canonical book of the Old Testament.

Most of the psalms have a particular title, signifying either the name of the author, the person who was to set it to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined that David was the sole author of the Book of Psalms; but the titles of many of them prove the contrary, as psalm xix. which appears to have been written by Moses. Many of the psalms are inscribed with the names *Korah*, *Jeduthun*, &c. from the persons who were to sing them.

PSALMANAZAR, GEORGE, the fictitious name of a pretended Formosan, a person of learning and ingenuity. He was born in France, and educated in a

free

free-school, and and afterwards in a college of Jesuits, in an archiepiscopal city, the name of which, as likewise those of his birth-place and of his parents, are unknown. Upon leaving the college, he was recommended as a tutor to a young gentleman; but soon fell into a mean rambling life which involved him in disappointments and misfortunes. His first pretence was that of being a sufferer for religion. He procured a certificate that he was of Irish extraction, that he left that country for the sake of the Catholic faith, and was going on a pilgrimage to Rome. Being unable to purchase a pilgrim's garb, and observing one in a chapel, dedicated to a miraculous saint, which had been set up as a monument of gratitude by some wandering pilgrims, he contrived to take both the staff and cloak away; and, being thus accoutred, begged his way in fluent Latin, accosting only clergymen or persons of figure; whom he found so generous and credulous, that, before he had gone 20 miles, he might easily have saved money, and put himself in a much better dress: but as soon as he had got what he thought was sufficient, he begged no more; but viewed every thing worth seeing, and then retired to some inn, where he spent his money as freely as he had obtained it. Having heard the Jesuits speak much of China and Japan, he started the wild scheme, when he was in Germany, of passing for a native of the island of Formosa; and what he wanted in knowledge, he supplied by a pregnant invention. He formed a new character and language on grammatical principles, which, like other oriental languages, he wrote from right to left with great readiness; and planned a new religion, and a division of the year into 20 months, with other novelties, to credit his pretensions. He was now a Japanese convert to Christianity, travelling for instruction, with an appearance more wretched than even that of common beggars. He then entered as a soldier in the Dutch service: but, still desirous of passing for a Japanese, he altered his plan to that of being an unconverted heathen; and at Sluys, Brigadier Lauder, a Scots colonel, introduced him to the chaplain, who, with the view of recommending himself to the bishop of London, resolved to carry him over to England. At Rotterdam, some persons having put shrewd questions to him, that carried the air of doubt, he took one more whimsical step, which was to live upon raw flesh, roots, and herbs; which strange food he thought would remove all scruples. The bishop of London patronized him with credulous humanity; and Psalmanazar found a large circle of friends, who extolled him as a prodigy. Yet were there some who entertained a just opinion of him, particularly the Drs Halley, Mead, and Woodward; but their endeavours to expose him as a cheat only made others think the better of him, especially as those gentlemen were supposed to be unfriendly to revelation. But in this instance at least, easiness of belief was no great evidence of penetration. He was employed to translate the church-catechism into the Formosan language, which was examined, approved, and laid up as a valuable MS.; and the author, after writing his well-known *History of Formosa*, was rewarded and sent to Oxford to study what he liked, while his patrons and opponents were learnedly disputing at London on the merits of his work. The learned members of the university were no better agreed in their opinions than those at London; but at length the sceptics triumphed. Some absurdities were discovered in his history, of such a nature as to discredit the whole narration, and saved him the trouble of an open declaration of his imposture; which however he owned at length to his private friends. For the remainder of his life, his learning and ingenuity enabled him to procure a comfortable support by his pen: he was concerned in several works of credit, particularly *The Universal History*. He lived irreproachably for many years, and died in 1763.

PSALMIST, in the church of Rome, one of the lesser ecclesiastical orders; the same with what among us is called *clerk*, *precentor*, or *singer*.

PSALMODY, the art or act of singing psalms. See PSALM.

Psalmody was always esteemed a considerable part of devotion, and usually performed in the standing posture: and as to the manner of pronunciation, the plain song was sometimes used, being a gentle inflexion of the voice, not much different from reading, like the chant in cathedrals; at other times more artificial compositions were used, like our anthems.

As to the persons concerned in singing, sometimes a single person sung alone; sometimes the whole assembly joined together, which was the most ancient and general practice. At other times the psalms were sung alternately, the congregation dividing themselves into two parts, and singing verse about, in their turns. There was also a fourth way of singing pretty common in the fourth century, which was, when a single person began the verse, and the people joined with him in the close: this was often used for variety, in the same service with alternate psalmody.

The use of musical intruments in the singing of psalms, seem to be as ancient as psalmody itself; the first psalm we read of being sung to the timbrel, viz. that of Moses and Miriam, after the deliverance of the Israelites from Egypt; and afterwards, musical instruments were in constant use in the temple of Jerusalem. See ORGAN.

PSALTER, the same with the book of psalms. See the article PSALM.

Among the religious in the Popish countries, the term *psalter* is also given to a large chaplet or rosary, consisting of 150 beads, according to the number of psalms in the psalter.

PSALTERY, a musical instrument, much in use among the ancient Hebrews, who called it *nebel*.

We know little or nothing of the precise form of the ancient psaltery. That now in use is a flat instrument, in form of a trapezium or triangle truncated at top: it is strung with 13 wire-chords, set to unison or octave, and mounted on two bridges, on the two sides: it is struck with a plectrum, or little iron rod, and sometimes with a crooked stick. Its chest or body resembles that of a spinet.

PSAMMETICUS, or PSAMMITICHUS, a renowned conqueror, who subduing 11 other petty kings of Egypt, became the founder of the kingdom of Egypt, about 670 B. C. He is memorable likewise for taking the city of Azot, after a siege of 29 years; and for discovering the sources of the river Nile. See EGYGT, N° 10.

PSATYRIANS, a sect of Arians, who, in the council of Antioch, held in the year 360, maintained that

Psatyrians | Pseudo.

that the Son was not like the Father as to will; that he was taken from nothing, or made of nothing; and that in God, generation was not to be distinguished from creation.

Enfield's History of Philosophy.

PSELLUS, MICHAEL, a learned Christian of the 11th century, was, by birth, a Constantinopolitan of consular rank, and flourished under the emperor Constantine Monomachus. His genius and industry raised him far above the level of his cotemporaries; and the female historian Anna Comnena speaks of him as one who had been more indebted for his attainments to his own excellent talent than to the instructions of his preceptors; adding, that having made himself master of all the wisdom of the Greeks and the Chaldeans, he was justly esteemed the most learned man of the age. Thus furnished, he became the chief instructor of the Constantinopolitan youth. He was at the same time the companion and the preceptor of the emperor, who was so captivated by the studies and amusements in which Psellus engaged him, that, according to Zonaras, he neglected the concerns of the empire. The Byzantine historians complain, that the emperor, deluded by the head of the philosophers (the title with which Psellus was honoured), lost the world. Meeting, towards the close of this life, with some disappointment, Psellus retired into a monastery, and soon afterwards died; the time of his death is uncertain. His works, which have been much celebrated, are, Commentaries upon Aristotle's Logic and Physics; a Compendium of Questions and Answers; and an Explanation of the Chaldean Oracles. The two latter works prove him to have been conversant, not only with Grecian, but with Oriental, philosophy.

PSEUDO, from ψευδος, a Greek term used in the composition of many words to denote *false* or *spurious*: as the pseudo-acacia, or bastard acacia; pseudo-fumaria, or bastard-fumitory; pseudo-ruta, or bastard-rue, &c.

We also say, a pseudo-apostle or false apostle; a pseudo-prophet, or false prophet, &c.

PSEUDO-China. See SMILAX.

PSEUDO-Galena, or *Black-Jack*. See ZINC, ORES of, MINERALOGY *Index*.

PSEUDO-Tinea, in *Natural History*, the name of a very remarkable species of insect described by M Reaumur, approaching to the nature of the *tinea*, or *clothes moth*, while in the worm-state, but not making themselves coats of the substance of leaves, cloth, &c. though they form a sort of cases for their defence against a very terrible enemy.

These creatures are of the caterpillar kind, and have, in the manner of many of these insects, 16 legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, though at the expence of their habitations and the cells of their reservoirs of honey: so that it is no uncommon thing for a swarm of bees to be forced to change their place of habitation, and make new combs elsewhere; leaving the old ones to this contemptible victor, whom they know not how to drive out or dispossess.

Virgil and Aristotle, and all the authors who have written on bees, have complained of this destructive animal. It never eats the honey, but feeds only on the wax; attacking principally those waxy cells where the female bee deposits her eggs for the future progeny.

Pseudo, Pseudonymous.

The bees, who are a match for most other creatures by means of their stings, would easily destroy these weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter. The first, which immediately covers the body, is of a kind of silk of their own spinning; and the outer covering over this is of the bees-wax: this is laid considerably thick; and the creature, just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their stings. He never forsakes his covering, but lengthens and enlarges it as he goes; and gnawing down the sides of the cells in his march, without staying to eat them one by one, the havock and destruction he occasions are scarcely to be conceived. When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nympth state; whence, after a proper time, it comes forth in form of a moth, with granulated horns and a crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form; and as this is a weak and defenceless state, they attack and destroy all the moths of this species they meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren. All the flies of the moth kind lay a vast number of eggs, and this is behind hand with none of them in that particular: the young ones produced from the eggs of one surviving female of this species are sufficient to destroy many honey-combs; nay, many hives of them. The moth produced by this caterpillar flies but little; yet it is very nimble in avoiding danger, by running, which it does with great swiftness.

There is a species of these pseudo-tineæ, or wax-eating caterpillars, which infest the subterraneous hives of wasps and other creatures which make wax: the manner of living, feeding, and defending themselves from their enemies, is the same in all the species. These last, if they are at any time distressed for food, will eat their own dung; the wax having passed almost unaltered through their bodies, and being still wax, and capable of affording them more nourishment on a second digestion. These species, though they naturally live on this soft food, yet if by any accident they meet with harder only, they know how to live upon it; and can eat a way into the covers and leaves of books, and make themselves cases and coverings of the fragments of these substances. The accurate author† of these observations describes also a kind of *pseudo-tinea* which feeds on wool, and another that eats leather; both making themselves houses also of the materials they feed on.

† *Reaumur's History of Insects.*

There is also another kind very destructive to corn: these make themselves a covering by fastening together a great number of the grains, and there living and eating in secret. All these creatures, whatever be their food or habitation, finally become *phalenæ*, or moths; and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a proboscis, or trunk, more or less incurvated.

PSEUDONYMOUS, among critics, an author who publishes a book under a false or feigned name; as *cryptonymous*

tonymous is given to him who publishes one under a disguised name, and *anonymous* to him who publishes without any name at all.

PSIDIUM, the GUAVA; a genus of plants belonging to the icosandria class, and in the natural method ranking under the 19th order, *Hesperideæ*. See BOTANY *Index*.

A decoction of the roots of guava is employed with success in dysenteries: a bath of the decoction of the leaves is said to cure the itch and other cutaneous eruptions. Guayava, or guava, is distinguished from the colour of the pulp into two species, the white and the red; and, from the figure of the fruit, into the round and the pear-fashioned or perfumed guava. The latter has a thicker rind and a more delicate taste than the other. The fruit is about the bigness of a large tennis ball; the rind or skin generally of a russet stained with red. The pulp within the thick rind is of an agreeable flavour, and interspersed with a number of small white seeds. The rind, when stewed, is eaten with milk, and preferred to any other stewed fruit. From the same part is made marmalade; and from the whole fruit is prepared the finest jelly in the world. The fruit is very astringent, and nearly of the same quality with the pomegranate. The seeds are so hard as to resist the effects of the stomachs of animals; so that, when voided with the excrements, they take root, germinate, and produce thriving trees. Whole meadows in the West Indies are covered with guavas, which have been propagated in this manner.

PSITTACUS, or PARROT, a genus of birds, belonging to the order of *Picæ*. See ORNITHOLOGY *Index*.

PSOAS, in *Anatomy*. See there, *Table of the Muscles*.

PSOPHIA, a genus of birds belonging to the order of *Gallinæ*. See ORNITHOLOGY *Index*.

PSORALEA, a genus of plants belonging to the diadelphia class, and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

PSYCHOTRIA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 47th order, *Stellatæ*. See BOTANY *Index*.

PSYLLI, (Strabo, Ptolemy): a people in the south of Cyrenaica, so called from King Psyllus, (Agathargides, quoted by Pliny): almost all overwhelmed by sand driven by a south wind (Herodotus). They had something in their bodies fatal to serpents, and their very smell proved a charm against them, according to Pliny, Lucan, &c.

Though we may justly look upon it as fabulous, that these people had any thing in their bodies different from others; it is, however, certain that there are in Egypt at this day some persons who have a method of handling the most poisonous serpents without any hurt. Of these Mr Hasselquist gives the following account:

"They take the most poisonous vipers with their bare hands, play with them, put them in their bosoms, and use a great many more tricks with them, as I have often seen. I have frequently seen them handle those that were three or four feet long, and of the most horrid sort. I inquired and examined whether they had cut out the vipers poisonous teeth; but I have with my own eyes seen they do not. We may therefore conclude, that there are to this day Psylli in Egypt; but what art they use is not easily known. Some people are very superstitious, and the generality believe this to be done by some supernatural art which they obtain from invisible beings. I do not know whether their power is to be ascribed to good or evil; but I am persuaded that those who undertake it use many superstitions.

"The art of fascinating serpents is a secret amongst the Egyptians. It is worthy the endeavours of all naturalists, and the attention of every traveller, to learn something decisive as to this affair. How ancient this art is among the Africans, may be concluded from the ancient Marii and Psylli, who were from Africa, and daily showed proofs of it at Rome. It is very remarkable that this should be kept a secret for more than 2000 years, being known only to a few, when we have seen how many other secrets have within that time been revealed. The circumstances relating to the fascination of serpents in Egypt, related to me, were principally, 1. That the art is only known to certain families, who propagate it to their offspring. 2. The person who knows how to fascinate serpents, never meddles with other poisonous animals, such as scorpions, lizards, &c. There are different persons who know how to fascinate these animals; and they again never meddle with serpents. 3. Those that fascinate serpents, eat them both raw and boiled, and even make broth of them, which they eat very commonly amongst them; but in particular, they eat such a dish when they go out to catch them. I have been told, that serpents fried or boiled are frequently eaten by the Arabians both in Egypt and Arabia, though they know not how to fascinate them, but catch them either alive or dead. 4. After they have eaten their soup, they procure a blessing from their scheik (priest or lawyer), who uses some superstitious ceremonies, and amongst others, spits on them several times with certain gestures. This manner of getting a blessing from the priest is pure superstition, and certainly cannot in the least help to fascinate serpents; but they believe, or will at least persuade others, that the power of fascinating serpents depends upon this circumstance."

Notwithstanding this testimony of Hasselquist, the story of the incantation of serpents, though frequently alluded to in Scripture, has been generally treated as a fable. It is, however, affirmed as a certain truth, both by Mr Bruce and M. Savary. "There is no doubt (says the former of these travellers) of its reality. The Scriptures are full of it. All that have been in Egypt have seen as many different instances as they chose. Some have doubted that it was a trick; and that the animals thus handled had been first trained, and then deprived of their power of hurting; and fond of the discovery, they have rested themselves upon it, without experiment, in the face of all antiquity. But I will not hesitate to aver, that I have seen at Cairo (and this may be seen daily without any trouble or expence), a man who came from the catacombs, where the pits of the mummy-birds are kept, who has taken a cerastes with his naked hand from a number of others lying at the bottom of a tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast, and tied it about his neck like a necklace; after which it has been applied to a hen, and bit it, which died in a few minutes; and,

and, to complete the experiment, the man has taken it by the neck, and beginning at his tail, has ate it as one would do a carrot or stock of celery, without any seeming repugnance.

"We know from history, that where any country has been remarkably infested with serpents, there the people have been screened by this secret.

"To leave ancient history, I can myself vouch, that all the black people in the kingdom of Sennaar, whether Funge or Nuba, are perfectly armed against the bite of either scorpion or viper. They take the cerastes in their hands at all times, put them in their bosoms, and throw them to one another as children do apples or balls, without having irritated them by this usage so much as to bite. The Arabs have not this secret naturally, but from their infancy they acquire an exemption from the mortal consequences attending the bite of these animals, by chewing a certain root, and washing themselves (it is not anointing) with an infusion of certain plants in water,"

From this account we should be apt to think, that these vipers really *would not* bite any who were thus armed against their poison; especially as he adds, that he "constantly observed, that the viper, however lively before, upon being seized by any of these barbarians, seemed as if taken with sickness and feebleness, frequently shut his eyes, and never turned his mouth towards the arm of the person who held him." Yet in another place, speaking of the activity of the cerastes, he says, "I saw one of them at Cairo, in the house of Julian and Rosa, crawl up the side of a box in which there were many, and there lie still, as if hiding himself, till one of the people who brought them to us came near him; and though in a very disadvantageous posture, sticking as it were perpendicularly to the side of the box, he leaped near the distance of three feet, and fastened between the man's fore-finger and thumb, so as to bring the blood. The fellow showed no signs of either pain or fear, and even kept him with us full four hours, without his applying any sort of remedy, or seeming inclined to do so."

It is difficult to see how these two accounts can be reconciled. If those who catch vipers are in danger of being bit by them *after* they are catched, certainly they must be so before, and then the whole relation becomes contradictory. Our author tells us, that these feats were performed *for a season*, by those who were artificially armed against the viper's poison, as well as those who had the exemption naturally; but though put in possession of the drugs, he never had the courage to make the experiment. That he should have made such a dreadful experiment on *himself*, no person in his senses would expect; but it is indeed very surprising, that he did not attempt by means of these medicines to arm some of the brute creatures, of the lives of which he was sufficiently prodigal, against the effects of that deadly poison by which so many of them perished. As surprising it is, that he did not try what effect the root or its decoction would have upon the serpents themselves; or that, though he says he had a small quantity of this extraordinary root by him, he gave neither drawing nor description of it.

Though it is impossible to reconcile the particulars of this account to one another, the general fact of the incantation is confirmed by the testimony of M. Savary. This writer tells us, that he saw at the feast of Sidi Ibrahim, a troop of people, seemingly possessed, with naked arms and a fierce look, holding in their hands enormous serpents, which twined round their body, and endeavoured to escape. These Psylli, grasping them strongly by the neck, avoided the bite; and notwithstanding their hissing, tore them with their teeth, and ate them alive, while the blood streamed from their mouth.

PTARMIGAN. See TETRAO, ORNITHOLOGY *Index*.

PTELEA, SHRUB-TREFOIL; a genus of plants belonging to the tetrandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

PTERIS, a genus of plants belonging to the order of filices, and to the cryptogamia class. See BOTANY *Index*. The fructifications are in lines under the margin. There are 19 species; the most remarkable is the aquilina, or common female fern. The root of this is viscid, nauseous, and bitterish; and like all the rest of the fern tribe, has a salt, mucilaginous taste. It creeps under the ground in some rich soils to the depth of five or six feet, and is very difficult to be destroyed. Frequent mowing in pasture grounds, plentiful dunging in arable lands, but, above all, pouring urine upon it, are the most approved methods of killing it. It has, however, many good qualities to counterbalance the few bad ones. Fern cut while green, and left to rot upon the ground, is a good improver of land; for its ashes, if burnt, will yield the double quantity of salt that most other vegetables will. Fern is also an excellent manure for potatoes; for if buried beneath their roots, it never fails to produce a good crop.—Its astringency is so great, that it is used in many places abroad in dressing and preparing kid and chamois leather. In several places in the north, the inhabitants mow it green, and, burning it to ashes, make those ashes up into balls, with a little water, which they dry in the sun, and make use of them to wash their linen with instead of soap. In many of the Western Isles the people gain a very considerable profit from the sale of the ashes to soap and glass makers. In Glenelg in Inverness-shire, and other places, the people thatch their houses with the stalks of this fern, and fasten them down with ropes made either of birk-bark or heath. Sometimes they use the whole plant for the same purpose, but that does not make so durable a covering. Swine are fond of the roots, especially if boiled in their wash. In some parts of Normandy we read that the poor have been reduced to the miserable necessity of mixing them with their bread. And in Siberia, and some other northern countries, the inhabitants brew them in their ale, mixing one-third of the roots to two-thirds of malt. The ancients used the root of this fern, and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds, arising from obstructions of the viscera and the spleen. Some of the moderns have given it a high character in the same intentions, but it is rarely used in the present practice. The country people, however, still continue to retain some of its ancient uses; for they give the powder of it to destroy worms, and look upon a bed of the green plant as a sovereign cure for the rickets in children.

PTEROCARPUS, a genus of plants belonging to the

the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*. There are four species, viz. 1. *Draco*; 2. *Ecastaphyllum*; 3. *Lunatus*; and, 4. *Santalinus*. This last is by some referred to the genus *Santalum*. It is called *red saunders*; and the wood is brought from the East Indies, in large billets, of a compact texture, a dull red almost blackish colour on the outside, and a deep brighter red within. This wood has no manifest smell, and little or no taste. It has been commended as a mild astringent, and a corroborant of the nervous system; but these are qualities that belong only to the yellow sort.

The principal use of red saunders is as a colouring drug; with which intention it is employed in some formulæ, particularly in the *tinctura lavendulæ composita*. It communicates a deep red to rectified spirit, but gives no tinge to aqueous liquors; a small quantity of the resin, extracted by means of spirit, tinges a large one of fresh spirit of an elegant blood-red. There is scarcely any oil, that of lavender excepted, to which it communicates its colour. Geoffrey and others take notice, that the Brazil woods are sometimes substituted for red saunders; and the college of Brussels are in doubt whether all that is sold among them for saunders be not really a wood of that kind. According to the account which they have given, their saunders is certainly the Brazil wood; the distinguishing character of which is, that it imparts its colour to water.

PTEROCOCEUS, a species of plant belonging to the genus Calligonum. See CALLIGONUM, BOTANY *Index*.

PTERONIA, a genus of plants belonging to the monodelphia class; and in the natural method ranking under the 37th order, *Columniferæ*. See BOTANY *Index*.

PTINUS, a genus of insects belonging to the order of coleoptera. See ENTOMOLOGY *Index*.

PTISAN, is properly barley decorticated, or deprived of its hulls, by beating in a mortar, as was the ancient practice; though the cooling potion obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice-root, is what at present goes by the name of *ptisan*; and to render it laxative, some add a little sena or other ingredient of the same intention.

PTOLEMAIC *System of Astronomy*, is that invented by Claudius Ptolemæus. See PTOLEMY, *Claudius*.

PTOLEMAIS, in *Ancient Geography*; the port of Arsinoë, situated on the west branch of the Nile, which concurs to form the island called *Nomos Heracleotes*, to the south of the vertex of the Delta.

PTOLEMAIS, (Strabo); the largest and most considerable town of the Thebais, or Higher Egypt, and in nothing short of Memphis; governed in the manner of a Greek republic; situated on the west side of the Nile, almost opposite to Coptos. This town, which was built by Ptolemy Philadelphus, is now known by the name of *Ptolometa*. The walls and gates are still entire, and there are a vast number of Greek inscriptions, but only a few columns of the portico remain. There is likewise an Ionic temple done in the most ancient manner of executing that order, of which Mr Bruce took a drawing, which is preserved in the king's collection. Another, of Cyrenaica, anciently called *Barce*. A third of the Troglodytica, surnamed *Epitheras*, from the chace of wild beasts, as elephants; lying in the same parallel with Meroe (Strabo); on the Arabian gulf (Pliny); 4820 stadia to the south of Berenice. A fourth, of Galilee, anciently called *Aca*, or *Acon*; made a Roman colony under the emperor Claudius (Pliny). A fifth of Pamphylia; situated near the river Melas, on the borders of Cilicia Aspera.

PTOLEMY SOTER, or *Lagus*, king of Egypt, a renowned warrior, and an excellent prince: he established an academy at Alexandria, and was himself a man of letters. Died 284 B. C. aged 92.

PTOLEMY *Philadelphus*, his second son, succeeded him to the exclusion of Ptolemy Ceraunus. He was renowned as a conqueror, but more revered for his great virtues and political abilities. He established and augmented the famous Alexandrian library, which had been begun by his father. He greatly increased the commerce of Egypt, and granted considerable privileges to the Jews, from whom he obtained a copy of the Old Testament, which he caused to be translated into Greek, and deposited in his library. This is supposed to have been the version called the *Septuagint*. He died 246 years B. C. aged 64.

PTOLEMY *Ceraunus*, the elder brother, fled to Seleucus king of Macedon, who received him hospitably; in return for which he assassinated him, and usurped his crown. He then invited Arsinoë, who was his widow and his own sister, to share the government with him; but as soon as he got her in his power, he murdered her and her children. He was at length defeated, killed, and torn limb from limb by the Gauls, 279 B. C.

PTOLEMY, *Claudius*, a celebrated mathematician and astrologer, was born at Pelusium, and surnamed by the Greeks *Most Divine* and *Most Wise*. He flourished at Alexandria in the second century, under the reigns of Adrian and Marcus Aurelius, about the 138th year of the Christian era. There are still extant his Geography, and several learned works on astronomy. The principal of which are, 1. The Almagest; 2. *De Judiciis Astrologicis*; 3. *Planisphærium*. His system of the world was for many years adopted by the philosophers and astronomers; but the learned have rejected it for the system of Copernicus. See ASTRONOMY, N° 16.

PTYALISM, in *Medicine*, a salivation, or frequent and copious discharge of saliva. The word is Greek, formed from πτυω, "to spit."

PUBERTY, denotes the age at which the person is capable of procreating or begetting children. See MAN.

PUBERTY, in *Law*, is fixed at the age of 12 in females, and 14 in males; after which they are reckoned to be fit for marriage. But as to crimes and punishments, the age of puberty is fixed at 14 in both sexes.

PUBES, in *Anatomy*, denotes the middle part of the hypogastric region in men or women, lying between the two inguina or groins.

Section of the Pubes. See MIDWIFERY and SIGAULTIAN *Operation*.

PUBES, in *Botany*, the hair or down on the leaves of some plants. See HAIR.

PUBLICAN, among the Romans, one who farmed the taxes and public revenues.

PUBLICATION, the art of making a thing known to the world; the same with promulgation.

PUBLIUS SYRUS, a Syrian mimic poet, who flourished about 44 years before Christ. He was originally a slave sold to a Roman patrician, called *Domitius*, who brought him up with great attention, and gave him his freedom when of age. He gained the esteem of the most powerful men at Rome, and reckoned Julius Cæsar among his patrons. He soon eclipsed the poet Laberius, whose burlesque compositions were in general esteem. There remains of Publius a collection of moral sentences, written in iambics, and placed in alphabetical order.

OAK PUCERON, a name given by naturalists to a very remarkable species of animal of the puceron kind. They bury themselves in the clefts of the oak and some other trees, and getting into the crevices, where the bark is a little separated from the wood, they there live at ease, and feed to their fill, without being exposed to their common enemies. They are larger than the other pucerons, the winged ones being nearly as large as a common house fly; and those without wings are also larger than any other species of the same genus. The winged ones are black, and the others of a coffee colour. Their trunk is twice the length of their bodies, and, when walking, it is carried straight along the belly, trailing behind it with the point up. When the creature has a mind to suck a part of the tree that is just before it, it draws up and shortens the trunk, till it brings it to a proper length and direction; but when it sucks in the common way, it crawls upon the inner surface of the bark, and the turned up end of the trunk, which resembles a tail, fixes itself against the wood that is behind it, or contiguous to its back, and sucks there. The extremity of this trunk holds so fast by the wood, that when it is pulled away, it frequently brings a small piece of the wood away with it.

The ants are as fond of these as of the other species of pucerons, and that for the same reason, not feeding upon them, but on their dung, which is a liquid matter of a sweet taste, and is the natural juice of the tree, very little altered. These creatures are the surest guides where to find this species of puceron; for if we at any time see a number of these crawling up an oak to a certain part, and there creeping into the clefts of the bark, we may be assured that in that place there are quantities of these oak pucerons. The ants are so extremely fond of the juices of the tree, when prepared for them by passing through the body of this animal, that when the puceron has a drop not yet evacuated, but hanging only in part out at the passage, an ant will often seize on it there.

PUCERONS, *Vine-fretters*, or *Plant-lice*. See APHIS.

PUDENDA, the parts of generation in both sexes. See ANATOMY, N° 107 and 108.

PUERILITY, in discourse, is defined by Longinus to be a thought which, by being too far fetched, becomes flat and insipid. Puerility, he adds, is the common fault of those who affect to say nothing but what is brilliant and extraordinary.

PUFFENDORF, SAMUEL DE, was born in 1631 at Fleh, a little village in Misnia, a province in Upper Saxony; and was son of Elias Puffendorf, minister of that place. After having made great progress in the sciences at Leipsic, he turned his thoughts to the study of the public law, which in Germany consists of the knowledge of the rights of the empire over the princes and states of which it is composed, and those of the princes and states with respect to each other. But though he used his utmost efforts to distinguish himself, he despised those pompous titles which are so much sought for at universities, and never would take the degree of doctor. He accepted the place of governor to the son of M. Coyet, a Swedish nobleman, who was then ambassador from Sweden to the court of Denmark. For this purpose he went to Copenhagen, but continued not long at ease there; for the war being renewed some time after between Denmark and Sweden, he was seized with the whole family of the ambassador. During his confinement, which lasted eight months, as he had no books, and was allowed to see no person, he amused himself by meditating on what he read in Grotius's treatise *De Jure Belli et Pacis*, and the political writings of Mr Hobbes. Out of these he drew up a short system, to which he added some thoughts of his own, and published it at the Hague in 1660, under the title of *Elementa Jurisprudentiæ Universalis*. This recommended him to the elector Palatine, who invited him to the university of Heidelberg, where he founded in his favour a professorship of the law of nature and nations, which was the first of that kind established in Germany. Puffendorf remained at Heidelberg till 1673, when Charles XI. of Sweden gave him an invitation to be professor of the law of nature and nations at Lunden; which place the elector Palatine reluctantly allowed him to accept. He went thither the same year; and after that time his reputation greatly increased. Some years after, the king of Sweden sent for him to Stockholm, and made him his historiographer, and one of his counsellors. In 1688, the elector of Brandenburg obtained the consent of his Swedish majesty, that he should come to Berlin, in order to write the history of the elector William the Great; and in 1694 made him a baron. But he died that same year of an inflammation in his feet, occasioned by cutting his nails; having attained his grand climacteric. Of his works, which are numerous, the following are the principal: 1. A Treatise on the law of Nature and Nations, written in German; of which there is an English translation with Barbeyrac's Notes. 2. An Introduction to the History of the Principal States which at present subsist in Europe; written in German; which has been also translated into English. 3. The History of Sweden, from Gustavus Adolphus's expedition into Germany to the abdication of Queen Christina. 4. The History of Charles Gustavus, two volumes folio, &c.

PUFFIN. See ALCA, ORNITHOLOGY *Index*.

PUGET, PETER PAUL, one of the greatest painters and sculptors France ever produced, though but little noticed by their own writers, was born at Marseilles in 1623. In his youth he was the disciple of Roman, an able sculptor; and then went to Italy, where he studied painting and architecture. In painting he so well imitated the manner of Peter de Cortona, that this painter desired to see him, and entered into a friendship with him. In 1657, a dangerous disorder obliged him to renounce the pencil, and devote himself to sculpture; and his reputation causing him to be invited to Paris, he enjoyed a pension of 1200 crowns, as sculptor and director of the works relating to vessels and galleys.

gallcys. He died at Marseilles in 1695, and has left a number of admirable statues behind him both in France and Italy.

PUGIL, in *Materia Medica*, such a quantity of flowers, seeds, or the like, as may be taken up between the thumb and two fore-fingers. It is reckoned the eighth part of the manipulus or handful.

PULEGIUM, or *Penny-Royal*. See MENTHA, BOTANY *Index*.

PULEX, the FLEA, in *Zoology*, a genus of insects belonging to the order of aptera. See ENTOMOLOGY *Index*.

By keeping fleas in a glass tube corked up at both ends, but so as to admit fresh air, their actions and manners may be observed. They are thus seen to lay their eggs, not all at once, but ten or twelve in a day, for several days successively; which eggs will be afterwards found to hatch successively in the same order. The flea may easily be dissected in a drop of water; and by this means the stomach and bowels, with their peristaltic motion, may be discovered very plainly, as also their testes and penis, with the veins and arteries, though minute beyond all conception. Mr Leuwenhoek affirms also, that he has seen innumerable animalcules, shaped like serpents, in the semen masculinum of a flea. This blood-thirsty insect, which fattens at the expence of the human species, prefers the more delicate skin of women; but prays neither upon epileptic persons, nor upon the dead or dying. It loves to nestle in the fur of dogs, cats, and rats. The nests of river-swallows are sometimes plentifully stored with them.

Barbut's Genera of Insects, p. 330, &c.

Fleas are apterous; walk but little, but leap to a height equal to 200 times that of their own body. This amazing motion is performed by means of the elasticity of their feet, the articulations of which are so many springs. Thus it eludes, with surprising agility, the pursuit of the person on whom it riots. Among the memorabilia of fleas, one, they say, has been seen to draw a small silver piece of ordnance to which it was fastened, the firing of the gun nowise daunting its intrepidity. The owner carried it about in a little box lined with velvet, every now and then placing it on her arm to let it feed; but winter put an end to the being of this martial flea. Another flea that became slave to an Englishman, had, for its daily and easy task, to drag its golden chain and padlock, of the weight of one grain. A third flea served as a thill-horse to an English artist, who had made an ivory coach and six, that carried a coachman and his dog between his legs, a postillion, two footmen, and four inside riders. At Surat fleas, bugs, and other voracious vermin, are in so great veneration, that they have an hospital endowed, where every night a poor fellow, for hire, suffers himself to be preyed upon. He is fastened naked on a bed, when the feast begins at his expence. In Turkey there is a similar foundation for decayed dogs; an institution less ridiculous than the other. Mercurial ointment brimstone, a fumigation with the leaves of pennyroyal, or fresh-gathered leaves of that plant sewed up in a bag, and laid in the bed, are remedies pointed out as destructive of fleas.

Pulex Arboreus, in *Natural History*, the name given by Mr Reaumur to a very large genus of small animals. They are a kind of half-winged creatures: they have granulated antennæ; and some of them, in their most perfect state, have complete wings. These are distinguished from the others by the name of *musca-pulex*, or the *winged pulex*. See COCCUS, ENTOMOLOGY *Index*.

Pulex Aquaticus auctorum (monoculus pulex of Linnæus) is a species of the genus MONOCULUS; which see, under ENTOMOLOGY *Index*.

Pulex-Eaters, a name given by naturalists to a sort of worms frequently found on the leaves of trees, where they devour the animals called *pulices arborei*.

Of these there are several species, which owe their origin to the eggs of different creatures; for there are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, these are of different form and structure. Some are hexapodes, or endued with six feet; these belong to the beetle-tribe, and finally change into beetles like the parent animal from whose eggs they sprung. Others have no legs, and are produced from the eggs of flies of various kinds. And, finally, others are genuine caterpillars, though small; but these are the most rare of all.

The two general kinds are the hexapodes, or beetle-worms; and the apodes, or fly-worms. The fly which gives origin to the last of these is a four-winged one; and takes care always to deposit her eggs in a place where there are plenty of the pulices, usually on the stalk or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenceless. The stalks of the elder and woodbine are frequently found covered over with these pulices; and among them there may usually be found one or more of these destroyers feeding at will, sucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged fly, there is one of a two-winged wasp-fly, very destructive of these animals.

PULLEY, in *Mechanics*, one of the five mechanical powers. See MECHANICS.

PULMO, the LUNGS, in *Anatomy*. See ANATOMY *Index*.

PULMONARIA, LUNGWORT, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 41st order, *Asperifoliæ*. See BOTANY *Index*.

PULO, the name of several Asiatic islands, in the Indian ocean, the principal of which only, it is said, is inhabited. It is denominated

Pulo-Condore, an island about 13 miles long and three broad, which was visited by Lord Macartney on his way to China. It has convenient anchoring places during either monsoon. Here his lordship's squadron came to anchor on the 17th of May. The bay is formed by four small islands approaching so near to each other, as to exhibit the appearance of meeting together in different points. They all seem to be the rude fragments of primitive mountains, which have been detached from the great continent in the lapse of ages. Condore lies in 8° 40′ North Lat. and 105° 55′ E. Long.

The English at one period had a settlement here, but being driven from it by some Malay soldiers in their pay, probably for some unjustifiable treatment, no Europeans, it is said, have resided in it ever since. When a party went on shore from Lord Macartney's squadron,

they

they were welcomed by the natives with much urbanity of manners, and conducted to the house of their chief. Their dress consisted chiefly of blue cotton garments hanging loosely about them; and their flat faces and noses seemed to denote that they were descended from the Chinese. A missionary being of the party, could not understand their language as they spoke it; but as soon as committed to writing it was perfectly intelligible to him. This led to the conclusion, that the inhabitants of Pulo-Condore were originally Cochin Chinese, who fled from their own country in consequence of their attachment to one of its sovereigns who had been dethroned by a number of his own subjects.

Here the squadron was to purchase provisions, and the people promised to have the proposed quantity in readiness, if possible, at the appointed time. Next morning, a party of pleasure went from the Hindostan to a small island near Pulo-Condore; but being apprehensive of an approaching storm, they made towards the ship with all convenient speed. The weather again becoming favourable, they set off for the island again, and were astonished, on their arrival, to find it wholly abandoned. In the principal cabin a letter was found, written in the Chinese language, expressing their terror at the arrival of such great ships and powerful persons; not being able to satisfy their demands as to cattle and other provisions, the poor inhabitants of Pulo-Condore having scarcely any to supply, they therefore fled to preserve their lives; declared themselves to be few in number, and very poor, but honest; and concluded with requesting the *great people* to have pity on them, as they had left their all behind, and earnestly implored them not to burn their cabins.

The generous English left them an intimation that they called merely for refreshment on fair and equitable terms, without harbouring against them any evil designs. They claimed a connection to a civilized nation, actuated by principles of humanity, by which they were prohibited from plundering or doing injury to others, who might have the misfortune to be fewer or weaker than themselves. No doubt the poor terrified inhabitants would be agreeably surprised to find, on their return, not only that all their tents were in perfect safety, but that nothing was either disturbed or removed, and a small present left to their chief in the principal dwelling.

Pulo-Lingen, another island of the cluster mentioned above, is of some extent, though inferior in size to Pulo-Condore. It is chiefly remarkable for a mountain in its centre, terminating in a fork like Parnassus, but denominated by mariners the *asses ears*. The people of Lord Macartney's squadron were constantly discovering new islands, many of which were clothed with verdure; some had lofty trees growing upon them; others were nothing but naked rocks, the resort of innumerable birds, and whitened with their dung.

PULO PENANG. See *Prince of Wales's Island*.

PULP, in *Pharmacy*, the fleshy and succulent parts of fruits extracted by infusion or boiling, and passed through a sieve.

PULPIT, an elevated place in a church, whence sermons are delivered. The French give the same name to a reading desk.

PULPITUM, in the Grecian and Roman theatres, was a place where the players performed their parts. It was lower than the scena, and higher than the orchestra. It nearly answered to what we call the stage, as distinguished from the pit and galleries. *Pulpitum* was also a moveable desk or pulpit, from which disputants pronounced their dissertations, and authors recited their works.

PULSE, in the animal economy, denotes the beating or throbbing of the heart and arteries.

No doctrine has been involved in more difficulties than that of pulses; since, in giving a physiological account of them, physicians have espoused quite opposite sentiments; whilst some doubt whether the pulse is owing to the systole or diastole; as also, whether the motion of the heart and arteries is one and the same, for a moment of time.

With regard to motion, the pulses are reckoned only four; great and little, quick and slow. When quickness and greatness are joined together, it becomes violent; and when it is little and slow it is called a *weak pulse*. They are also said to be *frequent* and *rare*, *equal* and *unequal;* but these are not the essential affections of motion. Frequency and quickness are often confounded with each other. A pulse is said to be *hard* or *soft*, with regard to the artery, according as it is tense, renitent, and hard, or flaccid, soft, and lax: for the disposition of the arteries contributes greatly to the change of the pulse; wherefore it sometimes happens, that the pulse in both arms is not alike, which is very common in a hemiplexy. Add to these a convulsive pulse, which does not proceed from the blood, but from the state of the artery; and is known by a tremulous subsultory motion, and the artery seems to be drawn upwards: this, in acute fevers, is the sign of death; and is said to be the pulse in dying persons, which is likewise generally unequal and intermitting. A *great* pulse shows a more copious afflux of the blood to the heart, and from thence into the arteries: a *little* pulse the contrary.

The pulses of persons differ according to the largeness of the heart and vessels, the quantity and temperies of the blood, the elastic force of the canals; as also with regard to the sex, age, season, air, motion, food, sleep, watchings, and passions of the mind. The pulse is larger and more quick in men than in women; in the bilious and sanguineo-bilious, than in the phlegmatic and melancholic. Those who are lean, with tense fibres, and large vessels, have a greater and a stronger pulse, than those that are obese, with lax fibres and small vessels; whence they are more healthy, robust, and apt for labour. In children, the pulse is quick and soft; in adults greater and more violent. In the old, it is commonly great, hard, and slow. Labour, motion, and exercise of the body, increase the circulation of the blood, the excretions, and particularly respiration; rest renders the circulation slow and weak; intense speaking increases the circulation, and consequently renders the pulse large and quick. In watching, the pulse is more evident; in sleep, more slow and languid. After drinking hot things, such as coffee and tea, or hot bath-waters, as well as after meals, the pulse vibrates more quick. But nothing produces a greater change in the pulse than affections of the mind: in terror, it is unequal, small, and contracted: in joy, frequent and great; in anger, quick and hard; in sadness, slow, small, deep, and weak; and in intense study, languid and weak. With regard to the air, when, after the predominancy

predominancy of a west or south wind, it becomes north or east, the pulse is stronger and larger; as also when the quicksilver rises in the barometer. But when the atmosphere is dense, humid, rainy, with a long south wind; as also where the life is sedentary, the sleep long, and the season autumnal, the pulse is languid and small, and the perspiration decreased. In May it is great, and sometimes violent; in the middle of summer, quick but weak; in the autumn, slow, soft, and weak; in the winter, hard and great. A drastic purge and an emetic render the pulse hard, quick, and weak, with loss of strength; chalybeates, and the bark, render it great and robust, and the complexion lively; volatiles amplify and increase the pulse; acids and nitrous remedies refrigerate the body, and appease the pulse; opiates and the like render it small and weak, and decrease the elasticity of the solids; and poisons render it small, contracted, and hard. When the quantity of the blood is too great, bleeding raises the pulse.

Pulse, is also used for the stroke with which any medium is affected by the motion of light, sound, &c. through it.

Sir Isaac Newton demonstrates, that the velocities of the pulses in an elastic fluid medium (whose elasticity is proportionable to its density) are in a ratio compounded of half the ratio of the elastic force directly, and half the ratio of the density inversely; so that in a medium whose elasticity is equal to its density, all pulses will be equally swift.

Pulse, in *Botany*, a term applied to all those grains or seeds which are gathered with the hand; in contradistinction to corn, &c. which are reaped, or mowed: or, It is the seed of the leguminous kind of plants, as beans, vetches, &c.; but is by some used for artichokes, asparagus, &c.

PULTENEY, William, the famous opposer of Sir Robert Walpole in parliament, and afterward earl of Bath, was descended from one of the most ancient families in the kingdom, and was born in 1682. Being well qualified in fortune, he early procured a seat in the house of commons, and distinguished himself as a warm partisan against Queen Anne's ministry; whose errors he had sagacity to detect, and spirited eloquence to expose. When King George I. came to the throne, Mr Pulteney was made secretary at war, and soon after cofferer to the king's household; but the good understanding between this gentleman and Sir Robert Walpole, who then acted as prime minister, was interrupted in 1725, on a suspicion that Walpole was desirous of extending the limits of prerogative, and of promoting the interests of Hanover, to the prejudice of those of Britain. His opposition to Sir Robert was indeed carried to such indiscriminate lengths, that some have been of opinion he often acted against measures beneficial to the public, merely from personal motives. It would be impracticable here to trace his parliamentary conduct: so it must suffice to observe in general, that he became so obnoxious to the crown, that in 1731 the king called for the council-book, and with his own hand struck out his name from the list of privy-counsellors; a proceeding that only served to inflame his resentment and increase his popularity. Thus he still continued to attack the minister with a severity of eloquence and sarcasm that worsted every antagonist; so that Sir Robert was heard to declare, he dreaded that man's tongue more than another man's sword. At length, when Walpole found the place of prime minister no longer tenable, and resigned in 1741, among other promotions Mr Pulteney resumed his place in the privy-council, and was created earl of Bath; a title purchased at the expence of that popularity which afterward he naturally enough affected to contemn. In 1760, toward the close of the war, he published *A Letter to two Great Men*, recommending proper articles to be insisted on in a treaty of peace; which, though the writer was then unknown, was greatly applauded, and went through several impressions. He died in 1764; and as his only son died before him, the title became extinct.

PULVERIZATION, the art of pulverizing, or reducing a dry body into a fine powder; which is performed in friable bodies by pounding or beating them in a mortar, &c; but to pulverize malleable ones, other methods must be taken. To pulverize lead, or tin, the method is this: Rub a round wooden box all over the inside with chalk; pour a little of the melted metal nimbly into the box; when shutting the lid, and shaking the box briskly, the metal will be reduced to powder.

PUMEX, the Pumice-stone. See Mineralogy *Index*.

Pumice-stone is used in some mechanical arts; as for rubbing and smoothing the surface of metals, wood, pasteboard, and stone; for which it is well fitted by reason of its harsh and brittle texture; thus scouring and carrying off the little inequalities from the surfaces just mentioned.

PUMICE-stone. See Mineralogy *Index*.

PUMP, an hydraulic machine for raising water by means of the pressure of the atmosphere.

1 Of the invention of pumps.

It would be an entertaining and not an uninstructive piece of information to learn the progressive steps by which the ingenuity of man has invented the various methods of raising water. A pump must be considered as the last step of this progress. Common as it is, and overlooked even by the curious, it is a very abstruse and refined invention. Nothing like it has been found in any of the rude nations whom the restless spirit of the Europeans has discovered, either in the new continent of America, or the islands of the Pacific ocean. Nay, it was unknown in the cultivated empire of China at the time of our arrival there by sea; and it is still a rarity everywhere in Asia, in places unfrequented by the Europeans. It does not appear to have been known to the Greeks and Romans in early times; and perhaps it came from Alexandria, where physical and mathematical science was much cultivated by the Greek school under the protection of the Ptolemies. The performances of Ctesibius and Hero are spoken of by Pliny and Vitruvius as curious novelties (A). It is perhaps not difficult to trace the steps by which those mechanicians were led to

(A) In the early Greek writings, it does not appear that the words ἄντλος, ἀντλεῖν, ἀντλία, &c, were used to express any thing like what we call a pump. In all these passages the words either express generally the drawing of water, to the invention. The Egyptian wheel was a common machine all over Asia, and is still in use in the remotest corners, and was brought by the Saracens into Spain, where it is still very common under its ancient name NORIA. The Danish missionaries found in a remote village in the kingdom of Siam the immediate off-spring of the noria (*Lettres Edifiantes et Curieuses*). It was a wheel turned by an ass, and carrying round, not a string of earthen pots, but a string of wisps of hay, which it drew through a wooden trunk. This rude chain-pump was in frequent use for watering the rice fields. It is highly probably that it is of great antiquity, although we do not recollect its being mentioned by any of the Greek or Roman writers. The Arabs and Indians were nothing less than innovators; and we may suppose with great safety, that what arts we now find among them they possessed in very remote periods. Now the step from this to the pump is but short, though it is nice and refined; and the forcing pump of Ctesibius is the easiest and most natural.

Plate CCCCXLIX. fig. 1.

2 Ctesibius's pump.

Let AB (fig. 1.) be the surface of the water in the well, and D the height where it is to be delivered. Let DC be a long wooden trunk, reaching as deep under water as possible. Let the rope EF be fitted with its knot of hay F. When it is drawn up through the trunk, it will bring up along with it all the water lying between C and A, which will begin to run out by the spout D as soon as the knot gets to G, as far below D as C is below A. All this is very obvious: and it required but little reflection to be assured, that if F was let down again, or pushed down, by a rod instead of a rope, it would again perform the same office. Here is a very simple pump. And if it was ever put in practice, it behoved to show the supporting power of the atmosphere, because the water would not only be lifted by the knot, but would even follow it. The imperfection of this pump behoved to appear at first sight, and to suggest its remedy. By pushing down the knot F, which we shall henceforth call the *piston*, all the force expended in lifting up the water between A and G is thrown away, because it is again let down. A valve G, at the bottom would pervent this. But then there must be a passage made for the water by a lateral tube KBD (fig. 2.) And if this be also furnished with a valve H, to prevent its losing the water, we have the pump of Ctesibius, as sketched in fig. 2. The valve is the great refinement: but perhaps even this had made its appearance before in the noria. For, in the more perfect kinds of these machines, the pots have a stop or valve in their bottom, which hangs open while the pot descends with its mouth downwards, and then allows it to fill readily in the cistern: whereas, without the valve, it would occasion a double load to the wheel. If we suppose that the valve had made its appearance so early, it is not improbable that the common pump sketched in fig. 3. was as old as that of Ctesibius. In this place we shall first give a short description of the chief varieties of these engines, considering them in their simplest form, and we shall explain in very general terms their mode of operation. We shall then give a concise and popular theory of their operation, furnishing principles to direct us in their construction; and we shall conclude with the description of a few peculiarities which may contribute to their improvement or perfection.

Fig. 2.

Fig. 3.

There are but two sorts of pumps which essentially differ; and all the varieties that we see are only modifications of these. One of these original pumps has a solid piston; the other has a piston with a perforation and a valve. We usually call the first a FORCING PUMP, and the second a LIFTING OR SUCKING PUMP.

3 Forcing pump described. Fig. 2.

Fig. 2. is a sketch of the forcing pump in its most simple form and situation. It consists of a hollow cylinder AC c a, called the WORKING BARREL, open at both ends, and having a valve G at the bottom, opening upwards. This cylinder is filled by a solid piston EF, covered externally with leather or tow, by which means it fits the box of the cylinder exactly, and allows no water to escape by its sides. There is a pipe KHD, which communicates laterally with this cylinder, and has a valve at some convenient place H, as near as possible to its junction with the cylinder. This valve also opens upwards. This pipe, usually called the RISING PIPE, or MAIN, terminates at the place D, where the water must be delivered.

4 Its mode of operation.

Now suppose this apparatus set into the water, so that the upper end of the cylinder may be under or even with the surface of the water AB; the water will open the valve G, and after filling the barrel and lateral pipe, will also open the valve H, and at last stand at an equal height within and without. Now let the piston be put in at the top of the working barrel, and thrust down to K. It will push the water before it. This will shut the valve G, and the water will make its way through the valve H, and fill a part B b of the rising pipe, equal to the internal capacity of the working barrel. When this downward motion of the piston ceases, the valve H will fall down by its own weight and shut this passage. Now let the piston be drawn up again: The valve H hinders the water in the rising pipe from returning into the working barrel. But now the valve G is opened by the pressure of the external water, and the water enters and fills the cylinder as the piston rises. When the piston has got to the top, let it be thrust down again: The valve G will again be shut, and the water will be forced through the passage at H, and rise along the main, pushing before it the water already there, and will now have its surface at L. Repeating this operation, the water must at last arrive at D, however

water, or, more particularly, the drawing it with a bucket or something similar. Ἄντλος, which is the primitive, is a drain, sink, or receptacle for collecting scattered water, either for use, or to get rid of it; hence it came to signify the sink or well of a ship; and ἀντλεῖν was synonymous with our verb "to bale the boat." (*Odyss.* O. 476 M. 411. *Eurip. Hecuba*, 1025). Ἀντλίον is the *vessel* or *bucket* with which water is drawn. Ἀντλία is the service (generally a punishment) of drawing water. Ἀντλεῖν, "to draw water with a bucket:" hence the force of Aristotle's expression (*Oecon.* I.) τὸ γὰρ ὕδωρ ἀντλεῖν τοῦτ' ἐστι. See even the late authority of the New Testament, John ii. 8.; iv. 7. 11. Here ἄντλημα is evidently something which the woman brought along with her; probably a bucket and rope.

ever remote, and the next stroke would raise it to e; so that during the next rise of the piston the water in e D will be running off by the spout.

The effect is the same whatever be the position of the working barrel, provided only that it be under water. It may lie horizontally or sloping, or it may be with its mouth and piston rod undermost. It is still the same forcing pump, and operates in the same manner and by the same means, viz. the pressure of the surrounding water.

The external force which must be applied to produce this effect is opposed by the pressure exerted by the water on the opposite face of the piston. It is evident, from the common laws of hydrostatics, that this opposing pressure is equal to the weight of a pillar of water, having the face of the piston for its base, and the perpendicular height d A of the place of delivery above the surface of the water AB in the cistern for its height. The form and dimensions of the rising pipe are indifferent in this respect, because heavy fluids press only in the proportion of their perpendicular height. Observe that it is not d F, but d A, which measures this pressure, which the moving force must balance and surmount. The whole pressure on the under surface F f of the piston is indeed equal to the weight of the pillar d F $f\delta$; but part of this is balanced by the water AFf a. If indeed the water does not get into the upper part of the working barrel, this compensation does not obtain. While we draw up the piston, this pressure is removed, because all communication is cut off by the valve H, which now bears the whole pressure of the water in the main. Nay, the ascent of the piston is even assisted by the pressure of the surrounding water. It is only during the descent of the piston therefore that the external force is necessary.

Observe that the measure now given of the external force is only what is necessary for *balancing* the pressure of the water in the rising pipe. But in order that the pump may perform work, it must *surmount* this pressure, and cause the water to issue at D with such a velocity that the required quantity of water may be delivered in a given time. This requires force, even although there were no opposing pressure; which would be the case if the main were horizontal. The water fills it, but it is at rest. In order that a gallon, for instance, may be delivered in a second, the whole water in the horizontal main must be put in motion with a certain velocity. This requires force. We must therefore always distinguish between the state of equilibrium and the state of actual working. It is the equilibrium only that we consider at present; and no more is necessary for understanding the operation of the different species of pumps. The other force is of much more intricate investigation, and will be considered by itself.

5 Lifting pump.

The simplest form and situation of the lifting pump is represented by the sketch fig. 3. The pump is immersed in the cistern till both the valve G and piston F are under the surface AB of the surrounding water. By this means the water enters the pump, opening both valves, and finally stands on a level within and without.

6 Its mode of operating.

Now draw up the piston to the surface A. It must lift up the water which is above it (because the valve in the piston remains shut by its own weight); so that its surface will now be at a, A a being made equal to AF. In the mean time, the pressure of the surrounding water forces it into the working barrel, through the valve G; and the barrel is now filled with water. Now, let the piston be pushed down again; the valve G immediately shuts by its own weight, and in opposition to the endeavours which the water in the barrel makes to escape this way. This attempt to compress the water in the barrel causes it to open the valve F in the piston; or rather, this valve yields to our endeavour to push the piston down through the water in the working barrel. By this means we get the piston to the bottom of the barrel; and it has now above it the whole pillar of water reaching to the height a. Drawing up the piston to the surface A a second time, must lift this double column along with it, and its surface now will be at b. The piston may again be thrust down through the water in the barrel, and again drawn up to the surface; which will raise the water to c. Another repetition will raise it to d; and it will now show itself at the intended place of delivery. Another repetition will raise it to e; and while the piston is now descending to make another stroke, the water in e d will be running off through the spout D; and thus a stream will be produced, in some degree continual, but very unequal. This is inconvenient in many cases: thus, in a pump for domestic uses, such a hobbling stream would make it very troublesome to fill a bucket. It is therefore usual to terminate the main by a cistern LMNO, and to make the spout small. By this means the water brought up by the successive strokes of the piston rises to such a height in this cistern, as to produce an efflux by the spout nearly equable. The smaller we make the spout D the more equable will be the stream; for when the piston brings up more water than can be discharged during its descent, some of it remains in the cistern. This, added to the supply of next stroke, makes the water rise higher in the cistern than it did by the preceding stroke. This will cause the efflux to be quicker during the descent of the piston, but perhaps not yet sufficiently quick to discharge the whole supply. It therefore rises higher next stroke; and at last it rises so high, that the increased velocity of efflux makes the discharge precisely balance the supply. Now, the quantity supplied in each stroke is the same, and occupies the same room in the cistern at top; and the surface will sink the same number of inches during the descent of the piston, whether that surface has been high or low at the beginning. But because the velocities of the efflux are as the square roots of the heights of the water above the spout, it is evident that a sink of two or three inches will make a smaller change in the velocity of efflux when this height and velocity are great. This seems but a trifling observation; but it serves to illustrate a thing to be considered afterwards, which is important and abstruse, but perfectly similar to this.

It is evident, that the force necessary for this operation must be equal to the weight of the pillar of water d A a D, if the pipe be perpendicular. If the pump be standing aslope, the pressure which is to be balanced is still equal to the weight of a pillar of water of this perpendicular height, and having the surface of the piston for its base.

Such is the simplest, and, we may add, by far the best, form of the forcing and lifting pumps; but it is not the most usual. Circumstances of convenience, economy, and more frequently of fancy and habit, have caused the pump-makers to deviate greatly from this form. It is not usual to have the working barrel in the

the water; this, especially in deep wells, makes it of difficult access for repairs, and requires long piston rods. This would not do in a forcing pump, because they would bend.

7 Effect of giving the piston a longer stroke

We have supposed, in our account of the lifting pump, that the rise of the piston always terminated at the surface of the water in the cistern. This we did in order that the barrel might always be filled by the pressure of the surrounding water. But let us suppose that the rise of the piston does not end here, and that it is gradually drawn up to the very top: it is plain that the pressure of the atmosphere is by this means taken off from the water in the pipe (see PNEUMATICS), while it remains pressing on the water of the cistern. It will therefore cause the water to follow the piston as it rises through the pipe, and it will raise it in this way 33 feet at a medium. If, therefore, the spout D is not more than 33 feet above the surface of the water in the cistern, the pipe will be full of water when the piston is at D. Let it be pushed down to the bottom; the water will remain in the pipe, because the valve G will shut: and thus we may give the piston a stroke of any length not exceeding 33 feet. If we raise it higher than this, the water will not follow; but it will remain in the pipe, to be lifted by the piston, after it has been pushed down through it to the bottom.

8 inconvenient and unnecessary.

But it is not necessary, and would be very inconvenient, to give the piston so long a stroke. The great use of a pump is to render effectual the reciprocation of a short stroke which we can command, while such a long stroke is generally out of our power. Suppose that the piston is pushed down only to *b*; it will then have a column *bf* incumbent on it, and it will lift this column when again drawn up. And this operation may be repeated like the former, when the piston was always under water; for the pressure of the atmosphere will always cause the water to follow the piston to the height of 33 feet.

Nor is it necessary that the fixed valve G be placed at the lower orifice of the pipe, nor even under water. For, while things are in the state now described, the piston drawn up to *f*, and the whole pipe full of water; if we suppose another valve placed at *b* above the surface of the cistern, this valve can do no harm. Now let the piston descend, both valves G and *b* will shut. G may now be removed, and the water will remain supported in the space *b* G by the air; and now the alternate motions of the piston will produce the same effect as before.

9 Effect of the weight of the water and pressure of the atmosphere.

We found in the former case that the piston was carrying a load equal to the weight of a pillar of water of the height AD, because the surrounding water could only support it at its own level. Let us see what change is produced by the assistance of the pressure of the atmosphere. Let the under surface of the piston be at *b*; when the piston was at *f*, 33 feet above the surface of the cistern, the water was raised to that height by the pressure of the atmosphere. Suppose a partition made at *b* by a thin plate, and all the water above it taken away. Now piece a hole in this plate. The pressure of the atmosphere was able to carry the whole column *fa*. Part of this column is now removed, and the remainder is not a balance for the air's pressure. This will therefore cause the water to spout up through this hole and rise to *f*. Therefore the under surface of this plate is pressed up by the contiguous water with a force equal to the weight of that pillar of water which it formerly supported; that is, with a force equal to the weight of the pillar *fb*. Now the under surface of the piston, when at *b*, is in the same situation. It is pressed upwards by the water below it, with a force equal to the weight of the column *fb*: But it is pressed downwards by the whole pressure of the atmosphere, which presses on all bodies; that is, with the weight of the pillar *fa*. On the whole, therefore, it is pressed downwards by a force equal to the difference of the weights of the pillars *fa* and *fb*; that is, by a force equal to the weight of the pillar *ba*.

It may be conceived better perhaps in this way. When the piston was under the surface of the water in the cistern, it was equally pressed on both sides, both by the water and atmosphere. The atmosphere exerted its pressure on it by the intervention of the water; which being, to all sense, a perfect fluid, propagates every external pressure undiminished. When the piston is drawn up above the surface of the pit-water, the atmosphere continues to press on its upper surface with its whole weight, through the intervention of the water which lies above it; and its pressure must therefore be added to that of the incumbent water. It also continues to press on the under surface of the piston by the intervention of the water; that is, it presses this water to the piston. But, in doing this, it carries the weight of this water which it is pressing on the piston. The pressure on the piston therefore is only the excess of the whole pressure of the atmosphere above the weight of the column of water which it is supporting. Therefore the difference of atmospheric pressure on the upper and under surfaces of the piston is precisely equal to the weight of the column of water supported in the pipe by the air. It is not, however, the individual weight of this column that loads the piston; it is the part of the pressure of the atmosphere on its upper surface, which is not balanced by its pressure on the under surface.

In attempting, therefore, to draw up the piston, we have to surmount this unbalanced part of the pressure of the atmosphere, and also the weight of the water which lies above the piston, and must be lifted by it: and thus the whole opposing pressure is the same as before, namely, the weight of the whole vertical pillar reaching from the surface of the water in the cistern to the place of delivery. Part of this weight is immediately carried by the pressure of the atmosphere; but, in lieu of it, there is an equal part of this pressure of the atmosphere abstracted from the under surface of the piston, while its upper surface sustains its whole pressure.

10 Other circumstances to be attended to.

So far, then, these two states of the pump agree.—But they differ exceedingly in their mode of operation; and there are some circumstances not very obvious which must be attended to, in order that the pump may deliver any water at the spout D. This requires, therefore, a serious examination.

Let the fixed value G (fig. 4.) be supposed at the surface of the cistern water. Let M*m* be the lowest, and N*n* the highest, positions of the piston, and let HA=*h* be the height of a column of water equiponderant with the atmosphere. Fig. 4.

When the pump is filled, not with water, but with air, and the piston is in its lowest position, and all in equilibrio, the internal air has the same density and elasticity

elasticity with the external. The space MA $a\,m$, therefore, contains air of the common density and elasticity. These may be measured by h, or the weight of a column of water whose height is h. Now, let the piston be drawn up to N n. The air which occupied the space MA $a\,m$ now occupies the space NAan, and its density is now $\frac{\mathrm{MA}\,a\,m}{\mathrm{NA}\,a\,n}$. Its elasticity is now diminished, being proportionable to its density (see PNEUMATICS), and no longer balances the pressure of the atmosphere. The valve G will therefore be forced up by the water, which will rise to some height SA. Now let the piston again descend to M m. It cannot do this with its valve shut; for when it comes down so far as to reduce the air again to its common density, it is not yet at M, because the space below it has been diminished by the water which got into the pipe, and is retained there by the valve G. The piston valve, therefore, opens by the air which we thus attempt to compress, and the superfluous air escapes. When the piston has got to M, the air is again of the common density, and occupies the space MS$\,s\,m$. Now draw the piston up to N. The air will expand into the space NS$\,s\,n$, and its density will be reduced to $\frac{\mathrm{MS}\,s\,m}{\mathrm{NS}\,s\,n}$, and its elasticity will no longer balance the pressure of the atmosphere, and more water will enter, and it will rise higher. This will go on continually. But it may happen that the water will never rise so high as to reach the piston, even though not 33 feet above the water in the cistern: For the successive diminutions of density and elasticity are a series of quantities that decrease geometrically, and therefore will have a limit. Let us see what determines this limit.

At whatever height the water stands in the lower part of the pipe, the weight of the column of water SA $a\,s$, together with the remaining elasticity of the air above it, exactly balances the pressure of the atmosphere (see PNEUMATICS, N° 108.). Now the elasticity of the air in the space NS$\,s\,n$ is equal to $h \times \frac{\mathrm{MS}\,s\,m}{\mathrm{NS}\,s\,n}$. Therefore, in the case where the limit obtains, and the water rises no farther, we must have $h = \mathrm{AS} + h\frac{\mathrm{MS}\,s\,m}{\mathrm{NS}\,s\,n}$, or, because the column is of the same diameter throughout, $h = \mathrm{AS} + h\frac{\mathrm{MS}}{\mathrm{NS}}$, and $\frac{\mathrm{MS}}{\mathrm{NS}}\,h = h - \mathrm{AS}, = \mathrm{HS}$, and NS : MS = HA : HS, and NS—MS : NS = HA—HS : HA, or NM : NS = AS : AH, and NM × AH = NS × AS. Therefore, if AN, the distance of the piston in its highest position from the water in the cistern, and NM the length of its stroke, be given, there is a certain determined height AS to which the water can be raised by the pressure of the air: For AH is a constant quantity; and therefore when MN is given, the rectangle AS × SN is given. If this height AS be less than that of the piston in its lowest position, the pump will raise no water, although AN may be less than AH. Yet the same pump will raise water very effectually, if it be first of all filled with water; and we have seen professional engineers much puzzled by this capricious failure of their pumps. A little knowledge of the principles would have prevented their disappointment.

To insure the delivery of water by the pump, the stroke must be such that the rectangle MN × AH may be greater than any rectangle that can be made of the parts of AN, that is, greater than the square of half AN. Or, if the length of the stroke be already fixed by other circumstances, which is a common case, we must make AN so short that the square of its half, measured in feet, shall be less than 33 times the stroke of the piston.

11
Mode of ensuring the delivery of water.

Suppose that the fixed valve, instead of being at the surface of the water in the cistern, is at S, or anywhere between S and A, the performance of the pump will be the same as before: But if it be placed anywhere above S, it will be very different. Let it be at T. It is plain that when the piston is pushed down from N to M, the valve at T prevents any air from getting down; and therefore, when the piston is drawn up again, the air contained in the space MT$\,t\,m$ will expand into the space NT$\,t\,n$, and its density will be $\frac{\mathrm{MT}}{\mathrm{NT}}$. This is less than $\frac{\mathrm{MS}}{\mathrm{NS}}$, which expresses the density of the air which was left in the space TS$\,s\,t$ by the former operations.—The air, therefore, in TS$\,s\,t$ will also expand, will open the valve, and now the water will rise above S. The proportion of SN to NT may be evidently such that the water will even get above the valve T. This diminishes the space NT$\,t\,n$; and therefore, when the piston has been pushed down to M, and again drawn up to N, the air will be still more rarefied, and the water will rise still higher. The foregoing reasoning, however, is sufficient to show that there may still be a height which the water will not pass, and that this height depends on the proportion between the stroke of the piston and its distance from the water in the cistern. We need not give the determination, because it will come in afterwards in combination with other circumstances. It is enough that the reader sees the physical causes of this limitation: And, lastly, we see plainly that the utmost security will be given for the performance of the pump, when the fixed valve is so placed that the piston, when in its lowest position, shall come into contact with it. In this case, the rarefaction of the air will be the completest possible; and, if there were no space left between the piston and valve, and all were perfectly air-tight, the rarefaction would be complete, and the valve might be any thing less than 33 feet from the surface of the water in the cistern.

12
Valves not easily kept air-tight.

But this perfect contact and tightness is unattainable; and though the pump may be full of water, its continual downward pressure causes it to filtrate slowly through every crevice, and the air enters through every pore, and even disengages itself from the water, with which a considerable portion had been chemically combined. The pump by this means loses water, and it requires several strokes of brisk working to fill it again: and if the leathers have become dry, so much admission may be given to the air, that the pump will not fill itself with water by *any working*. It is then necessary to pour water into it, which shuts up these passages, and soon sets all to rights again. For these reasons it is always prudent to place the fixed valve as low as other circumstances will permit, and to make the piston rod of such a length, that when it is at the bottom of its stroke it shall be almost in contact with the valve. When we we are not limited by other circumstances, it is evident that the best possible form is to have both the piston and the fixed valve under the surface of the water of the cistern. In this situation they are always wet and air-tight. The chief objection is, that by this disposition they are not easily come at when needing repair. This is a material objection in deep mines. In such situations, therefore, we must make the best compensation of different circumstances that we can. It is usual to place the fixed valve at a moderate distance from the surface of the water, and to have a hole in the side of the pipe, by which it may be got out. This is carefully shut up by a plate firmly screwed on, with leather or cement between the parts. This is called the *clack door*. It would, in every case, be very proper to have a fixed valve in the lower end of the pipe. This would combine all advantages. Being always tight, the pipe would retain the water, and it would leave to the valve above it its full effect of increasing the rarefaction. A similar hole is made in the working barrel, a little above the highest position of the piston. When this needs repair, it can be got at through this hole, without the immense trouble of drawing up the whole rods.

Thus we have conducted the reader step by step, from the simplest form of the pump to that which long experience has at last selected as the most generally convenient. This we shall now describe in some detail.

13 **Description of the sucking-pump. Fig. 5.**

The SUCKING PUMP consists of two pipes DCCD, BAAB (fig. 5.); of which the former is called the *Barrel*, or the *Working Barrel*, and the other is called the *Suction-pipe*, and is commonly of a smaller diameter.—These are joined by means of flanches F, F, pierced with holes to receive screwed bolts. A ring of leather, or of lead, covered with a proper cement, is put between them; which, being strongly compressed by the screw-bolts, renders the joint perfectly air-tight.—The lower end A of the suction-pipe is commonly spread out a little to facilitate the entry of the water, and frequently has a grating across at AA to keep out filth or gravel. This is immerged in the standing water YZ. The working barrel is cylindrical, as evenly and smoothly bored as possible, that the piston may fill it exactly through its whole length, and move along it with as little friction as may be consistent with air-tightness.

The piston is a sort of truncated cone OPKL, generally made of wood not made to slip, such as elm or beech. The small end of it is cut off at the sides, so as to form a sort of arch OQP, by which it is fastened to the iron rod or spear. It is exhibited in different positions in figures 6, 7. which will give a more distinct notion of it than any description. The two ends of the conical part may be hooped with brass. This cone has its larger end surrounded with a ring or band of strong leather fastened with nails, or by a copper hoop, which is driven on at the smaller end. This band should reach to some distance beyond the base of the cone; the farther the better: and the whole must be of uniform thickness all round, so as to suffer equal compression between the cone and the working barrel.

Fig. 6. and 7.

14 **Necessity of air-tightness not properly attended to.**

The seam or joint of the two ends of this band must be made very close, but not sewed or stitched together. This would occasion bumps or inequalities, which would spoil its tightness; and no harm can result from the want of it, because the two edges will be squeezed close together by the compression in the barrel. It is by no means necessary that this compression be great. This is a very detrimental error of the pump-makers. It occasions enormous friction, and destroys the very purpose which they have in view, viz. rendering the piston air-tight; for it causes the leather to wear through very soon at the edge of the cone, and it also wears the working barrel. This very soon becomes wide in that part which is continually passed over by the piston, while the mouth remains of its original diameter, and it becomes impossible to thrust in a piston which shall completely fill the worn part.

15 **An easy mode of rendering pumps tight.**

Now, a very moderate pressure is sufficient for rendering the pump perfectly tight, and a piece of glove leather would be sufficient for this purpose, if loose or detached from the solid cone; for suppose such a loose and flexible, but impervious, band of leather put round the piston, and put into the barrel; and let it even be supposed that the cone does not compress it in the smallest degree to its internal surface.—Pour a little water carefully into the inside of this sort of cup or dish; it will cause it to swell out a little, and apply itself close to the barrel all round, and even adjust itself to all its inequalities. Let us suppose it to touch the barrel in a ring of an inch broad all round. We can easily compute the force with which it is pressed. It is half the weight of a ring of water an inch deep and an inch broad. This is a trifle, and the friction occasioned by it not worth regarding; yet this trifling pressure is sufficient to make the passage perfectly impervious, even by the most enormous pressure of a high column of incumbent water: for let this pressure be ever so great, the pressure by which the leather adheres to the barrel always exceeds it, because the incumbent fluid has no *preponderating* power by which it can force its way between them, and it must insinuate itself precisely so far, that its pressure on the inside of the leather shall still exceed, and only exceed, the pressure by which it endeavours to insinuate itself; and thus the piston becomes perfectly tight with the smallest possible friction. This reasoning is perhaps too refined for the uninstructed artist, and probably will not persuade him.

16 **Proved to be practicable from the human frame.**

To such we would recommend an examination of the pistons and valves contrived and executed by that artist, whose skill far surpasses our highest conceptions, the all-wise Creator of this world. The valves which shut up the passages of the veins, and this in places where an extravasation would be followed by instant death, are cups of thin membrane which adhere to the sides of the channel about half way round, and are detached in the rest of their circumference. When the blood comes in the opposite direction, it pushes the membrane aside, and has a passage perfectly free. But a stagnation of motion allows the tone of the muscular (perhaps) membrane, to restore it to its natural shape, and the least *motion* in the opposite direction causes it instantly to clap close to the sides of the vein, and then no pressure whatever can force a passage.

17 **Best form of a piston recommended.**

We shall recur to this again, when describing the various contrivances of valves, &c. What we have said is enough for supporting our directions for constructing a tight piston. But we recommended thick and strong leather, while our present reasoning seems to render thin leather preferable. If the leather be thin, and the solid piston in any part does not press it gently to the barrel, there will be in this part an unbalanced pressure of the incumbent column of water, which would instantly burst even a strong leather bag; but when the solid piston, covered with leather, exactly fills the barrel, and is even pressed a little to it, there is no such risk; and now that part of the leather band which reaches beyond the solid piston performs its office in the completest manner. We do not hesitate, therefore, to recommend this form of a piston, which is the most common and simple of all, as preferable, when well executed, to any of those more artificial, and frequently very ingenious, constructions, which we have met with in the works of the first engineers. To proceed, then, with our description of the sucking-pump.

18

Further description of the sucking-pump.

At the joining of the working barrel with the suction-pipe there is a hole H, covered with a valve opening upwards. This hole H is either made in a plate which makes a part of the suction-pipe, being cast along with it, or it is made in a separate plate. This last is the most convenient, being easily removed and replaced. Different views are given of this valve in figs. 8, 9, 10. The diameter EF (fig. 10.) of this plate is the same with that of the flanches, and it has holes corresponding to them, through which their bolts pass which keep all together. A ring of thick leather NKL is applied to this plate, having a part cut out between N and L, to make room for another piece of strong leather NR (fig. 9.) which composes the valve. The circular part of this valve is broader than the hole in the middle of fig. 10. but not quite so broad as to fill up the inside of the ring of leather OQP of this fig. which is the same with GKI of fig. 10. The middle of this leather valve is strengthened by two brass (not iron) plates, the uppermost of which is seen at R of fig. 9.: the one on its underside is a little smaller than the hole in the valve-plate, that it may go freely in; and the upper plate R is larger than this hole, that it may compress the leather to its brim all round. It is evident, that when this plate with its leathers is put between the joint flanches, and all is screwed together, the tail of leather N of fig. 9. will be compressed between the plates, and form a hinge, on which the valve can turn, rising and falling. There is a similar valve fastened to the upper side, or broadest base of the piston. This description serves for both valves, and in general for most valves which are to be found in any parts of a pump.

Fig. 8.

Fig. 9.

Fig. 10.

19

Its mode of operation.

The reader will now understand, without any repetition, the process of the whole operation of a sucking-pump. The piston rarefies the air in the working barrel, and that in the suction-pipe expands through the valve into the barrel; and, being no longer a balance for the atmospheric pressure, the water rises into the suction-pipe; another stroke of the piston produces a similar effect, and the water rises farther, but by a smaller step than by the preceding stroke: by repeating the strokes of the piston, the water gets into the barrel; and when the piston is now pushed down through it, it gets above the piston, and must now be lifted up to any height. The suction-pipe is commonly of smaller size than the working barrel, for the sake of economy. It is not necessary that it be so wide; but it may be, and often is, made too small. It should be of such a size, that the pressure of the atmosphere may be able to fill the barrel with water as fast as the piston rises. If a void is left below the piston, it is evident that the piston must be carrying the whole weight of the atmosphere, besides the water which is lying above it. Nay, if the pipe be only so wide, that the barrels shall fill precisely as fast as the piston rises, it must sustain all this pressure. The suction-pipe should be wider than this, that all the pressure of the atmosphere which exceeds the weight of the pillar in the suction-pipe may be employed in pressing it on the under surface of the piston, and thus diminish the load. It cannot be made too wide; and too strict an economy in this respect may very sensibly diminish the performance of the pump, and more than defeat its own purpose. This is most likely when the suction-pipe is long, because there the length of the pillar of water nearly balances the air's pressure, and leaves very little accelerating force; so that water will rise but slowly even in the widest pipe. All these things will be made the subjects of computation afterwards.

It is plain that there will be limitations to the rise of the water in the suction-pipe, similar to what we found when the whole pump was an uniform cylinder. Let a be the height of the fixed valve above the water in the cistern: let B and b be the spaces in cubic measure between this valve and the piston in its highest and lowest positions, and therefore express the bulks of the air which may occupy these spaces: let y be the distance between the fixed valve and the water in the suction-pipe, when it has attained its greatest height by the rarefaction of the air above it: let h be the height of a column of water in equilibrio, with the whole pressure of the atmosphere, and therefore having its weight in equilibrio with the elasticity of common air; and let x be the height of the column whose weight balances the elasticity of the air in the suction-pipe, when rarefied as much as it can be by the action of the piston, the water standing at the height $a-y$.

Then, because this elasticity, together with the column $a-y$ in the suction-pipe, must balance the whole pressure of the atmosphere, (see PNEUMATICS, N° 108.), we must have $h=x+a-y$, and $y=a+x-h$.

When the piston was in its lowest position, the bulk of the air between it and the fixed valve was b. Suppose the valve kept shut, and the piston raised to its highest position, the bulk will be B, and its density $\frac{b}{B}$, and its elasticity, or the height of the column whose weight will balance it, will be $h\frac{b}{B}$. If the air in the suction-pipe be denser than this, and consequently more elastic, it will lift the valve, and some will come in; therefore, when the pump has rarefied the air as much as it can, so that none does, in fact, come in, the elasticity of the air in the suction-pipe *must* be the same. Therefore $x=h\frac{b}{B}$.

We had $y=a+x-h$. Therefore $y=a+h\frac{b}{B}-h, =a+\frac{b-B}{B}h, =a-\frac{B-b}{B}h$.

Therefore when $\frac{B-b}{B}h$ is less than a, the water will stop before it reaches the fixed valve. But when a is less than $\frac{B-b}{B}h$, the water will get above the fixed valve, y becoming negative.

But

Pump.

But it does not follow that the water will reach the piston, that is, will rise so high that the piston will pass through it in its descent. Things now come into the condition of a pump of uniform dimensions from top to bottom; and this point will be determined by what was said when treating of such a pump.

20 The same pump is used in an inverted position; Fig. 11.

There is another form of the sucking-pump which is much used in great water works, and is of equal efficacy with the one now described. It is indeed the same pump in an inverted position. It is represented in fig. 11. where ABCD is the working barrel, immersed, with its mouth downwards, in the water of the cistern. It is joined by means of flanches to the rising pipe or MAIN.

This usually consists of two parts. The first, BEFC, is bent to one side, that it may give room for the iron frame TXYV, which carries the rod NO of the piston M, attached to the traverses RS, TOV of this frame. The other part, EGHF, is usually of a less diameter, and is continued to the place of delivery. The piston frame XTVY hangs by the rod Z, at the arm of a lever or working beam, not brought into the figure. The piston is perforated like the former, and is surrounded like it with a band of leather in form of a taper-dish. It has a valve K on its broad or upper base, opening when pressed from below. The upper end of the working barrel is pierced with a hole, covered with a valve I, also opening upwards.

Now suppose this apparatus immersed into the cistern till the water is above it, as marked by the line 2, 3, and the piston drawn up till it touch the end of the barrel. When the piston is allowed to descend by its own weight, the water rises up through its valve K, and fills the barrel. If the piston be now drawn up by the moving power of the machinery with which it is connected, the valve K shuts, and the piston pushes the water before it through the valve I into the main pipe EFGH. When the the piston is again let down, the valve I shuts by its own weight and the pressure of the water incumbent on it, and the barrel is again filled by the water of the cistern. Drawing up the piston pushes this water into the main pipe, &c. and then the water is at length delivered at the place required.

21 and is called a *lifting pump*.

This pump is usually called the *lifting pump*; perhaps the simplest of all in its principle and operation.—It needs no farther explanation: and we proceed to describe

22 Forcing-pump described. Fig. 12.

The FORCING PUMP, represented in fig. 12. It consists of a working barrel ABCD, a suction-pipe CDEF, and a main or rising pipe. This last is usually in three joints. The first GHKI may be considered as making part of the working barrel, and is commonly cast in one piece with it. The second IKLM is joined to it by flanches, and forms the elbow which this pipe must generally have. The third LNOM is properly the beginning of the main, and is continued to the place of delivery. At the joint IK there is a hanging valve or clack S; and there is a valve R on the top of the suction-pipe.

The piston PQTV is solid, and is fastened to a stout iron rod which goes through it, and is fixed by a key drawn through its end. The body of the piston is a sort of double cone, widening from the middle to each end, and is covered with two bands of very strong leather, fitted to it in the manner already described.

The operation of this pump is abundantly simple. When the piston is thrust into the pump, it pushes the air before it through the valve S, for the valve R remains shut by its own weight. When it has reached near the bottom, and is drawn up again, the air which filled the small space between the piston and the valve S now expands into the barrel; for as soon as the air begins to expand, it ceases to balance the pressure of the atmosphere, which therefore shuts the valve S. By the expansion of the air in the barrel the equilibrium at the valve R is destroyed, and the air in the suction-pipe lifts the valve, and expands into the barrel; consequently it ceases to be a balance for the pressure of the atmosphere, and the water is forced into the suction-pipe. Pushing the piston down again forces the air in the barrel through the valve S, the valve R in the mean time shutting. When the piston is again drawn up, S shuts, R opens, the air in the suction-pipe dilates anew, and the water rises higher in it. Repeating these operations, the water gets at last into the working barrel, and is forced into the main by pushing down the piston, and is pushed along to the place of delivery. 23 Its mode of operation.

The operation of this pump is therefore two-fold, sucking and forcing. In the first operation, the same force must be employed as in the sucking-pump, namely, a force equal to the weight of a column of water having the section of the piston for its base, and the height of the piston above the water in the cistern for its height. It is for the sake of this part of the operation that the upper cone is added to the piston. The air and water would pass by the sides of the lower cone while the piston is drawn up; but the leather of the upper cone applies to the surface of the barrel, and prevents this. The space contained between the barrel and the valve S is a great obstruction to this part of the operation, because this air cannot be rarefied to a very great degree. For this reason, the suction-pipe of a forcing-pump must not be made long. It is not indeed necessary; for by placing the pump a few feet lower, the water will rise into it without difficulty, and the labour of suction is as much diminished as that of impulsion is increased. However, an intelligent artist will always endeavour to make this space between the valve S and the lowest place of the piston as small as possible. 24 Is two-fold.

The power employed in forcing must evidently surmount the pressure of the whole water in the rising pipe, and (independent of what is necessary for giving the water the required velocity, so that the proper quantity per hour may be delivered), the piston has to withstand a force equal to the weight of a column of water having the section of the piston for its base, and the perpendicular altitude of the place of delivery above the lower surface of the piston for its height. It is quite indifferent in this respect what is the diameter of the rising pipe; because the pressure on the piston depends on the altitude of the water only, independent of its quantity. We shall even see that a small rising pipe will require a greater force to convey the water along it to any given height or distance.

When we would employ a pump to raise water in a crooked pipe, or in any pipe of moderate dimensions, this form of pump, or something equivalent, must be used. In bringing up great quantities of water from mines, the common sucking-pump is generally employed, ed, as really the best of them all; but it is the most expensive, because it requires the pipe to be perpendicular, straight, and of great dimensions, that it may contain the piston rods. But this is impracticable when the pipe is crooked.

If the forcing pump, constructed in the manner now described, be employed, we cannot use forcers with long rods. These would bend when pushed down by their further extremity. In this case, it is usual to employ only a short and stiff rod, and to hang it by a chain, and load it with a weight superior to the weight of water to be raised by it. The machinery therefore is employed, not in forcing the water along the rising-pipe, but in raising the weight which is to produce this effect by its subsequent descent.

In this case, it would be much better to employ the lifting-pump of fig. 11. For as the load on the forcers must be greater than the resistances which it must surmount, the force exerted by the machine must in like manner be greater than this load. This double excess would be avoided by using the lifting-pump.

25 Measure of the quantity of water delivered by any pump.

It will readily occur to the reader that the quantity of water delivered by any pump will be in the joint proportion of the surface or base of the piston and its velocity: for this measures the capacity of the part of the working barrel which the piston passes over. The velocity of the water in the conduit pipe, and in its passage through every valve, will be greater or less than the velocity of the piston, in the same proportion that the area of the piston or working barrel is greater or less than the area of the conduit or valve. For whatever quantity of water passes through any section of the working barrel in a second, the same quantity must go through any one of these passages. This enables us to modify the velocity of the water as we please: we can increase it to any degree at the place of delivery by diminishing the aperture through which it passes, provided we apply sufficient force to the piston.

26 The operation of pumps not equable;

It is evident that the operation of a pump is by starts, and that the water in the main remains at rest, pressing on the valve during the time that the piston is withdrawn from the bottom of the working barrel. It is in most cases desirable to have this motion equable, and in some cases it is absolutely necessary. Thus, in the engine for extinguishing fires, the spout of water going by jerks could never be directed with a certain aim, and half of the water would be lost by the way; because a body at rest cannot in an instant be put in rapid motion, and the first portion of every jerk of water would have but a small velocity.

27 and the mode of making them so.

A very ingenious contrivance has been fallen upon for obviating this inconvenience, and procuring a stream nearly equable. We have not been able to discover the author. At any convenient part of the rising-pipe beyond the valve S there is annexed a capacious vessel VZ (fig. 13. N° 1. and 2.) close a-top, and of great strength.

Fig. 13.

When the water is forced along this pipe, part of it gets into this vessel, keeping the air confined above it, and it fills it to such a height V, that the elasticity of the confined air balances a column reaching to T, we shall suppose, in the rising-pipe. The next stroke of the piston sends forward more water, which would fill the rising-pipe to some height above T. But the pressure of this additional column causes some more of it to go into the air vessel, and compress its air so much more that its elasticity now balances a longer column. Every succeeding stroke of the piston produces a like effect. The water rises higher in the main pipe, but some more of it goes into the air vessel. At last the water *appears* at the place of delivery; and the air in the air vessel is now so much compressed that its elasticity balances the pressure of the whole column. The next stroke of the piston sends forward some more water. If the diameter of the orifice of the main be sufficient to let the water flow out with a velocity equal to that of the piston, it will so flow out, rising no higher, and producing no sensible addition to the compression in the air vessel. But if the orifice of the main be contracted to half its dimensions, the water sent forward by the piston cannot flow out in the time of the stroke without a greater velocity, and therefore a greater force. Part of it, therefore, goes into the air vessel, and increases the compression. When the piston has ended its stroke, and no more water comes forward, the compression of the air in the air vessel being greater than what was sufficient to balance the pressure of the water in the main pipe, now forces out some of the water which is lying below it. This cannot return towards the pump, because the valve S is now shut. It therefore goes forward along the main, and produces an efflux during the time of the piston's rising in order to make another stroke. In order that this efflux may be very equable, the air vessel must be very large. If it be small, the quantity of water that is discharged by it during the return of the piston makes so great a portion of its capacity, that the elasticity of the confined air is too much diminished by this enlargement of its bulk, and the rate of efflux must diminish accordingly. The capacity of the air vessel should be so great that the change of bulk of the compressed air during the inaction of the piston may be inconsiderable. It must therefore be very strong.

It is pretty indifferent in what way this air vessel is connected with the rising-pipe. It may join it laterally, as in fig. 13. N° 1. and the main pipe go on without interruption; or it may be made to *surround* an interruption of the main pipe, as in fig. 13. N° 2. It may also be in any part of the main pipe. If the sole effect intended by it is to produce an equable jet, as in ornamental water-works, it may be near the end of the main. This will require much less strength, because there remains but a short column of water to compress the air in it. But it is, on the whole, more advantageous to place it as near the pump as possible, that it may produce an equable motion in the whole main pipe. This is of considerable advantage: when a column of water several hundred feet long is at rest in the main pipe, and the piston at one end of it put at once into motion, even with a moderate velocity, the strain on the pipe would be very great. Indeed if it were possible to put the piston instantaneously into motion with a finite velocity, the strain on the pipe, tending to burst it, would be next to infinite. But this seems impossible in nature; all changes of motion *which we observe* are gradual, because all impelling bodies have some elasticity or softness by which they yield to compression. And, in the way in which pistons are commonly moved, viz. by cranks or something analogous to them, the motion is *very sensibly* gradual. But still the air vessel tends to make the motion along the main pipe less desultory, and therefore diminishes those strains which would really take place

28 The desultory motion of the pistons.

5

place in the main-pipe. It acts like the springs of a travelling-carriage, whose jolts are incomparably less than those of a cart; and by this means really enables a given force to propel a greater quantity of water in the same time.

29 Corrected.

We may here by the way observe, that the attempts of mechanicians to correct this unequal motion of the piston-rod are misplaced, and if it could be done, would greatly hurt a pump. One of the best methods of producing this effect is to make the piston-rod consist of two parallel bars, having teeth in the sides which front each other. Let a toothed wheel be placed between them, having only the half of its circumference furnished with teeth. It is evident, without any farther description, that if this wheel be turned uniformly round its axis, the piston-rod will be moved uniformly up and down without intermission. This has often been put in practice; but the machine always went by jolts, and seldom lasted a few days. Unskilled mechanicians attributed this to defect in the execution: but the fault is essential, and lies in the principle.

30 But on a wrong principle.

The machine could not perform one stroke, if the first mover did not slacken a little, or the different parts of the machine did not yield by bending or by compression; and no strength of materials could withstand the violence of the strains at every reciprocation of the motion. This is chiefly experienced in great works which are put in motion by a water-wheel, or some other equal power exerted on the mass of matter of which the machine consists. The water-wheel being of great weight, moves with considerable steadiness or uniformity; and when an additional resistance is opposed to it by the beginning of a new stroke of the piston, its great quantity of motion is but little affected by this addition, and it proceeds very little retarded; and the machine must either yield a little by bending and compression, or go to pieces, which is the common event. Cranks are free from this inconvenience, because they accelerate the piston gradually, and bring it gradually to rest, while the water-wheel moves round with almost perfect uniformity. The only inconvenience (and it may be considerable) attending this slow motion of the piston at the beginning of its stroke is, that the valves do not shut with rapidity, so that some water gets back through them. But when they are properly formed and loaded, this is but trifling.

31 These equable pumps deliver very little more water than the others.

We must not imagine, that because the stream produced by the assistance of an air-barrel is almost perfectly equable, and because as much water runs out during the returning of the piston as during its active stroke, it therefore doubles the quantity of water. No more water can run out than what is sent forward by the piston during its effective stroke. The continued stream is produced only by preventing the whole of this water from being discharged during this time, and by providing a propelling force to act during the piston's return. Nor does it enable the moving force of the piston to produce a double effect: for the compression which is produced in the air-vessel, more than what is necessary for merely balancing the quiescent column of water, reacts on the piston, resisting its compression just as much as the column of water would do which produces a velocity equal to that of the efflux. Thus if the water is made to spout with the velocity of eight feet per second, this would require an additional column of one foot high, and this would just balance the compression in the air-vessel, which maintains this velocity during the non-action of the piston. It is, however, a matter of fact, that a pump furnished with an air-vessel delivers a little more water than it would do without it. But the difference depends on the combination of many very dissimilar circumstances, which it is extremely difficult to bring into calculation. Some of these will be mentioned afterwards.

To describe, or even to enumerate, the immense variety of combinations of these three simple pumps would fill a volume. We shall select a few, which are more deserving of notice.

I. The common sucking-pump may, by a small addition, be converted into a lifting pump, fitted for propelling the water to any distance, and with any velocity. 32 The sucking-pump converted into a lifting pump.

Fig. 14. is a sucking-pump, whose working-barrel ACDB has a lateral pipe AEGHF connected with it close to the top. This terminates in a *main* or rising pipe IK, furnished or not with a valve L. The top of the barrel is shut up by a strong plate MN, having a hollow neck terminating in a small flanch. The piston rod QR passes through this neck, and is nicely turned and polished. A number of rings of leather are put over the rod, and strongly compressed round it by another flanch and several screwed bolts, as is represented at OP. By this contrivance the rod is closely grasped by the leathers, but may be easily drawn up and down, while all passage of air or water is effectually prevented. Fig. 14.

The piston S is perforated, and furnished with a valve opening upwards. There is also a valve T on the top of the suction-pipe YX; and it will be of advantage, though not absolutely necessary, to put a valve L at the bottom of the rising pipe. Now suppose the piston at the bottom of the working-barrel. When it is drawn up, it tends to compress the air above it, because the valve in the piston remains shut by its own weight. The air therefore is driven through the valve L into the rising pipe, and escapes. In the mean time, the air which occupied the small space between the piston and the valve T expands into the upper part of the working-barrel; and its elasticity is so much diminished thereby, that the atmosphere presses the water of the cistern into the suction-pipe, where it will rise till an equilibrium is again produced. The next downward stroke of the piston allows the air, which had come from the suction-pipe into the barrel during the ascent of the piston, to get through its valve. Upon drawing up this piston, the air is also drawn off through the rising pipe. Repeating this process brings the water at last into the working-barrel, and it is then driven along the rising-pipe by the piston.

This is one of the best forms of a pump. The rarefaction may be very perfect, because the piston can be brought so near to the bottom of the working-barrel: and, for forcing water in opposition to great pressures, it appears preferable to the common forcing-pump; because in that the piston rods are compressed and exposed to bending, which greatly hurts the pump by wearing the piston and barrel on one side. This soon renders it less tight, and much water squirts out by the sides of the piston. But in this pump the piston rod is always drawn or pulled, which keeps it straight; 33 Advantages of this conversion.

and rods exert a much greater force in opposition to a pull than in opposition to compression. The collar of leather round the piston-rods is found by experience to need very little repairs, and is very impervious to water. The whole is very accessible for repairs; and in this respect much preferable to the common pump in deep mines, where every fault of the piston obliges us to draw up some hundred feet of piston-rods. By this addition, too, any common pump for the service of a house is converted into an engine for extinguishing fire, or may be made to convey the water to every part of the house; and this without hurting or obstructing its common uses. All that is necessary is to have a large cock on the upper part of the working barrel opposite to the lateral pipe in this figure. This cock serves for a spout when the pump is used for common purposes: and the merely shutting this cock converts the whole into an engine for extinguishing fire or for supplying distant places with water. It is scarcely necessary to add, that for these services it will be proper to connect an air-vessel with some convenient part of the rising pipe, in order that the current of the water may be continual.

34 Equable streams produced in great works by combinations.

We have frequently spoken of the advantages of a continued current in the main pipe. In all great works a considerable degree of uniformity is produced by the manner of disposing the actions of the different pumps; for it is very rarely that a machine works but one pump. In order to maintain some uniformity in the resistance, that it may not all be opposed at once to the moving power, with intervals of total inaction, which would produce a very hobbling motion, it is usual to distribute the work into portions, which succeed alternately; and thus both diminish the strain, and give greater uniformity of action, and frequently enable a natural power which we can command, to perform a piece of work, which would be impossible if the whole resistance were opposed at once. In all pump machines, therefore, we are obviously directed to construct them so that they may give motion to at least two pumps, which work alternately. By this means a much greater uniformity of current is produced in the main pipe. It will be rendered still more uniform if four are employed, succeeding each other at the interval of one quarter of the time of a complete stroke.

35 A single pump for this purpose described.

But ingenious men have attempted the same thing with a single pump, and many different constructions for this purpose have been proposed and executed. The thing is not of much importance, or of great research. We shall content ourselves therefore with the description of one that appears to us the most perfect, both in respect of simplicity and effect.

Fig. 15.

II. It consists of a working-barrel AB (fig. 15.) close at both ends. The piston C is solid, and the rod OP passes through a collar of leathers in the plate, which closes the upper end of the working-barrel. This barrel communicates laterally with two pipes H, K; the communications *m* and *n* being as near to the top and bottom of the barrel as possible. Adjoining to the passage *m* are two valves F and G opening upwards. Similar valves accompany the passage *n*. The two pipes H and K unite in a larger rising pipe L. They are all represented as in the same plane; but the upper ends must be bent backwards, to give room for the motion of the piston-rod OP.

Suppose the piston close to the entry of the lateral pipe *n*, and that it is drawn up: it compresses the air above it, and drives it through the valve G, where it escapes along the rising pipe; at the same time it rarefies the air in the space below it. Therefore the weight of the atmosphere shuts the valve E, and causes the water of the cistern to rise through the valve D, and fill the lower part of the pump. When the piston is pushed down again, this water is first driven through the valve E, because D immediately shuts; and then most of the air which was in this part of the pump at the beginning goes up through it, some of the water coming back in its stead. In the mean time, the air which remained in the upper part of the pump after the ascent of the piston is rarefied by its descent; because the valve G shuts as soon as the piston begins to descend, the valve F opens, the air in this suction pipe F *f* expands into the barrel, and the water rises into the pipes by the pressure of the atmosphere. The next rise of the piston must bring more water into the lower part of the barrel, and must drive a little more air through the valve G, namely, part of that which had come out of the suction-pipe F *f*; and the next descent of the piston must drive more water into the rising pipe H, and along with it most if not all of the air which remained below the piston, and must rarefy still more the air remaining above the piston; and more water will come in through the pipe F *f*, and get into the barrel. It is evident, that a few repetitions will at last fill the barrel on both sides of the piston with water. When this is accomplished, there is no difficulty in perceiving how, at every rise of the piston, the water of the cistern will come in by the valve D, and the water in the upper part of the barrel will be driven through the valve G; and, in every descent of the piston, the water of the cistern will come into the barrel by the valve F, and the water below the piston will be driven through the valve E: and thus there will be a continual influx into the barrel through the valves D and F, and a continual discharge along the rising pipe L through the valves E and G.

This machine is, to be sure, equivalent to two forcing pumps, although it has but one barrel and one piston; but it has no sort of superiority. It is not even more economical in most cases; because we apprehend that the additional workmanship will fully compensate for the barrel and piston that is saved. There is indeed a saving in the rest of the machinery, because one lever produces both motions. We cannot therefore say that it is inferior to two pumps; and we acknowledge that there is some ingenuity in the contrivance. 36 It is equivalent to two forcing-pumps.

We recommend to our readers the perusal of Belidor's *Architecture Hydraulique*, where is to be found a great variety of combinations and forms of the simple pumps; but we must caution them with respect to his theories, which in this article are extremely defective. Also in Leupold's *Theatrum Machinarum Hydraulicarum*, there is a prodigious variety of all kinds of pumps, many of them very singular and ingenious, and many which have particular advantages, which may suit local circumstances, and give them a preference. But it would be improper to swell a work of this kind with so many peculiarities; and a person who makes himself master of the principles delivered here in sufficient detail, can be at no loss to suit a pump to his particular 37 Authors recommended.

iews,

Pump. views, or to judge of the merit of such as may be proposed to him.

We must now take notice of some very considerable and important varieties in the form and contrivance of the essential parts of a pump.

38 The forcing pump differently constructed. Plate CCCCL. fig. 16.

III. The forcing pump is sometimes of a very different form from that already described. Instead of a piston, which applies itself to the inside of the barrel, and slides up and down in it, there is a long cylinder POQ (fig. 16.) nicely turned and polished on the outside, and of a diameter somewhat less than the inside of the barrel. This cylinder (called a PLUNGER) slides through a collar of leathers on the top of the working-barrel, and is constructed as follows. The top of the barrel terminates in a flanch *ab*, pierced with four holes for receiving screw-bolts. There are two rings of metal, *c d*, *e f*, of the same diameter, and having holes corresponding to those in the flanch. Four rings of soft leather, of the same size, and similarly pierced with holes, are well soaked in a mixture of oil, tallow, and a little rosin. Two of these leather rings are laid on the pump flanch, and one of the metal rings above them. The plunger is then thrust down through them, by which it turns their inner edges downwards. The other two rings are then slipped on at the top of the plunger, and the second metal ring is put over them, and then the whole are slid down to the metal ring. By this the inner edges of the last leather rings are turned upwards. The three metal rings are now forced together by the screwed bolts; and thus the leathern rings are strongly compressed between them, and made to grasp the plunger so closely that no pressure can force the water through between. The upper metal ring just allows the plunger to pass through it, but without any play: so that the turned-up edges of the leathern rings do not come up between the plunger and the upper metal ring, but are lodged in a little conical taper, which is given to the inner edge of the upper plate, its hole being wider below than above. It is on this trifling circumstance that the great tightness of the collar depends. To prevent the leathers from shrinking by drought, there is usually a little cistern formed round the head of the pump, and kept full of water. The plunger is either forced down by a rod from a working beam, or by a set of metal weights laid on it, as is represented in the figure.

39 Its mode of operation.

It is hardly necessary to be particular in explaining the operation of this pump. When the plunger is at the bottom of the barrel, touching the fixed valve M with its lower extremity, it almost completely fills it. That it may do it completely, there is sometimes a small pipe RSZ branching out from the top of the barrel, and fitted with a cock at S. Water is admitted till the barrel is completely filled, and the cock is then shut. Now when the plunger is drawn up, the valve N in the rising pipe must remain shut by the pressure of the atmosphere, and a void must be made in the barrel. Therefore the valve M on the top of the suction-pipe must be opened by the elasticity of the air in this pipe, and the air must expand into the barrel; and being no longer a balance for the atmosphere, the water in the cistern must be forced into the suction-pipe, and rise in it to a certain height. When the plunger descends, it must drive the water through the valve N (for the valve M will immediately shut), and along with it most of the air which had come into the barrel. And as this air occupied the upper part of the barrel, part of it will remain when the plunger has reached the bottom; but a stroke or two will expel it all, and then every succeeding stroke of the descending piston will drive the water along the rising pipe, and every ascent of the plunger will be followed by the water from the cistern.

The advantage proposed by this form of piston is that it may be more accurately made and polished than the inside of a working barrel, and it is of much easier repair. Yet we do not find that it is much used, although an invention of the 17th century (we think by Sir Samuel Morland), and much praised by the writers on these subjects.

40 Sucking-pump similarly varied.

It is easy to see that the sucking-pump may be varied in the same way. Suppose this plunger to be open both at top and bottom, but the bottom filled with a valve opening upward. When this is pushed to the bottom of the barrel, the air which it tends to compress lifts the valve (the lateral pipe FIK being taken away and the passage shut up), and escapes through the plunger. When it is drawn up, it makes the same rarefaction as the solid plunger, because the valve at O shuts, and the water will come up from the cistern as in the former case. If the plunger be now thrust down again, the valve M shuts, the valve O is forced open, and the plunger is filled with water. This will be lifted by it during its next ascent; and when it is pushed down again, the water which filled it must now be pushed out, and will flow over its sides into the cistern at the head of the barrel. Instead of making the valve at the bottom of the piston, it may be made at the top; but this disposition is much inferior, because it cannot rarefy the air in the barrel one half. This is evident; for the capacity of the barrel and plunger together cannot be twice the capacity of the barrel.

41 Another form of the sucking-pump, Fig. 17.

IV. It may be made after a still different form, as represented in fig. 17. Here the suction-pipe CO comes up through a cistern KMNL deeper or longer than the intended stroke of the piston, and has a valve C at top. The piston, or what acts in lieu of it, is a tube AHGB, open at both ends, and of a diameter somewhat larger than that of the suction-pipe. The interval between them is filled up at HG by a ring or belt of soft leather, which is fastened to the *outer* tube, and moves up and down with it, sliding along the smoothly polished surface of the suction-pipe with very little friction. There is a valve I on the top of this piston, opening upwards. Water is poured into the outer cistern.

42 and its mode of operation.

The outer cylinder or piston being drawn up from the bottom, there is a great rarefaction of the air which was between them, and the atmosphere presses the water up through the suction-pipe to a certain height; for the valve I keeps shut by the pressure of the atmosphere and its own weight. Pushing down the piston causes the air, which had expanded from the suction-pipe into the piston, to escape through the valve I; drawing it up a second time, allows the atmosphere to press more water into the suction-pipe, to fill it, and also part of the piston. When this is pushed down again, the water which had come through the valve C is now forced out through the valve I into the cistern KMNL, and now the whole is full of water. When, therefore, the piston is drawn up, the water follows, and fills it, if not

not 33 feet above the water in the cistern; and when it is pushed down again, the water which filled the piston is all thrown out into the cistern; and after this it delivers its full contents of water every stroke. The water in the cistern KMNL effectually prevents the entry of any air between the two pipes; so that a very moderate compression of the belt of soft leather at the mouth of the piston cylinder is sufficient to make all perfectly tight.

43
The piston cylinder differently formed.

It might be made differently. The ring of leather might be fastened round the top of the inner cylinder at DE, and slid on the inside of the piston cylinder; but the first form is most easily executed. Muschenbroeck has given a figure of this pump in his large system of natural philosophy, and speaks very highly of its performance. But we do not see any advantage which it possesses over the common sucking-pump. He indeed says that it is without friction, and makes no mention of the ring of leather between the two cylinders. Such a pump will raise water extremely well to a small height, and it seems to have been a model only which he had examined: But if the suction-pipe is long, it will by no means do without the leather; for on drawing up the piston, the water of the upper cistern will rise between the pipes, and fill the piston, and none will come up through the suction-pipe.

44
Pumps without friction not of important use.

We may take this opportunity of observing, that the many ingenious contrivances of pumps without friction are of little importance in great works; because the friction which is completely sufficient to prevent all escape of water in a well-constructed pump is but a very trifling part of the whole force. In the great pumps which are used in mines, and are worked by a steam-engine, it is very usual to make the pistons and valves without any leather whatever. The working barrel is bored truly cylindrical, and the piston is made of metal of a size that will just pass along it without sticking. When this is drawn up with the velocity competent to a properly loaded machine, the quantity of water which escapes round the piston is insignificant. The piston is made without leathers, not to aviod friction, which is also insignificant in such works; but to avoid the necessity of frequently drawing it up for repairs through such a length of pipes.

45
Example of a simple pump without friction.
Fig. 18.

V. If a pump absolutely without friction be wanted, the following seems preferable for simplicity and performance to any we have seen, when made use of in proper situations. Let NO (fig. 18.) be the surface of the water in the pit, and K the place of delivery. The pit must be as deep in water as from K to NO. ABCD is a wooden trunk, round or square, open at both ends, and having a valve P at the bottom. The top of this trunk must be on a level with K, and has a small cistern EADF. It also communicates laterally with a rising pipe GHK, furnished with a valve at H opening upwards. LM is a beam of timber so fitted to the trunk as to fill it without sticking, and is of at least equal length. It hangs by a chain from a working beam, and is loaded on the top with weights exceeding that of the column of water which it displaces. Now suppose this beam allowed to descend from the position in which it is drawn in the figure; the water must rise all around it, in the crevice which is between it and the trunk, and also in the rising pipe; because the valve P shuts, and H opens; so that when the plunger has got to the bottom, the water will stand at the level of K. When the plunger is again drawn up to the top by the action of the moving power, the water sinks again in the trunk, but not in the rising pipe, because it is stopped by the valve H. Then allowing the plunger to descend again, the water must again rise in the trunk to the level of K, and it must now flow out at K; and the quantity discharged will be equal to the part of the beam below the surface of the pit-water, deducting the quantity which fills the small space between the beam and the trunk. This quantity may be reduced almost to nothing; but if the inside of the trunk and the outside of the beam be made tapering, the beam may be let down till they exactly fit; and as this may be done in square work, a good workman can make it exceedingly accurate. But in this case, the lower half of the beam and trunk must not taper: and this part of the trunk must be of sufficient width round the beam to allow free passage into the rising pipe. Or, which is better, the rising pipe must branch off from the bottom of the trunk. A discharge may be made from the cistern EADF, so that as little water as possible may descend along the trunk when the piston is raised.

46
Its excellencies are considerable,

One great excellence of this pump is, that it is perfectly free from all the deficiencies which in common pumps result from want of being air-tight. Another is, that the quantity of water raised is precisely equal to the power expended; for any want of accuracy in the work, while it occasions a diminution of the quantity of water discharged, makes an equal diminution in the weight which is necessary for pushing down the plunger. We have seen a machine consisting of two such pumps suspended from the arms of a long beam, the upper side of which was formed into a walk with a rail on each side. A man stood on one end till it got to the bottom, and then walked soberly up to the other end, the inclination being about twenty-five degrees at first, but gradually diminished as he went along, and changed the load of the beam. By this means he made the other end go to the bottom, and so on alternately, with the easiest of all exertions, and what we are most fitted for by our structure. With this machine, a very feeble old man, weighing 110 pounds, raised 7 cubic feet of water $11\frac{1}{2}$ feet high in a minute, and continued working 8 or 10 hours every day. A stout young man, weighing nearly 135 pounds, raised $8\frac{1}{3}$ to the same height, and when he carried 30 pounds, conveniently slung about him, he raised $9\frac{1}{4}$ feet to this height, working 10 hours a-day without fatiguing himself. This exceeds Desagulier's maximum of a hogshead of water 10 feet high in a minute, in the proportion of 9 to 7 nearly. It is limited to very moderate heights; but in such situations it is very effectual. It was the contrivance of an untaught labouring man, possessed of uncommon mechanical genius. We shall have occasion to mention, with respect, some other contrivances of the same person, in the article *Water-Works*.

47
but it is limited.

48
Haskin's pump described.

VI. The most ingenious contrivance of a pump without friction is that of Mr Haskins, described by Desaguliers, and called by him the QUICKSILVER PUMP. Its construction and mode of operations are pretty complicated; but the following preliminary observations will, we hope, render it abundantly plain.

Let

Pump.

Fig. 19.

Let $i\,l\,m\,k$ (fig. 19.) be a cylindrical iron pipe, about six feet long, open at top. Let $e\,g\,h\,f$ be another cylinder, connected with it at the bottom, and of smaller diameter. It may either be solid, or, if hollow, it must be close at top. Let $a\,c\,d\,b$ be a third iron cylinder, of an intermediate diameter, so that it may move up and down between the other two without touching either, but with as little interval as possible. Let this middle cylinder communicate, by means of the pipe AB, with the upright pipe FE, having valves C and D (both opening upwards) adjoining to the pipe of communication. Suppose the outer cylinder suspended by chains from the end of a working beam, and let mercury be poured into the interval between the three cylinders till it fills the space to $o\,p$, about $\frac{1}{4}$ of their height. Also suppose that the lower end of the pipe FE is immersed into a cistern of water, and that the valve D is less than 33 feet above the surface of this water.

49
Its mode of operation.

Now suppose a perforation made somewhere in the pipe AB, and a communication made with an air-pump. When the air-pump is worked, the air contained in CE, in AB, and in the space between the inner and middle cylinders, is rarefied, and is abstracted by the air-pump; for the valve D immediately shuts. The pressure of the atmosphere will cause the water to rise in the pipe CE, and will cause the mercury to rise between the inner and middle cylinders, and sink between the outer and middle cylinders. Let us suppose mercury 12 times heavier than water: Then for every foot that the water rises in EC, the level between the outside and inside mercury will vary an inch; and if we suppose DE to be 30 feet, then if we can rarefy the air so as to raise the water to D, the outside mercury will be depressed to q, r, and the inside mercury will have risen to s, t, $s\,q$ and $t\,r$, being about 30 inches. In this state of things, the water will run over by the pipe BA, and every thing will remain nearly in this position. The columns of water and mercury balance each other, and balance the pressure of the atmosphere.

While things are in this state of equilibrium, if we allow the cylinders to descend a little, the water will rise in the pipe FE, which we may now consider as a suction-pipe; for by this motion the capacity of the whole is enlarged, and therefore the pressure of the atmosphere will still keep it full, and the situation of the mercury will again be such that all shall be in equilibrio. It will be a little lower in the inside space and higher in the outside.

Taking this view of things, we see clearly how the water is supported by the atmosphere at a very considerable height. The apparatus is analogous to a syphon which has one leg filled with water and the other with mercury. But it was not necessary to employ an air-pump to fill it. Suppose it again empty, and all the valves shut by their own weight. Let the cylinders descend a little. The capacity of the spaces below the valve D is enlarged, and therefore the included air is rarefied, and some of the air in the pipe CE must diffuse itself into the space quitted by the inner cylinder. Therefore the atmosphere will press some water up the pipe FE, and some mercury into the inner space between the cylinders. When the cylinders are raised again, the air which came from the pipe CE would return into it again, but is prevented by the valve C.— Raising the cylinders to their former height would compress this air; it therefore lifts the valve D, and escapes. Another depression of the cylinders will have a similar effect. The water will rise higher in FC, and the mercury in the inner space; and then, after repeated strokes, the water will pass the valve C, and fill the whole apparatus, as the air-pump had caused it to do before.— The position of the cylinders, when things are in this situation, is represented in fig. 20. the outer and inner cylinders in their lowest position having descended about 30 inches. The mercury in the outer space stands at q, r, a little above the middle of the cylinders, and the mercury in the inner space is near the top $t\,s$ of the inner cylinder. Now let the cylinders be drawn up. The water above the mercury cannot get back again through the valve C, which shuts by its own weight. We therefore attempt to compress it; but the mercury yields, and descends in the inner space, and rises in the outer, till both are quickly on a level, about the height $v\,v$. If we continue to raise the cylinders, the compression forces out more mercury, and it now stands lower in the inner than in the outer space. But that there may be something to balance this inequality of the mercurial columns, the water goes through the valve D, and the equilibrium is restored when the height of the water in the pipe ED above the surface of the internal mercury is 12 times the difference of the mercurial columns (on the former supposition of specific gravity). If the quantity of water is such as to rise two feet in the pipe ED, the mercury in the outer space will be two inches higher than that in the inner space. Another depression of the cylinders will again enlarge the space within the apparatus, the mercury will take the position of fig. 19. and more water will come in. Raising the cylinders will send this water four feet up the pipe ED, and the mercury will be four inches higher in the inner than in the outer space. Repeating this operation, the water will be raised still higher in DE; and this will go on till the mercury in the outer space reaches the top of the cylinder; and this is the limit of the performance. The dimensions with which we set out will enable the machine to raise the water about 30 feet in the pipe ED; which, added to the 30 feet of CF, makes the whole height above the pit-water 60 feet. By making the cylinders longer, we increase the height of FD. This machine must be worked with great attention, and but slowly; for at the beginning of the forcing stroke the mercury very rapidly sinks in the inner space and rises in the outer, and will dash out and be lost. To prevent this as much as possible, the outer cylinder terminates in a sort of cup or dish, and the inner cylinder should be tapered a-top.

Fig. 20.

50
Ingenuity of the contrivance great,

The machine is exceedingly ingenious and refined; and there is no doubt but that its performance will exceed that of any other pump which raises the water to the same height, because friction is completely avoided, and there can be no want of tightness of the piston.— But this is all its advantage; and from what has been observed, it is but trifling. The expence would be enormous; for with whatever care the cylinders are made, the interval between the inner and outer cylinders must contain a very great quantity of mercury. The middle cylinder must be made of iron plate, and must be without a seam, for the mercury would dissolve every solder. For such

51
but the advantage trifling.

Pump. such reasons, it has never come into general use. But it would have been unpardonable to have omitted the description of an invention which is so original and ingenious; and there are some occasions where it may be of great use, as in nice experiments for illustrating the theory of hydraulics, it would give the finest pistons for measuring the pressures of water in pipes, &c. It is on precisely the same principle that the cylinder bellows, described in the article PNEUMATICS, are constructed.

52 Description of another pump without friction. We beg leave to conclude this part of the subject with the description of a pump without friction, which may be constructed in a variety of ways by any common carpenter, without the assistance of the pump-maker or plumber, and will be very effective for raising a great quantity of water to small heights, as in draining marshes, marl-pits, quarries, &c. or even for the service of a house.

Fig. 21. VII. ABCD (fig. 21.) is a square trunk of carpenter's work, open at both ends, and having a little cistern and spout at top. Near the bottom there is a partition made of board, perforated with a hole E, and covered with a clack. *ffff* represents a long cylindrical bag or pudding, made of leather or of double canvas, with a fold of thin leather such as sheep skin between the canvas bags. This is firmly nailed to the board E with soft leather between. The upper end of this bag is fixed on a round board, having a hole and valve F. This board may be turned in the lathe with a groove round its edge, and the bag fastened to it by a cord bound tight round it. The fork of the piston-rod EG is firmly fixed into this board; the bag is kept distended by a number of wooden hoops or rings of strong wire *ff*, *ff*, *ff*, &c. put into it at a few inches distance from each other. It will be proper to connect these hoops before putting them in, by three or four cords from top to bottom, which will keep them at their proper distances. Thus will the bag have the form of a barber's bellows powder-puff. The distance between the hoops should be about twice the breadth of the rim of the wooden ring to which the upper valve and piston-rod are fixed.

53 Its mode of operation, &c. Now let this trunk be immersed in the water. It is evident that if the bag be stretched from the compressed form which its own weight will give it by drawing up the piston-rod, its capacity will be enlarged, the valve F will be shut by its own weight, the air in the bag will be rarefied, and the atmosphere will press the water into the bag. When the rod is thrust down again, this water will come out by the valve F, and fill part of the trunk. A repetition of the operation will have a similar effect; the trunk will be filled, and the water will at last be discharged by the spout.

Here is a pump without friction, and perfectly tight. For the leather between the folds of canvas renders the bag impervious both to air and water. And the canvas has very considerable strength. We know from experience that a bag of six inches diameter, made of sail-cloth N° 3. with a sheep skin between, will bear a column of 15 feet of water, and stand six hours work per day for a month without failure, and that the pump is considerably superior in effect to a common pump of the same dimensions. We must only observe, that the length of the bag must be three times the intended length of the stroke; so that when the piston-rod is in its highest position, the angles or ridges of the bag may be pretty acute. If the bag be more stretched than this, the force which must be exerted by the labourer becomes much greater than the weight of the column of water which he is raising. If the pump be laid aslope, which is very usual in these occasional and hasty drawings, it is necessary to make a guide for the piston-rod within the trunk, that the bag may play up and down without rubbing on the sides, which would quickly wear it out.

The experienced reader will see that this pump is very like that of Gosset and De la Deuille, described by Belidor, vol. ii. p. 120. and most writers on hydraulics. It would be still more like it, if the bag were on the under side of the partition E, and a valve placed farther down the trunk. But we think that our form is greatly preferable in point of strength. When in the other situation, the column of water lifted by the piston tends to *burst* the bag, and this with a great force, as the intelligent reader well knows. But in the form recommended here, the bag is *compressed*, and the strain on each part may be made much less than that which tends to burst a bag of six inches diameter. The nearer the rings are placed to each other, the smaller will the strain be.

The same bag-piston may be employed for a forcing pump, by placing it below the partition, and inverting the valve; and it will then be equally strong, because the resistance in this case too will act by compression.

We now come naturally to the consideration of the different forms which may be given to the pistons and valves of a pump. A good deal of what we have been describing already is reducible to this head; but, having a more general appearance, changing as it were the whole form and structure of the pump, it was not improper to keep these things together.

The great desideratum in a piston is, that it be as tight as possible, and have as little friction as is consistent with this indispensable quality. We have already said, that the common form, when carefully executed, has these properties in an eminent degree. And accordingly this form has kept its ground amidst all the improvement which ingenious artists have made. Mr Belidor, an author of the first reputation, has given the description of a piston which he highly extols, and is undoubtedly a very good one, constructed from principle, and extremely well composed. 54 Pistons should have little friction.

It consists of a hollow cylinder of metal *g h* (fig. 22.) pierced with a number of holes, and having at top a flanch AB, whose diameter is nearly equal to that of the working-barrel of the pump. This flanch has a groove round it. There is another flanch IK below, by which this hollow cylinder is fastened with bolts to the lower end of the piston, represented in fig. 23. This consists of a plate CD, with a grooved edge similar to AB, and an intermediate plate which forms the seat of the valve. The composition of this part is better understood by inspecting the figure than by any description. The piston-rod HL is fixed to the upper plate by bolts through its different branches at G, G. This metal body is then covered with a cylindrical bag of leather fastened on it by cords bound round it, filling up the grooves in the upper and lower plates. The operation of the piston is as follows. 55 An improved one by Belidor. Fig. 22. Fig. 23.

A little water is poured into the pump, which gets past

Pump.

past the sides of the piston, and lodges below in the fixed valve. The piston being pushed down dips into this water, and it gets into it by the valve. But as the piston in descending compresses the air below it, this compressed air also gets into the inside of the piston, swells out the bag which surrounds it, and compresses it to the sides of the working-barrel. When the piston is drawn up again, it must remain tight, because the valve will shut and keep in the air in its most compressed state; therefore the piston must perform well during the suction. It must act equally well when pushed down again, and acting as a forcer; for however great the resistance may be, it will affect the air within the piston to the same degree, and keep the leather close applied to the barrel. There can be no doubt therefore of the piston's performing both its offices completely; but we imagine that the adhesion to the barrel will be greater than is necessary: it will extend over the whole surface of the piston, and be equally great in every part of its surface; and we suspect that the friction will therefore be very great. We have very high authority for supposing that the adhesion of a piston of the common form, carefully made, will be such as will make it perfectly tight; and it is evident that the adhesion of Belidor's piston will be much greater, and it will be productive of worse consequences. If the leather bag be worn through in any one place, the air escapes, and the piston ceases to be compressed altogether; whereas in the common piston there will very little harm result from the leather being worn through in one place, especially if it project a good way beyond the base of the cone. We still think the common piston preferable. Belidor's piston would do much better inverted as the piston of a sucking pump; and in this situation it would be equal, but not superior to the common.

56 Its defects.

57 Another by the same author.

Belidor describes another forcing piston, which he had executed with success, and prefers to the common wooden forcer. It consists of a metal cylinder or cone, having a broad flanch uniting to it at one end, and a similar flanch which is screwed on the other end. Between these two plates are a number of rings of leather strongly compressed by the two flanches, and then turned in a lathe like a block of wood, till the whole fits tight, when dry, into the barrel. It will swell, says he, and soften with the water, and withstand the greatest pressures. We cannot help thinking this but an indifferent piston. When it wears, there is nothing to squeeze it to the barrel. It may indeed be taken out and another ring or two of leather put in, or the flanches may be more strongly screwed together; but all this may be done with any kind of piston; and this has therefore no peculiar merit.

58 Objections to it.

59 Another recommended as preferable. Fig 24.

The following will, we presume, appear vastly preferable. ABCD (fig. 24,) is the solid wooden or metal block of the piston; EF is a metal plate, which is turned hollow or dish-like below, so as to receive within it the solid block. The piston rod goes through the whole, and has a shoulder above the plate EF, and a nut H below. Four screw-bolts, such as *i k*, *l m*, also go through the whole, have their heads *k*, *m* sunk into the block, and nuts above at *i*, *l*. The packing or stuffing, as it is termed by the workmen, is represented at NO. This is made as solid as possible, and generally consists of soft hempen twine well soaked in a mixture of oil, tallow, and rosin. The plate EF is gently screwed down, and the whole is then put into the barrel, fitting it as tight as may be thought proper. When it wears loose, it may be tightened at any time by screwing down the nuts *i l*, which cause the edges of the dish to squeeze out the packing, and compress it against the barrel to any degree.

Pump.

60 Difficulties in constructing pistons.

The greatest difficulty in the construction of a piston is to give a sufficient passage through it for the water, and yet allow a firm support for the valve, and fixture for the piston rod. We shall see presently that it occasions a considerable expence of the moving power to force a piston with a narrow perforation through the water lodged in the working barrel. When we are raising water to a small height, such as 10 or 20 feet, the power so expended amounts to a fourth part of the whole, if the water-way in the piston is less than one-half of the section of the barrel, and the velocity of the piston two feet per second, which is very moderate. There can be no doubt, therefore, that metal pistons are preferable, because their greater strength allows much wider apertures.

61 considerably removed in one described by Belidor.

The following piston, described and recommended by Belidor, seems as perfect in these respects as the nature of things will allow. We shall therefore describe it in the author's own words as a model, which may be adopted with confidence in the greatest works.

Plate CCCCLI. Fig. 25. Fig. 26. Fig. 27. Fig. 28.

"The body of the piston is a truncated metal cone (fig. 25.), having a small fillet at the greater end. Fig. 26. shows the profile, and fig. 27. the plan of its upper base; where appears a cross bar DD, pierced with an oblong mortise E for receiving the tail of the piston-rod. A band of thick and uniform leather AA (fig. 26. and 28.) is put round this cone, and secured by a brass hoop BB firmly driven on its smaller end, where it is previously made thinner to give room for the hoop.

Fig. 9.

"This piston is covered with a leather valve fortified with metal plates GG (fig. 29.). These plates are wider than the hole of the piston, so as to rest on its rim. There are similar plates below the leather of a smaller size, that they may go into the hollow of the piston; and the leather is firmly held between the metal plates by screws H, H, which go through all. This is represented by the dotted circle IK. Thus the pressure of the incumbent column of water is supported by the plates GG, whose circular edges rest on the brim of the water-way, and their straight edges rest on the cross bar DD of fig. 26. and 27. This valve is laid on the top of the conical box in such a manner that its middle FF rests on the cross bar. To bind all together, the end of the piston-rod is formed like a cross, and the arms MN (fig. 30.) are made to rest on the diameter FF of the valve, the tail EP going through the hole E in the middle of the leather, and through the mortise E of the cross bar of the box; and also through another bar QR (fig. 28. and 29.) which is notched into the lower brim of the box. A key V is then driven into the hole T in the piston-rod; and this wedges all fast. The bar QR is made strong; and its extremities project a little, so as to support the brass hoop BB which binds the leather band to the piston-box. The adjoining scale gives the dimensions of all the parts, as they were executed for a steam-engine near Condé, where the piston gave complete satisfaction."

Fig. 30.

This piston has every advantage of strength, tightness, and

and large water-way. The form of the valve (which has given it the name of the *butterfly-valve*) is extremely favourable to the passage of the water; and as it has but half the motion of a complete circular valve, less water goes back while it is shutting.

62 Advantages of this piston.

The following piston is also ingenious, and has a good deal of merit. OPPO (fig. 31.) is the box of the piston, having a perforation Q, covered above with a flat valve K, which rests in a metal plate that forms the top of the box. ABCBA is a stirrup of iron to which the box is fixed by screws *a, a, a, a*, whose heads are sunk in the wood. This stirrup is perforated at C, to receive the end of the piston-rod, and a nut H is screwed on below to keep it fast. DEFED is another stirrup, whose lower part at DD forms a hoop like the sole of a stirrup, which embraces a small part of the top of the wooden box. The lower end of the piston-rod is screwed; and before it is put into the holes of the two stirrups (through which holes it slides freely) a broad nut G is screwed on it. It is then put into the holes, and the nut H firmly screwed up. The packing RR is then wound about the piston as tight as possible, till it completely fills the working barrel of the pump. When long use has rendered it in any degree loose, it may be tightened again by screwing down the nut G. This causes the ring DD to compress the packing between it and the projecting shoulder of the box at PP; and thus cause it to swell out, and apply itself closely to the barrel.

63 Another ingenious and useful piston described.

We shall add only another form of a perforated piston; which being on a principle different from all the preceding, will suggest many others; each of which will have its peculiar advantages. OO in fig. 32. represents the box of this piston, fitted to the working barrel in any of the preceding ways as may be thought best. AB is a cross bar of four arms, which is fixed to the top of the box. CF is the piston-rod going through a hole in the middle of AB, and reaching a little way beyond the bottom of the box. It has a shoulder D, which prevents its going too far through. On the lower end there is a thick metal plate, turned conical on its upper side, so as to fit a conical seat PP in the bottom of the piston-box.

64 Another on a different principle. Fig. 32.

When the piston-rod is pushed down, the friction on the barrel prevents the box from immediately yielding. The rod therefore slips through the hole of the cross bar AB. The plate E, therefore, detaches itself from the box. When the shoulder D presses on the bar AB, the box must yield, and be pushed down the barrels, and the water gets up through the perforation. When the piston-rod is drawn up again, the box does not move till the plate E lodge in the seat PP, and thus shuts the water-way; and then the piston lifts the water which is above it, and acts as the piston of a sucking pump.

65 Its advantages.

This is a very simple and effective construction, and makes a very tight valve. It has been much recommended by engineers of the first reputation, and is frequently used; and from its simplicity, and the great solidity of which it is capable, it seems very fit for great works. But it is evident that the water-way is limited to less than one-half of the area of the working-barrel. For if the perforation of the piston be one-half of the area, the diameter of the plate or ball EF must be greater; and therefore less than half the area will be left for the passage of the water by its sides.

66 Observations on valves.

We come now to consider the forms which may be given to the valves of a hydraulic engine.

The requisites of a valve are, that it shall be tight, of sufficient strength to resist the great pressures to which it is exposed, that it afford a sufficient passage for the water, and that it do not allow much to go back while it is shutting.

67 Clack valves.

We have not much to add to what has been said already on this subject. The valves which accompany the pump of fig. 5. are called *clack valves*, and are of all the most obvious and common; and the construction described on that occasion is as perfect as any. We only add, that as the leather is at last destroyed at the hinge by such incessant motion, and it is troublesome, especially in deep mines, and under water, to undo the joint of the pump in order to put in a new valve, it is frequently annexed to a box like that of a piston, made a little conical on the outside, so as to fit a conical seat made for it in the pipe, as represented in fig. 33. and it has an iron handle like that of a basket, by which it can be laid hold of by means of a long grappling-hook let down from above. Thus it is drawn up; and being very gentle tapered on the sides, it sticks very fast in its place. Fig. 33.

68 Defect in them.

The only defect of this valve is, that by opening very wide when pushed up by the stream of water, it allows a good deal to go back during its shutting again. In some great machines which are worked by a slow turning crank, the return of the piston is so very slow, that a sensible loss is incurred by this; but it is nothing like what Dr Desaguliers says, one-half of a cylinder whose height is equal to the diameter of the valve.— For in such machines, the last part of the upward stroke is equally slow, and the velocity of the water through the valve exceedingly small, so that the valve is at this time almost shut.

69 Utility of the butterfly-valve.

The butterfly-valve represented in figures 29, &c. is free from most of these inconveniences, and seems the most perfect of the clack valves. Some engineers make their great valves of a pyramidal form, consisting of four clacks, whose hinges are in the circumference of the water-way, and which meet with their points in the middle, and are supported by four ribs which rise up from the sides and unite in the middle. This is an excellent form, affording the most spacious water-way, and shutting very readily. It seems to be the best possible for a piston. The rod of the piston is branched out on four sides, and the branches go through the piston-box, and are fastened below with screws. These branches form the support for the four clacks. We have a seen a valve of this form in a pump of six feet diameter, which discharged 20 hogsheads of water every stroke, and made 12 strokes in a minute, raising the water above 22 feet.

70 Button valves. Fig. 34.

There is another form of valve, called the *button* or *tail-valve*. It consists of a plate of metal AB (fig. 34.) turned conical, so as exactly to fit the conical cavity *a b* of its box. A tail CD projects from the under side, which passes through a cross bar EF in the bottom of the box, and has a little knob at the end, to hinder the valve from rising too high.

This valve, when nicely made, is unexceptionable. It

It has great strength, and is therefore proper for all severe strains, and it may be made perfectly tight by grinding. Accordingly it is used in all cases where this is of indispensable consequence. It is most durable, and the only kind that will do for passages where steam or hot water is to go through. Its only imperfection is a small water-way; which, from what has been said, cannot exceed, or indeed equal, one half of the area of the pipe.

72 Though somewhat imperfect in the water-way.

If we endeavour to enlarge the water-way, by giving the cone very little taper, the valve frequently sticks so fast in the seat that no force can detach them.—And this sometimes happens during the working of the machine; and the jolts and blows given to the machine in taking it to pieces, in order to discover what has been the reason that it has discharged no water, frequently detach the valve, and we find it quite loose, and cannot tell what has deranged the pump. When this is guarded against, and the diminution of the water-way is not of very great consequence, this is the best form of a valve.

73 A very simple valve described. Fig. 35.

Analogous to this is the simplest of all valves, represented in fig. 35. It is nothing more than a sphere of metal A, to which is fitted a seat with a small portion BC of a spherical cavity. Nothing can be more effectual than this valve; it always falls into its proper place, and in every position fits it exactly. Its only imperfection is the great diminution of the water-way. If the diameter of the sphere does not considerably exceed that of the hole, the touching parts have very little taper, and it is very apt to stick fast. It opposes much less resistance to the passage of the water than the flat under-surface of the button-valve. *N. B.* It would be an improvement of that valve to give it a taper-shape below like a boy's top. The spherical valve must not be made too light, otherwise it will be hurried up by the water, and much may go back while it is returning to its place.

74 A valve by Belidor uniting every requisite.

Belidor describes with great minuteness (vol. ii. p. 221, &c.) a valve which unites every requisite. But it is of such nice and delicate construction, and its defects are so great when this exactness is not attained, or is impaired by use, that we think it hazardous to introduce it into a machine in a situation where an intelligent and accurate artist is not at hand. For this reason we have omitted the description, which cannot be given in few words, nor without many figures; and desire our curious readers to consult that author, or peruse Dr Desaguliers's translation of this passage. Its principle is precisely the same with the following rude contrivance, with which we shall conclude the descriptive part of this article.

75 Another valve on the same principle. Fig. 36.

Suppose ABCD (fig. 36.) to be a square wooden trunk. EF is a piece of oak board, exactly fitted to the trunk in an oblique position, and supported by an iron pin which goes through it at I, one-third of its length from its lower extremity at E. The two ends of this board are bevelled, so as to apply exactly to the sides of the trunk. It is evident, that if a stream of water come in the direction BA, its pressure on the part IF of this board will be greater than that upon EI. It will therefore force it up and rush through, making it stand almost parallel to the sides of the trunk. To prevent its rising so far, a pin must be put in its way. When this current of water changes its direction, the pressure on the upper side of the board being again greatest on the portion IF, it is forced back again to its former situation; and its two extremities rising on the opposite sides of the trunk, the passage is completely stopped. This board therefore performs the office of a valve; and this valve is the most perfect that can be, because it offers the freest passage to the water, and it allows very little to get back while it is shutting; for the part IE brings up half as much water as IF allows to go down. It may be made extremely tight, by fixing two thin fillets H and G to the sides of the trunk, and covering those parts of the board with leather which applies to them; and in this state it perfectly resembles Belidor's fine valve.

76 Description of an occasional pump easily constructed. Fig. 36.

And this construction of the valve suggests, by the way, a form of an occasional pump, which may be quickly set up by any common carpenter, and will be very effectual in small heights. Let *a b c d e* (fig. 36.) be a square box made to slide along this wooden trunk without shake, having two of its sides projecting upwards, terminating like the gable-ends of a house. A piece of wood *e* is mortised into these two sides, and to this the piston-rod is fixed. This box being furnished with a valve similar to the one below, will perform the office of a piston. If this pump be immersed so deep in the water that the piston shall also be under water, we scruple not to say that its performance will be equal to any. The piston may be made abundantly tight by covering its outside neatly with soft leather. And as no pipe can be bored with greater accuracy than a very ordinary workman can make a square trunk, we presume that this pump will not be very deficient even for a considerable suction.

77 The motion of water in pumps,

We now proceed to the last part of the subject, to consider the motion of water in pumps, in reference to the force which must be employed. What we have hitherto said with respect to the force which must be applied to a piston, related only to the sustaining the water at a certain height: but in actual service we must not only do this, but we must discharge it at the place of delivery in a certain quantity; and this must require a force superadded to what is necessary for its mere support at this height.

78 an intricate subject.

This is an extremely intricate and difficult subject, and very imperfectly understood even by professed engineers. The principles on which this knowledge must be founded are of a much more abstruse nature than the ordinary laws of hydrostatics; and all the genius of Newton was employed in laying the foundation of this part of physical science. It has been much cultivated in the course of this century by the first mathematicians of Europe. Daniel and John Bernoulli have written very elaborate treatises on the subject, under the very apposite name of HYDRODYNAMICS; in which, although they have added little or nothing to the fundamental propositions established in some sort by Newton, and acquiesced in by them, yet they have greatly contributed to our progress in it by the *methods* which they have pursued in making application of those fundamental propositions to the most important cases. It must be acknowledged, however, that both these propositions, and the extensions given them by these authors, are supported by a train of argument that is by no means unexceptionable; and that they proceed on assumptions or postulates which are but nearly true in any

79 The theory denominated *Hydrodynamics*,

any case, and in many are inadmissible: and it remains to this hour a wonder or puzzle how these propositions and their results correspond with the phenomena which we observe.

But fortunately this correspondence does obtain to a certain extent. And it seems to be this correspondence chiefly which has given these authors, with Newton at their head, the confidence which they place in their respective principles and methods: for there are considerable differences among them in those respects; and each seems convinced that the others are in a mistake. Messieurs d'Alembert and De la Grange have greatly corrected the theories of their predecessors, and have proceeded on postulates which come much nearer to the real state of the case. But their investigations involve us in such an inextricable maze of analytical investigation, that even when we are again conducted to the light of day by the clue which they have given us, we can make no use of what we there discovered.

80 though imperfect is very useful.

But this theory, imperfect as it is, is of great service. It generalizes our observations and experiments, and enables us to compose a *practical doctrine* from a heap of facts which otherwise must have remained solitary and unconnected, and as cumbersome in their application as the characters of the Chinese writing.

81 Fundamental proposition.

The fundamental proposition of this practical hydrodynamics is, that water or any fluid contained in an open vessel of indefinite magnitude, and impelled by its weight only, will flow through a small orifice with the velocity which a heavy body would acquire by falling from the horizontal surface of the fluid. Thus, if the orifice is 16 feet under the surface of the water, it will issue with the velocity of 32 feet in a second.

Its velocity corresponding to any other depth h of the orifice under the surface, will be had by this easy proportion: "As the square root of 16 is to the square root of h; so is 32 feet to the velocity required: or, alternately, $\sqrt{16} : 32 = \sqrt{h} : v$, and $v = \frac{32\sqrt{h}}{\sqrt{16}}, = \frac{32}{4}\sqrt{h}, = 8\sqrt{h}$: that is, multiply the square root of the height in feet by eight, and the product is the required velocity.

On the other hand, it frequently occurs, that we want to discover the depth under the surface which will produce a known velocity v. Therefore, $\sqrt{h} = \frac{v}{8}$, and $h = \frac{v^2}{64}$: that is, divide the square of the velocity by 64, and the quotient is the depth wanted in feet.

82 Its utility.

This proposition is sufficient for all our purposes. For since water is nearly a perfect fluid, and propagates all impressions undiminished, we can, in place of any pressure of a piston or other cause, substitute a perpendicular column of water whose weight is equal to this pressure, and will therefore produce the same efflux — Thus, if the surface of a piston is half a square foot, and it be pressed down with the weight of 500 pounds, and we would wish to know with what velocity it would cause the water to flow through a small hole, we know that a column of water of this weight, and of half a foot base, would be 16 feet high. And this proposition teaches us, that a vessel of this depth will have a velocity of efflux equal to 32 feet in a second.

If therefore our pressing power be of such a kind that it can continue to press forward the piston with the force of 500 pounds, the water will flow with this velocity, whatever be the size of the hole. All that remains is, to determine what change of *actual pressure* on the piston results from the motion of the piston itself, and to change the velocity of efflux in the subduplicate ratio of the change of actual pressure.

83 Remark previous to its application.

But before we can apply this knowledge to the circumstances which take place in the motion of water in pumps, we must take notice of an important modification of the fundamental proposition, which is but very obscurely pointed out by any good theory, but is established on the most regular and unexceptionable observation.

If the efflux is made through a hole in a thin plate, and the velocity is computed as above, we shall discover the quantity of water which issues in a second by observing, that it is a prism or cylinder of the length indicated by the velocity, and having its transverse section equal to that of the orifice. Thus, in the example already given, supposing the hole to be a square inch, the solid contents of this prism, or the quantity of water issuing in a second, is $1 \times 32 \times 12$ cubic inches, or 384 cubic inches. This we can easily measure by receiving it in a vessel of known dimensions. Taking this method, we uniformly find a deficiency of nearly 38 parts in 100; that is, if we should obtain 100 gallons in any number of seconds, we shall in fact get only 62. This is a most regular fact, whether the velocities are great or small, and whatever be the size and form of the orifice. The deficiency increases indeed in a very minute degree with the velocities. If, for instance, the depth of the orifice be one foot, the discharge is $\frac{6211}{10000}$; if it be 15 feet, the discharge is $\frac{6172}{10000}$.

This deficiency is not owing to a diminution of velocity; for the velocity may be easily and accurately measured by the distance to which the jet will go, if directed horizontally. This is found to correspond very nearly with the proposition, making a very small allowance for friction at the border of the hole, and for the resistance of the air. Sir Isaac Newton ascribed the deficiency with great justice to this, that the lateral columns of water, surrounding the column which is incumbent on the orifice, press towards the orifice, and contribute to the expence equally with that column. These lateral filaments, therefore, issue obliquely, crossing the motion of the central stream, and produce a contraction of the jet; and the whole stream does not acquire a parallel motion and its ultimate velocity till it has got to some distance from the orifice. Careful observation showed him that this was really the case. But even his genius could not enable him to ascertain the motion of the lateral filaments by theory, and he was obliged to measure every thing as he saw it. He found the diameter of the jet at the place of the greatest contraction to be precisely such as accounted for the deficiency. His explication has been unanimously acquiesced in; and experiments have been multiplied to ascertain all those circumstances which our theory cannot determine *à priori*. The most complete set of experiments are those of Michelotti, made at Turin at the expence of the prince of Piedmont.

Piedmont. Here jets were made of 1, 2, 3, and 4 inches diameter; and the water received into cisterns most accurately formed of brick, and lined with stucco. It is the result of these experiments which we have taken for a measure of the deficiency.

We may therefore consider the water as flowing through a hole of this contracted dimension, or substitute this for the real orifice in all calculations. For it is evident that if a mouth-piece (so to call it) were made, whose internal shape precisely tallied with the form which the jet assumes, and if this mouth-piece be applied to the orifice, the water will flow out without any obstruction. The vessel may therefore be considered as really having this mouth-piece.

Nay, from this we derive a very important observation, "that if, instead of allowing the water to flow through a hole of an inch area made in a thin plate, we make it flow through a hole in a thick plank, so formed that the external orifice shall have an inch area, but be widened internally, agreeably to the shape which nature forms, both the velocity and quantity will be that which the fundamental proposition determines. Michelotti measured with great care the form of the great jets of three and four inches diameter, and found that the bounding curve was an elongated trochoid. He then made a mouth-piece of this form for his jet of one inch, and another for his jet of two inches; and he found the discharges to be $\frac{979}{1000}$ and $\frac{987}{1000}$; and he, with justice, ascribed the trifling deficiency which still remained, partly to friction and partly to his not having exactly suited his mouth-piece to the natural form. We imagine that this last circumstance was the sole cause: For, in the first place, the water in his experiments, before getting at his jet-holes, had to pass along a tube of eight inches diameter. Now a jet of four inches bears too great a proportion to this pipe; and its narrowness undoubtedly hindered the lateral columns from contributing to the efflux in their due proportion, and therefore rendered the jet less convergent. And, in the next place, there can be no doubt (and the observations of Daniel Bernoulli confirm it) but that this convergency begins within the vessel, and perhaps at a very considerable distance from the orifice. And we imagine, that if accurate observations could be made on the motion of the remote lateral particles within the vessel, and an internal mouth-piece were shaped according to the curve which is described by the remotest particle that we can observe, the efflux of water would almost perfectly tally with the theory. But indeed the coincidence is already sufficiently near for giving us very valuable information. We learn that the quantity of water which flows through a hole, in consequence of its own weight, or by the action of any force, may be increased one half by properly shaping the passage to this hole; for we see that it may be increased from 62 to near 99.

But there is another modification of the efflux, which we confess our total incapacity to explain. If the water issues through a hole made in a plate whose thickness is about twice the diameter of the hole, or, to express it better, if it issues through a pipe whose length is about twice its diameter, the quantity discharged is nearly $\frac{82}{100}$ of what results from the proposition. If the pipe be longer than this, the quantity is diminished by friction, which increases as the length of the pipe increases. If the pipe be shorter, the water will not fill it, but detaches itself at the very entry of the pipe, and flows with a contracted jet. When the pipe is of this length, and the extremity is stopped with the finger, so that it begins to flow with a full mouth, no subsequent contraction is observed; but merely striking on the pipe with a key or the knuckle is generally sufficient to detach the water in an instant from the sides of the pipe, and reduce the efflux to $\frac{62}{100}$.

This effect is most unaccountable. It certainly arises from the mutual adhesion or attraction between the water and the sides of the pipe; but how this, acting at right angles to the motion, should produce an increase from 62 to 82, nearly $\frac{1}{3}$, we cannot explain. It shows, however, the prodigious force of this attraction, which in the space of two or three inches is able to communicate a great velocity to a very great body of water. Indeed the experiments on capillary tubes show that the mutual attraction of the parts of water is some thousands of times greater than their weight.

We have only further to add, that every increase of pipe beyond two diameters is accompanied with a diminution of the discharge; but in what ratio this is diminished it is very difficult to determine. We shall only observe at present that the diminution is very great. A pipe of 2 inches diameter and 30 feet long has its discharge only $\frac{54}{100}$ of what it would be if only 4 inches long. If its length be 60 feet, its discharge will be no more than $\frac{39}{100}$. A pipe of 1 inch diameter would have a discharge of $\frac{44}{100}$, and $\frac{31}{100}$, in the same situation. Hence we may conclude that the discharge of a 4 inch pipe of 30 feet long will not exceed $\frac{2}{3}$ of what it would be if only 8 inches long. This will suffice for our present purposes; and the determination of the velocities and discharges in long conduits from pump machines must be referred to the article *Water-Works*. At present we shall confine our attention to the pump itself, and to what will contribute to its improvement.

Before we can proceed to apply this fundamental proposition to our purpose, we must anticipate in a loose way a proposition of continual use in the construction of *water-works*.

Let water be supposed stagnant in a vessel EFGH (fig. 37.), and let it be allowed to flow out by a cylindrical pipe HIKL, divided by any number of partitions B, C, D, &c. Whatever be the areas B, C, D, of these orifices, the velocity in the intermediate parts of the pipe will be the same; for as much passes through any one orifice in a second as passes through any other in the same time, or through any section of the intervening pipe. Let this velocity in the pipe be V, and let the area of the pipe be A. The velocity in the orifices B, C, D, must be $\frac{VA}{B}$, $\frac{VA}{C}$, $\frac{VA}{D}$, &c. Let g be the velocity acquired in a second by a heavy body. Then, by the general proposition, the height of water in the vessel which will produce the velocity $\frac{VA}{B}$ in the first orifice alone, is $\frac{V^2 A^2}{2g B^2}$. After this passage the velocity is again reduced to V in the middle of the space between the first and second orifices. In the second orifice this velocity is changed to $\frac{VA}{C}$. This Fig. 37.

 alone

Pump.

alone would have required a height of water $\frac{V^2 A^2}{2g\,C^2}$. But the water is already moving with the velocity V, which would have resulted from a height of water in the vessel (which we shall, in the language of the art, call the HEAD OF WATER) equal to $\frac{V^2}{2g}$. Therefore there is only required a head of water $\frac{V^2 A^2}{2g\,C^2} - \frac{V^2}{2g}$, or $\frac{V^2}{2g} \times \overline{\frac{A^2}{C^2} - 1}$. Therefore the whole height necessary for producing the efflux through both orifices, so as still to preserve the velocity V in the intervening pipe, is $\frac{V^2}{2g} \times \overline{\frac{A^2}{B^2} + \frac{A^2}{C^2} - 1}$. In like manner the third orifice D would alone require a head of water $\frac{V^2}{2g} \times \overline{\frac{A^2}{D^2} - 1}$; and all the three would require a head $\frac{V^2}{2g} \times \overline{\frac{A^2}{B^2} + \frac{A^2}{C^2} + \frac{A^2}{D^2} - 2}$. By this induction may easily be seen what head is necessary for producing the efflux through any number of orifices.

Let the expence or quantity of water discharged in an unit of time (suppose a second) be expressed by the symbol Q. This is measured by the product of the velocity by the area of the orifice, and is therefore $= VA$, or $\frac{VA}{B} \times B$, or $\frac{VA}{C} \times C$, &c. and $V^2 = \frac{Q^2}{A^2}$. Therefore we may compute the head of water (which we shall express by H) in reference to the quantity of water discharged, because this is generally the interesting circumstance. In this view we have $H = \frac{Q^2}{2gA} \times \overline{\frac{A^2}{B^2} + \frac{A^2}{C^2} + \frac{A^2}{D^2} - 2}$: which shows that the head of water necessary for producing the discharge increases in the proportion of the square of the quantity of water which is discharged.

84 To determine the motion of water, &c.

These things being premised, it is an easy matter to determine the motion of water in a pump, and the quantity discharged, resulting from the action of any force on the piston, or the force which must be applied to the piston in order to produce any required motion or quantity discharged. We have only to suppose that the force employed is the pressure of a column of water of the diameter of the working barrel; and this is over and above the force which is necessary for merely supporting the water at the height of the place of delivery. The motion of the water will be the same in both cases.

85 In the sucking-pump,

Let us, first of all, consider a sucking-pump. The motion here depends on the pressure of the air, and will be the same as if the pump were lying horizontally, and communicated with a reservoir, in which is a head of water sufficient to overcome all the obstructions to the motion, and produce a velocity of efflux such as we desire. And here it must be noted that there is a limit. No velocity of the piston can make the water rise in the suction-pipe with a greater velocity than what would be produced by the pressure of a column of water 33 feet high; that is, about 46 feet per second.

Pump.

Let the velocity of the piston be V, and the area of the working barrel be A. Then, if the water fills the barrel as fast as the piston is drawn up, the discharge during the rise of the piston, or the number of cubic feet of water per second, must be $= V \times A$. This is always supposed, and we have already ascertained the circumstances which ensure this to happen. If, therefore, the water arrived with perfect freedom to the piston, the force necessary for giving it this velocity, or for discharging the quantity $V \times A$ in a second, would be equal to the weight of the pillar of water whose height is $\frac{V^2}{2g}$, and base A.

It does not appear at first sight that the force necessary for producing this discharge has any thing to do with the obstructions to the ascent of the water into the pump, because this is produced by the pressure of the atmosphere, and it is the action of this pressure which is measured by the head of water necessary for producing the internal motion in the pump. But we must always recollect that the piston, before bringing up any water, and supporting it at a certain height, was pressed on both sides by the atmosphere. While the air supports the column below the piston, all the pressure expended in this support is abstracted from its pressure on the under part of the piston, while its upper part still supports the whole pressure. The atmosphere continues to press on the under surface of the piston, through the intermedium of the water in the suction-pipe, with the difference of these two forces. Now, while the piston is drawn up with the velocity V, more of the atmospheric pressure must be expended in causing the water to follow the piston; and it is only with the remainder of its whole pressure that it continues to press on the under surface of the piston. Therefore, in order that the piston may be raised with the velocity V, a force must be applied to it, over and above the force necessary for merely supporting the column of water, equal to that part of the atmospheric pressure thus employed; that is, equal to the weight of the head of water necessary for forcing the water up through the suction-pipe, and producing the velocity V in the working barrel.

Therefore let B be the area of the mouth of the suction-pipe, and C the area of the fixed valve, and let the suction-pipe be of equal diameter with the working barrel. The head necessary for producing the velocity V on the working barrel is $\frac{V^2}{2g}\left(\frac{A^2}{B^2} + \frac{A^2}{C^2} - 1\right)$. If d express the density of water; that is, if d be the number of pounds in a cubic foot of water, then $d\,A\frac{V^2}{2g}$ will express the weight of a column whose base is A, and height $\frac{B^2}{2g}$, all being reckoned in feet. Therefore the force which must be applied, when estimated in pounds, will be $p, = \frac{d\,AV^2}{2g}\left(\frac{A^2}{B^2} + \frac{A^2}{C^2} - 1\right)$.

The first general observation to be made on what has been said is, that the power which must be employed to produce the necessary motion, in opposition to all the obstacles, is in the proportion of the square of the velocity.

city which we would produce, or the square of the quantity of water we would discharge.

We have hitherto proceeded on the supposition, that there is no contraction of the jet in passing through these two orifices. This we know would be very far from the truth. We must therefore accommodate things to these circumstances, by diminishing B and C in the ratio of the contraction, and calling the diminished areas b and c; then we have $p = \frac{AdV^2}{2g}\left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - 1\right)$.

What this diminution may be, depends on the form of the parts. If the fixed valve, and the entry into the pump, are simply holes in thin plates, then $b = \frac{62}{100}$ B and $c = \frac{62}{100}$ C. The entry is commonly widened or trumpet-shaped, which diminishes greatly the contraction: but there are other obstacles in the way, arising from the strainer usually put round it to keep out filth. The valve may have its contraction greatly diminished also by its box being made bell-shaped internally; nay, even giving it a cylindrical box, in the manner of fig. 33. is better than no box at all, as in fig. 5.; for such a cylindrical box will have the unaccountable effect of the short tube, and make $b = \frac{82}{100}$ B, instead of $\frac{62}{100}$ B. Thus we see that circumstances seemingly very trifling may produce great effects in the performance of a pump. We should have observed that the valve itself presents an obstacle which diminishes the motion, and requires an increase of power; and it would seem that in this respect the clack or butterfly valve is preferable to the button valve.

Example. Suppose the velocity of the piston to be 2 feet or 24 inches per second, and that the two contracted areas are each $\frac{1}{5}$ of the area of the pump, which is not much less than what obtains in ordinary pumps. We have $\frac{V^2}{2g}\left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - 1\right) = \frac{576}{768}(25 + 25 - 1)$ $= 36{,}75$ inches, and the force which we must add to what will merely support the column is the weight of a pillar of water incumbent on the piston, and something more than three feet high. This would be a sensible portion of the whole force in raising water to small heights.

We have supposed the suction-pipe to be of the same diameter with the working barrel; but it is usual to make it of smaller diameter, generally equal to the water way of the fixed valve. This makes a considerable change in the force necessary to be applied to the piston. Let a be the area of the suction-pipe, the area of the entry being still B; and the equivalent entry without contraction being still b, we have the velocity at the entrance $= \frac{AV}{b}$, and the producing head of water $= \frac{A^2V^2}{2g\,b^2}$. After this the velocity is changed to $\frac{AV}{a}$ in the suction-pipe, with which the water arrives at the valve, where it is again changed to $\frac{AV}{c}$, and requires for this change a head of water equal to $\frac{A^2V^2}{2g\,c^2}$. But the velocity retained in the suction pipe is equivalent to the effect of a head of water $\frac{A^2V^2}{2g\,a^2}$. Therefore the head necessary for producing such a current through the fixed valve, that the water may follow the piston with the velocity V, is $\frac{A^2V^2}{2g\,b^2} + \frac{A^2V^2}{2g\,c^2} - \frac{A^2V^2}{2g\,a^2}$, or $= \frac{V^2}{2g}\left(\frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{a^2}\right)$. This is evidently less than before, because a is less than A, and therefore $\frac{A^2}{a^2}$ is greater than unity, which was the last term of the former formula. There is some advantage, therefore, derived from making the diameter of the suction-pipe less than that of the working barrel: but this is only because the passage of the fixed valve is smaller, and the inspection of the formula plainly points out that the area of the suction-pipe should be equal to that of the fixed valve. When it is larger, the water must be accelerated in its passage through the valve; which is an useless expence of force, because this velocity is to be immediately reduced to V in the working barrel. If the foregoing example be computed with a equal to $\frac{1}{4}$ of A, we shall find the head H equal to 29 inches instead of 37.

But this advantage of a smaller suction-pipe is in all cases very moderate; and the pump is always inferior to one of uniform dimensions throughout, having the orifice at the fixed valve of the same area. And if these orifices are considerably diminished in any proportion, the head necessary for overcoming the obstacles, so that the required velocity V may still be produced in the working barrel, is greatly increased. If we suppose the area a $\frac{1}{9}$ of A, which is frequently done in house pumps, where the diameter of the suction-pipe does seldom exceed $\frac{1}{3}$ of that of the working-barrel; and suppose every thing made in proportion to this, which is also usual, because the unskilled pump-makers study a symmetry which satisfies the eye; we shall find that the pump taken as an example will require a head of water = 13 feet and upwards. Besides, it must be observed that the friction of the suction-pipe itself has not been taken into the account. This alone is greater, in most cases, than all the obstructions we have been speaking of; for if this pipe is three inches diameter, and that of the working-barrel is six, which is reckoned a liberal allowance for a suction-pipe, and if the fixed valve is 25 feet above the surface of the water-pit; the friction of this pipe will amount to one-third of the whole propelling force.

Thus we have enabled the reader to ascertain the force necessary for producing any required discharge of water from a pump of known dimensions: and the converse of this determination gives us the discharge which will be produced by any given force. For making $\frac{A^2}{b^2} + \frac{A^2}{c^2} - \frac{A^2}{a^2}$ (which is a known quantity, resulting from the dimensions of the pump) = M, we have $H = \frac{V^2}{2g}M$, and $V^2 = \frac{2gH}{M}$, and $V = \sqrt{\frac{2gH}{M}}$. Now H is that part of the natural power which we have at command which exceeds what is necessary for merely supporting the column of water. Thus, if we have a pump whose piston has an area of $\frac{1}{4}$ of a square foot, its diameter being $6\frac{3}{4}$ inches; and we have to raise the water 32 feet, and can apply a power of 525 pounds to the piston; we wish to know at what rate the piston will be moved, and the quantity of water discharged?

Merely

Pump.

Merely to support the column of water of this height and diameter, requires 500 pounds. Therefore the remaining power, which is to produce the motion, is 25 pounds. This is the weight of a column 1 foot 4 inches high, and H $=1,333$ feet. Let us suppose the diameter of the suction-pipe $\frac{1}{2}$ of that of the working-barrel, so that $\frac{A}{B}=4$. We may suppose it executed in the best manner, having its lower extremity trumpet-shaped, formed by the revolution of the proper trocheid. The contraction at the entry may therefore be considered as nothing, and $\frac{A}{b}=4$, and $\frac{A^2}{b^2}=16$. We may also suppose the orifice of the fixed valve equal to the area of the suction-pipe, so that $\frac{A^2}{C^2}$ is also $=16$, and there is no contraction here; and therefore $\frac{A^2}{c^2}$ is also 16. And lastly, $\frac{A^2}{a^2}$ is also 16. Therefore $\frac{A^2}{b^2}+\frac{A^2}{c^2}-\frac{A^2}{a^2}$ or M, $=16+16-16,=16$. We have also $2g=64$. Now $N=\sqrt{\frac{2g\,H}{M}}$. $=\sqrt{\frac{64\times 1,333}{16}}$, $=2,309$ feet, and the piston will move with the velocity of 2 feet 4 inches nearly. Its velocity will be less than this, on account both of the friction of the piston and the friction of the water in the suction-pipe. These two circumstances will probably reduce it to one foot eight inches; and it can hardly be less than this.

We have taken no notice of the friction of the water in the working-barrel, or in the space above the piston; because it is in all cases quite insignificant. The longest pipes employed in our deep mines do not require more than a few inches of head to overcome it.

But there is another circumstance which must not be omitted. This is the resistance given to the piston in its descent. The pistons of an engine for drawing water from deep mines must descend again by their own weight in order to repeat their stroke. This must require a preponderance on that end of the working-beam to which they are attached, and this must be overcome by the moving power during the effective stroke. It makes, therefore, part of the whole work to be done, and must be added to the weight of the column of water which must be raised.

This is very easily ascertained. Let the velocity of the piston in its descent be V, the area of the pump-barrel A, and the area of the piston-valve a. It is evident, that while the piston descends with the velocity V, the water which is displaced by the piston in a second is $(A-a)\,V$. This must pass through the hole of the piston, in order to occupy the space above, which is left by the piston. If there were no contraction, the water would go through with the velocity $\frac{A-a}{a}V$; but as there will always be some contraction, let the diminished area of the hole (to be discovered by experiment) be b, the velocity therefore will be $V\frac{A-a}{b}$. This requires for its production a head of water $\frac{V^2}{2g}\left(\frac{A-a}{b}\right)^2$.

Pump.

This is the height of a column of water whose base is not A but $A-a$. Calling the density of water d, we have for the weight of this column, and the force p in $d\times\overline{A-a}+\left(\frac{A-a}{b}\right)\times\frac{V^2}{2g},=\frac{dV^2(A-a)^3}{2g\,b^2}$. This, we see again, is proportional to the square of the velocity of the piston in its descent, and has no relation to the height to which the water is raised.

If the piston has a button valve, its surface is at least equal to a; and therefore the pressure is exerted on the water by the whole surface of the piston. In this case we shall have $p=\frac{d\,V^2\,A^3}{2g\,b^2}$ considerably greater than before. We cannot ascertain this value with great precision, because it is extremely difficult, if possible, to determine the resistance in so complicated a case. But the formula is exact, if b can be given exactly; and we know within very moderate limits what it may amount to. In a pump of the very best construction, with a button valve, b cannot exceed one-half of A; and therefore $\frac{A^2}{b^2}$ cannot be less than 8. In this case, $\frac{V^2\,A^3}{2g\,b^2}$ will be $\frac{V^2}{8}$. In a good steam-engine pump V is about three feet per second, and $\frac{V^2}{8}$ is about $1\frac{1}{8}$ feet, which is but a small matter.

85 and in the forcing-pump.

We have hitherto been considering the sucking-pump alone: but the forcing pump is of more importance, and apparently more difficult of investigation.—Here we have to overcome the obstructions in long pipes, with many bends, contractions, and other obstructions. But the consideration of what relates merely to the pump is abundantly simple. In most cases we have only to force the water into an air-vessel, in opposition to the elasticity of the air compressed in it, and to send it thither with a certain velocity, regulated by the quantity of water discharged in a given time. The elasticity of the air in the air-vessel propels it along the *Main*. We are not now speaking of the force necessary for counterbalancing this pressure of the air in the air-vessel, *which is equivalent to all the subsequent obstructions*, but only of the force necessary for propelling the water out of the pump with the proper velocity.

We have in a manner determined this already. The piston is solid, and the water which it forces has to pass through a valve in the lateral pipe, and then to move in the direction of the main. The change of direction requires an addition of force to what is necessary for merely impelling the water through the valve. Its quantity is not easily determined by any theory, and it varies according to the abruptness of the turn. It appears from experiment, that when a pipe is bent to a right angle, without any curvature or rounding, the velocity is diminished about $\frac{1}{18}$. This would augment the head of water about $\frac{1}{9}$. This may be added to the contraction of the valve hole. Let c be its natural area, and whatever is the contraction competent to its form, increase it $\frac{1}{18}$, and call the contracted area c. Then this will a require a head of water $=\frac{V^2\,A^2}{2g\,c^2}$.

This

Pump. This must be added to the head $\frac{V^2}{2g}$, necessary for merely giving the velocity V to the water. Therefore the whole is $\frac{V^2}{2g}\left(\frac{A^2}{c^2}+1\right)$; and the power p necessary for this purpose is $\frac{d\,AV^2}{2g}\left(\frac{A^2}{c^2}+1\right)$.

It cannot escape the observation of the reader, that in all these formulæ, expressing the height of the column of water which would produce the velocity V in the working barrel of the pump, the quantity which multiplies the constant factor $\frac{d\,AV^2}{2g}$ depends on the contracted passages which are in different parts of the pump, and increases in the duplicate proportion of the sum of those contractions. It is therefore of the utmost consequence to avoid all such, and to make the main which leads from the forcing-pump equal to the working barrel. If it be only of half the diameter, it has but one-fourth of the area, the velocity in the main is four times greater than that of the piston, and the force necessary for discharging the same quantity of water is 16 times greater.

It is not, however, possible to avoid these contractions altogether, without making the main pipe wider than the barrel. For if only so wide, with an entry of the same size, the valve makes a considerable obstruction. Unskilful engineers endeavour to obviate this by making an enlargement in that part of the main which contains the valve. This is seen in fig. 14. at the valve L. If this be not done with great judgment, it will increase the obstructions. For if this enlargement is full of water, the water must move in the direction of its axis with a diminished velocity; and when it comes into the main, it must again be accelerated. In short, any abrupt enlargement which is to be afterwards contracted, does as much harm as a contraction, unless it be so short that the water in the axis keeps its velocity till it reaches the contraction. Nothing would do more service to an artist, who is not well founded in the theory of hydrodynamics, than to make a few simple and cheap experiments with a vessel like that of fig. 37. Let the horizontal pipe be about three inches diameter, and made in joints which can be added to each other. Let the joints be about six inches long, and the holes from one-fourth to a whole inch in diameter. Fill the vessel with water, and observe the time of its sinking three or four inches. Each joint should have a small hole in its upper side to let out the air; and when the water runs out by it, let it be stopped by a peg. He will see that the larger the pipe is in proportion to the orifices made in the partitions, the efflux is *more diminished*. We believe that no person would suspect this who has not considered the subject minutely.

87 Use of experiments.

All angular enlargements, all boxes, into which the pipes from different working barrels, unite their water before it goes into a main, must therefore be avoided by an artist who would execute a good machine; and the different contractions which are unavoidable at the seats of valves and the perforations of pistons, &c. should be diminished by giving the parts a trumpet-shape.

In the air-vessels represented in fig. 13. this is of very great consequence. The throat O, through which the water is forced by the expansion of the confined air, should always be formed in this manner. For it is this which produces the motion during the returning part of the stroke in the pump constructed like fig. 13. N° 1. and during the whole stroke in N° 2. Neglecting this seemingly trifling circumstance will diminish the performance at least one-fifth. The construction of N° 1. is the best, for it is hardly possible to make the passage of the other so free from the effects of contraction. The motion of the water during the returning stroke is very much contorted.

88 Acceleration of the motion of water in pumps.

There is one circumstance that we have not taken any notice of, viz. the gradual acceleration of the motion of water in pumps. When a force is applied to the piston, it does not in an instant communicate all the velocity which it acquires. It acts as gravity acts on heavy bodies; and if the resistances remained the same, it would produce, like gravity, an uniformly accelerated motion. But we have seen that the resistances (which are always measured by the force which just overcomes them) increase as the square of the velocity increases. They therefore quickly balance the action of the moving power, and the motion becomes uniform, in a time so short that we commit no error of any consequence by supposing it uniform from the beginning. It would have prodigiously embarrassed our investigations to have introduced this circumstance; and it is a matter of mere speculative curiosity: for most of our moving powers are unequal in their exertions, and these exertions are regulated by other laws. The pressure on a piston moved by a crank is as variable as its velocity, and in most cases is nearly in the inverse proportion of its velocity, as any mechanician will readily discover. The only case in which we could consider this matter with any degree of comprehensibility is that of a steam-engine, or of a piston which forces by means of a weight lying on it. In both, the velocity becomes uniform in a very small fraction of a second.

89 Deficiency of elementary books on this subject.

We have been very minute on this subject. For although it is the only view of a pump which is of any importance, it is hardly ever understood even by professed engineers. And this is not peculiar to hydraulics, but is seen in all the branches of practical mechanics. The elementary knowledge to be met with in such books as are generally perused by them, goes no farther than to state the forces which are in equilibrio by the intervention of a machine, or the proportion of the parts of a machine which will set two known forces in equilibrio. But when this equilibrium is destroyed by the superiority of one of the forces, the machine must move; and the only interesting question is, *what will be the motion?* Till this is answered with some precision, we have learned nothing of any importance. Few engineers are able to answer this question even in the simplest cases; and they cannot, from any confident science, say what will be the performance of an untried machine. They guess at it with a success proportioned to the multiplicity of their experience and their own sagacity. Yet this part of mechanics is as susceptible of accurate computation as the cases of equilibrium.—We therefore thought it our duty to point out the manner of proceeding so circumstantially, that every step should be plain and easy, and that conviction should always accompany our progress. This we think it has been in our power to do, by the very simple method of substituting a column

lumn of water acting by its weight in lieu of any natural power which we may chance to employ.

To such as wish to prosecute the study of this important part of hydraulics in its most abstruse parts, we recommend the perusal of the dissertations of Mr Pitot and Mr Bossut, in the memoirs of the Academy of Paris; also the dissertations of the Chevalier de la Borda, 1766 and 1767; also the *Hydraulique* of the Chevalier De Buat. We shall have occasion to consider the motion of the water in the mains of forcing or lifting pumps which send the water to a distance, in the article *WATER-Works;* where the reader will see how small is the performance of all hydraulic machines, in comparison of what the usual theories, founded on equilibrium only, would make him expect.

PUN, or PUNN, an expression where a word has at once different meanings. The practice of punning is the miserable refuge of those who wish to pass for wits, without having a grain of wit in their composition. James the I. of England delighted in punning; and the taste of the sovereign was studied by the courtiers, and even by the clergy. Hence the sermons of that age abound with this species of false wit. It continued to be more or less fashionable till the reign of Queen Anne, when Addison, Swift, Pope, and Arbuthnot, with the other real wits of that classical age, united their efforts to banish punning from polite composition. It is still admitted sparingly in conversation; and no one will deny that a happy pun, when it comes unsought, contributes to excite mirth in a company. A professed *punster*, however, who is always pouring forth his senseless quibbles, as Sancho Pança poured forth his proverbs, is such an intolerable nuisance in society, that we do not wonder at Pope or Swift having written a pamphlet with the title of *God's Revenge against Punning*.

PUNCH, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and take away the piece. The punch is a principal instrument of the metal-button makers, shoemakers, &c.

PUNCH is also a name for a sort of compound drink, much used here, and in many parts abroad, particularly in Jamaica, and several other parts of the West Indies.

Its basis is spring-water; which being rendered cooler, brisker, and more acid, with lemon or lime juice, and sweetened again to the palate with fine sugar, makes what they call *sherbet;* to which a proper quantity of spirituous liquor, as brandy, rum, or arrack, being added, the liquor becomes punch.

PUNCHEON, PUNCHIN, or *Punchion*, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraven either in creux or relievo, impressions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraved. There are various kinds of these puncheons used in the mechanical arts; such, for instance, are those of the goldsmiths, cutlers, pewterers, &c.

The puncheon, in coining, is a piece of iron steeled, whereon the engraver has cut in relievo the several figures, arms, effigy, inscription, &c. that there are to be in the matrices, wherewith the species are to be marked. Minters distinguish three kinds of puncheons, according to the three kinds of matrices to be made; that of the effigy, that of the cross or arms, and that of the legend or inscription. The first includes the whole portrait in relievo; the second are small, such only containing a piece of the cross or arms; for instance, a fleur-de-lis, an harp, a coronet, &c. by the assemblage of all which the entire matrice is formed. The puncheons of the legend only contain each one letter, and serve equally for the legend on the effigy side and the cross side, See the article COINAGE.

For the puncheons used in stamping the matrices wherein the types of printing characters are cast, see *LETTER-Foundery.*

PUNCHEON is also used for several iron tools, of various sizes and figures, used by the engravers en creux on metals. Seal-engravers particularly use a great number for the several pieces of arms, &c. to be engraven, and many stamp the whole seal from a single puncheon.

PUNCHEON is also a common name for all those iron instruments used by stone-cutters, sculptors, blacksmiths, &c. for the cutting, inciding, or piercing their several matters.

Those of sculptors and statuaries serve for the repairing of statues when taken out of the moulds. The locksmiths use the greatest variety of puncheons; some for piercing hot, others for piercing cold; some flat, some square, some round, others oval, each to pierce holes of its respective figure in the several parts of locks.

PUNCHEON, in *Carpentry*, is a piece of timber placed upright between two posts, whose bearing is too great; serving, together with them, to sustain some large weights.

This term is also used for a piece of timber raised upright, under the ridge of a building, wherein the legs of a couple, &c. are jointed.

PUNCHEON, is also the name of a measure for liquids. Rum is brought from the colonies in puncheons, which are large casks containing about 130 gallons.

PUNCTUATION, in *Grammar*, the art of pointing, or of dividing a discourse into periods, by points expressing the pauses to be made therein.

The points used are four, viz. the period, colon, semicolon, and comma. See the particular use of each under its proper article, COMMA, COLON, PERIOD, and SEMICOLON.

In general, we shall only here observe, that the comma is to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together. The semi-colon serves to suspend and sustain the period when too long: the colon, to add some new supernumerary reason, or consequence, to what is already said: and the period to close up the sense and construction, and release the voice.

It has been asserted, that punctuation is a modern art, and that the ancients were entirely unacquainted with the use of our commas, colons, &c. and wrote not only without any distinction of numbers and periods, but also without distinction of words: which custom, Lipsius observes, continued till the hundred and fourth Olympiad;

lympiad; during which time the sense alone divided the discourse.

What within our own knowledge at this day puts this beyond dispute, is the Alexandrian manuscript, which is at present in the king's library, at the British Musæum. Whoever examines this, will find that the whole is written *continuo ductu*, without distinction of words or sentences. How the ancients read their works written in this manner, it is not easy to conceive.

After the practice of joining words together ceased, notes of distinction were placed at the end of every word. In all the editions of the *Fasti Capitolini* these points occur. The same are to be seen on the *Columna Rostrata*. For want of these, we find much confusion in the *Chronicon Marmoreum*, and the covenant between the Smyrnæans and Magnesians, which are both now at Oxford. In Salmasius's edition of *Dedicatio statuæ rigillæ Herodis*, the like confusion occurs, where we find ΔΕΥΡΊΤΕ and Δευς ιτι.

Of these marks of distinction, the Walcote inscription found near Bath may serve as a specimen;

IVLIUSv VITALISv FABRI
CESISv LEGv XXVv Vv V
STIPENDIORUMv &c.

After every word here, except at the end of a line, we see this mark v. There is an inscription in Montfaucon, which has a capital letter laid in an horizontal position, by way of interstitial mark, which makes one apt to think that this way of pointing was sometimes according to the fancy of the graver.

P. FERRARIVS HERMES
CAECINIAE ⊢ DIGNAE
CONIVGI ⊣ KARISSIMAE
NVMERIAE ⊢ &c.

He we observe after the words a T laid horizontally, but not after each word, which proves this to be of a much later age than the former.

As the improvement of stops appears not to have taken place while manuscripts and monumental inscriptions were the only known methods to convey knowledge, it is conjectured that it was introduced with the art of printing. The 14th century, to which we are supposed to be indebted for this invention, did not, however, bestow those appendages we call *stops:* whoever will be at the pains of examining the first printed books, will discover no stops of any kind; but arbitrary marks here and there, according to the humour of the printer. In the 16th century, we observe their first appearance. We find, from the books of this age, that they were not all produced at the same time; those we meet with there in use, being only the comma, the parenthesis, the interrogation, and the full point. To prove this, we need but look into Bale's Acts of English Worthies, black letter, printed 1550. Indeed, in the dedication of this book, which is to Edward VI. we discover a colon: but, as this is the only one of the kind throughout the work, it is plain this stop was not established at this time, and so warily put in by the printer; or if it was, that it was not in common use. Thirty years after this time, in that sensible and judicious performance of Sir Thomas Elyot, entitled *The Governour*, imprinted 1580, we see the colon as frequently introduced as any other stop; but the semicolon and the admiration were still wanting, neither of these being visible in this book. In Hackluyt's Voyages, printed 1599, we see the semicolon: and, as if the editors did not fully apprehend the propriety of its general admission, it is but sparingly introduced. It has been said, indeed, that the semicolon was brought into use at a much earlier period; but it appears that it was only for the purpose of an abbreviation, as in (*namq;*) (*neq;*) for *namque*, *neque*, and not in the sense in which it is now employed, *Month. Mag.* v. 411.

The semicolon, indeed, as well as all the ordinary points, is used in a work entitled "Imagines Deorum," printed at Leyden, in the year 1581, in Roman characters. We likewise meet with them in the translation of a justly celebrated book, written in French by that wise and good man, Philip Mornay, lord of Plessis; in the "Schoolmaster" of Roger Ascham, printed in 1570, with the exception of the semicolon; and in the "Trewnesse of the Christian Religion," by Sir Philip Sidney, published in 1587, in which we find the asterisk, brackets, the interrogation, the comma and the semicolon, all as we now use them; and the colon and period are square dots.

In an alchemical manuscript of the date of 1572, the semicolon is said to be met with, as well as the other three points which are in common use. The colon and period are abundant in a work entitled "Dionisius de Situ Orbis," printed at Venice in 1498, but none of the other stops or points. The single point (.) appears to be the most ancient. Since the year 1485 the colon was introduced; the comma is first seen about the year 1521; and the more refined semicolon was brought into use about the year 1570.

The invention of the semicolon is most probably due to the English; for from the Leyden edition of Pliny, 1553, it is evident that the Dutch printers were not then in the practice of using it; and if in 1570, they were, Roger Ascham would probably have employed it; for the Dutch were the principal classical printers in his time; but we find that some English books were marked with it at that period.

The admiration was the last stop that was invented, and seems to have been added to the rest in a period not so far distant from our own time.

Thus we see that these notes of distinction came into use as learning was gradually advanced and improved; one invention indeed, but enlarged by several additions.

But notwithstanding what has been said relative to the use of stops as being a modern invention, we shall find reason to be satisfied that the ancients were not unacquainted with the method of making pauses in speaking and writing, if we attend to the following elaborate investigation of Mr Warburton, which we shall lay before our readers in the words of the author.

"Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols.

"Suidas* says, that the *period* and the *colon* were discovered and explained by Thrasymachus, about 380 years before the Christian æra. Cicero† says, that Thrasymachus was the first who studied oratorical numbers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle‡, that punctuation was known in his time. The learned

* *De Thrasymacho.*

† *Cicero Orat.* § 33.

‡ *Rhet.* lib. iii. c. 5.

Punctuation.

learned Dr Edward Bernard * refers the knowledge of pointing to the time of that philosopher, and says, that it consisted in the different position of one single point. At the bottom of a letter; thus, (A.) it was equivalent to a comma; in the middle (A·) it was equal to a colon; at the top (A˙) it denoted a period, or the conclusion of a sentence.

* *Bern. Orbis erud. Literat.* tom. 30. edit. 1689.

"This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the ninth century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. *Unciales literas hodierno usu dicimus eas in vetustis codicibus, quæ priscam formam servant, ac solutæ sunt, nec mutuò colligantur. Hujus modi literæ unciales observantur in libris omnibus ad nonum usque sæculum.* Montf. Palæog. Recens. p. xii.

"According to Cicero, the ancient Romans as well as the Greeks made use of points. He mentions them under the appellation of *librariorum notæ;* and in several parts of his works he speaks of '*interpunctæ clausulæ in orationibus*', of '*clausulæ atque interpunctæ verborum*', of *interpunctiones verborum, &c.* †.

"Seneca, who died A. D. 65, expressly says, that Latin writers in his time, had been used to punctuation. '*Nos* ‡, *cum scribimus interpungere consuevimus.*' Muretus and Lipsius imagined that these words alluded to the insertion of a point after each word; but they certainly were mistaken, for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these words occur, Seneca is speaking of one Q. Haterius, who made no pauses in his orations.

† *Cic. de Orat.* lib. iii § 26. *Ibid.* 7. *Orat. pro Muraena,* § 25.
‡ *Sen. Epist.* 40.

"According to Suetonius in his Illust. Gram. Valerius Probus procured copies of many old books, and employed himself in correcting, pointing and illustrating them; devoting his time to this and no other part of grammar. *Multa exemplaria contracta emendare, ac distinguere et adnotare curavit; soli huic, nec ulli præterea, grammatices parti deditus.*

"It appears from hence that in the time of Probus, or about the year 68, Latin manuscripts had not been usually pointed; and that grammarians made it their business to supply this deficiency.

"Quintilian, who wrote his celebrated treatise on Oratory about the year 88, speaks of commas, colons, and periods; but it must be observed that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation §.

"Ælius Donatus || published a treatise on Grammar in the fourth century, in which he explains the *distinctio*, the *media distinctio*, and the *subdistinctio:* that is, the use of a single point in the various positions already mentioned.

§ *Quinct.* lib. ix. c. iv.
|| A. D. 340.

"Jerom *, who had been the pupil of Donatus, in his Latin version of the scriptures, made use of certain distinctions or divisions, which he calls *cola* and *commata.* It has however been thought probable, that these divisions were not made by the addition of any points or stops; but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. These divisions were called στιχοι or ῥηματα; and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant which are written in this manner †.

* *Hieron. Præf. in Esaiam.* Vide etiam *Præf. in Josuam,* &c. tom. iii. p. 26.
† Vide *Montf Palæog. Græca,* lib. iii. c. 4.

"The best treatise upon punctuation I have seen, and from which these authorities are partly taken, was published some years since and dedicated to Sir Clifton Wintringham, Bart. the name of the author I know not *."

Punctum Punishment.

* *Month. Rev.* vol. li. p. 136.

PUNCTUM SALIENS, in *Anatomy*, the first rudiments of the heart in the formation of the fœtus, where a throbbing motion is perceived. This is said to be easily observed with a microscope in a brood-egg, wherein after conception, we see a little speck or cloud, in the middle whereof is a spot that appears to beat or leap a considerable time before the fœtus is formed for hatching. See the articles FOETUS and ANATOMY.

PUNCTUM stans, a phrase by which the schoolmen vainly attempt to bring within the reach of human comprehension the positive eternity of God. Those subtile reasoners seem to have discovered that nothing, which is made up of parts, whether continuous or discrete, can be absolutely infinite, and that therefore eternity cannot consist of a boundless series of successive moments. Yet, as if such a series had always existed, and were commensurate in duration with the supreme Being, they compared his eternity to one of the moments which compose the flux of time arrested in its course: and to this eternal moment they gave the name of *punctum stans*, because it was supposed to stand still, whilst the rest followed each other in succession, all vanishing as soon as they appeared. We need not waste time or room in exposing the absurdity of this conceit, as we have elsewhere endeavoured, in the best manner we can, to ascertain the meaning of the words *eternity* and *infinity*, and to show that they cannot be predicated of time or space, of points or moments, whether flowing or standing still. See METAPHYSICS, Part II. chap. 7. 8. and Part III. chap. 6.

PUNCTURE, in *Surgery*, any wound made by a sharp-pointed instrument.

PUNDITS, or PENDITS, learned Bramins devoted to the study of the Sanscrit language, and to the ancient science, laws, and religion of Hindostan. See PHILOSOPHY, N° 4—12.

PUNICA, the POMEGRANATE TREE, a genus of plants belonging to the icosandria class, and in the natural method ranking under the 36th order, *Pomaceæ.* See BOTANY *Index.*

PUNISHMENT, in *Law*, the penalty which a person incurs on the commission of a crime. See the article *CRIME and Punishment.*

The ingenuity of men has been much exerted to torment each other; but the following are the punishments that have been usually adopted in the different countries of the world. The capital punishments have been beheading, crucifixion, burning, roasting, drowning, scalping, hanging by the neck, the arm, or the leg, starving, sawing, exposing to wild beasts, rending asunder by horses drawing opposite ways, burying alive, shooting, blowing from the mouth of a cannon, compulsory deprivation of sleep, rolling in a barrel stuck with nails pointed inwards, poisoning, pressing slowly to death by a weight laid on the breast, casting headlong from a rock, tearing out the bowels, pulling to pieces with redhot pincers, the rack, the wheel, impaling, flaying alive, &c. &c.

The punishments short of death have been fine, pillory, imprisonment, compulsory labour at the mines, galleys, Punishment ‖ Purflew.

leys, highways, or correction-house; whipping, bastinading, mutilation by cutting away the ears, the nose, the tongue, the breasts of women, the foot, the hand; squeezing the marrow from the bones with screws or wedges, castration, putting out the eyes, banishment, running the gauntlet, drumming, shaving off the hair, burning on the hand or forehead, &c.

PUNNING. See Pun.

PUPIL, in the civil law, a boy or girl not yet arrived at the age of puberty; i. e. the boy under 14 years, the girl under 12.

Pupil, is also used in universities, &c. for a youth under the education or discipline of any person.

Pupil, in *Anatomy*, a little aperture in the middle of the uvea and iris of the eye, through which the rays of light pass to the crystalline humour, in order to be painted on the retina, and cause vision. See Anatomy *Index*.

PURCELL, Henry, a justly celebrated master of music, began early to distinguish himself. As his genius was original, it wanted but little forming, and he rose to the height of his profession with more ease than others pass through their rudiments. He was made organist to Westminster abbey in the latter end of the reign of Charles II. In that of William, he set several songs for Dryden's *Amphytrion* and his *King Arthur*, which were received with just applause. His notes in his operas were admirably adapted to his words, and so echoed to the sense, that the sounds alone seemed capable of exciting those passions which they never failed to do in conjunction. His music was very different from the Italian. It was entirely English, and perfectly masculine. His principal works have been published under the title of *Orpheus Britannicus*. He died in 1695, in the 37th year of his age, and was interred in Westminster abbey, where a monument is erected to his memory.

PURCHAS, Samuel, an English divine, famous for compiling a valuable collection of voyages, was born in 1577, at Thacksted in Essex. After studying at Cambridge, he obtained the vicarage of Eastwood in his native county; but leaving that cure to his brother, he settled in London, in order to carry on the great work in which he was engaged. He published the first volume in folio, 1613, and the four last, 12 years after, under the title of *Purchas his Pilgrimage, or Relations of the world, and the Religions observed in all ages and places.* Meanwhile he was collated to the rectory of St Martin's, Ludgate, in London, and made chaplain to Dr Abbot, archbishop of Canterbury. His *Pilgrimage*, and the learned Hackluyt's *Voyages*, led the way to all the other collections of that kind, and have been justly valued and esteemed. But unhappily, by his publishing, he involved himself in debt: he did not, however, die in prison, as some have asserted; but at his own house, about the year 1628.

PURCHASE, in *Law*, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

Purchase, in the sea-language, is the same as *draw in:* thus, when they say, the capstan purchases a-pace, they only mean it draws in the cable a-pace.

PURE, something free from any admixture of foreign or heterogeneous matters.

PURFLEW, a term in heraldry, expressing ermins, peans, or any of the furs, when they compose a bordure round a coat of arms: thus they say, He beareth gules, a bordure, purflew, vairy; meaning, that the bordure is vairy.

Purflew ‖ Purgatory.

PURGATION, the art of purging, scouring, or purifying a thing, by separating, or carrying off any impurities found therein. Thus,

In pharmacy, purgation is the cleansing of a medicine by retrenching its superfluities. In chemistry, it is used for the several preparations of metals and minerals intended to clear them of their impurities, more usually called *purification* and *refining*.

In medicine, purgation is an excretory motion arising from a quick and orderly contraction of the fleshy fibres of the stomach and intestines, whereby the chyle, corrupted humours, and excrements lodged therein, are protruded further and further, and at length quite excluded the body by stool. See Materia Medica.

Purgation, in *Law*, signifies the clearing a person's self of a crime of which he is suspected and accused before a judge. This purgation is either canonical or vulgar. Canonical purgation is prescribed by the canon-law, and the form thereof in the spiritual court is usually thus: The person suspected takes his oath that he is innocent of the crime charged against him; and at the same time brings some of his neighbours to make oath that they believe he swears truly. Vulgar purgation was anciently by fire or water, or else by combat, and was practised here till abolished by our canons. See Battel, *in law;* Ordeal, &c.

PURGATIVE or *Purging Medicines*, medicaments, which evacuate the impurities of the body by stool, called also *cathartics*.

PURGATORY, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation. Broughton has endeavoured to prove, that this notion has been held by Pagans, Jews, and Mahometans, as well as by Christians; and that in the days of the Maccabees the Jews believed that sin might be expiated by sacrifice after the death of the sinner, cannot be questioned.

Papist misrepresented and represented.

Much abuse has been poured upon the church of Rome for her doctrine of purgatory, and many false representations have been made of the doctrine itself. The following view of it is taken from a work which is considered as a standard by the British Catholics. 1. Every sin, how slight soever, though no more than an idle word, as it is an offence to God, deserves punishment from him, and will be punished by him hereafter, if not cancelled by repentance here. 2. Such small sins do not deserve eternal punishment. 3. Few depart this life so pure as to be totally exempt from spots of this nature, and from every kind of debt due to God's justice. 4. Therefore few will escape without suffering something from his justice for such debts as they have carried with them out of this world; according to that rule of divine justice, by which he treats every soul hereafter according to its works, and according to the state in which he finds it in death. From these propositions, which the Papist considers as so many self-evident truths, he infers that there must be some third place of punishment; for, since the infinite goodness of God can admit nothing into heaven which is not clean and pure from all sin both great and small; and his infinite justice can permit none to receive the reward of bliss, who as yet are not out of debt, but have something in justice to suffer; there must of necessity be some place or state, where souls, departing this life, pardoned as to the eternal guilt or pain, yet obnoxious to some temporal penalty, or with the guilt of some venial faults, are purged and purified before their admittance into heaven. And this is what he is taught concerning purgatory. Which, though he knows not where it is, of what nature the pains are, or how long each soul is detained there; yet he believes, that those that are in this place, being the living members of Jesus Christ, are relieved by the prayers of their fellow members here on earth, as also by alms and masses offered up to God for their souls. And as for such as have no relations or friends to pray for them, or give alms, or procure masses for their relief; they are not neglected by the church, which makes a general commemoration of all the faithful departed in every mass, and in every one of the canonical hours of the divine office.

Such is the Popish doctrine of purgatory, which is built chiefly upon 2 Macc. xii. 43, 44, 45; St Matth. xii. 31, 32; and 1 Cor. iii. 15. By Protestants the books of Maccabees are not acknowledged to be inspired scripture; but if they were, the texts referred to would rather prove that there is no such place as purgatory, since Judas did not expect the souls departed to reap any benefit from his sin-offering till the resurrection. Our Saviour, in St Luke, speaks of remission in *this world*, and in the world to *come;* but surely neither of these is purgatory. The world to come is the state after the resurrection, and the remission spoken of is the sentence of absolution to be pronounced on the penitent from the seat of general judgment. In the obscure verse referred to in the epistle to the Corinthians, the apostle is, by the best interpreters, thought to speak of the difficulty with which Christians should be saved from the destruction of Jerusalem. Of the state of souls departed he cannot well be supposed to speak, as upon disembodied spirits fire could make no impression. We cannot help, therefore, thinking with the church of England, that "the Romish doctrine of purgatory is a fond thing, vainly invented, and grounded on no warranty of scripture;" but we must confess at the same time, that it appears to us to be a very harmless error, neither hostile to virtue nor dangerous to society. See RESURRECTION.

PURIFICATION, in matters of religion, a ceremony which consists in cleansing any thing from a supposed pollution or defilement.

The Pagans, before they sacrificed, usually bathed or washed themselves in water; and they were particularly careful to wash their hands, because with these they were to touch the victims consecrated to the gods. It was also customary to wash the vessel with which they made their libations. The Mahometans also use purifications previous to the duty of prayer; which are also of two kinds, either bathing, or only washing the face, hands and feet. The first is required only in extraordinary cases, as after having lain with a woman, touched a dead body, &c. But lest so necessary a preparation for their devotions should be omitted, either where water cannot be had, or when it may be of prejudice to a person's health, they are allowed in such cases to make use of fine sand, or dust, instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male child, she was esteemed impure for 40 days; and when of a female, for 60: at the end of which time she carried a lamb to the door of the temple to be offered for a burnt-offering, and a young pigeon or turtle for a sin offering; and by this ceremony she was cleansed or purified.

PURIM, or *The Feast of Lots*, a solemn festival of the Jews, instituted in memory of the deliverance they received, by means of Mordecai and Esther, from Haman's wicked attempt to destroy them.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of the profession to follow the pure word of God, in opposition to all traditions and human constitutions. It was likewise given in the primitive church to the Novatian schismatics, because they would never admit to communion any one who from dread of death had apostatized from the faith.

PURITY, the freedom of any thing from foreign admixture.

Purity of Style. See ORATORY, p. 411, &c.

PURLIEU, signifies all that ground near any forest, which being made forest by King Henry II. Richard I. and King John, was afterwards by perambulations and grants of Henry III. severed again from the same, and made purlieu; that is to say, pure and free from the laws of the forest.—The word is derived from the French *pur*, "pure," and *lieu*, "place."

PURLINS, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

By the act of parliament for rebuilding London, it is provided, that all purlins from 15 feet 6 inches to 18 feet 6 inches long, be in their square 9 inches and 8 inches; and all in length from 18 feet 6 inches to 21 feet 6 inches, be in their square 12 inches and 9 inches.

PURPLE, a colour composed of a mixture of red and blue. See *Colour-Making*, N° 29, and DYEING *Index*.

PURPURA, in *Natural History*. See MUREX, CONCHOLOGY *Index*. The Tyrian method of dyeing purple was with a liquid extracted from this fish. It has been affirmed, however, that no such method was ever practised. "At Tyre (says Mr Bruce) I engaged two fishermen, at the expence of their nets, to drag in those places where they said shell-fish might be caught, in hopes to have brought out one of the famous purple-fish. I did not succeed; but in this I was, I believe, as lucky as the old fishers had ever been. The purple-fish at Tyre seems to have been only a concealment of their knowledge of cochineal; as, had they depended upon the fish for their dye, if the whole city of Tyre applied to nothing else but fishing, they would not have coloured 20 yards of cloth in a year."

PURPURE, in *Heraldry*. The colour so called, which signifies *purple*, is in engraving represented by diagonal lines, from the left to the right. See HERALDRY.

It may serve to denote an administrator of justice, a lawgiver, or a governor equal to a sovereign: and according to G. Leigh, if it is compounded with

Or,	it signifies	Riches.
Arg.		Quietness.
Gul.		Politics.
Az.		Fidelity.
Ver.		Cruelty.
Sab.		Sadness.

PURRE, or PERKIN. See AGRICULTURE *Index*.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it be well stowed, and keeps an account of what he every day delivers to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out; and that the paymaster or treasurer of the navy may issue out the debursements, and pay off the men, according to his book.

PURSLAIN. See PORTULACA, BOTANY *Index*.

PURVIEW, a term used by some lawyers for the body of an act of parliament, or that part which begins with "Be it enacted, &c." as contradistinguished from the preamble.

PURULENT, in *Medicine*, something mixed with, or partaking of, pus or matter.

PUS, in *Medicine*, a white or yellowish matter designed by nature for the healing and cementing of wounds and sores.

The origin and formation of pus is as much unknown as that of any other animal fluid. In an inaugural dissertation published at Edinburgh by Dr Hendy, the author supposes pus to be a secreted fluid. It has been thought by many, that pus is either a sediment from serum when beginning to putrefy, or that it is the same fluid inspissated by the heat of the body. But both these opinions are refuted by some experiments of our author, which show, that pus is much less inclined to putrefaction than serum, and the putrefaction of both is hastened by an addition of some of the red part of the blood. Some other experiments were made in order to try whether pus could be artificially produced. A thin piece of lamb's flesh, applied to an ulcer discharging laudable pus, and covered over with lead, did not assume the appearance of pus, but became fetid, and was much lessened. Serum, in its inflammatory and in its ordinary state, and lymph in different states, were applied to the same ulcer, which still discharged good pus; but none of these were converted into pus; on the contrary, they became very putrid.

In opposition to these arguments of our author, however, it may be alleged, that if pus was a secreted fluid, the vessels by which it was secreted would certainly be visible; but no such thing has ever been observed: on the contrary, it is certain that pus cannot be formed unless the air is excluded from the wound. These disputes, however, are of no great consequence: but in some cases it becomes a matter of real importance to distinguish pus from mucus; as thus we may be enabled to know whether a cough is consumptive, or merely catarrhous. See MUCUS. Mr Hume, in a dissertation on the properties of pus, in which he avails himself of the experiments of Mr Hunter, as delivered in his *Physiological Lectures*, says, "that the characteristic of pus is its being composed of globules; and he thinks that the presence of globules seems to depend upon the pus being in a perfect state. It differs from the blood in the colour of the globules; in their not being soluble in water, which those of the blood are; and from the fluid in which they swim being coagulable by a solution of sal ammoniac, which serum is not." Respecting the formation of pus, our author adopts the idea suggested by Mr Hunter, that the vessels of the part assume the nature of a gland, and secrete a fluid which becomes pus. Mr Horne ascertains, by experiment, that pus, at its formation, is not globular, but a transparent fluid, of a consistence, in some sort, resembling jelly; and that the globules are formed while lying upon the surface of the sore; requiring, in some instances, while the influence of the external air is excluded, fifteen minutes for that purpose.

PUSTULE, a pimple, or small eruption on the skin full of pus; such as the eruptions of the smallpox.

PUTAMINEÆ, (from *putamen*, "a shell,") the name of the 25th order of Linnæus's fragments of a natural method; consisting of a few genera of plants allied in habit, whose fleshy seed-vessel or fruit is frequently covered with a hard woody shell. See BOTANY.

PUTEOLI, (Livy, Strabo): a town of Campania; so called either from its wells, there being many hot and cold springs thereabouts; or from its stench, *putor*, caused by sulphureous exhalations, (Varro, Strabo). It is now called *Puzzuoli*, and is pleasantly and advantageously situated for trade. In a very remote age, the Cumeans made it their arsenal and dockyard; and to this naval establishment gave the sublime appellation of *Dicearchia* or *Just Power*.

Swinburne's Travels in the Two Sicilies.

The Romans were well aware of the utility of this port, and took great pains to improve its natural advantages. Nothing remains of their works but a line of piers, built to break the force of a rolling sea: they are vulgarly called the *bridge of Caligula*, because that madman is said to have marched in triumph from Puzzuoli to Baiæ on a bridge; but his was a bridge of boats.

The ruins of its ancient edifices are widely spread along the adjacent hills and shores. An amphitheatre still exists entire in most of its parts, and the temple of Serapis offers many curious subjects of observation; half of its buildings are still buried under the earth thrown upon it by volcanical commotions, or accumulated by the crumblings of the hill; the inclosure is square, environed with buildings for priests and baths for votaries; in the centre remains a circular platform, with four flights of steps up to it, vases for fire, a centrical altar, rings for victims, and other appendages of sacrifice, entire and not displaced; but the columns that held its roof have been removed to the new palace of Caserta (see CASERTA). Behind this round place of worship stand three pillars without capitals, part of the pronaos of a large temple, they are of cipoline marble, and at the middle of their height are full of holes eaten in them by the file-fish *.

The present city contains near 10,000 inhabitants, and occupies a small peninsula; the cathedral was a pagan temple, dedicated to the divinities that presided over commerce and navigation. E. Long. 14. 40. N. Lat. 41. 15.

* *Pholas Dactylus, Linn.*

In

In the neighbourhood of Puteoli are many relicks of ancient grandeur, of which none deserve more attention than the Campanian way paved with lava, and lined on each side with venerable towers, the repositories of the dead, which are richly adorned with stucco in the inside. This road was made in a most solid expensive manner by order of Domitian, and is frequently the subject of encomium in the poems of Statius.

PUTI CARAJA, in *Botany*, is a genus of Indian plants, of which the characters, as given by Sir William Jones in the Asiatic Researches, vol. ii. p. 351. are these. The calyx is five-cleft, the corolla has five equal petals, the pericarpium a thorny legumen and two seeds, the leaves oval and pinnated, and the stem armed. "The seeds (says the learned president) are very bitter, and perhaps tonic; since one of them, bruised and given in two dozes, will, as the Hindoos assert, cure an intermittent fever."

PUTORIUS. See MUSTELA, MAMMALIA *Index*.

PUTREFACTION, is the natural process by which organized bodies are dissolved, and reduced to what may be called *original elements*.

Putrefaction differs from chemical solution; because in the latter, the dissolved bodies are kept in their state of solution by being combined with a certain agent from which they cannot easily be separated; but in putrefaction, the agent which dissolves the body appears not to combine with it in any manner of way, but merely to separate the parts from each other. It differs also from the resolution of bodies by distillation with violent fire; because, in distillation, new and permanent compounds are formed, but by putrefaction every thing seems to be resolved into substances much more simple and indestructible than those which are the result of any chemical process.

The bodies most liable to putrefaction are those of animals and vegetables, especially when full of juices. Stones, though by the action of the weather they will moulder into dust, yet seem not to be subject to any thing like a real putrefaction, as they are not resolved into any other substance than sand, or small dust, which still preserves its lapideous nature. In like manner, vegetables of any kind, when deprived of their juices by drying, may be preserved for many ages without being subjected to any thing like a putrefactive process. The same holds good with respect to animals; the parts of which, by simple drying, may be preserved in a sound state for a much longer time than they could be without the previous exhalation of their juices.

Putrefaction is generally allowed to be a kind of fermentation, or rather to be the last stage of that process; which beginning with the vinous fermentation, goes on through the acetous, to the stage of putridity, where it stops. It is argued, however, and seemingly not without a great deal of reason, that if putrefaction be a fermentation, it must necessarily be a kind distinct from either the vinous or acetous; since we frequently observe that it takes place where neither the vinous nor the acetous stages have gone before; of consequence, it must be, in some cases at least, entirely independent of and unconnected with them. In several other respects it differs so much from these processes, that it seems in some degree doubtful whether it can with propriety be called a *fermentation* or not. Both the vinous and acetous fermentations are attended with a considerable degree of heat; but in the putrefaction of animal matters especially, the heat is for the most part so small, that we cannot be certain whether there is any degree of it or not produced by the process. In cases, indeed, where the quantity of corrupting animal matter is very great, some heat may be perceived: and accordingly Dr Monro tells us, that he was sensible of heat on thrusting his hand into the flesh of a dead and corrupting whale. But the most remarkable difference between the putrefactive fermentation and that of the vinous and acetous kinds is, that the end of both these processes is to produce a new and permanent compound; but that of the putrefactive process is not to produce any new form, but to destroy, and resolve one which already exists into the original principles from which all things seem to proceed. Thus the vinous fermentation produces ardent spirits; the acetous, vinegar: but putrefaction produces nothing but earth, and some effluvia, which, though most disagreeable, and even poisonous to the human body, yet, being imbibed by the earth and vegetable creation, give life to a new race of beings. It is commonly supposed, indeed, that volatile alkali is a production of the putrefactive process: but this seems liable to dispute. The vapour of pure volatile alkali is not hurtful to the human frame, but that of putrefying substances is exceedingly so; and, excepting in the case of urine, the generation of volatile alkali in putrid substances is very equivocal. This substance, which produces more alkali than any other, is much less offensive by its putrid fetor than others; and all animal substances produce a volatile alkali on being exposed to the action of fire, of quicklime, or of alkaline salts. In these cases the volatile alkali is not supposed to be produced by the quicklime or fixed salt, but only to be extricated from a kind of ammoniacal salt pre-existing in the animal matters; the probability is the same in the other case, viz. that volatile alkali is not produced, but only extricated, from these substances by putrefaction.

The only thing in which the putrefactive fermentation agrees with the other kinds is, that in all the three there is an extrication of fixed air. In the putrefactive process, it has been thought that this escape of the fixed air deprives the body of its cohesion: and Dr Macbride has written a treatise, in which he endeavours to prove that fixed air is the very power of cohesion itself, and that all bodies when deprived of their fixed air entirely lose their cohesion. According to this hypothesis, the cause of putrefaction is the escape of fixed air; but it is impossible to give a reason why fixed air, after having so long remained in a body, and preserved its cohesion, should of a sudden begin to fly off without being acted upon by something else. To a similar objection the hypothesis of those is liable, who suppose putrefaction to be occasioned by the escape of phlogiston; for phlogiston is now known to be a chimera: and though it were a reality, it would not fly off without something to carry it off, any more than fixed air. Animalcules have been thought to be the cause of putrefaction: but if animal substances are covered so as to exclude the access of flies or other insects, no such animalcules are to be discovered though putrefaction has taken place; and indeed it requires little proof to convince us, that animals are produced in corrupted bodies only because such substances prove a proper nidus for the eggs of the parent insects.

To

Putrefaction.

To understand the true cause of putrefaction, we must take notice of the circumstances in which the process goes on most rapidly. These are, heat, a little moisture, and confined air. Extreme cold prevents putrefaction, as well as perfect dryness; and a free circulation of air carries off the putrid effluvia; a stagnation of which seems to be necessary for carrying on the process. It seems also to hold pretty generally, that putrefying bodies swell and become specifically lighter; for which reason the carcases of dead animals, after having sunk in water, rise to the top and float. This last phenomenon, as has been observed under the article BLOOD, N° 29. shows that these bodies have received a certain quantity of an elastic principle from the air, which thus swells them up to such a size. It may be said indeed, that this increase of size in putrefying bodies is owing only to the extrication of air within themselves: but this amounts to the same thing; for the air which exists internally in the body of any animal, is entirely divested of elasticity while it remains there, and only shows its elastic properties upon being extricated. The elastic principle which combines with the air fixed in the animal substance, therefore, must come from the external atmosphere; and consequently the agent in putrefaction must be the elastic principle of the atmosphere itself, probably the same with elementary fire.

But, granting this to be true, it is difficult to show why putrefaction should not take place in a living body as well as in a dead one; seeing the one is as much exposed to the action of the air as the other. This difficulty, however, is not peculiar to the present hypothesis; but will equally occur whatever we may suppose the cause of putrefaction to be. The difficulty seems to be a little cleared up by Dr Priestley, who shows, that, by means of respiration, the body is freed from many noxious effluvia which would undoubtedly destroy it; and by the retention of which, he thinks, a living body would putrefy as soon as a dead one. The way in which respiration prevents the putrefaction of the body, is evidently the same with that in which the wind prevents fish or flesh hung up in it from becoming putrid. The constant inspiration of the air is like a stream of that element continually blown upon the body, and that not only upon its surface, but into it; by which means putrefaction is prevented in those parts that are most liable to become putrid. On the other hand, the elastic principle received from the air by the blood *, by invigorating the powers of life, quickening the circulation, and increasing perspiration, enables the body to expel noxious particles from other parts of the body which cannot conveniently be expelled by the lungs.

* See Blood, N° 29.

This leads us to consider the reason why a free exposure to the air prevents the coming on of putrefaction, or why the confining of the putrid effluvia should be so necessary to this process. Here it will be proper to recollect, that putrefaction is a simple resolution of the body into earth, air, &c. of which it seems originally to have been composed. This resolution is evidently performed by an expansive power seemingly situated in every particle of the body. In consequence of this principle, the body first swells, then bursts, flies off in vapour, and its particles fall asunder from each other. The action of the putrefactive process, then, is analogous to that of fire, since these are the very properties of fire, and the very effects which follow the action of fire upon any combustible body. It is therefore exceedingly probable, that the agent in the air, which we have all along considered as the cause of putrefaction, is no other than fire itself; that is, the ethereal fluid expanding itself every where, as from a centre to a circumference. The force of the fluid, indeed, is much less in putrefaction than in actual ignition; and therefore the effects also take place in a much smaller degree, and require a much longer time: nevertheless, the same circumstances that are necessary for keeping up the action of fire, are also necessary for keeping up the putrefactive process. One of these is a free access of air, yet without too violent a blast; for as fire cannot burn without air, neither can it endure too much of it: thus a candle goes out if put under a receiver, and the air exhausted; and it will do the same if we blow violently upon it. In like manner, putrefaction requires a certain quantity of air, much less indeed than fire: and as it requires less to support it, so it can also endure much less air than fire; for a stream of air which would not put out a fire, will effectually prevent putrefaction. The cause of this in both is the same. Fire cannot burn because the vapour is carried off too fast; and thus the latent heat, which ought to support the flame, is entirely dissipated. In like manner putrefaction is as certainly attended with an emission of azotic gas as fire is with an emission of flame. These gases contain a great quantity of latent heat, or of the expansive principle already mentioned; and if these are carried off with greater rapidity than the heat of the atmosphere can produce them, the consequence must be, that an opposite principle to that which produces putrefaction, namely, a principle of cold, or condensation, instead of expansion, must take place, and the body cannot putrefy. That this must be the case, is evident from the property which all evaporations have of producing cold; and it is well known that a brisk current of air promotes evaporation to a great degree. Hence also the reason is evident why bodies are preserved uncorrupted by cold; for thus the action of the expansive principle is totally overcome and suspended, so that none of its effects can be perceived.

Thus we may say, that one reason why an animal body does not putrefy while alive, is its ventilation, as we may call it, by respiration; and another is, the continual accession of new particles, less disposed to putrefy than itself, by the food and drink which is constantly taken in. But if either of these ways of preventing the commencement of this process are omitted, then putrefaction will take place as well in a living as in a dead body. Of the truth of this last fact we have innumerable instances. When air is infected with the putrid effluvia of marshes, and thus the natural effluvia are not carried off from the human body, but, on the contrary, some enter into it which are not natural to it, the most putrid diseases are produced. The same thing happens from the putrid effluvia of dead bodies. Of this we have a remarkable instance in the fever which took place in Germany in the war of 1755: one reason of which is said to have been an infection of the air by the vast numbers of people killed in battle, to which was added a calm in the atmosphere for a long time; the putrid effluvia being by this prevented from flying off †. When Mr Holwell with 145 others were imprisoned in the black-hole at Calcutta, after passing a

† See *Medicine*, N° 167.

a night in that dismal habitation, he found himself in a high putrid fever. When sailors in long voyages are obliged to feed upon putrid aliments; when, through stormy weather, they are much exposed to wet; in the one case the putrescent effluvia being kept from flying off, and in the other a greater quantity being thrown into the body than what it naturally contains, the scurvy, malignant fevers, &c. make their appearance (A). Neither can these diseases be removed without removing every one of the causes just now mentioned: for as putrid diseases will be the consequence of confined air, nastiness, &c. though the provisions be ever so good; so on the other hand, if the provisions be bad, the best air, and most exact cleanliness, nay, the best medicines in the world, will be of no service; as hath been often observed in the scurvy.

From this account of the nature, cause, and method of preventing putrefaction by means of a current of air, we may easily see the reason why it does not take place in some other cases also. Bodies will not putrefy *in vacuo*, because there the atmosphere has not access to impart its elastic principle; and though in the vacuum itself the principle we speak of does undoubtedly exist, yet its action there is by far too weak to decompose the structure of an animal body. In extreme cold, the reason why putrefaction does not take place, has been already shown. If the heat is extremely great, the process of ignition or burning takes place instead of putrefaction. If the body is very dry, putrefaction cannot take place, because the texture is too firm to be decomposed by the weak action of the elastic principle. Putrefaction may also be prevented by the addition of certain substances; but they are all of them such as either harden the texture of the body, and thus render it proof against the action of the elastic fluid, or, by dissolving its texture entirely, bring it into a state similar to what it would be brought by the utmost power of putrefaction, so that the process cannot then take place. Thus various kinds of salts and acids harden the texture of animal substances, and thus are successfully used as antiseptics. The same thing may be said of ardent spirits; while oils and gums of various kinds prove antiseptic by a total exclusion of air, which is necessary in some degree for carrying on the process of putrefaction. Many vegetables, by the astringent qualities they possess, harden the texture of animal substances, and thus prove powerfully antiseptic; while, on the other hand, fixed alkaline salts, quicklime, and caustic volatile alkali, though they prevent putrefaction, yet they do it by dissolving the substances in such a manner that putrefaction could do no more though it had exerted its utmost force. There is only one other antiseptic substance whose effects deserve to be considered, and that is sugar. This, though neither acid nor alkaline, is yet one of the most effectual means of preventing putrefaction: and this seems to be owing to its great tendency to run into the vinous fermentation, which is totally inconsistent with that of putrefaction; and this tendency is so great, that it can scarce be counteracted, by the tendency of animal substances to putrefy in any circumstances whatever.

Some kinds of air are remarkably antiseptic, though this subject has not been so fully inquired into as could be wished. The most powerful of them in this respect is the nitrous air; next to it, is fixed air; but the powers of the other airs are not so well known. It is probable that the antiseptic properties of fixed and nitrous air, are owing to their quality of extinguishing fire, or at least that the principle is the same; but till the nature of these two kinds of air are better known, little can be said with certainty on the subject.

Sir John Pringle has made experiments to determine the powers of certain substances to promote or to prevent putrefaction. From these experiments he has formed the following Table, showing the relative antiseptic powers of the saline substances mentioned. Having found that two drams of beef put in a phial with two ounces of water, and placed in a heat equal to 90° of Fahrenheit's

(A) This aeriform fluid, which is exhaled from animal bodies in a state of putrefaction, acts at certain times more powerfully than at others, and is indeed in one stage of the process infinitely more noxious than any other elastic fluid yet discovered. In the Gentleman's Magazine for August 1788, Dr St John informs us, that he knew a gentleman who, by slightly touching the intestines of a human body beginning to liberate this corrosive gas, was affected with a violent inflammation, which in a very short space of time extended up almost the entire length of his arm, producing an extensive ulcer of the most foul and frightful appearance, which continued for several months, and reduced him to a miserable state of emaciation. The same writer mentions a celebrated professor who was attacked with a violent inflammation of the nerves and fauces, from which he with difficulty recovered, merely by stooping for an instant over a body which was beginning to give forth this deleterious fluid. Hence he infers, that the same gas modified or mixed, or united with others, may be the occasion of the plague, which has so often threatened to annihilate the human species. It is happy, however, for mankind that this particular stage of putrefaction continues but for a few hours; and what may appear very remarkable, this destructive gas is not very disagreeable in smell, and has nothing of that abominable and loathsome fetor produced by dead bodies in a less dangerous state of corruption; but has a certain smell totally peculiar to itself, by which it may be instantly discovered by any one that ever smelled it before. This is an object very worthy the attention of physicians: it is both extremely interesting, and very little known; but at the same time it is a study in the highest degree unpleasant, from the detestable smell and nastiness which attend the putrefaction of animal bodies; and a man must be armed with uncommon philanthropy and resolution to attempt it.

Dr St John thinks it probable that there is a rapid fixation of the basis of vital air in dead bodies at a certain state of putrefaction, on account of the luminous appearance which they sometimes make, and which exists but for a few hours: but whether this luminous appearance takes place in every body, or whether it precedes or follows the exhalations of the corrosive gas above mentioned, he had not, when he wrote his paper, been able to discover.

Fahrenheit's thermometer, became putrid in 14 hours, and that 60 grains of sea-salt preserved a similar mixture of beef and water more than 30 hours, he made the antiseptic power of the sea-salt a standard, to which he compared the powers of the other salts. The algebraic character + signifies, that the substance to which it is annexed had a greater antiseptic power than is expressed by the numbers:

Sea-salt, or the standard	1
Sal-gem	1+
Vitriolated tartar	2
Spiritus Mindereri	2
Soluble tartar	2
Sal diureticus	2+
Crude sal ammoniac	3
Saline mixture	3
Nitre	4+
Salt of hartshorn	4+
Salt of wormwood	4+
Borax	12
Salt of amber	20
Alum	30

N.B. The quantities of spiritus Mindereri and of the saline mixture were such, that each of them contained as much alkaline salt as the other neutral salts.

Myrrh, aloes, asafœtida, and terra Japonica were found to have an antiseptic power 30 times greater than the standard. Gum ammoniacum and sagapenum showed little antiseptic power.

Of all resinous substances, camphor was found to resist putrefaction most powerfully. Sir John Pringle believes that its antiseptic power is 300 times greater than that of sea-salt.

Chamomile flowers, Virginian snake-root, pepper, ginger, saffron, contrayerva root, and galls, were found to be 12 times more antiseptic than sea-salt.

Infusions of large quantities of mint, angelica, ground-ivy, green tea, red-roses, common wormwood, mustard, and horse-radish, and also decoctions of poppy-heads, were more antiseptic than sea-salt.

Decoctions of wheat, barley, and other farinaceous grains, checked the putrefaction by becoming sour.

Chalks and other absorbent powders, accelerated the putrefaction, and resolved meat into a perfect mucus. The same powders prevented an infusion of farinaceous grains, from becoming mucilaginous and sour.

One dram of sea-salt was found to preserve two drams of fresh beef in two ounces of water, above 30 hours, uncorrupted, in a heat equal to that of the human body, or above 20 hours longer than meat is preserved in water without salt: but half a dram of salt did not preserve it more than two hours longer than pure water. Twenty-five grains of salt had little or no antiseptic quality. Twenty grains, 15 grains, but especially 10 grains only of sea-salt, were found to accelerate and heighten the putrefaction of two drams of flesh. These small quantities of sea-salt did also soften the flesh more than pure water.

The same learned and ingenious physician made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being beat to the consistence of pap, and exposed to 90° of heat according to Fahrenheit's thermometer, began to ferment in a few hours, and continued in fermentation during two days. When it began to ferment and swell, the putrefaction had begun; and in a few hours afterwards, the smell was offensive. Next day the putrid smell ceased, and an acid taste and smell succeeded. Fresh alimentary vegetables, as spinach, asparagus, scurvy-grass, produced similar effects as bread on flesh, but in a weaker degree. From several other experiments he found, that animal substances excite the fermentation of vegetable substances, and that the latter substances correct the putrescency of the former.

By adding saliva to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no saliva was used.

By added an oily substance to the common mixture of flesh, bread, and water, a stronger fermentation was produced, which could not be moderated by the quantity of saliva used in the following experiment, till some fixed alkaline salt was added; which salt was found, without saliva, to stop suddenly very high fermentations.

He did not find that small quantities of the following salts, sal ammoniac, nitre, vitriolated tartar, sal diureticus, salt of hartshorn, salt of wormwood, were septic, as small quantities of sea-salt were.

Sugar was found to resist putrefaction at first, as other salts do, and also to check the putrefaction after it had begun by its own fermentative quality, like bread and other fermentative vegetables.

Lime-water made some small resistance to putrefaction.

Port-wine, small-beer, infusions of bitter vegetables, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an unstrained decoction of bark considerably increased that fermentation.

Crab-eyes accelerated and increased the fermentation of a mixture of flesh and bread.

Lime-water neither retarded nor hastened the fermentation of such a mixture: but when the fermentation ceased, the liquor was neither putrid nor acid, but smelt agreeably.

Flesh pounded in a mortar was found to ferment sooner than that which had not been bruised.

The tough inflammatory crust of blood was found to be most putrescent; next to which the crassamentum, or red coagulated mass; and lastly the serum.

Dr Macbride's experiments confirm many of those above related, especially those which show that the fermentation of vegetable substances is increased by a mixture of animal or purescent matter; that the putrescency of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances were accelerated by additions of absorbent earths and of Peruvian bark. He also found, that although unburnt calcareous earths were septic, quicklime and lime-water prevented putrefaction, but that they destroyed or dissolved the texture of flesh.

The experiments of the author of the *Essai pour servir à l'Histoire de la Putrefaction*, show that metallic salts,

salts, resinous powders, extracts of bark, and opium, are very powerfully antiseptic, and that salts with earthy bases are less antiseptic than any other salts.

PUTTOCK-SHROUDS. See *Puttock-Shrouds*.

PUTTY, in its popular sense, is a kind of paste compounded of whiting and linseed oil, beaten together to the consistence of a thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PUTTY sometimes also denotes the powder of calcined tin, used in polishing and giving the last gloss to works of iron and steel.

PUY DE DOME, a department in the south of France, forming part of the ancient province of Auvergne. The soil is mountainous, but fertile in all kinds of grain, vines, and fruits; and contains mines of iron, lead, coal, and many mineral springs. There are manufactures of cloth of various kinds, lace, serges, ribbons, &c. The territorial extent of this department is 794,370 hectares, and the population in 1817 was 548,834. The contributions for 1802 amounted to 3,656,547 francs. Clermont is the chief town.

TERRA PUZZULANA, or POZZOLANA, is a grayish kind of earth used in Italy for building under water. The best is found about Puteoli, Baiæ, and Cumæ, in the kingdom of Naples, from the first of which places it derives its name. It is a volcanic product, composed of heterogeneous substances, thrown out from the burning mouths of volcanoes in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance. In the year 79 of the common era, the cities of Herculaneum, Pompeii, and Stabia, although at the distance of many miles from Vesuvius, were, nevertheless, buried under the matters of these dreadful eruptions; as Bergman relates in his Treatise of the Volcanic Products. This volcanic earth is of a gray, brown, or blackish colour; of a loose glanular, or dusty and rough, porous or spongy texture, resembling a clay hardened by fire, and then reduced to a gross powder. It contains various heterogeneous substances mixed with it. Its specific gravity is from 2500 to 2800; and it is, in some degree, magnetic: it scarcely effervesces with acids, though partially soluble in them. It easily melts *per se;* but its most distinguishing property is, that it hardens very suddenly when mixed with $\frac{1}{3}$ of its weight of lime and water; and forms a cement which is more durable in water than any other.

According to Bergman's Analysis, 100 parts of it contain from 55 to 60 of siliceous earth, 20 of argillaceous, five or six of calcareous, and from 15 to 20 of iron. Its effects, however, in cement may perhaps depend only on the iron it contains.

It is evidently a martial argillaceous marl, that has suffered a moderate heat. Its hardening power arises from the dry state of the half-baked argillaceous particles, which makes them imbibe water rapidly, and thus accelerates the desiccation of the calcareous part; and also from the quantity and peculiar state of the iron and manganese which it contains; on which metals its properties chiefly depend. It is found not only in Italy but in France, and also in England and elsewhere.

PUZZUOLI. See PUTEOLI.

PYANEPSIA, in antiquity, an Athenian festival celebrated on the seventh day of the month *Pyanepsion;* which, according to the generality of critics, was the same with our September.

Plutarch refers the institution of this feast to Theseus, who, after the funeral of his father, on this day paid his vows to Apollo, because the youths who returned with him safe from Crete then made their entry into the city. On this occasion, these young men putting all that was left of their provisions into one kettle, feasted together on it, and made great rejoicing. Hence was derived the custom of boiling pulse on this festival. The Athenians likewise carried about an olive branch, bound about with wood, and crowned with all sorts of first-fruits, to signify that scarcity and barrenness were ceased, singing in procession a song. And when the solemnity was over, it was usual to erect the olive branch before their doors, as a preservative against scarcity and want.

PYCNOSTYLE, in the ancient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations.

According to Mr Evelyn, the pycnostyle chiefly belonged to the Composite order, and was used in the most magnificent buildings; as at present in the peristyle at St Peter's at Rome, which consists of near 300 columns; and in such as yet remain of the ancients, among the ruins of Palmyra.

PYGARGUS, a species of falco. See ORNITHOLOGY *Index*.

PYGMALION, in fabulous history, a king of Cyprus, who, being disgusted at the dissolute lives of the women of his island, resolved to live in perpetual celibacy; and making a statue of ivory, he fell so passionately in love with it, that the high festival of Venus being come, he fell down before the altar of that goddess, and besought her to give him a wife like the statue he loved. At his return home, he embraced, as usual, his ivory form, when he perceived that it became sensible by degrees, and was at last a living maid, who found herself in her lover's arms the moment she saw the light. Venus blessed their union; and, at the end of nine months, she was delivered of a boy, who was named *Paphos*.

PYGMY, a person not exceeding a cubit in height. This appellation was given by the ancients to a fabulous nation inhabiting Thrace; who brought forth young at five years of age, and were old at eight: these were famous for the bloody war they waged with the cranes. As to this story, and for the natural history of the true pygmy, see SIMIA, MAMMALIA *Index*.

PYKAR, a broker in India, inferior to those called *dallals*, who transacts the business at first hand with the manufacturer, and sometimes carries goods about for sale.

PYKE, a watchman in India, employed as a guard at night. Likewise a footman or runner on business. They are generally armed with a spear.

PYLADES, a son of Strophius, king of Phocis, by one of the sisters of Agamemnon. He was educated together with his cousin Orestes, with whom he formed the most inviolable friendship, and whom he assisted to revenge the murder of Agamemnon, by assassinating Clytemnestra and Ægysthus. He also accompanied him into Taurica Chersonesus; and for his ser-

 vices

vices Orestes rewarded him, by giving him his sister Electra in marriage. Pylades had by her two sons, Medon and Strophius. The friendship of Orestes and Pylades became proverbial.

PYLORUS, in *Anatomy*, the under orifice of the stomach. See ANATOMY, N° 91.

PYLUS, in *Ancient Geography*, a town of Elis; its ruins to be seen on the road from Olympia to Elis, (Pausanias); situated between the mouths of the Peneus and Selles, near Mount Scollis, (Strabo). Built by Pylas of Megara, and destroyed by Hercules, (Pausanias). Another Pylus in Triphylia, (Strabo); by which the Alpheus runs, (Pausanias); on the confines of Arcadia, and not in Arcadia itself, (id.).—A third in Messenia, (Strabo, Ptolemy); situated at the foot of Mount Ægaleus on the sea coast, over-against the island Sphagea or Sphacteria: built by Pylas, and settled by a colony of Leleges from Megara; but thence expelled by Neleus and the Pelasgi, and therefore called *Nelea*, (Homer.) A sandy territory. The royal residence of Neleus, and of Nestor his son: the more ancient and more excellent Pylus; whence the proverb *Pylus ante Pylum* (Aristophanes, Plutarch), used when we want to repress the arrogance and pride of any one: said to be afterwards called *Coryphasium*. It made a figure in the Peloponnesian war; for being rebuilt by the Athenians, it proved of great benefit to them for the space of 15 years, and of much annoyance to the Lacedæmonians, (Thucydides). All the three *Pyli* were subject to Nestor, (Strabo).

PYRAMID, in *Geometry*, a solid standing on a triangular, square, or polygonal basis, and terminating in a point at the top; or, according to Euclid, it is a solid figure, consisting of several triangles, whose bases are all in the same plane, and have one common vertex.

Pyramids are sometimes used to preserve the memory of singular events, and sometimes to transmit to posterity the glory and magnificence of princes. But as they are esteemed a symbol of immortality, they are most commonly used as funeral monuments and temples to the gods. Such is that of Cestius at Rome; the pyramids of Dashur drawn by Pococke; and those other celebrated ones of Egypt, as famous for the enormity of their size as their antiquity. Of these the largest are the pyramids of *Geeza*, so called from a village of that name on the banks of the Nile, distant from them about 11 miles. The three which most attract the attention of travellers stand near one another on the west side of the river, almost opposite to Grand Cairo, and not far from the place where the ancient Memphis stood. They were visited by M. Savary, of whose description of them we shall here give an abstract.

He took his journey in the night time, in order to get up to the top of the great one by sunrise. Having got within sight of the two great ones, while the full moon shone upon them, he informs us, that they appeared, at the distance of three leagues, like two points of rock crowned by the clouds.

It is in the rich territory which surrounds them that fable has placed the Elysian fields. The canals which intersect them are the Styx and Lethe.

" The aspects of the pyramids, varied according to the circuits he made in the plain, and the position of the clouds, displayed themselves more and more to view. At half past three in the morning we arrived (says he) at the foot of the greatest. We left our clothes at the gate of the passage which leads to the inside, and descended, carrying each of us a flambeau in his hand. Towards the bottom you must creep like serpents to get into the interior passage, which corresponds with the former. We mounted it on our knees, supporting ourselves with our hands against the sides. Without this precaution one runs the risk of slipping on the inclined plane, where the slight notches are insufficient to stop the foot, and one might fall to the bottom. Towards the middle we fired a pistol, the frightful noise of which, repeated in the cavities of this immense edifice, continued a long time, and awakened thousands of bats, which flying round us, struck against our hands and faces, and extinguished several of our wax candles. They are much larger than the European bats. Arrived above, we entered a great hall, the gate of which is very low. It is an oblong square, wholly composed of granite. Seven enormous stones extend from one wall to the other, and form the roof. A sarcophagus made of a single block of marble lies at one end of it. It is empty; and the lid of it has been wrenched off. Some pieces of earthen vases lie around it. Under this beautiful hall is a chamber not so large, where you find the entrance to a conduit filled with rubbish. After examining these caves, where daylight never penetrated, we descended the same way, taking care not to fall into a well, which is on the left, and goes to the very foundations of the pyramid. Pliny makes mention of this well, and says it is 26 cubits deep. The internal air of this edifice never being renewed, is so hot and mephitic that one is almost suffocated. When we came out of it, we were dropping with sweat, and pale as death. After refreshing ourselves with the external air, we lost no time in ascending the pyramid. It is composed of more than 200 layers of stone. They overlap each other in proportion to their elevation, which is from two to four feet. It is necessary to climb up all these enormous steps to reach the top. We undertook it at the north-east angle, which is the least damaged. It took us, however, half an hour with great pains and many efforts to effect it.

" The sun was rising, and we enjoyed a pure air, with a most delicious coolness. After admiring the prospect around us, and engraving our names on the summit of the pyramid, we descended cautiously, for we had the abyss before us. A piece of stone detaching itself under our feet or hands might have sent us to the bottom.

" Arrived at the foot of the pyramid, we made the tour of it, contemplating it with a sort of horror. When viewed close, it seems to be made of masses of rocks; but at a hundred paces distance, the largeness of the stones is lost in the immensity of the whole, and they appear very small.

" To determine its dimensions is still a problem. From the time of Herodotus to our days it has been measured by a great number of travellers and learned men, and their different calculations, far from clearing up doubts, have only increased the uncertainty. The following table will serve at least to prove how difficult it is to come at the truth.

Pyramid.

Height of the great Pyramid.		*Width of one of its sides.*
Ancients.		French Feet.
Herodotus	800	800
Strabo	625	600
Diodorus Siculus	600 and a fraction	700
Pliny	-	708
Moderns.		
Le Bruyn	616	704
Prosper Alpinus	625	750
Thevenot	520	682
Niebuhr	440	710
Greaves	444	648

Number of layers of Stone which form it.

Greaves	207
Maillet	208
Albert Liewenstein	260
Pococke	212
Belon	250
Thevenot	208

"It appears that Messrs Greaves and Niebuhr have prodigiously deceived themselves in measuring the perpendicular height of the great pyramid. All the travellers allow that it has at least 200 layers of stone. These layers are from two to four feet high. According to Pococke, they are from four feet and a half to four feet high, being not so high at the top as at the base. Prosper Alpinus informs us, that the elevation of the first layer is five feet, but it diminishes insensibly in proportion as one mounts. Thevenot mentions 208 steps of large stones, the thickness of which makes the height of them about two feet and a half one with another: He measured some of them more than three feet high. I have measured several of them which were more than three feet high, and I found none less than two; the least height of them we can take as a medium therefore is two feet and a half, which, even according to Mr Greaves's calculation, who reckons 207 layers, would make 517 feet 6 inches perpendicular height. Messrs Greaves, Maillet, Thevenot, and Pococke, who only differ in the number of the layers from 207 to 212, all mounted by the north-east angle, as the least injured. I followed the same route, and counted only 208 steps. But if we reflect that the pyramid has been open on the side next the desert, that the stones on that side have been thrown down, that the sand which covers them has formed a considerable hill, we shall not be astonished that Albert Liewenstein, Belon, and Prosper Alpinus, who must have mounted by the south-east or south-west angle, which are less exposed to the sands of Libya, should have found a greater number of steps: so that the calculation of these travellers, agreeing with that of Diodorus Siculus and Strabo, appears to be nearest the true height of the pyramid taken at its natural base; whence we may conclude with reason that it is at least 600 feet high. Indeed this is authenticated by a passage of Strabo. These are his words: 'Towards the middle of the height of one of the sides is a stone that may be raised up. It shuts an oblique passage which leads to a coffin placed in the centre of the pyramid.' This passage, open in our days, and which in the time of Strabo was towards the middle of one face of the pyramid, is at present only 100 feet from the base. So that the ruins of the covering of the pyramid, and of the stones brought from within, buried by the sand, have formed a hill in this place 200 feet high. Pliny confirms this opinion. The great sphynx was in his time upwards of 62 feet above the surface of the ground. Its whole body is at present buried under the sand. Nothing more appears of it than the neck and head, which are 27 feet high. If even the sphynx, though defended by the pyramids against the northerly winds, which bring torrents of sand from Libya, be covered as high as 38 feet, what an immense quantity must have been heaped up to the northward of an edifice whose base is upwards of 700 feet long? It is to this we must attribute the prodigious difference between the accounts of the historians who have measured the great pyramid at distant periods, and at opposite angles. Herodotus, who saw it in the age nearest to its foundation, when its true base was still uncovered, makes it 800 feet square. This opinion appears very probable. Pliny also says that it covered the space of eight acres.

"Messrs Shaw, Thevenot, and the other travellers who pretend that this pyramid was never finished, because it is open and without coating, are in an error. It is only necessary to observe the remains of the mortar, with the splinters of white marble which are to be found in many parts of the steps, to see that it has been coated. After reading attentively the description given of it by the ancients, every doubt vanishes, and the truth is as clear as day-light. Herodotus tells us, 'The great pyramid was covered with polished stones, perfectly well jointed, the smallest of which was 30 feet long. It was built in the form of steps, on each of which were placed wooden machines to raise the stones from one to another.' According to Diodorus, 'The great pyramid is built of stones, very difficult of workmanship, but of an eternal duration. It is preserved to our days (towards the middle of the Augustan age) without being in the least injured. The marble was brought from the quarries of Arabia.' This historian thought that the whole building was composed of stones, similar to those of the coating, which were of very hard marble. Had there been some pieces torn off, he would have perceived under that covering a calcareous stone rather soft. Pliny says that it 'is formed of stones brought from the quarries of Arabia. It is not far from the village of Busiris (which still exists under the name of *Bousir*), where those persons reside who are so skilful as to climb up the top.'

"This passage shows that Pliny, deceived by the appearance, was in the same error with Diodorus Siculus. It demonstrates also that it was covered: for what difficulty would there have been for the inhabitants of Busiris to scale a building raised by steps? but it was really a prodigy for them to get up it when it formed a mountain, the four inclined planes of which presented a surface covered with polished marble. It is indeed, an incontestable fact, that the great pyramid was coated. It is as certain too that it has been shut, as Strabo gives us to understand; and that by removing a stone placed in the middle of one of the sides, one found a passage which led to the tomb of the king. But I shall leave Mr Maillet, who visited it 40 times with all imaginable

imaginable attention, the honour of relating the means employed to open it. I have examined the inside of it in two different journeys: twice I have mounted it: and I cannot help admiring the sagacity with which that author has developed the mechanism of that astonishing edifice."

Our author next proceeds to give a particular description of the methods by which it is most probable that the pyramids were closed, and the immense labour requisite to open them. We must remark, that the final outlet to the workmen he supposes to have been the well at the entrance formerly mentioned. This well descends towards the bottom of the pyramid by a line not quite perpendicular to the horizon, but slanting a little, in such a manner as to resemble the figure of the Hebrew letter Lamed. About 60 feet from the aperture there is a square window in this passage, from whence we enter a small grotto hewn out of the mountain; which in this place is not a solid stone, but a kind of gravel concreted together. The grotto extends about 15 feet from east to west, where there is another groove hollowed likewise, but almost perpendicular. It is two feet four inches wide by two and a half in height. It descends through a space of 123 feet, after which we meet with nothing but sand and stones. M. Savary is convinced that the only use of this passage was to serve as a retreat for the labourers who constructed the pyramid; and of this he looks upon the slope of the conduit, its winding road, its smallness, and its depth, to be certain proofs. The way out of it he supposes to have been formed by a passage over which hung a row of stones, which they had discovered the secret of suspending, and which falling down into the passage by the means of some spring they set in motion, shut up the entrance for ever, as soon as the workmen were withdrawn from the pyramid.

It is not known in Europe when the pyramids were built; but we have reason to expect a history of them soon from Shanscrit records examined by Mr Wilford lieutenant of engineers. It is as little known at what time, or from what motive, the great pyramid was opened. Some think it was done by one of the khalifs about the beginning of the eighth century, in expectation of finding a great treasure; but all he met with was the king's body, with some golden idols which had been buried along with it.—By others, it is supposed to have been done by the celebrated Harun Al Raschid khalif of Bagdad; but all are agreed that this pyramid was opened in the time of the Arabs. The second pyramid has likewise been opened; and an attempt was made not long ago upon the third by one of the Beys of Cairo: but after removing a number of stones at a considerable expence, he thought proper to desist from the enterprise.—Mr Bryant is of opinion that the pyramids, at least the three great ones, are not artificial structures of stone and mortar, but solid rocks cut into a pyramidal shape, and afterwards cased with stone; and to this we find that Mr Bruce likewise assents. The reason given for this opinion is, that the passages within it seem rather to answer to the natural cavities and rents in rocks than to the artificial ones in buildings. The opinion, however, we think sufficiently confuted by Savary and Maillet: and, as an acute critic observes, it is in itself as improbable, as that the caverns inhabited by the *Troglodytes* were dug by the hands of man. See TROGLODYTES.

On the east side of the second pyramid is the sphynx, an enormous mass of one solid stone, but so buried in the sand that only the top of the back is visible, which is 100 feet long. Its head rises, as we have seen, 27 feet above the sand; and its face has been disfigured by the Arabs, who hold all representations of men and living animals in detestation. This figure was more completely exposed by digging round it in 1816.

In the desert of Saccara there is a great number of pyramids, which, in Mr Bruce's opinion, are composed of clay. They terminate in what the inhabitants call a *dagiour* or *false pyramid*, about two miles from the Nile, between Suf and Woodan. This is no other than a hill cut into the shape of a pyramid, or naturally so formed, for a considerable height; on the top of which is a pyramidal building of brick terminating in a point, and having its basis so exactly adapted to the top of the hill, that at a distance the difference cannot be perceived; especially as the face of the stones resembles very nearly the clay of which the pyramids of the Saccara are composed.

But a very different opinion concerning the purposes to which the great pyramid was originally destined, and the period in which that extraordinary edifice was erected, is held by Mr Gabb, who has not long since published an elaborate treatise on this subject. According to this author not only the great pyramid, but also the smaller pyramids are of antediluvian origin; the immense accumulation of sand around those stupendous structures took place at the time of the deluge; the height of this sand, when the waters subsided, probably reached the summit of the pyramid, and the apex of the great pyramid was torn off by the violent agitation of the waters.

But the most curious part of this author's disquisition concerning the pyramid relates to the purpose for which that stupendous fabric was raised; and here he is decidedly of opinion, that it was originally intended as a standard of measure, and not as has been more generally supposed as a sepulchral monument; and farther that the excavation of the celebrated granite chest in the interior of the pyramid was intended not for the repository of a corpse, but for a standard measure of capacity, as its length was for linear measure. This is also the opinion of the French sçavans who accompanied the army of Bonaparte to Egypt, and very successfully ascertained the dimensions of that remarkable building. The plan of the pyramid is a geometrical square, the side of which is equal to 400 cubits of Cairo, or the great Egyptian stadium. The length of the granite chest in the upper chamber of the pyramid is exactly four cubits, which is precisely one hundredth part of the base of the side of the pyramid. The commensurability of the component parts of the pyramid now mentioned, as well as of others discussed by the author, is undoubtedly a curious circumstance.

These wondrous structures still excite the curiosity of ingenious and enterprising men. In 1816 some researches were made by Mr Caviglia, who discovered a chamber in the pyramid of Cheops which had not been visited by any modern traveller. But the most interesting discovery was made by Mr Belzoni in March

1818. Long investigations among the monuments of Egypt had enabled this traveller to detect certain relations in their construction, from which he divined that an entrance existed into the interior of the pyramid of Cephrenes, and that this entrance was to be sought in a particular part of the north side, though no outward marks of it appeared, and though preceding travellers had acquiesced in the opinion that no chambers were to be found in it. With incredible labour, and after many discouragements, he was so fortunate as to find a passage which first led downward, at an angle of 26 degrees, and then horizontally to the centre of the pyramid. Here he entered a chamber 46 feet 3 inches long, 16 feet 3 inches wide, and 23 feet 6 inches high, for the most part cut out of the solid rock, except that part of the roof towards the western end. In the midst was a sarcophagus of granite, partly buried in the ground to the level of the floor, 8 feet long, 3 feet six inches wide, and 2 feet 3 inches deep inside, surrounded by large blocks of granite, being placed apparently to guard it from being taken away. The lid of it had been opened. He found in it only a few bones, supposed to be those of a human skeleton, but which it is said have since been found to belong to the skeleton of a bull. On the wall of the western side of the chamber is an Arabic inscription, a translation of which was said to be sent to the British Museum, but has not yet been published. It testifies that this pyramid was opened by Mahomet El Aghar, and Otman, and that it was inspected in presence of the sultan Ali Mahomet the first, Ugloch (a Tartaric title). There were several other inscriptions on the walls, supposed to be Coptic. Another chamber was found nearer the exterior of the pyramid on the north side, but sunk farther into the rock. It was smaller in size, and contained some inscriptions, but no sarcophagus was observed.

In the various exterior passages opened, it has been remarked that they have nearly all the same degree of declivity, forming an angle of about 26 degrees with the horizon. There is reason to suppose that this coincidence is not accidental, but that it was connected with astronomical purposes. It may have been intended to observe the passage over the meridian of a particular star. The dip gives a line of direction not very different from that point in the heavens where the north pole star now crosses the meridian below the pole.

These researches tend to confirm the opinions of Strabo and Diodorus Siculus, that the pyramids are sepulchral monuments. Some of them were probably destined to receive the bodies of their deities, and others those of their kings. But the cells discovered yet in the interior of these immense structures, occupy so small a part of their solid contents, that it is probable many more remain to be laid open. It is probable some will yet be found which have never been entered by the Arabs, or any of the other conquerors whose lust for hidden treasures made them ransack these mysterious depositories; and when some of these unviolated chambers are found, we will have a better idea of the original destination and use of these singular monuments. See DENON'S TRAVELS, and QUARTERLY REVIEW, N° 37 and 38.

PYRAMIDALES, in *Anatomy*, one of the muscles of the abdomen. See ANATOMY, *Table of the Muscles*.

PYRAMIDOID, a term which is occasionally employed to denote the parabolic spindle, or the solid formed by the rotation of a semiparabola about its base or greatest ordinate.

PYRENEAN MOUNTAINS, or **PYRENEES**, are the mountains which divide France from Spain, and are the most celebrated in Europe, except the Alps. They reach from the Mediterranean sea as far as the ocean, and are about 212 miles in length. They have different names, according to the different places wherein they stand. Mount Perdu, the highest of the Pyrenees, has an elevation of 1763 French toises, or 11,270 English feet.

PYRENEES, *Lower*, a department of France, lying at the foot of the Western Pyrenees. The country is beautifully diversified with mountains, valleys, forests, and wastes. The soil is better adapted for pasturage than tillage; but barley, wheat, oats, and maize, and vines, are cultivated; and there are mines of iron, copper, cobalt, with coal, slate, and marble. There are manufactories of coarse cloth, druggets, hosiery, linen, dimity, cotton yarn, &c. The superficial extent of this department is 755,950 hectares. The population in 1817 was 383,502; and the contributions for the year 1802 amounted to 1,523,760 francs. Pau is the chief town.

PYRENEES, *Upper*, a department in the south of France, lying at the foot of the mountains of the same name. The surface of the ground is mountainous, and feeds great numbers of cattle and sheep. Rye and barley are raised, but little wheat. Vines, mulberries, and flax are also cultivated. There are in the department 45 lead mines, 13 of iron, and 9 of copper, few of which however are wrought. It has few manufactures. Its territorial extent is 469,915 hectares; and the population in 1817 was 198,763. The contributions for 1802 amounted to 893,637 francs. Tarbes is the chief town.

PYRENEES, *Eastern*, a department in the south of France, at the eastern extremity of the mountains whose name it bears. The soil, though mountainous, produces corn, wine, oil, barley, flax, hemp, and legumes. Irrigation is practised here, and the lands to which it is applied yield two or three crops a-year. Oranges, lemons, and pomegranates are also produced here. There are many mines of iron; besides some of copper, lead, and coal. Wood is scarce. There are few manufactures. The extent of this department is 411,376 hectares. The population in 1817 was 126,625. Perpignan is the chief town.

PYRITES, a metallic substance combined with sulphur; as iron pyrites, composed of sulphur and iron; copper pyrites, of sulphur and copper. See MINERALOGY *Index*.

PYRMONT, a town of Lippe in Germany, in the circle of Westphalia, and capital of a country of the same name. It has a castle, kept by a governor, who is under the counts of Waldeck. At a small distance from hence there are mineral waters, which are much esteemed. The Protestants have here the free exercise of their religion. It is seated on the confines of the duchy of Brunswick, 40 miles south-west of Hanover. E. Long. 9. 0. N. Lat. 52. 0.

PYROLA, a genus of plants belonging to the decandria class, and in the natural method ranking under the 18th order, *Bicornes*. See BOTANY *Index*.

PYROMANCY,

Pyromancy, Pyrometer.

PYROMANCY, a kind of divination by means of fire. See DIVINATION, N° 6.

PYROMETER, an instrument for measuring the expansion of bodies by heat. See CHEMISTRY *Index*. Muschenbroeck, who was the original inventor of this machine, has given a table of the expansion of the different metals in the same degree of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at 32 degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the $\frac{1}{12500}$ part of an inch.

Expansion of	Iron.	Steel.	Copper.	Brass.	Tin.	Lead.
By one flame	80	85	89	110	153	155
By two flames placed close together.	117	123	115	220		274
By two flames $2\frac{1}{2}$ inches distant.	109	94	92	141	219	263
By three flames placed close together.	142	168	193	275		
By four flames placed close together.	211	270	270	361		
By five flames.	230	310	310	377		

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments, it appears at first view that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames placed together, cause a greater rarefaction than when they have a sensible interval between them; iron in the former case, being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious.

By comparing the expansions of the same metal produced by one, two, three, or more flames, it appears that two flames do not cause double the expansion of one, nor three flames three times that expansion, but always less; and these expansions differ so much the more from the ratio of the number of flames as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more some less. Thus tin began to run when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

Mr Ellicot found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow:

Gold,	Silver,	Brass,	Copper,	Iron,	Steel,	Lead,
73	103	95	89	60	56	149

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat. See PENDULUM.

Mr Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Mr Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw.

The following table shows how much a foot in length of each metal grows longer by an increase of heat, corresponding to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expressed in such parts of which the unit is equal to the 10,000th part of an inch.

1. White-glass barometer tube,	100
2. Martial regulus of antimony,	130
3. Blistered steel,	138
4. Hard steel,	147
5. Iron,	151
6. Bismuth,	167
7. Copper hammered,	204
8. Copper eight parts, with tin one,	218
9. Cast brass,	225
10. Brass sixteen parts, with tin one,	229
11. Brass-wire,	232
12. Speculum metal,	232
13. Spelter solder, viz. brass two parts, zinc one,	247
14. Fine pewter,	274
15. Grain tin,	298
16. Soft solder, viz. lead two, tin one,	301
17. Zinc eight parts, with tin one, a little hammered,	323
18. Lead,	344
19. Zinc or spelter,	353
20. Zinc hammered half an inch per foot,	373

We shall close this article with a brief description of a pyrometer invented by M. De Luc, in consequence of a hint suggested to him by Mr Ramsden. The basis of this instrument is a rectangular piece of deal-board two feet and a half long, 15 inches broad, and one inch and a half thick; and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long and an inch

Pyrometer. inch and a half square, well fitted near its four angles, and kept together at the other ends by four firm cross-pieces. This small table is suspended by a hook to a stand; the board being in a vertical situation in the direction of its grain, and bearing its legs forward in such a manner as that the cross-pieces which join them may form a frame, placed vertically facing the observer. This frame sustains a microscope, which is firmly fixed in another frame that moves in the former by means of grooves, but with a very considerable degree of tightness; the friction of which may be increased by the pressure of four screws. The inner sliding frame, which is likewise of deal, keeps the tube of the microscope in a horizontal position, and in great part without the frame, insomuch that the end which carries the lens is but little within the space between the frame and the board. This microscope is constructed in such a manner as that the object observed may be an inch distant from the lens: and it has a wire which is situated in the focus of the glasses, in which the objects appear reversed. At the top of the apparatus there is a piece of deal, an inch and a half thick and two inches broad, laid in a horizontal direction from the board to the top of the frame. To this piece the rods of the different substances, whose expansion by heat is to be measured, are suspended: one end of it slides into a socket, which is cut in the thickness of the board; and the other end, which rests upon the frame, meets there with a screw, which makes the piece move backward and forward, to bring the objects to the focus of the microscope. There is a cork very strongly driven through a hole bored vertically through this piece; and in another vertical hole made through the cork, the rods are fixed at the top; so that they hang only, and their dilatation is not counteracted by any pressure. In order to heat the rods, a cylindrical bottle of thin glass, about 21 inches high, and four inches in diameter, is placed in the inside of the machine, upon a stand independent of the rest of the apparatus. In this bottle the rods are suspended at a little less than an inch distance from one of the insides, in order to have them near the microscope. Into this bottle is poured water of different degrees of heat, which must be stirred about, by moving upwards and downwards, at one of the sides of the bottle, a little piece of wood, fastened horizontally at the end of a stick: in this water is hung a thermometer, the ball of which reaches to the middle of the height of the rods. During these operations the water rises to the cork, which thus determines the length of the heated part; the bottle is covered, to prevent the water from cooling too rapidly at the surface; and a thin case of brass prevents the vapour from fixing upon the piece of deal to which the rods are fixed.

Pyrometer. Pyrophorus.

PYROPHORUS, formed of πυρ, "fire," and φερω, "I bear," in *Chemistry*, the name usually given to that substance called by some black phosphorus; a chemical preparation possessing the singular property of kindling spontaneously when exposed to the air. See CHEMISTRY *Index*.

PYROTECHNY,

1 Definition.

LITERALLY signifies the art of fire, and is derived from πυρ, "fire," and τεχνη, "art." The term is now, however, generally confined to denote the art of making artificial fire-works, which has become a particular trade.

As this art depends chiefly on chemical principles, and as the objects about which it is employed afford some of the most gratifying spectacles on occasions of public rejoicing, we have not considered it unworthy of a place in our Encyclopædia; and we shall endeavour to give such an account of the operations and principles of the art as may satisfy those who wish to practise it by way of rational amusement.

2 Origin of the art uncertain.

Of the origin of artificial fire-works nothing certain appears to be recorded. We know that in Europe their invention is of a recent date, and appears due to the Italians. The use of fire-works in China seems to have been very general long before their invention in Europe, and that ingenious people have carried these exhibitions to a degree of perfection which European artists have yet scarcely attained. The following description of a Chinese display of fire-works by one of the gentlemen who accompanied Lord Macartney's embassy to Pekin, will give our readers some idea of the state of the art among that people.

3 Description of Chinese fire-works.

"The fire-works in some particulars, exceeded any thing of the kind I had ever seen. In grandeur, magnificence, and variety, they were, I own, inferior to the Chinese fire-works we had seen at Batavia, but infinitely superior in point of novelty, neatness, and ingenuity of contrivance. One piece of machinery I greatly admired; a green chest of five feet square was hoisted up by a pulley to the height of 50 or 60 feet from the ground; the bottom was so constructed as then suddenly to fall out, and make way for 20 or 30 strings of lanterns enclosed in the box to descend from it, unfolding themselves from one another by degrees, so as at last to form a collection of at least 500, each having a light of a beautifully coloured flame burning brightly within it. This devolution and developement of lanterns (which appeared to me to be composed of gauze and paper) were several times repeated, and every time exhibited a difference of colour and figure. On each side was a correspondence of smaller boxes, which opened in like manner as the others, and let down an immense net-work of fire, with divisions and compartments of various forms and dimensions, round and square, hexagons, octagons, and lozenges, which shone like the brightest burnished copper, and flashed like prismatic lightning, with every impulse of the wind. The diversity of colours indeed with which the Chinese have the secret of clothing fire seems one of the chief merits of their pyrotechny. The whole concluded with a volcano, or general explosion and discharge of suns and stars, squibs, bouncers, crackers, rockets, and grenadoes, which involved the gardens for above an hour after in a cloud of intolerable smoke *."

* Barrow's Travels in China, p. 106.

4 Till of late the French and Italian makers of fire-works

Apparatus, Materials, &c. of Fire-works.

works much excelled our British artists, and even now, though the practice of the art is well understood among us, its principles are almost entirely unknown; and no English work of any respectability has appeared on the subject. In France, the art has been more fortunate, and several men of eminent literary abilities have condescended to make it an object of their attention. It will be sufficient, in proof of this, to mention the names of Ozanam and Montucla. The following works are recommended by the latter, as containing the best account of this amusing art; viz.

Traité des Feux d'Artifice (Treatise on Artificial Fire-works), by M. Frezier, a new edition of which appeared in 1745.

Traité des Feux d'Artifice pour le Spectacle et pour la Guerre, (Treatise on Artificial Fire-Works, employed in Exhibitions and in War), by M. Perrinet d'Orval.

Manuel d'Artificier, (Artificial Fire-Work-Maker's Manuel), published at Paris in 1757, by Father d'Incarville.

Indeed most of the written information which we possess on the making of fire-works, is derived from the French; and many of these productions still retain French names, such as *gerbes*, *balloons*, *marroons*, *tourbillons*, *saucissons*, &c.

5 We shall divide this article into two chapters; in the first of which we shall consider the apparatus required for forming the cases or shells of artificial fire-works, and the materials employed in their construction; and in the second we shall describe the different kinds of fire works and the most approved methods of constructing them.

Chap. I. *Of the Apparatus and Materials employed in making Fire-Works.*

Sect. I. *Of Apparatus.*

6 Apparatus.

The apparatus used in making fire-works consists chiefly of solid wooden cylinders, called *formers*, for rolling the cases on; similar cylinders either of wood or metal for ramming down the composition; moulds for holding the cases while filling, a machine for *choaking* or contracting the cavity of the cases, another for grinding the materials, and a particular apparatus for boring some cases after they are filled.

7 Rocket moulds Plate CCCLII. fig. 1.

We shall begin with describing the moulds, as on the size of these depends that of the *formers* and *rammers*. As the performance of rockets depend much on their moulds, it is requisite to give a description of them and their proportions: They are made and proportioned by the diameter of their orifice, which is divided into equal parts. Fig. 1. represents a mould made by its diameter AB: its height from C to D is six diameters and two-thirds; from D to E is the height of the foot, which is one diameter and two-thirds; F the *choak* or cylinder, whose height is one diameter and one third; it must be made out of the same piece as the foot, and fit tight in the mould; G is an iron pin that goes through the cylinder to keep the foot fast; H the nipple, which is half a diameter high, and two-thirds thick, and of the same piece of metal as the *piercer* I, whose height is three diameters and a half, and at the bottom it is one-third of the diameter thick, from thence tapering to one-sixth of the diameter. The piercer is an iron pin rising from the nipple, and intended to preserve a vacuity in the centre of the charge. The best way to fix the piercer in the cylinder, is to make that part below the nipple long enough to go quite through the foot, and rivet it at bottom. Fig. 2. is a *former* or roller for the cases, whose length from the handle is seven diameters and a half, and its diameter two-thirds of the bore. Fig. 3. is a part attached to the former, which is of the same thickness, and one diameter and two-thirds long; the small part, which fits into the hole in the end of the roller when the case is pinching is one-sixth, and one half of the mould's diameter thick. Fig. 4. the first drift or rammer, which must be six diameters from the handle; and this, as well as all other rammers, must be a little thinner than the former, to prevent the sacking of the paper when driving in the charge. In the end of this rammer is a hole to fit over the piercer: the line K marked on this is two diameters and one-third from the handle; so that, when filling the rocket, this line appears at top of the case: you must then take the second rammer, (fig. 5.) which from the handle is four diameters, and the hole for the piercer is one diameter and a half long. Fig. 6. is the short and solid drift which is used when the case has been filled as high as the top of the piercer.

Fig. 2. Fig. 3. Fig. 4. Fig. 5, 6.

Rammers must have a collar of brass at the bottom, to keep the wood from spreading or splitting, and the same proportion must be given to all moulds, from one ounce to six pounds. We mentioned nothing concerning the handles of the rammers; however, if their diameters be equal to the bore of the mould, and two diameters long, it will be a very good proportion: but the shorter they can be used, the better; for the longer the drift, the less will be the pressure on the composition by the blow given with the mallet.

The following are the dimensions for rocket moulds, when the rockets are rammed solid.

Weight of Rockets		Length of the moulds without their feet.	Interior diameter of the moulds.	Height of the nipples.
lb	oz.	Inches.	Inches.	Inches
6	0	34,7	3,5	1,5
4	0	38,6	2,9	1,4
2	0	13,35	2,1	1,0
1	0	12,25	1,7	0,85
0	8	10,125	1,333	0,6
0	4	7,75	1,125	0,5
0	2	6,2	0,9	0,45
0	1	4,9	0,7	0,33
0	½	3,9	0,55	0,25
6 drams		3,5	0,5	0,225
4 drams		2,2	0,3	0,2

N. B. The diameter of the nipple must always be equal to that of the former.

We shall now show the method of finding the diameters or calibres of rockets, according to their weight; but we must first observe, that a pound rocket, is that just

just capable of admitting a leaden bullet of a pound weight, and so of the rest. The calibre for the different sizes may be found in the two following tables, one of which is calculated for rockets of a pound weight and under; and the other for those from a pound to 50 pounds.

8 Method of finding the diameters of rockets according to their weight.

TABLE I. *Of the Calibre of Moulds of a pound weight and below.*

Ounces.	Lines.	Drams.	Lines.
16	19½	14	7¼
12	17	12	7
8	15	10	6⅓
7	14¾	8	6¼
6	14¼	6	5⅔
5	13	4	4½
4	12⅔	2	3¼
3	11½		
2	9⅙		
1	6½		

The use of this table will be understood merely by inspection; for it is evident that the mould for a rocket of 12 ounces ought to be 17 lines in diameter; one of eight ounces, 15 lines; one of 10 drams, 6⅓ lines; and so of the rest.

On the other hand, if the diameter of the rocket be given, it will be easy to find the weight of the ball corresponding to that calibre. For example, if the diameter be 13 lines, it will be immediately seen, by looking for that number in the column of lines, that it corresponds to a ball of five ounces.

II. *Table of the Calibre of Moulds from one to 50 pounds ball.*

Pounds.	Calibre.	Pounds.	Calibre.	Pounds.	Calibre.
1	100	18	262	35	326
2	126	19	267	36	330
3	144	20	271	37	333
4	158	21	275	38	336
5	171	22	280	39	339
6	181	23	284	40	341
7	191	24	288	41	344
8	200	25	292	42	347
9	208	26	296	43	350
10	215	27	300	44	353
11	222	28	304	45	355
12	228	29	307	46	358
13	235	30	310	47	361
14	241	31	314	48	363
15	247	32	317	49	366
16	252	33	320	50	368
17	257	34	323		

The use of this second table is as follows: If the weight of the ball be given, which we shall suppose to be 24 pounds, seek for that number in the column of pounds, and opposite to it, in the column of calibres, will be found the number 288. Then say, as 100 is to 19½, so is 288 to a fourth term, which will be the number of lines of the calibre required; or multiply the number found, that is 288, by 19½, and from the produce 5616, cut off the two last figures; the required calibre, therefore, will be 56,16 lines, or four inches eight lines.

On the other hand, the calibre being given in lines, the weight of the ball may be found with equal ease. If the calibre, for example, be 28 lines, say as 19½ is to 28, so is 100 to a fourth term, which will be 143.5, or nearly 144. But in the above table, opposite to 144 in the second column, will be found the number 3 in the first; which shows that a rocket, the diameter or calibre of which is 28 lines, is a rocket of a three pounds ball.

Fig. 7. represents a mould, in which the cases are driven solid; L the nipple, with a brass point at top, (flat at top, and of the same length as the neck of the case), which, when the case is filling, serves to stop the neck, and prevent the composition from falling out, as without this point it would; and, in consequence, the air would get into the vacancy in the charge, and at the time of firing cause the case to be burst. These moulds are made of any length or diameter, according as the cases are required; but the diameter of the rollers must be equal to half the bore, and the rammers made quite solid. The nipple and cylinders must bear the same proportion as those for rockets.

Fig. 7. 9 Moulds for serpents & wheel-cases.

The rolling and formation of cases is so intimately connected with the construction of *moulds* and *formers*, that we shall introduce what we have to say on that subject into the same section.

Sky-rocket cases are to be made 6½ of their exterior diameter long; and all other cases that are to be filled in moulds must be as long as the moulds, within half its interior diameter.

10 Method of rolling cases.

Rocket cases from the smallest to four or six pounds, are generally made of the strongest sort of cartridge-paper, and rolled dry; but the large sort are made of pasted pasteboard. As it is very difficult to roll the ends of the cases quite even, the best way will be to keep a pattern of the paper for the different sorts of cases; which pattern should be somewhat longer than the case it is designed for, and on it marked the number of sheets required, which will prevent any paper being cut to waste. Having cut the papers of a proper size, and the last sheet for each case with a slope at one end, so that when the cases are rolled it may form a spiral line round the outside, and that this side may always be the same, let the pattern be so cut for a guide. Before you begin to roll, fold down one end of the first sheet, so far that the fold will go two or three times round the former: then, on the double edge, lay the former with its handle off the table; and when you have rolled on the paper within two or three turns, lay the next sheet on that part which is loose, and roll it all on.

Having thus done, you must have a smooth board, about 20 inches long, and equal in breadth to the length of the case. In the middle of this board must be a handle placed lengthwise. Under this board lay the case, and let one end of the board lie on the table; then press hard on it, and push it forwards, which will roll the paper very tight; do this three or four times before you roll on any more paper. This must be repeated with every other sheet of paper, till the case is thick enough;

Apparatus, Materials, &c. of Fire-works.

enough; but if the rolling board be drawn backwards, it will loosen the paper: you are to observe when you roll on the last sheet, that the point of the slope be placed at the small end of the roller. Having rolled your case to fit the mould, push in the small end of the former F, about one diameter from the end of the case, and put in the end-piece within a little distance of the former; then give the pinching cord one turn round the case, between the former and the end-piece; at first pull gently, and keep moving the case, which will make the neck smooth, and without large wrinkles. When the cases are hard to choak, let each sheet of paper (except the first and last, in that part where the neck is formed) be a little moistened with water: immediately after you have struck the concave stroke, bind the neck of the case round with small twine, which must not be tied in a knot, but fastened with two or three hitches.

Having thus pinched and tied the case, so as not to give way, put it into the mould without its foot, and with a mallet drive the former hard on the end-piece, which will force the neck close and smooth. This done, cut the case to its proper length, allowing from the neck to the edge of the mouth half a diameter, which is equal to the height of the nipple; then take out the former, and drive the case over the piercer with the long rammer, and the vent will be of a proper size. Wheel-cases must be driven on a nipple with a point to close the neck, and make the vent of the size required; which, in most cases, is generally one fourth of their interior diameter. As it is very often difficult, when the cases are rolled, to draw the roller out, you may make a hole through the handle, and put in it a small iron pin, by which you may easily turn the former round and pull it out. Fig. 8. shows the method of pinching cases; P a treddle, which, when pressed hard with the foot will draw the cord tight, and force the neck as close as you please; Q a small wheel or pulley, with a groove round it for the cord to run in.

Fig. 8.

Cases for wheels and fixed pieces are commonly rolled wet; and when they are required to contain a great length of charge, the method of making those cases is this: The paper must be cut as usual, only the last sheet must not be cut with a slope: Having the paper ready, paste each sheet on one side; then fold down the first sheet as before directed: but be careful that the paste does not touch the upper part of the fold; for if the roller be wetted, it will tear the paper in drawing it out. In pasting the last sheet, observe not to wet the last turn or two in that part where it is to be pinched; for if that part be damp, the pinching cord will stick to it, and tear the paper: therefore when you choke those cases, roll a bit of dry paper once round the case before you put on the pinching cord; but this bit of paper must be taken off after the case is choked. The rolling board, and all other methods, according to the former directions for the rolling and pinching of cases, must be used to these as well as all other cases.

11 Tourbillon cases.

Tourbillon cases are generally made about eight diameters long; but if very large, seven will be sufficient: tourbillons will answer very well from four ounces to two pounds; but when larger there is no certainty. The cases are best rolled wet with paste, and the last sheet must have a straight edge, so that the case may be all of a thickness: when the cases have been rolled in the manner of wheel cases, pinch them at one end quite close; then with the rammer drive the ends down flat, and afterwards ram in about one-third of a diameter of dried clay. The diameter of the former for these cases must be the same as of that for sky-rockets.

N. B. Tourbillons are to be rammed in moulds without a nipple, or in a mould without its foot.

12 Balloon cases, or paper shells.

For *balloons*, first prepare an oval former turned of smooth wood; over which pasting a quantity of brown or cartridge paper, let it lie till the paste has quite soaked through; this done, rub the former with soap or grease, to prevent the paper from sticking to it; then lay the paper on in small slips till you have made it one-third of the thickness of the intended shell. This being done, set it to dry; and when dry, cut it round the middle, and the two halves will easily come off; but observe, when you cut, to leave about one inch uncut, which will make the halves join much better than if they had been quite separated. When there are some ready to join, place the halves evenly together, paste a slip of paper round the opening to hold them together, and let that dry; then lay on paper all over as before, everywhere equal, excepting that end which goes downwards in the mortar, which may be a little thicker than the rest; for that part which receives the impulse from the powder in the chamber of the mortar requires the greatest strength. When the shell is thoroughly dry, burn a round hole at top, with square iron, large enough for the fuze: this method will do for balloons from four inches two-fifths, to eight inches diameter; but if they are larger, or required to be thrown a great height, let the first shell be turned of elm, instead of being made of paper.

For a balloon of four inches two-fifths, let the *former* be three inches one-eighth diameter, and five inches and a half long. For a balloon of five inches and a half, the diameter of the *former* must be four inches, and eight inches long. For a balloon of eight inches, let the diameter of the *former* be five inches and 15-16ths, and 11 inches seven-eighths long. For a 10-inch balloon, let the *former* be seven inches three-sixteenths diameter, and 14 inches and a half long. The thickness of a shell for a balloon of four inches two-fifths, must be one-half inch. For a balloon of five inches and a half, let the thickness of the paper be five-eighths of an inch. For an eight-inch balloon, seven-eighths of an inch. And for a 10-inch balloon, let the shell be one inch one-eighth thick.

Shells that are designed for stars only, may be made quite round, and the thinner they are at the opening, the better; for if they are too strong, the stars are apt to break at the bursting of the shell: when making the shell, use a pair of calibre compasses, or a round gage, so that the paper may not be laid thicker in one place than another; and also to know when the shell is of a proper thickness. Balloons must always be made to go easy into the mortars.

13 Cases for port-fires.

Port-fire cases must be made very thin, and rolled on *formers*, from two inches to $\frac{5}{8}$ of an inch diameter, and from two to six inches long: they are pinched close at one end, and left open at the other. When they are to be filled, put in but little composition at a time, and ram it lightly, so as not to break the case: three or four rounds of paper, with the last round pasted, will be strong enough for these cases.

Common port-fires are intended for the purpose of firing

Apparatus, Materials, &c. of Fire-works.

ing the works, their fire being very slow, and the heat of the flame so intense, that, if applied to rockets, leaders, &c. it will fire them immediately. Portfires may be made of any length, but are seldom made more than 21 inches long: the interior diameter of portfire moulds should be 10-16ths of an inch, and the diameter of the former half an inch. The cases must be rolled wet with paste, and one end pinched, or folded down. The moulds should be made of brass, and such as will take in two pieces lengthwise; when the case is in the two sides, they are held together by brass rings, or hoops, which are made to fit over the outside. The bore of the mould must not be made quite through, so that there will be no occasion for a foot. These portfires, when used, are held in copper sockets, fixed on the end of a long stick: these sockets are made like port crayons, only with a screw instead of a ring.

14 For common portfires.

15 Method of grinding the ingredients.

There have been many methods contrived for grinding the ingredients for fire-works to a powder, such as large mortars and pestles made of ebony and other hard wood, and horizontal mills with brass barrels; but none have proved so effectual and speedy, as that of the mealing-table, represented in fig. 9. made of elm, with a rim round its edge four or five inches high; and at the narrow end A, furnished with a slider that runs in a groove, and forms part of the rim: so that when you have taken out of the table as much powder as you can with the copper shovel (fig. 10.), sweep all clean out at the slider A. When about to meal a quantity of powder, observe not to put too much in the table at once; but when you have put in a good proportion, take the muller (fig. 11.) and rub it till all the grains are broken; then sift it in a lawn sieve that has a receiver and top to it, such as is used by the apothecaries, and that which does not pass through the sieve, must be returned again to the table, and ground till it is fine enough to go through the sieve. Sulphur and charcoal are ground in the same manner, only the muller must be made of ebony; for these ingredients being harder than powder, would stick in the grain of elm, and be difficult to grind. As sulphur is apt to stick and clod to the table, it will best to keep one for that purpose, by which means you will always have your brimstone clean and well ground.

Fig. 9.

Fig. 10.

Fig. 11.

Fig. 12.

16 Apparatus for boring rockets that are rammed solid.

Fig. 12. represents the plan of an apparatus, or lathe, for boring rockets. A the large wheel, which turns the small one B, that works the rammer C: these rammers are of different sizes according to the rockets; they must be of the same diameter as the top of the intended bore, and continue that thickness a little longer than the depth of the bore required, and their points must be like that of an augre: the thick end of each rammer must be made square, and all of the same size, so as to fit into one socket, into which they are fastened by a screw D. E the guide for the rammer, which is made to move backwards and forwards; so that, after the rammer has been marked three diameters and a half of the rocket from the point, set the guide, allowing for the thickness of the fronts of the rocket boxes, and the neck and mouth of the rocket; so that when the front of the large box is close to the guide, the rammer may not go too far up the charge. F, boxes for holding the rockets, which are made so as to fit one within; their sides must be equal in thickness to the difference of the diameters of the rockets, and their interior diameters equal to the exterior diameters of the rockets. To prevent the rocket from turning round while boring, a piece of wood must be placed against the end of the box in the inside, and pressed against the tail of the rocket. This will also hinder the rammer from forcing the rocket backwards. G, a rocket in the box. H, a box that slides under the rocket-boxes to receive the borings for the rockets, which fall through holes made on purpose in the boxes; these holes must be just under the mouth of the rocket, one in each box, and all to correspond with each other.

Fig. 13. is a front view of the large rocket-box. I, an iron plate, in which are holes of different sizes, through which the rammer passes; this plate is fastened with a screw in the centre, so that when the rammer is changed the plate is turned round, but the hole you are going to use must always be at the bottom: the fronts of the other boxes must have holes in them to correspond with those in the plate. K, the lower part of the large box; which is made to fit the inside of the lathe, that all the boxes may move quite steadily. Fig. 13.

Fig. 14. is a perspective view of the lathe. L, the guide for the rammer, which is set by the screw at bottom. Fig. 14.

Fig. 15. A view of the front of the guide facing the rammer. M, an iron plate, of the same dimensions as that on the front of the box, and placed in the same direction, and also to turn on a screw in the centre. N, the rocket-box which slides backwards and forwards: when a rocket is fixed in the box, it is to be pushed forwards against the rammer; and when the scoop of the rammer appears to be full, draw the box back, and knock out the composition: this must be done till the rocket is bored, or it will be in danger of taking fire; and if the boring be done in a hurry, wet the end of the rammer now and then with oil to keep it cool. Fig. 15.

Having bored a number of rockets, you must have taps of different sorts according to the rockets. These taps are a little longer than the bore: but when used they must be marked 3½ diameters from the point, allowing for the thickness of the rocket's neck; then, holding the rocket in one hand, tap it with the other. One of these taps is represented by fig. 16. They are made in the same proportion as the fixed piercers, and are hollowed their whole length. Fig. 16.

17 Hand machine for boring. Fig. 17.

There are hand machines for boring, which answer very well, though not so expeditious as the lathes. But they are not so expensive, and they may be worked by one man; whereas the lathe will require three. Fig. 17. represents the machine. O, the rocket boxes, which are to be fixed, and not to slide as those in the lathe. PQ are guides for the rammers, that are made to slide together, as the rammer moves forward; the rammers for these machines must be made of a proper length, allowing for the thickness of the front of the boxes, and the length of the mouth and neck of the case; on the square end of these rammers must be a round shoulder of iron, to turn against the outside of the guide Q, by which means the guides are forced forwards. R, the stock which turns the rammer, and which while turning, must be pressed towards the rocket by the body of the man who works it; all the rammers are to be made to fit one stock.

SECT.

Apparatus, Materials, &c of Fire-works.

Sect. II. *Of the Ingredients for composing the Charges of Fire-works.*

18
Ingredients for the charges of fire works.

The charges or compositions with which the cases that we have described are to be filled, consist chiefly of gunpowder, or of a powder composed of the same materials in various proportions, and some other combustible substances, intended either to give the composition a stronger impelling force, or to increase the beauty and splendour of the exhibition. As the nature and composition of gunpowder have been fully explained under the article Gunpowder, it is unnecessary to consider them in this place; but as the makers of fire-works commonly employ considerable quantities of the substances of which gunpowder is composed, it may be proper to give some directions for obtaining these in the greatest purity. We may also notice, that gunpowder, in its ordinary state, is called *corn-powder;* while, when ground down, as directed in N° 15. it is denominated *meal-powder.*

19
Nitre.

The ingredient on which the force of the compositions chiefly depends, is nitre or saltpetre; but as this substance, in its usual state, is very impure, being much contaminated with earthy matter, and as pure nitre is now become very expensive, it is of consequence to know how the nitre of commerce may be purified.

20
Method of purifying nitre.

Nitre, like most other saline bodies, is much more soluble in boiling water, than in water of the ordinary temperature. If, therefore, the nitre of commerce be dissolved in a small quantity of boiling water, and the solution be properly strained, the liquor, when cold, will afford crystals that are very pure. The following is the most convenient method of proceeding. Dissolve the nitre in boiling water, in the proportion of about an English quart, or Scotch chopin, to each pound of nitre; and that the solution may be more easily effected, let the nitre be reduced to powder, and let the vessel containing the nitre and water be kept at the boiling heat till all the salt is dissolved. Then strain the liquor while hot through thick blotting paper, placed in a clean funnel, and set by the filtered liquor in a shallow vessel, in some cold place, till crystals are formed. These must be removed from the liquor, and dried with a gentle heat; and if the remaining liquor be slowly evaporated over the fire, in an earthen unglazed vessel, till a film appears on the top, and then set by to crystallize as before, an additional quantity of pure nitre will be procured; and thus, by repeated evaporations and crystallizations, the whole of the salt will be obtained.

21
Method of procuring nitre from damaged gunpowder.

Nitre may be obtained in great purity from damaged gunpowder, which may often be bought at a cheap rate. The damaged powder must be ground with a small quantity of hot water, in a large wooden or stone mortar, or it may be boiled over a gentle fire, with as much water as will cover it. When the water seems to have dissolved as much of the nitre as it will retain, it is to be poured off from the sediment, and filtered or strained through a flannel bag, then heated again, and, while hot, filtered through blotting paper, and set by to crystallize, as in the former case. Fresh quantities of hot water are to be successively added to the sediment, and strained as before, till the whole of the nitre is obtained.

22
Speedy method of powdering nitre.

Nitre may be speedily reduced to a fine powder, by dissolving it in a little more than its own weight of boiling water, in a kettle with a round bottom, keeping the solution over a gentle fire, and continually stirring it with a wooden spatula till all the water is evaporated, and the remaining powder is pretty well dried. Care must be taken, however, not to suffer it to remain too long, or expose it to too great a heat, otherwise it will be melted into a firm cake. The drying may be completed by suffering it to lie for a sufficient time on paper before the fire.

23
Sulphur.

Sulphur or brimstone, may be employed in three states. 1. As it is brought from the neighbourhood of volcanoes, or what is called *sulphur vivum.* 2. Roll brimstone, which is sold by most grocers, and is employed for making matches; and, 3. Flowers of sulphur, or sublimed sulphur. The first of these is the cheapest, and answers very well for coarse fire-works; the second is considered as the strongest, and is most used; but the third is the purest sulphur, and will answer best for the nicer and more delicate fire-works. It also has the advantage of being in a state of fine powder, whereas the two former require to be ground or mealed, as directed in N° 15.

24
Charcoal.

Charcoal may, in general, be procured at the shops of founders and hardware dealers; but when this is not the case, it may easily be prepared by putting a quantity of small pieces of wood into a large earthen crucible or iron pot, and covering them to the head with sand, and placing the crucible or the pot in the middle of a strong fire, where it must be kept red hot for an hour or two, in proportion to the quantity of wood. Charcoal should be chosen soft and light, and such as may easily be reduced to powder. It should be kept in a dry place, but is always best when fresh burned.

Several other ingredients are employed in the composition of fire-works, such as camphor, antimony (*sulphuret of antimony*), raspings of ivory, yellow amber, sal ammoniac, verdigris, common pitch, and Greek pitch, all of which are used on different occasions, to produce a change of colour in the fire; filings of iron and copper, for giving a sparkling appearance to the flame, and salt of benjamin (*benzoic acid*) to produce an agreeable odour. 25

26
Method of powdering cast-iron.

Iron filings answer very well for ordinary fire-works; but they do not produce such a brilliant appearance as powdered cast-iron. The introduction of this latter is an improvement of the Chinese, and its use is now very general.

Cast-iron being of so hard a nature as not to be cut by a file, we are obliged to reduce it into grains, though this is rather difficult to perform; but if we consider what beautiful sparks this iron yields, no pains should be spared to granulate such an essential material: to do this, procure at an iron-foundery some thin pieces of iron, such as generally run over the mould at the time of casting: then have a square block made of cast-iron, and an iron square hammer about four lb. weight; then, having covered the floor with cloth or something to catch the beatings, lay the thin pieces of iron on the block, and beat them with the hammer till reduced into small grains; which afterwards sift with a very fine sieve, to separate the fine dust, which is sometimes used in small cases of brilliant fire, instead of steel dust; and when you have got out all the dust, sift what remains with a sieve

Apparatus, Materials, &c. of Fire-works.

sieve a little larger, and so on with sieves of different sizes, till the iron passes through about the bigness of small bird-shot: the iron, thus beaten and sifted, is to be put separately, according to its fineness, into wooden boxes or oiled paper, to keep it from rusting. When used, observe the difference of its size, in proportion to the cases for which the charge is intended; for the coarse sort is proper only for very large gerbes of six or eight pounds.

When these pieces of iron cannot be procured, an old cast-iron pot may be employed; but care must be taken that its surface be perfectly freed from rust. This pulverized cast iron is sometimes called *iron sand*, and is denominated, according to its fineness, sand of the first, second, third, &c. order, that of the first order being the finest.

It sometimes happens, that fire-works may be required to be kept a long time, or sent abroad; neither of which could be done with brilliant fires, if made with filings unprepared, for this reason; that the saltpetre being of a damp nature, it causes the iron to rust; the consequence of which is, that when the works are fired, there will appear but very few brilliant sparks, but instead of them a number of red and drossy sparks; and besides, the charge will be so much weakened, that if this were to take place in wheels, the fire would scarcely be strong enough to force them round. But to prevent such accidents, the filings may be thus prepared: Melt in a glazed earthen pan some brimstone over a slow fire, and when melted throw in some filings; which keep stirring till they are covered with brimstone: this must be done while it is on the fire; then take it off, and stir it very quickly till cold, when it must be rolled on a board with a wooden roller, till broken as fine as corn powder; after which sift from it as much of the brimstone as possible. There is another method of preparing filings, so as to keep two or three months in winter; this may be done by rubbing them between strong brown paper, which before has been moistened with linseed oil.

N. B. If the brimstone should take fire, it may be extinguished, by covering the pan close at top: it does not signify what quantity of brimstone is used, provided there is enough to give each grain of iron a coat; but as much as will cover the bottom of a pan of about one foot diameter, will do for five or six pounds of filings or cast-iron for gerbes.

28 Chinese fire.

Before we enumerate the various compositions generally employed in filling cases for rockets, wheels, &c. we shall describe two compositions that are much valued for the brilliancy of their appearance. One of these is called *Chinese fire*, and is either red or white. The following tables shew the proportions of the different ingredients for each of these compositions; as they are adapted to rockets (in the construction of which the Chinese fire is much employed) of from 12 to 36 lbs.

Composition of Red Chinese Fire.

Calibres.	Saltpetre	Sulphur.	Charcoal.	Sand of the first order.	
Pounds.	Pounds.	Ounces.	Ounces.	Oz.	Dr.
12 to 15	1	3	4	7	0
18 to 21	1	3	5	7	8
24 to 36	1	4	6	8	0

For White Chinese Fire.

Calibres.	Saltpetre.	Bruised Gunpowder.	Charcoal.		Sand of the third order.	
Pounds.	Pounds.	Ounces.	Oz.	Dr.	Oz.	Dr.
12 to 15	1	12	7	8	11	0
18 to 21	1	11	8	0	11	8
14 to 36	1	11	8	8	12	0

The other composition is called spur-fire, because the sparks yielded by it have a starry appearance like the rowel of a spur. 29 Spur-fire.

Spur-fire.—This fire is the most beautiful and curious of any yet known; and was invented by the Chinese, but now is in greater perfection in England than in China. As it requires great trouble to make it to perfection, it will be necessary that beginners should have full instructions; therefore care should be taken that all the ingredients are of the best, that the lamp black is not damp and clodded, that the saltpetre and brimstone are thoroughly refined. This composition is generally rammed in one or two ounce cases about five or six inches long, but not drove very hard; and the cases must have their concave stroke struck very smooth, and the choak or vent not quite so large as the usual proportion: this charge, when driven and kept a few months, will be much better than when rammed; and will not spoil, if kept dry, in many years.

As the beauty of this composition cannot be seen at so great a distance as brilliant fire, it has a better effect in a room than in the open air, and may be fired in a chamber without any danger: it is of so innocent a nature, that, though with an improper phrase, it may be called a *cold fire;* and so extraordinary is the fire produced from this composition, that, if well made, the sparks will not burn a handkerchief when held in the midst of them; you may hold them in your hand while burning, with as much safety as a candle; and if you put your hand within a foot of the mouth of the case, you will feel the sparks like drops of rain.—When any of these spur-fires are fired singly, they are called *artificial flower-pots;* but some of them placed round a transparent pyramid of paper, and fired in a large room, make a very pretty appearance.

The composition consists of saltpetre, four pounds eight ounces; sulphur two pounds, and lamp-black one pound eight ounces; or, saltpetre one pound, sulphur, half a pound, and lamp-black four quarts.—This composition is very difficult to mix. The saltpetre and brimstone must be first sifted together, and then put into a marble mortar, and the lamp-black with them, which you work down by degrees with a wooden pestle, till all the ingredients appear of one colour, which will be something grayish, but very near black: then drive a little into a case for trial, and fire it in a dark place; and if the sparks which are called *stars*, or *pinks*, come out in clusters, and afterwards spread well without any other sparks, it is a sign of its being good, otherwise not; for if any drossy sparks appear, and the stars not full, it is then not mixed enough; but if the pinks are very small, and soon break, it is a sign that it has been rubbed too much.

This

Apparatus, Materials, &c. of Fire-works.

This mixture, when rubbed too much, will be too fierce, and hardly show any stars; and, on the contrary, when not mixed enough, will be too weak, and throw out an obscure smoke, and lumps of dross, without any stars.

The following compositions are those commonly employed in ordinary fire-works.

30 Charges for sky-rockets.

Rockets of four ounces.—Mealed powder 1 lb. 4 oz. saltpetre 4 oz. and charcoal 2 oz.

Rockets of eight ounces.—I. Mealed powder 1 lb. saltpetre 4 oz. brimstone 3 oz. and charcoal $1\frac{1}{2}$ oz. II. Meal-powder $1\frac{1}{2}$ lb. and charcoal $4\frac{1}{4}$ oz.

Rockets of one pound.—Meal-powder 2 lb. saltpetre 8 oz. brimstone 4 oz. charcoal 2 oz. and steel-filings $1\frac{1}{2}$ oz.

Sky-rockets in general.—I. Saltpetre 4 lb. brimstone 1 lb. and charcoal $1\frac{1}{2}$ lb. II. Saltpetre 4 lb. brimstone $1\frac{1}{2}$ lb. charcoal 1 lb. 12 oz. and meal-powder 2 oz.

Large sky-rockets.—Saltpetre 4 lb. meal-powder 1 lb. and brimstone 1 lb.

Rockets of a middling size.—I. Saltpetre 8 lb. sulphur 3 lb. meal-powder 3 lb. II. Saltpetre 3 lb. sulphur 2 lb. meal-powder 1 lb. charcoal 1 lb.

31 For rocket stars.

White stars.—Meal-powder 4 oz. saltpetre 12 oz. sulphur vivum 6 oz. oil of spike 2 oz. and camphor 5 oz.

Blue stars.—Meal-powder 8 oz. saltpetre 4, sulphur 2, spirit of wine 2, and oil of spike 2.

Coloured or *variegated stars.*—Meal-powder 8 drams, rochpetre 4 oz. sulphur vivum 2, and camphor 2.

Brilliant stars.—Saltpetre $3\frac{1}{2}$ oz. sulphur $1\frac{1}{2}$, and meal-powder $\frac{1}{4}$, worked up with spirits of wine only.

Common stars.—Saltpetre 1 lb. brimstone 4 oz. antimony $4\frac{3}{4}$, isinglass $\frac{1}{2}$, camphor $\frac{1}{2}$, and spirit of wine $\frac{3}{4}$.

Tailed stars.—Meal-powder 3 oz. brimstone 2, saltpetre 1, and charcoal (coarsely ground) $\frac{3}{4}$.

Drove stars.—I. Saltpetre 3 lb. sulphur 1 lb. brass dust 12 oz. antimony 3. II. Saltpetre 1 lb. antimony 4 oz. and sulphur 8.

Fixed pointed stars.—Saltpetre $8\frac{1}{2}$ oz. sulphur 2, antimony 1 oz. 10 dr.

Stars of a fine colour.—Sulphur 1 oz. meal-powder 1, saltpetre 1, camphor 4 dr. oil of turpentine 4 dr.

32 Rains.

Gold rain for sky-rockets.—I. Saltpetre 1 lb. meal-powder 4 oz. sulphur 4, brass-dust 1, saw-dust $2\frac{1}{4}$, and glass-dust 6 dr. II. Meal-powder 12 oz. saltpetre 2, charcoal 4. III. Saltpetre 8 oz. brimstone 2, glass-dust 1, antimony $\frac{3}{4}$, brass-dust $\frac{1}{4}$, and saw-dust 12 dr.

Silver rain.—I. Saltpetre 4 oz. sulphur, meal-powder, and antimony, of each 2 oz. sal prunella $\frac{1}{2}$ oz. II. Saltpetre $\frac{1}{2}$ lb. brimstone 2 oz. and charcoal 4. III. Saltpetre 1 lb. brimstone $\frac{1}{4}$ lb. antimony 6 oz. IV. Saltpetre 4 oz. brimstone 1, powder 2, and steel-dust $\frac{3}{4}$ oz.

33 For water rockets.

I. Meal-powder 6 lb. saltpetre 4, brimstone 3, charcoal 5. II. Saltpetre 1 lb. brimstone $4\frac{1}{2}$ oz. charcoal 6. III. Saltpetre 1 lb. brimstone 4 oz. charcoal 12. IV. Saltpetre 4 lb. brimstone $1\frac{1}{2}$ lb. charcoal 1 lb. 12 oz. V. Brimstone 2 lb. saltpetre 4 lb. and meal-powder 4. VI. Saltpetre 1 lb. meal-powder 4 oz. brimstone $8\frac{1}{2}$, charcoal 2. VII. Meal-powder 1 lb. saltpetre 3, brimstone 1; sea-coal 1 oz. charcoal $8\frac{1}{2}$, saw-dust $\frac{3}{4}$, steel-dust $\frac{1}{2}$, and coarse charcoal $\frac{1}{4}$ oz. VIII. Meal-powder $1\frac{1}{4}$ lb. saltpetre 3, sulphur $1\frac{1}{2}$, charcoal 12 oz. saw-dust 2.

Sinking charge for water-rockets.—Meal-powder 8 oz. charcoal $\frac{1}{4}$ oz.

Wheel-cases from two ounces to four pounds.—I. Meal-powder 2 lb. saltpetre 4 oz. iron-filings 7. II. Meal-powder 2 lb. saltpetre 12 oz. sulphur 4, steel-dust 3. III. Meal-powder 4 lb. saltpetre 1 lb. brimstone 8 oz. charcoal $4\frac{1}{2}$. IV. Meal-powder 8 oz. saltpetre 4, saw-dust $1\frac{1}{2}$, sea-coal $\frac{3}{4}$. V. Meal-powder 1 lb. 4 oz. brimstone 4 oz. 10 dr. saltpetre 8 oz. glass-dust $2\frac{1}{2}$. VI. Meal-powder 12 oz. charcoal 1, saw-dust $\frac{1}{2}$. VII. Saltpetre 1 lb. 9 oz. brimstone 4 oz. charcoal $4\frac{1}{2}$. VIII. Meal-powder 2 lb. saltpetre 1, brimstone $\frac{1}{2}$, and sea-coal 2 oz. IX. Saltpetre 2 lb. brimstone 1, meal-powder 4, and glass-dust 4 oz. X. Meal-powder 1 lb. saltpetre 2 oz. and steel-dust $3\frac{1}{2}$. XI. Meal-powder 2 lb. and steel-dust 2 and a half oz. with 2 and a half of the fine dust of beat iron. XII. Saltpetre 2 lb. 13 oz. brimstone 8 oz. and charcoal. 34 For wheels.

Slow fire for wheels.—I. Saltpetre 4 oz. brimstone 2, and meal-powder 1 and a half. II. Saltpetre 4 oz. brimstone 1, and antimony 1 oz. 6 dr. III. Saltpetre 4 oz. and a half, brimstone 1 oz. and mealed powder 1 and a half.

Dead fire for wheels.—I. Saltpetre $1\frac{1}{4}$ oz. brimstone $\frac{1}{4}$, lapis-calaminaris $\frac{1}{4}$, and antimony 2 dr.

35 For fixed or standing cases.

I. Meal-powder 4 lb. saltpetre 2, brimstone and charcoal 1. II. Meal-powder 2 lb. saltpetre 1, and steel-dust 8 oz. III. Meal-powder 1 lb. 4 oz. and charcoal 4 oz. IV. Meal-powder 1 lb. and steel-dust 4 oz. V. Meal-powder $2\frac{1}{2}$ lb. brimstone 4 oz. and sea-coal 6. VI. Meal-powder 3 lb. charcoal 5 oz. and saw-dust 1 and a half.

36 For sun cases.

I. Meal-powder $8\frac{1}{2}$ lb. saltpetre 1 lb. 2 oz. steel-dust 2 lb. 10 oz. brimstone 4. II. Meal-powder 3 lb. saltpetre 6 oz. and steel-dust $7\frac{1}{2}$.

37 For a brilliant fire.

Meal-powder 11 lb. saltpetre 1, brimstone 4 oz. steel-dust 1 lb. and a half.

38 For gerbes.

Meal-powder 6 lb. and beat-iron 2 lb. 1 oz. and a half.

39 For tourbillons.

Charge for four ounce Tourbillons.—Meal-powder 2 lb. 4 oz. and charcoal 4 oz. and a half.

Eight ounce Tourbillons.—Meal-powder 2 lb. and charcoal $4\frac{1}{4}$ oz.

Large Tourbillons.—Meal-powder 2 lb. saltpetre 1, brimstone 8 oz. and beat iron 8.

N. B. Tourbillons may be made very large, and of different-coloured fires: only you are to observe, that the larger they are, the weaker must be the charge; and, on the contrary, the smaller, the stronger their charge.

40 For water balloons.

I. Saltpetre 4 lb. brimstone 2, meal-powder 2, antimony 4 oz. saw-dust 4, and glass-dust 1 and a fourth. II. Saltpetre 9 lb. brimstone 3 lb. meal-powder 6 lb. rosin 12 oz. and antimony 8 oz.

41 For water squibs.

I. Meal-powder 1 lb. and charcoal 1 lb. II. Meal-powder 1 lb. and charcoal 9 oz.

42 Mine ports or serpents.

I. Meal-powder 1 lb. and charcoal 1 oz. II. Meal-powder 9 oz. charcoal 1 oz.

43 Port-fires.

For firing rockets, &c.—I. Saltpetre 12 oz. brimstone 4 oz. and meal-powder 2 oz. II. Saltpetre 8 oz. brimstone 4 oz. and meal-powder 2 oz. III. Saltpetre 1 lb. 2 oz. meal-powder 1 lb. and a half, and brimstone 10 oz. This composition must be moistened with one gill of linseed oil. IV. Meal-powder 6 oz. saltpetre 2 lb. 2 oz. and brimstone 10 oz. V. Saltpetre 1 lb. 4 oz. meal-powder 4 oz. brimstone 5 oz. saw-dust 8 oz. VI. Saltpetre 8 oz. brimstone 2 oz. and meal-powder 2 oz.

For illuminations.—Saltpetre 1 lb. brimstone 8 oz. and meal-powder 6 oz.

Saltpetre.

Apparatus, Materials, &c. of Fire-works.

Saltpetre 1 lb. and a half, brimstone 6 oz. meal-powder 14 oz. and glass-dust 14 oz.

Saltpetre 6 oz. brimstone 2 lb. antimony 4 oz. and camphor 2 oz.

44 Cones or spiral wheels. I. Saltpetre 1 lb. 10 oz. brimstone 8 oz. and meal-powder 1 lb. 6 oz. II. Saltpetre 1 lb. and a half, brimstone 8 oz. and meal-powder 1 lb. 8 oz.

45 Crowns or globes. Meal-powder 1 lb. 8 oz. saltpetre 12 oz. and charcoal 2 oz.

46 Air balloon fuzes. I. Saltpetre 5 lb. brimstone 1 lb. meal-powder 1 lb. and a half, and glass-dust 1 lb. II. Saltpetre 5 lb. 8 oz. brimstone 2 lb. meal-powder 1 lb. 8 oz. and glass-dust 1 lb. 8 oz.

47 Serpents for pots des brin. I. Saltpetre 2 lb. brimstone 3 lb. antimony 1 lb. II. Saltpetre 3½ lb. sulphur 2½ lb. meal-powder 1 lb. antimony half a lb. glass-dust 4 oz. brass-dust 1 oz.

48 Fire pumps. N. B. These compositions, driven 1½ inch in a 1 oz.
49 A slow white flame. case, will burn one minute, which is much longer time than an equal quantity of any composition yet known will last.

50 Amber lights. Meal-powder 9 oz. amber 3 oz. This charge may be drove in small cases, for illuminations.

51 Other lights. Saltpetre 3 lb. brimstone 1 lb. meal-powder 1 lb. antimony 10½ oz. All these must be mixed with the oil of spike.

52 A red fire. Meal-powder 3 lb. charcoal 12 oz. and saw-dust 8 oz.

53 A common fire. Saltpetre 3 lb. charcoal 10 oz. and brimstone 2 oz.

54 For stars of different colours. I. Meal-powder 4 oz. saltpetre 2 oz. brimstone 2 oz. steel-dust 1 oz. and a half, and camphor, white amber, antimony, and mercury-sublimate, of each ½ oz. II. Rochepetre 10 oz. brimstone, charcoal, antimony, meal-powder, and camphor, of each ½ oz. moistened with oil of turpentine. These compositions are made into stars, by being worked to a paste with aqua vitæ, in which has been dissolved some gum-tragacanth; and after you have rolled them in powder, make a hole through the middle of each, and string them on quick-match, leaving about 2 inches between each. III. Saltpetre 8 oz. brimstone 2 oz. yellow amber 1 oz. antimony 1 oz. and powder 3 oz. IV. Brimstone 2½ oz. saltpetre 6 oz. olibanum or frankincense in drops 4 oz.; mastick, and mercury-sublimate, of each 4 oz. meal-powder 5 oz. white amber, yellow amber, and camphor, of each 1 oz. antimony and orpiment half an oz. each. V. Saltpetre 1 lb. brimstone half a lb. and meal-powder 8 oz. moistened with petrolio-oil. VI. Powder half a lb. brimstone and saltpetre, of each 4 oz. VII. Saltpetre 4 oz. brimstone 2 oz. and meal-powder 1 oz.

Stars that carry tails of sparks.—I. Brimstone 6 oz. crude antimony 2 oz. saltpetre, 4 oz. and rosin 4 oz. II. Saltpetre, rosin, and charcoal, of each 2 oz. brimstone 1 oz. and pitch 1 oz.

These compositions are sometimes melted in an earthen pan, and mixed with chopped cotton-match, before they are rolled into stars; but will do as well if wetted, and worked up in the usual manner.

Stars that yield some sparks.—I. Camphor 2 oz. saltpetre 1 oz. meal-powder 1 oz. II. Saltpetre 1 oz. ditto melted half an oz. and camphor 2 oz. When you would make stars of either of these compositions, you must wet them with gum-water, or weak spirits, in which has been dissolved some gum-arabic, or gum-tragacanth, that the whole may have the consistence of a pretty thick liquid; having thus done, take 1 oz. of lint, and stir it about in the composition till it becomes dry enough to roll into stars.

Stars of a yellowish colour.—Take 4 oz. of gum-tragacanth or gum-arabic, pounded and sifted through a fine sieve, camphor dissolved in braudy 2 oz. saltpetre 1 lb. sulphur half a lb. coarse powder of glass 4 oz. white amber 1 oz. and a half, orpiment 2 oz. Being well incorporated, make them into stars after the common method.

Stars of another kind.—Take 4 oz. of camphor, and melt it in half a pint of spirit of wine over a slow fire; then add to it ½ lb. of gum-arabic that has been dissolved; with this liquor mix 1 lb of saltpetre, 6 oz. of sulphur, and 5 oz. of meal-powder; and after you have stirred them well together, roll them into stars proportionable to the rockets for which you intend them.

As variety of fires adds greatly to a collection of works, it is necessary that every artist should know the different effect of each ingredient. For which reason, we shall here explain the colours they produce of themselves; and likewise how to make them retain the same when mixed with other bodies: as for example, sulphur gives a blue, camphor a white or pale colour, saltpetre a clear white-yellow, amber a colour inclining to yellow, sal-ammoniac a green, antimony a reddish, rosin a copper colour, and Greek pitch a kind of bronze, or between red and yellow. All these ingredients are such as show themselves in a flame, viz.

White flame.—Saltpetre, sulphur, meal-powder, and camphor; the saltpetre must be the chief part.

Blue flame.—Meal-powder, saltpetre, and sulphur vivum; sulphur must be the chief: or meal-powder, saltpetre, brimstone, spirit of wine, and oil of spike; but let the powder be the principal part.

Flame inclining to red.—Saltpetre, sulphur, antimony, and Greek-pitch; saltpetre the chief.

By the above method may be made various colours of fire, as the practitioner pleases; for, by making a few trials, he may cause any ingredient to be predominant in colour.

The set colours of fire produced by sparks are divided into four sorts, viz. the black, white, gray, and red. The black charges are composed of two ingredients, which are meal-powder and charcoal; the white of three, viz. saltpetre, sulphur, and charcoal; the gray of four, viz. meal-powder, saltpetre, brimstone, and charcoal; and the red of three, viz. meal-powder, charcoal, and saw-dust.

There are, besides these four regular or set charges, two others, which are distinguished by the names of *compound* and *brilliant charges;* the compound being made of many ingredients, such as meal-powder, saltpetre, brimstone, charcoal, saw-dust, sea-coal, antimony, glass-dust, brass-dust, steel filings, cast-iron, tanner's dust, &c. or any thing that will yield sparks; all which must be managed with discretion. The brilliant fires are composed of meal-powder, saltpetre, brimstone, and steel-dust; or with meal-powder and steel-filings only.

The beauty of fire-works depends much on the compositions being well mixed; therefore great care must be taken in this part of the work, particularly for the composition for sky-rockets. When there are four or five pounds of ingredients to be mixed, which is a sufficient quantity at a time (for a larger proportion will not do so pparatus, aterials, &c. of Fire-Works.

so well), first put the different ingredients together; then work them with your hands, till you think they are pretty well incorporated: after which put them into a lawn sieve with a receiver and top to it; and if, after it is fitted, any remains that will not pass through the sieve, grind it again till fine enough; and if it be twice sifted, it will not be amiss; but the compositions for wheels and common works are not so material, and need not be so fine. But in all fixed works, from which the fire is to play regularly, the ingredients must be very fine, and great care taken in mixing them well together; and in all compositions in which are iron filings, the hands must not touch; nor will any works which have iron or steel in their charge keep long in damp weather, unless properly prepared, according to the former directions.

58 tton ck-match.

Cotton quick-match is generally made of such cotton as is put in candles, of several sizes, from one to six threads thick, according to the pipe for which it is designed; which pipe must be large enough for the match, when made, to be pushed in easily without breaking. Having doubled the cotton into as many threads as is proper, coil it very lightly into a flat-bottomed copper or earthen pan; then put in the saltpetre and the liquor, and boil them about twenty minutes; after which coil it again into another pan, as in fig. . and pour on it what liquor remains; then put in some meal powder, and press it down with the hand till it is quite wet; afterwards place the pan before the wooden frame (fig. 18.) which must be suspended by a point in the centre of each end; and place yourself before the pan, tying the upper end of the cotton to the end of one of the sides of the frame.

When every thing is ready, an assistant must turn the frame round, while the cotton passes through the hand, holding it very lightly, and at the same time keeping the hand full of the wet powder; but if the powder should be too wet to stick to the cotton, more must be added, so as to keep a continual supply till the match is all wound up; it may be wound as close on the frame as you please, so that it may not stick together; when the frame is full, take it off the points, and sift dry meal-powder on both sides the match, till it seem quite dry: in winter the match will be a fortnight before it is fit for use; when it is thoroughly dry, cut it along the outside of one of the sides of the frame, and tie it up in skains for use.

N. B. The match must be wound tight on the frames.

The ingredients for the match, are, cotton 1 lb. 12 oz. saltpetre 1 lb. spirit of wine 2 quarts, water 3 quarts, isinglass 3 gills, and meal powder 10 lb. To dissolve 4 oz. of isinglass, take 3 pints of water.

59 uch paper for capping fire-works.

Dissolve in spirit of wine or vinegar, a little saltpetre; then take some purple or blue paper, and wet it with this liquor, and when dry it will be fit for use; when this paper is to be pasted on any fire-works, take care that the paste does not touch that part which is to burn. The method of using this paper is by cutting it into slips, long enough to go once round the mouth of a serpent, cracker, &c. When these slips are pasted on, leave a little above the mouth of the case not pasted; then prime the case with meal-powder, and twist the paper to a point.

60 ste for present- g objects fire.

We are indebted to the Chinese for the contrivance of a paste which may be employed for representing animals and other objects in fire. To prepare this paste, take sulphur reduced to a very fine powder, or flowers of sulphur, and having formed it into a paste with starch, cover with it the figure you are desirous of representing on fire: it is here to be observed, that the figure must first be coated over with clay, to prevent it from being burnt.

When the figure has been covered with this paste, besprinkle it while still moist with pulverized gunpowder; and when the whole is perfectly dry, arrange some small matches on the principal parts of it, that the fire may be speedily communicated to it on all sides.

The same paste may be employed on figures of clay, to form devices and various designs. Thus, for example, festoons, garlands, and other ornaments, the flowers of which might be imitated by fire of different colours, could be formed on the frieze of a piece of architecture covered with plaster. The Chinese imitate grapes exceedingly well, by mixing pounded sulphur with the pulp of the jujube, instead of flour paste.

61 Method of preserving fire-works from being easily burnt by accident.

It is usual to paint the frames or stands of large fire-works of some dark colour, but this renders them very combustible. It would be better to wash them with the following composition, which will both give them a proper colour, and render them less combustible. Take equal parts of brick-dust, coal-ashes, and iron-filings, and mix them with a double size while hot. With this wash over the frames, &c. and when dry repeat the washing.

Chap. II. *Of the principal varieties of Fire-Works, and the most approved Methods of constructing them.*

62 Division of fire-works.

Artificial fire-works differ from each other very much in point of simplicity of construction. Some require very little dexterity in the preparation; and are either employed as appendages to works of greater importance, or, if used by themselves, are confined to the sports of schoolboys. Of this nature are *squibs*, *serpents*, *crackers*, *stars*, *sparks*, *marrons*, *saucissons*, *pin wheels*, *leaders*, and *gerbes* or *Roman candles*. Others are very complex in their structure, require considerable address and ingenuity, and form the amusement of fashionable circles on occasion of public rejoicings or private festivity: Such are *rockets*, of various kinds, *wheels*, *suns*, *globes*, *balloons*, *pyramids*, &c. We shall first describe the more simple kinds, and then give an account of the method of constructing those of a more complex nature.

Sect. I. *Of Simple Fire-Works.*

63 Leaders.

As in the subsequent directions for fire-works, we shall have frequent occasion to mention pipes of communication commonly called *leaders*, by which the several parts of a compound fire-work are connected with each other, it will be proper to show how these are constructed. Leaders consist of small tubes of paper of different lengths, according to the distance to which they must extend; and these tubes are filled with a combustible composition that will not burn too fast.

The best paper for leaders is that called elephant; which is cut into long slips 2 or 3 inches broad, so that they may go 3 or 4 times round the *former*, but not more: when they are very thick, they are too strong for

Varieties of Construction.

for the paper which fastens them to the works, and will sometimes fly off without leading the fire. The *formers* for these leaders are made from 2 to 6-16ths of an inch diameter; but 4-16ths is the size generally used. The *formers* are made of smooth brass wire: when used, rub them over with grease, or keep them wet with paste, to prevent their sticking to the paper, which must be pasted all over. In rolling pipes, make use of a rolling-board, but use it lightly: having rolled a pipe, draw out the former with one hand, holding the pipe as light as possible with the other; for if it press against the former, it will stick and tear the paper.

N. B. Make the leaders of different lengths, or in clothing works many will be wasted. Leaders for marron batteries must be made of strong cartridge paper.

Joining and placing leaders is a very essential part of fire-works, as it is on the leaders that the performance of all complex works depends; for which reason the method of conducting pipes of communication shall be here explained in as plain a manner as possible. Your works being ready to be clothed, proceed thus: Cut your pipes of a sufficient length to reach from one case to the other; then put in the quick-match, which must always be made to go in very easy: when the match is in, cut it off within about an inch of the end of the pipe, and let it project as much at the other end: then fasten the pipe to the mouth of each case with a pin, and put the loose ends of the match into the mouths of the cases, with a little meal-powder: this done to all the cases, paste over the mouth of each two or three bits of paper. The preceding method is used for large cases, and the following for small, and for illuminations: First thread a long pipe; then lay it on the tops of the cases, and cut a bit off the under side, over the mouth of each case, so that the match may appear; then pin the pipe to every other case; but before you put on the pipes, put a little meal-powder in the mouth of each case. If the cases thus clothed are port-fires or illuminated works, cover the mouth of each case with a single paper; but if they are choked cases, situated so that a number of sparks from other works may fall on them before they are fired, secure them with three or four papers, which must be pasted on very smooth, that there may be no creases for the sparks to lodge in, which often set fire to the works before their time. Avoid as much as possible placing the leaders too near, or one across the other so as to touch, as it may happen that the flash of one will fire the other; therefore if your works should be so formed that the leaders must cross or touch, be sure to make them very strong, and secure at the joints, and at every opening.

When a great length of pipe is required, it must be made by joining several pipes in this manner: Having put on one length of match as many pipes as it will hold, paste paper over every joint; but, if a still greater length is required, more pipes must be joined, by cutting about an inch off one side of each pipe near the end, and laying the quick-match together, and tying them fast with small twine; after which, cover the joining with pasted paper.

64 Serpents.

One of the simplest fire-works is what is called a *serpent*, which consists of a cylindrical paper case, about 4 or 5 inches long, and not made very thick. AC, fig. 19. represents the usual form of the serpent, except that in general they have not the contraction in the middle, represented in this figure. The name serpent has been given to this fire-work, either from the hissing noise which it makes when fired, or from the zigzag or undulating direction in which it moves, when properly constructed. The case or cartridge is rolled round a cylindrical stick, rather larger than a goose quill, and provided at one end with a narrow appendage, such as that used for rockets, fig. 3. by means of which it is choked at one end. This case is filled about half way with some of the compositions described for making small rockets, see N° 30, rammed moderately hard in the proper mould, and then it is either choked in the middle, or some obstructing body, such as a small piece of paper, is introduced, and the remainder of the case is filled with grained or corn powder. Lastly, this other extremity is well secured with twine, and commonly dipt into melted pitch; a little moistened meal powder is introduced into the extremity next the choak, and a piece of touch-paper being properly fastened on this end, the serpent is complete.

65 Crackers.

Crackers are composed of a pretty long paper case, filled with the proper composition, as will be described immediately, and folded up in such a manner as, when fired, to make successive reports at short intervals. To construct these crackers, cut some cartridge paper into pieces $3\frac{1}{2}$ inches broad, and one foot long; one edge of each fold down lengthwise about $\frac{1}{4}$ of an inch broad; then fold the double edge down $\frac{1}{4}$ of an inch, and turn the single edge back half over the double fold; then open it and lay all along the channel, which is formed by the folding of the paper, some meal-powder; then fold it over and over till all the paper is doubled up, rubbing it down every turn; this done, bend it backwards and forwards, 2 inches and a half, or thereabouts, at a time, as oft as the paper will allow; then hold all these folds flat and close, and with a small pinching cord give one turn round the middle of the cracker, and pinch it close; then bind it with a packthread as tight as possible; then in the place where it was pinched, prime one end of it, and cap it with touch-paper. When these crackers are fired, they will give a report at every turn of the paper: if you would have a great number of reports, the paper must be cut longer, or join them after they are made; but if they are made very long before they are pinched, you must have a piece of wood with a groove in it, deep enough to let in half the cracker; this will hold it straight while it is pinching. Fig. 20. represents a cracker complete. Plate CCCCLIII.

66 Stars.

Stars are small balls, prepared of a composition which emits a brilliant, radiating light, and are much employed in the construction of rockets, Roman candles, and similar fire-works. They are made of various sizes, but generally about as large as a musket bullet. Compositions for stars have been described in N° 31. and 54. The ingredients must be thoroughly incorporated, and in forming the ball, unless the paste is sufficiently glutinous, it must be wrapped up in a piece of paper, or linen rag, tied closely round with pack thread, and a hole must be pierced through its middle for the insertion of a piece of match. These stars, when lighted, will exhibit a most beautiful appearance; for the fire, as it issues from the two ends of the hole in the middle, will extend to a

Varieties of Construction.

a great distance, and thus make the fiery ball appear much larger.

Strung stars. First take some thin paper, and cut it into pieces of one inch and a half square, or thereabouts; then on each piece lay as much dry star-composition as the paper will easily contain; then twist up the paper as tight as possible; when done, rub some paste on your hands, and roll the stars between them; then set them to dry: the stars being thus made, get some flax or fine tow, and roll a little of it over each star; then paste the hand and roll the stars as before, and set them again to dry; when they are quite dry, with a piercer make a hole through the middle of each, into which run a cotton quick-match, long enough to hold 10 or 12 stars at 3 or 4 inches distance: but any number of stars may be strung together by joining the match.

Tailed stars. These are called *tailed stars*, because there are a great number of sparks issuing from them, which represent a tail like that of a comet. Of these there are two sorts; which are *rolled*, and *driven*: when rolled, they must be moistened with a liquor made of half a pint of spirit of wine and half a gill of thin size, of this as much as will wet the composition enough to make it roll easy; when they are rolled, sift meal powder over them, and set them to dry.

When tailed stars are driven, the composition must be moistened with spirit of wine only, and not made so wet as for rolling: 1 and 2 oz. cases, rolled dry, are best for this purpose: and when they are filled, unroll the case within 3 or 4 rounds of the charge, and all that are unrolled cut off; then paste down the loose edge: 2 or 3 days after the cases are filled, cut them in pieces 5 or 6 8ths of an inch in length: then melt some wax, and dip one end of each piece into it, so as to cover the composition: the other end must be rubbed with meal-powder wetted with spirit of wine.

Driven stars. Cases for driven stars are rolled with paste, but are made of paper very thin. Before they are filled, damp the composition with spirit of wine that has had some camphor dissolved in it: ram them indifferently hard, so that the case be not broken or sacked; to prevent which, they should fit tight in the mould. They are driven in cases of several sizes, from 8 drams to 4 oz. When they are filled in half ounce cases, cut them in pieces of three fourths of an inch long; if 1 oz. cases, cut them in pieces of 1 inch; if 2 oz. cases, cut them in pieces of 1 and one fourth inch long; and if 4 oz. cases, cut them in pieces of 1 inch and a half long: having cut the stars of a proper size, prime both ends with wet meal-powder. These stars are seldom put in rockets, they being chiefly intended for air-balloons, and driven in cases, to prevent the composition from being broken by the force of the blowing powder in the shell.

Rolling stars are commonly made about the size of a musket ball; though they are rolled of several sizes, from the bigness of a pistol ball to 1 inch diameter; and sometimes very small, but are then called *sparks*. Great care must be taken in making stars, first, that the several ingredients are reduced to a fine powder; secondly, that the composition may be well worked and mixed. Before beginning to roll, take about a pound of composition, and wet it with the following liquid, enough to make it stick together and roll easy: Spirit of wine 1 quart, in which dissolve one fourth of an ounce of isinglass. If a great quantity of composition be wetted at once, the spirit will evaporate, and leave it dry, before it is rolled into stars: having rolled up one proportion, shake the stars in meal-powder, and set them to dry, which they will do in 3 or 4 days; but if they should be wanted for immediate use, dry them in an earthen pan over a slow heat, or in an oven. It is very difficult to make the stars all of an equal size when the composition is taken up promiscuously with the fingers; but by the following method they may be made very exactly. When the mixture is moistened properly, roll it on a flat smooth stone and cut it into square pieces, making each square large enough for the stars intended. There is another method used by some to make stars, which is by rolling the composition in long pieces, and then cutting off the star, so that each star will be of a cylindrical form: but this method is not so good as the former; for, to make the composition roll this way, it must be made very wet, which makes the stars heavy, as well as weakens them. All stars must be kept as much from air as possible, otherwise they will grow weak and bad.

67 Sparks.

Sparks differ from stars, only in their size and duration, as they are made smaller than stars, and are sooner extinguished. The following is the most approved method of making them. Having put into an earthen vessel an ounce of mealed gunpowder, 3 oz. of powdered saltpetre, and 4 oz. of camphor, reduced to powder by rubbing it in a mortar with a little spirit of wine; pour over this mixture some weak gum water, or some weak brandy, in which some gum dragant has been dissolved, till the composition acquires the consistence of thick soup. Then take some lint or caddice, which has been boiled in brandy, vinegar, or with saltpetre, and afterwards dried and unravelled, and throw into the composition as much of it as is necessary to absorb the whole, taking care to stir it well. This matter is to be formed into small balls of about the size of a pea, which being dried in the air, are to be sprinkled with meal gunpowder, that they may more readily take fire.

Another method of making sparks is, to take some saw dust of any wood that burns readily, such as fir, and boil it in water that has been saturated with saltpetre. When it has been boiled for some time, the vessel is to be removed from the fire, and the solution of nitre poured off, so as to leave the saw dust at the bottom. The saw dust thus impregnated with nitre, is then to be poured on a table, and, while moist, to be sprinkled with powdered sulphur, to which a little bruised gunpowder has been added; and when the whole is well mixed, and of a proper consistence, sparks are to be made of it as before.

68 Marroons.

Marroons are small boxes made either of paper or pasteboard, and of a roundish or cubical form, so prepared as when fired to make a loud and sudden report. They are usually employed either as appendages to other fire-works, or a great many of them are so arranged, as to explode successively at certain intervals.

Formers for marroons are from three fourths of an inch to one and a half diameter; but the paper for the cases twice the diameter of the *former* broad, and long enough to go three times round. When you have rolled a case, paste down the edge and tie one end close; then with the *former* drive it down to take away the wrinkles,

Varieties of Construction.

kles, and make it flat at bottom; then fill the case with corn-powder one diameter and one fourth high, and fold down the rest of the case tight on the powder. The marroon being thus made, wax some strong pack-thread with shoemakers wax: this thread wind up in a ball, then unwind two or three yards of it, and that part which is near the ball make fast to a hook; then take a marroon, and stand as far from the hook as the packthread will reach, and wind it lengthwise round the marroon as close as possible, till it will hold no more that way; then turn it, and wind the packthread on the short way, then lengthwise again, and so on till the paper is all covered; then make fast the end of the packthread, and beat down both ends of the marroon to bring it in shape. The method of firing marroons is by making a hole at one end with an awl, and putting in a piece of quick-match; then taking a piece of strong paper, in which wrap up the marroon with two leaders, which must be put down to the vent, and the paper tied tight round them with small twine: these leaders are bent on each side, and their loose ends tied to the other marroons, and are nailed in the middle to the rail of the stand, as in fig. 21. The use of winding the packthread in a ball is, that it may be let out as wanted, according to the quantity the marroon may require; and that it may not be tied in knots, which would spoil the marroon. These oblong marroons are, by the French, called *Saucissons*, as they are supposed to resemble a saussage.

Fig. 21.

69 Marroon batteries.

Batteries of Marroons.—These, if well managed, will keep time to a march, or a slow piece of music. Marroon batteries are made of several stands, with a number of cross rails for the marroons; which are regulated by leaders, by cutting them of different lengths, and nailing them tight, or loose, according to the time of the music. In marroon batteries you must use the large and small marroons, and the nails for the pipes must have flat heads.

The proper marroon boxes are made of strong pasteboard, cut as represented in fig. 22. so as to fold up in the form of a cube, one side of which is to be left uncemented till the box be filled. The cavity being filled with gun-powder, strong paper is to be pasted over the box in various directions, and the whole is to be wrapped round with strong pack-thread dipt in glue. Lastly, a hole is to be made in the corner of the box, and a piece of match introduced, by which it may be fired.

Sometimes it is required to render marroons luminous, or to prepare them in such a way, that they shall emit a brilliant light before they burst. To effect this, they are to be covered on the outside with one of the compositions directed for stars, and then rolled in bruised gunpowder.

70 Pin-wheels.

For Pin-Wheels.—First roll some paper pipes about 14 inches long each; these pipes must not be made thick of paper, two or three rounds of elephant paper being sufficient. When the pipes are thoroughly dried, you must have a tin tube 12 inches long, to fit easy into the pipes; at one end of this tube fix a small conical cup, called a *funnel*; then bend one end of one of the pipes, and put the funnel in at the other as far as it will reach, and fill the cup with composition: then draw out the funnel by a little at a time, shaking it up and down, and it will fill the pipe as it comes out. Having filled some pipes, have some small circular blocks made about one inch diameter and half an inch thick: round one of these blocks wind and paste a pipe, and to the end of this pipe join another; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other with a little paste: in this manner join four or five pipes, winding them one upon the other so as to form a spiral line. Having wound on your pipes, paste two slips of paper across them to hold them together: besides these slips of paper, the pipes must be pasted together.

There is another method of making these wheels, viz. by winding on the pipes without paste, and sticking them together with sealing-wax at every half turn; so that when they are fired, the end will fall loose every time the fire passes the wax, by which means the circle of fire will be considerably increased. The formers for these pipes are made from one and a half to 4-16ths of an inch diameter; and the composition for them is as follows: Meal-powder 8 oz. saltpetre 2 oz. and sulphur 1; among these ingredients may be mixed a little steel-filings or the dust of cast iron: this composition should be very dry, and not made too fine, or it will stick in the funnel. These wheels may be fired on a large pin, and held in the hand with safety.

71 Shower of fire or rain.

There is a pleasing decoration frequently added to rockets, called a *shower of fire*, rain, or rain fall, and it is called gold or silver rain, according as its colour is more or less intense. It consists of several small cases filled with a brilliant composition, such as the following variety of Chinese fire, viz. meal powder 1 pound, flower of sulphur 2 oz. and iron sand of the first order, 5 oz.

Gold and silver rain compositions are rammed in cases that are pinched quite close at one end; if rolled dry, 4 or 5 rounds of paper will be strong enough; but if they are pasted, 3 rounds will do; and the thin sort of cartridge-paper is best for those small cases, in rolling which you must not turn down the inside edge as in other cases, for a double edge would be too thick for so small a bore. The moulds for rain-falls should be made of brass, and turned very smooth in the inside; or the cases, which are so very thin, would tear in coming out; for the charge must be rammed in tight; and the better the case fits the mould, the more driving it will bear. These moulds have no nipple, but instead of it they are made flat. As it would be very tedious and troublesome to shake the composition out of such small ladles as are used for these cases, it will be necessary to have a funnel made of thin tin, to fit on the top of the case, by the help of which they may be filled very fast. For single rain-falls for 4 oz. rockets, let the diameter of the former be 2-16ths of an inch, and the length of the case 2 inches; for 8 oz. rockets, 4-16ths and 2 diameters of the rocket long; for 1 lb. rockets, 5-16ths, and 2 diameters of the rocket long; for 2 lb. rockets, 5-16ths, and 3 inches and a half long; for 4 lb. rockets, 6-16ths, and 4 inches and a half long; and for 6-pounders, 7-16ths diameter, and 5 inches long.

Of double rain-falls there are two sorts. For example, some appear first like a star, and then the rain; and some appear first like rain, and then like a star. When you would have stars first, you must fill the cases, within half an inch of the top, with rain-composition, and the remainder with star-composition; but when you intend

Varieties of Construction.

tend the rain should be first, drive the case half an inch with star-composition, and the rest with rain. By this method may be made many changes of fire; for in large rockets you may make them first burn as stars, then rain, and again as stars; or they may first show rain, then stars, and finish with a report; but when thus managed, cut open the first rammed end, after they are filled and bounced, at which place prime them. The star-composition for this purpose must be a little stronger than for rolled stars.

72 Gerbes.

Gerbes consist of a strong case of thick paper or pasteboard, filled with a brilliant composition, and generally with stars or balls placed at small distances, so that the composition and the balls are introduced alternately. Immediately below each ball is placed a little grained powder. These last gerbes are sometimes called Roman candles. When fired, they first throw up a beautiful jet of flame, which in some measure resembles a water-spout, whence the name. Gerbes are either employed singly, or batteries are formed of them, and frequently those filled with brilliant fire without balls, are placed in rows along the front of the frames of large compound fire-works. They are sometimes made perfectly cylindrical; at others they have a contracted part at the top called the *neck*.

Fig. 23. and 24.

Fig. 23. represents a wooden *former;* fig. 24. a gerbe complete with its foot or stand. The cases for gerbes are made very strong, on account of the strength of the composition; which, when fired, comes out with great velocity; therefore, to prevent their bursting, the paper should be pasted, and the cases made as thick at the top as at the bottom. They should also have very long necks, for this reason; first, that the particles of iron will have more time to be heated, by meeting with greater resistance in getting out, than with a short neck, which would be burnt too wide before the charge be consumed, and spoil the effect: secondly, that with long necks the stars will be thrown to a great height, and will not fall before they are spent, or spread too much; but, when made to perfection, will rise and spread in such a manner as to form exactly a wheat sheaf.

In ramming of gerbes, there will be no need of a mould, the cases being sufficiently strong to support themselves. But you must be careful, before you begin to ram, to have a piece of wood made to fit in the neck; for if this be not done, the composition will fall into the neck, and leave a vacancy in the case, which will cause the case to burst as soon as the fire arrives at the vacancy. You must likewise observe, that the first ladleful of charge, or second, if proper, be of some weak composition. When the case is filled, take out the piece of wood, and fill the neck with some slow charge. Gerbes are generally made about six diameters long, from the bottom to the top of the neck: their bore must be one-fifth narrower at top than at bottom. The neck S is one-sixth diameter and three-fourths long. T, a wooden foot or stand, on which the gerbe is fixed. This may be made with a choak or cylinder four or five inches long to fit the inside of the case, or with a hole in it to put in the gerbe; both these methods will answer the same purpose. Gerbes produce a most brilliant fire, and are very beautiful when a number of them are fixed in the front of a building or a collection of fire-works.

N. B. Gerbes are made by their diameters, and their cases at bottom one-fourth thick. The method of finding the interior diameter of a gerbe is this: Supposing the exterior diameter of the case, when made, to be five inches, then, by taking two-fourths for the sides of the case, there will remain $2\frac{1}{2}$ inches for the bore, which will be a very good size. These gerbes should be rammed very hard.

Varieties of Construction.

Small Gerbes, or *white Fountains*.

May be made of four ounces, eight ounces, or one pound cases, pasted and made very strong, of any length: but before they are filled, drive in clay one diameter of their orifice high; and when the case is filled, bore a vent through the centre of the clay to the composition: the common proportion will do for the vent, which must be primed with a slow charge. These cases, without the clay, may be filled with Chinese fire.

Sect. II. *Of Compound Fire-works.*

Among the most pleasing compound fire-works are rockets, which are of various kinds. Some are made to ascend to a great height in the air, where they burst, and throw out the contents of the head with which they are provided. These are called *sky-rockets*. Others are so constructed as to run with great velocity along a line, and are called *line-rockets*. Some are arranged at the extremities of the spokes of a wheel, and are denominated *wheel-rockets;* while a fourth variety have their cases made water tight, and are filled with a very strong composition, so as to admit of their burning below water. These last are called *water-rockets*. Sky rockets are tied to a stick, which renders their ascent into the air more equable and steady. 73 Rockets.

Fig. 25. represents a rocket complete without its stick. Its length from the neck is five diameters one-sixth: the cases should always be cut to this length after they are filled. M is the head, which is two diameters high, and one diameter one-sixth and a half in breadth; N the cone or cap, whose perpendicular height must be one diameter one-third. Fig. 26. the collar to which the head is fixed: this is turned out of fir or any light wood, and its exterior diameter must be equal to the interior diameter of the head; one-sixth will be sufficient for its thickness, and round the outside edge must be a groove; the interior diameter of the collar must not be quite so wide as the exterior diameter of the rocket: when this is to be glued on the rocket, two or three rounds of paper must be cut off the case, which will make a shoulder for it to rest upon. Fig. 27. a *former* for the head: two or three rounds of paper well pasted will be enough for the head, which, when rolled, put the collar on that part of the *former* marked O, which must fit the inside of it; then, with the pinching cord, pinch the bottom of the head into the groove, and tie it with small twine. Fig. 28. a *former* for the cone. To make the caps, cut the paper in round pieces, equal in diameter to twice the length of the cone to be made; which pieces being cut into halves, will make two caps each, without wasting any paper; having formed the caps, paste over each of them a thin white paper, which must be a little longer than the cone, so as to project about half an inch below the bottom: this projection of paper, being notched and pasted, serves to fasten the cap to the head.

74 Sky-rockets. Fig. 25. Fig. 26. Fig. 27. Fig. 28.

When

Varieties of Construction.

When you load the heads of the rockets with stars, rains, serpents, crackers, or any thing else, according to fancy, remember always to put one ladleful of meal-powder into each head, which will be enough to burst the head, and disperse the stars, or whatever it contains: when the heads are loaded with any cases, let their mouths be turned downwards; and after the heads are filled, paste on the top of them a piece of paper before putting on the caps. As the size of the stars often differs, it would be needless to give an exact number for each rocket; but this rule may be observed, that the heads may be nearly filled with whatever they are to contain.

75 Dimensions and poise of rocket-sticks.

Dimensions and Poise of Rocket-sticks.

Weight of the Rocket.		Length of the stick.		Thickness at top.	Breadth at top.	Square at bottom.	Poise from the point of the cone.

	¼	1	10½	0,1	0,15	0,5	5	0,5

Fig. 25.

The last column on the right, in the above table, expresses the distance from the top of the cone, where the stick, when tied on, should balance the rocket, so as to stand in an equilibrium on one's finger, or the edge of a knife. The best wood for the sticks is dry fir, and they are thus made: When you have cut and planned the stick, according to the dimensions given in the table, cut, on one of the flat sides at the top, a groove the length of the rocket, and as broad as the stick will allow; then on the opposite flat side, cut two notches for the cord, which ties on the rocket, to lie in; one of these notches must be near the top of the stick, and the other facing the neck of the rockets; the distance between these notches may easily be known, for the top of the stick should always touch the head of the rocket. When the rockets and sticks are ready, lay the rockets in the grooves in the sticks and tie them on. Those who, merely for curiosity, may choose to make rockets of different sizes from those expressed in the table of dimensions, may find the length of their sticks, by making them for rockets, from half an ounce to one pound, 60 diameters of the rocket long; and for rockets above one pound 50 or 52 diameters will be a good length; their thickness at top may be about half a diameter, and their breadth a very little more; their square at bottom is generally equal to half the thickness at top. But although the dimensions of the sticks be very nicely observed, we can depend only on their balance; for, without a proper counterpoise, the rockets, instead of mounting perpendicularly, will take an oblique direction, and fall to the ground before they are burnt out.

Rockets rammed over a piercer must not have so much composition put into them at a time as when rammed solid; for the piercer, taking up great part of the bore of the case, would cause the rammer to rise too high; so that the pressure of it would not be so great on the composition, nor would it be rammed everywhere equal. To prevent this, observe the following rule: That for those rockets which are rammed over a piercer, let the ladle hold as much composition as, when drove, will raise the drift one-half the interior diameter of the case, and for those rammed solid to contain as much as will raise it one-half the exterior diameter of the case: ladles are generally made to go easy in the case, and the length of the scoop about one and a half of its own diameter.

76 Method of ramming rockets.

The charge of rockets must always be rammed one diameter above the piercer, and on it must be rammed one-third of a diameter of clay; through the middle of which bore a small hole to the composition, that, when the charge is burnt to the top, it may communicate its fire, through the hole, to the stars in the head. Great care must be taken to strike with the mallet, and with an equal force, the same number of strokes to each ladleful of charge; otherwise the rockets will not rise with an uniform motion, nor will the composition burn equally and regularly: for which reason they cannot carry a proper tail: for it will break before the rocket has got half way up, instead of reaching from the ground to the top, where the rocket breaks and disperses the stars, rains, or whatever is contained in the head. When ramming, keep the drift constantly turning or moving; and when you use the hollow rammers, knock out of them the composition now and then, or the piercer will split them. To a rocket of four ounces, give to each ladleful of charge, 16 strokes; to a rocket of one pound, 28; to a two pounder, 36; to a four pounder, 42; and to a six pounder, 56; but rockets of a larger sort cannot be rammed well by hand, but must be rammed with a machine made in the same manner as those for driving piles.

The method of ramming wheel cases, or any other sort, in which the charge is rammed solid, is much the same as in sky-rockets; for the same proportion may be observed in the ladle, and the same number of strokes given, according to their diameters, all cases being distinguished by their diameters. In this manner, a case, whose bore is equal to a rocket of four ounces, is called a four ounce case, and that which is equal to an eight ounce rocket an eight ounce case, and so on, according to the different rockets.

Having taught the method of ramming cases in moulds, we shall here say something concerning those filled without moulds; which method, for strong pasted cases, will do extremely well, and save the expence of making so many moulds. The reader must here observe, when filling any cases, to place the mould on a perpendicular block of wood, and not on any place that is hollow; for we have found by experience, that when cases were rammed on driving benches, which were formerly used, the works frequently miscarried, on account of the hollow resistance of the benches, which often jarred and loosened the change in the cases; but this accident never happens when the driving blocks are used.

When cases are to be filled without moulds, proceed thus: Have some nipples made of brass or iron, of

Varieties of Construction.

of several sizes, in proportion to the cases, and to screw or fix in the top of the driving block; when you have fixed in a nipple, make, at about one inch and a half from it, a square hole in the block, six inches deep and one inch diameter; then have a piece of wood, six inches longer than the case intended to be filled, and two inches square; on one side of it cut a groove almost the length of the case, whose breadth and depth must be sufficient to cover near one-half of the case; then cut the other end to fit the hole in the block, but take care to cut it so that the groove may be at a proper distance from the nipple; this half mould being made and fixed tight in the block, cut, in another piece of wood nearly of the same length as the case, a groove of the same dimensions as that in the fixed piece; then put the case on the nipple, and with a cord tie it and the two half moulds together, and the case will be ready for filling.

The dimensions of the above-described half-moulds are proportionable for cases of eight ounces, but notice must be taken, that they differ in size in proportion to the cases.

The best wood for mallets is dry beech. If a person uses a mallet of a moderate size, in proportion to the rocket, according to his judgment, and if the rocket succeeds, he may depend on the rest, by using the same mallet; yet it will be necessary that cases of different sorts be driven with mallets of different sizes.

The following proportion of the mallets for rockets of any size, from one oz. to six lb. may be observed; but as rockets are seldom made less than one oz. or larger than six lb. we shall leave the management of them to the curious; but all cases under one oz. may be rammed with an ounce rocket mallet. The mallets will strike more solid, by having their handles turned out of the same piece with the head, and made in a cylindrical form. Let their dimensions be worked by the diameters of the rockets: for example; let the thickness of the head be three diameters, and its length four, and the length of the handle five diameters, whose thickness must be in proportion to the hand.

77 Ascent of sky-rockets explained.

As the cause which occasions the ascent of a rocket into the air is the same as that which makes a musket recoil when fired, it will be proper, before explaining the ascent of rockets, to show how the recoil of fire-arms is produced. When the powder is suddenly inflamed in the chamber, or at the bottom of the barrel, it necessarily exercises an action two ways at the same time; that is to say, against the breech of the piece, and against the bullet or wadding, which is placed above it. Besides this, it acts also against the sides of the chamber which it occupies; and as they oppose a resistance almost insurmountable, the whole effort of the elastic fluid, produced by the inflammation, is exerted in the two derections above mentioned. But the resistance opposed by the bullet, being much less than that opposed by the mass of the barrel or cannon, the bullet is forced out with great velocity. It is impossible, however, that the body of the piece itself should not experience a movement backwards; for if a spring is suddenly let loose, between two moveable obstacles, it will impel them both, and communicate to them velocities in the inverse ratio of their masses; the piece, therefore, must acquire a velocity backwards nearly in the inverse ratio of its mass to that of the bullet. We make use of the term *nearly*, because there are various circumstances which give to this ratio certain modifications; but it is always true that the body of the piece is driven backwards, and that if it weighs with its carriage 1000 times more than the bullet, it acquires a velocity which is 1000 times less, and which is soon annihilated by the friction of the wheels against the ground, &c.

The cause of the ascent of a rocket is nearly the same. At the moment when the powder begins to inflame, its expansion produces a torrent of elastic fluid, which acts in every direction; that is, against the air which opposes its escape from the cartridge, and against the upper part of the rocket; but the resistance of the air is more considerable than the weight of the rocket, on account of the extreme rapidity with which the elastic fluid issues through the neck of the rocket to throw itself downwards, and therefore the rocket ascends by the excess of the one of these forces above the other.

This however would not be the case, unless the rocket were pierced to a certain depth. A sufficient quantity of elastic fluid would not be produced; for the composition would inflame only in circular coats of a diameter equal to that of the rocket; and experience shews that this is not sufficient. Recourse then is had to the very ingenious idea of piercing the rocket with a conical hole, which makes the composition burn in conical strata which have much greater surface, and therefore produce a much greater quantity of inflamed matter and fluid. This expedient was certainly not the work of a moment *.

* Hutton's Recreations, vol. iii. p. 461.

78 To fix one rocket on the top of another.

When sky-rockets are fixed one on the top of another, they are called *towering rockets*, on account of their mounting so very high. Towering rockets are made after this manner: Fix on a pound-rocket a head without a collar; then take a four ounce rocket, which may be headed or bounced, and rub the mouth of it with meal-powder wetted with spirit of wine: this done, put it in the head of the large rocket with its mouth downwards; but before it is put in, stick a bit of quick-match in the hole of the clay of the pound-rocket, which match should be long enough to go a little way up the bore of the small rocket, to fire it when the large rocket is burnt out. As the four ounce rocket is too small to fill the head of the other, roll round it as much tow as will make it stand upright in the centre of the head: the rocket being thus fixed, paste a single paper round the opening of the top of the head of the large rocket. The large rocket must have only half a diameter of charge rammed above the piercer; for, if filled to the usual height, it would turn before the small one takes fire, and entirely destroy the intended effect: when one rocket is headed with another, there will be no occasion for any blowing powder; for the force with which it goes off will be sufficient to disengage it from the head of the first fired rocket. The sticks for these rockets must be a little longer than for those headed with stars, rains, &c.

79 Caduceus rockets.

Caduceus rockets are such as, in rising, form two spiral lines, by reason of their being placed obliquely, one opposite to the other; and their counterpoise in their centre, which causes them to rise in a vertical direction. Rockets for this purpose must have their ends choaked close, without either head or bounce, for a weight at top would be a great obstruction to their mounting. No caduceus rockets ascend so high as single, because of their

Varieties of Construction.

their serpentine motion, and likewise the resistance of air, which is much greater than two rockets of the same size would meet with if fired singly.

Fig. 30. shews the method of fixing these rockets: the sticks for this purpose must have all their sides equal, and the sides should be equal to the breadth of a stick proper for a sky-rocket of the same weight as those you intend to use, and made to taper downwards as usual, long enough to balance them, one length of a rocket from the cross stick; which must be placed from the large stick six diameters of one of the rockets, and its length seven diameters; so that each rocket, when tied on, may form with the large stick an angle of 60 degrees. In tying on the rockets, place their heads on the opposite sides of the cross stick, and their ends on the opposite sides of the long stick; then carry a leader from the mouth of one into that of the other. When these rockets are to be fired, suspend them between two hooks or nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of one lb. are a good size for this use.

80 Honorary rockets.

Honorary rockets are the same as sky-rockets, except that they carry no head nor report, but are closed at top, on which is fixed a cone: then on the case, close to the top of the stick is tied on a two ounce case, about five or six inches long, filled with a strong charge, and pinched close at both ends; then in the reverse sides, at each end, bore a hole in the same manner as in tourbillons, to be presently described; from each hole carry a leader into the top of the rocket. When the rocket is fired, and arrived to its proper height, it will give fire to the case at top; which will cause both rocket and stick to spin very fast in their return, and represent a worm of fire descending to the ground.

There is another method of placing the small case, which is by letting the stick rise a little above the top of the rocket, and tying the case to it, so as to rest on the rocket: these rockets have no cones.

A third method by which they are managed is this; In the top of a rocket fix a piece of wood, in which drive a small iron spindle; then make a hole in the middle of the small case, through which put the spindle: then fix on the top of it a nut, to keep the case from falling off; when this is done, the case will turn very fast, without the rocket: but this method does not answer so well as either of the former.

Fig. 31. is the honorary rocket complete. The best sized rockets for this purpose are those of one lb.

81 To make a rocket form an arch in rising.

Having some rockets made, and headed according to fancy, and tied on their sticks; get some sheet tin, and cut it into round pieces about three or four inches diameter; then on the stick of each rocket, under the mouth of the case, fix one of these pieces of tin 16 inches from the rocket's neck, and support it by a wooden bracket, as strong as possible: the use of this is, that when the rocket is ascending the fire may play with great force on the tin, which will divide the tail in such a manner that it will form an arch as it mounts, and will have a very good effect when well managed: if there is a short piece of port-fire, of a strong charge, tied to the end of the stick, it will make a great addition; but this must be lighted before the rocket is fired.

82 To make several rockets rise in the same direction, and at the same distance.

Take six, or any number of sky-rockets, of any size; then cut some strong packthread into pieces of three or four yards long, and tie each end of these pieces to a rocket in this manner; Having tied one end of the packthread round the body of one rocket, and the other end to another, take a second piece of packthread, and make one end of it fast to one of the rockets already tied, and the other end to a third rocket, so that all the rockets, except the two on the outside, will be fastened to two pieces of packthread: the length of thread from one rocket to the other may be what the maker pleases; but the rockets must be all of a size, and their heads filled with the same weight of stars, rains, &c.

Having thus done, fix in the mouth of each rocket a leader of the same length; and when about to fire them, hang them almost close; then tie the ends of the leaders together, and prime them: this prime being fired, all the rockets will mount at the same time, and divide as far as the strings will allow; and this division they will keep, provided they are all rammed alike, and well made. They are sometimes called *chained rockets*.

83 Signal rockets.

Signal rockets are made of several kinds, according to the different signals intended to be given; but in artificial fire-works, two sorts are only used, which are one with reports and the other without; but those for the use of the navy and army are headed with stars, serpents, &c.—Rockets which are to be bounced must have their cases made one and a half or two diameters longer than the common proportion; and after they are filled, drive in a double quantity of clay, then bounce and pinch them after the usual manner, and fix on each a cap.

Signal sky-rockets without bounces, are only sky-rockets closed and capped: these are very light, therefore do not require such heavy sticks as those with loaded heads; for which reason the rocket may be cut from the stick, or else be made thinner.

Signal rockets with reports are fired in small flights; and often both these, and those without reports, are used for a signal to begin firing a collection of works.

84 To fix several rockets to the same stick.

Two, three, or six sky-reckets, fixed on one stick, and fired together, make a grand and beautiful appearance; for the tails of all will seem but as one of an immense size, and the breaking of so many heads at once will resemble the bursting of an air-balloon. The management of this device requires a skilful hand; but if the following instructions be well observed, even by those who have not made a great progress in this art, there will be no doubt of the rockets having the desired effect.

Rockets for this purpose must be made with the greatest exactness, all rammed by the same hand, in the same mould, and filled with the same proportion of composition; and after they are filled and headed, must all be of the same weight. The stick must also be well made (and proportioned) to the following directions: first, supposing the rockets to be half pounders, whose sticks are six feet six inches long, then if two, three, or six of these are to be fixed on one stick, let the length of it be nine feet nine inches: then cut the top of it into as many sides as there are rockets, and let the length of each side be equal to the length of one of the rockets without its head; and in each side cut a groove (as usual); then from the grooves plane it round, down to the bottom, where its thickness must be equal to half the top of the round part. As their thickness cannot be exactly ascertained, we shall give a rule which generally answers for

for any number of rockets above two: the rule is this; that the stick at top must be thick enough, when the grooves are cut, for all the rockets to lie, without pressing each other, though as near as possible.

When only two rockets are to be fixed on one stick, let the length of the stick be the last given proportion, but shaped after the common method, and the breadth and thickness double the usual dimensions. The point of poise must be in the usual place (let the number of rockets be what they will): if sticks made by the above directions should be too heavy, plane them thinner; and if too light, make them thicker; but always make them of the same length.

When more than two rockets are tied on one stick, there will be some danger of their flying up without the stick, unless the following precaution is taken: For cases being placed on all sides, there can be no notches for the cord which ties on the rockets to lie in; therefore, instead of notches, drive a small nail in each side of the stick, between the necks of the cases: and let the cord, which goes round their necks, be brought close under the nails; by this means the rockets will be as secure as when tied on singly. The rockets being thus fixed, carry a quick-match, without a pipe, from the mouth of one rocket to the other; this match being lighted will give fire to all at once.

Though the directions already given may be sufficient for these rockets, we shall here add an improvement on a very essential part of this device, which is, that of hanging the rockets to be fired; for before the following method was contrived, many attempts proved unsuccessful. Instead, therefore, of the old and common manner of hanging them on nails or hooks, make use of the following contrivance: Have a ring made of strong iron wire large enough for the stick to go in as far as the mouths of the rockets; then have another ring supported by a small iron, at some distance from the post or stand to which it is fixed: then have another ring fit to receive and guide the small end of the stick. Rockets thus suspended will have nothing to obstruct their fire; but when they are hung on nails or hooks, in such a manner that some of their mouths are against or upon a nail, there can be no certainty of their rising in a vertical direction.

85 To fire rockets without sticks.

To fire rockets without sticks, you must have a stand, of a block of wood, a foot diameter, and make the bottom flat, so that it may stand steady: in the centre of the top of this block draw a circle two inches and a half diameter, and divide the circumference of it into three equal parts; then take three pieces of thick iron wire, each about three feet long, and drive them into the block, one at each point made on the circle; when these wires are driven in deep enough to hold them fast and upright, so that the distance from one to the other is the same at top as at bottom, the stand is complete.

The stand being thus made, prepare the rockets thus: Take some common sky-rockets of any size, and head them as you please; then get some balls of lead, and tie to each a small wire two or two feet and a half long, and the other end of each wire tie to the neck of a rocket. These balls answer the purpose of sticks when made of a proper weight, which is about two-thirds the weight of the rocket; but when they are of a proper size, they will balance the rocket in the same manner as a stick, at the usual point of poise. To fire these, hang them, one at a time, between the tops of the wires, letting their heads rest on the point of the wires, and the balls hang down between them: if the wires should be too wide for the rockets, press them together till they fit; and if too close, force them open; the wires for this purpose must be softened, so as not to have any spring, or they will not keep their position when pressed close or opened.

86 Scrolls for rockets.

Cases for scrolls should be made four or five inches in length, and their interior diameters three-eighths of an inch: one end of these cases must be pinched quite close before beginning to fill; and when filled, close the other end: then in the opposite sides make a small hole at each end, to the composition, as in tourbillons; and prime them with wet meal-powder. You may put in the head of a rocket as many of these cases as it will contain: being fired they turn very quick in the air, and form a scroll or spiral line. They are generally filled with a strong charge, as that of serpents or brilliant fire.

87 Swarmers.

Rockets that pass under the denomination of *swarmers*, are those from two ounces downwards. These rockets are fired sometimes in flights, and in large water-works, &c. Swarmers of one and two ounces are bored, and made in the same manner as large rockets, except that, when headed, their heads must be put on without a collar: the number of strokes for driving one ounce must be eight, and for two ounces twelve.

All rockets under one ounce are not bored, but must be filled to the usual height with composition, which generally consists of fine meal-powder four ounces, and charcoal or steel-dust two drams: the number of strokes for ramming these small swarmers is not material, provided they are rammed truly, and moderately hard. The necks of unbored rockets must be in the same proportion as in common cases.

88 Stands for rockets.

Care must be taken, in placing the rockets, when they are to be fired, to give them a vertical direction at their first setting out; which may be managed thus: Have two rails of wood, of any length, supported at each end by a perpendicular leg, so that the rails may be horizontal, and let the distance from one to the other be almost equal to the length of the sticks of the rockets intended to be fired; then in the front of the top rail drive square hooks at eight inches distance, with their points turning sidewise, so that when the rockets are hung on them, the points will be before the sticks and keep them from falling or being blown off by the wind; in the front of the rail at bottom must be staples, driven perpendicular under the hooks at top; through these staples put the small ends of the rocket sticks. Rockets are fired by applying a lighted port-fire to their mouths.

N. B. When sky-rockets are made to perfection, and fired, they will stand two or three seconds on the hook before they rise, and then mount up briskly, with a steady motion, carrying a large tail from the ground all the way up, and just as they turn, break, and disperse the stars.

89 Girandole chests for flights of rockets.

Girandole chests are generally composed of four sides of equal dimensions; but may be made of any diameter, according to the number of rockets designed to be fired; their height must be in proportion to the rockets, but must always be a little higher than the rockets with their sticks. When the sides are joined, fix in the top as

Varieties of Construction. as far down the chest as the length of one of the rockets with its cap on. In this top, make as many square or round holes to receive the rocket sticks as there are to be rockets; but let the distance between them be sufficient for the rockets to stand without touching one another; then from one hole to another cut a groove large enough for a quick match to lie in; the top being thus fixed, put in the bottom, at about one foot and a half distance from the bottom of the chest, in this bottom must be as many holes as in the top, and all to correspond: but these holes need not be so large as those in the top.

To prepare the chest, a quick match must be laid in all the grooves, from hole to hole: then take some sky-rockets, and rub them in the mouth with wet meal-powder, and put a bit of match up the cavity of each; which match must be long enough to hang a little below the mouth of the rocket. The rockets and chest being prepared according to the above directions, put the sticks of the rockets through the holes in the top and bottom of the chest, so that their mouths may rest on the quick-match in the grooves: by which all the rockets will be fired at once; for by giving fire to any part of the match, it will communicate to all the rockets in an instant. As it would be rather troublesome to direct the sticks from the top to the proper holes in the bottom, it will be necessary to have a small door in one of the sides, through which, when opened, you may see how to place the sticks. Flights of rockets being seldom set off at the beginning of any fire-works, they are in danger of being fired by the sparks from wheels, &c.; therefore, to preserve them, a cover should be made to fit on the chest, and the door in the side kept shut.

90 Line-rockets. Line-rockets are made and rammed as the sky-rockets, but have no heads, and the cases must be cut close to the clay: they are sometimes made with six or seven changes, but in general not more than four or five. The method of managing these rockets is the following: First, have a piece of light wood, the length of one of the rockets turned round about two inches and a half diameter, with a hole through the middle lengthwise, large enough for the line to go easily through; if four changes are intended, have four grooves cut in the swivel, one opposite the other, in which to lay the rockets.

The mouths of the rockets being rubbed with wet meal-powder, lay them in the grooves head to tail, and tie them fast; from the tail of the first rocket carry a leader to the mouth of the second, and from the second to the third, and so on to as many as there are on the swivel, making every leader very secure; but in fixing these pipes, take care that the quick-match does not enter the bores of the rockets: the rockets being fixed on the swivel and ready to be fired, have a line 100 yards long, stretched and fixed up tight, at any height from the ground; but be sure to place it horizontally: this length of line will do for half-pound rockets; but if larger, the line must be longer. Before you put up the line, put one end of it through the swivel; and when you fire the line rocket, let the mouth of that rocket which is first fired face that end of the line where you stand; then the first rocket will carry the rest to the other end of the line, and the second will bring them back; and so they will run out and in according to the number of rockets: at each end of the line there must be a piece of flat wood for the rocket to strike against, or its force will cut the line. Let the line be well soaped, and the hole in the swivel very smooth. Varieties of Construction.

To line rockets may be fixed a great variety of figures, such as flying dragons, Mercuries, ships, &c.; or they may be made to run on the line like a wheel; which is done in this manner. Have a flat swivel made very exactly, and on it tie two rockets obliquely one on each side, which will make it turn round as it goes, and form a circle of fire; the charge for these rockets should be a little weaker than common. If you would show two dragons fighting, get two swivels made square, and on each tie three rockets together on the under side; then have two flying dragons made of tin, and fix one of them on the top of each swivel, so as to stand upright; in the mouth of each dragon put a small case of common fire, and another at the end of the tail; put two or three port-fires, of a strong charge, on one side of their bodies, to show them. This done, put them on the line, one at each end; but let there be a swivel in the middle of the line to keep the dragons from striking together: before firing the rockets, light the cases on the dragons; and if care be taken in firing both at the same time, they will meet in the middle of the line, and seem to fight. Then they will run back and return with great violence, which will have a very pleasing effect. The line for these rockets must be very long, or they will strike too hard together. 91 Different decorations for line rockets.

Cases for Chinese flyers may be made of different sizes, from one to eight ounces; they must be made thick of paper, and eight interior diameters long; they are rolled in the same manner as tourbillons, with a straight pasted edge, and pinched close at one end. The method of filling them is, the case being put in a mould, whose cylinder, or foot, must be flat at top without a nipple, fill it within half a diameter of the middle; then ram in half a diameter of clay, on that as much composition as before, on which drive half a diameter of clay; then pinch the case close, and drive it down flat: after this is done, bore a hole exactly through the centre of the clay in the middle; then in the opposite sides, at both ends, make a vent; and in that side intended to be fired first make a small hole to the composition near the clay in the middle, from which carry a quick-match, covered with a single paper, to the vent at the other end; then, when the charge is burnt on one side, it will, by means of the quick-match, communicate to the charge on the other (which may be of a different sort). The flyers being thus made, put an iron pin, that must be fixed in the work on which they are to be fired, and on which they are to run, through the hole in the middle; on the end of this pin must be a nut to keep the flyer from running off. If they are to turn back again after they are burnt, make both the vents at the ends on the same side, which will alter its course the contrary way. 92 Cases for Chinese flyers.

Table rockets are designed merely to show the truth of driving, and the judgment of a fire-worker; they having no other effect, when fired, than spinning round in the same place where they begin, till they are burnt out, and showing nothing more than an horizontal circle of fire. 93 Table rockets.

The method of making these rockets is,—Have a cone turned out of hard wood two inches and a half in diameter, and as much high; round the base of it drive a line;

Varieties of Construction.

line; on this line fix four spokes, each two inches long, so as to stand one opposite the other; then fill four nine-inch one pound cases with any strong composition, within two inches of the top: these cases are made like tourbillons, and must be rammed with the greatest exactness.

The rockets being filled, fix their open ends on the short spokes; then in the side of each case bore a hole near the clay; all these holes, or vents, must be so made that the fire of each case may act the same way; from these vents carry leaders to the top of the cone, and tie them together. When the rockets are to be fired, set them on a smooth table, and light the leaders in the middle, and all the cases will fire together (see fig. 32.) and spin on the point of the cone.

These rockets may be made to rise like tourbillons, by making the cases shorter, and boring four holes in the under side of each at equal distances: this being done they are called *double tourbillons*.

Note, All the vents in the under side of the cases must be lighted at once; and the sharp point of the cone cut off, at which place make it spherical.

94 Aerial globes or bombs.

Fireworks called aerial globes or bombs consist of a spherical case made of strong paper, or of wood, prepared as will be immediately described, and thrown from a mortar commonly made of pasteboard, with a copper chamber to contain the charge, such as AB, fig. 33. (Fig. 33.) This small mortar must be made of light wood, or of paper pasted together, and rolled up in the form of a cylinder, or truncated cone, the bottom excepted; which, as already said, must be of wood. The chamber for the powder AC must be pierced obliquely, with a small gimlet, as seen at BC; so that the aperture B corresponding to the aperture of the metal mortar, in which this paper mortar must be placed when the globe is fired, the fire applied to the latter may be communicated to the powder which is at the bottom of the chamber AC, immediately below the globe. By these means the globe will catch fire and make an agreeable noise as it rises into the air; but it would not succeed so well if any vacuity were left between the powder and globe.

A profile or perpendicular section of such a globe is represented by the right-angled parallelogram ABCD, fig. 34.; the breadth of which AB is nearly equal to the height AD. The thickness of the wood towards the two sides L, M, is equal to about the twelfth part of the diameter of the globe; and the thickness E, F, of the cover, is double the preceding, or equal to a sixth part of the diameter. The height GK, or HI of the chamber GHIK, where the match is applied, and which is terminated by the semicircle LGKM, is equal to the fourth part of the breadth AB, and its breadth GH is equal to the sixth part of AB.

We must here observe, that it is dangerous to put wooden covers, such as EF, on aerial balloons or globes, for these covers may be so heavy as to wound those on whom they happen to fall. It will be sufficient to place turf or hay above the globe, in order that the powder may experience some resistance.

The globe must be filled with several pieces of cane or common reed, equal in length to the interior height of the globe, and charged with a slow composition, made of three ounces of pounded gunpowder, an ounce of sulphur moistened with a small quantity of petroleum oil, and two ounces of charcoal; and in order that these reeds or canes may catch fire sooner, and with more facility, they must be charged at the lower ends, which rest on the bottom of the globe, with pulverized gunpowder moistened in the same manner with petroleum oil, or well besprinkled with brandy, and then dried.

The bottom of the globe ought to be covered with a little gunpowder half pulverized and half grained; which, when set on fire by means of a match applied to the end of the chamber GH, will set fire to the lower part of the reed. But care must have been taken to fill the chamber with a composition similar to that in the reeds, or with another slow composition made of eight ounces of gunpowder, four ounces of saltpetre, two ounces of sulphur, and one ounce of charcoal: the whole must be well pounded and mixed.

Instead of reeds, the globe may be charged with running rockets, or paper petards, and a quantity of fiery stars or sparks mixed with the pulverized gunpowder, placed without any order above these petards, which must be choked at unequal heights, that they may perform their effect at different times.

These globes may be constructed in various other ways, which it would be tedious here to enumerate. We shall only observe, that when loaded they must be well covered at the top; they must be wrapped up in a piece of cloth dipped in glue, and a piece of woollen cloth must be tied round them, so as to cover the hole which contains the match.

95 Fuzes for globes or air balloons.

Fuzes for air balloons are sometimes turned out of dry beech, with a cup at top to hold the quick-match, or other firing material; but if made with pasted paper, they will do as well: the diameter of the *former* for fuzes for coehorn balloons must be half an inch; for a royal fuze, five-eighths of an inch; for an eight inch fuze, three-fourths of an inch; and for a ten inch fuze, seven-eighths of an inch. Having rolled the cases, pinch and tie them almost close at one end: then drive them down, and let them dry. Before beginning to fill them, mark on the outside of the case the length of the charge required, allowing for the thickness of the bottom; and when the composition is rammed in, take two pieces of quick-match about six inches long, and lay one end of each on the charge, and then a little meal-powder, which ram down hard; the loose ends of the match double up into the top of the fuze, and cover it with a paper cap to keep it dry. When the shells are put into the mortars, uncap the fuzes, and pull out the loose ends of the match, and let them hang on the sides of the balloons. The use of the match is, to receive the fire from the powder in the chamber of the mortar, in order to light the fuze: the shell being put in the mortar with the fuze uppermost, and exactly in the centre, sprinkle over it a little meal-powder, and it will be ready to be fired. Fuzes made of wood must be longer than those of paper, and not bored quite through, but left solid about half an inch at bottom; and when used saw them off to a proper length, measuring the charge from the cut at top.

96 Tourbillons.

To make Tourbillons.—Having filled some cases within about one diameter and a half, drive in a ladleful of clay; then pinch the ends close, and drive them down with a mallet. When done, find the centre of gravity of each case: where the nail and stick are tied, which should

Varieties of Construction.

should be half an inch broad at the middle, and run a little narrower to the ends: these sticks must have their ends turned upwards, so that the cases may turn horizontally on their centres: at the opposite sides of the cases, at each end, bore a hole close to the clay with a gimblet, the size of the neck of a common case of the same nature: from these holes draw a line round the case, and at the under part of the case bore a hole with the same gimblet, within half a diameter of each line towards the centre; then from one hole to the other draw a right line. Divide this line into three equal parts; and at X and Y (fig. 35.) bore a hole; then from these holes to the other two lead a quickmatch, over which paste a thin paper. Fig. 36. represents a tourbillon as it should lie to be fired, with a leader from one side hole A to the other B. When tourbillons are fired lay them on a smooth table, with their sticks downwards, and burn the leader through the middle with a portfire. They should spin three or four seconds on the table before they rise, which is about the time the composition will be burning from the side holes to those at bottom.

To tourbillons may be fixed reports in this manner: In the centre of the case at top make a small hole, and in the middle of the report make another; then place them together, and tie on the report, and with a single paper secure it from fire: this done, the tourbillon is completed. By this method you may fix on tourbillons small cones of stars, rains, &c. but be careful not to load them too much. One eighth of an inch will be enough for the thickness of the sticks, and their length equal to that of the cases.

97 Aigrettes.

Mortars to throw aigrettes are generally made of pasteboard, of the same thickness as balloon mortars, and two diameters and a half long in the inside from the top of the foot: the foot must be made of elm without a chamber, but flat at top, and in the same proportion as those for balloon mortars; these mortars must also be bound round with a chord: sometimes eight or nine of these mortars, of about three or four inches diameter, are bound all together, so as to appear but one: but when they are made for this purpose, the bottom of the foot must be of the same diameter as the mortars, and only half a diameter high. The mortars being bound well together, fix them on a heavy solid block of wood. To load these mortars, first put on the inside bottom of each a piece of paper, and on it spread one ounce and a half of meal and corn powder mixed; then tie the serpents up in parcels with quickmatch, and put them in the mortar with their mouths downwards; but take care the parcels do not fit too tight in the mortars, and that all the serpents have been well primed with powder wetted with spirit of wine. On the top of the serpents in each mortar lay some paper or tow; then carry a leader from one mortar to the other all round, and then from all the outside mortars into that in the middle: these leaders must be put between the cases and the sides of the mortar, down to the powder at bottom: in the centre of the middle mortar fix a fire pump, or brilliant fountain, which must be open at bottom, and long enough to project out of the mouth of the mortar; then paste paper on the tops of all the mortars.

Mortars thus prepared are called a *nest of serpents*, as represented by fig. 37. When these mortars are to be fired, light the fire pump C, which when consumed will communicate to all the mortars at once by means of the leaders. For mortars of 8, 9, or 10 inches diameter, the serpents should be made in one and two ounce cases, six or seven inches long, and fired by a leader brought out of the mouth of the mortar, and turned down the outside, and the end of it covered with paper, to prevent the sparks of the other works from setting it on fire. For a six-inch mortar, let the quantity of powder for firing be two ounces; for an eight-inch, two ounces and three quarters; and for a ten-inch, three ounces and three quarters. Care must be taken in these, as well as small mortars, not to put the serpents in too tight for fear of bursting the mortars. These mortars may be loaded with stars, crackers, &c.

If the mortars, when loaded, are sent to any distance, or liable to be much moved, the firing powder should be secured from getting amongst the serpents, which would endanger the mortars, as well as hurt their performance. To prevent this, load the mortars thus: First put in the firing powder, and spread it equally about; then cut a round piece of blue touch-paper, equal to the exterior diameter of the mortar, and draw on it a circle equal to the interior diameter of the mortar, and notch it all round as far as that circle: then paste that part which is notched, and put it down the mortar close to the powder, and stick the pasted edge to the mortar; this will keep the powder always smooth at bottom, so that it may be moved or carried anywhere without receiving damage. The large single mortars are called *pots des aigrettes*.

Pots des Brins are formed of pasteboard, and must be rolled pretty thick. They are usually made three or four inches diameter, and four diameters long; and pinched with a neck at one end, like common cases. A number of these are placed on a plank thus: Having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg; through all the holes run a quickmatch, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that when lighted at one end it may discharge the whole almost instantaneously: in all the pots put about one ounce of meal and corn powder; then in some put stars, and in others rains, snakes, serpents, crackers, &c.: when they are all loaded, paste paper over their mouths. Two or three hundred of these pots being fired together make a very pretty show, by affording so great a variety of fires. Fig. 38. is a range of pots des brins, with a leader A, by which they are fired. 98 Pots des brins.

Pots des Saucissons are generally fired out of large mortars without chambers, the same as those for aigrettes, only somewhat stronger. Saucissons are made of one and two ounce cases, five or six inches long, and choked in the same manner as serpents. Half the number which the mortar contains must be driven one diameter and a half with composition, and the other half two diameters, so that when fired they may give two volleys of reports. But if the mortars are very strong, and will bear a sufficient charge to throw the saucissons very high, you may make three volleys of reports, by dividing the number of cases into three parts, and making a difference 99 Pots des saucissons.

difference in the height of the charge. After they are filled, pinch and tie them at top of the charge almost close; only leaving a small vent to communicate the fire to the upper part of the case, which must be filled with corn-powder very near the top; then pinch the end quite close, and tie it: after this is done, bind the case very tight with waxed packthread, from the choke at top of the composition to the end of the case; this will make the case very strong in that part, and cause the report to be very loud. Saucissons should be rolled a little thicker of paper than the common proportion. When they are to be put in the mortar, they must be primed in their mouths, and fired by a case of brilliant fire fixed in their centre.

The charge for these mortars should be one-sixth or one-eighth more than for *pots des aigrettes* of the same diameter.

100 **Single vertical wheels.**

There are different sorts of vertical wheels; some having their fells of a circular form, others of an hexagonal, octagonal, or decagonal form, or of any number of sides, according to the length of the cases you design for the wheel: the spokes being fixed in the nave, nail slips of tin, with their edges turned up so as to form grooves for the cases to lie in, from the end of one spoke to that of another; then tie the cases in the grooves head to tail, in the same manner as those on the horizontal water-wheel, so that the cases successively taking fire from one another, will keep the wheel in an equal rotation. Two of these wheels are very often fired together, one on each side of a building; and both lighted at the same time, and all the cases filled alike, to make them keep time together; as they will, if made by the following directions: In all the cases of both wheels, except the first, on each wheel drive two or three ladlesful of slow fire, in any part of the cases; but be careful to ram the same quantity in each case, and in the end of one of the cases, on each wheel, you may ram one ladleful of dead-fire composition, which must be very lightly driven; you may also make many changes of fire by this method.

Let the hole in the nave of the wheel be lined with brass, and made to turn on a smooth iron spindle. On the end of this spindle let there be a nut, to screw off and on; when you have put the wheel on the spindle, screw on the nut, which will keep the wheel from flying off. Let the mouth of the first case be a little raised. See fig. 39. Vertical wheels are made from ten inches to three feet diameter, and the size of the cases must differ accordingly; four-ounce cases will do for wheels of 14 or 16 inches diameter, which is the proportion generally used. The best wood for wheels of all sorts is a light and dry beech.

101 **Horizontal wheels.**

Horizontal wheels are best when their fells are made circular; in the middle of the top of the nave must be a pintle, turned out of the same piece as the nave, two inches long, and equal in diameter to the bore of one of the cases of the wheel: there must be a hole bored up the centre of the nave, within half an inch of the top of the pintle. The wheel being made, nail at the end of each spoke (of which there should be six or eight) a piece of wood, with a groove cut in it to receive the case. Fix these pieces in such a manner that half the cases may incline upwards and half downwards, and that, when they are tied on, their heads and tails may come very nearly together; from the tail of one case to the mouth of the other carry a leader, which should be secured with pasted paper. Besides these pipes, it will be necessary to put a little meal-powder within the pasted paper, to blow off the pipe, that there may be no obstruction to the fire from the cases. By means of these pipes the cases will successively take fire, burning one upwards and the other downwards. On the pintle fix a case of the same sort as those on the wheel; this case must be fired by a leader from the mouth of the last case on the wheel, which case must play downwards: instead of a common case in the middle, you may put a case of Chinese fire, long enough to burn as long as two or three of the cases on the wheel.

Horizontal wheels are often fired two at a time, and made to keep time like vertical wheels, only they are made without any slow or dead fire; 10 or 12 inches will be enough for the diameter of wheels with six spokes. Fig. 40. represents a wheel on fire, with the first case burning. Plate CCCCLIV. fig. 40.

102 **Spiral wheels.**

Spiral wheels, are only double horizontal wheels, and made thus: The nave must be about six inches long, and rather thicker than the single sort; instead of the pintle at top, make a hole for the case to be fixed in, and two sets of spokes, one set near the top of the nave, and the other near the bottom. At the end of each spoke cut a groove wherein you tie the cases, there being no fell; the spokes should not be more than two inches and a half long from the naves, so that the wheel may not be more than eight or nine inches diameter; the cases are placed in such a manner, that those at top play down, and those at bottom play up, but let the third or fourth case play horizontally. The case in the middle may begin with any of the others: six spokes will be enough for each set, so that the wheel may consist of 12 cases, besides that on the top: the cases six inches each.

103 **Plural wheels.**

Plural wheels are made to turn horizontally, and to consist of three sets of spokes, placed six at top, six at bottom, and four in the middle, which last must be a little shorter than the rest: let the diameter of the wheel be 10 inches; the cases must be tied on the ends of the spokes in grooves cut on purpose, or in pieces of wood nailed on the end of the spokes, with grooves cut in them as usual: in clothing these wheels, make the upper set of cases play obliquely downwards, the bottom set obliquely upwards, and the middle set horizontally. In placing the leaders, they must be managed so that the cases may burn thus, viz. first up, then down, then horizontal, and so on with the rest. But another change may be made, by driving in the end of the eighth case two or three ladlesful of slow fire, to burn till the wheel has stopped its course; then let the other cases be fixed the contrary way, which will make the wheel run back again: for the case at top you may put a small gerbe; and let the cases on the spokes be short, and filled with a strong brilliant charge.

104 **Illuminated spiral wheels.**

Illuminated spiral wheels.—First have a circular horizontal wheel made two feet diameter, with a hole quite through the nave,; then take three thin pieces of deal, three feet long each, and three-fourths of an inch broad each: one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular to that in the block of the wheel, but not so large. The wheel being thus made, have

1. Varieties of Construction.

have a hoop planed down very thin and flat; then nail one end of it into the fell of the wheel, and wind it round the three sticks in a spiral line from the wheel to the block at top: on the top of this block fix a case of Chinese fire; on the wheel you may place any number of cases, which must incline downwards, and burn two at a time. If the wheel should consist of ten cases, you may let the illuminations and Chinese fire begin with the second cases. The spindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper block is to turn, and the whole weight of the wheel to rest. See fig. 41.

105 Double spiral wheel.

Double spiral wheel.—For this wheel the block, or nave, must be as long as the height of the worms, or spiral lines, but must be made very thin, and as light as possible. In this block must be fixed several spokes, which must diminish in length, from the wheel to the top, so as not to exceed the surface of a cone of the same height. To the ends of these spokes nail the worms, which must cross each other several times: clothe these worms with illuminations, the same as those on the single wheels; but the horizontal wheel you may clothe as you like. At top of the worm place a case of spur-fire, or an amber light, see fig. 42. This figure is shown without leaders, to prevent a confusion of lines.

106 Balloon wheels.

Balloon wheels are made to turn horizontally: they must be made two feet diameter, without any spokes; and very strong, with any number of sides. On the top of a wheel range and fix in pots, three inches diameter and seven inches high each, as many of these as there are cases on the wheel: near the bottom of each pot make a small vent; into each of these vents carry a leader from the tail of each case; load some of the pots with stars, and some with serpents, crackers, &c. As the wheels turn, the pots will successively be fired, and throw into the air a great variety of fires.

107 Fruiloni wheels.

For fruiloni wheels first have a nave made nine inches long and three in diameter: near the bottom of this nave fix eight spokes, with a hole in the end of each, large enough to receive a two or four ounce case: each of these spokes may be 14 inches long from the block. Near the top of this block fix eight more of the same spokes, exactly over the others, but not so long by two inches. As this wheel is to run horizontally, all the cases in the spokes must play obliquely upwards, and all those in the spokes at bottom obliquely downwards. This being done, have a small horizontal wheel made with eight spokes, each five inches long from the block: on the top of this wheel place a case of brilliant fire: all the cases on this wheel must play in an oblique direction downwards, and burn two at a time, and those on the large wheel four at a time; that is, two of those in the top set of spokes, and two of those in the bottom set of spokes.

The four first cases on the large wheel, and the two first on the small, must be fired at the same time, and the brilliant fire at top at the beginning of the last cases. The cases of the wheels may be filled with a gray charge. When these wheels are completed, you must have a strong iron spindle, made four feet six inches long, and fixed perpendicularly on the top of a stand: on this put the large wheel, whose nave must have a hole quite through from the bottom to the top. This hole must be large enough to turn easily round the bottom of the spindle, at which place there must be a shoulder, to keep the wheel from touching the stand: at the top of the spindle put the small wheel, and join it to a large one with a leader, in order that they may be fired both together.

Varieties of Construction.

Cascades of fire are made of any size; but one made according to the dimensions of that shown in fig. 43. will be large enough for eight-ounce cases. Let the distance from A to B be three feet; from B to C two feet six inches; and from C to D two feet; and let the cross piece at A be four feet long: then from each end of this piece draw a line to D; then make the other cross pieces so long as to come within those lines. The top piece D may be of any length, so as to hold the cases, at a little distance from each other; all the cross pieces are fixed horizontally, and supported by brackets; the bottom cross piece should be about one foot six inches broad in the middle, the second one foot, the third nine inches, and the top piece four inches: the cases may be made of any length, but must be filled with a brilliant charge. On the edges of the cross pieces must be nailed bits of wood, with a groove cut in each piece, large enough for a case to lie in. These bits of wood are fixed so as to incline downwards, and that the fire from one tier of cases may play over that of the other. All the cases being tied fast on, carry leaders from one to the other; and let there be a pipe hung from the mouth of one of the cases, covered at the end with a single paper, which you burn to fire the cascade. 108 Cascades of fire.

The Fire Tree.—To make a fire tree, as shown by fig. 44. you must first have a piece of wood six feet long, and three inches square; then at E, nine inches from the top, make a hole in the front, and in each side; or, instead of holes, you may fix short pegs, to fit the inside of the cases. At F, nine inches from E, fix three more pegs; at G, one foot nine inches from F, fix three pegs; at H nine inches from G, fix three pegs; at I, nine inches from H, fix three pegs, inclining downwards; but all the other pegs must incline upwards, that the cases may have the same inclination as is seen in the figure: then at top place a four-inch mortar, loaded with stars, rains, or crackers. In the middle of this mortar place a case filled with any sort of charge, but let it be fired with the other cases: a brilliant charge will do for all the cases; but the mortar may be made of any diameter, and the tree of any size; and on it any number of cases, provided they are placed in the manner described. 109 Fire tree.

Chinese Fountains.—To make a Chinese fountain, you must have a perpendicular piece of wood seven feet long and two inches and a half square. Sixteen inches from the top, fix on the front a cross piece one inch thick, and two and a half broad, with the broad side upwards; below this, fix three more pieces of the same width and thickness, at sixteen inches from each other; let the bottom rail be five feet long, and the others of such a length as to allow the fire-pumps to stand in the middle of the intervals of each other. The pyramid being thus made, fix in the holes made in the bottom rail five fire pumps, at equal distances; on the second rail, place four pumps; on the third, three; on the fourth, two; and on the top of the post, one; but place them all to incline a little forwards, that, when they throw out the stars, they may not strike against the 110 Chinese fountains.

the cross rails. Having fixed your fire-pumps, clothe them with leaders, so that they may all be fired together. See fig. 45.

111 Illuminated globes with horizontal wheels.

Of illuminated Globes with horizontal Wheels.—The hoops for these globes may be made of wood, tin, or iron wire, about two feet in diameter. For a single globe, take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave six inches long; on the top of which the globe is fixed, so as to stand three or four inches from the wheel: on this wheel you may put any number of cases, filled with what charge you please; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will stand within two inches and a half of each other: fasten these on the hoops with small iron binding wire; and when they are all on, put on the pipes of communication, which must be so managed as to light them all with the second or third case on the wheel. The spindle on which the globe is to run must go through the block of the wheel, up to the inside of the top of the globe; where must be fixed a bit of brass, or iron, with a hole in it to receive the point of the spindle, on which the whole weight of the wheel is to bear, as in fig. 46. which represents a globe on its spindle. By this method may be made a crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are managed so as to stand still, and the wheel only to turn round; but when you would have the globe or crown to stand still, and the wheel to run by itself, the block of the wheel must not be so long, nor the spindle any longer than just to raise the globe a little above the wheels; and the wheel cases and illumination must begin together.

112 Dodecahedron.

The Dodecahedron.—So called because it nearly represents a twelve-sided figure, is made thus: First have a ball turned out of some hard wood, 14 inches diameter: divide its surface into 14 equal parts, from which bore holes one inch and a half diameter, perpendicular to the centre, so that they may all meet in the middle: then let there be turned in the inside of each hole a female screw; and to all the holes but one must be made a round spoke five feet long, with four inches of the screw at one end to fit the holes; then in the screw-end of all the spokes bore a hole, five inches up, which must be bored slanting, so as to come out at one side, a little above the screw; from which cut a small groove along the spoke, within six inches of the other end, where make another hole through to the other side of the spoke. In this end fix a spindle, on which put a small wheel of three or four sides, each side six or seven inches long; these sides must have grooves cut in them, large enough to receive a two or four ounce case. When these wheels are clothed, put them on the spindles, and at the end of each spindle put a nut to keep the wheel from falling off. The wheels being thus fixed, carry a pipe from the mouth of the first case on each wheel, through the hole in the side of the spoke, and from thence along the groove, and through the other hole, so as to hang out at the screw-end about an inch. The spokes being all prepared in this manner, you must have a post, on which you intend to fire the work, with an iron screw in the top of it, to fit one of the holes in the ball: on the screw fix the ball; then in the top hole of the ball put a little meal-powder, and some loose quick-match: then screw in all the spokes; and in one side of the ball bore a hole, in which put a leader, and secure it at the end; and the work will be ready to be fired. By the leader the powder and match in the centre is fired, which will light the match at the ends of the spokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A gray charge will be proper for the wheel cases.

113 Yew tree of brilliant fire.

The Yew Tree of Brilliant Fire is represented by fig. 47. as it appears when burning. First, let A be an upright piece of wood, four feet long, two inches broad, and one thick: at top of the piece, on the flat side, fix a hoop 14 inches diameter; and round its edge and front place illuminations, and in the centre a five-pointed star; then at E, which is one foot and a half from the edge of the hoop, place two cases of brilliant fire, one on each side; these cases should be one foot long each: below these fix two more cases of the same size, and at such a distance that their mouths may almost meet them at top: then close to the ends of these fix two more of the same cases; they must stand parallel to them at E. The cases being thus fixed, clothe them with leaders; so that they, with the illuminations and stars at top, may all take fire together.

114 Stars with points.

Stars with Points for regulated Pieces, &c.—These stars are made of different sizes, according to the work for which they are intended; they are made with cases from one ounce to one pound, but in general with four-ounce cases, four or five inches long: the case must be rolled with paste, and twice as thick as that of a rocket of the same bore. Having rolled a case, pinch one end of it quite close: then drive in half a diameter of clay; and when the case is dry, fill it with composition two or three inches to the length of the cases with which it is to burn: at top of the charge drive some clay; as the ends of these cases are seldom pinched, they would be liable to take fire. Having filled a case, divide the circumference of it at the pinched end close to the clay into five equal parts; then bore five holes with a gimblet about the size of the neck of a common four-ounce case, into the composition: from one hole to the other carry a quick-match, and secure it with paper: this paper must be put on in the manner of that on the end of wheel-cases, so that the hollow part, which projects from the end of the case, may serve to receive a leader from any other work, to give fire to the points of the stars. These stars may be made with any number of points.

115 Fixed sun with a transparent face.

Fixed Sun with a transparent Face.—To make a sun of the best kind, there should be two rows of cases, as in fig. 48. which will show a double glory, and make the rays strong and full. The frame or sun-wheel, must be made thus: Have a circular flat nave made very strong, 12 inches diameter: to this fix six strong flat spokes, A, B, C, D, E, F. On the front of these fix a circular fell, five feet diameter; within which fix another fell, the length of one of the sun-cases less in diameter; within this fix a third fell, whose diameter must be less than the second by the length of one case and one-third. The wheel being made, divide the fells into so many equal

parts

Varieties of Construction.

parts as there are to be cases (which may be done from 24 to 44): at each division fix a flat iron staple; these staples must be made to fit the cases, to hold them fast on the wheel; let the staples be so placed, that one row of cases may lie in the middle of the intervals of the other.

In the centre of the block of the sun drive a spindle, on which put a small hexagonal wheel, whose cases must be filled with the same charge as the cases of the sun: two cases of this wheel must burn at a time, and begin with them on the fells. Having fixed on all the cases, carry pipes of communication from one to the other, as you see in the figure, and from one side of the sun to the wheel in the middle, and from thence to the other side of the sun. These leaders will hold the wheel steady while the sun is fixing up, and will also be a sure method of lighting both cases of the wheel together. A sun thus made is called a *brilliant sun*, because the wood work is entirely covered with fire from the wheel in the middle, so that there appears nothing but sparks of brilliant fire: but if you would have a transparent face in the centre, you must have one made of pasteboard of any size. The method of making a face is, by cutting out the eyes, nose, and mouth for the sparks of the wheel to appear through; but instead of this face, you may have one painted on oiled paper, or Persian silk, strained tight on a hoop; which hoop must be supported by three or four pieces of wire at six inches distance from the wheel in the centre, so that the light of it may illuminate the face. By this method may be shown in the front of a sun, VIVAT REX, cut in pasteboard, or Apollo painted on silk; but, for a small collection, a sun with a single glory, and a wheel in front, will be most suitable. Half pound cases, filled ten inches with composition, will be a good size for a sun of five feet diameter; but if larger, the cases must be greater in proportion.

116 Three vertical wheels illuminated.

Three Vertical Wheels illuminated, which turn on their own Naves upon a horizontal Table.—A plan of this is shown by fig. 49. Let D be a fir table three feet in diameter: this table must be fixed horizontally on the top of a post; on this post must be a perpendicular iron spindle, which must come through the centre of the table: then let A, B, C, be three spokes joined to a triangular flat piece of wood, in the middle of which make a hole to fit easily over the spindle: let E, F, G, be pieces of wood, four or five inches long each, and two inches square, fixed on the under sides of the spokes; in these pieces make holes lengthwise to receive the thin part of the blocks of the wheels, which, when in, are prevented from coming out by a small iron pin being run through the end of each. K, L, M, are three vertical octagonal wheels, 18 inches diameter each: the blocks of these wheels must be long enough for three or four inches to rest on the table; round which part drive a number of sharp points of wire, which must not project out of the blocks more than 1-16th of an inch: the use of these points is, that, when the blocks run round, they will stick in the table, and help the wheels forward: if the naves are made of strong wood, one inch will be enough for the diameter of the thin part, which should be made to turn easily in the holes of the pieces E, F, G. On the front of the wheels make four or five circles of strong wire, or flat hoops, and tie on them as many illuminations as they will hold at two inches distant from each other: instead of circles, you may make spiral lines, clothed with illuminations, at the same distance from each other as those on the hoops. When illuminations are fixed on a spiral line in the front of a wheel, they must be placed a little on the slant, the contrary way from that in which the wheel runs; the cases for these wheels may be filled with any coloured charge, but must burn only one at a time.

Varieties of Construction.

The wheels being thus prepared, you must have a globe, crown, or spiral wheel, to put on the spindle in the middle of the table: this spindle should be just long enough to raise the wheel of the globe, crown, or spiral wheel, so high that its fire may play over the three vertical wheels: by this means their fires will not be confused, nor will the wheels receive any damage from the fire of each other. In clothing this work, let the leaders be so managed, that all the wheels may light together, and the illuminations after two cases of each wheel are burned.

117 Illuminated chandelier.

Illuminated works are much admired by the Italians, and indeed are a great addition to a collection of works: in a grand exhibition an illuminated piece should be fired after every two or three wheels, or fixed pieces of common and brilliant fires; and likewise illuminated works may be made cheap, quick, and easy.

To make an illuminated chandelier, you must first have one made of thin wood (see fig. 50.). The chandelier being made, bore in the front of the branches, and in the body, and also in the crown at top, as many holes for illuminations as they will contain at three inches distance from each other: in these holes put illuminations filled with white, blue, or brilliant charge. Having fixed in the port-fires, clothe them with leaders. so that the chandelier and crown may light together The small circles on this figure represent the mouths of the illuminations, which must project straight from the front.

118 Flaming star with brilliant wheels.

To make a flaming star with brilliant wheels, you must first have made a circular piece of strong wood about one inch thick and two feet diameter? round this block fix eight points, two feet six inches long each; four of these points must be straight and four flaming: these points being joined on very strong, and even with the surface of the block, nail tin or pasteboard on their edges, from the block to the end of each, where they must be joined; this tin must project in front eight inches, and be joined where they meet at the block; round the front of the block fix four pieces of thick iron wire, eight inches long each, equally distant from each other: this being done, cut a piece of pasteboard round, two feet diameter, and draw on it a star, as may be seen in fig. 51. Cut out this star, and on the back of it paste oiled paper; then paint each point half red and half yellow, lengthwise; but the body of the star must be left open, wherein must run a brilliant wheel, made thus: Have a light block turned nine inches long: at each end of it fix six spokes; at the end of each spoke put a two ounce case of brilliant fire: the length of these cases must be in proportion to the wheel, and the diameter of the wheel when the cases are on must be a little less than the diameter of the body of the small star: the cases on the spokes in front must have their mouths incline outwards, and those on the inside spokes must be placed so as to form a vertical circle of fire. When you place the leaders, carry the first pipe from the tail of one of the cases

Varieties of Construction.

cases in front to the mouth of one of the inside cases, and from the tail of that to another in front, and so on to all the cases. The wheel being made, put it on a spindle, in the centre of the star; this spindle must have a shoulder at bottom, to keep the wheel at a little distance from the block. The wheel must be kept on the spindle by a nut at the end; having fixed on the wheel, fasten the transparent star to the four pieces of wire: when you fire it, you will only see a common horizontal wheel; but when the first case is burnt out, it will fire one of the vertical cases, which will show the transparent star, and fill the large flames and points with fire; then it will again appear like a common wheel, and so on for 12 charges.

119 Projected regulated piece with mutations.

A regulated piece, if well executed, is as curious as any in fire-works: it consists of fixed and moveable pieces on one spindle, representing various figures, which take fire successively one from another, without any assistance after lighting the first mutation. See fig. 53.

Fig. 53. Plate CCCCLV.

I. Names of the mutations, with the colour of fire and size of the case belonging to each.

First mutation is a hexagon vertical wheel, illuminated in front with small portfires tied on the spokes; this wheel must be clothed with two ounce cases, filled with black charge; the length of these cases is determined by the size of the wheel, but must burn singly.

Second mutation is a fixed piece, called a *golden glory*, by reason of the cases being filled with spur-fire. The cases must stand perpendicular to the block on which they are fixed, so that, when burning, they may represent a glory of fire. This mutation is generally composed of five or seven two ounce cases.

Third mutation is moveable; and is only an octagon vertical wheel, clothed with four ounce cases, filled with brilliant charge: two of these cases must burn at a time. In this wheel you may make changes of fire.

Fourth mutation is a fixed sun of brilliant fire, consisting of 12 four ounce cases; the necks of these cases must be a little larger than those of four ounce wheel-cases. In this mutation may be made a change of fire, by filling the cases half with brilliant charge, and half with gray.

Fifth mutation is a fixed piece, called the *porcupine's quills*. This piece consists of 12 spokes, standing perpendicular to the block on which they are fixed; on each of those spokes, near the end, must be placed a four ounce case of brilliant fire. All these cases must incline either to the right or left, so that they may all play one way.

Sixth mutation is a standing piece, called the *cross-fire*. This mutation consists of eight spokes fixed in a block; near the end of each of those spokes must be tied two four ounce cases of white charge, one across the other, so that the fires from the cases on one spoke may may intersect the fire from the cases on the other.

Seventh mutation is a fixed wheel, with two circular fells, on which are placed 16 eight ounce cases of brilliant fire, in the form of a star. This piece is called a *fixed star of wild fire*.

Eighth mutation.—This is a beautiful piece, called a *brilliant star-piece*. It consists of six spokes, which are strengthened by two fells of a hexagon form, at some distance from each other: at the end of each spoke, in the front, is fixed a brilliant star of five points; and on each side of every star is placed a four ounce case of black or gray charge; these cases must be placed with their mouths sidewise, so that their fires may cross each other.

Ninth mutation is a wheel-piece. This is composed of six long spokes, with a hexagon vertical wheel at the end of each: these wheels run on spindles in the front of the spokes; all the wheels are lighted together: two ounce cases will do for these wheels, and may be filled with any coloured charge.

II. Proportions of the mutations, with the method of conveying the fire from one to the other, and the distance at which they stand one from the other on the spindle.

First mutation must be a hexagon vertical wheel, 14 inches diameter; on one side of the block, whose diameter is two inches and a quarter, is fixed a tin barrel A (see fig. 53. N° 1.). This barrel must be a little less in diameter than the nave; let the length of the barrel and block be six inches. Having fixed the cases on the wheel, carry a leader from the tail of the last case into the tin barrel through a hole made on purpose, two inches from the block; at the end of this leader let there be about one inch or two of loose match, but take care to securé well the hole wherein the pipe is put, to prevent any sparks falling in, which would light the second mutation before its time, and confuse the whole.

Second mutation is thus made: Have a nave turned two inches and a half diameter, and three long; then let half an inch of that end which faces the first wheel be turned so as to fit easy into the tin barrel of the first mutation, which must turn round it without touching. On the other end of the block fix a tin barrel B, N° 2. This barrel must be six inches long, and only half an inch of it to fit on the block. Round the nave fix five spokes, one inch and a half long each; the diameter of the spokes must be equal to a two ounce *former*. On these spokes put five seven inch two ounce cases of spur-fire, and carry leaders from the mouth of one to the other, that they may all light together. Then from the mouth of one of the cases carry a leader through a hole bored slantwise in the nave, from between the spokes, to the front of the block near the spindle hole: the end of this leader must project out of the hole into the barrel of the first mutation, so that when the pipe which comes from the end of the last case on the first wheel flashes, it may take fire, and light the second mutation. To communicate the fire to the third mutation, bore a hole near the bottom of one of the five cases to the composition, and from thence carry a leader into a hole made in the middle of the barrel B: this hole must be covered with pasted paper.

Third mutation may be either an octagon or hexagon wheel, 20 inches diameter; let the nave be three inches and a quarter diameter, and three and a half in length; one inch and a half of the front of the nave must be made to fit in the barrel B. On the other end of the block fix a tin barrel C, N° 3. This barrel must be six inches and a half in length, one inch of which must fit over the block. The cases of this wheel must burn two at a time; and from the mouths of the first two cases carry a leader, through holes in the nave, into the barrel of the second mutation, after the usual manner: but besides these leaders let a pipe go across the wheel from the first case to the other; then from the tail of one of the

Varieties of Construction

the last cases carry a pipe into a hole in the middle of the barrel C: at the end of this pipe let there be some loose quick-match.

Fourth and fifth mutations.—These may be described under one head, as their naves are made of one piece, which from E to F is 14 inches; E, a block four inches diameter, with 10 or 12 short spokes, on which are fixed 11 inch eight ounce cases: let the front of this block be made to fit easily in the barrel C, and clothe the cases so that they may all light together; and let a pipe be carried through a hole in the block into the barrel C, in order to receive the fire from the leader brought from the last case on the wheel. G is the nave of the 5th mutation; whose diameter must be four inches and a half: in this nave fix 10 or 12 spokes, one foot and a half in length each; these spokes must stand seven inches distant from the spokes of the 4th mutation; and at the end of each spoke tie a four ounce case, as N° 5. All these cases are to be lighted together, by a leader brought from the end of one of the cases on N° 4. Let F and H be of the same piece of wood as E and G, but as much thinner as possible, to make the work light.

Sixth and seventh mutations.—The blocks of these two mutations are turned out of one piece of wood, whose length from F to P is 15 inches. L, a block five inches diameter, in which are fixed eight spokes, each two feet four inches long; at the end of each spoke tie two four ounce cases, as in N° 6. All these cases must be fired at the same time, by a pipe brought from the end of one of the cases on the 5th mutation. Let the distance between the spokes at L, and those in the 5th mutation, be seven inches. M, the nave of the 7th mutation, whose diameter must be five inches and a half: in this nave fix eight spokes, and on the front of them two circular fells, one of four feet eight inches diameter, and one of three feet 11 diameter; on these fells tie 16 eight ounce or pound cases, as in N° 7. and carry leaders from one to the other, so that they may be all fired together. This mutation must be fired by a leader brought from the tail of one of the cases on the 6th mutation.

Eighth and ninth mutations.—The blocks of these may be turned out of one piece, whose length from P to D must be 12 inches. O, the block of the 8th mutation, which must be six inches diameter; and in it must be fixed six spokes, each three feet in length, strengthened by a hexagon fell within three or four inches of the ends of the spokes: close to the end of each spoke, in the front, fix a five-pointed brilliant star; then seven inches below each star tie two 10 inch eight ounce cases, so that the upper ends of the cases may rest on the fells, and their ends on the spokes. Each of these cases must be placed parallel to the opposite fell (see N° 8.) NNN, &c. are the cases, and kkk, &c. the stars.

The 9th mutation is thus made: Let D be a block seven inches diameter. In this block must be screwed six spokes, six feet long each, with holes and grooves for leaders, as those in the dodecahedron; at the end of each spoke, in the front, fix a spindle for a hexagon vertical wheel, 10 inches diameter, as in N° 9. When these wheels are on, carry a leader from each into the block, so that they may all meet; then lead a pipe from the end of one of the cases of the 8th mutation, through a hole bored in the block D, to meet the leaders from the vertical wheels, so that they may all be fired together.

The spindles for larger pieces are required to be made very strong, and exact as possible; for a piece of nine mutations, let the spindle be at the large end one inch diameter, and continue that thickness as far as the 7th mutation; and thence to the 5th, let its diameter be three-fourths of an inch; from the fifth to the fourth, five-eighths of an inch; from the fourth to the second half an inch; and from the second to the end three eighths of an inch. At the small end must be a nut to keep on the first wheel, and at the thick end must be a large nut, as shown by the figure; so that the screw part of the spindle being put through a post, and a nut screwed on tight, the spindle will be held fast and steady: but you are to observe, that that part of the spindle on which the moveable pieces are to run, be made long enough for the wheels to run easy without sticking; the fixed pieces being made on different blocks, the leaders must be joined after they are fixed on the spindle. The best method of preventing the fixed mutations from moving on the spindle, is to make that part of the spindle which goes through them square; but as it would be difficult to make square holes through such long blocks as are sometimes required, it will be best to make them thus: Bore a hole a little larger than the diameter of the spindle; and at each end of the block, over the hole, fasten a piece of brass with a square hole in it to fit the spindle.

120 Horizontal changed to a vertical wheel.

To make a horizontal wheel change to a vertical wheel with a sun in front.—The sudden change of this piece is very pleasing; and gives great surprise to those who are not acquainted with the contrivance. A wheel for this purpose should be about three feet diameter, and its fell circular: on which tie 16 half pound cases filled with brilliant charge: two of these cases must burn at a time: and on each end of the nave must be a tin barrel of the same construction as those on the regulated piece. The wheel being completed, prepare the post or stand thus: First have a stand made of any height, about three or four inches square; then saw off from the top a piece two feet long; this piece join again at the place where it was cut with a hinge on one side, so that it may lift up and down in the front of the stand; then fix on the top of the bottom part of the stand, on each side, a bracket; and these brackets must project at right angles with the stand, one foot from the front, for the short piece to rest on. These brackets must be placed a little above the joint of the post, so that when the upper stand falls, it may lie between them at right angles with the bottom stand; which may be done by fixing a piece of wood, one foot long, between the brackets, and even with the top of the bottom stand; then, as the brackets rise above the bottom stand, they will form a channel for the short post to lie, and keep it steady without straining the hinge. On the side of the short post, opposite the hinge, nail a piece of wood, of such a length, that, when the post is perpendicular, it may reach about one foot and a half down the long post; to which being tied, it will hold the short stand upright. The stand being thus prepared, in the top of it fix a spindle 10 inches long: on this spindle put the wheel: then fix on a brilliant sun with a single glory; the diameter of this sun must be six inches less than that of the wheel. When you fire this piece, light the wheel first, and let it run horizontally till four cases are consumed: then from the end of the fourth case carry a leader into the tin barrel that turns over the end of the stand: this leader must be met by another brought through the top of

Varieties of Construction.

of the post, from a case filled with a strong port-fire charge, and tied to the bottom post, with its mouth facing the packthread which holds up the stand; so that when this case is lighted, it will burn the packthread, and let the wheel fall forward, by which means it will become vertical: then from the last case of the wheel, carry a leader into the barrel next the sun, which will begin as soon as the wheel is burnt out.

121 Grand illuminated volute.

Grand volute illuminated with a projected wheel in front.—First have two hoops made of strong iron wire, one of six feet diameter, and one of four feet two inches; these hoops must be joined to scrolls A, A, A, &c. as in fig. 54. These scrolls must be made of the same sort of wire as the hoops; on these scrolls tie, with iron-binding wire, as many illuminating port-fires as they will hold, at two inches distance; clothe these port-fires with leaders, so that they may all take fire together.—Then let C be a circular wheel of four spokes, three feet six inches diameter; and on its fell tie as many four ounce cases, head to tail, as will complete the circle, only allowing a sufficient distance between the cases, that the fire may pass free; which may be done by cutting the upper part of the end of each case a little shelving: on each spoke fix a four ounce case, about three inches from the fell of the wheel: these cases are to burn one at a time, and the first of them to begin with those on the fell, of which four are to burn at a time; so that the wheel will last no longer than one-fourth of the cases on the fell, which in number should be 16 or 20. On the front of the wheel form a spiral line with strong wire, on which tie port fires, placing them on a slant, with their mouths to face the same way as the cases on the wheel: all these port-fires must be fired with the second cases of the wheel. Let D, D, D, &c. be spokes of wood, all made to screw into a block in the centre; each of these spokes may be in length about four feet six inches; in the top of each fix a spindle, and on each spindle put a spiral wheel of eight spokes, such as E, E, E, &c. The blocks of these wheels must have a hole at top for the centre case, and the spindle must have nuts screwed on their ends; which nuts should fit in the holes at top of the blocks, so that all the wheels must be put on before you fix in the centre cases: as some of these wheels, from their situation, will not bear on the nut, it will be necessary to have smooth shoulders made on the spindles for the blocks to run on. The cases of these wheels are to burn double; and the method of firing them, is by carrying a leader from each down the spokes into the block in the centre, as in the dodecahedron, but the centre case of each wheel must begin with the two last cases as usual. It is to be observed, that the large circular wheel in front must have a tin barrel on its block, into which a pipe must be carried from one of the second cases on the wheel; this pipe being met by another from the large block, in which the eight spokes are screwed, will fire all the spiral wheels and the illuminating port-fires at the same time. The cases of the projected wheel may be filled with a white charge, and those of the spiral wheels with a gray charge.

Fig. 54.

122 Moon and seven stars.

Fig. 55.

Let fig. 55. be a smooth circular board six feet diameter: out of the middle of it cut a circular piece 12 or 14 inches diameter; and over the vacancy put white Persian silk, on which paint a moon's face: then let I, I, I, &c. be stars, each four or five inches diameter, cut out with five points, and covered with oiled silk: on the front of the large circular board draw a seven pointed star as large as the circle will allow; then on the lines which form this star bore holes, wherein fix pointed stars. When this case is to be fired, it must be fixed upon the front of a post, on a spindle, with a wheel of brilliant fire behind the face of the moon; so that while the wheel burns, the moon and stars will appear transparent: and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of pointed stars, will begin, being lighted by a pipe of communication from the last case of the vertical wheel, behind the moon; this pipe must be managed in the same manner as those in regulated pieces.

123 Double cone wheel illuminated.

Fig. 56.

Double cone-wheel illuminated.—This piece is represented by fig. 56. Let A be a strong decagonal or ten-sided wheel, two feet six inches diameter; then on each side of it fix a cone B and C: these cones are to consist of a number of hoops, supported by three or four pieces of wood, in the manner of the spiral wheels. Let the height of each cone be three feet six inches; and on all the hoops tie port-fires horizontally, with their mouths outwards, and clothe the wheel with eight-ounce cases, all to play horizontally, two at a time: the cones may be fired with the first or second cases. The spindle for this piece must go through both the cones, and rise three feet above the point of the cone at top; so that its length will be 10 feet four inches from the top of the post H, in which it is fixed, allowing four inches for the thickness of the block of the wheel. The whole weight of the wheel and cones must bear on a shoulder in the spindle, on which the block of the wheel must turn.—Near the top of the spindle must be a hole in the front, into which screw a small spindle, after the cones are on: then on this small spindle fix a sun D, composed of sixteen nine inch four-ounce cases of brilliant fire; which cases must not be placed on a fell, but only stuck into a block of six inches diameter: then in the front of this sun must be a circular vertical wheel, 16 inches diameter; on the front of this wheel form with iron-wire a spiral line, and clothe it with illuminations after the usual method. As this wheel is not to be fired till the cones are burnt out, the method of firing it is this: Let the hole in the block, at the top of the uppermost cone, be a little larger than the spindle which passes through it. Then, from the first case of the vertical wheel before the sun, carry a leader down the side of the spindle to the top of the block of the horizontal wheel, on which must be a tin barrel: then this leader being met by another brought from the end of the last case of the horizontal wheel, will give fire to the vertical wheel as soon as the cones are extinguished: but the sun D must not be fired till the vertical wheel is quite burned out.

124 Fire pumps.

Cases for fire pumps are made as those for tourbillons; only they are pasted, instead of being rolled dry. Having rolled and dried the cases, fill them: first put in a little meal-powder, and then a star; on which ram lightly a ladleful or two of composition, then a little meal-powder, and on that a star, then again composition; and so on till the cases are filled. Stars for fire pumps should not be round; but must be made either square, or flat and circular, with a hole through the middle: the quantity of powder for throwing the stars must increase near the top of the case; for, if much powder be put at the bottom, it will burst the case. The stars must differ in size in this manner: Let the star which is put

Varieties of Construction.

put in first be about a quarter less than the bore of the case; but let the next star be a little larger, and the third star a little larger than the second, and so on: let them increase in diameter till within two of the top of the case, which two must fit in tight. As the loading of fire-pumps is rather difficult, it will be necessary to make two or three trials before depending on their performance: when you fill a number of pumps, take care not to put in each an equal quantity of charge between the stars, so that when they are fired, they may not throw up too many stars together. Cases for fire-pumps should be made very strong, and rolled on four or eight ounce formers, 10 or 12 inches long each.

125 Vertical scroll wheel, Fig. 57.

A vertical scroll wheel may be made of any diameter, but must be constructed as in fig. 57. to do which proceed thus: Have a block made of a moderate size, in which fix four flat spokes, and on them fix a flat circular fell of wood; round the front of this fell place port-fires; then on the front of the spokes form a scroll, either with a hoop or strong iron wire; on this scroll tie cases of brilliant fire, in proportion to the wheel, head to tail, as in the figure. When you fire this wheel, light the first case near the fell; then, as the cases fire successively, the circle of fire will gradually diminish; but whether the illuminations on the fell begin with the scroll or not, is immaterial.

N. B. This wheel may be put in the front of a regulated piece, or fired by itself, occasionally.

126 Fire-globe.

There are two sorts of *fire-globes;* one with projected cases; the other with the cases concealed. For the latter have a globe made of wood, of any diameter, and divide the surface of it into 14 equal parts, and at each division bore a hole perpendicular to the centre: these holes must be in proportion to the cases intended to be used: in every hole, except one, put a case filled with brilliant or any other charge, and let the mouths of the cases be even with the surface of the globe; then cut in the globe a groove, from the mouth of one case to the other, for leaders which must be carried from case to case, so that they may all be fired together; this done, cover the globe with a single paper, and paint it. These globes may be used to ornament a building.

Fire-globes with projected cases are made thus: the globe being made with 14 holes bored in it as usual, fix in every hole except one, a case, and let each case project from the globe two-thirds of its length; then clothe all the cases with leaders, so that they may all take fire at the same time. Fire-globes are supported by a pintle, made to fit the hole in which there is no case.

127 Method of placing fire-works to be exhibited.

Nothing adds more to the appearance of fire-works than placing them properly; though this chiefly depends on the judgment of the maker. The following are the rules generally observed, whether the works are to be fired on a building or on stands: if they are a double set, place one wheel of a sort on each side of the building; and next to each of them, towards the centre, place a fixed piece, then wheels, and so on; leaving a sufficient distance between them for the fire to play from one without burning the other. Having fixed some of the works thus in front, place the rest behind them, in the centre of their intervals: The largest piece, which is generally a regulated or transparent piece, must be placed in the centre of the building, and behind it a sun, which must always stand above all the other works. A little before the building, or stands, place the large gerbes; and at the back of the works six marroon batteries, *pots des aigrettes, pots des brins, pots des saucissons*, air-balloons, and flights of rockets: the rocket stands may be fixed behind, or anywhere else, so as not to be in the way of the works.

Single collections are fired on stands; which are made in the same manner as theodolite stands, only the top part must be long or short occasionally: these stands may be fixed up very soon without much trouble.

The following order of Firing will serve as a specimen of the Plan to be pursued in an exhibition of Fire-works.

1. Two signal } rockets
2. Six sky } rockets
3. Two honorary } rockets
4. Four caduceus } rockets
5. } Two { vertical } wheels illuminated
6. } Two { spiral } wheels illuminated
7. } Two { transparent stars
8. A line rocket of five changes
9. Four tourbillons
10. } Two { horizontal wheels
11. } Two { air balloons illuminated
12. } Two { Chinese fountains
13. } Two { regulating pieces of four mutations each
14. } Two { *pots des aigrettes*
15. Three large gerbes
16. A flight of rockets
17. } Two { balloon wheels
18. } Two { cascades of brilliant fire
19. Twelve sky rockets
20. } Two { illuminated yew trees
21. } Two { air-balloons of serpents and two compound
22. Four tourbillons
23. } Two { Fruiloni wheels
24. } Two { illuminated globes with horizontal wheels
25. One *pot des saucissons*
26. Two plural wheels
27. Marroon battery
28. Two chandeliers illuminated
29. Range of *pots des brins*
30. Twelve sky-rockets
31. Two yew-trees of fire
32. Nest of serpents
33. Two double cones illuminated
34. Regulating piece of seven mutations, viz.
    1. Vertical wheel illuminated
    2. Golden glory
    3. Octagon vertical wheel
    4. Porcupine's quills
    5. Cross fires
    6. Star-piece with brilliant rays
    7. Six vertical wheels
35. Brilliant sun
36. Large flight of rockets.

When water-works are to be exhibited, divide them into several sets, and fire one set after every fifth or sixth change of land and air-works. Observe this rule in firing a double set of works: Always begin with sky-rockets, then two moveable pieces, then two fixed pieces, and so on; ending with a large flight of rockets, or a marroon battery: if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works.

Fig.

'arieties of Con-ruction.

128 ountain of rockets. ℥. 58.

Fig. 58. represents a fountain of 30 rockets. Let A be a perpendicular post, 16 feet high from the ground, and 4 inches square. Let the rail, or cross piece C, be one foot six inches long, three inches broad, and one thick. The rail D, at bottom, must be six feet long, one foot broad, and one inch thick. F and G are the two sides which serve to supply the rails D, E, H, I, C: these sides are one foot broad at bottom, and cut in the front with a regular slope, to three inches at top; but their back edges must be parallel with the front of the pots A. The breadth of the rails E, H, I, will be determined by the breadth of the sides: all the rails must be fixed at two feet distance from each other, and at right angles with the pots, Having placed the rails thus, bore in the bottom rail 10 holes, at equal distances, large enough to receive the stick of a one pound rocket: in the back edge of this rail cut a groove from one end to the other, fit to contain a quick-match; then cut a groove in the top of the rail, from the edge of each hole, into the groove in the back: in the same manner cut in the second rail, E, eight holes and grooves; in the third rail, H, six holes and grooves; in the fourth rail, I, four holes and grooves; and in the top rail, two holes and grooves. B, a rail with holes in it to guide the ends of the rocket sticks; this rail must be fixed six feet from the rail D. The fountain frame being thus made, prepare the rockets thus: Tie round the mouth of each a piece of thin paper, large enough to go twice round, and to project about an inch and a half from the mouth of the rocket, which must be rubbed with wet meal-powder; in the mouth of each rocket put a leader, which secure well with the paper that projects from the mouth of the case: these leaders must be carried into the grooves in the back of the rails, in which lay a quick-match from one end to the other, and cover it with pasted paper: holes must be made in the rail D, to receive the ends of the sticks of the rockets in the rail E, and so on to the fourth rail; so that the sticks of the rockets at top may go through all the rails. The rockets being so prepared, fix a gerbe, or white flower-pot, on each rail, before the post, with its mouth inclining a little forwards: these gerbes must be lighted all at once. Behind or before each gerbe, fix a case of brilliant or slow fire: these cases must be filled so that they may burn out one after the other, to regulate the fountain; which may be done by carrying a leader from the end of each slow or brilliant fire, into the groove in the back of each rail. Different fixed rockets may be used in these fountains: but it will be best to fill the heads of the rockets on each rail with different sorts of things, in this manner; those at top with crackers, the next with rains, the third with serpents, the fourth with tailed stars, and the last flight with common or brilliant stars.

29 ı tree.

The piece called a *palm tree*, though made of common fires, and of a simple construction, has a very pleasing effect; from the fires intersecting so often, that
59. they resemble the branches of trees. Let A (fig. 59.) be a perpendicular post, of any thickness, so that it be sufficiently strong to hold the cases; let the distance from B to C be two feet six inches, and from C to D two feet six inches, and let the length of each cross-piece be two feet; on each end of each fix a five-pointed star: then fix, on pegs made for the purpose, twelve inch half-pound cases of brilliant fire, as in the figure. All the cases and stars must be fired at once. This piece should be fixed high from the ground.

Varieties of Construction.

130 Illuminated pyramid. Fig. 60. Plate CCCCLVI.

An illuminated pyramid, with Archimedian screws, a globe, and vertical sun, may be of any size. One made according to the dimensions of fig. 60. will be of a good proportion, whose height is 21 feet; from C to D, six feet; from E to F, nine feet: the space between the rails must be six inches, and the rails as thin as possible: in all the rails stick portfires at four inches distance. The Archimedian screws, G, K, are nothing more than double spiral wheels, with the cases placed on their wheels horizontally instead of obliquely. The vertical sun, I, need not consist of more than 12 rays, to form a single glory. The globe at top must be made in proportion to the pyramid; which being prepared according to the preceding directions, place the leaders so that all the illuminating portfires, screws, globe, and sun, may take fire together. The pyramid must be supported by the two sides, and by a support brought from a pole, which must be placed two feet from the back of the pyramid, that the wheels may run freely.

131 Rose piece and sun. Fig. 61.

A rose-piece may be used for a mutation of a regulated piece, or fired by itself: it makes the best appearance when made large; if its exterior diameter be six feet, it will be of a good size. Fig. 61. shows the manner in which it appears before it is fired. Let the outer fell be made of wood, and supported by four wooden spokes: all the other parts, on which the illuminations are fixed, must be made of strong iron wire: on the outer fell place as many half-pound cases of brilliant charge as you think proper, but the more the better; for the nearer the cases are placed, the stronger will be the rays; the illuminations should be placed within three inches of each other: they must all be fired together, and burn some time before the sun is lighted: which may be done by carrying a leader from the middle of one of the illuminations, to the mouth of one of the sun cases.

132 Transparent stars with illuminated rays. Fig. 62.

Fig. 62. represents an *illuminated star*. Let the diameter from A to B be two feet, and from C to D seven feet. First make a strong circular back or body of the star, two feet diameter, to which fix the illuminated rays: in the centre of the front of the body fix a spindle, on which put a double triangular wheel, six inches diameter, clothed with two ounce cases of brilliant charge: the cases on this wheel must burn but one at a time. Round the edge of the body, nail a hoop made of thin wood or tin: this hoop must project in front six or seven inches; in this hoop cut three or four holes to let out the smoke from the wheel. The star and garter may be cut out of strong pasteboard or tin, made in this manner: Cut a round piece of pasteboard or tin, two feet diameter, on which draw a star, and cut it out; then over the vacancy paste Persian silk; paint the letters yellow; four of the rays yellow, and four red; the cross in the middle may be painted half red and half yellow, or yellow and blue. This transparent star must be fastened to the wooden hoop by a screw, made so as to take off and on; the illuminated rays are made of thin wood, with tin sockets fixed on their sides within four inches of each other; in these sockets stick illuminating portfires: behind the point of each ray fix a half-pound case of gray, black, or Chinese fire.

N. B. The illuminated rays are to be lighted at the same

Varieties of Construction. same time as the triangular wheel, or after it is burnt out; which may be done by a tin barrel being fixed to the wheel, after the manner of those in the regulated pieces. Into this barrel carry a leader from the illuminated rays, through the back of the star; and this leader must be met by another, brought from the tail of the last case on the wheel.

133 Transparent illuminated table star. Fig. 63.

Fig. 63. represents a *table star*, whose diameter from E to F, is 12 feet; and from E to I, four feet. This proportion, observed on each side, will make the centre frame four feet square: in this square fix a transparent star, as in the figure. This star may be painted blue, and its rays made as those of the flaming stars described before. The wheel for this star may be composed of different coloured fires, with a charge or two of slow fire; the wheels *a, a, a, a*, may be clothed with any number of cases, so that the star-wheel consist of the same: the illuminating portfires, which must be placed very near each other on the frames, must be so managed as to burn as long as the wheels, and lighted at the same time.

134 Regulated illuminated spiral piece. Fig. 64.

The regulated illuminated spiral piece, with a projected star-wheel illuminated, is represented by fig. 64. and is thus made. Have a block made eight inches diameter; in this block screw six iron spokes, which must serve for spindles for the spiral wheels: these wheels are made as usual, each one foot and a half diameter, and three feet in height: the spindles must be long enough to keep the wheels four or five inches from one another: at the end of each spindle must be a screw-nut, on which the wheels that hang downwards will run; and on the spindles which stand upwards must be a shoulder, for the blocks of the wheels to run on.

The projected star-wheel must turn on the same spindle on which the large block is fixed; this spindle must be long enough to allow the star-wheel to project a little before the spiral wheels: the exterior diameter of the star-wheel must be three feet five inches. On this wheel fix three circles of iron wire, and on them portfires; on the block place a transparent star, or a large five-pointed brilliant star. The cases on this wheel may burn four at once, as it will contain nearly twice the number of one of the spiral wheels: the cases on the spiral wheels must be placed parallel to their fells, and burn two at a time.

135 Illuminated figure piece. Fig. 65.

A figure piece illuminated with five-pointed stars.—The construction of this piece is very easy, as shown by fig. 65. whose diameter from B to C is eight feet, and from D to F two feet: the vertical wheel in the centre must be one foot diameter, and consist of six four-ounce cases of different coloured charge, which cases must burn double: on the frames fix five-pointed brilliant or blue stars, rammed four inches with composition: let the space between each star be eight inches; at each point fix a gerbe, or case of Chinese fire. When to be fired, let the gerbe, stars, and wheel, be lighted at the same time.

136 Illuminated star-wheel. Fig. 66.

The star-wheel illuminated, is shown by fig. 66. Its exterior fell is made of wood, three feet six inches or four feet diameter; within this fell, form with iron wire three circles, one less than the other, so that the diameter of the least may be about 10 inches: place the portfires on these fells with their mouths inclining outwards, and the portfires on the points of the star with their mouths projecting in front; let the exterior fell be clothed with four-ounce cases of gray charge: these cases must burn four at a time, and be lighted at the same time as the illuminations.

Pyramid of flower-pots is represented at fig. 67. and made thus. Let the distance from A to B be six feet; and from one rail to the other, two: on the bottom rail fix five paper mortars, each three inches and a half diameter; these mortars load with serpents, crackers, stars, &c.

In the centre of each mortar fix a case of spur-fire: on the second rail fix four mortars, so as to stand exactly in the middle of the intervals of those on the bottom rail; on the third rail place three mortars; on the fourth, two; and on the top of the posts, 1; the bottom rail must be six feet long: all the mortars must incline a little forwards, that they may be easily discharged; and the spur-fires rammed exactly alike, that the mortars may all be fired at the same time. Having prepared the pyramid according to the preceding directions, carry pipes of communication from one spur-fire to the other.

Fig. 68. represents one half of *the illuminated regulating piece.*—A, A, A, A, are flat wooden spokes, each five feet long: at the end of each place a vertical wheel, 10 inches diameter, clothed with six four-ounce cases of brilliant fire: these cases must burn but one at a time: on two of the spokes of each wheel place two portfires, which must be lighted with the first case of the wheel: on each spoke A, A, &c. behind the wheels, place six cases of the same size with those on the wheels: these cases must be tied across the spokes with their mouths all one way, and be made to take fire successively one after the other, so that they may assist the whole piece to turn round.

The diameter of the large wheel must be two feet and a half; and its fell made of wood, which must be fixed to the large spokes: on this wheel place 24 cases of the same sort with those on the small wheels; these cases must burn four at a time: in this wheel make three circles with iron wire, and on them place illuminating portfires, as in the figure: the star-points on the large spokes may be made of thin ash-hoops; the diameter of these points close to the centre-wheel must be 11 inches: on these points place portfires, at three inches and a half distance one from the other.

Fig. 69. represents the blocks of this piece. The diameters of these blocks, at A and B, must be eight inches; and C and D, four inches and a half: the length of each of those blocks must be six inches: at the small ends of these blocks fix an iron wheel, five inches diameter, and these wheels must have teeth, to turn the wheel F: this wheel is fixed on a small spindle screwed into the large spindle, which goes through the two blocks, and on which they run.

Supposing fig. 68. to be on the block A, in fig. 69. and to turn to the right, and another piece of the same construction on the block B, with its fires placed so as to turn it to the left; you will find them move very true and fast, by the help of the three iron wheels, which serve to regulate their motions, as well as to assist them in turning: let the iron circles in the front of the great wheels be of different diameters, so that when fired there may appear six circles. When this piece is fired all the wheels and illuminations must be lighted at one time.

atic works.

Aquatic Fireworks.

139 Works that sport in the water are much esteemed by most admirers of fire-works, particularly water-rockets; and as they seem of a very extraordinary nature to those who are unacquainted with this art, they merit a particular explanation.

40 r-roc- *Water-rockets*, may be made from four ounces to two pounds. If larger, they are too heavy; so that it will be difficult to make them keep above water without a cork float, which must be tied to the neck of the case; but the rockets will not dive so well with as without floats.

Cases for these are made in the same manner and proportion as sky-rockets, only a little thicker of paper. When you fill those which are driven solid, put in first one ladleful of slow fire, then two of the proper charge, and on that one or two ladles of sinking charge, then the proper charge, then the sinking charge again, and so on, till you have filled the case within three diameters; then drive on the composition one ladleful of clay; through which make a small hole to the charge; then fill the case, within half a diameter, with corn-powder, on which turn down two or three rounds of the case in the inside; then pinch and tie the end very tight; having filled the rockets (according to the above directions), dip their ends in melted rosin or sealing-wax, or else secure them well with grease. When you fire those rockets, throw in six or eight at a time; but, if you would have them all sink, or swim, at the same time, you must fill them with an equal quantity of composition, and fire them altogether.

1 of uni- for *Pipes of communication, which may be used under water*, must be a little thicker in the paper than those for land. Having rolled a sufficient number of pipes, and kept them till dry, wash them over with drying oil, and set them to dry; but when you oil them, leave about an inch and a half at each end dry, for joints; as if they were oiled all over, when you come to join them, the paste would not stick where the paper is greasy; after the leaders are joined, and the paste dry, oil the joints. These pipes will lie many hours under water, without receiving any damage.

2 ntal *To make horizontal wheels for the water*, first get a large wooden bowl without a handle; then have an eight-sided wheel made of a flat board 18 inches diameter, so that the length of each side may be near seven inches: in all the sides cut a groove for the cases to lie in. This wheel being made, nail it on the top of the bowl; then take four eight-ounce cases, filled with a proper charge, each about six inches in length. Now, to clothe the wheel with these cases, get some whitish-brown paper, and cut it into slips four or five inches broad and seven or eight long: these slips being pasted all over on one side, take one of the cases, and roll one of the slips of paper about an inch and a half on its end, so that there will remain about two inches and a half of the paper hollow from the end of the case: tie this case on one of the sides of the wheel, near the corners of which must be holes bored, through which put the packthread to tie the cases: having tied on the first case at the neck and end, put a little meal powder in the hollow paper; then paste a slip of paper on the end of another case, the head of which put into the hollow paper on the first, allowing a sufficient distance from the tail of one to the head of the other for the pasted paper to bend without tearing: tie on the second case as you did the first: and so on with the rest, except the last, which must be closed at the end, unless it is to communicate to any thing on the top of the wheel, such as fire-pumps or brilliant fires, fixed in holes cut in the wheel, and fired by the last or second case, as the fancy directs: six, eight, or any number, may be placed on the top of the wheel, provided they be not too heavy for the bowl. Aquatic Fireworks.

Before tying on the cases, cut the upper part of all their ends, except the last, a little shelving, that the fire from one may play over the other, without being obstructed by the case. Wheel cases have no clay drove in their ends, nor pinched, but are always left open, only the last, or those which are not to lead fire, which must be well secured. 143

For water mines you must have a bowl with a wheel on it, made in the same manner as the water-wheel; only in its middle there must be a hole, of the same diameter as that of the intended mine. These mines are tin pots, with strong bottoms, and a little more than two diameters in length: the mine must be fixed in the hole in the wheel, with its bottom resting on the bowl; then loaded with serpents, crackers, stars, small water-rockets, &c. in the same manner as pots of aigrettes; but in their centre fix a case of Chinese fire, or a small gerbe, which must be lighted at the beginning of the last case on the wheel. These wheels are to be clothed as usual. Water mines.

Bowls for water-globes must be very large, and the wheels on them of ten sides; on each side nail a piece of wood four inches long; and on the outside of each piece cut a groove, wide enough to receive about one-fourth of the thickness of a four-ounce case: these pieces of wood must be nailed in the middle of each face of the wheel, and fixed in an oblique direction, so that the fire from the cases may incline upwards: the wheel being thus prepared, tie in each groove a four-ounce case filled with a gray charge; then carry a leader from the tail of one case to the mouth of the other. 144 Fire-globes for the water.

Globes for these wheels are made of two tin hoops, with their edges outwards, fixed one within the other, at right angles. The diameter of these hoops must be rather less than that of the wheel. Having made the globe, drive in the centre of a wheel an iron spindle, which must stand perpendicular, and its length four or six inches more than the diameter of the globe.

The spindle serves for an axis, on which is fixed the globe, which must stand four or six inches from the wheel: round one side of each hoop must be soldered little bits of tin, two inches and a half distance from each other; which pieces must be two inches in length each, and only fastened at one end, the other ends being left loose, to turn round the small portfires, and hold them on: these portfires must be made of such a length as will last out the cases on the wheel. There need not be any portfires at the bottom of the globe within four inches of the spindle; as they would have no effect, but to burn the wheel: all the portfires must be placed perpendicularly from the centre of the globe, with their mouths outwards; and must be clothed with leaders so as all to take fire with the second case of the wheel; and the cases must burn two at a time, one opposite the other. When two cases of a wheel begin together, two will

Aquatic Fireworks.

will end together; therefore the two opposite end cases must have their ends pinched and secured from fire. The method of firing such wheels is, by carrying a leader from the mouth of one of the first cases to that of the other; and the leader being burnt through the middle, will give fire to both at the same time.

145 Odoriferous water-balloons.

Odoriferous water balloons are made in the same manner as air balloons, but very thin of paper, and in diameter one inch and three-fourths, with a vent of half an inch diameter. The shells being made, and quite dry, fill them with any of the following compositions, which must be rammed in tight: these balloons must be fired at the vent, and put into a bowl of water. Odoriferous works are generally fired in rooms.

Composition I. Saltpetre two ounces, flour of sulphur one ounce, camphor half an ounce, yellow amber half an ounce, charcoal-dust three-fourths of an ounce, salt of benjamin half an ounce, all powdered very fine and well mixed.

II. Saltpetre 12 ounces, meal-powder three ounces, frankincense one ounce, myrrh half an ounce, camphor half an ounce, charcoal three ounces, all moistened with the oil of spike.

III. Saltpetre two ounces, sulphur half an ounce, antimony half an ounce, amber half an ounce, cedar raspings one-fourth of an ounce, all mixed with the oil of roses and a few drops of bergamot.

IV. Saltpetre four ounces, sulphur one ounce, saw-dust of juniper half an ounce, saw-dust of cypress one ounce, camphor one-fourth of an ounce, myrrh two drams, dried rosemary one-fourth of an ounce, all moistened a little with the oil of roses.

N. B. Water-rockets may be made with any of the above compositions, with a little alteration, to make them weaker or stronger, according to the size of the cases.

146 A sea-fight with small ships and a fire-ship.

Having procured four or five small ships, of two or three feet in length, make a number of small reports, which are to serve for guns. Of these range as many as you please on each side of the upper decks; then at the head and stern of each ship fix a two-ounce case, eight inches long, filled with a slow portfire composition; but take care to place it in such a manner that the fire may fall in the water, and not burn the rigging: in these cases bore holes at unequal distances from one another, but make as many in each case as half the number of reports, so that one case may fire the guns on one side, and the other those on the opposite. The method of firing the guns is, by carrying a leader from the holes in the cases to the reports on the decks; you must make these leaders very small, and be careful in calculating the burning of the slow fire in the regulating cases, that more than two guns be not fired at a time. When you would have a broadside given, let a leader be carried to a cracker, placed on the outside of the ship; which cracker must be tied loose, or the reports will be too slow: in all the ships put artificial guns at the port-holes (A).

Having filled and bored holes in two portfires for regulating the guns in one ship, make all the rest exactly the same; then, when you begin the engagement, light one ship first, and set it a sailing, and so on with the rest, sending them out singly, which will make them fire regularly, at different times, without confusion; for the time between the firing of each gun will be equal to that of lighting the slow fires.

The fire-ship may be of any size; and need not be very good, for it is always lost in the action. To prepare a ship for this purpose, make a portfire equal in size with those in the other ships, and place it at the stern; in every port place a large portfire, filled with a very strong composition, and painted in imitation of a gun, and let them all be fired at once by a leader from the slow fire, within two or three diameters of its bottom; all along both sides, on the top of the upper deck, lay star-composition about half an inch thick and one broad, which must be wetted with thin size, then primed with meal-powder, and secured from fire by pasting paper over it; in the place where you lay this composition, drive some little tacks with flat heads, to hold it fast to the deck: this must be fired just after the sham guns, and when burning will show a flame all round the ship: at the head take up the decks, and put in a tin mortar loaded with crackers, which mortar must be fired by a pipe from the end of the slow fire; the firing of this mortar will sink the ship, and make a pretty conclusion. The regulating portfire of this ship must be lighted at the same time with the first fighting ship.

Having prepared all the ships for fighting, we shall next proceed with the management of them when on the water. At one end of the pond, just under the surface of the water, fix two running blocks, at what distance you choose the ships should fight; and at the other end of the pond, opposite to each of these blocks, under the water, fix a double block; then on the land, by each of the double blocks, place two small windlasses; round one of them turn one end of a small cord, and put the other end through one of the blocks; then carry it through the single one at the opposite end of the pond, and bring it back through the double block again, and round the other windlass: to this cord, near the double block, tie as many small strings as half the number of the ships, at any distance; but these strings must not be more than two feet long each: make fast the loose end of each to a ship, just under her bowsprit; for if tied to the keel, or too near the water, it will overset the ship. Half the ships being thus prepared, near the other double block fix two more windlasses, to which fasten a cord, and to it tie the other half of the ships as before: when you fire the ships, pull in the cord with one of the windlasses, to get all the ships together; and when you have set fire to the first, turn that windlass which draws them out, and so on with the rest, till they are all out in the middle of the pond; then, by turning the other windlass, you will draw them back again; by which method you may make them change sides, and tack about backwards and forwards at pleasure. For the fire ship fix the blocks and windlasses between the others;

(A) Reports for these and similar occasions are made, by filling small cartridges with grained powder; pinching them close at each end, and, when used, boring a hole in the side, to which is placed a match or leader for firing them.

Aquatic Fireworks. others; so that when she sails out, she will be between the other ships: you must not let this ship advance till the guns at her ports take fire.

147 To fire sky-rockets under water. *To fire sky-rockets under water*, you must have stands made as usual, only the rails must be placed flat instead of edgewise, and have holes in them for the rocket-sticks to go through; for if they were hung upon hooks, the motion of the water would throw them off: the stands being made, if the pond is deep enough, sink them at the sides so deep, that, when the rockets are in, their heads may just appear above the surface of the water; to the mouth of each rocket fix a leader, which put through the hole with the stick; then a little above the water must be a board, supported by the stand, and placed along one side of the rockets; then the ends of the leaders are turned up through holes made in this board, exactly opposite the rockets. By this means you may fire them singly or all at once. Rockets may be fired by this method in the middle of a pond, by a Neptune, a swan, a water-wheel, or any thing else you choose.

148 Neptune in his chariot. *To represent Neptune in his chariot*, you must have a Neptune (made of wood, or basket work) as big as life, fixed on a float large enough to bear his weight; on which must be two horses heads and necks, so as to seem swimming, as shown by fig. 70. Fig. 70. For the wheels of the chariot, there must be two vertical wheels of black fire, and on Neptune's head a horizontal wheel of brilliant fire, with all its cases, to play upwards. When this wheel is made, cover it with paper or pasteboard, cut and painted like Neptune's coronet; then let the trident be made without prongs, but instead of them, fix three cases of a weak gray charge, and on each horse's head put an eight ounce case of brilliant fire, and on the mouth of each fix a short case, of the same diameter, filled with the white-flame composition enough to last out all the cases on the wheels: these short cases must be open at bottom, that they may light the brilliant fires; for the horses eyes put small portfires, and in each nostril put a small case half filled with gray charge, and the rest with portfire composition.

If Neptune is to give fire to any building on the water; at his first setting out, the wheels of the chariot, and that on his head, with the white flames on the horses heads, and the portfires in their eyes and nostrils, must all be lighted at once; then from the bottom of the white flames carry a leader to the trident. As Neptune is to advance by the help of a block and cord, you must manage it so as not to let him turn about, till the brilliant fires on the horses and the trident begin; for it is by the fire from the horses (which plays almost upright) that the building, or work, is lighted; which must be thus prepared. From the mouth of the case which is to be first fired, hang some loose quick-match to receive the fire from the horses. When Neptune is only to be shown by himself, without setting fire to any other works, let the white flames on the horses be very short, and not to last longer than one case of each wheel, and let two cases of each wheel burn at a time.

149 Swans and ducks in water. If you would have swans or ducks discharge rockets into the water, they must be made hollow, and of paper, and filled with small water rockets, with some blowing powder to throw them out: but if this is not done, they may be made of wood, which will last many times. Having made and painted some swans, fix them on floats: then in the places where their eyes should be, bore holes two inches deep, inclining downwards, and wide enough to receive a small portfire; the portfire cases for this purpose must be made of brass, two inches long, and filled with a slow bright charge. In the middle of one of these cases make a little hole; then put the portfire in the eye-hole of the swan, leaving about half an inch to project out; and in the other eye put another portfire, with a hole made in it: then in the neck of the swan, within two inches of one of the eyes, bore a hole slantwise, to meet that in the portfire; in this hole put a leader, and carry it to a water-rocket, that must be fixed under the tail with its mouth upwards. On the top of the head place two one-ounce cases, four inches long each, drove with brilliant fire; one of these cases must incline forwards, and the other backwards: these must be lighted at the same time as the water-rocket; to do which, bore a hole between them in the top of the swan's head, down to the hole in the portfire, to which carry a leader: if the swan is filled with rockets, they must be fired by a pipe from the end of the water-rocket under the tail. When you set the swan a swimming, light the two eyes.

To make a fire-fountain for the water, first have a float made of wood, three feet diameter; then in the middle fix a round perpendicular post, four feet high, and two inches diameter; round this post fix three circular wheels made of thin wood, without any spokes. 150 Water fire-fountains. The largest of these wheels must be placed within two or three inches of the float, and must be nearly of the same diameter. The second wheel must be two feet two inches diameter, and fixed at two feet distance from the first. The third wheel must be one foot four inches diameter, and fixed within six inches of the top of the post: the wheels being fixed, take 18 four or eight-ounce cases of brilliant fire, and place them round the first wheel with their mouths outwards, and inclining downwards; on the second wheel place 13 cases of the same, and in the same manner as those on the first; on the third, place eight more of these cases, in the same manner as before, and on the top of the post fix a gerbe; then clothe all the cases with leaders, so that both they and the gerbe may take fire at the same time. Before firing this work, try it in the water to see whether the float is properly made, so as to keep the fountain upright.

151 Optical imitations of fire-works. As the artificial fire-works which we have described, require considerable caution in their preparation and management, and are attended with great expence, attempts have been made to imitate some of the more simple kinds by optical delusion, and to give to the objects represented the appearance of moving fire, though they be really fixed, and no fire be employed. These attempts have been tolerably successful; and by means of this invention, a spectacle of artificial fire-works may be apparently exhibited at a trifling expence; and if the pieces employed are constructed with ingenuity, and with a proper attention to the rules of perspective, while in viewing them we employ glasses which magnify the objects, and prevent them from being too distinctly seen, a very agreeable illusion will be produced.

Optical Imitations of Fire-works. The artificial fire-works imitated with most success by this invention, are fixed suns, gerbes, and jets of fire, cascades, globes, pyramids, and columns, moveable around their axes. To represent a gerbe of fire, take paper

Optical Imitations of Fire-works

Fig. 71.

paper blackened on both sides, and very opaque; and having delineated on a piece of white paper the figure of a gerbe of fire, apply it to the black paper, and with the point of a very sharp penknife make several slashes (Plate CCCCLVII. fig. 71.) in it, as 3, 5, or 7, proceeding from the origin of the gerbe: these lines must not be continued, but cut through at unequal intervals. Pierce these intervals with unequal holes made with a pinking iron, in order to represent the sparks of such a gerbe. In short, you must endeavour to paint, by these lines and holes, the well known effect of the fire of inflamed gunpowder, when it issues through a small aperture.

According to the same principles, you may delineate the cascades (fig. 72.) and jets of fire which you are desirous of introducing into this exhibition, which is purely optical; and those jets of fire which proceed from the radii of suns, either fixed or moveable. It may easily be conceived, that in this operation taste must be the guide.

If you are desirous of representing globes, pyramids, or revolving columns, draw the outlines of them on paper, and then cut them out in a helical form; that is, cut out spirals with the point of a penknife, and of a size proportioned to that of the piece.

It is to be observed also, that as these different pieces have different colours, they may be easily imitated by pasting on the back of the paper, cut as here described, very fine silk paper coloured in the proper manner. As jets, for example, when loaded with Chinese fire, give a reddish light, you must paste to the back of these jets transparent paper, slightly tinged with red; and proceed in the same manner in regard to the other colours by which the different fire-works are distinguished.

When these preparations have been made, the next thing is to give motion, or the appearance of motion, to this fire, which may be done two ways, according to circumstances.

If a jet of fire, for example, is to be represented, prick unequal holes, and at unequal distances from each other, in a band of paper, fig. 73. and then move this band, making it ascend between a light and the above jet; the rays of light which escape through the holes of the moveable paper will exhibit the appearance of sparks rising into the air. It is to be observed that one part of the paper must be whole; that another must be pierced with holes thinly scattered; that in another place they must be very close, and then moderately so: by these means it will represent those sudden jets of fire observed in fire-works.

To represent a cascade, the paper pierced with holes, instead of moving upwards, must be made to descend.

This motion may be easily produced by means of two rollers, on one of which the paper is rolled up, while it is unrolled from the other.

Suns are attended with some more difficulty; because in these it is necessary to represent fire, proceeding from the centre to the circumference. The artifice for this purpose is as follows.

On strong paper describe a circle, equal in diameter to the sun which you are desirous to exhibit, or even somewhat larger; then trace out on this circle two spirals, at the distance of a line or half a line from each other, and open the interval between them with a penknife, in such a manner, that the paper may be cut from the circumference, decreasing in breadth to a certain distance from the centre, fig. 74.: cut the remainder of the circle into spirals of the same kind, open and close alternately; then cement the paper circle to a small iron hoop, supported by two pieces of iron, crossing each other in its centre, and adjust the whole to a small machine, which will suffer it to revolve round its centre. If this moveable paper circle, cut in this manner, be placed before the representation of your sun, with a light behind it, as soon as it is made to move towards that side to which the convexity of the spirals is turned, the luminous spirals, or those which afford a passage to the light, will give, on the image of the radii or jets of fire of your sun, the appearance of fire in continual motion, as if undulating from the centre to the circumference.

The appearance of motion may be given to columns, pyramids, and globes, cut through in the manner above described, by moving in a vertical direction a band of paper cut through into apertures, inclined at an angle rather different from that of the spirals. By these means the spectators will suppose that they see fire continually circulating and ascending along the spirals; and thus will be produced an optical illusion, in consequence of which the columns or pyramids will seem to revolve.

We have thus briefly explained the principle on which artificial fire-works may be imitated; and as the taste of the artist may suggest to him many circumstances which may improve the representation, and render the illusion stronger, we shall not enlarge further on the subject, but shall conclude this article with a few observations on illuminated prints and drawings, which are sometimes introduced as accompaniments in these imitations of artificial fire-works.

The mode of preparing these illuminations is thus described in Hutton's translation of Montucla's *Recreations*. Take some prints representing a castle, or palace, &c.; and having coloured them properly, cement paper to the back of them, in such a manner that they shall be only semitransparent; then, with pinking irons of different sizes, prick small holes in the places and on the lines where the lamps are generally placed, as along the sides of the windows, on the cornices or balustrades, &c. But care must be taken to make these holes smaller and closer, according to the perspective diminution of the figure. With other irons of a larger size, cut out, in other places, some stronger lights, so as to represent fire-pots, &c. Cut out also the panes in some of the windows, and cement to the back of them transparent paper of a green or red colour, to represent curtains drawn before them, and concealing an illuminated apartment.

When the print is cut in this manner, place it in the front of a sort of small theatre, strongly illuminated from the back part, and look at it through a convex glass of a pretty long focus, like that used in those small machines called optical boxes. If the rules of perspective have been properly observed in the prints, and if the lights and shades have been distributed with taste, this spectacle will be highly agreeable.

151 Management of burns from fire-works.

Before dismissing this subject, it may not be improper to point out the most effectual means of relieving those burns, to which fire-workers are so much exposed. When the burn is first received, and before blisters arise, the best applications are *oil of turpentine*, *strong*

spirits,

spirits, *rectified spirit of wine*, or *camphorated spirit*, with which linen rags must be wetted and kept moist on the part till the pain abates. If no other remedy can be procured, immersing the part for a long time in cold water will often afford great relief. When these means have been neglected, and blisters arise, if these are small, they should not be opened; but if large, the water must be let out, and the sore covered with rags, spread with a mixture of *linseed oil* and *lime water*, in the proportion of one part of the former to three of the latter. We must remark, however, that in all cases of extensive burns, or where some very delicate part is injured, speedy recourse should be had to medical assistance.

Management of Burns.

P Y R — P Y T

PYROTICS, in *Medicine*, caustics, or remedies either actually or potentially hot; and which accordingly will burn the flesh, and raise an eschar. See CAUSTICITY.

PYRRHICA, in antiquity, a kind of exercise on horseback, or a feigned combat, for the exercise of the cavalry.

It was thus called from its inventor Pyrrhichus, or Pyrrhus of Cydonia, who first taught the Cretans to march in measure and cadence to battle, and to observe the pace of the Pyrrhic foot.—Others derive the name from Pyrrhus the son of Achilles, who instituted this exercise at the obsequies of his father.—Aristotle says, that it was Achilles himself who invented it.

The Romans also called it *ludus Trojanus*, "the Trojan game;" and Aulus Gellius *decursus*.—It is doubtless this exercise that we see represented on medals by two cavaliers in front running with lances, and the word *decursio* in the exergum.

PYRRHICHIUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short;—as, *Deus*.—Among the ancients this foot is also called *periambus*; by others *hegemona*.

PYRRHO, a Greek philosopher, born at Elis in Peloponnesus, flourished about 300 B. C. He was the disciple of Anaxarchus, whom he accompanied as far as India, where he conversed with the Brachmans and Gymnosophists. He had made painting his profession before he devoted himself to the study of philosophy. He established a sect whose fundamental principle was, That there is nothing true or false, right or wrong, honest or dishonest, just or unjust; or that there is no standard of any thing beyond law or custom, and that uncertainty and doubt belong to every thing. From this continual seeking after truth and never finding it, the sect obtained the name of *Sceptics* or *Pyrrhonians*, from the founder, who is said to have acted upon his own principles, and to have carried his scepticism to such a ridiculous extreme, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. If this was true, it was not without reason that he was ranked among those whose intellects were disturbed by intense study. But it is treated by a modern writer as a mere calumny invented by the dogmatists; and we are strongly inclined to be of his opinion, (see SCEPTICS). Pyrrho died about the 90th year of his age, when his memory was honoured with a statue at Athens, and a monument erected to him in his own country.

Pyrrhus ‖ Pythagoras

PYRRHUS, the name of two kings of Epirus. See EPIRUS.

PYRUS, the PEAR-TREE. See BOTANY *Index*; and for the culture of this fruit, see GARDENING. For an account of the processes followed in making perry, see AGRICULTURE.

PYTHAGORAS, a celebrated philosopher of antiquity, respecting the time and place of whose birth the learned are much divided. Eratosthenes asserts, that in the 48th Olympiad *, when he was very young, he was a victor at the Olympic games. Hence Dr Bentley † determines the date of his birth to be the 4th year of the 43d Olympiad; whilst Lloyd ‡, who denies that the Olympic victor was the same person with the philosopher places it about the 3d year of the 48th Olympiad. Mr Dodwell § differs from both, and wishes to fix the birth of Pythagoras in the 4th year of the 52d Olympiad. Of the arguments of these learned writers, Le Clerc has given a summary in the *Bibliotheque Choisée*, tom. x. p. 81. &c. and from a review of the whole, it would appear that he was not born earlier than the 4th year of the 43d Olympiad, or later than the 4th year of the 52d; but in what particular year of that period his birth took place, cannot with any degree of certainty be ascertained. It is generally believed that he was born in the island of Samos, and that he flourished about 500 years before Christ, in the time of Tarquin the last king of Rome *. His father Mnesarchus, who is thought by some to have been a lapidary, and by others a merchant of Tyre, appears to have been a man of some distinction, and to have bestowed upon his son the best eduction.

† *Dissert. on the Ep. of Phalaris.*

‡ *Chron. of Pythagoras.*

§ *Two Dissertations on the age of Phalereus and Pythagoras.*

* *Tusc. Quæst.* lib. iv. cap. 1.

Jamblicus† relates a number of wonderful stories respecting Pythagoras's descent from Jupiter, his birth, and early life; and represents him even in his youth as a prodigy of wisdom and manly seriousness. But most of these idle tales confute themselves, afford nothing of importance to be depended upon, and only prove the credulity, carelessness, and prejudice of their author. Of his childhood and early education we know nothing, except that he was first instructed in his own country by Creophilus, and afterwards in Scyrus by Pherecydes (see PHERECYDES). According to the custom of the times he was made acquainted with poetry and music; eloquence and astronomy became his private studies, and in gymnastic exercises he often bore the palm for strength and dexterity. He first distinguished himself in Greece at the Olympic games, where, beside gaining the prize, he is said to have excited the highest admiration by the elegance and dignity of his person, and the brilliancy of his understanding.

† *Vit Pythag.* 6. n.

Soon after his appearance at these games, Pythagoras commenced his travels in quest of knowledge. He first visited Egypt, where, through the interest of Polycrates tyrant of Samos, he obtained the patronage of Amasis king of Egypt, by whose influence, combined with his own assiduity, patience, and perseverance, he at length gained the confidence of the priests; from whom he learned their sacred mysteries, theology, and the whole system of symbolical learning. In Egypt, too, he became acquainted with geometry and the true solar system; and, before he left that country, made himself master of all the learning for which it was so famed among the nations of antiquity.

He afterwards visited Persia and Chaldea, where from the Magi he learnt divination, the interpreting of dreams, and astronomy. He is likewise said to have travelled into India, to have conversed with the Gymnosophists, and to have acquired from them a knowledge of the philosophy and literature of the east; and such was his ardour in the pursuit of science, that in quest of it, we are told by Cicero *, he crossed many seas, and travelled on foot through many barbarous nations.

* *De Finibus*, lib. iv. § 29.

After Pythagoras had spent many years in gathering information on every subject, especially respecting the nature of the gods, the rites of religion, and the immortality of the human soul, he returned to his native island, and attempted to make his knowledge useful by instituting a school for the instruction of his countrymen. Failing of success in this laudable undertaking, he repaired to Delos, where he pretended to receive moral dogmas from the priestess of Apollo. He also visited Crete, where he was initiated into the most sacred mysteries of Greece. He went likewise to Sparta and Elis, and again assisted at the Olympic games; where in the public assembly he was saluted with the title of *sophist* or *wise man*, which he declined for one more humble. See PHILOLOGY, N° 1. and PHILOSOPHY, N° 1.

He returned to Samos enriched with mythological learning and mysterious rites, and again instituted a school. His mysterious symbols and oracular precepts made this attempt more successful than the former had been; but meeting with some opposition, or being detected in some pious frauds, he suddenly left Samos, retired to Magna Grecia, and settled at Crotona.

Here he founded the Italic sect (see PHILOSOPHY, N° 20.); and his mental and personal accomplishments, the fame of his distant travels, and his Olympic crown, soon procured him numerous pupils. His bold and manly eloquence and graceful delivery attracted the most dissolute, and produced a remarkable change in the morals of the people of Crotona. His influence was increased by the regularity of his own example, and its conformity to his precepts. He punctually attended the temples of the gods, and paid his devotions at an early hour; he lived upon the purest and most innocent food, clothed himself like the priests of Egypt, and by his continual purifications and regular offerings appeared to be superior in sanctity to the rest of mankind. He endeavoured to assuage the passions of his scholars with verses and numbers, and made a practice of composing his own mind every morning, by playing on his harp, and singing along with it the pæans of Thales. To avoid the temptations of ease and the seductions of idleness, bodily exercises also made a considerable part of his discipline.

At Crotona he had a public school for the general benefit of the people, in which he taught them their duty, praising virtue and condemning vice; and particularly instructing them in the duties of social life. Besides this, he had a college in his own house, which he denominated κοινοβιον, in which there were two classes of students, viz. εξωτερικοι, who were also called *auscultantes*, and εσωτερικοι. The former of these were probationers, and were kept under a long examen. A silence of five years was imposed upon them; which Apuleius thinks was intended to teach them modesty and attention; but Clemens Alexandrinus thinks it was for the purpose of abstracting their minds from sensible objects, and inuring them to the pure contemplation of the Deity. The latter class of scholars were called *genuini*, *perfecti*, *mathematici*, and, by way of eminence, *Pythagoreans*. They alone were admitted to the knowledge of the arcana and depths of Pythagoric discipline, and were taught the use of ciphers and hieroglyphic writings.

Clemens observes, that these orders corresponded very exactly to those among the Hebrews: for in the schools of the prophets, there were two classes, viz. the sons of the prophets, who were the scholars, and the doctors or masters, who were also called *perfecti*; and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the proselytes there were two orders; *exoterici*, or proselytes of the gate; and *intrinseci* or *perfecti*, proselytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a proselyte of the gate, if not of the covenant. Gale endeavours to prove that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers and ancient authors, and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras's doctrine. But we believe the learned author was misled by the Christian Platonists.

The authority of Pythagoras among his pupils was so great, that it was even deemed a crime to dispute his word; and their arguments were considered as infallibly convincing, if they could enforce them by adding, that "the master said so;" an expression which afterwards became proverbial in *jurare in verba magistri*. This influence over his school was soon extended to the world, and even his pupils themselves divided the applause and approbation of the people with their master; and the rulers and legislators of all the principal towns of Greece, Sicily, and Italy, boasted of being the disciples of Pythagoras. To give more weight to his exhortations, as some writers mention, Pythagoras retired into a subterraneous cave, where his mother sent him intelligence of every thing which happened during his absence. After a certain number of months he again re-appeared on the earth with a grim and ghastly countenance, and declared in the assembly of the people that he was returned from hell. From similar exaggerations it has been asserted that he appeared at the Olympic games with a golden thigh, and that he could write in letters of blood whatever he pleased on a looking-glass; and that by setting it opposite to the moon, when full, all the characters which were on the glass became

became legible on the moon's disc. They also relate, that by some magical words he tamed a bear, stopped the flight of an eagle, and appeared on the same day and at the same instant in the cities of Crotona and Metapontum, &c.

At length his singular doctrines, and perhaps his strenuously asserting the rights of the people against their tyrannical governors, excited a spirit of jealousy, and raised a powerful party against him; which soon became so outrageous as to oblige him to fly for his life. His friends fled to Rhegium; and he himself, after being refused protection by the Locrians, fled to Metapontum, where he was obliged to take refuge in the temple of the muses, and where it is said he died of hunger about 497 years before Christ. Respecting the the time, place, and manner of his death, however, there are various opinions, and many think it uncertain when, where, or in what manner he ended his days. After his death his followers paid the same respect to him as was paid to the immortal gods; they erected statues in honour of him, converted his house at Crotona into a temple to Ceres, appealed to him as a deity, and swore by his name.

Pythagoras married Theano of Crotona, or, according to others, of Crete, by whom he had two sons, Telauges and Mnesarchus, who, after his death, took care of his school. He is said also to have had a daughter called *Damo*.

Whether he left any writings behind him is disputed. It seems probable, however, that he left none, and that such as went under his name were written by some of his followers. The *golden verses* which Hierocles illustrated with a commentary, have been ascribed to Epicharmus or Empedocles, and contain a brief summary of his popular doctrines. From this circumstance, and from the mysterious secrecy with which he taught, our information concerning his doctrine and philosophy is very uncertain, and cannot always be depended on.

The purpose of philosophy, according to the system of Pythagoras, is to free the mind from incumbrances, and to raise it to the contemplation of immutable truth and the knowledge of divine and spiritual objects. To bring the mind to this state of perfection is a work of some difficulty, and requires a variety of intermediate steps. Mathematical science was with him the first step to wisdom, because it inures the mind to contemplation, and takes a middle course between corporeal and incorporeal beings. The whole science he divided into two parts, *numbers* and *magnitude;* and each of these he subdivided into two others, the former into *arithmetic* and *music*, and the latter into *magnitude at rest and in motion;* the former of which comprehends *geometry*, and the latter *astronomy*. Arithmetic he considered as the noblest science, and an acquaintance with numbers as the highest good. He considered numbers as the principles of every thing; and divided them into scientific and intelligible. Scientific number is the production of the powers involved in unity, and its return to the same; number is not infinite, but is the source of that infinite divisibility into equal parts which is the property of all bodies. Intelligible numbers are those which existed in the divine mind before all things. They are the model or archetype of the world, and the cause of the essence of beings. Of the Monad, Duad, Triad, Tetrad, and Decad, various explanations have been given by various authors; but nothing certain or important is known of them. In all probability, numbers were used by Pythagoras as symbolical representations of the first principles and forms of nature, and especially of those eternal and immutable essences which Plato denominated ideas; and in this case the Monad was the simple root from which he conceived numbers to proceed, and as such, analogous to the simple essence of deity; from whence, according to his system, the various properties of nature proceed.

Music followed numbers, and was useful in raising the mind above the dominion of the passions. Pythagoras considered it as a science to be reduced to mathematical principles and proportions, and is said to have discovered the musical chords from the circumstance of several men successively striking with hammers a piece of heated iron upon an anvil. This story Dr Burney * discredits; but allows, from the uniform testimony of writers ancient and modern, that he invented the *harmónical canon* or monochord, (see MONOCHORD). The music of the spheres, of which every one has heard, was a most fanciful doctrine of Pythagoras. It was produced, he imagined, by the planets striking on the ether through which in their motion they passed; and he considered their musical proportions as exact, and their harmony perfect.

* *History of Music*, vol. i. p. 441.

Pythagoras, as we have already seen, learned geometry in Egypt; but by investigating many new theorems, and by digesting its principles, he reduced it to a more regular science. A geometrical point, which he defines to be a monad, or unity with position, he says corresponds to unity in arithmetic, a line to two, a superficies to three, and a solid to four. He discovered several of the propositions of Euclid; and on discovering the 47th of book 1st, he is said to have offered a hecatomb to the gods; but as he was averse to animal sacrifices, this assertion is surely false. His great progress in astronomical science has been mentioned elsewhere. See ASTRONOMY, N° 11, 22. and PHILOSOPHY, N° 15, 16.

Wisdom, according to Pythagoras, is conversant with those objects which are naturally immutable, eternal, and incorruptible; and its end is to assimilate the human mind to the divine, and to qualify us to join the assembly of the gods. Active and moral philosophy prescribes rules and precepts for the conduct of life, and leads us to the practice of public and private virtue.—On these heads many of his precepts were excellent, and some of them were whimsical and useless. Theoretical philosophy treats of nature and its origin, and is, according to Pythagoras, the highest object of study. It included all the profound mysteries which he taught, of which but little is now known. God he considers as the universal mind, diffused through all things, and the self-moving principle of all things (αυτοματισμος τῶν παντῶν), and of whom every human soul is a portion *. It is very probable, that he conceived of the Deity as a subtle fire, eternal, active, and intelligent; which is not inconsistent with the idea of incorporeality, as the ancients understood that term. This Deity was primarily combined with the chaotic mass of passive matter, but he had the power of separating himself, and since the separation he has remained distinct. The learned Cudworth

* *Cicero de Senect.* § 21.

Pythagoras. worth contends, that Pythagoras maintained a trinity of hypostases in the divine nature, similar to the Platonic triad (see PLATONISM). We cannot say that his arguments appear to have much force; but we think the conclusion which he wishes to establish extremely probable, as Plato certainly drew his doctrine from some of the countries which Pythagoras had visited before him.

Subordinate to the Deity there were in the Pythagorean creed three orders of intelligences, gods, demons, and heroes, of different degrees of excellence and dignity. These, together with the human soul, were considered as emanations from the Deity, the particles of subtle ether assuming a grosser clothing the farther they receded from the fountain. Hierocles defines a hero to be a rational mind united with a luminous body. God himself was represented under the notion of monad, and the subordinate intelligences as numbers derived from and included in unity. Man is considered as consisting of an elementary nature and a divine or rational soul. His soul, a self moving principle, is composed of two parts; the rational, seated in the brain; and the irrational, including the passions, in the heart. In both these respects he participates with the brutes, whom the temperament of their body, &c. allows not to act rationally. The sensitive soul perishes; the other assumes an ethereal vehicle, and passes to the region of the dead, till sent back to the earth to inhabit some other body, brutal or human. See METEMPSYCHOSIS. It was unquestionably this notion which led Pythagoras and his followers to deny themselves the use of flesh, and to be so peculiarly merciful to animals of every description. Some authors, however, say, that flesh and beans, the use of which he also forbade, were prohibited, because he supposed them to have been produced from the same putrified matter, from which, at the creation of the world, man was formed.

Of the symbols of Pythagoras little is known. They have been religiously concealed; and though they have awakened much curiosity, and occasioned many ingenious conjectures, they still appear to us dark and trifling. As a specimen we give the following: "Adore the sound of the whispering wind. Stir not the fire with a sword. Turn aside from an edged tool. Pass not over a balance. Setting out on a journey, turn not back, for the furies will return with you. Breed nothing that hath crooked talons. Receive not a swallow into your house. Look not in a mirror by the light of a candle. At a sacrifice pare not your nails. Eat not the heart or brain. Taste not that which hath fallen from the table. Break not bread. Sleep not at noon. When it thunders touch the earth. Pluck not a crow. Roast not that which has been boiled. Sail not on the ground. Plant not a palm. Breed a cock, but do not sacrifice it, for it is sacred to the sun and moon. Plant mallows in thy garden, but eat them not. Abstain from beans."

The following precepts are more important: "Discourse not of Pythagorean doctrines without light. Above all things govern your tongue. Engrave not the image of God in a ring. Quit not your station without the command of your general. Remember that the paths of virtue and of vice resemble the letter Y. To this symbol Persius refers *, when he says,

* Sat. iii. 56.

Et tibi quæ Samios diduxit litera ramos,
Surgentem dextro monstravit limite collem.

There has the Samian Y's instructive make
Pointed the road thy doubtful foot should take;
There warn'd thy raw and yet unpractis'd youth,
To tread the rising right-hand path of truth.

Pythagoras ‖ Python.

The scantiness and uncertainty of our information respecting Pythagoras, renders a regular and complete account of his life and doctrines impossible. A modern author † of profound erudition, pronounces him to have been *unquestionably* the wisest man that ever lived, if his masters the Egyptian priests must not be excepted. This is saying a great deal too much; but that he was one of the most distinguished philosophers of antiquity, or, as Cicero expresses it, *vir præstanti sapientia*, appears very evident; and his moral character has never been impeached. The mysterious air which he threw over his doctrines, and the apparent inanity of some of his symbols, have indeed subjected him to the charge of imposture, and perhaps the charge is not wholly groundless; but when we consider the age in which he lived, and the nature of the people with whom he had to deal, who would in all probability have resisted more open innovations, even this will not appear so blameable as at first sight we are apt to think it; and it is worthy of notice, that the worst stories of this kind have come down to us in a very questionable shape, and with much probability appear to be false.

† *Ancient Metaphysics.*

PYTHAGOREANS, a sect of ancient philosophers, so called from being the followers of Pythagoras. See the preceding article.

PYTHIA, the priestess of Apollo at Delphi, by whom he delivered oracles. She was so called from Pythius, a name of that god, which is said to have been given him on account of his victory over the serpent Python.

The Pythia was at first required to be a young girl, but in latter times she was a woman of 50 years of age. The first and most famous Pythia was Phemonöe. Oracles were at first delivered by her in hexameter verse. All the pythias were to be pure virgins, and all of them delivered their oracles with great enthusiasm and violent agitations. See ORACLE and DELPHI.

PYTHIAN GAMES, in Grecian antiquity, sports instituted near Delphos in honour of Apollo, on account of his slaying the serpent Python. See APOLLO.—These games, at their first institution, were celebrated only once in nine years; but afterwards every fifth year, from the number of the Parnassian nymphs who came to congratulate Apollo, and to make him presents on his victory. The victor was crowned with garlands.

PYTHON, in fabulous history, a monstrous serpent, produced by the earth after Deucalion's deluge. Juno being exasperated at Latona, who was beloved by Jupiter, commanded this serpent to destroy her; but flying from the pursuit of the monster, she escaped to Delos, where she was delivered of Diana and Apollo; the latter of whom at length destroyed Python with his arrows, in memory of which victory the Pythian games were instituted. See APOLLO.

Q.

Q, or *q*, the 16th letter and 12th consonant of our alphabet; but is not to be found either in the Greek, old Latin, or Saxon alphabets; and indeed some would entirely exclude it, pretending that k ought to be used wherever this occurs. However, as it is formed in the voice in a different manner, it is undoubtedly a distinct letter: for, in expressing this sound, the cheeks are contracted, and the lips, particularly the under one, are put into a canular form, for the passage of the breath.

The q is never sounded alone, but in conjunction with u, as in *quality, question, quite, quote*, &c. and never ends any English word.

As a numeral, Q stands for 500; and with a dash over it, thus $\bar{Q}$, for 500,000.

Used as an abbreviature *q* signifies *quantity*, or *quantum*. Thus, among physicians, *q. pl.* is *quantum placet*, i. e. "as much as you please" of a thing; and *q. s.* is *quantum sufficit*, i.e. "as much as is necessary." Q. E. D. among mathematicians, is *quod erat demonstrandum*, i. e. "which was to be demonstrated:" and Q. E. F. is *quod erat faciendum*, i. e. "which was to be done." Q. D. among grammarians is *quasi dictum*, i. e. "as if it were said;" or, "as who should say." In the notes of the ancients, Q stands for *Quintus*, or *Quintius;* Q. B. V. for *quod bene vertat;* Q. S. S. S. for *quæ supra scripta sunt;* Q. M. for *Quintus Mutius*, or *quomodo;* Quint. for *Quintilius;* and Quæs. for *quæstor*.

QUAB, in *Ichthyology*, the name of a Russian fish, which is said to be at first a tadpole, then a frog, and at last a fish. Dr Mounsey, who made many inquiries concerning these pretended changes, considers them all as fabulous. He had opportunity of seeing the fish itself, and found that they spawned like other fishes, and grew in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in standing lakes, or in rivers passing through marshes or mossy grounds, where frogs choose most to be.

QUABES, are a free people of Africa, inhabiting the southern banks of the river Sestos, and between that and Sierra Leona. They are under the protection of the emperor of Manow.

QUACHA, or QUAGGA. See EQUUS, MAMMALIA *Index*.

QUACHILTO, in *Ornithology*, is the name of a very beautiful Brasilian bird, called also *yacazintli* and *porphyrio Americanus*. It is of a fine blackish purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its basis, resembling in some sort the coot; its legs are of a yellowish green; it lives about the waters, and feeds on fish, yet is a very well tasted bird. It imitates the crowing of a common cock, and makes its music early in the morning.

Marc-grave's Hist. Bra-

QUACK, among physicians, the same with empiric. See EMPIRIC.

QUADI, (Tacitus); a people of Germany, situated to the south-east of the mountains of Bohemia, on the banks of the Danube, and extending as far as the river Marus, or March, running by Moravia, which country they occupied.

QUADRAGESIMA, a denomination given to lent, from its consisting of 40 days. See LENT.

QUADRANGLE, in *Geometry*, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the *as*, or pound.

QUADRANS, in English money, the fourth part of a penny. Before the reign of Edward I. the smallest coin was a *sterling*, or penny, marked with a cross; by the guidance of which a penny might be cut into halves for a halfpenny, or into quarters or four parts for farthings; till, to avoid the fraud of unequal cuttings, that king coined halfpence and farthings in distinct round pieces.

QUADRANT, in *Geometry*, the arch of a circle, containing 90°, or the fourth part of the entire periphery.

Sometimes also the space or area, included between this arch and two radii drawn from the centre to each extremity thereof, is called a *quadrant*, or, more properly, a *quadrantal space*, as being a quarter of an entire circle.

QUADRANT, also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also for taking angles in surveying, &c.

This instrument is variously contrived, and furnished with different apparatus, according to the various uses it is intended for; but they all have this in common, that they consist of a quarter of a circle, whose limb is divided into 90°. Some have a plummet suspended from the centre, and are furnished with sights to look through.

The principal and most useful quadrants are the common surveying quadrant, astronomical quadrant, Adams's quadrant, Cole's quadrant, Gunter's quadrant, Hadley's quadrant, horodictical quadrant, Sutton's or Collins's quadrant, and the sinical quadrant, &c. Of each of which in order.

1. The common surveying quadrant, is made of brass, wood, or any other solid substance; the limb of which is divided into 90°, and each of these farther divided into as many equal parts as the space will allow, either diagonally or otherwise. On one of the semidiameters are fitted two moveable sights; and to the centre is sometimes also fixed a label, or moveable index, bearing two other sights; but in lieu of these last sights there is sometimes fitted a telescope: also from the centre there is hung a thread with a plummet; and on the under side or face of the instrument is fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from

Quadrant. from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. But besides the parts already described, there is frequently added to the face, near the centre, a kind of compartment, called the *quadrat*, or *geometrical square*. See QUADRAT.

This quadrant may be used in different situations: for observing heights or depths, its plane must be disposed perpendicularly to the horizon; but to take horizontal distances, its plane is disposed parallel thereto. Again, heights and distances may be taken two ways, viz. by means of the fixed sights and plummet, or by the label: As to which, and the manner of measuring angles, see GEOMETRY and MENSURATION.

2. The astronomical quadrant is a large one, usually made of brass, or wooden bars faced with iron plates; having its limb nicely divided, either diagonally or otherwise, into degrees, minutes, and seconds; and furnished with two telescopes, one fixed on the side of the quadrant, and the other moveable about the centre, by means of the screw. There are also dented wheels which serve to direct the instrument to any object or phenomenon.—The use of this curious instrument, in taking observations of the sun, planets, and fixed stars, is obvious; for being turned horizontally upon its axis, by means of the telescope, till the object is seen through the moveable telescope, then the degrees, &c. cut by the index give the altitude required. See ASTRONOMY *Index*.

3. Cole's quadrant is a very useful instrument invented by Mr Benjamin Cole. It consists of six parts, viz. the staff AB (fig. 1.); the quadrantal arch DE; three vanes A, B, C; and the vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is also of wood; and is divided into degrees, and third-parts of a degree, to a radius of about nine inches; to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, round which it easily moves. The sight-vane A is a thin piece of brass, almost two inches in height and one broad, placed perpendicularly on the end of the staff A, by the help of two screws passing through its foot. Through the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizon vane B is about an inch broad, and two inches and a half high, having a slit cut through it of near an inch long and a quarter of an inch broad; this vane is fixed in the centre-pin of the instrument, in a perpendicular position, by the help of two screws passing through its foot, whereby its position with respect to the sight-vane is always the same, their angles of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one, which serves as an arm, is about four inches and a half long, and three quarters of an inch broad, being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin: the other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate, at about half an inch distance from that end next the arch; this vane may be used either by its shade or by the solar spot cast by a convex lens placed therein. And, because the wood-work is often apt to warp or twist, therefore this vane may be rectified by the help of a screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner: Set the line G on a vernier against a degree on the upper limb of the quadrant, and turn a screw on the backside of the limb forward or backward, till the hole in the sight-vane, the centre of the glass, and the sunk spot in the horizon-vane, lie in a right line.

Plate CCCCLVIII. fig. 1.

To find the sun's altitude by this instrument: Turn your back to the sun, holding the instrument by the staff with your right hand, so that it be in a vertical plane passing through the sun; apply your eye to the sight-vane, looking through that and the horizon-vane till you see the horizon; with the left hand slide the quadrantal arch upwards, until the solar spot or shade, cast by the shade-vane, fall directly on the spot or slit in the horizon-vane; then will that part of the quadrantal arch, which is raised above G or S (according as the observation respected either the solar spot or shade) show the altitude of the sun at that time. But if the meridian altitude be required, the observation must be continued; and as the sun approaches the meridian, the sea will appear through the horizon-vane, and then is the observation finished; and the degrees and minutes, counted as before, will give the sun's meridian altitude: or the degrees counted from the lower limb upwards will give the zenith-distance.

4. Adams's quadrant differs only from Cole's quadrant in having an horizontal vane, with the upper part of the limb lengthened; so that the glass, which casts the solar spot on the horizon-vane, is at the same distance from the horizon-vane as the sight-vane at the end of the index.

5. Gunter's quadrant, so called from its inventor Edmund Gunter, besides the usual apparatus of other quadrants, has a stereographical projection of the sphere on the plane of the equinoctial. It has also a kalendar of the months, next to the divisions of the limb.

Use of Gunter's quadrant. 1. To find the sun's meridian altitude for any given day, or the day of the month for any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; and the degree it cuts in the limb is the sun's meridian altitude. Thus the thread, being laid on the 15th of May, cuts 59° 30′, the altitude sought; and, contrarily, the thread, being set to the meridian altitude, shows the day of the month. 2. To find the hour of the day. Having put the bead, which slides on the thread, to the sun's place in the ecliptic, observe the sun's altitude by the quadrant; then, if the thread be laid over the same in the limb, the bead will fall upon the hour required. Thus suppose on the 10th of April, the sun being then in the beginning of Taurus, I observe the sun's altitude by the quadrant to be 36°; I place the bead to the beginning of Taurus in the ecliptic, and lay the thread over 36° of the limb; and find the bead to fall on the hour-line marked three and nine; accordingly the hour is either nine in the morning or three in the afternoon. Again, laying the bead on the hour given, having first rectified or put it to the sun's place, the degree cut by the thread on the limb gives the altitude. Note, the bead may be rectified otherwise, by bringing

bringing the thread to the day of the month, and the bead to the hour-line of 12. 3. To find the sun's declination from his place given, and contrariwise. Set the bead to the sun's place in the ecliptic, move the thread to the line of declination, and the bead will cut the degree of declination required. Contrarily, the bead being adjusted to a given declination, and the thread moved to the ecliptic, the bead will cut the sun's place. 4. The sun's place being given, to find his right ascension, or contrarily. Lay the thread on the sun's place in the ecliptic, and the degree it cuts on the limb is the right ascension sought. Contrarily, laying the thread on the right ascension, it cuts the sun's place in the ecliptic. 5. The sun's altitude being given, to find his azimuth, and contrariwise. Rectify the bead for the time, as in the second article, and observe the sun's altitude: bring the thread to the complement of that altitude; thus the bead will give the azimuth sought, among the azimuth lines. 6. To find the hour of the night from some of the five stars laid down on the quadrant. (1.) Put the bead to the star you would observe, and find how many hours it is off the meridian, by article 2. (2.) Then, from the right ascension of the star, subtract the sun's right ascension converted into hours, and mark the difference; which difference, added to the observed hour of the star from the meridian, shows how many hours the sun is gone from the meridian, which is the hour of the night. Suppose on the 15th of May the sun is in the 4th degree of Gemini, I set the bead to Arcturus; and, observing his altitude, find him to be in the west about 52° high, and the bead to fall on the hour-line of two in the afternoon; then will the hour be 11 hours 50 minutes past noon, or 10 minutes short of midnight: for 62°, the sun's right ascension, converted into time, makes four hours eight minutes; which, subtracted from 13 hours 58 minutes, the right ascension of Arcturus, the remainder will be nine hours 50 minutes; which added to two hours, the observed distance of Arcturus from the meridian, shows the hour of the night to be 11 hours 50 minutes.

The mural quadrant has been already described under the article ASTRONOMY. It is a most important instrument, and has been much improved by Mr Ramsden, who has distinguished himself by the accuracy of his divisions, and by the manner in which he finishes the planes by working them in a vertical position. He places the plumb-line behind the instrument, that there may be no necessity for removing it when we take an observation near the zenith. His manner of suspending the glass, and that of throwing light on the object-glass and on the divisions at the same time, are new, and improvements that deserve to be noticed. Those of eight feet, which he has made for the observatories of Padua and Vilna, have been examined by Dr Maskelyne; and the greatest error does not exceed two seconds and a half. That of the same size for the observatory of Milan is in a very advanced state. The mural quadrant, of six feet at Blenheim, is a most admirable instrument. It is fixed to four pillars, which turn on two pivots, so that it may be put to the north and to the south in one minute. It was for this instrument Mr Ramsden invented a method of rectifying the arc of 90 degrees, on which an able astronomer had started some difficulties; but by means of an horizontal line and a plumb-line, forming a kind of cross, without touching the circle, he showed him that there was not an error of a single second in the 90 degrees; and that the difference was occasioned by a mural quadrant of Bird, in which the arc of 90 degrees was too great by several seconds, and which had never been rectified by so nice a method as that of Mr Ramsden.

But the quadrant is not the instrument which stands highest in Mr Ramsden's opinion; it is the complete circle: and he has demonstrated to M. de la Lande, that the former must be laid aside, if we would arrive at the utmost exactness of which an observation is capable. His principal reasons are: 1. The least variation in the centre is perceived by the two diametrically opposite points. 2. The circle being worked on the turn, the surface is always of the greatest accuracy, which it is impossible to obtain in the quadrant. 3. We may always have two measures of the same arc, which will serve for the verification of each other. 4. The first point of the division may be verified every day with the utmost facility. 5. The dilatation of the metal is uniform, and cannot produce any error. 6. This instrument is a meridian glass at the same time. 7. It also becomes a moveable azimuth circle by adding a horizontal circle beneath its axis, and then gives the refractions independent of the mensuration of time.

6. Hadley's quadrant is an instrument of vast utility both in navigation and practical astronomy. It derives its name from Mr Hadley, who first published an account of it, though the first thought originated with the celebrated Dr Hooke, and was completed by Sir Isaac Newton (see ASTRONOMY, N° 32. and also N° 17. and 22.). The utility of this quadrant arises from the accuracy and precision with which it enable us to determine the latitude and longitude; and to it is navigation much indebted for the very great and rapid advances it has made of late years. It it easy to manage, and of extensive use, requiring no peculiar steadiness of hand, nor any such fixed basis as is necessary to other astronomical instruments. It is used as an instrument for taking angles in maritime surveying, and with equal facility at the mast head as upon the deck, by which its sphere of observation is much extended; for supposing many islands to be visible from the mast head, and only one from deck, no useful observation can be made by any other instrument. But by this, angles may be taken at the mast head from the one visible object with great exactness; and further taking angles from heights, as hills, or a ship mast's head, is almost the only way of describing exactly the figure and extent of shoals.

It has been objected to the use of this instrument for surveying, that it does not measure the horizontal angles, by which alone a plan can be laid down. This objection, however true in theory, may be reduced in practice by a little caution; and Mr Adams has given very good directions for doing so.

Notwithstanding, however, the manifest superiority of this instrument over those that were in use at the time of its publication, it was many years before the sailors could be persuaded to adopt it, and lay aside their imperfect and inaccurate instruments, so great is the difficulty to remove prejudice, and emancipate the mind from the slavery of opinion. No instrument has undergone, since the original invention, more changes than

than the quadrant of Hadley; of the various alterations, many had no better foundation than the caprice of the makers, who by these attempts have often rendered the instrument more complicated in construction, and more difficult in use, than it was in its original state.

It is an essential property of this instrument, derived from the laws of reflection, that half degrees on the arc answer to whole ones in the angles measured: hence an octant, or the eighth part of a circle, or 45 degrees on the arch, serves to measure 90 degrees; and sextants will measure an angular distance of 120 degrees, though the arch of the instrument is no more than 60 degrees. It is from this property that foreigners term that instrument an *octant*, which we usually call a *quadrant*, and which in effect it is. This property reduces indeed considerably the bulk of the instrument: but at the same time it calls for the utmost accuracy in the divisions, as every error on the arch is doubled in the observation.

Another essential, and indeed an invaluable, property of this instrument, whereby it is rendered peculiarly advantageous in marine observations, is, that it is not liable to be disturbed by the ship's motion; for provided the mariner can see distinctly the two objects in the field of his instrument, no motion nor vacillation of the ship will injure his observation.

Thirdly, the errors to which it is liable are readily discovered and easily rectified, while the application and use of it is facile and plain.

To find whether the two surfaces of any one of the reflecting glasses be parallel, apply your eye at one end of it, and observe the image of some object reflected very obliquely from it; if that image appear single, and well-defined about the edges, it is a proof that the surfaces are parallel: on the contrary, if the edge of the reflected images appear misted, as if it threw a shadow from it, or separated like two edges, it is a proof that the two surfaces of the glass are inclined to each other: if the images in the speculum, particularly if that image be the sun, be viewed through a small telescope, the examination will be more perfect.

To find whether the surface of a reflecting glass be plane. Choose two distant objects, nearly on a level with each other: hold the instrument in an horizontal position, view the left-hand object directly through the transparent part of the horizon-glass, and move the index till the reflected image of the other is seen below it in the silvered part; make the two images unite just at the line of separation, then turn the instrument round slowly on its own plane, so as to make the united images move along the line of separation of the horizon-glass. If the images continue united without receding from each other, or varying their respective position, the reflecting surface is a good plane.

To find if the two surfaces of a red or darkening glass are parallel and perfectly plane. This must be done by means of the sun when it is near the meridian, in the following manner: hold the sextant vertically, and direct the sight to some object in the horizon, or between you and the sky, under the sun; turn down the red glass and move the index till the reflected image of the sun is in contact with the object seen directly: fix then the index, and turn the red glass round in its square frame; view the sun's image and object immediately, and if the sun's image is neither raised nor depressed, but continues in contact with the object below, as before, then the surfaces of the darkening glass are true.

For a more particular description of Hadley's quadrant, and the mode of using it, see NAVIGATION, Book II. chap. i.

This instrument has undergone several improvements since its first invention, and among these improvers must be ranked Mr Ramsden. He found that the essential parts of the quadrant had not a sufficient degree of solidity; the friction at the centre was too great, and in general the alidada might be moved several minutes without any change in the position of the mirror; the divisions were commonly very inaccurate, and Mr Ramsden found that Abbé de la Caille did not exceed the truth in estimating at five minutes the error to which an observer was liable in taking the distance between the moon and a star; an error capable of producing a mistake of 50 leagues in the longitude. On this account Mr Ramsden changed the principle of construction of the centre, and made the instrument in such a manner as never to give an error of more than half a minute; and he has now brought them to such a degree of perfection as to warrant it not more than six seconds in a quadrant of fifteen inches. Since the time of having improved them, Mr Ramsden has constructed an immense number; and in several which have been carried to the East Indies and America, the deficiency has been found no greater at their return than it had been determined by examinations before their being taken out. Mr Ramsden has made them from 15 inches to an inch and a half, in the latter of which the minutes are easily distinguishable; but he prefers for general use those of 10 inches, as being more easily handled than the greater, and at the same time capable of equal accuracy. See SEXTANT.

A great improvement was also made in the construction of this quadrant by Mr Peter Dollond, famous for his invention of achromatic telescopes. The glasses of the quadrants should be perfect planes, and have their surfaces perfectly parallel to one another. By a practice of several years, Mr Dollond found out methods of grinding them of this form to great exactness; but the advantage which should have arisen from the goodness of the glasses was often defeated by the index-glass being bent by the frame which contains it. To prevent this, Mr Dollond contrived the frame so, that the glass lies on three points, and the part that presses on the front of the glass has also three points opposite to the former. These points are made to confine the glass by three screws at the back, acting directly opposite to the points between which the glass is placed. The principal improvements, however, are in the methods of adjusting the glasses, particularly for the back-observation. The method formerly practised for adjusting that part of the instrument by means of the opposite horizons at sea, was attended with so many difficulties that it was scarcely ever used: for so little dependence could be placed on the observations taken this way, that the best Hadley's sextants, made for the purpose of observing the distances of the moon from the sun or fixed stars, have been always made without the horizon-glass for the back-observation; for want of which, many valuable observations of the sun and moon have been lost, when their distance exceeded 120 degrees.

Quadrant. grees. To make the adjustment of the back-observation easy and exact, he applied an index to the back horizon-glass, by which it may be moved in a parallel position to the index-glass, in order to give it the two adjustments in the same manner as the fore horizon-glass is adjusted. Then, by moving the index to which the back horizon-glass is fixed exactly 90 degrees (which is known by the divisions made for that purpose), the glass will thereby be set at right angles to the index-glass, and will be properly adjusted for use; and the observations may be made with the same accuracy by this as by the fore-observation. To adjust the horizon-glasses in the perpendicular position to the plane of the instrument, he contrived to move each of them by a single screw, which goes though the frame of the quadrant, and is turned by means of a milled head at the back; which may be done by the observer while he is looking at the object. To these improvements also he added a method invented by Dr Maskelyne, of placing darkening-glasses behind the horizon-glasses. These, which serve for darkening the object seen by direct vision, in adjusting the instrument by the sun or moon, he placed in such a manner as to be turned behind the fore horizon-glass, or behind the back horizon-glass: there are three of these glasses of different degrees of darkness.

We have been the more particular in our description and use of Hadley's quadrant, as it is undoubtedly the best hitherto invented.

7. Horodictical quadrant, a pretty commodious instrument, so called from its use in telling the hour of the day.—Its construction is this: From the centre of the quadrant, C, fig. 3. whose limb AB is divided into 90°, describe seven concentric circles at intervals at pleasure; and to these add the signs of the zodiac, in the order represented in the figure. Then applying a ruler to the centre C and the limb AB, mark upon the several parallels the degrees corresponding to the altitude of the sun when therein, for the given hours; connect the points belonging to the same hour with a curve line, to which add the number of the hour. To the radius CA fit a couple of sights, and to the centre of the quadrant C tie a thread with a plummet, and upon the thread a bead to slide. If now the thread be brought to the parallel wherein the sun is, and the quadrant directed to the sun, till a visual ray pass through the sights, the bead will show the hour; for the plummet, in this situation, cuts all the parallels in the degrees corresponding to the sun's altitude. Since the bead is in the parallel which the sun describes, and through the degrees of altitude to which the sun is elevated every hour there pass hour lines, the bead must show the present hour. Some represent the hour-lines by arches of circles, or even by straight lines, and that without any sensible error. Fig. 3.

8. Sutton's or Collins's quadrant (fig. 4.) is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole: it is fitted to the latitude of London. The lines running from the right hand to the left are parallels of altitude; and those crossing them are azimuths. The lesser of the two circles bounding the projection, is one-fourth of the tropic of Capricorn; the greater is one-fourth of that of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and, by having the sun's altitude, the hour of the day may be found here to a minute. The quadrantal arches next the centre contain the kalendar of months; and under them, in another arch, is the sun's declination. On the projection are placed several of the most noted fixed stars between the tropics; and the next below the projection is the quadrant and line of shadows. To find the time of the sun's rising or setting, his amplitude, his azimuth, hour of the day, &c. by this quadrant: lay the thread over the day and the month, and bring the bead to the proper ecliptic, either of summer or winter, according to the season, which is called *rectifying*; then, moving the thread, bring the bead to the horizon, in which case the thread will cut the limb in the time of the sun's rising or setting before or after six; and at the same time the bead will cut the horizon in the degrees of the sun's amplitude.—Again, observing the sun's altitude with the quadrant, and supposing it found 45° on the fifth of May, lay the thread over the fifth of May, bring the bead to the summer ecliptic, and carry it to the parallel of altitude 45°; in which case the thread will cut the limb at 55° 15′, and the hour will be seen among the hour-lines to be either 41′ past nine in the morning, or 19′ past two in the afternoon.—Lastly, the bead among the azimuths shows the sun's distance from the south 50° 41′. But note, that if the sun's altitude be less than what it is at six o'clock, the operation must be performed among those parallels above the upper horizon, the bead being rectified to the winter ecliptic. Fig. 4.

9. Sinical quadrant (fig. 5.) consists of several concentric quadrantal arches, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles. Now any one of the arches, as BC, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then BC be taken for a quadrant of the horizon, either of the sides, as AB, may represent the meridian; and the other side, AC, will represent a parallel, or line of east and west: and all the other lines, parallel to AB, will be also meridians; and all those parallel to AC, east and west lines, or parallels.—Again, the eight spaces into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11° 15′. The arch BC is likewise divided into 90°, and each degree subdivided into 12, diagonal-wise. To the centre is fixed a thread, which, being laid over any degree of the quadrant, serves to divide the horizon. Fig. 5.

If the sinical quadrant be taken for a fourth part of the meridian, one side thereof, AB, may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degrees of the circumference, BC, will represent degrees of latitude; and the parallels to the side AB, assumed from every point of latitude to the axis AC, will be radii of the parallels of latitude, as likewise the sine complement of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lesser leagues in the parallel of 48°; lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues on

AB, beginning at A; this will terminate in H, allowing every small interval four leagues. Then tracing out the parallel HE, from the point H to the thread; the part AE of the thread shows that 125 greater or equinoctial leagues make 60° 15′; and therefore that the 83 lesser leagues AH, which make the difference of longitude of the course, and are equal to the radius of the parallel HE, make 60° 15′ of the said parallel.

If the ship sails an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westerly, to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional parallel between them. To find this, we have on the instrument a scale of cross latitudes. Suppose then it were required to find a mean parallel between the parallels of 40° and 60°; with your compasses take the middle between the 40th and 60th degree on this scale: the middle point will terminate against the 51st degree, which is the mean parallel required.

The principal use of the sinical quadrant is to form triangles upon, similar to those made by a ship's way with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants and the lines N and S, E and W: and every fifth line and arch is made deeper than the rest. Now, suppose a ship to have sailed 150 leagues north-east, one-fourth north, which is the third point, and makes an angle of 33° 44′ with the north part of the meridian: here are given the course and distance sailed, by which a triangle may be formed on the instrument similar to that made by the ship's course; and hence the unknown parts of the triangle may be found. Thus, supposing the centre A to represent the place of departure, count, by means of the concentric circles along the point the ship sailed on, viz. AD, 150 leagues: then in the triangle AED, similar to that of the ship's course, find AE=difference of latitude, and DE=difference of longitude, which must be reduced according to the parallel of latitude come to.

Fig. 6.

10. Gunner's quadrant (fig. 6.), sometimes called *gunner's square*, is that used for elevating and pointing cannon mortars, &c. and consists of two branches either of brass or wood, between which is a quadrantal arch divided into 90 degrees, beginning from the shorter branch, and furnished with a thread and plummet, as represented in the figure.—The use of the gunner's quadrant is extremely easy; for if the longest branch be placed in the mouth of the piece, and it be elevated till the plummet cut the degree necessary to hit a proposed object, the thing is done. Sometimes on one of the surfaces of the long branch are noted the division of diameters and weights of iron bullets, as also the bores of pieces.

QUADRANT *of Altitude*, is an appendage of the artificial globe, consisting of a lamina, or slip of brass, the length of a quadrant of one of the great circles of the globe, and graduated. At the end, where the division terminates, is a nut rivetted on, and furnished with a screw, by means whereof the instrument is fitted on the meridian, and moveable round upon the rivet to all points of the horizon.—Its use is to serve as a scale in measuring altitudes, amplitudes, azimuths, &c. See ASTRONOMY.

QUADRANTAL, in *Antiquity*, the name of a vessel in use among the Romans for the measuring of liquids. It was at first called *amphora*; and afterwards *quadrantal*, from its form, which was square every way like a die. Its capacity was 80 libræ, or pounds of water, which made 48 sextaries, two urnæ, or eight congii.

QUADRAT, a mathematical instrument, called also a *Geometrical Square*, and *Line of Shadows*: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrants.

QUADRAT, in Printing, a piece of metal used to fill up the void spaces between words, &c. There are quadrats of different sizes; as m-quadrats, n-quadrats, &c. which are respectively of the dimensions of these letters, only lower, that they may not receive the ink.

QUADRATIC EQUATIONS, in *Algebra*, those wherein the unknown quantity is of two dimensions, or raised to the second power. See ALGEBRA.

QUADRATRIX, in *Geometry*, a mechanical line, by means whereof we can find right lines equal to the circumference of circles, or other curves, and their several parts.

QUADRATURE, in *Geometry*, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c. The quadrature, especially among the ancient mathematicians, was a great postulatum. The quadrature of rectilineal figures is easily found, for it is merely the finding their areas or surfaces, i. e. their squares; for the squares of equal areas are easily found by only extracting the roots of the areas thus found. The quadrature of curvilinear spaces is of more difficult investigation; and in this respect extremely little was done by the ancients, except the finding the quadrature of the parabola by Archimedes. In 1657, Sir Paul Neil, Lord Brouncker, and Sir Christopher Wren, geometrically demonstrated the equality of some curvilinear spaces to rectilinear spaces; and soon after the like was proved both at home and abroad of other curves, and it was afterwards brought under an analytical calculus; the first specimen of which was given to the public in 1688 by Mercator, in a demonstration of Lord Brouncker's quadrature of the hyperbola, by Dr Wallis's reduction of a fraction into an infinite series by division. Sir Isaac Newton, however, had before discovered a method of attaining the quantity of all quadruple curves analytically by his fluxions before 1668. It is disputed between Sir Christopher Wren and Mr Huyghens which of them first discovered the quadrature of any determinate cycloidal space. Mr Leibnitz afterwards found that of another space; and in 1669 Bernoulli discovered the quadrature of an infinity of cycloidal spaces both segments and sectors, &c. See *SQUARING the Circle.*

QUADRATURE, in *Astronomy*, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters. See ASTRONOMY *Index*.

QUADRATUS, in *Anatomy*, a name given to several muscles on account of their square figure. See ANATOMY, *Table of the Muscles*.

QUADREL, in *Building*, a kind of artificial stone, so called from its being perfectly square. The quadrels are made of a chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

QUADRIGA, in *Antiquity*, a car or chariot drawn by four horses. On the reverses of medals, we frequently see the emperor or Victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called *nummi quadrigati*, and *victoriati*.

QUADRILATERAL, in *Geometry*, a figure whose perimeter consists of four sides and four angles; whence it is also called a *quadrangular figure*.

QUADRILLE, a little troop or company of cavaliers, pompously dressed, and mounted for the performance of carousals, justs, tournaments, runnings at the ring, and other gallant divertisements.

QUADRILLE, a game played by four persons, with 40 cards; which are the remains of a pack after the four tens, nines, and eights are discarded; these are dealt three and three, and one round four, to the right-hand player; and the trump is made by him that plays with or without calling, by naming spades, clubs, diamonds, or hearts, and the suit named is trumps. If the person who names the trump should mistake, and say spades instead of clubs, or if he name two suits, the first named is the trump.

In this game the order of the cards, according to their natural value, is as follows: of hearts and diamonds, *king, queen, knave, ace, deuce, three, four, five, six, seven;* in all 10: of spades and clubs, *king, queen, knave, seven, six, five, four, three, deuce;* in all 9. The reason why the ace of spades and ace of clubs are not mentioned, is, because they are always trumps in whatever suit that is played. The ace of spades being always the first, and the ace of clubs the third trump, for the cards ranked according to their value when *trumps* stand in the following order.

Hearts and diamonds, SPADILL, or the *ace of spades;* MANILL, the *seventh* of the two *red suits;* BASTO, the *ace of clubs;* PONTO, the *ace of hearts and diamonds; king, queen, knave, deuce, three, four, five, six;* in all 12. Spades and clubs, SPADILL, the ace of spades, MANILL, the *deuce* of spades and clubs, BASTO the ace of clubs, *king, queen, knave, seven, six, five, four, three;* in all 11. It is here to be observed, that the card which is *manill* and the second trump, is always the lowest in its suit when not trumps; and that the ace of hearts or diamonds, which when trump is above the king, is below the knave when not trump.

There are three matadores; spadill, manill, and basto; the privilege of which is, that when the player has no other trumps but them, and trumps are led, he is not obliged to play them, but may play what card he thinks proper, provided, however, that the trump led is of an inferior rank; but if spadill should be led, he that has manill or basto only is obliged to play it; it is the same of manill basto, with respect to the superior matadore always forcing the inferior. Though there are properly but three matadores, nevertheless all those trumps which follow the three first without interruption, are likewise called matadores; but the three first only enjoy the privilege above mentioned.

Each person is to play as he judges most convenient for his own game. He is not to encourage his friend to play; but each person ought to know what to do when it is his turn to play. The stakes consist of seven equal mils or *contrats*, as they are sometimes called, comprising the ten counters and fishes, which are given to each player. A mil is equal to ten fish, and each fish to ten counters: the value of the fish is according to the players agreement, as also the number of tours, which are generally fixed at ten, and marked by turning the corners of a card.

If the cards should happen not to be dealt right, or that there should be two cards of the same sort, as two deuces of spades, for example, there must be a new deal; provided it is discovered before the cards are all played. The cards must likewise be dealt over again in case a card is turned in dealing, as it might be of prejudice to him who should have it, and of course if there should be several cards turned. There is no penalty for dealing wrong, he who does so must only deal again.

When each player has got his ten cards, he that is on the right hand of the dealer, after examining his game, and finding his hand fit to play, asks if they play; or if he has not a good hand, he passes, and so the second, third, and fourth. All the four may pass; but he that has spadill, after having shown or named it, is obliged to play by calling a king. Whether the deal is played in this manner, or that one of the players has asked leave, nobody choosing to play without calling, the eldest hand must begin the play, first naming the suit, and the king which he calls; he who wins the trick plays another card, and so of the rest till the game is finished. The tricks then are counted; and if the ombre, that is, he who stands the game, has together with him who is the king called, six tricks, they have won and are paid the game, the consolation, and the matadores, if they have them, and divide what is upon the game, and the beasts if there are any. But if they make only five tricks, it is a remise, and they are beasted, what goes upon the game, paying to the other players the consolation and the matadores. If the tricks are equally divided betwixt them, they are likewise beasted; and if they make only four tricks between them, it is a remise; if they make less they lose codill (A), and in that case they pay to their adversaries what they should have received if they had won; that is, the game, the consolation, and the matadores, if they have them, and are beasted what is upon the game: they who win codill, divide the stakes. The beast and every thing else that is paid, is paid equally betwixt the two losers; one half by him that calls, and the other half by him that is called, as well in case of codill as a remise;

(A) Codill is when those who defend the pool make more tricks than they who stand the game; which is called *winning the codill*.

Quadrille. mise; unless the ombre does not make three tricks, in which case he that is called is not only exempted from paying half the beast, but also the game, the consolation, and the matadores if there are any, which the ombre in that case pays alone; and as well in case of a codill as a remise. This is done in order to oblige players not to play games that are unreasonable. There is nevertheless, one case in which if the ombre makes only one trick, he is not beasted alone, and that is, when not having a good hand he passes, and all the other players have passed likewise; he having spadill is obliged to play. Here it would be unjust to oblige him to make three or four tricks; in this case, therefore, he that is called pays one half of the losings. For which reason he that has spadill with a bad hand, should pass, that if he is afterwards obliged to play by calling a king (which is called *forced spadill*), he may not be beasted alone. He that has once passed cannot be admitted to play; and he that has asked leave cannot refuse to play, unless any one should offer to play without calling.

He that has four kings, may call a queen to one of his kings, except that which is trump. He that wants one or more kings, may call one of those kings; but in that case, he must make six tricks alone, and consequently he wins or loses alone. The king of that suit in which he plays cannot be called. No one should play out of his turn, although he is not beasted for so doing. If he who is not the eldest hand has the king called, and plays spadill, manill, or basto, or even the king called in order to show that he is the friend, having other kings that he fears the ombre should trump, he is not to be allowed to go for the vole; he is even beasted, if it appears to be done with that intent. It is not permitted to show a hand though codill may already be won; that it may be seen whether the ombre is beasted alone. If the ombre or his friend shows their cards before they have made six tricks, thinking that they have made them, and there appears a possibility of preventing their making them, the other players can oblige them to play their cards as they think proper.

A player need only name his suit when he plays, without calling a king. He who plays without calling must make six tricks alone to win; for all the other players are united against him, and they are to do what they can to prevent his winning. He who plays without calling, is admitted to play in preference to him who would play with calling; however, if he that has asked leave will play without calling, he has the preference of the other who would force him. These are the two methods of play without calling that are called forced.

As he who plays without calling does not divide the winnings with any person, he consequently, when he loses, pays all by himself: if he loses by remise he is beasted, and pays each of the other players the consolation, the *sans appeller* (which is commonly, but improperly, called the *sans prendre*), and the matadores if there are any; if he loses codill he is likewise beasted and pays to each player what he would have received from each if he had won. They who win codill divide what there is; and if there are any counters remaining, they belong to him of the three who shall have spadill or the highest trump the next deal. It is the same with regard to him who calls one of his own kings; he wins alone or loses alone as in the other case, except the sans appeller, which he does not pay if he loses, or receive if he wins, although he plays alone. Quadrille.

If he plays sans appeller, though he may have a sure game, he is obliged to name his suit; which if he neglects to do, and shows his cards, and says "I play sans appeller;" in that case neither of the other players can oblige him to play in what suit he pleases, although he should not have one trump in that suit.

He who has asked leave is not permitted to play sans appeller, unless he is forced; in which case, as was said before, he has the preference of the other that forces him.

A player is not obliged to trump when he has none of the suit led, nor play a higher card in that suit if he has it, being at his option although he is the last player, and the trick should belong to the ombre; but he is obliged to play in the suit led if he can, otherwise he renounces. If he separates a card from his game and shows it, he is obliged to play it, if by not doing it the game may be prejudiced, or if he can give any intelligence to his friend; but especially if it should be a matadore.—He that plays sans appeller, or by calling himself, is not subject to this law. He may turn the tricks made by the other players, and count what has been played as often as it is his turn to play, but not otherwise. If instead of turning a player's tricks, he turns and see his game, or shows it to the other players, he is beasted, together with him whose cards he turned; and each of them must pay one half of the beast.

If any one renounces, he is beasted as often as he has renounced and it is detected; but a renounce is not made till the trick is turned. If the renounce is discovered before the deal is finished, and has been detrimental to the game, the cards must be taken up again, and the game replayed from that trick where the renounce was made; but if the cards are all played, the beast is still made, and the cards must not be replayed; except there should be several renounces in the same deal: then they are to be played again, unless the cards should be mixed. If several beasts are made in the same deal, they all go together, unless it is otherwise agreed at the beginning of the party; and when there are several beasts, the greatest always goes first.

A great advantage accrues from being eldest hand at quadrille, which often renders it very disagreeable to the rest of the players, being obliged to pass with a good hand unless they choose to play alone; and when it happens that the eldest hand having asked leave, the second player has three matadores, several trumps in back, and all small cards, he cannot then even play alone; and having no chance of being called, he must pass with this good hand. On account of which, this method has been thought expedient to remedy this defect of the game; each player having an opportunity of availing himself of the goodness of his game, by adding to the usual method of playing the game that of the mediateur, and the favourite suit.

The first thing to be observed is that of drawing for places, which is done in this manner: One of the players takes four cards; a king, a queen, a knave, and an ace; each player draws one of these cards; and commonly he who comes in last, draws first. The per-

son

son who draws the king sits where he pleases, the queen at his right hand, the knave next the queen, and the ace on the left of the king. The king draws the favourite suit. The number of cards and persons is the same at this game as the other, and is played in the same manner.

The favourite suit is determined by drawing a card out of the pack, and is of the same suit, during the whole party, of the card so drawn.

A king is the mediateur, which is demanded of the others by one of the players, who has a hand he expects to make five tricks of; and through the assistance of this king he can play alone and make six tricks.

In return for the king received, he gives what card he thinks proper with a fish; but must give two fish if it is in the favourite suit. He who asks by calling in the favourite suit, has the preference to him who asks by calling in another; he who asks with the mediateur, has the preference to him who asks by calling in the favourite suit, and by playing alone is obliged to make six tricks to win. He who asks with the mediateur in the favourite suit, has the preference to him who asks with the mediateur in any other suit, and is obliged to play alone, and to make six tricks.

If sans prendre is played in any other suit than the favourite, he who plays it has the preference to him who asks only, or with the mediateur, or even he who plays in the favourite suit with the mediateur; and the sans prendre in the favourite suit has the preference to all other players whatever.

The only difference between this method of playing the game and the other is, that when one of the players demands the mediateur he is obliged to play alone, and to make six tricks, as if he played sans prendre. In this case he should judge from the strength of his hand, whether the aid of the king will enable him to play alone or not.

With the mediateur and without the favourite suit it is played in this manner. The game is marked and played the same as in common, except that a fish extraordinary is given to him who plays the mediateur, and to him who plays sans prendre; that is, he who wins the mediateur receives 13 counters from each; and if he loses by remise he pays 12 to each; and 13 if by codill. The winner of sans prendre receives 17 counters from each; and if by remise he loses, he pays 16 to each, and 17 if by codill:

The vole with the mediateur receives one fish only, as at common quadrille. The beasts are also the same as the common game. The last game is generally played double, and is called *paulans;* but for those who choose to play a higher game, they may play the double colour, which is called the *Turk*, and is double of the favourite suit. There is also a higher game than this, called the *aubde*, which is paying whatever is agreed to him who happens to hold the two aces in his hand.

We have omitted many things respecting the mode of marking the game, and playing the vole, because these are different in different cases, and are to be learned only by practice. The game itself is a very inferior one; but he who wishes to know more of it, may consult Hoyle's games improved by James Beaufort, Esq, from which we have, with very little alteration, taken this article.

QUADRIPARTITION, the dividing by four, or into four equal parts. Hence comes the term *quadripartite*, the fourth part, or something divided into four.

QUADRUPEDS, in *Zoology;* those animals which have four limbs or legs proceeding from the trunk of their body. See MAMMALIA.

QUADRUPLE, four-fold, or something taken four times, or multiplied by four, on which account it is the converse of quadripartition.

QUÆSTOR, see QUESTOR.

QUAGGA, or QUACHA. See EQUUS, MAMMALIA *Index*.

QUAIL. See TETRAO, ORNITHOLOGY *Index*.

Quails are to be taken by means of the call during their whole wooing time, which lasts from April to August. The proper times for using the call are at sunrising, at nine o'clock in the morning, at three in the afternoon, and at sunset; for these are the natural times of the quail's calling. The notes of the cock and hen quail are very different; and the sportsman who expects to succeed in the taking them must be expert in both: for when the cock calls, the answer is to be made in the hen's note; and when the hen calls, the answer is to be made in the cock's. By this means they will come up to the person, so that he may, with great ease, throw the net over them and take them. If a cock-quail be single, on hearing the hen's note he will immediately come; but if he have a hen already with him, he will not forsake her. Sometimes, though only one quail answers to the call, there will three or four come up; and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings, they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top; and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; that is to be stuffed half-full of horse-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone: this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the purse; the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax; then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a sort of shake. This is the most useful call; for it imitates the note of the hen quail; and seldom fails to bring a cock to the net if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must

Quail, Quakers.

must be a small thread or strap of leather, and at the other end must be placed the same sort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same sound that the cock does when he gives the hen a signal that he is near her.

QUAKERS, a religious society, which took its rise in England about the middle of the 17th century, and rapidly found its way into other countries in Europe, and into the English settlements in North America.—The members of this society, we believe, called themselves at first *seekers*, from their seeking the truth; but after the society was formed, they assumed the appellation of *friends*. The name of *quakers* was given to them by their enemies; and though an epithet of reproach, seems to be stamped upon them indelibly. Their founder is generally believed to have been George Fox, an illiterate shoemaker (see *George Fox*), but this opinion has been lately controverted. An ingenious writer * having found, or fancied, a similarity of sentiments among the ancient Druids and modern Quakers, seems to think that Fox must have been nothing more than a tool employed by certain deists to pave the way for their system of natural religion, by allegorizing the distinguishing article of the Christian faith.

* See *Month. Rev.* Sept. 1793, art. 5.

It must be confessed, for experience will not allow it to be denied, that extremes in religion are very apt to beget each other; and if the deists alluded to reasoned from this fact, they could not have pitched upon a tool fitter for their purpose than George Fox. From his works still extant he appears to have been one of the most extravagant and absurd enthusiasts that ever lived, and to have fancied himself, in his apostolic character, something infinitely superior to man. In a book called *News coming out of the North*, (p. 15.), he says of himself, "I am the Door that ever was, the same Christ yesterday, to-day, and for ever." And in the introduction to his *Battle-door for Teachers and Professors*, he says, "All languages are to me no more than dust, who was before languages were." But one of the most extraordinary and blasphemous things that he ever wrote, is an answer to the Protector, who had required him to promise not to disturb his goverment as then established. It is as follows:

"I who am of the world called G: F: doth deny the carrying or drawing any carnal sword against any, or against thee O: C: or any man, in the presence of the Lord I declare it, God is my witness, by whom I am moved to give this forth for the truth's sake, from him whom the world calls G: Fox, *who is the son of God*, who is sent to stand a witness against all violence and against the works of darkness, and to turn the people from darkness to light, and to bring them from the occasion of the war and from the occasion of the magistrates sword, which is a terror to the evil doer, which acts contrary to the light of the Lord *Jesus Christ;* which is a praise to them that do well; which is a protection to them that do well, and not the evil; and such soldiers as are put in place no false accusers must be, no violence must do, but be content with their wages: and that magistrate bears not the sword in vain, from under the occasion of that sword do I seek to bring people: my weapons are not carnal but spiritual, and *my kingdom is not of this world;* therefore with carnal weapon I do not fight, but am from those things dead, from him who is not of this world, called of the world by the name of G: F: and this I am ready to seal with my blood; this I am moved to give forth for the truth's sake, who a witness stands against all unrighteousness, and all ungodliness, who a sufferer is for the righteous seed's sake, waiting for the redemption of it, who a crown that is mortal seeks not, for that fadeth away; but in the light dwells which comprehends that crown, which light is the condemnation of all such, in which light I witness the crown that is immortal, which fades not away from him who to all your souls is a friend, for establishing of righteousness, and clearing the land of evil doers, and a witness against all the wicked inventions of man, and murderer's plots, which answer shall be with the light in all your consciences, which makes no covenant with death; to which light in you all I speak, and am clear, G: F: who a new name hath, which the world knows not (A)."

The Quakers, however, did not long entrust the defence of their principles to such senseless enthusiasts as George Fox: They were joined by a number of learned, ingenious, and pious men, who new-modelled their creed; and though they did not bring it to what is generally deemed the Christian standard, they so reformed it as that its tenets do not shock common sense, nor the duties prescribed scandalize a man of piety. The chief of these reformers were George Keith, the celebrated Penn, and our countryman Barclay. Keith was indeed excommunicated for the liberties which he took with the great apostle; but we have not a doubt but his writings contributed to the moderation of Penn, and to the elegant and masterly apology of Barclay. From that apology we selected the summary of their opinions which was given in the former edition of this work; but they have lately published such a summary themselves, of which the reader will be pleased with the following abstract:

They tell us, that about the beginning of the 17th century a number of men, dissatisfied with all the modes of religious worship then known in the world, withdrew from the communion of every visible church to seek the Lord in retirement. Among these was their *honourable elder George Fox*, who being quickened by the immediate touches of divine love, could not satisfy his apprehensions of duty to God without directing the people where to find the like consolation and instruction. In the course of his

(A) We have transcribed this letter from the theological works of Mr Leslie, where it is preserved in its original form. The Quakers, after the death of their apostle, expunged from their edition of it the words which we have printed in Italics; ashamed, as we hope, of the blasphemy imputed to them: but that Mr Leslie's copy is authentic, is thus attested by two of the friends, who saw Fox deliver it to the protector's messenger: "We are witnesses of this testimony, whose names in the flesh are, *Tho. Adam.* *Rob. Craven.*"

Quakers.

his travels, he met with many seeking persons in circumstances similar to his own, and these readily receivved his testimony. They then give us a short account of their sufferings and different settlements; and with a degree of candour which does them infinite credit, they vindicate Charles II. from the character of a persecutor; acknowledging, that though they suffered much during his reign, he gave as little countenance as he could to the severities of the legislature. They even tell us, that he exerted his influence to rescue their friends from the unprovoked and cruel persecutions of the New England fanatics; and they speak with becoming gratitude of the different acts passed in their favour during the reigns of William and Mary, and George I. They then proceed to give us the following account of their doctrine:

"We agree with other professors of the Christian name, in the belief in one eternal God, the Creator and Preserver of the universe; and in Jesus Christ his Son, the Messiah, and Mediator of the new covenant (Heb. xii. 24.).

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour, we prefer the use of such terms as we find in Scripture; and, contented with that knowledge which divine wisdom hath seen meet to reveal, we attempt not to explain those mysteries which remain under the veil, nevertheless, we acknowledge and assert the divinity of Christ, who is the wisdom and power of God unto salvation (1 Cor. i. 24.).

"To Christ alone we give the title of the Word of God (John i. 1.), and not to the Scriptures; although we highly esteem these sacred writings, in subordination to the Spirit (2 Pet. i. 21.), from which they were given forth; and we hold, with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus (2 Tim. iii. 15.).

"We reverence those most excellent precepts which are recorded in Scripture to have been delivered by our great Lord, and we firmly believe that they are practicable, and binding on every Christian; and that in the life to come every man will be rewarded according to his works (Mat. xvi. 27.). And farther, it is our belief, that, in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the unregenerate will of man (John i. 9.), every man coming into the world is endued with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, within the reach of temptation; but this divine grace, which comes by Him who hath overcome the world (John xvi. 33.) is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation; whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God.

"Being thus persuaded that man, without the Spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable, even the worship of the Father of lights and of spirits, in spirit and in truth; therefore we consider as obstructions to pure worship, all forms which divert the attention of the mind from the secret influence of this unction from the Holy One (1 John ii. 20, 27.). Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet often together (Heb. x. 25.) in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength: nevertheless, in the performance of worship, we dare not depend for our acceptance with Him, on a formal repetition of the words and experiences of others; but we believe it to be our duty to cease from the activity of the imagination, and to wait in silence to have a true sight of our condition bestowed upon us: believing even a single sigh (Rom. viii. 26.) arising from such a sense of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man.

"From what has been said respecting worship, it follows, that the ministry we approve must have its origin from the same source; for that which is needful for a man's own direction, and for his acceptance with God (Jer. xxiii. 30, to 32.), must be eminently so to enable him to be helpful to others. Accordingly, we believe the renewed assistance of the light and power of Christ to be indispensably necessary for all true ministry: and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to his chosen and devoted servants.—From hence arises our testimony against preaching for hire, and in contradiction to Christ's positive command, "Freely ye have received, freely give" (Mat. x. 8.); and hence our conscientious refusal to support such ministry by tithes or other means.

"As we dare not encourage any ministry but that which we believe to spring from the influence of the Holy Spirit, so neither dare we attempt to restrain this influence to persons of any condition in life, or to the male sex alone; but, as male and female are one in Christ, we allow such of the female sex as we believe to be endued with a right qualification for the ministry, to exercise their gifts for the general edification of the church: and this liberty we esteem to be a peculiar mark of the gospel dispensation, as foretold by the prophet Joel (Joel ii. 28, 29.), and noticed by the apostle Peter (Acts ii. 16, 17.).

"There are two ceremonies in use amongst most professors of the Christian name; Water-baptism, and what is termed the Lord's Supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter of maintaining communion with him. But as we have been convinced, that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin, by this power alone we believe salvation to be effected. We hold that as there is one Lord and one faith (Eph. iv. 5.), so his baptism is one in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, administered

nistered by his fore-runner John, belonged, as the latter confessed, to an inferior and decreasing dispensation (John iii. 30.).

"With respect to the other rite, we believe that communion between Christ and his church is not maintained by that nor any other external performance, but only by a real participation of his divine nature (2 Pet. i. 4.) through faith; that this is the supper alluded to in the Revelation (Rev. iii. 20.), "Behold I stand at the door and knock, if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me;" and that where the substance is attained, it is unnecessary to attend to the shadow, which doth not confer grace, and concerning which opinions so different, and animosities so violent, have arisen.

"Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation, we can neither admit that it is conferred on a few only, whilst others are left without it; nor, thus, asserting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthier notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to assist the obedient to experience a total surrender of the natural will to the guidance of his pure unerring Spirit; through whose renewed assistance they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank (Mat. v. 48.; Eph. iv. 13.; Col. iv. 12.).

"There are not many of our tenets more generally known than our testimony against oaths and against war. With respect to the former of these, we abide literally by Christ's positive injunction, delivered in his sermon on the mount, "Swear not at all" (Mat. v. 34.)*. From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself (Mat. chap. v. 39, 44, &c. ch. xxvi. 52, 53.; Luke xxii. 51.; John xviii. 11.), and from the correspondent convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the Gospel, which still breathes peace and good-will to men. We also are clearly of the judgment, that if the benevolence of the Gospel were generally prevalent in the minds of men, it would effectually prevent them from oppressing, much more from enslaving, their brethren, (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan the victims of their avarice, and of their false ideas of pleasure.

* See *Oath*.

"Some of our tenets have in former times, as hath been shown, subjected our friends to much suffering from government, though to the salutary purposes of government our principles are a security. They inculcate submission to the laws in all cases wherein conscience is not violated. But we hold, that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion; but to maintain the external peace and good order of the community. We therefore think persecution, even in the smallest degree, unwarrantable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

"It is well known that the society, from its first appearance, has disused those names of the months and days which, having been given in honour of the heroes or false gods of the heathens, originated in their flattery or superstition; and the custom of speaking to a single person in the plural number (B), as having arisen also from motives of adulation. Compliments, superfluity of apparel and furniture, outward shows of rejoicing and mourning, and observation of days and times, we esteem to be incompatible with the simplicity and sincerity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time which is given us for nobler purposes, and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance.

"To conclude, although we have exhibited the several tenets which distinguish our religious society, as objects of our belief, yet we are sensible that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God (Eph. ii. 8.) in Christ Jesus, nourished and increased by the progressive operation of his spirit in our hearts, and our proportionate obedience (John vii. 17.). Therefore, although, for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as the condition of membership, or to qualify for the service of the church. We prefer the judging of men by their fruits, in a dependence on the aid of Him who, by his prophet, hath promised to be "a spirit of judgment to him that sitteth in judgment" (Isaiah xxviii. 6.). Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual sheepfold, whereof our blessed Lord declared himself to be both the door and the shepherd (John x. 7, 11.), that is, such as know his voice, and follow him in the paths of obedience."

Such are the doctrines of this people as we find them stated in a small pamphlet lately presented by themselves to the public; and in the same tract they give the following account of their discipline.

"In the practice of discipline, we think it indispensable that the order recommended by Christ himself be invariably observed: (Matth. xviii. 15. to 17.). 'If thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses every word may be

(B) Speaking of this custom, Fox says; "When the Lord sent me into the world, he forbade me to put off my hat to any; and I was required to *thee* and *thou*, all men and women." *Journal*, p. 24.

be established; and if he shall neglect to hear them, tell it unto the church.'

"To effect the salutary purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being held, were called quarterly meetings. It was afterwards found expedient to divide the districts of those meetings, and to meet more often; whence arose monthly meetings, subordinate to those held quarterly. At length, in 1669, a yearly meeting was established, to superintend, assist, and provide, rules for the whole; previous to which, general meetings had been occasionally held.

"A monthly meeting is usually composed of several particular congregations, situated within a convenient distance of each other. Its business is to provide for the subsistence of their poor, and for the education of their offspring; to judge of the sincerity and fitness of persons appearing to be convinced of the religious principles of the society, and desiring to be admitted into membership; to excite due attention to the discharge of religious and moral duty; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct; without which they cannot gain membership in such meetings. Each monthly meeting is required to appoint certain persons under the name of *overseers*, who are to take care that the rules of our discipline be put in practice; and when any case of complaint or disorderly conduct comes to their knowledge, to see that private admonition, agreeable to the gospel rule before mentioned, be given previously to its being laid before the monthly meeting.

"When a case is introduced, it is usual for a small committee to be appointed to visit the offender, to endeavour to convince him of his error, and to induce him to forsake and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence; if not, he is disowned as a member of the society.

"In disputes between individuals, it has long been the decided judgment of the society that its members should not sue each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeable to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly meeting that such be disowned.

"To monthly meetings also belongs the allowing of marriages; for our society hath always scrupled to acknowledge the exclusive authority of the priests in the solemnization of marriage. Those who intend to marry, appear together and propose their intention to the monthly meeting; and if not attended by their parents or guardians, produce a written certificate of their consent, signed in the presence of witnesses. The meeting then appoints a committee to inquire whether they are clear of other engagements respecting marriage; and if at a subsequent meeting, to which the parties also come and declare the continuance of their intention, no objections are reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship; towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations and others as witnesses. Of such certificates the monthly meeting keeps a record; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of one of these last-mentioned records; and an order for the interment, countersigned by the grave-maker, of the other. The naming of children is without ceremony. Burials are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave a pause is generally made; on both which occasions it frequently falls out that one or more friends present have somewhat to express for the edification of those who attend; but no religious rite is considered as an essential part of burial.

"Several monthly meetings compose a quarterly meeting. At the quarterly meeting are produced written answers from the monthly meetings, to certain queries respecting the conduct of their members, and the meeting's care over them. The accounts thus received are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly meeting.—Appeals from the judgment of monthly meetings are brought to the quarterly meetings; whose business also it is to assist in any difficult case, or where remissness appears in the care of the monthly-meetings over the individuals who compose them.

"The yearly meeting has the general superintendance of the society in the country in which it is established (c); and therefore, as the accounts which it receives discover the state of inferior meetings, as particular exigencies require, or as the meeting is impressed with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made; and sometimes appoints committees to visit those quarterly meetings which appear to be in need of immediate help. Appeals from the judgment of quarterly meetings are here finally determined; and a brotherly correspondence, by epistles, is maintained with other yearly meetings.

"In this place it is proper to add, that as we believe women may be rightly called to the work of the ministry, we also think, that to them belongs a share in the support of our Christian discipline; and that some parts of it, wherein their own sex is concerned, devolve on them with peculiar propriety. Accordingly they have monthly, quarterly, and yearly meetings of their own sex, held at the same time and in the same place with those of the men; but separately, and without the power of

(c) There are seven yearly meetings, 1st, London, to which come representatives from Ireland; 2d, New-England; 3d, New-York; 4th, Pennsylvania and New-Jersey; 5th, Maryland; 6th, Virginia; 7th, the Carolinas and Georgia.

Quakers.

of making rules: and it may be remarked, that during the persecutions, which in the last century occasioned the imprisonment of so many of the men, the care of the poor often fell on the women, and was by them satisfactorily administered.

"In order that those who are in the situation of ministers may have the tender sympathy and counsel of those of either sex, who, by their experience in the work of religion, are qualified for that service; the monthly meetings are advised to select such, under the denomination of *elders*. These, and ministers approved by their monthly meetings (D), have meetings peculiar to themselves, called meetings of ministers and elders; in which they have an opportunity of exciting each other to a discharge of their several duties, and of extending advice to those who may appear weak, without any needless exposure. These meetings are generally held in the compass of each monthly, quarterly, and yearly meeting. They are conducted by rules prescribed by the yearly meeting, and have no authority to make any alteration or addition to them. The members of them unite with their brethren in the meetings for discipline, and are equally accountable to the latter for their conduct.

"It is to a meeting of this kind held in London, called the second-day-morning-meeting, that the revisal of manuscripts concerning our principles, previously to publication, is intrusted by the yearly meeting held in London; and also the granting, in the intervals of the yearly meeting, certificates of approbation to such ministers as are concerned to travel in the work of the ministry in foreign parts When a visit of this kind doth not extend beyond Great Britain, a certificate from the monthly meeting of which the minister is a member is sufficient; if to Ireland, the concurrence of the quarterly meeting is also required. Regulations of similar tendency obtain in other yearly meetings.

"The yearly meeting held in London, in the year 1675, appointed a meeting to be held in that city, for the purpose of advising and assisting in cases of suffering for conscience sake, which hath continued with great use to the society to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on emergency. The names of all these correspondents, previous to their being recorded as such, are submitted to the approbation of the yearly meeting. Those of the men who are approved ministers are also members of this meeting, which is called the *meeting for sufferings;* a name arising from its original purpose, which is not yet become entirely obsolete.

"The yearly meeting has intrusted the meeting for sufferings with the care of printing and distributing books, and with the management of its stock; and considered as a standing committee of the yearly meeting, it hath a general care of whatever may arise, during the intervals of that meeting, affecting the society, and requiring immediate attention: particularly of those circumstances which may occasion an application to government.

Quakers, Quality.

"There is not in any of the meetings which have been mentioned any president, as we believe that Divine Wisdom alone ought to preside; nor hath any member a right to claim pre-eminence over the rest. The office of clerk, with a few exceptions, is undertaken voluntarily by some member; as is also the keeping of the records. Where these are very voluminous, and require a house for their deposite (as is the case in London, where the general records of the society in Great Britain are kept), a clerk is hired to have the care of them; but except a few clerks of this kind, and persons who have the care of meeting-houses, none receive any stipend or gratuity for their services in our religious society."

It is remarkable, that all the settlements of the Europeans in America, except the Quaker settlement of Pennsylvania, were made by force of arms, with very little regard to any prior title in the natives. The kings of Spain, Portugal, France, and Britain, together with the States of Holland, then the only maritime powers, gave grants of such parts of America as their people could lay hold on, studying only to avoid interference with their European neighbours. But Mr Penn, being a Quaker, did not think his power from King Chas. II. a sufficient title to the country since called *Pennsylvania:* He therefore assembled the sachems or princes then in that country, and purchased from them the extent of land that he wanted. The government of this province is mostly in the hands of the Quakers, who never have any quarrels with the natives. When they desire to extend their settlements, they purchase new lands of the sachems, never taking any thing from them by force. How unlike is this conduct to that of the Spaniards, who murdered millions of the natives of Mexico, Terra Firma, Peru, Chili, &c.

Quality characterized by Aristotle.

QUALITY is a word which, as used in philosophical disquisitions, cannot be explained by any periphrasis. That which is expressed by it must be brought into the immediate view of the senses or intellect, and the name properly applied, or he who is a stranger to the word will never be made to comprehend its meaning. Aristotle, who treated it as a general conception, second in order among the ten *predicaments* or *categories* (see CATEGORY), gives several characters of it; but though they are all in some respects just, no man could from them, without other assistance, learn what *quality* is. Thus he tells us *, 'Υπαρχει δε εναντιοτης κατα το ποιον; Επιδεχεται δε το μαλλον και το ἡττον τα ποια. And again, 'Ομοια δε ἡ ανομοια κατα μονας τας ποιοτητας λεγεται· ὁμοιοι γαρ ἑτερον ἑτερῳ ουκ εστι κατ' αλλο ουδεν, η καθ' ὁ ποιον εστιν.

* Pred. 8 Sylb p. 44 45.

When

(D) "Those who believe themselves required to speak in meetings for worship, are not immediately acknowledged as ministers by their monthly meetings; but time is taken for judgment, that the meeting may be satisfied of their call and qualification. It will sometimes happen, that such as are not approved, will obtrude themselves as ministers, to the grief of their brethern; but much forbearance is used towards these, before the disapprobation of the meeting is publicly testified.

When a man comprehends, by means of his senses and intellect, what it is which the word *quality* denotes, he will indeed perceive that the first of these characters is applicable to some qualities and not to others; that the second is more applicable to *quantity* than to quality; and that it is only the third which can with propriety be considered as the general characteristic of this predicament. Thus when we have learned by our sense of sight that *whiteness* is a quality of snow, and *blackness* of coal; and by means of observation and reflection, that *wisdom* is a quality of one man and *folly* of another—we must admit that the sensible quality of the snow is *contrary* to that of the coal; and the intellectual quality of wisdom contrary to that of folly. There is, however, no contrariety between *wisdom* and *whiteness* or *blackness*, nor between *hardness* or *softness* and *any particular colour;* for sensible and intellectual qualities can never be compared; and it is not easy, if possible, to make a comparison between qualities perceptible only by different senses: Nay, among qualities perceptible by the same sense, we often meet with a difference where there is no contrariety; for though the *figure* of a *cube* is *different* from that of a *sphere*, and the figure of a *square* from that of a *circle*, the sphere is not *contrary* to the cube, nor the circle to the square.

His second characteristic of this genus is still less proper than the first. It is indeed true that some qualities admit of *intension* and *remission;* for snow is whiter than paper, and one woman is handsomer than another; but of the species of quality called *figure* we cannot predicate either *more* or *less*. A crown-piece may have as much of the *circular quality* in it as the plane of the equator, and a musket-bullet as much of the *spherical quality* as the orb of the sun. It is indeed a property of all *quantity* to admit of *intension* and *remission;* and therefore this ought to have been given as the character not of the second but of the third category. See QUANTITY.

2 Nothing known but qualities.

That it is only from a *comparison of their qualities that things are denominated like or unlike*, or that *one thing cannot resemble another but in some quality*, is indeed a just observation. We know nothing directly but qualities sensible and intellectual (see METAPHYSICS, N° 149, 150, 151, and 227); and as these have no resemblance to each other, we conclude that body or matter, the subject of the former, is a being unlike mind, the subject of the latter. Even of bodies themselves we can say, that one is like or unlike another only by virtue of their qualities. A ball of ivory resembles a ball of snow in its *figure* and *colour*, but not in its *coldness* or *hardness;* a ball of lead may resemble a ball of snow in its *figure* and *coldness*, but not in its *colour;* and a cube of ivory resembles not a ball of lead either in *figure*, *colour*, or *coldness*. The mind of a brute resembles that of a man in its powers of *sensation* and *perception*, but does not resemble it in the powers of *volition* and *reasoning;* or at least the resemblance, in this latter instance, is very slight. All bodies resemble one another in being solid and extended, and all minds in being more or less active. *Likeness* or *unlikeness* therefore is the universal characteristic of the category *quality*.

3 Important of quality.

Aristotle has other speculations respecting quality, which are worthy of notice. He distinguishes between qualities which are *essential* and those which are *accidental;* between qualities which are *natural* and those which are *acquired;* and he speaks of the qualities of *capacity* and those of *completion*. *Extension* and *figure* in *general* are qualities essential to all bodies: but a *particular* extension, such as an *inch* or an *ell*, and a *particular* figure, such as a *cube* or a *sphere*, are qualities accidental to bodies. Among the *natural* qualities of glass it is one to transmit objects of vision; but to enlarge these objects is an *adventitious* or *acquired* quality. The same quality may be *natural* in one substance, as attraction in the magnet; and *acquired* in another, as the same attraction in the magnetic bar. *Docility* may be called a quality *natural* to the mind of man, science an *acquired* one. To understand what he means by qualities of *capacity* and *completion*, it may be sufficient to observe that every piece of iron has the qualities of a razor in *capacity*, because it may be converted into steel, and formed into a razor: when it is so formed, it has, in the language of this sage, the quality of a razor in *completion*. Among the qualities of *capacity* and *completion*, the most important, and what may lead to interesting speculations, is the reasoning faculty of man. A *capacity* of reasoning is essential to the human mind; but the *completion* of this capacity or *actual reasoning* is not, otherwise *infants* and persons *asleep* would be excluded from the human species.

4 overlooked by Locke.

Mr Locke has puzzled his readers, and perhaps himself, with a question respecting the species of an idiot or changeling, whom he pronounces to be something between a man and a brute *. It is not often that we feel ourselves inclined to regret Locke's ignorance of Aristotle's distinctions; but we cannot help thinking, that had the British philosopher attended to the Stagyrite's account of qualities in *capacity* and qualities in *completion*, this perplexing question would never have been started. It is justly observed in the Essay on Human Understanding, that of *real essences* we know nothing: but that every man selects a certain number of qualities which he has always perceived united in certain beings; and forming these into one complex conception, gives to this conception a *specific* name, which he applies to every being in which he finds those qualities united. This is undoubtedly the process of the mind in forming genera and species; and as the excellent author refuses the name of *man* to the changeling, it is obvious that the complex conception, to which he gives that name, must imply *rationality* or the *actual exercise* of reason. But this limitation will exclude many beings from the species *man*, whom Mr Locke certainly considered as men and women. Not to mention infants and persons in sound sleep, how shall we class those who, after having lived 30 or 40 years in the full exercise of reason, have been suddenly or by degrees deprived of it by some disorder in the brain?

* Book iv. ch. 4. § 13. &c.

5 Strange consequence of this oversight.

> From Marlb'rough's eyes the streams of dotage flow;
> And Swift expires a driveller and a show. JOHNSON.

But were the hero and the wit in those deplorable circumstances excluded from the human species, and classed between men and brutes? No surely; they were both acknowledged to be men, because they were known to have the quality of reason in what Aristotle would have called *capacity*. Their dotage and drivelling originated from some disorder in their bodies, probably in the region of the brain; and Locke himself contends that no defect in body is sufficient to degrade a person from the rank

rank of manhood. Again, lunatics have the exercise of reason, except at new and full moon. Are these unhappy beings sometimes men and sometimes a species by themselves between men and brutes?

6 Fallacy of his doctrine respecting the human species.

It appears, therefore, that *not* the *actual exercise* of reason, but reason in *capacity*, ought to be included in the complex conception to which we give the specific name of *man*, as some of the greatest men that ever lived have been during parts of their lives deprived of the power of *actual reasoning*. This, however, it will be said, does not remove the difficulty; for the occasional exercise of reason in lunatics, and the great exertions of it in such men as Swift and Marlborough, show that they had it in *capacity* at all times; whereas we have no evidence that changelings have even a *capacity* of reasoning at any time, since they never do a rational action, nor ever utter a sentence to the purpose. That we have no *direct* and *positive* evidence of the minds of changelings being capable of reasoning, were they supplied with proper organs, must be granted; but the probabilities of their being so are many and great. We know by experience that the actual exercise of reason may be interrupted by an occasional and accidental pressure on the brain: and therefore we cannot doubt but that if this pressure were rendered permanent by any wrong configuration of the skull given to it in the womb, or in the act of being born into the world, an infant, with a mind capable of reasoning by means of proper organs, would by this accident be rendered, through the whole of life, an idiot or changeling. That idiotism is caused by such accidents, and is not the quality of an inferior mind occasionally given to a human body, will at least seem probable from the following considerations.

7 True doctrine.

It does not appear that an animal body can live and move but while it is actuated by some mind. Whence then does the unborn infant derive its mind? It must be either immediately from God, or *ex traduce* from its parents; but if the mind of man be immaterial, it cannot be *ex traduce*. Now, as idiots are very few in number when compared with the rational part of the human species, and as God in the government of this world acts not by partial but by general laws; we must conclude that the law which he has established respecting the union of mind and matter, is, that human bodies shall be animated with minds endowed with a capacity of reasoning, and that those who never exert this capacity are prevented by some such accident as we have assigned.

For a further account of qualities, why they are supposed to inhere in some subject, together with the usual distinction between the primary and secondary qualities of matter, see Metaphysics, Part II. chap. i.

Chemical Qualities, those qualities principally introduced by means of chemical experiments, as fumigation, amalgamation, cupellation, volatilization, precipitation, &c.

Quality, is also used for a kind of title given to certain persons, in regard of their territories, signiories, or other pretensions.

QUANGA. See Capra.

QUANG-ping-fou, a city in China, is situated in the northern part of the province of Pe-tcheli, between the provinces of Chang-tong and Ho-nan, and has nine cities of the third class dependent on it; all its plains are well watered by rivers. Among its temples, there is one dedicated to those men who, as these Chinese pretend, discovered the secret of rendering themselves immortal.

QUANGSI, a province of China, bounded on the north by Koe-Tcheau and Hu-Quang; on the east, by Yunan and Quantong; on the south, by the same and Tonquin; and on the west, by Yun-nan. It produces great plenty of rice, being watered by several large rivers; and contains 10,000,000 of inhabitants. The southern part is a flat country, and well cultivated; but the northern is full of mountains covered with trees. It contains mines of all sorts; and there is a gold mine lately opened. The capital town is Quie-ling.

A very singular tree, says Grosier, grows in this province; instead of pith, it contains a soft pulp, which yields a kind of flour: the bread made of it is said to be exceedingly good. Besides paroquets, hedgehogs, porcupines, and rhinoceroses, a prodigious number of wild animals, curious birds, and uncommon insects, are found here. This province contains 12 cities of the first class, and 80 of the second and third. See China, Supplement.

QUANG-tong, a province of China, bounded on the east by Kiang-si and Fokien; on the south, by the ocean; and on the west, by Tonquin. This province is diversified by valleys and mountains; and yields two crops of corn in a year. It abounds in gold, jewels, silk, pearls, tin, quicksilver, sugar, brass, iron, steel, saltpetre, ebony, and several sorts of odoriferous wood; besides fruits of all sorts proper to the climate. They have a prodigious number of ducks, whose eggs they hatch in ovens; and a tree, whose wood is remarkably hard and heavy, and thence called *iron-wood*. The mountains are covered with a sort of osiers which creep along the ground, and of which they make baskets, hurdles, matts, and ropes.

Although the climate of this province is warm, the air is pure, and the people are robust and healthy. They are very industrious; and it must be allowed that they possess in an eminent degree the talent of imitation: if they are only shown any of our European works, they execute others like them with the most surprising exactness. This province suffered much during the civil wars; but at present it is one of the most flourishing in the empire; and, as it is at a great distance from court, its government is one of the most important. This province is divided into ten districts, which contain ten cities of the first class, and 84 of the second and third. Canton is the capital town.

1 Quantity

QUANTITY, as explained by the great English lexicographer, is that property of any thing which may be increased or diminished. This interpretation of the *word* is certainly just, and for the purposes of common conversation it is sufficiently determinate; but the man of science may expect to find in a work like ours a definition of the *thing* signified. This, however, cannot be given him. A logical definition consists of the *genus* under which the thing defined is ranked, and the *specific* difference (see Logic, N° 20, &c.); but quantity is ranked under no genus. In that school where such definitions were most valued, it was considered as one of the ten *categories*, or general conceptions, under which all the objects of human apprehension were mustered, like soldiers in an army (see Category and Philosophy, N° 22.). On this account, even Aristotle himself,

Quantity.

2 characterized by Aristotle.

himself, who delighted in definitions, and was not easily deterred from a favourite pursuit, could not consistently with his own rules attempt to define *quantity*. He characterizes it, however, in several parts of his works: and particularly in the 15th chapter of the 4th book of his metaphysics, where he gives the following account of the three first *categories*: Ταυτα μεν γαρ, ων μια ἡ ουσια. ὁμοια δ' ων ἡ ποιοτης μια ισα δε, ων το ποσον εν. "Things are the *same* of which the SUBSTANCE is one; *similar*, of which the QUALITY is one; *equal*, of which the QUANTITY is one. Again, he tells us *, that the chief characteristic of quantity is, that it may be denominated *equal* and *unequal*.

* *Præd.* p. 34. edit. Sylb.

That any man can become wiser by reading such descriptions as these, none but an idolater of Aristotle will suppose. There is, indeed, no periphrasis by which we can explain what is meant by quantity to those who have not previously formed such a notion.—All that can be done by making the attempt is only to settle language, by stating exactly the cases in which we use this word in the greatest conformity to general custom; for there is a laxness or carelessness of expression in the language of most men, and our notions are frequently communicated by speech in a way by no means precise; so that it is often a great chance that the notions excited in the mind of the hearer are not exact counterparts of those in the mind of the speaker.

The understandings of men differ in nothing more remarkably than in their power of abstraction, and of rapidly forming conceptions so general and simple as not to be clogged with distinguishing circumstances, which may be different in different minds while uttering and hearing the same words: and it is of great consequence to a man of scientific habits, either to cultivate, if possible, this talent, or to supersede its use, by studiously forming to himself notions of the most important *universals* in his own course of contemplation, by careful abstraction of every thing extraneous. His language by this means becomes doubly instructive by its extreme precision; and he will even judge with greater certainty of notions intended to be communicated by the more slovenly language of another person.

We cannot say that there is much ambiguity in the general use of the term *quantity*: But here, as in all other cases, a love of refinement, of novelty, and frequently of vanity, and the wish of appearing ingenious and original, have made men take advantage of even the small latitude with which the careless use of the word will furnish them, to amuse themselves and the public by giving the appearance of science to empty sounds.

3 The subject of mathematical reasoning.

Mathematics is undoubtedly employed in discovering and stating many relations of quantity; and it is in this category alone that any thing is contemplated by the mathematician, whether in geometry, arithmetic, or algebra. Hence mathematics has been called the science of quantity. The simplicity of the object of the mathematician's contemplation, and the unparalleled distinctness with which he can perceive its modifications, have enabled him to erect a body of science, eminent not only for its certainty, but also for the great length to which he can carry his reasonings without danger of error; and the intimate connection which this science has with the arts of life, and the important services which it has performed, have procured it a most respectable place in the circle of the sciences. Ingenious men have availed themselves of this pre-eminence of mathematics, and have endeavoured to procure respect for their disquisitions on other subjects, by presenting them to the public as branches of mathematical science, and therefore susceptible of that accuracy and certainty which are its peculiar boast. Our moral affections, our sensations, our intellectual powers, are all susceptible of augmentation and diminution, are conceivable as greater and less when stated together, and are familiarly spoken of as admitting of degrees of comparison. We are perfectly well understood when we say that one pain, heat, grief, kindness, is greater than another; and as this is the distinguishing characteristic of quantity, and as quantity is the subject of mathematical discussion, we suppose that these subjects may be treated mathematically. Accordingly, a very celebrated and excellent philosopher * has said, among many things of the same kind, that the greatness of a favour is in the direct compound ratio of the service performed and the dignity of the performer, and in the inverse ratio of the merit and rank of the receiver; that the value of a character is in the compound ratio of the talents and virtue, &c.; and he has delivered a number of formal propositions on the most interesting questions in morals, couched in this mathematical language, and even expressed by algebraic formulæ. But this is merely play, and conveys no instruction. We understand the words; they contain no absurdity; and in as far as they have a sense, we believe the propositions to be true. But they give no greater precision to our sentiments than the more usual expressions would do. If we attend closely to the meaning of any one of such propositions, we shall find that it only expresses some vague and indistinct notions of degrees of those emotions, sentiments, or qualities, which would be just as well conceived by means of the expressions of ordinary language; and that it is only by a sort of analogy or resemblance that this mathematical language conveys any notions whatever of the subjects.

* *Dr Francis Hutchinson.*

4 Which is improperly introduced into other subjects.

5 The mathematician contemplates only quantities that are measurable.

The object of contemplation to the mathematician is not whatever is susceptible of greater and less, but what is measurable; and mathematics is not the science of magnitude, in its most abstracted and general acceptation, but of magnitude which can be measured. It is, indeed the SCIENCE of MEASURE, and whatever is treated in the way of mensuration is treated mathematically. Now, in the discourse of ordinary life and ordinary men, many things are called quantities which we cannot or *do not* measure. This is the case in the instances already given of the affections of the mind, pleasure, pain, beauty, wisdom, honour, &c. We do not say that they are incapable of measure; but we have not yet been able to measure them, nor do we think of measuring them when we speak rationally and usefully about them. We therefore do not consider them mathematically; nor can we introduce mathematical precision into our discussions of these subjects till we can, and actually do, measure them. Persons who are precise in their expression will even avoid such phrases on these subjects as suppose, or strictly express, such measurement. We should be much embarrassed how to answer the question, How much pain does the toothache give you just now; and how much is it easier since yesterday?

Quantity. yesterday? Yet the answer (if we had a measure) would be as easy as to the question, How many guineas did you win at cards? or how much land have you bought? Nay, though we say familiarly, "I know well how much such a misfortune would affect you," and are understood when we say it, it would be awkward language to say, "I know well the quantity of your grief." It is in vain, therefore, to expect mathematical precision in our discourse or conceptions of quantities in the most abstracted sense. Such precision is confined to quantity which may be and is measured (A). It is only trifling with the imagination when we employ mathematical language on subjects which have not this property.

It will therefore be of some service in science to discriminate quantities in this view; to point out what are susceptible of measure, and what are not.

6 Measuring explained.

What is measuring? It is one of these two things: It is either finding out some known magnitude of the thing measured, which we can demonstrate to be equal to it; or to find a known magnitude of it, which being taken so many times shall be equal to it. The geometer measures the contents of a parabolic space when he exhibits a parallelogram of known dimensions, and demonstrates that this parallelogram is equal to the parabolic space. In like manner, he measures the solid contents of an infinitely extended hyperbolic spindle, when he exhibits a cone of known dimensions, and demonstrates that three of these cones are equal to the spindle.

In this process it will be found that he actually subdivides the quantity to be measured into parts of which it consists, and states these parts as actually making up the quantity, specifying each, and assigning its boundaries. He goes on with it, piece by piece, demonstrating the respective equalities as he goes along, till he has exhausted the figure, or considered all its parts.—When he measures by means of a submultiple, as when he shows the surface of a sphere to be equal to four of its great circles, he stops, after having demonstrated the equality of one of these circles to one part of the surface: then he demonstrates that there are other three parts, each of which is precisely equal to the one he has minutely considered. In this part of the process he expressly assigns the whole surface into its distinct portions, of which he demonstrates the equality.

But there is another kind of geometrical measurement which proceeds on a very different principle. The geometer conceives a certain individual portion of his figure, whether line, angle, surface, or solid, as known in respect to its dimensions. He conceives this to be lifted from its place, and again laid down on the *adjoining* part of the figure, and that it is equal to the part which it now covers; and therefore that this part together with the first is double of the first: he lifts it again, and lays it down on the next adjoining part, and affirms that this, added to the two former, make up a quantity triple of the first. He goes on in this way, making similar inferences, till he can demonstrate that he has in this manner covered the whole figure by twenty applications, and that his moveable figure will cover no more; and he affirms that the figure is twenty times the part employed.

This mode is precisely similar to the manner of practical measurement in common life: we apply a foot-rule successively to two lines, and find that 30 applications exhaust the one, while it requires 35 to exhaust the other. We say therefore, that the one line is 30 and the other 35 feet long; and that these two lines are to each other in the ratio of 30 to 35. Having measured two shorter lines by a similar application of a stick of an inch long, 30 times to the one and 35 times to the other, we say that the ratio of the two first lines is the same with that of the two last. Euclid has taken this method of demonstrating the fourth proposition of the first book of his celebrated Elements.

7 Euclid's fourth proposition.

But all this process is a fiction of the mind, and it is the fiction of an impossibility. It is even *inconceivable*, that is, we cannot in imagination make this application of one figure to another; and we presume to say, that, if the elements of geometry cannot be demonstrated in some other way, the science has not that title to pure, abstract, and infallible knowledge, which is usually allowed it. We cannot *suppose* one of the triangles lifted and laid on the other, without supposing it something different from a triangle *in abstracto*. The *individuality* of such a triangle consists solely in its being in the precise place where it is, and in occupying *that* portion of space. If we could distinctly conceive otherwise, we should perceive that, when we have lifted the triangle from its place, and applied it to the other, it is gone from its former place, and that there is no longer a triangle *there*. This is inconceivable, and space has always been acknowledged to be immoveable. There is therefore some logical defect in Euclid's demonstration. We apprehend that he is labouring to demonstrate, or rather illustrate, a simple apprehension. This indeed is the utmost that can be done in any demonstration (see METAPHYSICS, N° 82.): but the mode by which he guides the mind to the apprehension of the truth of his fourth proposition is not consistent either with pure mathematics or with the laws of corporeal nature. The real process, as laid down by him, seems to be this. We suppose something different from the abstract triangle; some *thing* that, in conjunction with other properties, has the property of being triangular, with certain dimensions of two of its sides and the included angle. It has avowedly another property, not essential to, and not contained in, the abstract notion of a triangle, viz. mobility. We also suppose it permanent in shape and dimensions, or that although, *during* its motion, it does not occupy *the same space*, it continues, and all its parts, to occupy *an equal space*. In short, our conception is very mixed, and does not perceptibly differ from our conception of a triangular piece of matter, where the

(A) To talk intelligibly of the quantity of a pain, we should have some standard by which to measure it; some known degree of it so well ascertained, that all men, when talking of it, should mean the same thing.—And we should be able to compare other degrees of pain with this, so as to perceive distinctly, not only whether they exceed or fall short of it, but also how much, or in what proportion; whether by an half, or a fifth, or a tenth. *Reid.*

the triangle is not the subject, but an adjunct, a quality. And when we suppose the application made, we are not in fact supposing two abstract triangles to coincide. This we cannot do with any thing like distinctness; for our distinct conception now is, not that of two triangles coinciding, but of one triangle being now exactly occupied by that moveable thing which formerly occupied the other. In short, it is a vulgar measurement, restricted by suppositions which are inadmissible in all *actual* measurements in the present universe, in which no moveable material thing is *known* to be permanent, either in shape or magnitude.

This is an undeniable consequence of the principle of universal gravitation, and the compressibility of every kind of tangible matter with which we are acquainted. Remove the brass rule but one inch from its place; its gravitation to the earth and to the rest of the universe is immediately changed, and its dimensions change of consequence. A change of temperature will produce a similar effect; and this is attended to and considered in all nice mensurations. We do the best we can to assure ourselves that our rule always occupies a sensibly equal space; and we must be contented with chances of error which we can neither perceive nor remove.

We might (were this a proper place) take notice of some other logical defects in the reasoning of this celebrated proposition: but they are beside our present purpose of explaining the different modes of mathematical measurement, with the view of discovering that circumstance in which they all agree, and which (if the only one) must therefore be the characteristic of mensuration.

8
The characteristic notion of mensuration.

We think that the only circumstance in which all modes of mensuration agree, or the only notion that is found in them all, is, that the quantity is conceived as consisting of parts, distinguishable from each other, and separated by assignable boundaries; so that they are at once conceived separately and jointly. We venture to assert that no quantity is directly measured which we cannot conceive in this way, and that such quantities only are the immediate objects of mathematical contemplation, and should be distinguished by a generic name. Let them be called MATHEMATICAL QUANTITIES, EXTENSION, DURATION, NUMBER, and PROPORTION, have this characteristic, and they are the only quantities which have it. Any person will be convinced of the first assertion by attending to his own thoughts when contemplating these notions. He will find that he conceives every one of them as made up of its own parts, which are distinguishable from each other, and have assignable boundaries, and that it is only in consequence of involving this conception that they can be added to or subtracted from each other; that they can be multiplied, divided, and conceived in any proportion to each other.

He may perhaps find considerable difficulty in acquiring perfectly distinct notions of the mensurability, and the accuracy of the modes of mensuration. He will find that the way in which he measures duration is very similar to that in which he measures space or extension. He does not know, or does not attend to, any thing which hinders the brass foot-rule in his hand from continuing to occupy equal spaces during his use of it, in measuring the distance of two bodies. In like manner he selects an event which nature or art can repeat continually, and in which the circumstances which contribute to its accomplishment are invariably the same, or their variations and their effects are insensible. He concludes that it will always occupy an equal portion of time for its accomplishment, or always last an equal time. Then, observing that, during the event whose duration he wishes to measure, this standard event is accomplished $29\frac{1}{2}$ times, and that it is repeated $365\frac{1}{4}$ times during the accomplishment of another event, he affirms that the durations of these are in the ratio of $29\frac{1}{2}$ to $365\frac{1}{4}$. It is thus (and with the same logical defect as in the measuring a line by a brass rod) that the astronomer measures the celestial revolutions by means of the rotation of the earth round its axis, or by the vibrations of a pendulum.

We are indebted for most of the preceding observations to Dr Reid, the celebrated author of the Inquiry into the Human Mind on the Principles of Common Sense, and of the Essays on the Intellectual and Active Powers of Man. He has published a dissertation on this subject in the 45th volume of the Philosophical Transactions, N° 489, which we recommend to our philosophical readers as a performance eminent for precision and acuteness. If we presume to differ from him in any trivial circumstance, it is with that deference and respect which is due to his talents and his worth.

9
Characters of mathematical quantity.

Dr Reid justly observes, that as nothing has proportion which has not either extension, duration, or number, the characters of mathematical quantity may be restricted to these three. He calls them PROPER quantities, and all others he calls IMPROPER. We believe that, in the utmost precision of the English language, this denomination is very apposite, and that the word *quantity* derived from *quantum*, always supposes measurement: But the word is frequently used in cases where its original is not kept in view, and we use other words as synonymous with it, when all mensuration, whether possible or not, is out of our thoughts. According to practice, therefore, the *jus et norma loquendi*, there seems to be no impropriety in giving this name, in our language at least, to whatever can be conceived as great or little. There is no impropriety in saying that the pain occasioned by the stone is greater than that of the toothache; and when we search for the category to which the assertion may be referred, we cannot find any other than quantity. We may be allowed therefore to say, with almost all our scientific countrymen, that every thing is conceivable in respect of quantity which we can think or speak of as greater and less; and that this notion is the characteristic of quantity as a genus, while measureableness is the characteristic of mathematical quantity as a species.

10
Other quantities that cannot be considered mathematically.

But do we not measure many quantities, and consider them mathematically, which have not this characteristic of being made up of their own distinguishable parts? What else is the employment of the mechanician, when speaking of velocities, forces, attractions, repulsions, magnetic influence, chemical affinity, &c. &c.? Are not these mathematical sciences? And if the precision and certainty of mathematics arise from the nature of their specific object, are not all the claims of the mechanician and physical astronomer ill-founded pretensions? These questions require and deserve a serious answer.

It is most certain that we consider the notions which are expressed by these terms velocity, force, density, and the

Quantity.

the like, as susceptible of measure, and we consider them mathematically.

11 Velocity, force, density, how measured.

Some of these terms are nothing but names for relations of measurable quantity, and only require a little reflection to show themselves such. VELOCITY is one of these. It is only a name expressing a relation between the space described by a moving body and the time which elapses during its description. Certain moderate rates of motion are familiar to us. What greatly exceeds this, such as the flight of a bird when compared with our walking, excites our attention, and this excess gets a name. A motion not so rapid as we are familiar with, or as we wish, also gets a name; because in this the excess or defect may interest us. We wish for the flight of the hawk; we chide the tardy pace of our messenger: but it is scientific curiosity which first considers this relation as a *separate* object of contemplation, and the philosopher must have a name for it. He has not formed a new one, but makes use of a word of common language, whose natural meaning is the combination of a great space with a short time. Having once appropriated it, in his scientific vocabulary, to this very general use, it loses with him its true signification. Tardity would have done just as well, though its true meaning is diametrically opposite; and there is no greater impropriety in saying the tardity of a cannon bullet than in saying the velocity of the hour-hand of a watch. Velocity is a quality or affection of motion, the notion of which includes the notions of space and duration (two mathematical quantities), and no other. It does not therefore express a mathematical quantity itself, but a relation, a combination of two mathematical quantities of different kinds; and as it is measurable in the quantities so combined, its measure must be a unit of its own kind, that is, an unit of space *as combined* with an unit of time.

DENSITY is another word of the same kind, expressing a combination of space with number. *Densæ arbores* means trees standing at a small distance from each other; and the word is used in the same sense when we say that quicksilver is denser than water. The expression always suggests to the reflecting mind the notions of particles and their distances. We are indeed so habituated to complicated views of things, that we can see remote connections with astonishing rapidity; and a very few circumstances are sufficient for leading forward the mind in a train of investigation. Common discourse is a most wonderful instance of this. It is in this way that we say, that we found by weighing them that inflammable air had not the sixth part of the density of common air. Supposing all matter to consist of equal atoms equally heavy, and knowing that the weight of a bladder of air is the sum of the weights of all the atoms, and also knowing that the *vicinity* of the atoms is in a certain proportion of the *number* contained in a given bulk, we affirm that common air is more than six times denser than inflammable air; but this rapid decision is entirely the effect of habit, which makes us familiar with certain groupes of conceptions, and we instantaneously distinguish them from others, and thus think and discourse rationally. The Latin language employs the word *frequens* to express both the combination of space and number, and that of time and number.

There are perhaps a few more words which express combinations of mathematical quantities of different kinds; and the corresponding ideas or notions are therefore proper and immediate subjects of mathematical discussion: But there are many words which are expressive of things, or at least of notions, to which this way of considering them will not apply. All those affections or qualities of external bodies, by which they are conceived to act on each other, are of this kind: IMPULSIVE FORCE, WEIGHT, CENTRIPETAL AND CENTRIFUGAL FORCE, MAGNETICAL, ELECTRICAL, CHEMICAL ATTRACTIONS AND REPULSIONS; in short, all that we consider as the immediate causes of natural phenomena. These we familiarly measure, and consider mathematically.

12 Forces measured in the phenomena.

What was said on this subject in the article PHYSICS will give us clear conceptions of this process of the mind. These forces or causes are not immediate objects of contemplation, and are known only *by* and *in* the phenomena which we consider as their effects. The phenomenon is not only the indication of the agency of any cause, and the characteristic of its kind, but the measure of its degree. The necessary circumstances in this *train of human thought* are, 1st, The notion of the force as something susceptible of augmentation and diminution. 2d, The notion of an inseparable connection of the force with the effect produced, and of every degree of the one with a corresponding degree of the other. From these is formed the notion that the phenomenon or effect is the proper measure of the force or cause. All this is strictly logical.

But when we are considering these subjects mathematically, the immediate objects of our contemplation are not the forces which we are thus treating. It is not their relations which we perceive, and which we combine with such complication of circumstances and certainty of inference as are known in all other sciences: by no means; they are the phenomena only, which are subjects of purely mathematical discussion. They are motions, which involve only the notions of space and time; and when we have finished an accurate mathematical investigation, and make our affirmation concerning the forces, we are certain of its truth, because we *suppose* the forces to have the proportions and relations, and no other, which we observe in the phenomena. Thus, after having demonstrated, by the geometrical comparison of the lines and angles and surfaces of an ellipse, that the momentary deflection of the moon from the tangent of her orbit is the 3600th part of the simultaneous deflection of a stone from the tangent of its parabolic path; Newton affirms, that the force by which a particle of the moon is retained in her orbit is the 3600th part of the weight of a particle of the stone; and having farther shown, from fact and observation, that these momentary deflections are inversely as the squares of the distances from the centre of the earth, he affirms, that all this is produced by a force which varies its intensity in this manner.

Now all this investigation proceeds on the two suppositions mentioned above, and the measures of the forces are in fact the measures of the phenomena. The whole of physical astronomy, and indeed the whole of mechanical philosophy, might be taught and understood, without ever introducing the word force, or the notion which it is supposed to express: for our mathematical reasonings are really about the phenomena, which are subjects purely mathematical.

The precision, therefore, that we presume to affirm to attend these investigations, arises entirely from the measurable

Quantity.

measurable nature of the quantities which are the real objects of our contemplation, and the suitableness and propriety of the measures which we adopt in our comparisons.

Since, then, the phenomena are the *immediate* subjects of our discussion, and the operating powers are only inferences from the phenomena considered as effects, the quantity ascribed to them must also be an inference from the quantity of the effect, or of some circumstance in the effect. The measure, therefore, of the cause, or natural power or force, cannot be one of its own parts; for the whole and the part are equally unperceived by us. Our measure, therefore, must be a measure of some interesting part, or of the only interesting part of the phenomenon. It is therefore in a manner arbitrary, and depends chiefly on the interest we take in the phenomenon. It must, however, be settled with precision, so that all men in using it may mean the same thing. It must be settled, therefore, by the description of that part or circumstance of the phenomenon which is characteristic of the natural power. This description is the *definition* of the measure.

13 Measures of centripetal force.

Thus Newton assumes as his measure of the centripetal force, the momentary deviation from uniform rectilineal motion. Others, and sometimes Newton himself, assumes the momentary change of velocity, which again is measured by *twice this deviation*. These measures, being thus selected, are always proper in a mathematical sense; and if strictly adhered to, can never lead us into any paralogism. They may, however, be physically wrong: there may not be that indissoluble connection between the phenomenon and the supposed cause. But this is no mathematical error, nor does it invalidate any of our mathematical inferences: it only makes them useless for explaining the phenomenon by the principle which we adopted; but it prepares a modification of the phenomenon for some more fortunate application of physical principles.

14 Requisites of such measures.

All that can be desired in the definitions or descriptions of these measures is, that they may not deviate from the ordinary use of the terms, because this would always create confusion, and occasion mistakes. Dr Reid has given an example of an impropriety of this kind, which has been the subject of much debate among the writers on natural philosophy. We mean the measure of the force inherent in a body in motion. Descartes, and all the writers of his time, assumed the velocity produced in a body as the measure of the force which produces it; and observing that a body, in consequence of its being in motion, produces changes in the state or motion of other bodies, and that these changes are in the proportion of the velocity of the changing body, they asserted that there is in a moving body a VIS INSITA, an INHERENT FORCE, and that this is proportional to its velocity; saying that its force is twice or thrice as great, when it moves twice or thrice as fast at one time as at another. But Leibnitz observed, that a body which moves twice as fast, rises four times as high, against the uniform action of gravity; that it penetrates four times as deep into a piece of uniform clay; that it bends four times as many springs, or a spring four times as strong, to the same degree; and produces a great many effects which are four times greater than those produced by a body which has half the initial velocity. If the velocity be triple, quadruple, &c. the effects are nine times, 16 times, &c. greater; and, in short, are proportional, not to the velocity, but to its square. This observation had been made before by Dr Hooke, who has enumerated a prodigious variety of important cases in which this proportion of effect is observed. Leibnitz, therefore, affirmed, that the force inherent in a moving body is proportional to the square of the velocity.

15 Controversy between the Cartesians and Leibnitzians on this subject.

It is evident that a body, moving with the same velocity, has the same inherent force, whether this be employed to move another body, to bend springs, to rise in opposition to gravity, or to penetrate a mass of soft matter. Therefore these measures, which are so widely different, while each is agreeable to a numerous class of facts, are not measures of this something inherent in the moving body which we call its force, but are the measures of its exertions when modified according to the circumstances of the case; or, to speak still more cautiously and securely, they are the measures of certain classes of phenomena consequent on the action of a moving body. It is in vain, therefore, to attempt to support either of them by a demonstration. The measure itself is nothing but a definition. The Cartesian calls that a double force which produces a double velocity in the body on which it acts. The Leibnitzian calls that a quadruple force which makes a quadruple penetration. The reasonings of both in the demonstration of a proposition in dynamics may be the same, as also the result, though expressed in different numbers.

But the two measures are far from being equally proper: for the Leibnitzian measure obliges us to do continual violence to the common use of words. When two bodies moving in opposite directions meet, strike each other, and stop, all men will say that their forces are equal, because they have the best test of equality which we can devise. Or when two bodies in motion strike the parts of a machine, such as the opposite arms of a lever, and are thus brought completely to rest, we and all men will pronounce their mutual energies by the intervention of the machine to be equal. Now, in all these cases, it is well known that a perfect equality is found in the products of the quantities of matter and velocity. Thus a ball of two pounds, moving with the velocity of four feet in a second, will stop a ball of eight pounds moving with the velocity of one foot per second. But the followers of Leibnitz say, that the force of the first ball is four times that of the second.

All parties are agreed in calling gravity a uniform or invariable accelerating force; and the definition which they give of such a force is, that it always produces the same acceleration, that is, equal accelerations in equal times, and *therefore* produces augmentations of velocity proportionable to the times in which they are produced. The only effect ascribed to this force, and consequently the only thing which indicates, characterises, and measures it, is the augmentation of velocity. What is this velocity, considered not merely as a mathematical term, but as a phenomenon, as an event, a production by the operation of a natural cause? It cannot be conceived any other way than as a *determination* to move on for ever at a certain rate, if nothing shall change it. We cannot conceive this very clearly. We feel ourselves forced to animate, as it were, the body, and give it not only a will and intention to move in this manner, but a real exertion of some faculty in

Quantity. consequence of this determination of mind. We are conscious of such a train of operations in ourselves; and the last step of this train is the exertion or energy of some natural *faculty*, which we, in the utmost propriety of language, call force. By such analogical conception, we suppose a something, an energy, inherent in the moving body; and its only office is the production and continuation of this motion, as in our own case. Scientific curiosity was among our latest wants, and language was formed long before its appearance: as we formed analogical conceptions, we contented ourselves with the words already familiar to us, and to this something we gave the name FORCE, which expressed that energy in ourselves which bears some resemblance (in office at least) to the determination of a body to move on at a certain rate. This sort of allegory pervades the whole of our conceptions of natural operations, and we can hardly think or speak of any operation without a language, which supposes the animation of matter. And, in the present case, there are so many points of resemblance between the effects of our exertions and the operations of nature, that the language is most expressive, and has the strongest appearance of propriety. By exerting our force, we not only move and keep in motion, but we move other bodies. Just so a ball not only moves, but puts other bodies in motion, or penetrates them, &c.—This is the origin of that conception which so forcibly obtrudes itself into our thoughts, that there is inherent in a moving body a force by which it produces changes in other bodies. No such thing appears in the same body if it be not in motion. We therefore conclude, that it is the production of the moving force, whatever that has been. If so, it must be conceived as proportional to its producing cause. Now this force, thus produced or exerted in the moving body, is only another way of conceiving that determination which we call velocity, when it is conceived as a natural event. We can form no other notion of it. The *vis insita*, the determination to move at a certain rate, and the velocity, are one and the same thing, considered in different relations.

16 Vis insita.

Therefore the *vis insita corpori moventi*, the determination to move at a certain rate, and the velocity, should have one and the same measure, or any one of them may be taken for the measure of the other. The velocity being an object of perception, is therefore a proper measure of the inherent force; and the propriety is more evident by the perfect agreement of this use of the words with common language. For we conceive and express the action of gravity as uniform, when we think and say that its effects are proportional to the times of its action. Now all agree, that the velocity produced by gravity is proportional to the time of its action. And thus the measure of force, in reference to its producing cause, perfectly agrees with its measure, independent of this consideration.

But this agreement is totally lost in the Leibnitzian doctrine; for the body which has fallen four times as far, and has sustained the action of gravity twice as long, is said to have four times the force.

The quaintness and continued paradox of expression which this measure of inherent force leads us into, would have quickly exploded it, had it not been that its chief abettors were leagued in a keen and acrimonious warfare with the British mathematicians who supported the claim of Sir Isaac Newton to the invention of fluxions. They rejoiced to find in the elegant writings of Huyghens a physical principle of great extent, such as this is, which could be set in comparison with some of the wonderful discoveries in Newton's Principia. The fact, that in the mutual action of bodies on each other the product of the masses and the squares of the velocities remain always the same (which they call the *conservatio virium vivarum*) is of almost universal extent; and the knowledge of it enabled them to give ready and elegant solutions of the most abstruse and intricate problems, by which they acquired a great and deserved celebrity. Dr Robert Hooke, whose observation hardly any thing escaped, was the first (long before Huyghens) who remarked *, that in all the cases of the gradual production and extinction of motion, the sensible phenomenon is proportional to the square of the produced or extinguished velocity.

17 Conservatio virium vivarum.

* Micographia, vis restitutiva, &c. in his Posthumous Works.

John Bernoulli brought all these facts together, and systematized them according to the principle advanced by Huyghens in his treatise on the centre of oscillation. He and Daniel Bernoulli gave most beautiful specimens of the prodigious use of this principle for the solution of difficult physical problems in their dissertations on the motion and impulse of fluids, and on the communication of motion. It was however very early objected to them (we think by Marquis Poleni), that in the collision of bodies perfectly hard there was no such *conservatio virium vivarum;* and that, in this case, the forces must be acknowledged to be proportional to the velocities. The objections were unanswerable.—But John Bernoulli evaded their force, by affirming that there were and could be no bodies perfectly hard. This was the origin of another celebrated doctrine, on which Leibnitz greatly plumed himself, THE LAW OF CONTINUITY, viz. that nothing is observed to change abruptly, or *per saltum*. But no one will pretend to say that a perfectly hard body is an inconceivable thing; on the contrary, all will allow that softness and compressibility are adjunct ideas, and not in the least necessary to the conception of a particle of matter, nay totally incompatible with our notion of an ultimate atom.

18 Law of continuity.

Sir Isaac Newton never could be provoked to engage in this dispute. He always considered it as a wilful abuse of words, and unworthy of his attention. He guarded against all possibility of cavil, by giving the most precise and perspicuous definitions of those measures of forces, and all other quantities which he had occasion to consider, and by carefully adhering to them. And in one proposition of about 20 lines, viz. the 39th of the 1st book of the Principia, he explained every phenomenon adduced in support of the Leibnitzian doctrine, showing them to be immediate consequences of the action of a force measured by the velocity which it produces or extinguishes. There it appears that the heights to which bodies will rise in opposition to the uniform action of gravity are as the squares of the initial velocities: So are the depths to which they will penetrate uniformly resisting matter: So is the number of equal springs which they will bend to the same degree, &c. &c. &c. We have had frequent occasion to mention this proposition as the most extensively useful of all Newton's discoveries. It is this which gives the immediate application of mechanical principles to the explanation of natural phenomena. It is incessantly employed in

19 Great superiority of Newton.

in every problem by the very persons who hold by the other measure of forces, although such conduct is virtually giving up that measure. They all adopt, in every investigation the two theorems $f\dot{t}=\dot{v}$, and $f\dot{s}=v\dot{v}$; both of which suppose an accelerating force f proportional to the velocity v which it produces by its uniform action during the time t, and the theorem $\int f\dot{s}=v^2$ is the 39th 1. Princip. and is the *conservatio virium vivarum*.

This famous dispute (the only one in the circle of mathematical science) has led us somewhat aside. But we have little more to remark with respect to measurable quantity. We cannot say what varieties of quantity are susceptible of strict measure, or that it is impossible to give accurate measures of every thing susceptible of augmentation and diminution. We affirm, however, with confidence, that pain, pleasure, joy, &c. are not made up of their own parts, which can be contemplated separately: but they may chance to be associated by nature with something that is measurable; and we may one day be able to assign their degrees with as much precision as we now ascertain the degrees of warmth by the expansion of the fluid in the thermometer. There is one sense in which they may all be measured, viz. numerically, as Newton measures density, *vis motrix*, &c. We can conceive the pain of each of a dozen of men to be the same. Then it is evident that the pain of eight of these men is to that of the remaining four as two to one; but from such mensuration we do not foresee any benefit likely to arise.

Quantity, in *Grammar*, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained: or that which determines the syllable to be long or short.

Quantity is also the object of prosody, and distinguishes verse from prose; and the economy and arrangement of quantities, that is, the distribution of long and short syllables, makes what we call the *number*. See Poetry, Part III.

The quantities are used to be distinguished, among grammarians, by the characters ˘, short, as pĕr; and ¯, long, as rōs. There is also a common, variable, or dubious quantity; that is, syllables that are at one time taken for short ones, and at another time for long ones; as the first syllable in *Atlas*, *patres*, &c.

QUARANTINE, is a trial which ships must undergo when suspected of a pestilential infection. It may be ordered by the king, with advice of the privy-council, at such times, and under such regulations, as he judges proper. Ships ordered on quarantine must repair to the place appointed, and must continue there during the time prescribed (generally six weeks); and must have no intercourse with the shore, except for necessary provisions, which are conveyed with every possible precaution. When the time is expired, and the goods opened and exposed to the air as directed, if there be no appearance of infection, they are admitted to port.

Ships infected with the pestilence must proceed to St Helen's Pool, in the Scilly islands, and give notice of their situation to the customhouse officers, and wait till the king's pleasure be known.

Persons giving false information to avoid performing quarantine, or refusing to go to the place appointed, or escaping, also officers appointed to see quarantine performed, deserting their office, neglecting their duty, or giving a false certificate, suffer death as felons.

Quarantine ‖ Quarries.

Goods from Turkey, or the Levant, may not be landed without license from the king, or certificate that they have been landed and aired at some foreign port. See Plague.

QUARLES, Francis, the son of James Quarles clerk to the board of green cloth, and purveyor to Queen Elizabeth, was born in 1592. He was educated at Cambridge; became a member of Lincoln's Inn; and was for some time cup-bearer to the queen of Bohemia, and chronologer to the city of London. It was probably on the ruin of her affairs that he went to Ireland as secretary to Archbishop Usher; but the troubles in that kingdom forcing him to return, and not finding affairs more at peace in England, some disquiets he met with were thought to have hastened his death, which happened in 1644. His works both in prose and verse are numerous, and were formerly in great esteem, particularly his Divine Emblems: but the obsolete quaintness of his style has caused them to fall into neglect, excepting among particular classes of readers. "The memory of Quarles, says a late author, has been branded with more than common abuse, and he seems to have been censured merely from the want of being read. If his poetry failed to gain him friends and readers, his piety should at least have secured him peace and good-will. He too often, no doubt, mistook the enthusiasm of devotion for the inspiration of fancy: to mix the waters of Jordan and Helicon in the same cup, was reserved for the hand of Milton; and for him, and him only, to find the bays of Mount Olivet equally verdant with those of Parnassus. Yet, as the effusions of a real poetical mind, however thwarted by untowardness of subject, will be seldom rendered totally abortive, we find in Quarles original imagery, striking sentiment, fertility of expression, and happy combinations; together with a compression of style that merits the observation of the writers of verse. Gross deficiencies of judgment, and the infelicity of his subjects, concurred in ruining him. Perhaps no circumstance whatever can give a more complete idea of Quarles's degradation than a late edition of his Emblems; the following passage is extracted from the preface: 'Mr Francis Quarles, the author of the Emblems that go under his name, was a man of the most exemplary piety, and had a deep insight into the mysteries of our holy religion. But, for all that, the book itself is written in so old a language, that many parts of it are scarcely intelligible in the present age; many of his phrases are so affected, that no person who has any taste for reading can peruse them with the least degree of pleasure; many of his expressions are harsh, and sometimes whole lines are included in a parenthesis, by which the mind of the reader is diverted from the principal object. His Latin mottos under each cut can be of no service to an ordinary reader, because he cannot understand them. In order, therefore, to accommodate the public with an edition of Quarles's Emblems properly modernised, this work was undertaken.' Such an exhibition of Quarles is chaining Columbus to an oar, or making John Duke of Marlborough a train-band corporal."

Headley's select Beauties of Ancient English Poetry.

QUARRIES, a name commonly given to an extraordinary cavern under the city of Paris, the existence

ence of which is known to few even of the inhabitants, and many of those who have heard of it consider the whole as an idle story. Mr White visited this cavern in 1784, having, with many others, obtained leave (which is very cautiously granted) to inspect it, accompanied by guides with torches. He gives the following account of it in the second volume of the Manchester Transactions. "At the entrance by the *Observatoire Royal*, the path is narrow for a considerable way; but soon we entered large and spacious streets, all marked with names, the same as in the city; different advertisements and bills were found, as we proceeded, pasted on the walls, so that it had every appearance of a large town swallowed up in the earth.

"The general height of the roof is about nine or ten feet; but in some parts not less than 30 and even 40. In many places there is a liquor continually dropping from it, which congeals immediately, and forms a species of transparent stone, but not so fine and clear as rock crystal. As we continued our peregrination, we thought ourselves in no small danger from the roof, which we found but indifferently propped in some places with wood much decayed. Under the houses, and many of the streets, however, it seemed to be tolerably secured by immense stones set in mortar; in other parts, where there are only fields or gardens above it, it was totally unsupported for a considerable space, the roof being perfectly level, or a plain piece of rock. After traversing about two miles, we again descended about 20 steps, and here found some workmen in a very cold and damp place, propping up a most dangerous part, which they were fearful would give way every moment. The path is here not more than three feet in width, and the roof so low, that we were obliged to stoop considerably.

"On walking some little distance farther, we entered into a kind of saloon cut out of the rock, and said to be exactly under the *Eglise de St Jacques*. This was illuminated with great taste, occasioned an agreeable surprise, and made us all ample amends for the danger and difficulty we had just before gone through. At one end was a representation in miniature of some of the principal forts in the Indies, with the fortifications, draw-bridges, &c. Cannons were planted with a couple of soldiers to each ready to fire. Centinels were placed in different parts of the garrison, particularly before the governor's house; and a regiment of armed men was drawn up in another place with their general in the front. The whole was made up of a kind of clay which the place affords, was ingeniously contrived, and the light that was thrown upon it gave it a very pretty effect.

"On the other side of this hall was a long table set out with cold tongues, bread, and butter, and some of the best Burgundy I ever drank. Now every thing was hilarity and mirth; our fears were entirely dispelled, and the danger we dreaded the moment before was now no longer thought of. In short, we were all in good spirits again, and proceeded on our journey about two miles farther, when our guides judged it prudent for us to ascend, as we were then got to the steps which lead up to the town. We here found ourselves safe at the *Val de Grace*, near to the English Benedictine convent, without the least accident having happened to any one of the party. We imagined we had walked about two French leagues, and were absent from the surface of the earth betwixt four and five hours.

"There were formerly several openings into the quarries, but the two I have mentioned, viz. the *Observatory* and the *Val de Grace*, are, I believe, the only ones left; and these the inspectors keep constantly locked, and rarely open them, except to strangers particularly introduced, and to workmen who are always employed in some part by the king. The police thought it a necessary precaution to secure all the entrances into this cavern, from its having been formerly inhabited by a famous gang of robbers, who infested the country for many miles round the city of Paris.

"As to the origin of this quarry, I could not, on the strictest inquiry, learn any thing satisfactory; and the only account I know published is the following contained in the *Tableaux de Paris, nouvelle edition, tome premier, chapitre 5me, page 12me.*

"For the first building of Paris it was necessary to get the stone in the environs; and the consumption of it was very considerable. As Paris was enlarged, the suburbs were insensibly built on the ancient quarries, so that all that you see without is essentially wanting in the earth for the foundation of the city: hence proceed the frightful cavities which are at this time found under the houses in several quarters. They stand upon abysses. It would not require a very violent shock to throw back the stones to the place from whence they have been raised with so much difficulty. Eight men being swallowed up in a gulf of 150 feet deep, and some other less known accidents, excited at length the vigilance of the police and the government, and, in fact, the buildings of several quarters have been privately propped up; and by this means a support given to these obscure subterraneous places which they before wanted.

"All the suburbs of St James's, Harp-street, and even the street of Tournon, stand upon the ancient quarries; and pillars have been erected to support the weight of the houses. What a subject for reflections, in considering this great city formed and supported by means absolutely contrary! These towers, these steeples, the arched roofs of these temples, are so many signs to tell the eye that what we now see in the air is wanting under our feet."

QUARRY, a place under ground, out of which are got marble, freestone, slate, limestone, or other matters proper for building. See SRATA.

Some limestone quarries in Fife are highly worthy the attention of the curious, on account of an amazing mixture of organized marine productions found in them. One of this kind was opened about the year 1759, at a farm called *Enderteel*, in the neighbourhood of Kirkaldy, belonging to General St Clair.

The flakes of the stone, which are of unequal thickness, most of them from eight to ten inches, lie horizontally, dipping towards the sea. Each of these flakes, when broken, presents to our view an amazing collection of petrified sea bodies, as the bones of fishes, stalks of sea-weed, vast quantities of shells, such as are commonly found on those coasts, besides several others of very uncommon figures. In some places the shells are so numerous, that little else is to be seen but prodigious clusters or concretions of them. In the uppermost stratum the shells are so entire, that the outer crust or plate may be scraped off with the finger; and the stalks of the sea-weed have a darkish colour, not that glossy whiteness which they have in the heart of of the quarry. The smallest rays or veins of the shells are deeply indented on the stone, like the impression of a seal upon wax. In short, no spot at the bottom of the ocean could exhibit a greater quantity of sea-bodies than are to be found in this solid rock; for we have the skeletons of several fishes, the *antennæ* or feelers of lobsters, the roots and stalks of sea-weeds, with the very *capsulæ* which contain the seed. The place where all these curiosities are found is on an eminence about an English mile from the sea; and as the ground is pretty steep the whole way, it may be 200 feet higher at least.

There are two or three things to be remarked here. 1. That among all the bodies we have mentioned, there are none but what are specifically heavier than water. This holds so constantly true, that the sea-weed, which floats in water when the plant is entire, has been stripped of the broad leaves, which make it buoyant, before it has been lodged here. 2. The shells have been all empty; for the double ones, as those of the flat kind, are always found single, or with one side only. 3. The rock seems to have been gradually deserted by the sea, and for a long time, washed with the tides; for the upper surface is all eaten, and hollowed in many places like an honey-comb, just as we observe in flat rocks exposed every tide to the access and recess of the waters. See the article SEA.

QUARRY, or *Quarrel*, among glaziers, a pane of glass cut in a diamond form.

Quarries are of two kinds, square and long; each of which are of different sizes, expressed by the number of the pieces that make a foot of glass, viz. eighths, tenths, eighteenths, and twentieths: but all the sizes are cut to the same angles, the acute angle in the square quarrels being $77^{\circ}\ 19'$, and $67^{\circ}\ 21'$ in the long ones.

QUARRY, among hunters, is sometimes used for a part of the entrails of the beast taken, given by way of reward to the hounds.

QUARRY, in falconry, is the game which the hawk is in pursuit of, or has killed.

QUART, a measure of capacity, being the fourth part of some other measure. The English quart is the fourth part of the gallon, and contains two pints. The quart of the Romans was the fourth part of their congius. The French have various quarts, besides their quart or pot consisting of two pints, and are distinguished by the whole of which they are quarters; as *quart de muid*, and *quart de boisseau*.

QUARTAN, a measure containing the fourth part of some other measure.

QUARTAN, a species of intermitting fever. See MEDICINE *Index*.

QUARTATION, is an operation by which the quantity of one thing is made equal to a fourth part of the quantity of another thing. Thus when gold alloyed with silver is to be parted, we are obliged to facilitate the action of the aquafortis, by reducing the quantity of the former of these metals to one fourth part of the whole mass; which is done by sufficiently increasing the quantity of the silver, if it be necessary. This operation is called *quartation*, and is preparatory to the parting; and even many authors extend this name to the operation of parting. See ORES, *Analysis of*.

QUARTER, the fourth part of any thing, the fractional expression for which is $\frac{1}{4}$.

QUARTER, in weights, is generally used for the fourth part of an hundred weight avoirdupois, or 28 lb.

Used as the name of a dry measure, *quarter* is the fourth part of a ton in weight, or eight bushels.

QUARTER, a term in the manege. To work from quarter to quarter, is to ride a horse three times in upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second: and so to the third and fourth; always changing hands, and observing the same order.

QUARTERS, with respect to the parts of a horse, is used in various senses: thus the shoulders and fore-legs are called the *fore-quarters*, and the hips and hinder-legs the *hind-quarters*. The *quarters* of a horse's foot are the sides of the coffin, comprehending between the toe and the heel: the *inner* quarters are those opposite to one another, facing from one foot to the other; and these are always weaker than the *outside* quarters, which lie on the external sides of the coffin. *False-quarters*, are a cleft in the horn of a horse's hoof, extending from the coronet to the shoe. A horse is said to be a *quarter-cast* when for any disorder in the coffin we are obliged to cut one of the quarters of the hoof.

QUARTER, in *Astronomy*, the fourth part of the moon's period: thus, from the new moon to the quadrature is the first quarter; from this to full moon, the second quarter, &c.

QUARTER, in *Heraldry*, is applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters.

Franc QUARTER, in *Heraldry*, is a quarter single or alone; which is to possess one fourth part of the field. It makes one of the honourable ordinaries of a coat.

QUARTER *of a Ship*, that part of a ship's side which lies towards the stern; or which is comprehended between the aftmost end of the main chains and the sides of the stern, where it is terminated by the quarter-pieces.

Although the lines by which the quarter and bow of a ship, with respect to her length, are only imaginary, yet experience appears sufficiently to have ascertained their limits: so that if we were to divide the ships's sides into five equal portions, the names of each space would be readily enough expressed. Thus the first, from the stern, would be the quarter; the second, abaft the midships; the third, the midships; the fourth, before the midships; and the fifth, the bow. Whether these divisions, which in reality are somewhat arbitrary, are altogether improper, may be readily discovered by referring to the mutual situation or approach of two adjacent vessels. The enemy boarded us on the larboard side! Whereabouts? Abaft the midships, before the midships, &c.

Fig. 1. represents a geometrical elevation of a quarter of a 74 gun ship. A the keel, with *a* the false keel beneath it. B the stern-post. DD the quarter-gallery with its ballustrades and windows. EE the quarter-pieces, which limit and form the outlines of the stern. F the taffarel, or upper pieces of the stern. FG the profile of the stern, with its galleries. H the gun-ports of

Plate CCCCLVIII. fig. 1.

Quarter. of the lower deck; *h* the gun-ports of the upper and quarter-deck. I the after-part of the mizzen channel. K the wing transom. KG the lower counter. LB the station of the deck transom. LQ the after-part of the main-wale. DR the after-part of the channel-wale, parallel to the main-wale. SU the sheer-rail, parallel to both wales. T *t* the rudder. A *t* F the rake of the stern. P *i i* the drift-rails. TU the after-part of the load *water-line; k k l* the curve of the several decks corresponding to those represented in the head. See the article HEAD.

Fig. 2. 3. 4. 5. 6. 7. As the marks, by which vessels of different constructions are distinguished from each other, are generally more conspicuous on the stern or quarter than any other part, we have represented some of the quarters, which assume the most different shapes, and form the greatest contrast with each other. Fig. 2. shows the stern and quarter of a Dutch flight. Fig. 3. the stern and quarter of a cat. Fig. 4. is the stern and quarter of a common galley. Fig. 5. exhibits the quarter of a first-rate galley, otherwise called a *galleasse*. Fig. 6. the quarter of a Dutch dogger, or galliot. Fig. 7. represents the stern and quarter of a sloop of war.

The quarters of all other ships have a near affinity to those above exhibited. Thus all ships of the line, and East-Indiamen, are formed with a quarter little differing from the principal figure in this plate. Xebecs have quarters nearly resembling those of galleasses, only somewhat higher. Hagboats and pinks approach the figure of *cats*, the former being a little broader in the stern, and the latter a little narrower; and the sterns and quarters of cats seem to be derived from those of fly-boats. The sterns of Dutch doggers and galliots are indeed singular, and like those of no other modern vessel: they have nevertheless a great resemblance to the ships of the ancient Grecians, as represented in medals and other monuments of antiquity.

On the QUARTER, may be defined an arch of the horizon, contained between the line prolonged from the ship's stern and any distant object, as land, ships, &c. Thus if the ship's keel lies on an east and west line, the stern being westward, any distant object perceived on the north-west or south-west, is said to be on the larboard or starboard quarter.

QUARTER-*Bill*, a roll, or list, containing the different stations, to which all the officers and crew of the ship are quartered in the time of battle, and the names of all the persons appointed to those stations. See QUARTERS.

QUARTER-*Master*, an officer, generally a lieutenant, whose principal business is to look after the quarters of the soldiers, their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horse one, who are only warrant-officers, except in the Blues.

QUARTER-*Master-General*, is a considerable officer in the army; and should be a man of great judgment and experience, and well skilled in geography. His duty is to mark the marches and encampments of an army: he should know the country perfectly well, with its rivers, plains, marshes, woods, mountains, defiles, passages, &c. even to the smallest brook. Prior to a march, he receives the order and route from the commanding general, and appoints a place for the quarter-masters of the army to meet him next morning, with whom he marches to the next camp; where being come, and having viewed the ground, he marks out to the regimental quarter-masters the ground allowed each regiment for their camp: he chooses the head-quarters, and appoints the villages for the generals of the army's quarters: he appoints a proper place for the encampment of the train of artillery: he conducts foraging parties, as likewise the troops to cover them against assaults, and has a share in regulating the winter-quarters and cantonments.

QUARTER-*Netting*, a sort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork, or old sails; but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in battle.

QUARTER-*Sessions*, a general court held quarterly by the justices of peace of each county. This court is appointed by stat. 2 Hen. V. c. 4. to be in the first week after Michaelmas-day; the first week after the Epiphany; the first week after the close of Easter; and in the week after the translation of Saint Thomas à Becket, or the 7th of July. The court is held before two or more justices of the peace, one of whom must be of the *quorum*. The jurisdiction of this court by 34 Ed. III. c. 1. extends to the trying and determining of all felonies and trespasses whatsoever, though they seldom, if ever, try any greater offence than small felonies within the benefit of clergy, their commission providing, that if any case of difficulty arises, they shall not proceed to judgment, but in the presence of one of the justices of the court of king's bench or common pleas, or one of the judges of assize. And therefore murderers and other capital felons are usually remitted for a more solemn trial to the assizes. They cannot also try any new created offence, without express power given them by the statute which creates it. But there are many offences, and particularly matters, which by particular statutes belong properly to this jurisdiction, and ought to be prosecuted in this court; as, the smaller misdemeanors against the public or commonwealth, not amounting to felony, and especially offences relating to the game, highways, alehouses, bastard children, the settlement and provision for the poor, vagrants, servants wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment, and others in a summary way by motion and order thereupon; which order may, for the most part, unless guarded against by particular statutes, be removed into the court of king's bench, by writ of *certiorari facias*, and be there either quashed or confirmed. The records or rolls of the sessions are committed to the custody of a special officer, denominated the *custos rotulorum*. In most corporation towns there are quarter-sessions kept before justices of their own, within their respective limits, which have exactly the same authority as the general quarter-sessions of the county, except in very few instances: one of the most considerable of which is the matter of appeals from orders of removal of the poor, which, though they be from the orders of corporation justices, must be to the sessions of the county, by 8 and 9 Will. III. c. 30. In both corporations

Blackst. Comment. vol. iv. p. 271.

rations and countries at large, there is sometimes kept a special or petty session, by a few justices, for dispatching smaller business in the neighbourhood between the times of the general sessions, as for licensing alehouses, passing the accounts of parish-officers, and the like.

Quarter-Staff, a long staff borne by foresters, park-keepers, &c. as a badge of their office, and occasionally used as a weapon.

QUARTERS, a name given at sea to the several stations where the officers and crew of a ship of war are posted in action. See War, Part II.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are, in general, as follow, when the ship is well manned, so as to fight both sides at once occasionally:

Pounder.	No. of men.	Pounder.	No. of men.
To a 42	- 15	To a 9	- 6
32	- 13	6	- 5
24	- 11	4	- 4
18	- 9	3	- 3
12	- 7		

This number, to which is often added a boy to bring powder to every gun, may be occasionally reduced, and the guns nevertheless well managed. The number of men appointed to the small arms, on board his Majesty's ships and sloops of war, by order of the admiralty, are,

Rate of the ship.	No. of men to the small arms.
1st -	- 150
2d -	- 120
3d of 80 guns	- 100
— of 70 guns	- 80
4th of 60 guns	- 70
4th of 50 guns	- 60
5th -	- 50
6th -	- 40
Sloops of war	- 30

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the sails. The boatswain, and a sufficient number of men, are stationed to repair the damaged rigging; and the gunner and carpenter, wherever necessary, according to their respective offices.

The marines are generally quartered on the poop and forecastle, or gang-way, under the directions of their officers; although, on some occasions, they assist at the great guns, particularly in distant cannonading.

Quarters, at a siege, the encampment upon one of the principal passages round a place besieged, to prevent relief and convoys.

Head Quarters of an Army, the place where the commander in chief has his quarters. The quarters of generals of horse are, if possible, in villages behind the right and left wings, and the generals of foot are often in the same place: but the commander in chief should be near the centre of the army.

Quarters of Refreshment, the place or places where troops that have been much harassed are put to recover themselves during some part of the campaign.

Intrenched Quarters, a place fortified with a ditch and parapet to secure a body of troops.

Winter Quarters, sometimes means the space of time included between leaving the camp and taking the field; but more properly the places where the troops are quartered during the winter.

The first business, after the army is in winter-quarters, is to form the chain of troops to cover the quarters well: which is done either behind a river, under cover of a range of strong posts, or under the protection of fortified towns. Hussars are very useful on this service.

It should be observed, as an invariable maxim, in winter quarters, that your regiments be disposed in brigades, to be always under the eye of a general officer; and, if possible, let the regiments be so distributed, as to be each under the command of its own chief.

QUARTILE, an aspect of the planets when they are at the distance of 90° from each other, and it is denoted by the character □.

QUARTERING, in *Heraldry*, is dividing a coat into four or more quarters, or quarterings, by parting, couping, &c. that is, by perpendicular and horizontal lines, &c.

QUARTO-decimans, an ancient sect in the Christian church, who taught that Easter should always be celebrated according to the custom of the Jews, on the fourteenth day of the moon in the month of March, whensoever that day fell out. And hence they derived their name *quarto-decimani*, q. d. Fourteenthers. The Asiatics were mightily attached to this opinion, pretending that it was built on the authority of St John, who was their apostle; and Pope Victor could never bring them to obedience in this article, though he was upon the point of excommunicating them: but it is more probable he contented himself with menaces. See Easter.

QUARTZ, a mineral composed chiefly of siliceous earths. See Mineralogy *Index*.

QUASHING, in *Law*, the overthrowing and annulling a thing.

QUASI-contract, in the civil law, an act without the strict form of a contract, but yet having the force thereof. In a contract there must be the mutual consent of both parties, but in a *quasi-contract* one party may be bound or obligated to the other, without having given his consent to the act whereby he is obliged. For example: I have done your business, in your absence, without your procuration, and it has succeeded to your advantage. I have then an action against you for the recovery of what I have disbursed, and you an action against me to make me give an account of my administration, which amounts to a *quasi-contract*.

Quasi-Crime, or *Quasi-delict*, in the civil law, the action of a person who does damage, or evil, involuntarily. The reparation of *quasi-crimes* consists in making good the damages, with interest.

QUASS, a fermented liquor drunk in Russia. See Peasant.

QUASSIA, a genus of plants, belonging to the decandria class; and in the natural method ranking under the 14th order, *Gruinales*. See Botany *Index*.

QUATUORVIR, in antiquity, formerly written IIII. VIR, a Roman magistrate, who had three colleagues joined with him in the same administration, and had the care of conducting and settling the colonies sent into the provinces. There were also quatuorviri appointed to inspect and take care of repairs, &c.

QUAVER, in *Music*, a measure of time equal to half a crotchet, or an eighth part of a semibreve.

QUAY. See KEY.

QUEBEC, a handsome and large town of North America, and capital of Canada. The first place taken notice of when landing here is a square of an irregular figure, with well-built houses on each side; on the back of which is a rock; on the left it is bounded by a small church; and on the right are two rows of houses, parallel to each other. There is another between the church and the harbour; as also another long row on the side of the bay. This may be looked upon as a kind of suburb; and between this and the great street is a very steep ascent, in which they have made steps for the foot passengers to go up. This may be called the *Upper Town*, wherein is the bishop's palace; and between two large squares is a fort where the governor lodges. The Recolets have handsome houses over-against it, and on the right is the cathedral church: over-against this is the Jesuits college, and between them are well built houses; from the fort run two streets, which are crossed by a third, and between these are a church and a convent. In the second square are two descents to the river of St Charles. The Hotel Dieu is in the midway; and from thence are small houses, which reach to the house of the intendant. On the other side of the Jesuits college, where the church stands, is a pretty long street in which is a nunnery. Almost all the houses are built of stone, and there are about 15,000 inhabitants; the fort is a handsome building, but not quite finished. Quebec is not regularly fortified: but it cannot be easily taken; for the harbour is flanked with two bastions, which at high tides are almost level with the water. A little above one of the bastions is a demi-bastion, partly taken out of the rock; and above it, on the side of the gallery of the fort, is a battery of 25 pieces of cannon: still above this is a square fort called the *citadel*; and the ways from one fortification to another are difficult to pass. To the left of the harbour, on the side of the road, there are large batteries of cannon, and some mortars; besides these, there are several other fortifications not very easy to be described. In 1711 the British fitted out a fleet with a design to conquer Canada, which failed on account of the rashness of the admiral; who, contrary to the advice of his pilot, went too near the Seven isles, and so lost his largest ships, and 3000 of his best soldiers. It is about 300 miles north-west of Boston in New-England. On October, 18. 1759, it was taken by the British under the command of General Wolfe, who lost his life in the battle, after he had the satisfaction to know that our troops were victorious. Admiral Saunders commanded a squadron of men of war, and did immense service in reducing this place; there being not a man in the navy but what was active on this occasion, not excepting the sailors belonging to the transport vessels. After this valuable acquisition, all Canada came under the jurisdiction of the crown of Great Britain. W. Long. 69. 48. N. Lat. 46. 55.

QUEDA, a kingdom of Asia, in the peninsula beyond the Ganges, and near the straits of Malacca. The king is tributary to Siam. The principal town is of the same name, and said to contain about 8000 inhabitants. It has a harbour, and is 300 miles north of Malacca. E. Long. 100. 5. N. Lat. 7. 5.

QUEDLINGBURG, a town of Germany, in the circle of Upper Saxony, now belonging to Prussia. Here is a famous abbey, whose abbess was a princess of the empire, and sent deputies to the diets. Her contingent was one horseman and ten footmen. The inhabitants of the town live by brewing, husbandry, and feeding of cattle. It is 10 miles south-east of Halberstadt, and 32 west of Bernburg. E. Long. 11. 34. N. Lat. 52. 1.

QUEEN, a woman who holds a crown singly.

The title of *queen* is also given by way of courtesy to her that is married to a king, who is called by way of distinction *queen-consort*; the former being termed *queen-regent*. The widow of a king is also called *queen*, but with the addition of *dowager*. See ROYAL *Family*.

QUEEN *Charlotte's Sound* is situated at the northern extremity of the southern island of New Zealand, near Cook's Strait, lying in 41. 6. of south latitude, and 174. 19. of east longitude. The climate of this sound is much more mild than at Dusky Bay; and though there is not such plenty of wild fowl and fish, the defect is sufficiently compensated by the abundance of excellent vegetables. The hills about the sound consist mostly of an argillaceous stone of a greenish gray, or bluish or yellowish brown colour. A green talkous or nephritic (by the jewellers called *jade*) is likewise very common, together with horn-stone, shingle, several sorts of flinty stones and pebbles, some loose pieces of basaltes, strata of a compact mica or glimmer, with particles of quartz. Hence, Mr Forrester thinks, there is reason to believe that this part of New Zealand contains iron-ore, and perhaps several other metallic substances. The country is not so steep as at Dusky Bay, and the hills near the sea are generally inferior in height, but covered with forests equally intricate and impenetrable. Captain Cook sowed the seeds of many vegetables in this place, that have useful and nutritive roots. He sowed also corn of several sorts, beans, kidney-beans, and pease. The dogs here are of the long-haired sort, with pricked ears, and resemble the common shepherd's cur, but they are very stupid animals. They are fed with fish, and even dogs flesh, and perhaps human flesh, which the natives also eat. Captains Cook and Furneaux left on these islands a boar and two sows, with a pair of goats, male and female, with some geese, in order to benefit the natives and future generations of navigators. They left likewise among them a number of brass medals gilt, on one side of which was the head of his present Majesty, with the inscription "George III. King of Great Britain, France, and Ireland," &c. On the reverse, a representation of two men of war, with the names Resolution and Adventure over them; and on the exergue, "Sailed from England March MDCCLXXII."

QUEEN-*Gold*, is a royal duty or revenue belonging to to every queen of England during her marriage to the king, payable by persons in this kingdom and Ireland, on divers grants of the king by way of fine and oblation, &c. being one full tenth part above the entire fines, on pardons, contracts, or agreements, which becomes a real debt to the queen, by the name of *aurum reginæ*, upon the party's bare agreement with the king for his fine, and recording the same.

Queen's-County, a division of the province of Leinster in Ireland; so called from the popish Queen Mary, in whose reign it was first made a county by the earl of Sussex, then lord-deputy. It is bounded on the south by Kilkenny and Catherlogh: by King's county on the north and west; part of Kildare and Catherlogh on the east; and part of Tipperary on the west. Its greatest length from north to south is 35 miles, and its breadth near as much; but it is unequal both ways. This country was anciently full of bogs and woods, though now pretty well enclosed and cultivated. The number of inhabitants amounts to 82,000; and it sends two members to the imperial parliament.

Queen-Bee. See *Bee*, N° 3, &c.

QUEENBOROUGH, a town of the isle of Sheppey in Kent, which sends two members to parliament, though consisting only of about 100 low brick houses, and scarce 350 inhabitants. The chief employment of the people here is oyster-dredging; oysters being very plentiful, and of a fine flavour. E. Long. 0. 45 N. Lat. 51. 25.

QUEENSFERRY, which is sometimes denominated South Queensferry, is a royal borough in the shire of Linlithgow, on the coast of the frith of Forth, about 9 miles to the westward of Edinburgh. It obtained the name from Margaret, queen of Malcom Canmore, who was in the habit of frequenting the passage of the frith at this place, and was the principal patroness of the town. It is a small place, consisting of no more than one irregular street, the houses of which are small, and chiefly inhabited by people who lead a seafaring life. The principal manufacture is that of soap, begun in the year 1770, which from 1783 to 1789 was a trade of considerable extent, the works being then four in number, and paying about 10,000l. annually of excise duty.

The shipping of the port has considerably declined; and at present the chief consequence of the place may be regarded as arising from the ferry over the frith of Forth, which is very much frequented. The river here is about two miles broad, and on each side has convenient landing places. The passage is both safe and expeditious, and with the exception of a very few cases, may be had at all times. It is one of five boroughs that send a member to the British or Imperial parliament, the other four being Stirling, Dunfermline, Inverkeithing, and Culross. The parish is of very small extent, being confined to the borough. It is an erection in the parish of Dalmeny, which took place in the year 1636. The inhabitants were 558 in the year 1811.

Queensferry, North, a village in Fifeshire, situated on the Forth, directly opposite to the borough of Queensferry, between which there are regular passage boats. It lies in the parish of Dunfermline, but is annexed, *quoad sacra*, to the parish of Inverkeithing. The inhabitants in 1793 were 312.

QUEI-LING-FOU, the capital of the province of Quangsi in China, has its name from a flower called *quei*, which grows on a tree resembling a laurel; it exhales so sweet and agreeable an odour, that the whole country around is perfumed with it. It is situated on the banks of a river, which throws itself into the Taho; but it flows with such rapidity, and amidst so narrow valleys, that it is neither navigable nor of any utility to commerce. This city is large, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to the greater part of the capitals of the other provinces. A great number of birds are found in the territories belonging to it, the colours of which are so bright and variegated, that the artists of this country, in order to add to the lustre of their silks, interweave with them some of their feathers, which have a splendour and beauty that cannot be imitated. Quei-ling has under its jurisdiction two cities of the second class and seven of the third.

Grosier's General Description of China.

Quei, in *Natural History*, is a name given by the Chinese to a peculiar earth found in many parts of the east. It is of the nature of an indurated clay, and in some degree approaches to the talks, as our steatites and the galactites do. It is very white and abstersive, used by the women of China to take off spots from the skin, and render it soft and smooth, as the Italian ladies use talk of Venice. They sometimes use the fine powder of this stone dry, rubbing it on the hands and face after washing; sometimes they mix it in pomatum.

QUELPAERT, an island in the mouth of the channel of Japan, subject to the king of Corea. Before the last voyage of the unfortunate La Perouse, this island was only known to the Europeans by the wreck of the Dutch ship Sparrow-hawk, in the year 1635. Some of the crew of this ship were kept prisoners for about 18 years, during which period they were often severely treated; but having found means to escape to Japan, and from thence to Batavia, they at last arrived in safety at Amsterdam. La Perouse discovered the island on the 21st of May 1787, the south point of which is in N. Lat. 33° 14′, and E. Long. 124° 15′ from Paris. The land has a gradual slope towards the sea, which makes the habitations assume the appearance of an amphitheatre. The soil appeared to be highly cultivated, and the divisions of fields were perceived by the assistance of glasses, which afforded a convincing proof of an extensive population. It is unfortunately inhabited by a people who are prohibited from all intercourse with strangers, and who make slaves of all those who have the misfortune to suffer shipwreck on their coasts.

QUERCI, a province of Guienne in France; bounded on the north by Limosin, on the east by Rouergue and Auvergne, on the south by Upper Languedoc, and on the west by Agenois and Perigord. It was divided into Upper and Lower; and corresponds nearly with the department of Lot. Cahors is the capital town.

QUERCUS, a genus of plants, belonging to the monœcia class; and in the natural method ranking under the 50th order, *Amentaceæ*. See Botany *Index*.

The robur, or common English oak, grows from about 60 or 70 to 100 feet high, with a prodigious large trunk, and monstrous spreading head; oblong leaves, broadest towards the top, the edges acutely sinuated, having the angles obtuse. There is a variety, having the leaves finely striped with white. This species grows

Quercus. in great abundance all over England, in woods, forests, and hedge-rows; is naturally of an amazing large growth, there being accounts of some above 100 feet stature, with wonderful large trunks and spreading heads; and is supposed to continue its growth many centuries.

The suber, or cork-tree, grows 30 or 40 feet high, having a thick, rough, fungous, cleft bark, and oblong-oval undivided serrated leaves, downy underneath. This species furnishes that useful material cork; it being the bark of the tree, which becoming of a thick fungous nature, under which, at the same time, is formed a new bark, and the old being detached for use, the tree still lives, and the succeeding young bark becomes also of the same thick spongy nature in six or seven years, fit for barking, having likewise another fresh bark forming under it, becoming cork like the others in the like period of time; and in this manner these trees wonderfully furnish the cork for our use, and of which is made the corks for bottles, bungs for barrels, and numerous other useful articles. The tree grows in great plenty in Spain and Portugal, and from these countries we receive the cork. The Spaniards burn it, to make that kind of light black we call Spanish black, used by painters. Cups made of cork are said to be good for hectical persons to drink out of. The Egyptians made coffins of cork; which being lined with a resinous composition, preserved dead bodies uncorrupted. The Spaniards line stone-walls with it, which not only renders them very warm, but corrects the moisture of the air.

Oak-trees, of all the above sorts, may be employed in gardening to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive opens; the evergreen kinds in particular have great merit for all ornamental purposes in gardens. But all the larger growing kinds, both deciduous and evergreens, demand esteem principally as first-rate forest-trees for their timber. The English oak, however, claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood. Every possessor of considerable estates ought therefore to be particularly assiduous in raising woods of them, which is effected by sowing the acorns either in a nursery and the plants transplanted where they are to remain, or sowed at once in the places where they are always to stand. All the sorts will prosper in any middling soil and open situation, though in a loamy soil they are generally more prosperous: however, there are but few soils in which oaks will not grow; they will even thrive tolerably in gravelly, sandy, and clayey land, as may be observed in many parts of this country of the common oak.

The oak is of the utmost importance to Britain, and its cultivation deserves the utmost attention. Much, therefore, to the honour of the members of the *London Society for encouraging Arts, Manufactures, and Commerce*, they have excited particular attention to it; and many excellent observations, drawn from practice, will be found in their Transactions.

The propagation of the striped-leaved varieties of the common oak, and any particular variety of the other species, must be effected by grafting, as they will not continue the same from seed: the grafting may be performed upon any kind of oakling-stocks raised from the acorns, and train them for standards like the others.

The oak is remarkable for its slowness of growth, bulk, and longevity. It has been remarked that the trunk has attained to the size only of 14 inches in diameter, and of some to 20, in the space of fourscore years. As to bulk, we have an account of an oak belonging to Lord Powis, growing in Broomfield wood, near Ludlow in Shropshire, in the year 1764, the trunk of which measured 68 feet in girth, 23 in length, and which, reckoning 90 feet for the larger branches, contained in the whole 1455 feet of timber, round measure, or 29 loads and five feet, at 50 feet to a load.

The Greendale oak, &c. we have already mentioned (see OAK). In the opinion of many, the Cowthorp oak near Wetherby in Yorkshire is the father of the forest. Dr Hunter, in his edition of Evelyn, has given an engraving of it. Within three feet of the surface he says it measures 16 yards, and close to the ground 26. In 1776, though in a ruinous condition, it was 85 feet high, and its principal limb extended 16 yards from the bole. The foliage was very thin. If this measurement were taken as the dimension of the *real stem*, the size of this tree would be enormous; but, like most very large trees, its stem is short, spreading wide at the base, the roots rising above the ground like buttresses to the trunk, which is similar not to a cylinder but to the frustum of a cone. Mr Marsham says, "I found it in 1768, at four feet, 40 feet six inches; at five feet, [illegible] feet six inches; and at six feet, 32 feet one inch." In the principal dimensions then, *the size of the stem*, it is exceeded by the Bentley oak; of which the same writer gives the following account: "In 1759 the oak in Holt-Forest, near Bentley, was at seven feet 34 feet. There is a large excrescence at five and six feet that would render the measure unfair. In 1778, this tree was increased half an inch in 19 years. It does not appear to be hollow, but by the trifling increase I conclude it not sound." These dimensions, however, are exceeded by those of the Boddington oak. It grows in a piece of rich grass land, called the *Old Orchard-Ground*, belonging to Boddington-Manor Farm, lying near the turnpike-road between Cheltenham and Tewksbury, in the Vale of Gloucester. The stem is remarkably collected at the root, the sides of its trunk being much more upright than those of large trees in general; and yet its circumference at the ground is about [illegible] paces: measuring with a two-foot rule, it is more than 18 yards. At three feet high it is 43 feet, and where smallest, i. e. from five to six feet high, it is 36 feet. At six feet it swells out larger, and forms an enormous head, which has been furnished with huge, and probably extensive, arms. But time and the fury of the winds have robbed it of much of its grandeur; and the greatest extent of arm in 1793 was eight yards from the stem.

In the Gentleman's Magazine for May 1794 we have an account of an oak tree growing in Penshurst park in Kent, together with an engraving. It is called the *Bear* or *Bare oak*, from being supposed to resemble that which Camden thought gave name to the county of Berkshire. The tradition at Penshurst is that it is the very tree planted on the day that the celebrated Sir Philip Sydney was born. "Some late writers (says Mr

Mr Rawlet) have questioned this, and think that to have been a different tree, which was cut down some years ago, and was indeed much larger than this. I remember being once in the hollow of the present oak with the late Sir John Cullum; and his opinion then was, that its antiquity was greater than the period assigned. But, I assure you, the tradition of this place is constant for this tree; and, in confirmation of it, an old lady of 94 years of age, now living, has told me, that all the tenants used to furnish themselves with boughs from this tree, to stick in their hats, whenever they went to meet the earls of Leicester, as was always the custom to do at the end of the park when they came to reside at their seat here. This fine old oak stands upon a plain about 500 yards from their venerable mansion, near a large piece of water called *Lancut-well.* Ben Jonson and Waller have particularly noticed it; and from the distinguished owners of this place, it may be truly said to stand on classic ground. Within the hollow of it there is a seat, and it is capable of containing five or six persons with ease. The bark round the entrance was so much grown up, that it has lately been cut away to facilitate the access. The dimensions of the tree are these:

	Feet.	Inches.
Girth close to the ground - -	35	6
Ditto one foot from ditto - -	27	6
Ditto five feet from ditto - -	24	0
Height taken by shadow - -	73	0
Girth of lowest, but not largest, limb	6	9

With respect to longevity, Linnæus gives account of an oak 260 years old: but we have had traditions of some in England (how far to be depended upon we knew not) that have attained to more than double that age. Mr Marsham, in a letter to Thomas Beevor, Esq. Bath Papers, vol. i. p. 79, makes some very ingenious calculations on the age of trees, and concludes from the increase of the Bentley oak, &c. that the Fortworth chesnut is 1100 years old.

Besides the grand purposes to which the timber is applied in navigation and architecture, and the bark in tanning of leather, there are other uses of less consequence, to which the different parts of this tree have been referred. The Highlanders use the bark to dye their yarn of a brown colour, or, mixed with copperas, of a black colour. They call the oak *the king of all the trees in the forest;* and the herdsman would think himself and his flock unfortunate if he had not a staff of it. The acorns are a good food to fatten swine and turkeys; and, after the severe winter of the year 1709, the poor people in France were miserably constrained to eat them themselves. They are, however, acorns produced from another species of oak, which are eaten to this day in Spain and Greece, with as much pleasure as chesnuts, without the dreadful compulsion of hunger.

Quercus Marina, the *Sea Oak*, in *Botany*, the name of a broad-leaved dichotomous sea-fucus. It is not agreed, among the late botanists, what was the sea-oak of Theophrastus; and the most ancient botanists, Clusius and Cæsalpinus, suppose it to have been a species of the shrubby coralline; but that seems by no means to have been the case, since Theophrastus says his sea-oak had a long, thick, and fleshy leaf; whence we may much more naturally conclude it to have been of the fucus class.

QUERIA, a genus of plants, belonging to the triandria class; and in the natural method ranking under the 22d order, *Caryophyllei.* See Botany *Index*.

QUESNE, Abraham du, marquis of Quesne, admiral of the naval forces of France, and one of the greatest men of the 17th century, was born in Normandy in 1610. He contributed to the defeating of the naval power of Spain before Gattari; was dangerously wounded before Barcelona in 1642, and on other occasions: he went into the service of the Swedes, and became vice-admiral; gave the Danes an entire defeat, killed their admiral, and took his ship. He was recalled into France in 1647, and commanded the squadron sent to Naples. The sea-affairs of France being much fallen, he fitted out divers ships for the relief of the royal army that blocked up Bourdeaux; which was the principal cause of the surrender of the town. He was very fortunate in the last wars of Sicily, where he beat the Dutch thrice, and De Ruyter was killed. He also obliged the Algerines to sue in a very humble manner for peace from France. In short, Asia, Africa, and Europe, felt the effects of his valour. He was a Protestant; yet the king bestowed on him the land of Bouchet, and to immortalize his memory gave it the name of that great man. He died in 1688.

QUESTION, in *Logic*, a proposition stated by way of interrogation.

Question, or *Torture*. See Rack.

QUESTOR, or Quæstor, in Roman antiquity, an officer who had the management of the public treasure.

The questorship was the first office any person could bear in the commonwealth, and have a right to sit in the senate.

At first there were only two; but afterwards two others were created, to take care of the payment of the armies abroad, of selling the plunder, booty, &c. for which purpose they generally accompanied the consuls in their expeditions; on which account they were called *peregrini*, as the first and principal two were called *urbani*.

The number of questors was afterwards greatly increased. They had the keeping of the decrees of the senate: and hence came the two offices of *questor principis*, or *augusti*, sometimes called *candidatus principis*, whose office resembled in most respects that of our secretaries of state, and the *questor palatii*, answering in a great measure to our lord-chancellor.

QUEUE, in *Heraldry*, signifies the tail of a beast; thus, if a lion be borne with a forked tail, he is blazoned double-queued.

Queue *d'Aronde*, or *Swallow's Tail*, in *Fortification*, a detached or outwork, the sides of which open towards the champaign, or draw closer towards the gorge. Single or double tenailles are of this kind, and some hornworks, the sides of which are not parallel, but narrow at the gorge, and open at the head, resembling a swallow's tail. When the sides are less than the gorge, the work is called *centre queue d'aronde*.

Queue *d'Aronde*, in carpentry, a method of jointing, also called *dovetailing*.

QUEVEDO de Villegas, Francisco, a celebrated Spanish poet, born at Madrid in 1570. He was

descended

Quevedo, Quick.

descended from a noble family, and was made a knight of St James; but was thrown into prison by order of Count Olivarez, whose administration he satirized in his verses, and was not set at liberty till after that minister's disgrace. Quevedo wrote some heroic, lyric, and facetious poems. He also composed several treatises on religious subjects, and has translated some authors into Spanish. He died in 1644. The most known of his works are, 1. The Spanish Parnassus. 2. The Adventurer Buscon. 3. Visions of Hell Reformed, &c. Quevedo was one of the greatest scholars and most eminent poets of his time. His youth was spent in the service of his country in Italy, where he distinguished himself with the utmost sagacity and prudence. His moral discourses prove his sound doctrine and religious sentiments, while his literary pieces display his infinite judgment and refined taste. His great knowledge of Hebrew is apparent from the report of the historian Mariana to the king, requesting that Quevedo might revise the new edition of the Bible of Arias Montanus. His translations of Epictetus and Phocylides, with his imitations of Anacreon, and other Greek authors, show how well he was versed in that language: that he was a Latin scholar, his constant correspondence, from the age of twenty, with Lipsius, Chifflet, and Scioppius, will sufficiently illustrate. As a poet, he excelled both in the serious and burlesque style, and was singularly happy in that particular turn we have since admired in Butler and Swift. His library, which consisted of about five thousand volumes, was reduced at his death to about two thousand, and is preserved in the convent of St Martin at Madrid.

QUICK, or *Quickset Hedge*, among gardeners, denotes all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, under which name those young plants or sets are sold by the nursery-gardeners who raise them for sale.

The following method of propagating the common white thorn for hedges is recommended by Mr Taylor of Moston near Manchester, in a letter addressed to the Society for the Encouragement of Arts, &c. After premising that we have successfully repeated the experiment, we shall give the account of the process in his own words.

"Every one of you, I think, will allow that fences are material objects to be attended to in agriculture; you must also be convinced that there is no plant in this kingdom of which they can so properly be made as the *cratægus oxyacantha Linnæi*, or common white thorn. In consequence of my being convinced of this, I have been induced to make a few experiments to effect the better propagation of that valuable plant; the result of which, along with specimens of my success, I beg leave to submit to your inspection.

"In the year 1801, I had occasion to purchase a quantity of thorns, and finding them very dear, I was determined to try some experiments, in order if possible to raise them at a less expence. I tried to propagate them from cuttings of the branches, but with little or no success. I likewise tried if pieces of the root would grow; and I cut from the thorns which I had purchased about a dozen of such roots as pleased me, and planted them in a border along with those I had bought. To my great astonishment, not one of them died; and in two years they became as good thorns as the average of those I had purchased. The thorns I purchased were three years old when I got them. In April 1802, I had occasion to move a fence, from which I procured as many roots of thorns as made me upwards of two thousand cuttings, of which I did not lose five in the hundred.

"In the spring of 1803, I likewise planted as many cuttings of thorn roots as I could get. In 1804, I did the same; and this year I shall plant many thousands.

"I have sent for your inspection specimens of the produce of 1802, 1803, and 1804, raised after my method, with the best I could get of these raised from haws in the common way, which generally lie one year in the ground before they vegetate. They are exactly one, two, and three years old, from the day they were planted.—I was so pleased with my success in raising so valuable an article to the farming interest of this kingdom, at so trifling an expence (for it is merely that of cutting the roots into lengths and planting them), that I was determined to make it known to the world, and could think of no better method than communicating it to your society; and should you so far approve of this method of raising thorns, as to think me entitled to any honorary reward, I shall receive it with gratitude, but shall feel myself amply repaid for any trouble I have been at, should you think it worthy a place in the next volume of your Transactions.

"The method of raising the thorns from roots of the plant, is as follows.

"I would advise every farmer to purchase a hundred or a thousand thorns, according to the size of his farm, and plant them in his orchard or garden, and when they have attained the thickness of my three-year-old specimens, which is the size I always prefer for planting in fences, let him take them and prune the roots in the manner I have pruned the specimen sent you, from which he will upon an average get ten or twelve cuttings from each plant, which is as good as thorns of the same thickness; so that you will easily perceive that in three years he will have a succession of plants fit for use, which he may if he pleases increase tenfold every time he takes them up.

"The spring (say in all April) is the best time to plant the cuttings, which must be done in rows half a yard asunder, and about four inches from each other in the row; they ought to be about four inches long, and planted with the top one-fourth of an inch out of the ground, and well fastened; otherwise they will not succeed so well.

"The reason why I prefer spring to autumn for planting the roots, is, that were they to be planted in autumn, they would not have got sufficient hold of the ground before the frost set in, which would raise them all from the ground: and, if not entirely destroy the plants, would oblige the farmer to plant them afresh.

"I have attached the produce of my three-year-old specimen to the plants it came from, cut in the way I always practise; on the thick end of the root I make two, and on the other end one cut, by which means the proper end to be planted uppermost, which is the thick one, may easily be known.

"Although I recommend the roots to be planted in April,

April, yet the farmer may, where he pleases, take up the thorns he may want, and put the roots he has pruned off into sand or mould, where they will keep until he has leisure to cut them into proper lengths for planting; he will likewise keep them in the same way until planted.

"The great advantage of my plan is: first, that in case any one has raised from haws a thorn with remarkably large prickles, of vigorous growth, or possessing any other qualification requisite to make a good fence, he may propagate it far better and sooner, from roots, than any other way. Secondly, in three years he may raise from roots a better plant than can in six years be raised from haws, and with double the quantity of roots; my three-year-old specimen would have been half as big again, had I not been obliged to move all my cuttings the second year after they were planted.

"It would not be a bad way, in order to get roots, to plant a hedge in any convenient place, and on each side trench the ground two yards wide, and two grafts deep; from which, every two or three years, a large quantity of roots might be obtained, by trenching the ground over again, and cutting away what roots were found, which would all be young and of a proper thickness."

QUICKLIME, a general name for all calcareous substances when deprived of their fixed air; such as chalk, limestone, oyster-shells, &c. calcined. See LIME, CHEMISTRY, for an account of the properties and combinations of lime.

QUICKSILVER, or MERCURY, one of the metals, and so fusible that it cannot be reduced to a solid state but at a degree of cold, equal to 40 below 0 of Fahrenheit's thermometer. For the method of extracting quicksilver from its ore, &c. see *ORES, Reduction of*. For the various preparations, &c. see CHEMISTRY and MATERIA MEDICA *Index*; and for the natural history of the ores of quicksilver or mercury, see MINERALOGY *Index*.

Mines of quicksilver are very rare, insomuch that, according to the calculations of Hoffman, there is 50 times more gold got every year out of the mines than mercury and its ores. But Dr Lewis, in his notes upon Newmann, says, that Cramer suspects that Hoffman only meant five times instead of 50; but neither the Latin nor the English edition of this author expresses any such thought; on the contrary, he adopts the same opinion; and only adds, that mercury is much more frequently met with than is commonly believed; but being so volatile in the fire, it often flies off in the roasting of ores, and escapes the attention of metallurgists.

According to Newmann, the mines of Idria have produced at the rate of 231,778 pounds weight of mercury per annum; but those of Almaden in Spain produce much more. The chemists of Dijon inform us, that their annual produce is five or six thousand quintals, or between five and six hundred thousand pounds weight. In the year 1717 there were upwards of 2,500,000 pounds of quicksilver sent from them to Mexico, for the amalgamation of the gold and silver ores of that country.

At Guançavelica in Brasil the annual produce of the mines, according to Bomare, amounts to one million of pounds, which are carried overland to Lima, thence to Arica, and lastly to Potosi for the same purpose.

Besides these mines there are others in Brasil near Villa Rica, where such a quantity of cinnabar, and native running mercury, are found near the surface of the earth, that the black slaves often collect it in good quantities, and sell it for a trifling price to the apothecaries; but none of these mines have ever been worked or taken notice of by the owners. Gold naturally amalgamated with mercury is likewise met with in the neighbourhood of that place; and it is said that almost all the gold mines of that country are worked out by simply washing them out with running water, after reducing into powder the hard ores, which are sometimes imbedded in quartzose and rocky matrices.

In the duchy of Deux Ponts and in the Lower Austria the quicksilver flows from a schistose or stony matrice, and is probably, says Mr Kirwan, mixed with some other metal, as its globules are not perfectly spherical. The mines of Friuli are all in similar beds or strata. The metal is likewise found visibly diffused through masses of clay or very heavy stone, of a white, red, or blue colour; of which last kind are the mines of Spain, some of Idria, and of Sicily. Mascagni found fluid quicksilver, as well as native cinnabar and mineral ethiops, near the lake of Travale in the duchy of Sienna; but the quantity was so small as not to be worth the expence of working. On the other hand, the following mines afford profits to the owners after clearing all expences, viz. those at Kremnitz in Hungary; at Horowitz in Bohemia; Zorge in Saxony; Wolfstein, Stahlberg, and Moeschfeld in the Palatinate. Mercury is also brought from Japan in the East Indies; but the greatest part of what is sold in Europe as Japan cinnabar is said to be manufactured in Holland.

Lemery, Pomet, and others, lay down some external marks by which those places are distinguished where there are mines of quicksilver, viz. thick vapours like clouds arising in the months of April and May; the plants being much larger and greener than in other places: the trees seldom bearing flowers or fruit, and putting forth their leaves more slowly than in other places; but, according to Newmann, these marks are far from being certain. They are not met with in all places where there is quicksilver, and are observed in places where there is none. Abundance of these cloudy exhalations are met with in the Hartz forest in Germany, though no mercury has ever been found there; to which we may add, that though vast quantities of mercurial ores are found at Almaden in Spain, none of the above-mentioned indications are there to be met with.

Native mercury was formerly sought from the mines of Idria with great avidity by the alchemists for the purpose of making gold; and others have showed as ridiculous an attachment to the Hungarian cinnabar, supposing it to be impregnated with gold; nay, we are informed by Newmann, that not only the cinnabar, antimony, and copper of Hungary, but even the vine trees of that country, were thought to be impregnated with the precious metal. Not many years ago a French chemist advertised that he had obtained a considerable quantity of gold from the ashes of vine twigs and stems, as well as of the garden soil where they grew: but the falsehood of these assertions was demonstrated by the count de Lauragais to the satisfaction of the Royal Academy of Sciences.

The reduction of mercury into a solid state, so tha

it

it might be employed like silver, was another favourite alchemical pursuit. But all processes and operations of this kind, says Newmann, if they have mercury in them, are no other than hard amalgams. When melted lead or tin are just becoming consistent after fusion, if a stick be thrust into the metal, and the hole filled with quicksilver, as soon as the whole is cold, the mercury is found solid. Macquer informs us, that mercury becomes equally solid by being exposed to the fumes of lead. Maurice Hoffman, as quoted by Newmann, even gives a process for reducing mercury, thus coagulated, to a state of malleability, viz. by repeatedly melting and quenching it in linseed oil. Thus, he tells us, we obtain a metal which can be formed into rings and other utensils. But here the mercury is entirely dissipated by the repeated fusions, and nothing but the original lead is left. Wallerius, after mentioning strong soap-leys, or caustic lixivium, and some other liquors proper for fixing quicksilver, tells us, that by means of a certain gradatory water, the composition of which he learned from Creuling *de Aureo Vellere*, he could make a coagulum of mercury whenever he pleased, of such consistency that great part of it would resist cupellation; but what this gradatory water was, he has not thought proper to lay before the public.

QUICK-MATCH, among artillery men, a kind of combustible preparation formed of three cotton strands drawn into length, and dipped in a boiling composition of white-wine vinegar, saltpetre, and mealed powder. After this immersion it is taken out hot, and laid in a trough where some mealed powder, moistened with spirits of wine, is thoroughly incorporated into the twists of the cotton, by rolling it about therein. Thus prepared, they are taken out separately, and drawn through mealed powder; then hung upon a line and dried, by which they are fit for immediate service.

QUID PRO QUO, in *Law*, q. d. "what for what," denotes the giving one thing of value for another: or the mutual consideration and performance of both parties to a contract.

QUID *pro quo*, or QUI *pro quo*, is also used in physic to express a mistake in the physician's bill, where *quid* is wrote for *quo*, i. e. one thing for another; or of the apothecary in reading *quid* for *quo*, and giving the patient the wrong medicine. Hence the term is in the general extended to all blunders or mistakes committed in medicine, either in the prescription, the preparation, or application of remedies.

QUIDDITY, QUIDDITAS, a barbarous term used in the schools for *essence*. The name is derived hence that it is by the essence of a thing that it is a *tale quid*, such a *quid*, or thing, and not another. Hence what is essential to a thing is said to be *quiddative*.

QUIETISTS, a religious sect, famous towards the close of the last century. They were so called from a kind of absolute rest and inaction, which they supposed the soul to be in when arrived at that state of perfection which they called the *unitive life;* in which state they imagined the soul wholly employed in contemplating its God, to whose influence it was entirely submissive; so that he could turn and drive it where and how he would. In this state, the soul no longer needs prayers, hymns, &c. being laid, as it were, in the bosom and between the arms of its God, in whom it is in a manner swallowed up.

Molinos, a Spanish priest, is the reputed author of Quietism; though the Illuminati in Spain had certainly taught something like it before. The sentiments of Molinos were contained in a book which he published at Rome in the year 1681, under the title of the *Spiritual Guide;* for which he was cast into prison in 1685, and where he publicly renounced the errors of which he was accused. This solemn recantation, however, was followed by a sentence of perpetual imprisonment, and he died in prison in the year 1696. Molinos had numerous disciples in Italy, Spain, France, and the Netherlands. One of the principal patrons and propagators of Quietism in France was Marie Bouvieres de la Mothe Guyon, a woman of fashion, remarkable for goodness of heart and regularity of manners; but of an unsettled temper, and subject to be drawn away by the seduction of a warm and unbridled fancy. She derived all ideas of religion from the feelings of her own heart, and described its nature to others as she felt it herself. Accordingly her religious sentiments made a great noise in the year 1687; and they were declared unsound, after accurate investigation, by several men of eminent piety and learning, and professedly confuted, in the year 1697, by the celebrated Bossuet. Hence arose a controversy of greater moment between the prelate last mentioned and Fenelon archbishop of Cambray, who seemed disposed to favour the system of Guyon, and who in 1697 published a book containing several of her tenets. Fenelon's book, by means of Bossuet, was condemned in the year 1699, by Innocent XII. and the sentence of condemnation was read by Fenelon himself at Cambray, who exhorted the people to respect and obey the papal decree. Notwithstanding this seeming acquiescence, the archbishop persisted to the end of his days in the sentiments, which, in obedience to the order of the pope, he retracted and condemned in a public manner.

A sect similar to this had appeared at Mount Athos in Thessaly, near the end of the 14th century, called *Hesychasts*, meaning the same with Quietists. They were a branch of the mystics, or those more perfect monks, who, by long and intense contemplation, endeavoured to arrive at a tranquillity of mind free from every degree of tumult and perturbation. In conformity to an ancient opinion of their principal doctors (who thought there was a celestial light concealed in the deepest retirements of the mind), they used to sit every day, during a certain space of time, in a solitary corner, with their eyes eagerly and immoveably fixed upon the middle regions of the belly, or navel; and boasted, that while they remained in this posture, they found, in effect, a divine light beaming forth from their soul, which diffused through their hearts inexpressible sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the same celestial radiance that surrounded Christ during his transfiguration on the Mount. Barlaam, a monk of Calabria, from whom the Barlaamites derived their denomination, styled the monks who adhered to this institution *Massalians* and *Euchites;* and he gave them also the new name of *Umbilicani*. Gregory Palamas, archbishop of Thessalonica, defended their cause against Barlaam, who was condemned in a council held at Constantinople in the year 1341.—See *Fenelon's Max. des Saints*.

The Mahometans seem to be no strangers to quietism. They expound a passage in the 17th chapter of the Koran, viz. "O thou soul which art at rest, return unto the Lord, &c." of a soul which, having, by pursuing the concatenation of natural causes, raised itself to the knowledge of that being which produced them and exists of necessity, rests fully contented, and acquiesces in the knowledge, &c. of him, and in the contemplation of his perfection.

QUILLET, Claude, an eminent Latin poet of the 17th century, was born at Chinon, in Touraine, and practised physic there with reputation: but having declared against the pretended possession of the nuns of Loudun, in a manuscript treatise, the original of which was deposited in the library of the Sorbonne, he was obliged to retire into Italy, where he became secretary to the marshal d'Estrees, the French ambassador at Rome. In 1655, Quillet having published in Holland a Latin poem, entitled *Callipædia*, under the name of *Galvidius Lætus*, he there inserted some verses against the cardinal Mazarine and his family; but that cardinal making him some gentle reproaches, he retrenched what related to the cardinal in another edition, and dedicated it to him, Mazarine having, before it was printed, given him an abbey. He died in 1661, aged 59, after having given Menage all his writings, and 500 crowns to pay the expence of printing them; but the abbé took the money and papers, and published none of them. His *Callipædia*, or the art of getting beautiful children, has been translated into English verse.

QUILLS, the large feathers taken out of the end of the wing of a goose, crow, &c. They are denominated from the order in which they are fixed in the wing; the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow-quills are chiefly used for drawing. In order to harden a quill that is soft, thrust the barrel into hot ashes, stirring it till it is soft, and then taking it out, press it almost flat upon your knee with the back of a penknife, and afterwards reduce it to a roundness with your fingers. If you have a number to harden, set water and alum over the fire, and while it is boiling, put in a handful of quills, the barrels only, for a minute, and then lay them by.

QUIN, James, a celebrated performer on the English stage, was born at London in 1693. He was intended for the bar; but preferring Shakespeare to the statutes at large, he on the death of his father, when it was necessary for him to do something for himself, appeared on the stage at Drury-lane. In 1720, he first displayed his comic powers in the character of Falstaff, and soon after appeared to as great advantage in Sir John Brute; but it was upon Booth's quitting the stage that Quin appeared to full advantage, in the part of Cato. He continued a favourite performer until the year 1748, when, on some disgust between him and Mr Rich the manager, he retired to Bath, and only came up annually to act for the benefit of his friend Ryan; until the loss of two front teeth spoiled his utterance for the stage. While Mr Quin continued upon the stage, he constantly kept company with the greatest geniuses of the age. He was well known to Pope and Swift; and the earl of Chesterfield frequently invited him to his table: but there was none for whom he entertained a higher esteem than for the poet Thomson, the author of the Seasons, to whom he made himself known by an act of generosity that does the greatest honour to his character; and for an account of which see our life of Thomson. Mr Quin's judgment in the English language recommended him to his royal highness Frederick prince of Wales, who appointed him to instruct his children in speaking and reading with a graceful propriety; and Quin being informed of the elegant manner in which his present Majesty delivered his first gracious speech from the throne, he cried out in a kind of ecstasy, "Ay—I taught the boy to speak!" Nor did his majesty forget his old tutor; for, soon after his accession to the throne, he gave orders, without any application being made to him, that a genteel pension should be paid to Mr Quin during his life. Mr Quin indeed, was not in absolute need of this royal benefaction; for, as he was never married, and had none but distant relations, he sunk 2000l. which was half his fortune, in an annuity, for which he obtained 200l. a-year; and with about 2000l. more in the funds, lived in a decent manner during the latter part of his life at Bath, from whence he carried on a regular correspondence with Mr Garrick, and generally paid a visit to his friends in the metropolis once a-year, when he constantly passed a week or two at Mr Garrick's villa at Hampton. He died of a fever in 1766.

QUINARIUS, was a small Roman coin equal to half the denarius, and consequently worth about threepence three farthings of our money. See Money. It was called *quinarius*, because it contained the value of five asses, in the same manner as the denarius was named from its containing ten.

QUINAUT, Philip, a celebrated French poet, born of a good family at Paris in 1635. He cultivated poetry from his infancy, and 16 dramatic pieces of his were acted between the years 1653 and 1666. In the mean time, Quinaut was not so much devoted to poetry but that he applied himself to the study of the law; and made his fortune by marrying the widow of a rich merchant to whom he had been useful in his profession. Quinaut afterwards turned his attention to the composing of operas, which were set to music by the famous Lully; and Lully was charmed with a poet whose verses were not too nervous to yield to the capricious airs of music. He died in 1688, after having for many years enjoyed a handsome pension from Louis XIV.: and we are told he was extremely penitent in his last illness for all those of his compositions which tended to inspire love and pleasure.

QUINCE, in *Botany*. See Cydonia.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five-twelfths of another; but particularly of the *as*.

Quincunx *Order*, in *Gardening*, is a plantation of trees, disposed originally in a square consisting of five trees, one at each corner, and a fifth in the middle; which disposition, repeated again and again, forms a regular grove, wood, or wilderness.

QUINDECAGON, in *Geometry*, a plain figure with 15 sides and 15 angles.

QUINDECEMVIRI, in Roman antiquity, a college of 14 magistrates, whose business it was to preside over

over the sacrifices. They were also the interpreters of the Sybil's books; which, however, they never consulted but by an express order of the senate.

QUINQUAGENARIUS, in Roman antiquity, an officer who had the command of 50 men.

QUINQUAGESIMA SUNDAY, Shrove Sunday, so called as being about the 50th day before Easter.

QUINQUATRIA, or QUINQUATRUS, was a festival kept at Rome in honour of Minerva, which began on the 18th of March, or, as others will have it, on the 19th, and lasted five days. On the first day they offered sacrifices and oblations without the effusion of blood; the second, third, and fourth, were spent in shows of gladiators; and on the fifth day they went in procession through the city. Scholars had a vacation during the solemnity, and presented their masters at this time with a gift or fee, called *Minerval*. Boys and girls used now to pray to the goddess Minerva for wisdom and learning, of which she had the patronage. Plays were acted, and disputations held, at this feast, on subjects of polite literature. The quinquatria were so called, because they lasted for five days. There seems to be a strong resemblance betwixt this festival and the panathenæa of the Greeks.

QUINQUENNALIS, in Roman antiquity, a magistrate in the colonies and municipal cities of that empire, who had much the same office as the ædile at Rome.

QUINQUEREMIS, in the naval architecture of the ancients, is a name given to a galley which had five rows of oars. They divided their vessels in general into *monocrota* and *polycrota* *. The former had only one tire of rowers: the latter had several tires of them, from two or three up to 20, 30, or even 40; for such a vessel we have an account of in the time of Philopater, which required no less than 4000 men to row it.

* See *Polycrota*.

Meibom has taken off from the imaginary improbability of there ever having been such a vessel, by reducing the enormous height supposed necessary for such a number of rows of oars and men to work them, by finding a better way of placing the men than others had thought of. The quinqueremes of the ancients had 420 men in each; 300 of which were rowers, and the rest soldiers. The Roman fleet at Messina consisted of 330 of these ships; and the Carthaginian, at Lilybœum, of 350 of the same size. Each vessel was 150 feet long. Thus 130,000 men were contained in the one, and 150,000 in the other, with the apparatus and provisions necessary for such expeditions as they were intended for. This gives so grand an idea of the ancient naval armaments, that some have questioned the truth of the history: but we find it related by Polybius, an historian too authentic to be questioned, and who expresses his wonder at it while he relates it.

QUINQUEVIRI, in Roman antiquity, an order of five priests, peculiarly appointed for the sacrifices to the dead, or celebrating the rites of Erebus.

QUINQUINA. See CINCHONA, BOTANY and MATERIA MEDICA *Index*.

QUINSY, or QUINZY. See MEDICINE, N° 177—183.

QUINTEN, a town of France, in the department of Côtes de Nord, with a handsome castle. It is seated in a valley near the river Guy, and near a large forest of the same name, eight miles south of St Brieux, and 200 west of Paris. It had formerly the title of a duchy. W. Long. 2. 40. N. Lat. 48. 26.

QUINTESSENCE, in *Chemistry*, a preparation consisting of the essential oil of some vegetable substance, mixed and incorporated with spirit of wine.

QUINTESSENCE, in *Alchemy*, is a mysterious term, signifying the fifth or last and highest essence of power in a natural body.—Or when divested of its alchemistical signification, and employed to express something that is intelligible, the word denotes merely the highest state of purification in which any body can be exhibited.

QUINTAL, the weight of 100 lbs. in most countries, but in England it is the cwt. or 112 lbs. Quintal was formerly used for a weight of lead, iron, or other common metal, usually equal to 100 lbs. at six scores to the hundred.

QUINTILE, in *Astronomy*, an aspect of the planets when they are 72 degrees distant from one another, or a fifth part of a zodiac.

QUINTILIANUS, MARCUS FABIUS, a celebrated Latin orator, and the most judicious critic of his time, was a native of Calagurris, or Calahorra, in Spain; and was the disciple of Domitius Afer, who died in the year 59. He taught rhetoric at Rome for 20 years with great applause: and not only laid down rules for speaking, but exhibited his eloquence at the bar. Some authors imagine, but with little foundation, that he arrived at the consulship; but it is more certain that he was preceptor to the grandsons of the emperor Domitian's sister. There is still extant his excellent work, intitled, *Institutiones Oratoriæ*, which is a treatise of rhetoric in 12 books; where his precepts, judgment, and taste, are justly admired. These institutions were found entire by Poggius, in an old tower of the abbey of St Gal, and not in a grocer's shop in Germany as some authors have asserted. There is also attributed to Quintilian a dialogue *De causis corruptæ eloquentiæ*; but it is more commonly ascribed to Tacitus. The best editions of Quintilian's works are those of Mr Obreight, published at Strasburg in 2 vols 4to, in 1698, and of M. Capperonier, in folio. There is an English translation by Mr Guthrie.

Quintilian had a son of the same name, on whom he bestows great praises. This son ought not to be confounded with Quintilian the father, or rather the grandfather, of him who is the subject of this article, and who wrote 145 declamations. Ugolin of Parma published the first 136 in the 15th century; the nine others were published in 1563 by Peter Ayrault, and afterwards by Peter Pithou in 1580. There have also been 19 other declamations printed under the name of Quintilian the Orator; but, in the opinion of Vossius, they were written neither by that orator nor his grandfather.

QUINTILIANS, a sect of ancient heretics, thus called from their prophetess Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Mary the sister of Moses, as having been a prophetess, &c. They added, that Philip the deacon had four daughters, who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, personating prophetesses.

QUINTIN MATSYS, also called the *Farrier of Antwerp*, famous for being transformed, by the force of love, from a blacksmith to a painter. He had followed the trade of a blacksmith and farrier for near twenty years; when falling in love with a painter's daughter who was very handsome, and disliked nothing but his trade, he quitted it, and betook himself to painting, in which he made very great progress. He was a diligent and careful imitator of ordinary life, and succeeded better in representing the defects than the beauties of nature. Some historical performances of this master deserve commendation, particularly a Descent from the Cross, in the cathedral at Antwerp: but his best known picture is that of the two Misers in the gallery at Windsor. He died in 1529.
